I think many of these "experts" would be surprised, and perhaps even embarrassed, by their comments if and when they watch the film in its entirety.

For example, consider this from 'elsie':

"Ok, so this is another movie about a non-white woman being subjugated and perhaps arguably tortured by a white man?"

No, it's not. But 'elsie' is not really asking a question. He/she already "knows" what this film is about and in particular offers this brilliant suggestion:

"Now what really would have been interesting: the submissive woman gets her moxie, the tides turn, she subjugates the man, steals the formula, and…."

Well, 'elsie' might be surprised to find out that this is pretty close to what happens in this film.

SPOILER ALERT!

At the end of the film, the Mathematician kills himself and Mariko, the female character, walks away with his formula, leaving him dying on the floor.

The description of Mariko as "subjugated woman" is concocted by those who feel perfectly comfortable judging a film after watching a two-minute trailer.

It seems that these comments tell us more about the writers and their prejudices than about the film itself.

Another interesting comment from 'elsie':

"I do not see this being a big hit outside of Berkeley and some mathematics circles, if only for the controversy."

Interesting… Looking at the film Web site http://ritesofloveandmath.com, we find that the movie had a successful premiere in Paris last Spring and was selected at international film festivals, including a presigious festival in Spain in October. It has also been reviewed favorably in Le Monde, on Twitch.com (a popular Web site about movies), and in other publications…

Finally, about Kea2's comment:

"Mishima's film is generally seen as an extreme expression of his narcissism and ultra-romanticism; in other words, Mishima at his worst."

Really? I would be interested in seeing this claim backed up by something other than the Kea2's apparent self-confidence. In fact, Mishima's film was released on DVD in the United States by the Criterion Collection, which is a very important DVD series. And a cursory search on Google produces a large number of admiring reviews of his film.

21. **andreask**
December 21, 2010

so the questions remain a) why was the film thought to be advertised 'sufficiently well' by a trailer which conveys the impression that it contains at least to a certain degree misogynic content if it allegedly does not b) does commercial success or at least a 'succès d'estime' on european film festivals imply that the criticism presented above is wrong.

22. **Kea2**
December 23, 2010

@Oh Well. My comment was based on my knowledge and understanding of Mishima's oeuvre, not on a google search for the film.

23. **Oh well...**
December 24, 2010

@Kea2: Thanks for the clarification. In your original comment you wrote: "Mishima's film is generally seen as…" suggesting that you are not expressing your own opinion (to which you are certainly entitled), but rather a consensus view of the film. My point was that what you wrote is NOT the concensus view of Mishima's film.

24. **ak**
December 24, 2010

possibly Frenkel's remark

"(..)the film is an allegory in which the female character represents the truth and mathematics(..)"

exemplifies already the problematic traits in the general conception, the film is intensely absorbed in 'traditional' gender roles, the woman in 'patriarchal' societies representing the passive ‘truth’, ‘nature’ and the ‘unexplained’, and while this is obviously in perfect accordance to the film mainstream and good parts of its non-mainstream in Europe or the US, a mathematical environment still characterized by a grotesque under-representation of females has indeed reasons to oppose further amplification of what can clearly be understood as the ‘archaic truths’ of males and females in our societies.

This Week’s Hype

December 11, 2010
Categories: This Week's Hype

This week’s contribution to the long tradition of universities issuing press releases hyping non-existent “experimental tests of string theory” by their employees is from Duke University, which advertises “String Theory in a Lab“. This is based on a paper that just appeared in *Science* describing measurements of the viscosity of a Fermi gas. The paper explains the relationship of the measurements to string theory as:

> The measurement of the viscosity is of particular interest in the context of a recent conjecture, derived using string theory methods, which defines a perfect normal fluid.

referring to this paper which first suggested that gauge/gravity duality implied a value of $1/4\pi$ for the ratio of shear viscosity to entropy density.

In the press release, this connection to string theory has been promoted to a headline, as well as to the claim that:

> The results may also allow experimental tests of string theory in the future.

which I suppose is better than the usual claim in these press releases that what is being promoted is already an experimental test of string theory. It seems likely that one reason this isn’t yet an “experimental test” is that the data comes out 4 to 5 times higher than the string theory value.

Comments

1. **Amused**
   December 11, 2010

   Hi Peter,

   I`m just amused seeing You jump head on at every headline appearing somewhere containing the S-word, independent of what the context is …

   That`s so predictive and sure as death and taxes !

2. **Peter woit**
   December 11, 2010

   Amused,

   For years I’ve had a Google alert set up that lists new news stories involving the terms “string theory”. The long term pattern is that fewer and fewer of the things listed have anything to do with string theory itself. These days the majority come from music: “string theory” is very popular as the name of a musical group or event.

   Besides the music ones though, many of the rest are the all-too-familiar press releases promoting some kind of hype about a bogus “experimental test of string theory” (and the varying numbers of news stories that pick up the press release). I’m well aware that my pointing these out is all too predictable and kind of tedious by now, since I’m pretty bored with this myself. However, it still seems to me that someone should try and do something to slow down this phenomenon, and I’m not seeing anyone else interested in the job…

3. **Derek Teaney**
   December 11, 2010

   Peter,

   I have not read the article by Schafer et al. (I’m at home
   and its not free) but certainly the 1/4\pi result is not to be made
   light of. The 1/4\pi result does provide an “exact” example
   of a strongly coupled theory close to the quantum limit where
   the shear viscosity can be computed. Of course the 1/4\pi
   result does rely on
   the AdS/CFT and certain properties of black holes which haven’t
   been proven. Measuring the shear viscosity in fermions system
   close to unitarity does not prove the exsistence of strings or the validity of string theory. But, it does strongly suggest the inherent value in these methods as a tool of theoretical physics.

4. **Peter Woit**
   December 11, 2010

   Derek,

   I’m not making light of gauge-gravity duality, or its possible applications to computations in strongly-coupled quantum systems.

   I am making light of the endless less-than-honest attempts to use this to generate misleading press releases about “experimental test of string theory finally found!” Or, actually, I’m not really making light of it, I think it’s kind of disgraceful…

5. **Amused**
   December 12, 2010

   Ok Peter,

   the Google alert explains it …

   Perhaps nobody else does what You are doing because it`s really enough now and it`s the job of present and future experiments to decide what is right and what is not?

   Instead of trying to get any research on ST in particular or on all of the other approaches to quantum gravity which You seem not to be able to accept neither eliminated, it would be much more interesting to read about what You are working on and what You appreciate as good and fascinating news in physics …

Or perhaps Your intention is to merit a special chapter in the new
german popular science book “Kampfhähne der Wissenschaft” by
Heinrich Zankel ;-))) ?

See

http://www.amazon.de/Kampfh%C3%A4hne-Wissenschaft-Kontroversen-Feindschaften-Erlebnis/dp/3527325794

Seriously, I´d really prefere reading more about fascinating in interesting things You surely have to write about than seing this neverending picking on others …

At the present state of affairs, reading some physics text, on QFT for example, is much more promising for me to understand what is going on in modern physics.

Best wishes

6. **New**
December 12, 2010

Is the press release by string theorists? It looked like it was the experiementers at Duke who said (correctly) that it might be interesting from a string theory perspective. The Duke string theory group is into much more formal string theory, like CFTs for heterotic models etc.

In any event, I am not sure why this is hype. They say very clearly that the string theory computation is a lower bound and that the experiment is five times the bound or so. The actual claim is that “The results may also allow experimental tests of string theory in the future” which is hardly hype.

The reason why this is interesting is that standard approaches other than string theory give vastly bigger results, while the lower bound from string theory is within an order of magnitude of the experimental value.

What is so upsetting to Woit here is anybody’s guess.

7. **Peter Woit**
December 12, 2010

New,

The point is that this has nothing at all to do with experimentally testing string theory, either now or in the future, and those promoting this kind of hype know this, whether they’re condensed matter physicists or string theorists.

What one can’t now, but in principle might be able to test this way is the combination of some conjectured strongly coupled model for the system together with some conjectures from gauge/gravity duality about how solutions to the model behave. If such an experimental test fails it means either the model is wrong, or solutions to the model have different properties than conjectured.

The first alternative has nothing to do with string theory, and the second one is a mathematical question. Whatever the correct answer to the mathematical question is, there’s no “experimental test of string theory” there. If experiment disagrees with the gauge/gravity duality “prediction”, I doubt anyone is going to give up on gauge/gravity duality, instead they’ll give up on the particular strongly-coupled model used, or decide that the application of gauge/gravity duality in this situation is too naive.

8. **Chris Austin**
December 12, 2010

Hi Derek Teaney,

Would you be able to give the authors or title of the paper with page reference

Phys.Rev.D31:53-62,1985

mentioned by luny in response to your comment on the same topic here? I can’t find it on SPIRES just from the page reference.

9. **thomas**
December 12, 2010

Neither the heavy ion experiments nor the experiments involving dilute Fermi gases provided quantitative test of string theory right now. The heavy ion experiments do not produce an N=4 SUSY plasma at large N_c, and the Fermi gas experiments involve a scale invariant non-relativistic fluid, but not one of the systems for which a precise correspondence has been formulated.

The experiments nevertheless provide a path for testing the string theory framework. Ideally, this will happen when holographic dualities are extended to more realistic systems. Even if this turns out to be difficult, we can use the experiments to verify numerical calculations of transport properties (in lattice QCD or non-relativistic quantum Monte Carlo), and then check the dependence on the matter content numerically. If string theory correctly predicts the N=4 large N_c limit, and if at strong coupling the dependence on the precise matter content is indeed weak, then this would constitute a pretty non-trivial test of string theory as a quantum gravity framework, and a test of the holographic dualities.

Of course this does not directly tell us much about attempts at deriving physics beyond the standard model from string theory, but the Duke press release is actually fairly honest (on the scale of these things) in not claiming anything like this. The press release also points out connections to the physics of neutron stars. Here, the situation is not so different — some additional theory is required to extrapolate from cold atoms to cold neutrons.

Finally, as Derek points out, nobody can seriously doubt that string theory has been extraordinarily fruitful in thinking about strongly coupled fluids.

10. **Peter Woit**
December 12, 2010

Thomas,

You’re just exploiting ambiguities in language when you write about “testing the string theory framework”. Most people when they read that would assume that you are talking about the conjectured use of strings as elements of a fundamental theory, which is the way string theory has been advertised. You’re referring to something completely different, a string-theory-inspired mathematical conjecture that may or may not be right, and may or may not some day have a use as an approximate calculational method.

People have noticed that after 25 years the heavily promoted “string theory” predicts nothing and instead of admitting the reason for this failure, there’s an active campaign to avoid acknowledging this by misleading people with bogus claims of new “experimental tests of string theory”. I don’t think trying to justify these kinds of press releases is a good idea.

11. **Chris Austin**
December 12, 2010

With reference to my comment above, perhaps I should have pointed out that it would be interesting to see the arguments in the paper mentioned by luny, which luny states finds a limit that is surprisingly similar to 1/(4 pi), using back-of-the-envelope arguments stemming from the uncertainty principle, because Kovtun, Son, and Starinets find on page 5 that the uncertainty principle leads to a lower bound of about 1, rather than about 1/(4 pi), on the ratio of viscosity to entropy density.

12. **Derek Teaney**
December 12, 2010

Hi Chris,

The paper is a classic of our field

%\cite{Danielewicz:1984ww}
\bibitem{Danielewicz:1984ww}
P.~Danielewicz and M.~Gyulassy,
%“Dissipative Phenomena In Quark Gluon Plasmas,”
Phys.\ Rev.\ D {\bf 31}, 53 (1985).
%%CITATION = PHRVA,D31,53;%%

The point is though, that its based on extrapolation from weakly coupled theories to a regime where they are not valid, rather than
a valid scheme.

13. **Giotis**
December 12, 2010

Peter I’m curious; do you have any theoretical reasons to believe that String theory is wrong as a fundamental theory or the fact that it can’t be currently tested is an adequate reason for you to dismiss it altogether?

14. **Peter woit**
December 12, 2010

Giotis,

I wrote a whole book about this…

In brief, the mathematical structure of the standard model is quite marvelous and uses very deep mathematics. My guess is that going beyond the Standard Model will involve going deeper in those mathematical directions.

I never was a fan of the idea of throwing most of this out, with the idea that completely different objects (strings and extra dimensions) were what was really fundamental. When people first tried to get a unified theory from strings it was a reasonable (if not especially compelling) thing to try. It soon became clear though that this didn’t work. The lack of any predictions is just a symptom though of the underlying disease, which is that you have to choose more and more complicated backgrounds just to avoid contradiction with experiment. You never get more out than you put in, which is the signature of a bad idea.

15. **critic**
December 12, 2010

Peter wrote: For years I’ve had a Google alert set up that lists new news stories involving the terms “string theory”.

That’s quite an occupation you have invented for yourself. Is this the world’s newest profession?! If this is your occupation, of course you will always criticize these press releases, no matter what they say. Who cares anyway: you don’t have any working knowledge of string theory. It is easy to dismiss things you have no clue about!

Obviously, what you are doing is not stopping all the string theory chatter whether it makes sense or not. Quite the opposite, it brings it to the attention of a wider audience. And anyway, complaining is `un-American’ and rarely brings intended results.

You seem like a smart guy: find something better to do with your blog!

16. **Peter Woit**
December 12, 2010

Hi “critic” from Princeton, New Jersey,

You don’t have any substantive argument, but you seem to think an anonymous personal attack will help your cause. Thanks for the encouragement to keep devoting a small fraction of my time to this activity. If it’s causing behavior like yours, it must be having an effect…

17. **Peter Woit**
December 12, 2010

Many commenters claim to be annoyed that I’m spending too much of my time on this blog complaining about string theory. This seemed odd to me, since I couldn’t remember thinking or writing at all about the topic for quite a while until spending the fifteen minutes or so it took to write this post after reading the press release. So, I took at look at the last ten posts on the blog. No complaints about string theory in any of them, the only real reference to the subject was some links to postings about ALICE results in one of 5 parts of one multi-part post.

It’s pretty clear that as far as certain people are concerned, the problem is not that I’m spending too much of my time criticizing string theory, it’s that I’m doing it at all.

18. **luny**

December 12, 2010

To Derek and Chris, of course the limit in the paper is a “back of the envelope estimate”, since it uses an approximation beyond its range of validity.
However, while the “AdS/CFT limit” is certainly more accomplished, its physical foundations are exactly as shaky. We do not know to what extent does the strongly coupled theory with 4 supersymmetries and an infinite number of colors approximate any physical system. We do not know how stable is the “limit” against perturbative corrections (see, for example, http://arxiv.org/abs/0812.2521
Heck, we dont really know weather AdS/CFT is really “right”,its a conjecture.

So both approaches are based on assumptions and extrapolations.
If anything, the most interesting aspect is how close is the AdS/CFT result come to the “back of the envelope” result of 1985.

And Peter, keep ’em coming. Its true that the eta/s result is not to be made fun of, but its also true that a press release describing Fermi Gas measurements as “string theory in a lab” deserves as much making fun of as it can get.
I kind of disagree that this is exclusive to string theory though
(This whopper http://www.sciencedaily.com/releases/2010/03/100329214740.htm
is as hilarious as anything in your blog).
Unfortunately, in this day and age, scientists are under pressure of spinning anything they do into something fashionable, and these press releases are a byproduct of this

19. **New**
December 13, 2010

Woit: “If experiment disagrees with the gauge/gravity duality “prediction”, I doubt anyone is going to give up on gauge/gravity duality, instead they’ll give up on the particular strongly-coupled model used, or decide that the application of gauge/gravity duality in this situation is too naive.”

This is exactly the same as *not* throwing out quantum field theory because not all QFTs are experimentally relevant.

General predictions of QFT (like scalings of scattering amplitudes near fixed points etc.) still have value. Thomas is absolutely right that string theory as we underatand it now is a framwork and not a model.

20. **Peter Woit**
December 13, 2010

New,

Encouraged by thomas, you’re mixing up two completely different things:

1. string theory as a “framework” for producing TOEs that include the SM + GR in the low energy limit. The question of the value of such a “framework” is whether it predicts anything useful at all, allowing it to be tested, but that’s a different issue than the one addressed in this posting.

2. string theory as a “framework” for producing dualities between strongly interacting qfts and gravity theories in another dimension. Assuming this works as advertised, it can give a very useful approximate calculational method. That’s what this press release is about.

21. **Chris Austin**
December 13, 2010

Hi Derek, thanks for the reference.

22. **Mean and Anomalous**
December 13, 2010

I certainly do not see what the problem is with exposing over-hyped ‘scientific’ claims for what they are. Keep up the good work Peter.

23. **New**
December 14, 2010

Sorry Peter, I mixed up nothing. The press release said nothing about whether the potential predictivity of string theory was about Unification or not. You dragged that in, as your handy strawman.

24. **seth thatcher**
December 14, 2010

Peter, thanks for continuing to point out the hype associated with ‘tests’ of string theory. I’m as anxious as anyone to see progress in this area and have no animus toward string theory. Rather, as a layman, I prefer to read both sides of an argument so I can make an informed opinion of the science. As far as I can tell, you are the only one providing a reasoned alternative to string theory. It is a service to me. Of course, I also have no problem with those wanting to attack Peter’s viewpoint as long as it is based on logical objections of his analysis of the science. But most of these objections are not logic based.

25. **AL**
December 14, 2010

Very interesting……I have to agree with you in this case, since I published some work on the non-relativistic gas in question and calculated the ratio of viscosity to entropy-density and obtained about 6 times the conjectured “bound”, in agreement with experiments.
Though my calculation uses “standard” methods, I haven’t
checked, but I am pretty sure it wasn’t cited.

26. **AL**
December 14, 2010

Actually I just checked my paper again and obtained something between
4.5 and 5 times the bound, which is even better.

27. **New**
December 15, 2010

There are some calculations I have seen where people use the QCD Lagangian directly and try to do manipulations with it (or do naive manipulations with it inside the path integral) to get the eta/s ratio for quark-gluon plasma.

I have heard statements defending these approaches, like “at least these people are using the correct (i.e., QCD) Lagrangian, whereas AdS/CFT is using a conformal, supersymmetric theory”. This misses the point completely.

None of these computations are meangful. This is because asymptotic freedom and confinement make QCD an intrinsically quantum theory. The Lagrangian is an utterly meaningless thing to work with (outisde of lattice-based approaches) when the coupling is strong. Said another way, there are no classical, propagating Yang-Mills waves, unlike electromagnetic waves, so classical physics of this kind is useless. AdS/CFT is useful because it gives a direct handle on quantum QCD via classical gravity. At finite temperature, both supersymmetry and conformal invariance are broken and the theory is deconfined. So it is a far better candidate for comparison against the deconfined phase of QCD than any ill-conceived approach using the QCD Lagrangian.

Similar statements hold for any approach that claims to make predictions using “classical” approaches for strongly coupled quantum theories.

New/Somebody

28. **AL**
December 15, 2010

NEW, I agree, for gauge theories like QCD the Ads/CFT correspondence
has been very useful in offering new insights and even quantitative results. Although it remains a conjecture, there is a lot of evidence
that gauge theories are related to gravity in one higher dimension. But this post is about non-relativistic quantum gases, i.e. cold atoms, and it is fair to say that the attempts to use Ads/CFt ideas here are just not as successful.

29. **chris**
December 17, 2010

Dear Apple-Anny,

why don’t you sell oranges?

isn’t that kind of ridiculous?

so why on earth do people feel the need to pressurize an anti-string blogger into blogging about advances in QFT?

seriously people, if you are so bored, go somewhere else, read something different.

Oh and New,

“The Lagrangian is an utterly meaningless thing to work with (outisde of lattice-based approaches) when the coupling is strong.”

wow. why not tell this to Mr. Leutwyler? or to Mr. Goldstone? sure the QCD Lagrangean is entirely worthless at low energies. what a statement.

30. **AL**
December 19, 2010

There is excessive hype in the press release, but one has to distinguish between the media writers and the physicists. I looked at this paper, and it is a solid paper reporting interesting and difficult measurements in cold atoms. The paper itself does not try to promote string theory. I don’t see anything wrong with comparing with a conjecture on the lower bound of this quantity……it’s just interesting. Ads/CFT has certainly provided unique insights into Yang-Mills. Though the connection with relativistic quantum critical points of condensed matter is more speculative, it has nevertheless provided interesting perspectives on transport phenomena. This post was about cold atoms, which are non-relativistic and at LOW energy…..the success here has been nothing to write home about,
but the papers on the subject are honest and worthwhile attempts. Where things seem to go wrong is when the non-scientific media tries to make a splash.

Physicists Finally Find a Way to Test Superstring Theory

December 15, 2010
Categories: Experimental HEP News

More than ten years ago, the New York Times ran a story explaining that Physicists Finally Find a Way to Test Superstring Theory. At the time, the test was scheduled to start in 2005-6:

> In fact, it might be possible to concentrate so many heavy gravitons into a tiny volume of space that they would collapse in on themselves and create miniature black holes, those cosmic sinkholes from which nothing can escape. Experiments like this will be on the agenda when the Large Hadron Collider begins operation in five or six years at the CERN accelerator center in Geneva. "These black holes should be quite safe," Dr. Giddings said, for they would rapidly evaporate.

Today CMS released the results of the long awaited test of superstring theory, based on 35 inverse picobarns of data. It failed.

Update: Since this is getting wider than usual attention via Slashdot, I suppose I should remove tongue from cheek and make clear what is going on here. Claims such as the one in the 2000 Times headline always were nonsense: string theory unification failed long ago because it can't predict anything. Various physicists back then came up with "string theory inspired" models of extra dimensions that would in principle have observable effects at LHC energies. There never was any reason at all to believe these models (and they were no more "predictions of string theory" than anything else), but there was a lot of hype about them, often promoted to the media by people who should have known better. Now that the LHC is finally working, the result is exactly what everyone expected: these exotic phenomena that had no good reason to happen don't actually happen. It's great evidence that the LHC is working as expected, but not an experimental refutation of string theory.

Comments

1. **ted**
   December 15, 2010

   This is not failure. It's success in obtaining one more constraint. It's big business. A professor once told me that his whole academic career was to put increasingly stringent constraints on various models.

2. **Anonymous**
   December 15, 2010

   I suppose one could argue that the threshold of blackhole production based on superstring theory really starts at a higher energy? If this is so, wouldn't we also have seen blackhole production at the Fly's eye and other cosmic ray observatories (assuming they have the right detectors) where the energies can be much higher?

3. **Peter Woit**
   December 15, 2010

   Anonymous,

   The cosmic ray experiments observe only very small numbers of collisions at these high center of mass energies, and have very limited abilities to observe the products of the collision. I don't think they give any useful bounds on black hole production. The LHC results are based on trillions of collisions, and very sophisticated detectors.

   In case it's not clear, the 2000 Times headline always was complete nonsense. Even if you do believe in unification based on strings in extra dimensions, there's never been any good reason to think that the extra dimensions and associated black holes would show up at LHC-scale energies. This was a theoretical possibility that some people found useful as a selling point for string theory, but even they can't be surprised it's not working out.

4. **Tim van Beek**
   December 16, 2010

   Peter said:

   > This was a theoretical possibility that some people found useful as a selling point for string theory, but even they can't be surprised it's not working out.

   Ok, but nevertheless a lot of experimentalist teamed up and invested time and other resources to check it out, so there weren't sufficiently interesting alternatives, or were there?

5. **Peter Woit**
   December 16, 2010

   Tim,

   They're working on looking for a wide range of different things that would give evidence for something beyond the standard model. This is just one of the easier things to see, so the result is coming out first. Over the next year there should be a lot of similar null results in searches for exotic things that aren't expected to be there. But by late next year, there may be enough data to see the Higgs, and that's a very different story.

6. **Average Guy**
   December 16, 2010

   This is science at its best: formulate theories, make predictions, conduct experiments, … and deal with the more than occasional refutation. Some theories need "adjustments" (Newtonian physics) others are plain wrong (caloric, ether) but theories that allow to make predictions are always useful in advancing our knowledge, if only because they can be refuted by experiments and lead to better theories.

7. **Peter Woit**
   December 16, 2010

   Average Guy,

   The problem is that there never actually was a prediction made here. String theory unification failed a long time ago, not because of a bad prediction, but because it can't predict anything.

8. **basic philosophy of science**
December 16, 2010

This result puts constraints on possible hypotheses.

9. **Anonymous2**
December 16, 2010

As someone who actually did research on potential kaluza-klein gravitons produced by the LHC (another testable prediction of large extra dimensions), I thought I should clarify somethings that are glaringly incorrect in this summary:

First, there is a very good reason why these large extra dimensions might exist. They reduce the hierarchy problem to one of geometry. Also, this result doesn't even refute their existence, just reduces the parameter space.

In addition, you shouldn't lump all string theories into one, as if "string theory" would be refuted by the non-existence of large extra dimensions. I also disagree with your assertion that string theory failed because it couldn't predict anything. It in fact predicts quite a bit (for example, the existence of supersymmetric partners). While many predictions of, say, M-theory, can't be tested at energies below the GUT scale, that doesn't mean that none can. For example, many believe the LSP might be within reach of the LHC's energies.

The problem that many have with string theories – namely, that most of its new predictive power lies in the GUT scale – is a problem that faces many extensions of the Standard Model, because, well, that's unfortunately where the bulk of the new physics lies. Just because our experimental apparatuses on Earth are lacking doesn't mean it isn't science. If Einstein had lived a hundred years earlier and thought up relativity then (when no one had dreamed we would be able to measure the speed of light), it doesn't mean what he did wasn't science – it still made predictions that were testable in theory.

10. **Peter Woit**
December 16, 2010

Anonymous2,

Again, the suggestion that this refutes string theory was tongue-in-cheek, parroting the absurd and indefensible claims made over the years that this would be some sort of "test of string theory". You've got to admit though, if CMS had found something of this kind, we'd be seeing a lot of stories about "string theory found at the LHC". This is the usual way all these bogus "tests of string theory" go. If you see something, it's evidence for string theory, if you don't, that says nothing about string theory.

Saying that string theory predicts "the existence of supersymmetric partners" neglects to mention that it is completely silent on what breaks supersymmetry, not even able to say whether it is broken at the Planck scale or at some much lower scale. Saying "my theory predicts a symmetry", but then going on to admit that the symmetry is broken and your theory says nothing about how it's broken is kind of absurd. It's simply not true that string theory is predictive at the GUT scale, with the problem only how to extrapolate to low energies. We know how to extrapolate down from the GUT scale, the problem is that you can get anything you want at the GUT scale.

The question of whether one finds the large extra dimensions solution to the hierarchy problem compelling is to some extent a matter of taste. It's not something that ever appealed to me, and I like geometry, but tastes differ. I think it is a fact though that only a small minority of theorists ever claimed to find this idea appealing enough to lead them to expect evidence for it to show up at the LHC.

11. **Another Programmer**
December 16, 2010

I don't have a Google alert, but anytime I read anything about string theory in the general media, I always look up the reaction on your site and for comparison the site of that Czech guy (afraid to mention his name, don't want to restart the old wars). Please keep doing what you are doing here. In particular I really apreciate that you made an update that is more verbose and more accessible to the people who had strayed away from the real science to some nearby fields.

For this holiday season I was pondering some Marxist thoughts: How to make the physicists real owners of the tools of their trade? It seems like modern physicists are scientific sharecroppers who toil on the LHC-land owned by the absentee landowners and beholden under the opressive thumb of administrators always saying "publish or perish".

I'm trying to find an analogy in the human history where the distance (in tems of income) between owner/administrator and scientist/operator was as high as it is right now in the field of experimental physics. Make an IPO for the LHC and have the stock markets decide the further investments in research? How to make it work such that those expensive scientific tools like LHC are not under control of a secretive cabal that locked themselves in the ivory tower and doesn't want to talk to anyone outside?

12. **Peter Woit**
December 16, 2010

Another Programmer,

I encourage people to read both what I have to say and what Lubos has to say and make up their own minds on issues where we differ (we actually agree about physics more than many people realize). I see from one of his latest that I'm still a piece of "subhuman trash"…

I'm not convinced that lack of control over the means of production (the LHC) is the source of many problems. Just getting the thing to collide protons at high luminosity is a technological tour de force that I don't think could be done better or cheaper by anyone else. Similarly for the highly complex detectors. One can try and argue that someone out there is being kept from doing a really innovative analysis of the data, but all I know is that I have no ideas at all about how to do this better than those working there now.

13. **Eric**
December 16, 2010

Hi Peter,

I just want to say that your assertion that string theory has nothing to say about how supersymmetry is broken is wrong. In a fully worked-out model with all moduli-stabilized, it is in fact possible to calculate the supersymmetry-breaking soft terms. The problem is finding such a model and with knowing whether or not it is a unique solution.

14. **Peter Woit**
December 16, 2010

Eric,

Sure, at least for some classes of “string theory backgrounds” you can in principle stabilize moduli and calculate the soft supersymmetry breaking terms. But the problem is that it seems you can get pretty much whatever such terms you want by appropriate choice of “string theory background”. There’s also large classes of these backgrounds such that you can’t, even in principle calculate this kind of thing. It would be interesting if one could divide up the 105 or so dimensional space of these terms in the MSSM into values that could come from string theory and values that can’t, but I don’t believe that is possible.

15. **Ken**
December 16, 2010

Anonymous2,

“String theory doesn’t predict anything” is perhaps not the correct way to put it, however it is true that string theories lack significant predictive power. The problem is that a unified string theory requires so many arbitrary and independent variables that it effectively becomes a “fitting function” rather than a predictive model of reality.

As for predictions such as supersymmetry, string theories are hardly the only theories out there that require supersymmetry, and they face an occam’s razor problem on that count. Which of the “quite a bit” of predictions are *unique* to a string theory framework, and couldn’t be explained by something simpler?

Though IMO, if the problem of too many arbitrary variables isn’t solved, then there really isn’t any point talking about “predictions” of string theory in the first place.

16. **Eric**
December 16, 2010

Peter,

Yes, but the values of all parameters such as coupling constants and Yukawa couplings depend on the moduli VEVs. If such a model were found that could reproduce the correct values of these parameters with the moduli stablized, then I think the corresponding soft terms with be highly relevant.

17. **Giotis**
December 17, 2010

This article was referring to brane models with large extra dimensions. These models do not belong to String theory per se (although there are analogs in String compactifications where some of their benefits can be reproduced i.e. hierarchy). Every model with extra dimensions is not a priori related to String theory.

Of course the headline is obviously ridiculous.

18. **Chris Austin**
December 17, 2010

“If Einstein had lived a hundred years earlier and thought up relativity then (when no one had dreamed we would be able to measure the speed of light)”

In 1676 Olaf Romer and Giovanni Domenico Cassini found by observing the satellites of Jupiter that light took “about ten to eleven minutes” to cross the distance from the Sun to the Earth, and that distance was approximately known from simultaneous observations of Mars made in 1672 by Cassini in Paris and Jean Richer in French Guiana. The speed of light was estimated from this data by Christiaan Huygens, who died in 1695, 184 years before Einstein was born.

(Sorry for taking up an off-topic thread.)

19. **J. Patil**
December 17, 2010

The String theorist may have to pack up and look for another career. LHC has proven that they are on the wrong path. The early history of string theory also very interesting.
In 1968 a young Italian physicist was searching for an equation which would describe the strong force (the force that binds protons and neutrons). He found a book that contained an equation by a Swiss Mathematician named Leonhard Euler (1707-1783), which seemed to miraculously describe this force.
The discovery would eventually lead the physics community towards string theory, which has become a big part of theoretical physics. How did one guy’s mathematical gaming, translate into String theory and theory of everything?

20. **Markus Maute**
December 19, 2010

If you haven’t seen it yet, here is the latest of Roger Penrose on the subject:

Roger Penrose: Fashion, Faith, and Fantasy Part 7
http://www.youtube.com/watch?v=afsd3_PJais&feature=related

Have fun !

21. **Amos**
December 20, 2010

Peter – can you clarify the scope of the impact of this result?

I recognize that it can’t confirm or contradict string theory generally.

But does it at least exclude large extra dimension models? Or put a cap on the highest possible number of large extra dimensions? Or is it limited to large extra dimension models with particular features?

Those models may not be much of the landscape, or whatever, but they were certainly a pretty central topic of discussion for the past few years, so if that’s the exclusion it seems like it may be an even bigger deal.

22. **Peter Woit**
December 20, 2010

Amos,

For answers to your questions, you’ll have to consult someone who didn’t think these were contrived, implausible models not worth paying a lot of attention to. Can’t help you there.

23. **Amos**
December 20, 2010

    Can any of those people write coherent paragraphs in English? I tried reading Motls' blog post on the subject. It seemed to illustrate the proposition that the longest distance between two points isn't a straight line.

24. **SteveB**
December 21, 2010

    I happened to read a Letter to the Editor in New Scientist in the 08 December issue from noted string theorist Michael Duff and Nobel laureate Abdus Salam. They were commenting on a previous issue's article about the history of the relativity deniers in the early to mid 20th century. Then they took a crack at "us" — those of us who do not see String Theory as working out…

    Start of letter…

    'I enjoyed Milena Wazeck's analysis of the thought processes of those who denied Einstein's relativity (13 November, p 48). Yet it all sounded eerily familiar.

    Phrases such as "when people don't like what science tells them, they resort to conspiracy theories, mud-slinging and plausible pseudoscience" and "the increasingly mathematical approach of theoretical physics collided with the then widely held view that science is essentially simple mechanics, comprehensible to every educated layperson" call to mind the modern-day ramshackle alliance between unqualified scientists, the blogosphere and many science journalists when confronted with the academic consensus of superstrings and M-theory as the most promising candidates for unifying gravity with the other forces of nature. These people are quick to cry "this is not science", while themselves resorting to pseudoscientific alternatives.'

    …end of letter.

    Are we resorting to "pseudoscientific alternatives?". I do not think Peter is at all. I agree there is a strong message often found here that is similar to "this is not science."

25. **Peter Woit**
December 21, 2010

    Thanks SteveB,

    That's pretty amazing. But it's just from Duff, not from Salam, who died about 15 years ago. Duff is just invoking his title of "Abdus Salam professor".

String Theory Fails Another Test, the “Supertest”

December 17, 2010
Categories: Experimental HEP News

Wednesday’s CMS result finding no black holes in early LHC data has led to internet headlines such as String Theory Fails First Major Experimental Test (for what this really means, see here). At a talk today at CERN, yet another impressive new CMS result was announced, this one causing even more trouble for string theory (if you believe in purported LHC tests of string theory, that is…).

Back in 1997, Physics Today published an article by Gordon Kane with the title String Theory is Testable, Even Supertestable. It included as Figure 2 a detailed spectrum which was supposed to show the sort of thing that string theory predicts. Tevatron results have already caused trouble for many of these mass predictions. For example, gluinos are supposed to have a mass of 250 GeV, but the PDG lists a lower bound (under various assumptions) of 308 GeV. At CERN today, the CMS talk in the end-of-year LHC jamboree has a slide labeled “First SUSY Result at the LHC!”, showing dramatically larger exclusion ranges for possible squark and gluino masses. Over much of the relevant range, gluino masses are now excluded all the way up to 650 GeV. It looks like string theory has failed the “supertest”.

If you believe that string theory “predicts” low-energy supersymmetry, this is a serious failure. Completely independently of string theory, it’s a discouraging result for low-energy supersymmetry in general. The LHC has just dashed hopes that, at least for strongly-interacting particles, supersymmetry would show up just beyond the energy range accessible at the Tevatron.

Comments

1. **Glenn**
   December 17, 2010

   So, what’s the ‘motive’ towards “Supersymmetry” anyway? I see why people wanted to unify forces (electric force vs. weak force vs. strong force vs. gravity) but I’m not sure why having bosons vs. fermions is such a bad thing?

   And where are we in the strong plus electroweak unification theories anyway? The last I heard, combining them lead to predictions of proton decay that haven’t panned out.

   I always thought String Theory (TM) was supposed to resolve all this stuff.

2. **Peter Woit**
   December 17, 2010

   Glenn,

   Supersymmetry is a long and complicated story, I wrote a whole book to address questions like yours. Not much has changed since the book

   To all: please try and restrict comments to the topic of the post. While a general purpose place for people to ask questions and discuss particle physics would be a desirable thing, this isn’t it.

3. **Eric**
   December 17, 2010

   Hi Glenn,

   The main phenomenological motivation for supersymmetry is that it solves the hierarchy problem, which means that it prevents the Higgs mass from receiving large quantum corrections that would push the electroweak scale up to the Planck scale. Also, it improves the running of the gauge couplings to that they seem to unify at high energy. Finally, it includes a natural dark matter candidate.

   Peter: Looking at the supersymmetry particle spectra from some well-motivated string models, it appears that the viable parameter space prior to any results from LHC always has the gluino in the 1-2 TeV range. So, I don’t think that the current constraints represent an actual test that string theory has failed.

4. **Peter Woit**
   December 17, 2010

   Eric,

   The favored gluino mass in string theory models seems to have moved up from Kane’s 250 GeV back in 1997….

   I don’t doubt that string theory models can be found with whatever gluino mass one wants. Today’s news is presumably just the start of a long story during which superpartner mass limits will keep moving up, with favored string theory models keeping pace.

5. **Glenn**
   December 17, 2010

   Peter,

   Thanks, I own the book, read it, and even followed along pretty well for most of it, I think.

   I need to put it on the list to read again, along with “The Trouble With Physics.”

6. **Giotis**
   December 17, 2010

   Well 1997 was a long time ago…

   Currently and as far as I know String theory from a top down approach does not favour low energy SUSY in the sense that it is not expected these kind of vacua to be a majority in the landscape in comparison to vacua with other (high) breaking scales. I could even say that the opposite is true although this is debatable.

On the other hand low energy SUSY as it is well known is motivated mainly by theoretical considerations in order to solve problems like unification of couplings and the hierarchy. If it is excluded in LHC then one might naturally ask why we need SUSY after all if it doesn't solve the problems of the SM we want to solve. So SUSY as the most prominent candidate theory for physics beyond the SM will be strongly questioned. This will have at least a physiological impact to Supersymmetric theories in general like String theory.

7. **Peter Woit**
December 17, 2010

Giotis,

I see. If SUSY shows up at the LHC, string theorists will claim vindication. If it doesn't show up at the LHC, they'll just say it shows that the string theory landscape is right, that they knew very well SUSY wouldn't be at LHC scales since most of the vacua are at high supersymmetry-breaking scales.

8. **Mark**
December 17, 2010

Peter, if anything, this exclusion plot should only make Gordon Kane very happy because it excludes a region with light sfermions.

9. **Giotis**
December 17, 2010

Peter I understand but here is the point:

Let's say that we want to find a solution to the hierarchy problem and we have two ways for solving it, fine tuning (like the fine tuning of CC in the Bousso Polchinski model) and Low energy SUSY. Now in String theory there are models which can produce both mechanisms. Fine tuning may seem quite unlikely at first but given the plethora of vacua that can realize it this may well be the prediction of String theory after all and not low energy SUSY. This would be the case if we could estimate that the vacua which we obtain from these models are much more frequent and thus statistically favoured over the low energy SUSY vacua.

This is an over simplified picture of course and many other factors must be considered but it is the general idea. The fact that String theory is a Supersymmetric theory doesn't imply that String theory favours SUSY at LHC. You must first check the models and the statistics of the corresponding vacua. Of course if SUSY is found at LHC this would be very important for String theory but only as a theoretical framework regardless of any 'predictions'.

10. **anon**
December 17, 2010

Since landscape statistics is generally pulled out the nether regions of the body, the only way to judge any statement of the form 'most vacua are X' or 'X is more likely than Y in the landscape' is to see WHOSE nether regions it is pulled out from. A professor at Stanford — well, maybe I'll give it 2 minutes of thought. A grad student — not so much.

Given this is the only available criterion, I find it hard to judge statements made on a blog about what's common on the landscape.. I mean, how respectable is your nether region?

11. **anon**
December 17, 2010

as a string theorist (on the more mathematical end) and as a human being (who knows the general structure of issues being debated here), it drives me up the wall that clearly intelligent and thoughtful people like 'giotis' go through all these ridiculous constructions in clear denial of what is staring them in the face.

the world is so full of interesting ideas. science even more so, physics most so. Take a short walk and take the time to understand what a good non-high-energy physicist or scientist is thinking about — you'll be amazed at (and reminded of) how interesting ideas are formed and work out.

No twisting and turning and playing dodgeball for 20 years required.. You think up an interesting idea, try it, throw it out if it doesn't work and go on to something else.

It'll really seem like a breath of fresh air, compared to the landscape cr*p people here at talking about.

12. **Mitchell Porter**
December 18, 2010

anon @ 9.24pm, do you consider string theory itself a dead end, or just landscape statistics?

13. **Verified Armonyous**
December 18, 2010

anon @ 9.24pm, we would be happy to test our theories in our tabletop colliders on Fridays, but even a string theorist surely knows it's a bit more complicated than that. That's unfortunate but it's the only way when you're asking the most fundamental questions.

Glenn, Supersymmetry is the coolest thing you could expect to find at the TeV energy frontier. It is revolutionary (you heard about fermionic dimensions?), beautiful (people will wear the SUSY algebra in T-shirts :)), perturbatively well behaved (you can extend it to hugely large energy scales), solves neatly some SM problems, gives naturally a dark matter candidate, points to grand unification, passes switfly precision tests, etc.

14. **anon 924**
December 18, 2010

landscape statistics and related attempts to connect strings to particle physics are bad mathematics and bad physics. i think there are so many interesting things to think about and do in string theory and hep-th in general. I know many around me who do this.

On the other hand, it's seems stupid that some people need to twist themselves into pretzels and wave their hands and waste their youth writing the most non-rigorous worthless papers, trying to justify this as physics testable at the LHC, just so funding levels remain higher than it would if this were classified as mathematics or mathematical physics.

To all you younger landscape / string pheno people out there — do you really think your work will 1) be proven true? 2) be proven false? 3) neither but contributes a new physical IDEA? 4) none of the above?
My opinion is that (4) holds for all of the landscape. It's like biting into an air-filled pastry.

Oh, please stop with the “can’t test grand theories so easily”. My complaint is that pheno end of string theory is quackery with no rigor, not misunderstood genius that has come way before its time.

15. **Mark**
December 18, 2010

Dear anon 924,
String pheno is a huge field that has been around for a few decades before this landscape statistics bs came about. There are many far more important, in my opinion, and interesting problems in string pheno that people are working on. If you check out the talks at this year’s KITP program on string pheno you’ll see that landscape statistics is a rather marginal topic. On the other hand, understanding the mechanism of SUSY breaking is a very important problem and will remain one of the dominant topics in het in the years to come, especially if superpartners are discovered at the LHC. After years of research it is pretty clear that moduli stabilization and SUSY breaking are extremely closely related and one can already make some very specific statements about sparticle spectra based on very few known realistic scenarios.

16. **MathPhys**
December 19, 2010

“Fine tuning may seem quite unlikely at first but given the plethora of vacua that can realize it this may well be the prediction of String theory after all and not low energy SUSY. This would be the case if we could estimate that the vacua which we obtain from these models are much more frequent and thus statistically favoured over the low energy SUSY vacua.”

The above statement goes against the grain of every intuition that we have gained since Pierre-Simon Laplace wrote his book on probability theory.

17. **anon 924**
December 20, 2010

mark, i admit that string pheno is larger than landscape ramblings – but string pheno is often either rigorous and irrelevant to the LHC or very ad hoc and isn’t really ‘stringy’ anyway.

For example, to follow your example, i think there is VERY VERY little string theory has to add to the story of SUSY breaking.. besides in gravity mediation perhaps. i don’t think any serious honest person is working on stringy models of SUSY breaking.. even people with stringy knowledge and skills like Seiberg.

You can claim susy breaking is related to modulii stabilization in string theory but that’s like saying issue X is related to issue X + Y. True but I can ignore Y and work on X alone just fine.. modulii stabilization might have consequences for susy breaking but the latter can exist without the former.

18. **chris**
December 20, 2010

Mark,

i respect your opinion, but i can’t help noticing the irony in a statement like

“understanding the mechanism of SUSY breaking is a very important problem and will remain one of the dominant topics in het in the years to come, especially if superpartners are discovered at the LHC”

posted in a thread on the first huge exclusion sweep of the LHC.

i am asking this in honesty and not tongue in cheek (as i really would like to know): is your scientific judgement and gut feeling still pointing towards low energy SUSY?

in the 70s and 80s SUSY certainly had its appeal. we knew much less then about the TeV scale and even electroweak symmetry breaking. but looking at what has happened experimentally in between makes SUSY look like a dinosaur to me. W and Zs were found and later the top, the Higgs limit was pushed to 115GeV, the cc was found and anisotropies in the CMB. our view of the world has considerably changed and expanded since the invention of susy but still no trace of remnants of this elusive symmetry. are you not bothered by this or, in other words, was it to be expected that susy is so hard to find?

19. **Mark**
December 20, 2010

Dear anon 924,
The assumption that “modulii stabilization might have consequences for susy breaking but the latter can exist without the former.” is certainly not ruled out but appears to be very unlikely for very good reasons. Let us be conservative and assume that a given compactification is described by N=1 D=4 sugra. Then, decoupling moduli stabilization from SUSY breaking would require 1) Stabilizing all moduli by the superpotential only without relying on the Kahler potential. 2) Having an additional dial in the superpotential, essentially a constant, and using it to fine tune the total superpotential very close to zero so that the the resulting vacuum is very nearly SUSY Minkowski. 3) Breaking SUSY on top of that and decoupling the s-goldstino (aka a modulus) from the gravitino while maintaining a tiny CC (this is needed in gauge mediation to avoid a very light modulus) requires a rather contrived choice of a Kahler potential for the SUSY breaking field. While 1) is certainly possible, 2) is extremely non-generic because of the amount of fine tuning required to achieve SUSY Minkowski vacua. Furthermore, 1) + 2) would certainly kill any attempt to solve the strong CP problem via a QCD axion since all the axions would be rendered too heavy, as Joe Conlon has rigorously proved in the context of N=1 D=4. 4) Simply embedding a viable gauge mediation scenario into string theory is a rather daunting task in itself.
Therefore, unless you are so heavily invested in gauge mediation that you are willing to give up on naturalness, it is pretty clear from the top down perspective that gravity mediation is much more natural and that the problem of moduli stabilization is intimately related to the question of SUSY breaking.

20. **Mark**
December 20, 2010

“i am asking this in honesty and not tongue in cheek (as i really would like to know): is your scientific judgement and gut feeling still pointing towards low energy SUSY?”
Yes, there are at least four very compelling reasons to consider TeV scale superpartners. Stabilizing the gauge hierarchy, precision gauge coupling unification, radiative electroweak symmetry breaking, LSP as a dark matter candidate. The exclusion plot discussed in the posting considers a small portion in the parameter space of a very simplified, almost adhoc, set of GUT scale boundary conditions called msugra. Let us wait until the LHC collects at least 10/fb before we jump to premature conclusions.

“was it to be expected that susy is so hard to find?” In retrospect, if the SSC had not been cancelled, SUSY could have already been found a decade ago.

21. **piscator**
December 20, 2010

anon924,

If you have thought about the subject seriously, I find it hard to see how you can say string theory has little to add in susy breaking except perhaps in gravity mediation – so little except in the (arguably) best motivated type of susy breaking, where all the operators are coming from the Planck scale.

In any case every serious person knows (and has known for years) that in any context with a UV string embedding an honest discussion of susy breaking requires addressing moduli stabilisation. You're right it's possible to work on susy breaking in global field theory without thinking about moduli stabilisation. It's even possible to have a successful career doing so. There are lots of interesting results thereby obtained for susy breaking in worlds that don't have gravity. None of this means this has any real physics value to susy breaking in this world. It's like Feynman's example of the flow of dry water, it may be interesting qft but its missing a crucial part.

22. **MathPhys**
December 21, 2010

Dear Mark,

"In retrospect, if the SSC had not been cancelled, SUSY could have already been found a decade ago."

It's statements like this that give string theory and theorists a bad name.

23. **Eric**
December 21, 2010

Dear MathPhys,

Can you explain exactly how Mark's factual statement possibly gives string theory and theorists a bad name? If TeV-scale SUSY does exist, it would most certainly have been found at the SSC had it been constructed. Since it was cancelled, theorists have more or less had to wait for the LHC, although there was always an outside chance that it could have been seen at LEP or the Tevatron.

24. **Thomas Larsson**
December 22, 2010

In retrospect, if the SSC had not been cancelled, low-energy SUSY could have already been ruled out a decade ago.

25. **MathPhys**
December 22, 2010

Dear Eric,

To me, Mark's statement implied that

"There is supersymmetry, there is no doubt about it, but we were denied the chance to discover it".

It's this messianic approach to science that gives the subject a bad name. A better statement would have included Larsson's comment above

"In retrospect, if the SSC had not been cancelled, low energy SUSY could have either been found or ruled out a decade ago."

26. **Chris Oakley**
December 22, 2010

Not entirely. There is Occam's razor. If I posit that there is a real Father Christmas who charges around the sky on a sleigh pulled by reindeer, climbing down chimneys to leave presents – but only for children who have been good, then the onus is on me to prove it – not on you to DISprove it. Similarly, all experimental evidence so far leads one to the conclusion that there is no supersymmetry – its only value is as a band aid to patch up ailing theories that probably should have been binned instead. So unless someone can come up with something more compelling the default position should be that it does not exist.

27. **MathPhys**
December 22, 2010

On the one hand, supersymmetry is by and large the reason why quantum physics (starting with Witten's work on Morse theory in the early 80's to mirror symmetry) has been spectacularly successful in pure mathematics over the past 30 years.

On the other hand, after 35 years now, there is indeed not a shred of evidence of supersymmetry in the real world. It's a very peculiar situation.

28. **chris**
December 22, 2010

Hi Mark,

thanks for your honest answer. I see the standard arguments, but there is always this nagging feeling.

Let's take the unificaton of couplings. As far as I know, this is essentially still a 1-loop argument. But granted that it is true in the full, nonperturbative context, what does it tell us?
I am thinking in comparison of the Weinberg angle. It is really close to the predicted SU(5) GUT value. So close in fact that Georgi and Glashow in their original paper were about as sure as one can be that this is the true symmetry group of nature. Alas, it has been firmly ruled out by now.

So what does it tell me that 3 lines do intersect in one point instead of a larger region? unification looks not too bad if only very little is allowed to happen between the TeV and the GUT scale. I really find it very difficult to interpret anything furthter into it.

29. **Eric**
December 22, 2010

MathPhys,

I think you are misinterpreting Mark's statement. Saying that SUSY could have been discovered already if SSC had not been canceled is quite different than saying that it would have or should have, which is what you seem to think he said. I think it's fair to say that whatever new physics exists at the TeV-scale would have been discovered by now if the SSC had been built, SUSY or otherwise.

30. **MathPhys**
December 22, 2010

Dear Eric,

Yes, I agree with you. I took his statement more along the lines of "would have been discovered". I also wish he would have added "or otherwise" to make his statement more balanced.

31. **Mark**
December 22, 2010

Dear Chris,
"So what does it tell me that 3 lines do intersect in one point instead of a larger region?"
As you know, the unification idea, whether it is SU(5) or SO(10), is well motivated by the fact that the matter multiplets of the SM nicely fit into into complete GUT multiplets. This is a higly non-trivial clue and should be considered very seriously. However, for this idea to work: 1) the three gauge coupling must unify at some scale; 2) the unification scale must be high enough to suppress the proton decay. As we know now, if the SM is all there is between the EW scale and the GUT scale, this does not work. The proton decays too fast while the couplings do not actually unify.

Keep in mind that the MSSM was introduced to address the gauge hierarchy problem, first and foremost, and the other three properties I mentioned in my previous posting followed *automatically*.

In fact, to get the couplings to unify at 1-loop one does not need the full MSSM! Including light Higgsinos only can do the job to satisfy requirement 1). However, in this case the unification scale will be around 10^14 GeV – the same as the original non-susy GUT. This is deadly because of the proton decay. Including the MSSM gauginos changes the relative running speed and raises the scale at which the couplings unify, which is nice because the proton lifetime becomes much longer, hence satisfying requirement 2). On the other hand, at 1-loop, the MSSM matter multiplets play no essential role (they only change the slopes and thus the value of the unified coupling) as they come in complete GUT multiplets. So, if you only want to use SUSY for the purpose of preserving the gauge coupling unification you can completely decouple all the squarks and sleptons! This idea is called split SUSY and completely gives up on addressing the hierarchy problem but some people are taking this possibility seriously. A long-lived gluino is a robust prediction of such a model and it is actually being searched for at the LHC. It is perfectly possible to add a few heavy complete vector-like GUT multiplets to the largangian and not spoil the perturbative unification. Now, when you start to include 2-loop effects life becomes more interesting. In this case the running becomes slightly more sensitive and depending on the details of, say the gaugino spectrum at the unification scale, the couplings can unify even more precisely at 2-loops.

December 23, 2010

Dear Mark,

thank you very much for your detailed response. As you explained so nicely it is indeed a very nice feature of the MSSM to address several problems of unification at once. although I do not see the gauge hierarchy problem as solved by the MSSM but rather shifted to another sector, it is indeed intriguing circumstantial evidence that this solution also results in a dark matter candidate and unification of couplings.

but my problem really is with the circumstantial nature of this evidence and i would like to once again pick the unification of couplings as the example. since i first saw this plot, i always wondered about one thing: unification seems to happen at almost the planck scale (logarithmically). it is nice that susy at 1-loop brings the 3 couplings together, but to be completely compelling i would have somehow expected this intersection of 3 lines to – so to say – intersect with a 4th line, the naively computed fundamental scale (plank scale). you see, intersecting 3 lines is not such a big deal. as you so nicely pointed out yourself, you need just one new fermion with the appropriate couplings. that's it. and the advantage of intersecting higher that 10^14 TeV is also a two-edged sword: yes, one can portray it as a success given the experimental knowledge we have, but in fact the success consists of nothing more than evading another experiment. from an unprejudiced, purely theoretical point of view unification at a lower scale would be preferred a priori because of its increased testability or , put differently, because it decreases the extent of the region one has to proclaim as being a dessert. that is, if this scale is not found to be the planck scale or given by another, independent experimental hint.

to me it seems that susy does get some things right but not quite all of them. and i am sceptical as to whether the features it does get right are not just some rather universal ones.

33. **Mark**
December 23, 2010

Dear Chris,
Once the three gauge couplings unify at ~10^16 GeV, they keep running as a single coupling, i.e. one line. This is because all the GUT scale extra states complete the formerly incomplete GUT multiplets. So the higgses and higgsinos instead of doublets become 5-plets and \bar 5-plets, the gauge bosons become 24-plets etc. So after the three couplings unify they no longer diverge and run as one. However, above the GUT scale the theory may no longer be effectively 4-dimensional so one needs to take into account the contributions from the KK modes, etc. This will change the shape of the running. The unification of the SU(5) gauge coupling and the gravitational coupling will eventually take place at a scale a few orders of magnitude above the GUT scale.

34. **Mark**
December 23, 2010

Dear Chris,

"from an unprejudiced, purely theoretical point of view unification at a lower scale would be preferred a priori because of its increased testability or , put differently, because it decreases the extent of the region one has to proclaim as being a dessert."

I would qualify this point of view as motivated by experimental testability accessible with the current technology rather than a purely theoretical. I'm fairly certain that testing the proton decay lifetime in the context of SUSY GUTs will eventually be possible as new expreiments will come online.

"although I do not see the gauge hierarchy problem as solved by the MSSM but rather shifted to another sector, it is indeed intriguing circumstantial evidence that this solution also results in a dark matter candidate and unification of couplings."

Indeed, SUSY does not "solve" the gauge hierarchy problem, rather it "stabilizes" the electroweak scale while it does not really explain its origin. In order to *really* explain the origin of the electroweak scale once needs to have a model of SUSY breaking where the only dimensionful input is the Planck scale. Back in the early 80s Ed Witten suggested an excellent idea where some strong gauge dynamics in the hidden sector generates a small scale of SUSY breaking in the visible sector via dimensional transmutation. This is referred to as dynamical SUSY breaking. I personally think that this is the best idea we have and I don't agree with the landscapeologists that the EW scale is there because some fluxes are extremely fine-tuned.

By the way, as I said in my previous posting, in addition to the precision unification and the LSP as a dark matter candidate, the MSSM also naturally explains why the electroweak symmetry is broken. Recall that in the SM the higgs potential has a negative mass squared term in order to generate a minimum where the higgs vev is non-zero. In the SM this tachyonic potential is put in by hand and has no dynamical explanation. In the MSSM, on the other hand, the negative mass squared term has a dynamical explanation. It is generated via radiative corrections, mainly due to the large value of the top Yukawa coupling. So, in the context of the MSSM, one can claim that at least one of the SM quarks must be very heavy in order for the EW symmetry to be broken. Again, this rather non trivial result was not the reason why the MSSM was introduced but comes automatically as a bonus.

HEP News

December 17, 2010
Categories: Experimental HEP News

Besides the dramatic new CMS results mentioned in the last two postings, there's other news from the high-energy frontier as it moves from Illinois to Geneva.

Earlier this week the MCTP hosted a workshop on LHC First Data. Today at CERN was the LHC end-of-year jamboree, talks available here.

Plans for next year's LHC run were made at Evian last week and will be finalized at Chamonix next month. Beam re-commissioning will start February 21, and it looks like the goal will be to run the machine at 4 TeV/beam (up from 3.5 this year) and accumulate a total luminosity of 1-3 inverse femtobarns. Instead of shutting down during 2012 to fix magnet interconnections, the plan now is for the LHC to continue running through 2012, accumulating enough data to definitively see or rule out a Standard Model Higgs and finally put the Tevatron out of business.

Today at Fermilab people are looking backwards, with a symposium celebrating the 25th anniversary of first collisions at the Tevatron. While a proposal has been put forth to keep the machine running through FY 2014, the budgetary situation looks increasingly likely to put them out of business, no matter what CERN does. The dysfunctional nature of the US federal budget process means that the laboratory is already several months into FY 2011, with no budget, operating under a "continuing resolution" that allows them to spend money at the same rate as last year. Last night, an effort to pass an "omnibus" spending bill for the rest of FY 2011 allocating total spending at the same level of FY2010 was defeated. This means that until February and the next Congress, Fermilab and the rest of the government will operate without a budget. At some point after that, the Republicans plan to try and pass a budget cutting spending from the FY2010 level. Fermilab could very well find itself this Spring finally finding out that its FY2011 budget has been cut, with only a few months left to get spending down to the appropriated level. Budgetary problems are not just affecting the Tevatron, with plans for an underground laboratory in South Dakota dedicated to neutrino and other experiments now up in the air as the NSF has withdrawn its support for the project.

President Obama did make an inspiring speech about his dedication to support Research and Development spending.

   December 17, 2010

   I think you meant 4 TeV beams, not Gev. This would be a disappointing performance by the LHC.

2. **Peter Woit**
   December 17, 2010

   Thanks HET student. Fixed.

3. **Nickle Berry**
   December 18, 2010

   I suppose Obama pans to pay for scientific research with tax cuts for the rich.

4. **Chris Austin**
   December 18, 2010

   Is anything more known about the little dip at M_Inv = 1.6 TeV and the following bump at M_Inv = 1.9 TeV in the 3rd plot, labelled ATLAS-CONF-2010-088, in the top row of the graphs on page 28 of the Atlas talk? The dip seems to be 3 sigma, and since the data follow a smooth curve, with a dip and a bump that is not in the Monte Carlo, one could argue that the significance is more than that. But M_Inv of what? The vertical axis shows Entries/0.1 TeV, but Entries of what? The integrated luminosity for the plot seems to be just 295 per nb, so has that signal now vanished, or is it still there?

5. **Anonymous**
   December 18, 2010

   "…the plan now is for the LHC to continue running through 2012, accumulating enough data to definitively see or rule out a Standard Model Higgs…"

   So what happens if the Higgs is ruled out by the end of 2012? What do we look for next?

6. **Chris Austin**
   December 18, 2010

   One possibility would be a fourth Standard Model generation, which would also allow the Higgs to be heavier.

   With reference to page 15 of the Atlas talk, it is not clear to me how the lack of structure in what appears to be the 2-jet invariant mass can exclude the production of excited quarks, by which I assume they mean quarks of a 4th Standard Model generation, with masses in the range 0.3 to 1.5 TeV.

   For from the graph of cross sections that appears on pages 6, 7, 9, 13, etc., it appears that sigma_b = sigma_{4.2 GeV} is about 3 x 10^5 nb at 7 TeV, and sigma_t = sigma_{172 GeV} is about 0.2 nb, so the heavy quark production rate scales with mass as about m^{-3.83}. So we expect sigma_{600 GeV} to be around 0.002 nb, which for an integrated luminosity of 3.1 per pb corresponds to about 6 events, against a background of 10^3 events. And we expect sigma_{900 GeV} to be around 0.4 pb, which corresponds to about 1 event, against a background of 100 events. And we expect sigma_{1500 GeV} to be around 0.05 pb, which corresponds to about 0.2 events, against a background of 6 events.

   So the graph on page 15 seems to me only to limit the couplings of 4th generation quarks to be less than values somewhat larger than the Standard Model couplings.

7. **neo**
   December 18, 2010

   Does it make any sense to continue to run the Fermilab TEV now that the LHC is operational? Can it expect to compete with the reams of data being turned out by the LHC detectors?

8. **Peter Woit**

December 19, 2010

neo,

Whether to keep the Tevatron operational is currently being debated. For the moment it is far ahead of the LHC in the Higgs search business, and the argument has been made that it could remain competitive for a few more years as it accumulates data faster (although at lower energy) than the LHC. But that was based on the assumption that the LHC would shutdown for at more than a year after reaching 1 inverse femtobarn in luminosity sometime next year. If the LHC acquires 3 inverse femtobarns in 2011 and keeps going through 2012, then it will definitively outclass the Tevatron in the Higgs search.

The way the US budget situation is going, this may be a moot point anyway. It's still unclear whether there will be funds to get through this fiscal year, much less funds to run the Tevatron in FY 2012.

9. **Chris Austin**
December 20, 2010

With reference to my first comment above, a Google search for ATLAS-CONF-2010-088 turned up the full report, "Search for new physics in multi-body final states at high invariant masses with ATLAS", dated August 21, 2010. They selected events with at least three objects such as jets or leptons in the final state and an invariant mass above 800 GeV and total p_T greater than 700 GeV. The initial large peak is due to the cut on m_Inv at 800 GeV and the fact that the Standard Model background is rapidly decreasing. The graph appears on pages 8 and 9. The dip at 1.6 TeV and the peak at 1.9 TeV are definitely not in the Standard Model background. The data follow a very smooth curve, i.e. with almost no scatter, that departs substantially from the Monte Carlo, so although the dip is only 3 sigma below and the bump is only 1 sigma above the Monte Carlo, one could argue that the significance of the whole smooth curve is more than 3 sigma.

The analysis used just under 300 per nb of data, but ATLAS now has 45 per pb, i.e. 150 times more, so if the trend shown in the graph has continued, it will be a discovery by now. There is no update available yet in the ATLAS Conference Notes, nor on arXiv. It would be very interesting to hear from someone in ATLAS about the current status of this signal.

The search was designed to look for evidence of TeV-scale gravity, in the shape of high mass states decaying democratically to Standard Model states. The discussion on pages 10 and 11 refers only to semi-classical black holes, for which no evidence was seen. The bump could be a Kaluza-Klein graviton in the Randall-Sundrum-1 model, or it could be a KK mode of the graviton multiplet in the geometry of subsection 2.5 of my article arXiv:0704.1476, which is totally different from the Randall-Sundrum geometry, but also has the lightest massive gravitational KK modes around a TeV: their wavefunctions are pushed up against our boundary of the Horava-Witten interval by the warp factor.

The only way I know to force the subsection 2.5 geometry to occur uses very large electric fluxes of the 4-form, whose dual 7-form fluxes wrap the de Sitter 3-sphere times a 3-cycle of the compact hyperbolic 6-manifold times the Horava-Witten interval. Choosing the quantized flux numbers to be about 10^{126} forces the cosmological constant to be about right, i.e. the de Sitter radius is forced to be about 10^{26} metres, and Newton's constant and the electroweak breaking mass are also forced to be about right.

The flux quantization condition is invariant under the full de Sitter group, but the fluxes are not. However it seems possible that the only significant observable Lorentz violations will be in the dynamics of the massive gravitational KK modes, so it would be worth checking if the size or position of the dip and the bump vary in synchrony with the Earth's sidereal rotation, i.e. the Earth's absolute rotation with respect to the stars. (A sidereal day is approximately 23 hours and 56 minutes.)

10. **Shantanu**
December 20, 2010

Peter, maybe slightly OT,
but see the slides of NNN 2010 conference at Toyama
http://www-sk.icrr.u-tokyo.ac.jp/NNN10/
See in particular the talks by Nomura and concluding talk
by Jung. (again emphasis of this conference is proton decay
and underground detectors)

Short Items

December 21, 2010
Categories: Uncategorized

- The Tevatron last week passed the milestone of 10 inverse femtobarns of luminosity delivered to the experiments. That's about 1.5 quadrillion collisions.
- Presentations from the Simons Center Inaugural Conference, discussed here, are now on-line.
- Luis Alvarez-Gaume and John Ellis discuss here the Higgs mechanism, its history and the question of who should get a Nobel prize if the Higgs particle is found There's the usual attempt to cut Anderson out of the picture (for more see here), I gather this is payback for his opposition to the SSC.
- The Cambridge City Council has passed a resolution congratulating Yau and Nadis on the publication of their book about Calabi-Yaus, *The Shape of Inner Space*.
- Barry Mazur and William Stein are working on a book entitled *What is Riemann's Hypothesis?*, with a rough draft available here.
- If you want to seriously learn algebraic geometry, maybe the best way would be to take Ravi Vakil's Math 216 course on-line here. OK, I should have told you about this at the beginning of the semester, because if you start now you'll be way behind. But, since it's on-line, maybe that doesn't matter. You could try and catch up…
- There have been various recent claims to see evidence of pre-big bang physics in the CMB (see here and here), although the significance level of these results seems to be about that of the discovery of Stephen Hawking's initials in the same data. Several preprints have already appeared criticizing the first of these claims, Sabine Hossenfelder deals with the second here. John Horgan blogs about this as "science faction" here, and discusses it with George Johnson here.
- Mike Duff seems to now be deep in Lubosian territory, publishing a letter to New Scientist that accuses those who don't accept the supposed "academic consensus of superstrings and M-theory" as being just like the crackpots and anti-Semites who refused to accept Einstein's relativity back in the 20s. According to Duff, the explanation for criticism of string/M-theory is that:

> when people don't like what science tells them, they resort to conspiracy theories, mud-slinging and plausible pseudoscience.

Update: The America COMPETES Reauthorization has just passed the House and will go to the president to be signed, something no one expected to happen a week or so ago, more details about the legislation here. I gather that it authorizes 5 to 7% increases for science agencies. Problem is that these are not the actual appropriations, which are still up in the air, awaiting action next year by the next Congress. But this does indicate that there is bipartisan willingness to at least pay lip service to protecting the research and development part of the budget.

Comments

1. **Garrett**
December 21, 2010

In the Simons talks, Atiyah's slide 17 caught my eye. I wonder what he was saying to accompany that.

2. **Peter Woit**
December 21, 2010

Garrett,

I don't remember Atiyah giving any more details about that in the talk than in the slides. He was explicitly operating in an extremely speculative mode…

3. **Roger**
December 21, 2010

Do you have any idea what Duff is referring to where he said:

> These people are quick to cry "this is not science", while themselves resorting to pseudoscientific alternatives.

The closest I found was this 2002 letter, where he seems to complain that an article mentioned quantum gravity and human consciousness, without mentioning M-theory.

4. **Peter Woit**
December 21, 2010

Roger,

The 2002 letter seems to claim that M-theory explains everything, except consciousness, and that Duff likes that situation.

In the new letter, the culprits are "unqualified scientists, the blogosphere and many science journalists", and I'm pretty sure I qualify. He doesn't specify what pseudoscientific alternative I'm resorting to, maybe he is strongly opposed to the use of representation theory, or any tinkering with the BRST formalism. One other possible guess is that in his mind loop quantum gravity is a "pseudoscientific alternative" and Lee Smolin is an "unqualified scientist", but who knows. To me Duff sounds a lot like Lubos does these days, so maybe you can consult Lubos's extensive writings for more specifics.

5. **Roger**
December 21, 2010

If Duff is referring to you, then he is worse than Lubos. Lubos posts crazy rants every day. He has probably said worse things about you, but it is clear that he just doesn't like your negative comments about string theory. Duff's letter is published in a respectable journal. Some editor had to approve it as making a reasonable point. If Duff is going to say, in print, that you are unqualified and pseudoscientific, then he ought to back it up. Duff seems more irresponsible to me.

6. **Tim van Beek**
December 22, 2010

Since the letter of Michael Duff is not the daily abreaction of a lonely and troubled soul, there must be a concrete reason that prompted it, several years after most people lost interest in the "string wars". Does anyone know what it is?

(And does anyone know what is supposed to be the unpopular truth that string theory tells?).

7. **Peter Woit**
December 22, 2010

Tim,

It's hard to guess what might cause someone in Duff's position to start writing public letters comparing their situation to that of Einstein and accusing those who don't believe in their speculative theory of incompetence. I've never seen anything quite this odd.

8. **neo**
December 22, 2010

Duff appears to be attempting to continue an unfortunate but effective tactic of lumping all skeptics of a theory with some crackpots and classifying them as "deniers". He has a tough go in this case though because there isn't a shred of string evidence to deny.

9. **Marty**
December 22, 2010

The Nature paper by Luis Alvarez-Gaume and John Ellis is certainly payback…but not for Anderson and SSC. It is payback for this below spat from the summer – both in France and Nature Magazine (on-line).

http://www.nature.com/news/2010/100804/full/news.2010.390.html

The authors do a good job of looking fair but not really discussioning the merits of each of the papers. One of the last posts from 11/30 seems to get it.

http://www.math.columbia.edu/~woit/wordpress/?p=3282&cpage=1#comment-71745

10. **Coin**
December 22, 2010

"Duff's letter is published in a respectable journal"

Do you actually think of the New Scientist as respectable, or for that matter a "journal"?

11. **Roger**
December 22, 2010

Yes, New Scientist is a respectable journal, and I would be annoyed if it called me an unqualified pseudoscientist. Duff obviously thought that it was respectable enough to publish his letter. If the letter had been more specific, then I would suggest that Peter write a reply. As it is, I think that it just reinforces the reputation of string theorists as being arrogant, elitist, and detached from reality.

12. **Nickle Berry**
December 23, 2010

New Scientist is not respectable in the sense that it is not viewed by experts as a trustworthy source of information about technical subjects.

13. **Mean and Anomalous**
December 23, 2010

I agree with N. Berry about New Scientist. In general, it can be said that it isn't a trustworthy source of information about technical matters.

14. **Vladimir Kalitvianski**
December 23, 2010

> there must be a concrete reason that prompted it, several years after most people lost interest in the "string wars". Does anyone know what it is?

Yes, I think it is namely the loss of interest in strings that makes him mad.

15. **John Rennie**
December 24, 2010

Speaking as a physicist not a mathematician, I found The Shape of Inner Space a fascinating book and I strongly recommend it.

For anyone interested in the Riemann Hypothesis I recommend Prime Obsession: Bernhard Riemann and the Greatest Unsolved Problem in Mathematics by John Derbyshire. The maths shouldn't tax anyone with a physics degree, and it does an excellent job of describing why the roots of the Zeta function matter.

16. **John Baez**
January 2, 2011

New Scientist is not what I'd call a "journal", because scientists don't publish research papers there. It's a news magazine that focuses on science, like Scientific American.

I don't consider New Scientist particularly "respectable" on the topic of physics. For example, they published an uncritical article on Shawyer's "EM drive", a proposed propulsion system that violates conservation of momentum. But their articles aren't all bad: they vary wildly in quality, and they're often quite interesting.

Ancient History

December 31, 2010
Categories: Not Even Wrong: The Book

Sometime around now is the tenth anniversary of my first foray into the business of public criticism of string theory. I wrote something up over the end-of-year holiday in 2000, and circulated it by e-mail to a list of prominent theorists (some of whom I knew, some I didn't), asking for advice. The main motivation was that it seemed to me that it had become clear that string theory had failed as an idea about unification and while this was increasingly well understood in the particle theory community, the news had not gotten out to the wider world. Instead, a fairly active campaign to promote string theory to the public continued unabated. This was a rather peculiar situation, one that I felt someone should do something about, and I was curious what my correspondents thought of it. Most responded with quite interesting comments on their views on the matter, and one of them put me in touch with an editor at Physics Today. After some back and forth with Physics Today it became clear that they were unlikely to publish anything on the matter, especially from me, so in February I posted what I had written to the arXiv as String Theory: An Evaluation.

Hard as it is to imagine, back in those days there were no physics blogs. Perhaps the closest thing was Usenet newsgroups, especially sci.physics.research, where John Baez and others had taken on the thankless job of moderating discussions which often addressed issues about string theory. The archive of these discussions is here, and some discussion of my arXiv piece broke out there, appropriately in a thread about Lie algebra cohomology. For my first posting joining that discussion, see here. This led to my first encounters with the surprising phenomena of Jacques Distler and Lubos Motl.

Scientifically, not much has changed in ten years, but the public perception of string theory has changed a lot and become much more realistic. The next decade will undoubtedly be dominated by the effects of whatever we learn over the next few years at the LHC, although I don't think this is likely to affect proponents of string theory unification very much. Many of the remaining defenders of this idea are by now pretty well dug in and make it clear that "never give up" is their policy, even if it involves abandoning all hope of understanding this universe and putting faith in the existence of others.

One outcome of this that I never expected ten years ago is that I now have a book that has been published in Czech, with the title Dokonce ani ne spatne. I can't read a word of it, which doesn't matter except that I'm intrigued to see that Martin Schnabl has written an afterword and wonder what he has to say. The publisher just sent me a few copies, but I can't think of anyone I know who reads Czech to give them to. Other than Lubos, of course, but I suspect he wouldn't appreciate the gesture…

Comments

1. **Oleg T**
   December 31, 2010

   I don't speak any Chekh but Google Translate helped me with an interview that Martin Shnabl gave to newspapers:

   http://translate.google.com/translate?u=http://www.lidovky.cz/nejde-o-moc-ale-o-dobrou-vedu-dp8-/ln_noviny.asp%3Fc%3DA101130_000112_ln_noviny_sko%26klic%3D240160%26mes%3D101130_0&hl=en&langpair=auto|en&tbb=1&ie=windows-1250

   He says that string theory is getting money in the United States because it is the best science that is available and it has no competition. Everyone else is just waving his hands and no one has yet challenged string theory as a science, Shnabl concludes.

2. **ObsessiveMathsFreak**
   December 31, 2010

   Were it not for the generally high profile of theoretical physics, I think the last ten years of controversy would probably be described as an academic storm in a teacup by most. However, given the central important of theoretical physics in the pantheon of the sciences, I think this storm was one well worth having.

   Given the intersection of science, (academic) culture, society and new technology(by which I mean blogs), I would also say that the last ten years of the String Theory debate will be a topic of some historical interest.

3. **milkshake**
   December 31, 2010

   It is not about power, but about good science
   November 30, 2010

   No-one invalidated string theory yet, says Martin Schnabl from The Institute for Physics of Czech Academy of Sciences.

   LN (the newspaper): Are top faculty appointments and generous grants really won mostly by the string theorists?

   That's true in US. Although I see the origin somewhere else than Peter Woit. According to him, the Stringmen have been usurping power and they are now holding onto their position no matter what. I just think they are doing the best science. But the situation in Europe is different. I have also won a large grant for string theory research myself but I was only second one in our field within Europe.

   LN: What's behind the string domination in US?

   String theorists are getting grants because they are bright, hard-working and creative. They would have been successful even if they focused on another research subject. In reality the grant awards are based more on results and individual track record rather than hopes and promises. The scientists decide for themselves what they want to work on.

   LN: But why are the physicists so often choosing string theory? Is there really no other alternative?

   Fundamental physics can be approached in two ways. Going from bottom up, we find that there are abundant possible extensions of our current particle physics model. Scientist are testing them by performing experiments in accelerators, for example at CERN. It is an expensive but a very solid way of doing things. The string theory represents the opposite approach, from top down. It is the only one that explains gravitation within quantum framework. Since 30s when the scientists first started thinking about this, they had not come up with any other theory that could handle this. The alternatives, even if proposed with serious intentions, are still just little more than handwawing. String theory is in agreement with all experiments so far. Even though the String theory is pretty complicated and we don't fully understand it yet, it seems to describe and unify all laws of physics. There is however a large number of possible solutions and each one of them can correspond to a somewhat different physics. That's why it's very hard to invalidate this theory

4. **Giotis**

January 1, 2011

BTW Peter, have you seen this recent small article in the pop-ph arxiv (http://arxiv.org/abs/1012.5417)? Your book is presented as a representative example of contemporary criticism towards String theory.

5. **jpd**
January 1, 2011

the abstract mentions "sinergy".
is that the finnish rock band ?

6. **Peter**
January 1, 2011

I would like to know how did you manage to write the book in a language you can not read.

7. **Peter Woit**
January 1, 2011

Thanks Giotis, hadn't seen that.

Peter,

There's a translator, who presumably has done a good job…

milkshake,

Thanks. I like the argument for string theory that "it's in agreement with all experiments so far." There are lots of competitors though which can say the same thing, for instance my unified theory which is much simpler. It goes: "I dunno…"

8. **milkshake**
January 1, 2011

I think there are some unintended funny bits in that interview:

… It is [accelerator experiments] an expensive but a very solid way of doing things. The string theory represents the opposite approach…

The verbatim translation gets even better: "It is an expensive but honest way of doing things. The string theory represents the opposite approach"

9. **Shantanu**
January 1, 2011

Peter and others, happy new year. anyhow what do you think of the fact that we do not have any experimental evidence for physics beyond standard model for more than 30 years? what do you think will be
the future of particle physics if LHC sees nothing?
Given the fact that we have not found anything are we on a completely wrong track (wrt supersymmetry, technicolor etc)?

10. **Thomas Larsson**
January 2, 2011

Being the one who started the spr thread on Lie algebra cohomology, let me recall how the discussion started.

Anybody can criticize string theory on the grounds that it makes no hard predictions, and that all weak predictions (extra-dimensions, susy, etc.) disagree with experiments. Such critique, albeit well motivated, is not very constructive. In contrast, my point was more original and based on mathematical discoveries (by myself and mathematicians) that at the time were quite novel: the Virasoro-like extensions (an element in the Lie algebra cohomology, hence the title) of the spacetime diffeomorphism algebra and its off-shell representation theory. The Lie algebras that appear in string theory are either one-dimensional (Gelfand-Kirillov dimension = 1) or classical (no extensions, representations not of lowest-energy type), and this can not be good enough for a reality which is both four-dimensional and quantum.

At the time I harbored the idea that physicists might be interested in new mathematics, especially with such obviously close ties to the symmetry principles of both GR and QM. Ah, the naivité of the youth.

The "problem" with string theory (in my very humble opinion) is the fact that it is so very successful mathematically.

It is a framework, a way of thinking (that uses "physics words" as B Schroer would say) that effectively unifies almost all of mathematics. You want a short cut to very large chunks of 19th and 20th century mathematics? Read Wittens (and Vafa's) papers!

How could that be? How can we explain that? I would say that this is the reason why die hard string theorists would never give it up.

Happy 2011!

January 2, 2011

Peter Woit: If you ever need help translating something of interest from Czech, just drop me a message. I am an occasional reader of your blog already for many years and I will be glad to help, if it is needed.

Anyway, I haven't read a "popular science" book in ages, so this seems like a good place to start. I may even do a review for our magazine.

It is not surprising to me, that it is published in Czech, as the anti-string-world-dominance feelings were always quite strong among many physicists around here. I am not implying that the community here is anyhow against string theory (after all, I think we all value having Martin Schnabl here), only that plurality of opinions is (also historically) highly valued and the view advocated by some, that the string theory is the only truth in the universe, is simply unacceptable.

Greetings,
Jan

14. **David Berman**
January 2, 2011

Hi,
I made a vow of not contributing to blogs but you make it so hard. Its the throw away comments that insult the hard work of so many. How can you say, "Scientifically nothing has changed", in ten years! Are you really saying the intellectual endevours of so many for so long mean nothing. That is just not true. I am made happy by the excellent work produced by my colleagues over the last ten years. The huge number of insights and ideas. I cannot fathom a psyche that fails to see the beauty and wishes to see fault. There isn't a Hollywood Eureka moment; but that isn't science. There is the hard work of many and the results they produce. I am thankful and so should you, since exactly where would you be without string theory?

(How do you spell endevour?)

What about Lubos Motl?

16. **Peter Woit**
January 2, 2011

David,

Obviously the "scientifically nothing has changed" remark refers to what the posting was about: the argument I gave ten years ago that string theory unification was a failed idea. It's still a failed idea, for the same reasons as ten years ago. Actually, I was trying to be rather kind and not bring up the one thing that has changed, the promotion of landscape pseudo-science.

Outside of the unification failure, "string theory" is by now such a huge subject that of course there are plenty of interesting things learned over the past decade to point to.

And yes, I am saying that a lot of hard intellectual work by a lot of smart people turned out to be wasted as they worked their way into a dead end. But that's how science progresses, most of what one spends one's time trying to do doesn't work. The problem arises when people refuse to admit that an idea they put a lot of effort into has failed…

17. **Tim van Beek**
January 3, 2011

There is one common theme that keeps repeating itself in this discussion as exemplified by this statement…

> How can you say, "Scientifically nothing has changed", in ten years! Are you really saying the intellectual endevours of so many for so long mean nothing. That is just not true.

…besides Peter's point that string unification has failed. Of course there will always be some kind of progress in a scientific community consisting of at least 500 highly qualified scientists, progress that will be appreciated and occasionally celebrated. The question is if there are any results that are of interest to anyone outside of the community.

If you take any obscure method and calculate a scattering amplitude of a process that can be observed at a collider, this is a result that is of potential interest to experimentalists, regardless of the involved theory. But if all of the results are about answering questions that no one outside the community would ever have asked, and no one outside the community can do anything with the question and its answer, this will be of course observed as "no progress" from the outside.

In this situation there no point in lamenting the lacking interest in the progress of one's favorite topic.

18. **Somebdoy**
January 3, 2011

Time says: "But if all of the results are about answering questions that no one outside the community would ever have asked, and no one outside the community can do anything with the question and its answer, this will be of course observed as "no progress" from the outside. "

This is a reasonable querry from an interested outsider. The point however is that unification at the Planck scale is far away from our experimentally accessible scales, and we need quite a good control on the theory in order to make connections with low energy experiments. The "progress" that David talks about in string theory is (mostly) towards that goal: the goal of understanding the theory well enough. This is the necessary prerequisite to see whether it can say something about things of interest to "outsiders". By definition, such progress is of not direct interest to an outsider, especially if only the result at the end of the tunnel is considered as worthwhile.

Except for some universal statements (like those regarding black holes, and AdS/CFT inspired consistency checks) the detailed tests of string theory are very likely to require such an understanding. The reason to study string theory is that the universal things seem to work(!), which is way more than what other attempts at quantum gravity can claim.

Peter talks as if the experimental inaccessibility of string theory is an obvious fact. This is FAR from the case. Especially in light of the successes of string theory in producing the universal aspects of low energy physics, it is very worth investigating this matter in detail.

But I do think that David should have resisted the bait. Peter thrives on these… 🙂

19. **Peter Woit**
January 3, 2011

Somebody,

The problem with your argument is that all progress towards better understanding string theory in the past ten years has just given added force to the arguments for why string theory unification doesn't work. Most notably, 10 years ago one could have claimed "when we figure out how to stabilize moduli", then we will be able to make predictions. Instead what happened was that the moduli stabilization mechanism found gave us the landscape and a radically non-predictive unification scenario. Yes, this is progress towards understanding string theory, but it leads to understanding more clearly why string theory unification can't work.

As for claims about "the successes of string theory in producing the universal aspects of low energy physics", that's just ridiculous.

20. **David Berman**
January 3, 2011

Hi all,

I will resist the general discussion but in reply to Tim Van Beek, I couldn't quite figure out if you know that indeed progress in QCD scattering amplitudes is happening as a result of a stringy understanding. My colleagues at Queen Mary are amongst those that provide calculational tools for people interested in QCD amplitudes (I believe they are incorporated into the state of the art monte carlos at CERN). So indeed your example is completely poigniant to the discussion but perhaps not in the way you imagine. Or perhaps I've misunderstood you.

I will now gracefully bow out and now the holliday is over go back to my day job.

21. **El Cid**
January 3, 2011

Very fast damn Peter. You haven't wasted time. Peter, I hate you. You're just looking for money. I'm going to attack your blog. You hate physics, You hate the science.

22. **Mitchell Porter**
January 3, 2011

Peter Woit said

"the moduli stabilization mechanism found gave us the landscape and a radically non-predictive unification scenario. Yes, this is progress towards understanding string theory, but it leads to understanding more clearly why string theory unification can't work."

In fundamental physics, we are trying to learn about reality. We have a working model with all sorts of unexplained numbers. We may hope that all those numbers are uniquely determined for reasons we don't currently understand. But that is just a hope.

Meanwhile, we have string theory, with its landscape of solutions. Judging just by experimental adequacy – and not the apriori hope that all those numbers are uniquely determined – every single string vacuum which perfectly matches experiment is a candidate for the correct description of reality. This is true whether there's only one such vacuum, or whether there are infinitely many of them.

So what is the situation in string theory? There are many promising classes of vacua, but not even one vacuum has been *proven* to fully reproduce the standard model. This is a symptom of slow progress on topics like moduli dynamics, though such progress is occurring (e.g. see 1101.0108 at the arxiv today). Eventually we *will* know whether some of those promising vacua really do match experiment, or whether none of them do.

The moment that a string vacuum is found which is both mathematically tractable and fully consistent with experiment, then string theory will finally have delivered a candidate description of the world. If it produces a hundred or a million such vacua, they will all be possibilities – and most likely they will fall into classes which do make distinct predictions about higher energies, making them subject to future falsification. Finally, if it can be shown that *no* string vacuum can match experiment, then string theory really will have been falsified. Only then would you be able to say that string theory can't be the truth. And given the number of phenomenologically promising classes of vacua, it appears far more likely that string theory will instead provide the "standard models" of the future.

23. **Peter Woit**
January 3, 2011

Mitchell Porter,

"Finally, if it can be shown that *no* string vacuum can match experiment, then string theory really will have been falsified. Only then would you be able to say that string theory can't be the truth."

Well, since there's no way to computationally ever do that, there's no way to ever show that string theory is wrong. Your conclusion about a theory that can't be shown to be wrong is

"string theory will instead provide the "standard models" of the future."

My guess is that the idea of using a theory that can't be shown to be wrong as the "standard model" of the future is one that few physicists are willing to go along with.

24. **Mitchell Porter**
January 4, 2011

Peter,

Let's distinguish between falsifying string theory as a whole, falsifying a class of string models, and falsifying a specific string model.

So far as I can tell, the set of string models for which moduli dynamics are fully understood, and the set of string models that are of phenomenological interest, are completely disjoint. All of the latter, like the heterotic MSSM or the intersecting IIA braneworlds, still pose unsolved mathematical problems which prevent the calculation of standard-model masses and coupling constants.

Now let us suppose that with time, after sufficient mathematical progress, the models of phenomenological interest become fully tractable. This is when we can really talk about falsifying, not just specific models, but even whole classes of models, by *proving* that an empirically necessary conjunction of properties does not occur anywhere in the class.

When you say that "there's no way to computationally ever do that" (for the whole of string theory), you must be thinking of arguments like Denef & Douglas's, that the Bousso-Polchinski model of the cosmological constant would be NP-hard to test. But as Denef himself suggests, such complexity-theoretic results might be more like "no-go theorems", telling you how *not* to proceed.

In computer science, two things which can speed up search are (1) structure in the search space (2) search for a special property, and string phenomenology possesses both of these. Looking for the cosmological constant a la Bousso-Polchinski – a finely-tuned near-cancellation of numerous fluxes – must be just about the least efficient way to falsify string theory. The qualitative features of the standard model already suffice to rule out the vast majority of string vacua, and subtle facts like Koide's relation connecting the masses of the charged leptons will also be highly constraining.

When I say that string theory will supply the standard models of the future, I mean only that I expect some string vacua to pass all these tests. The standard model won't be "string theory, in which we believe because it contains gravity", it will be "string theory on background X, because it predicts the correct masses and coupling constants".

25. **Somebdoy**
January 4, 2011

Peter says: "As for claims about "the successes of string theory in producing the universal aspects of low energy physics", that's just ridiculous."

Alright, I'll bite. Here are some aspects of how string theory captures general features of low energy physics. While these will not impress you, I will keep an open mind that some of your readers are not as opinionated as you are.

All phases of string theory contain black holes. Whenever they are under computational control, the Bekenstein-Hawking entropy is reproducible microscopically. In the limit of small temperature of the black hole, even dynamical phenomena like Hawking decay rates and their greybody corrections can be produced from string computations. As Sen likes to emphasize, if there was a mismatch in *any* of the phases of string theory, then it would immediately have been game-over for string theory as a whole. Many spacetime singularities are naturally resolved in string theory. Chiral fermions, multiple generations, non-abelian gauge symmetry, hierarchies in Yukawa couplings etc. are all essentially automatic in any string compactification. Each of these things is a puzzle from a purely low energy perspective. Things like AdS/CFT and the qualitative matches with RHIC-like experiments is another generic test. Finally, all of these things are coming from a quantum theory that containes gravity – usually, attempts in this direction result in instantly-dead-at-birth theories. (Another one of the things that is lost on the layman is how remarkably gauge theories and gravity seem to mesh together to make AdS/CFT and string theory consistent, but this is more theoretical, so its not too relevant for this discussion.)

So yes, while you might argue that string theory hasn't made precise quantitative predictions yet, generic aspects of string theory do capture low energy physics. Its not "just ridiculous", sorry.

An over-riding theme in the things I mentioned above is that "whenever we understand string theory", things seem to work. This is the reason why it is interesting for some of us to work on understanding the theory fully.

26. **Peter Woit**
January 4, 2011

Somebody,

I see, the "successes of string theory" in low-energy physics that you are hyping have really nothing to do with the topic at hand: the failure of string theory unification. Black hole entropy tells us nothing about observable low-energy physics, and AdS/CFT is a completely irrelevant issue.

The one sentence you write that is relevant:

"Chiral fermions, multiple generations, non-abelian gauge symmetry, hierarchies in Yukawa couplings etc. are all essentially automatic in any string compactification."

is nonsense. You can find string theory "vacua" violating any of those, and if low-energy physics were different, I'm sure you'd be telling us that something else was "essentially automatic". For instance, in a non-chiral world, we'd probably be hearing a lot about how N=2 supersymmetry was crucial in string theory, so non-chiral couplings were "essentially automatic".

It's interesting that you don't mention the most famous argument of this kind: the "string theory predicts low-energy supersymmetry" argument. I notice that over the past ten years as the Tevatron has seen no evidence of supersymmetry, and as the arrival of relevant LHC results approaches, string theorists have started to back away from this argument. My prediction is that over the next few years they'll be running away from it, and claiming they never believed it. Unless of course, evidence for supersymmetry appears, in which case we'll hear something very different…

Mitchell,

You're creating for yourself a hypothetical world in which all the problems on which no progress has been made in 26 years (for very good reasons) have been solved, and then arguing on the basis of that. This is just wishful thinking, not science.

27. **Somebdoy**
January 4, 2011

"Black hole entropy tells us nothing about observable low-energy physics,… "

My low energy world contains gravity as well, Peter. And not just the standard model of particle physics. Since general relativity is part of low energy physics, we are forced to confront black holes. Its not an option.

About the rest, the claim was that string theory contains the ingredients of particle physics. That statement is true and non-trivial, notwithstanding your outbursts.

28. **Peter Woit**
January 4, 2011

Somebody,

We've gone from:

"the successes of string theory in producing the universal aspects of low energy physics"

to

"the claim was that string theory contains the ingredients of particle physics"

which is rather different. Sure, string theory contains "the ingredients of particle physics", along with 10^500 other things. The problem is that it has failed to tell us anything about these ingredients.

29. **Somebdoy**
January 4, 2011

There is only one particle physics in the real world. So the word "universal" doesn't make much sense in my original statement. I am pretty sure that you understood that what I meant was "generic".

If you want to be cynical … 🙂

30. **Eric**
January 4, 2011

I think it should be pointed out, lest someone get the wrong idea from the above arguments, that it is in fact possible to find string vacua which are very close to the observed Standard Model. This includes all of the features of the Standard Model such as chiral fermions, multiple generations, hieararchical Yukawa couplings, etc. as Somebody has pointed out. This by itself is reason enough to believe that string theory is on the right track.

What has not been accomplished up to this point is to uniquely fix the parameters of these models in order to determine the actual values of gauge and Yukawa couplings. The study of the mechanisms for doing this has been a very active area of research over the last decade and much has been accomplished. I fully expect to see a string model constructed in the next 10 years or so where this can be done. As to why our universe contains the three-generation Standard Model rather than some other gauge symmetry or matter content is a question that will take some time to answer.

31. **Giotis**
January 4, 2011

Somebody said:

"Chiral fermions, multiple generations, non-abelian gauge symmetry, hierarchies in Yukawa couplings etc. are all essentially automatic in any string compactification."

Such a statement is absurd of course and I find it strange that you could say such thing since as it seems you know quite a lot about the subject. Maybe the above nice properties are present in the models you know but this is exactly because they have been engineered to produce them. In any case I don't understand the point you are trying to make with similar statements.

In the current situation I think there are 5 options that someone could choose from regardless of any LHC findings:

1)Dismiss String theory as a framework for unification altogether.

2)Adopt the multiverse idea, eternal inflation, anthropic reasoning etc..

3)Dismiss the current concept of low energy effective vacua and wait until there is a better understanding of the theory hoping that this will eventually help us understand how our world emerges naturally from the theory.

4)Accept the validity of the current concept of low energy effective vacua and wait until a vacuum selection principle is found which will hopefully select our vacuum.

5)Do nothing of the above and continue to be skeptic.

32. **Tim van Beek**
January 5, 2011

David Berman said:

> I will resist the general discussion but in reply to Tim Van Beek, I couldn't quite figure out if you know that indeed progress in QCD scattering amplitudes is happening as a result of a stringy understanding.

This blog is mainly about string theory as a theory of unification (of the standard model and gravitation), and that's what my remark was about. If one counts the application of "stringy understanding" to QCD as a success of string theory is a matter of discretion, depending on one's understanding of what "string theory" comprises. In the sense of this blog's understanding of string theory as unification, it is not.

To pick another not too elementary example: One can use white noise calculus in order to give QFT an axiomatic foundation using the Osterwalder-Schrader axioms. One can also use white noise calculus to try to understand stochastic partial differential equations and turbulence in Navier-Stokes equations.

These are completely different physical theories, but of course one is free to claim that progress in QFT has led to a better understanding of turbulence in classical physics (and if you think both topics through and solve all problems, you could even win *two* millenia problem prices at once, think about that!).

33. **Somebdoy**
January 5, 2011

Giotis, the general context in which my statement is to be understood is the original Calabi-Yau compactification papers of Candelas, Horowitz, Strominger and Witten. As I repeatedly emphasized, the question was not what is possible[1], but what seems to arise essentially "automatically". This is admittedly a not very precise notion. For example, inherent in this claim there are some assumptions: like we demand four non-compact dimensions. But there exist large classes of string theory models where my statement is true, is the point. Its hard to define a measure on the space of theories, so it is not very meaningful to be more precise.

[1] There is a quote attributed to Coleman that string theory is not a theory of everything, but a theory of anything. (This is one of the things that bothers Peter and probably you.) This is in fact less true about string theory than quantum field theory, because UV completion puts constraints. The hope of the last decade (which seems completely unreasonable in hindsight) was that there will be a unique vacuum that will emerge. Instead it turns out that UV completion is constraining, but still we do have a large choice: in the industry-lingo, this is what distinguishes between the "swampland" and the "landscape". But a theory can be predictive without being unique. In fact, quantum field theory does just that, i.e, standard model, a specific quantum field theory is predictive. So string theory might turn out to be predictive if we could only wield it well.

I don't think your 5 bullet points cover all that is possible. Keep in mind that a theory doesn't have to predict the values of the couplings to make it a predictive theory. The choice of the vacuum might be anthropic or accidental or initial condition or whatever you want to call it, but after a finite number of experiments things can be predictive. The standard model contains 19 undetermined couplings, but (ideally) after 19 experiments to calibrate those numbers, the theory is predictive. String theory could work the same way: the choice of vacuum would determine the couplings, and indirectly we will be determining the vacuum by doing the calibration runs. We simply don't know if this situation is possible in string theory, which is why pronouncements irritate the practitioners. There are some subtleties here, like how much purely low energy experimenst will be able to fix the vacuum: I like the way Mitchell describes the situation in the last para of his post at 10:51.

Hope it was not too useless. I don't have the time to write a longer message.

34. **Giotis**
January 5, 2011

Somebody,

If there is no underlying principle which will point to a specific vacuum you could always change the vacuum to fit the experimental data by manipulating your model. That's the whole point of the criticism.

35. **Somebody**
January 5, 2011

Well, there is no underlying principle that uniquely picks out the standard model from the plethora of possible quantum field theories. But thats hardly a problem. As I said, uniqueness is not a necessary requirement for predictivity. You are thinking of computing the coupling constants, I am talking about fixing them experimentally. Please read my post again.

The point is whether you can fix a vacuum/model by doing a finite number of experiments. If you can, then all experiments after that are predictions. "Manipulating" a model as you call it, is what went into (for example) the construction of the standard model in the last century. One way to look at the question is whether this scenario can be realized in string theory. There is the possibility that string theory might provide the same kind of arena for UV complete model building that QFT provided for theories without gravity. Only time and hard work will tell. One trouble is that model-building in string theory as it stands is sketchy because we don't understand the theory well enough, so we have no good organizing principles (like gauge symmetry in QFT).

36. **Peter Woit**
January 5, 2011

Somebody,

The Calabi-Yau compactifications chosen for study in 1985 were chosen very specifically to have the right general characteristics to have some hope of giving the (supersymmetric) standard model at low energies. You can't point to this as providing "generic" features of string theory at low energies.

It's quite understandable that there was a flurry of excitement in 1985 when people started looking at these models. On the other hand, from the beginning there were also very obvious reasons to be skeptical. Not a single specific feature of the standard model was predicted (gauge groups, couplings, matter representations). As time went on, it soon became clear that there was so much freedom in how you chose your "string vacuum" that you could probably get just about anything. The only hard thing to understand is why 26 years later, people are still claiming this is a viable idea about unification.

As for the "string theory more predictive than qft" argument, it's a waste of time to keep pointing out why that's wrong. If someone wants to keep arguing that a theory that predicts nothing is more predictive than the most successful theory we have ever had, there's not much point in going there…

37. **pointless**
January 5, 2011

Hi Somebody (and others with similar intentions …),

isn`t it a bit pointless for You wanting to explain and discuss things in this blog? Your efforts will never change the positions of anybody here…

You have certainly more important things to do 😉 …

Happy New Year

38. **Somebody**
January 5, 2011

Hahaha! Its my holiday good deed. I like to think that I am talking to the lurkers who never post on this blog, but who might be more reasonable. Otherwise, it is easy to flip out and go on a shooting spree when faced with these relentless misrepresentations. 🙂

Cheers!

39. **pointless**
January 5, 2011

He he,

I sometimes silently lurk around 😉 …

Had to laugh about the joke linked to; most of these abstruse goose comics are fun.

I was just asking myself if the game they are playing here would lose it`s fascination if they could not evoke any response?

Anyway, enjoy Your holiday then 🙂

Cheers

40. **El Cid**
January 6, 2011

A question, If you say that you aren't an expert in string theory, what the hell are you criticising? You don't know of what you are talking about. You aren't a physicist, any longer. Maybe you've got in a Ph.D. in theoretical physics in a prestigious university long time ago, but now you don't want to learn theoretical physics. why don't you try to learn the hard and necessary math and then to try understanding string theory before to criticise the theory?
Because the only aim for you is to argue with the true physicists for laughing of them and your blog is only about sociology. Your book is for earning a lot of money with this dishonest behaviour. Because of this I hate you and I'm going to attack your blog. You are an enemy of science you are an enemy of the hard work.

41. **Shantanu**

January 6, 2011

Peter, probably you already know this. But Rutgers also archives their
HET seminars.
http://www.physics.rutgers.edu/het/video/het-video.html
there are two talks by Witten on this

42. **Igor Khavkine**
January 7, 2011

Somebdoy says: (January 5, 2011 at 6:21 am)
"But a theory can be predictive without being unique. In fact, quantum field theory does just that, i.e, standard model, a specific quantum field theory is predictive."

That's an excellent argument. In fact, it works so well that it also applies to not-necessarily renormalizable QFTs. It then puts gravity-as-a-QFT on the table as a theory of quantum gravity. That plus the standard model does an exceptionally good job of accounting for all known physics.

Obviously unknown physics cannot be accounted for, since we do not know what it is. It does sting a little bit that unknown physics currently includes the very interesting questions of the fate of evaporating black holes, the mass of the Higgs field, and the possible additional fields and interactions relevant in the early universe. But that can only be helped by looking for the answers in nature, rather than on paper.

Suddenly the rationale for using string theory at all, instead of plain old QFT, has evaporated…

43. **Eric**
January 7, 2011

I think probably the best way to view perturbative string theory is that it is really an effective theory which is valid up to some scale M_{string} < M_{Planck}. So, in this sense it isn't a complete unification theory, at least at the perturbative level, as Peter likes to say. However, I do believe it does take us a little closer to unification than do gauge theories/QFT by themselves since now gravity can be brought into the picture. It just doesn't take us close enough to say, uniquely predict the Standard Model, if that's even possible. What is needed is to find the theory which is valid at the Planck-scale, and to which perturbative string theory is an approximation. This sometimes goes by the name of "non-perturbative formulation" or "M-Theory".

44. **Somebody**
January 7, 2011

Khavkine says: "In fact, it works so well that it also applies to not-necessarily renormalizable QFTs. It then puts gravity-as-a-QFT on the table as a theory of quantum gravity… Suddenly the rationale for using string theory at all, instead of plain old QFT, has evaporated"

No, you will need an infinite number of experiments to fix all couplings if the theory is non-renormalizable. Thats not predictive, even in the best case scenario. UV completeness is key. Note that we are talking about all energies at once, not just low energies.

Here is one scenario: if we had all the control on string theory that we wanted, then we will be able to construct vacua which reproduce everything we see at low energies: standard model and black hole puzzles and cosmological constant and what not. The question that we don't know the answer to is, (1) is there any vacuum that allows this? (2) is there more than one vacuum which allow this? If the answer to (1) is no, string theory is ruled out. If the answer to (2) is yes, then it will not be within the realm of science to distinguish between these degenerate (at low energy) vacua without doing high energy experiments.

My strong suspicion is that if we fully understood string theory, it will actually enable us to relate low energy and high energy in more interesting ways, so the last setup may not even be realized. But even if it is, we will still have a candidate for a (universality class of) complete descriptions of Nature.

For the prupose of full disclosure, I should add that the "string phenomenology" as it is practised today is not really in line with this philosophy. It tries to construct vacua using more short-sighted approaches, because of our inadequacy in understanding non-perturbative string theory. But since it seems quite likely that the answer to question (1) is "yes", I think this might indeed be enough to settle that once and for all. But I suspect that answering (2) in any sort of useful way is going to require a real understanding of string theory, instead of the various bits and pieces that we currently refer to by that name.

45. **Igor Khavkine**
January 7, 2011

Somebody wrote: "No, you will need an infinite number of experiments to fix all couplings if the theory is non-renormalizable. Thats not predictive, even in the best case scenario. UV completeness is key. Note that we are talking about all energies at once, not just low energies."

Yes, thank you for pointing out the obvious difference between renormalizable and non-renormalizable theories. However, despite this difference, non-renormalizable theories are not any less predictive. In fact, once I pick any set of values for the infinite set of coupling constants needed to define my QFT, it is as predictive as desired and at all energies to boot. Whether this fixed theory is correct is, like any other hypothesis, to be tested by experiment. Do you still disagree?

Now, even if you agree with the above, you might take issue with exactly how the coupling constants were chosen. For the sake of argument, let me set all of them to zero, except the finitely many that have been directly probed by experiments to date; those I set to the measured values. I didn't have to use zeros, I could have used the outcomes of an imagined infinite sequence of coin flips. The point is that there is no known preferred mechanism for making that choice. And even if string theory is a candidate for such a mechanism, it is not known to be preferred to, for example, the two methods I just made up on the spot.

The other comments you've made rely on the hypothesis that the fundamental model we need will be a string theory. Now that is the hypothesis that IMHO severely lacks evidence.

46. **somebody**
January 8, 2011

Khavkine: "In fact, once I pick any set of values for the infinite set of coupling constants needed to define my QFT, it is as predictive as desired and at all energies to boot."

Hmm? How does one fix these coulings experimentally is the question. Couplings are fixed by EXPERIMENT, not by "picking" whatever value one wants. If you have a theory that had infinite number of couplings, one needs an infinite number of experiments to determine them, so the theory is not predictive. Simple as that. PS: Anomalies would rule out many theories, but this is even before that.

47. **somebody**
January 8, 2011

“Now, even if you agree with the above, you might take issue with exactly how the coupling constants were chosen. For the sake of argument, let me set all of them to zero, except the finitely many that have been directly probed by experiments to date; those I set to the measured values. I didn’t have to use zeros, I could have used the outcomes of an imagined infinite sequence of coin flips. The point is that there is no known preferred mechanism for making that choice.”

No, I don’t agree with the above. I agree that your setup is operationally okay at low energies, but is meaningless as a full theory. I expect that questions that we could ask at any energy should have reasonable answers. When all energies are allowed, your set up is *meaningless*.

Your claim is tantamount to arguing that the world is not predictive at a fundamental level. That was a valid argument at any stage of science when there was something we didn’t understand. But so far that argument has been wrong.

48. **Igor Khavkine**
January 8, 2011

Dear Somebody, I do not disagree that you are arguing from conventional wisdom. However, conventional wisdom needs to be shaken up and re-examined once in a while. With that in mind, perhaps you can be a bit more specific with your counter arguments when it comes to predictivity and meaningfulness at arbitrary energies.

I described two specific (though possibly appearing convoluted to some eyes) QFT models. What is it that these models cannot predict? A specific example would be nice. And what kind of question gets a meaningless answer at arbitrarily high energies? I cannot think of any such examples myself. After all, a fully renormalized QFT model yields n-point functions that are finite where expected and defined for all energies and all n. Moreover, any quantitative question posed comes down to the knowledge of n-point functions. So I’m puzzled by where your examples could come from.

“Your claim is tantamount to arguing that the world is not predictive at a fundamental level. That was a valid argument at any stage of science when there was something we didn’t understand. But so far that argument has been wrong.”

I’m sorry, I really do not see where you drew that conclusion from. I’m also completely stumped by the second sentence above. There are certainly many things in science we do not understand. One does not even need to stretch to meaning of the word “understand” to extremes. The particle/field content and their interactions that were relevant in the early universe is an example of something we do not understand. Though, still, I’m not sure how these factoids pertain to the discussion.

49. **Somebody**
January 8, 2011

Here is where your basic fallacy is (in my view):

“In fact, once I pick any set of values for the infinite set of coupling constants needed to define my QFT, it is as predictive as desired and at all energies to boot. Whether this fixed theory is correct is, like any other hypothesis, to be tested by experiment. Do you still disagree?”

One doesn’t fix the theory by devination and then check it against experient. The fixing itself done VIA experiment. And when you have infinite couplings there is no operational way to do it.

When you are truncating the theory to a finite number of operators the situation *qualitatively* changes. What I am saying is that the truncation can arise from either a UV complete theory or a non-renormalizable theory, but only one of them is really a theory (the UV complete one).

In any event, the situation regarding non-renormalizable theories being unpredictive is not something that I would refer to by the romantic term, “conventional wisdom”. I would say that it is an automatic consequence of what non-renormalizability means. So if you still don’t agree, maybe it is better that we agree to disagree.

Best wishes!

50. **Bugsy**
January 14, 2011

As usual, a great blog by Peter, giving space for fascinating comments from all sides. (I am speaking as a complete outsider to mathematical physics, and am grateful for this accessible window looking in). BTW: if Peter were more diplomatic and less provocative, I doubt the resulting discussions would be half as interesting!

What the M Stands For

January 3, 2011
Categories: Uncategorized

There's an explanation at the latest Abstruse Goose.

To recycle some of my own writing, from page 107 of NEW, the book:

> When I was a graduate student at Princeton, one day I was leaving the library perhaps thirty feet or so behind Witten. The library was underneath a large plaza separating the mathematics and physics buildings, and he went up the stairs to the plaza ahead of me, disappearing from view. When I reached the plaza he was nowhere to be seen, and it is quite a bit more than thirty feet to the nearest building entrance. While presumably he was just moving a lot faster than me, it crossed my mind at the time that a consistent explanation for everything was that Witten was an extra-terrestrial being from a superior race who, since he thought no one was watching, had teleported back to his office.

And, before anyone takes this seriously, I certainly don't believe this is the explanation for the "M" or that any actual teleportation occurred. To quote the next paragraph of the book:

> More seriously, Witten's accomplishments are very much a product of the combination of a huge talent and a lot of hard work. His papers are uniformly models of clarity and of deep thinking about a problem, of a sort that very few people can match. Anyone who has taken the time to try and understand even a fraction of his work finds it a humbling experience to see just how much he has been able to achieve.

Update: Clifford Johnson at Asymptotia points out a recent talk by Witten to a non-specialist audience about knots. It there is a Martian plot going on here, at least it has led to some wonderful insights about mathematics and quantum field theory that human beings might never have otherwise been able to figure out…

Comments

1. **wolfgang**
   January 4, 2011

   Peter,

   but maybe the truth is that *you* were sent by the Martians to confuse people about string theory 😎

2. **Peter Woit**
   January 4, 2011

   wolfgang,

   Actually, it's the Venusians who sent me, in a so far fruitless attempt to foil the Martian plot…

3. **MathPhys**
   January 5, 2011

   "And, before anyone takes this seriously, I certainly don't believe this is the explanation for the "M" or that any actual teleportation occurred."

   Did you really find it necessary to spell this out, Peter? You must have had such harrowing experiences in the past, you can no longer afford to take any chances.

4. **Nige Cook**
   January 5, 2011

   Dr Ed Witten's World of Mathematics biography states: "Witten, whom his students affectionately nicknamed "the Martian" because of his brilliance and soft voice, gave up his teaching duties in 1987 to concentrate on his research. … His wife reports that Witten does calculations only in his head."

5. **Chris Oakley**
   January 6, 2011

   MathPhys,

   You can't be too careful. When Steven Weinberg visited Oxford in 1983 there were a dozen or so alien space craft hovering above the city for a whole week. This may not have had anything to do with him, but the whole experience was quite unnerving. They only went when they found that the local shopkeepers were refusing to take their money, which was in plasma form.

6. **Thingumbobesquire**
   January 8, 2011

   Since M Theory is a product of Cambridge, it only make sense that it must like the M in MI5 stand for Mother. Hence its similarity to the pagan great mother worship of Gaia (which I believe is another project of like minded "thinkers.")

7. **Thomas Larsson**
   January 8, 2011

   There is of course Glashow's explanation: the M is really an up-side-down W, for Witten.

8. **Kris Krogh**
   January 9, 2011

   "it has led to some wonderful insights about mathematics and quantum field theory that human beings might never have otherwise been able to figure out"

   Peter, could you mention which of those insights you feel are important, and why?

A couple of decades ago, it was widely advertised that string theory had made a fundamental contribution to topology, of which mathematicians were in awe. The claim was that one topology could legitimately be converted to a different one via the singularity of a black hole. Haven't heard anything about that since. What's happened there?

9. **Yatima**
January 9, 2011

Okay. Linux does not have decoder for the Witten Talk. H.264? Patent-encumbered. HURRR!

10. **Peter Woit**
January 9, 2011

Kris,

That quote referred to Witten's talk about QFT and knots, and specifically I had in mind the work on this topic ("Chern-Simons-Witten theory") that won Witten a Fields medal. It doesn't have anything to do with string theory.

[joke]It seems that the clever Martian plot is to have Witten "discover" incredible deep and obviously significant insights into qft and math, thereby gaining a huge amount of credibility as a genius and guru of the field. This is then used to get people to believe the string theory unification stuff, which would not otherwise be taken seriously. [\joke]

11. **Marcus**
January 10, 2011

Malarkey

12. **zanibar**
January 10, 2011

NCZ

I would explain the joke more like this —

The Martians think that humans are becoming too advanced technologically — so they deliberately send an agent in disguise to lead the humans astray in order to halt any real scientific advancement …

Sort of a fake Mathematical Moses leading the Israelites into the desert, but not out of it.

KRLLL's credentials and following could have been established with "legitimate" science (unlike Peter's interpretation), the joke takes this as a given – obviously an insider's look at physics, going beyond merely copying buzz-words on the blackboard in panel 8.

The joke hinges on identifying Witten as KRLLL together with the implication that M-theory is really a Martian conceit.

The last three panels complete the joke. A classic parody of a classic sci-fi theme.

Reminds me of a truly great episode of the original Outer Limits – "O.B.I.T." (Out of Band Individuated Teletracer), including the finale.

See –

O.B.I.T. (wikipedia)

O.B.I.T. Epside Review (from David Schow's amazing site)

/NCZ

January 11, 2011

You can see Witten's talk just fine under Linux, e.g. just open the URL in Kaffeine.

Differential Cohomology at the Simons Center

January 11, 2011
Categories: Uncategorized

This week the Simons Center is hosting a workshop on Differential Cohomology and its applications in physics. I won't try and give an explanation of what differential cohomology is here, with a little luck the videos of the talks will soon be on-line. Very briefly, this subject is about an extension of the usual sort of cohomology theory that provides finer information. It was discovered independently by Deligne in an algebraic geometry context (his construction is often called "Deligne Cohomology") and by Jim Simons and Jeff Cheeger in a differential geometry context. The subject made its appearance in physics first through Wess-Zumino-Witten terms in non-linear sigma models and the Chern-Simons term in gauge theories.

Dan Freed's first lecture included an extensive discussion of one recent example that uses a generalized cohomology theory, and thus generalized differential cohomology, see here for details. Mike Hopkins discussed his work with Singer which led to this paper, and some ongoing work from a more generalized perspective. He started with some history, explaining that things began with a specific example he noticed in work on topological modular forms that Witten had found around the same time in work on the partition function of the fivebrane. He described this initial impetus as like discovering that they both were looking at the same intriguing specific tropical fish, with attempts to understand it leading to a huge ferocious formalism he characterizes as a shark that lept out of the tank.

In the afternoon, Jim Simons gave a wonderful description of the early history of his work on Chern-Simons invariants and Cheeger-Simons differential characters, leading up to recent work trying to prove that certain properties uniquely characterize this kind of theory. He began his talk by noting that only one small piece of chalk was available and complaining "I paid all this money for this place and all I get to use is one broken piece of chalk?". The story started when he tried to work out a combinatorial formula for the signature in 4 dimensions, by analogy with what one does starting with the Chern-Weil formula for the Euler characteristic. In the signature case, the evaluation of a 4d Pontryagin class leads to the study of a 3-form on the boundary, which he investigated with Chern, leading to Chern-Simons theory. This is much the same problem as the one that (more than a decade later) I started working on as a graduate student in physics, trying to figure out how to calculate the second Chern number of a lattice gauge field configuration.

Finally Krzysztof Gawedzi gave an interesting talk reviewing the by-now-extensive history of the use of this kind of mathematics in physics, including various incarnations of the notion of a "gerbe". Unfortunately I'm back in the city now, hope to follow the rest of the workshop via video at some point.

HEP News

January 11, 2011
Categories: Experimental HEP News

While I was away at Stony Brook yesterday, every other blog and news source out there had a story you've surely seen about the DOE's decision to turn down a proposal to seek funding to keep the Tevatron running past the end of this fiscal year. This means that soon the long era of physics at the high-energy frontier pioneered and often dominated by the US will conclusively be over, probably at least for the rest of my lifetime. It will continue in Europe at CERN, with the LHC and whatever follow-on machines get designed and built there. In some sense this was bound to happen sooner or later, once the decision was made to pull the plug on the SSC. See Cosmic Variance for a long history of the Tevatron from John Conway. Also, see here for the latest from the director of Fermilab.

The US is throwing in the towel for a combination of reasons that include a desire to devote all resources to new ventures with more of a future, the fact that continued running would not dramatically increase the total size of the data set, and faith that the LHC will reach its goal of several inverse femtobarns of data at 4 GeV/beam over the next couple years. It's still somewhat difficult though to understand why, in order to save 5% of its HEP budget, the US is shutting down a machine that continues to produce important new results, some of which cannot be easily studied at the LHC. An intriguing example is CDF's recent data on asymmetry in the production of top-anti-top pairs. For an explanation of this you can't do better than to see the discussion at Resonaances. This result uses the fact that the Tevatron collides protons and antiprotons, allowing measurements that can't be done with proton-proton data from the LHC.

Unlike the CDF result, the latest LHC results just exclude more and more popular extensions of the Standard model. CMS yesterday (see here and here) released results (discussed earlier here) that rule out a range of once popular values for masses of supersymmetric partners. In this arena, the LHC is quickly moving to outclass bounds from the Tevatron.

   The response from the Fermilab director is here
   http://www.fnal.gov/pub/today/archive_2011/today11-01-11.html

   The statements by John Conway about the history of the Tevatron (circa 1976-83) are not entirely accurate. (Tommaso Dorigo may offer his own take on this?) There is no mention of BNL (Brookhaven National Lab) and ISABELLE. When Fermilab started, there was a conflict between FNAL and BNL as to who would get the next big proton machine. The eventual agreement was that Fermilab would do fixed-target (synchrotrons) and BNL would do colliders. So when John says that (paraphrasing) "The lab was engaged in a wide range of fixed target experiments, using the Fermilab Main Ring proton synchrotron as its workhorse …. But Europe pulled ahead – it already had the Super Proton Synchrotron, and plans to convert it into a proton-antiproton collider…."

   Well … not quite. *Fermilab* was not building a collider, but *USHEP* as a whole was. BNL was building ISABELLE 1976-83 (approx). The design was 500×500 GeV (sqrt(s)=1 TeV), with the explicit goal of discovering the W and Z. The project failed miserably, and when CERN produced the W and Z using the SppS (UA1 and UA2 expts), then in July 1983 the ISABELLE project was cancelled. The proposal for the SSC was born around the same time.

   After the cancellation of ISABELLE, Fermilab went ahead and converted the Tevatron (originally visualized as a fixed-target machine) to be also a p-pbar collider. This was in 1985. But by then CERN had locked up the Nobel Prize (1984 to Carlo Rubbia and Simon van der Meer).

   Read this about ISABELLE

   Pt I
   http://www.springerlink.com/content/r114825754r38578/

   Pt II

2. **SpearMarktheSecond**
   January 11, 2011

   All good things come to an end, and no doubt, the Tevatron was a very good thing. The issue now is… what is the US experimental particle physics program? The space-based dark energy program (SNAP/JDEM/WFIRST) is delayed to infinity, as is the linear collider. DUSEL hangs by a thread. NOvA is a bit of a wimper. Meanwhile, Italy has green-lighted a super-B factory, China has a charm factory, and Japan has taken over accelerator neutrino physics and kaon physics.

   Well, maybe AMS II will make a great discovery.

   Are we not physicists? DEVO.

3. **Peter Woit**
   January 11, 2011

   SpearMarkII,

   Excellent question. By the way, this made me realize that I have no idea why the US gave up on B physics. As far as I can tell, the Italians are planning on building a B-factory with spare change left over after their CERN contribution (and with no longer needed equipment from the US). What's that all about?

4. **Shantanu**
   January 13, 2011

   Maybe whole of HEP community will switch to neutrino physics,
   particle astrophysics or LIGO (which is funded)

5. **El Cid**
   January 15, 2011

   The future of physics and engineering in USA is in the field of inertial confinement fusion to achieve ignition with the new device NIF. Experimental HEP is RIP in USA.

The only hope is in theoretical HEP where USA is still the world leader by far.

More Short Items

January 16, 2011
Categories: Uncategorized

- There's an excellent article by Michel Berube about the Sokal hoax, fifteen years later, entitled The Science Wars Redux.
- The latest Notices of the AMS has a review of the recent Yau-Nadis book by Nigel Hitchin (for my take, see here).
- My colleague Brian Greene has a new book coming out soon, The Hidden Reality: Parallel Universes and the Deep Laws of the Cosmos. I haven't seen a copy, but from what I can gather, it looks like it is probably the best of the many books about "multiverse" ideas, but still not exactly my cup of tea. If you're interested in the "multiverse" and want to read a popular level exposition, you should try this one. But you should also pay attention and see if there's any experimental evidence (or reasonable hope of getting some) for the ideas being discussed. The book has very extensive more technical notes, and the Amazon site gives access to these. Brian also has an Op-Ed piece in today's New York Times drawn from the book, about the fact that in an accelerating universe, in the distant future less and less will be visible.
- It seems that there recently was a Physics of the Universe Summit, along the lines of last year's (see here). There's a web-site here, but about all you tell without a password is that the participants were staying at a very trendy hotel in West Hollywood.
- A film has been made about the geometer Shiing-shen Chern. The title is "Taking the Long View" and there's a web-site here.

Update: Two more.

- XKCD on extra dimensions.
- Matthew Chalmers has an interesting new article at Physics World entitled Reality check at the LHC.

Update: There's a review of the new Brian Greene book by George Ellis at Nature this week. It emphasizes the problem of lack of testability.

4. **Peter G**
   January 17, 2011

   Back in '95 I interviewed Jean Bricmont about his book with Sokal for a leading newspaper in Belgium. I can assure you that he was very surprised by the fact that Sokal's hoax and Impostures Intellectuelles were described as some kind of 'war'. He had no intention to wage war against the humanities. For him, the book was more a Voltairian laugh.

   Michael Bérubé writes that "it turns out that the critique of scientific "objectivity" and the insistence on the inevitable "partiality" of knowledge can serve the purposes of climate-change deniers and young-Earth creationists quite nicely."

   That's a bit of revisionism. Already in the beginning of the 90s the "critique of scientific objectivity" was used by young-Earthers, evolution-doubters etc. to defend their views. I remember making a piece about it for a radio programme in '92 or '93. But I don't remember many people from the humanities taking a stance against it at that time. Bruno Latour's doubts ("Was I wrong to participate in the invention of this field known as science studies? Is it enough to say that we did not really mean what we meant?" etc.) came much later.

   There's a lot to be said about Impostures Intellectuelles and the hoax, but I think it was a necessary kick in the b!t.

5. **Peter G**
   January 17, 2011

   Mara Beller writes: "Yet physicists relate to Derrida's and Bohr's obscurities in fundamentally different ways: to Derrida's with contempt, to Bohr's with awe. Bohr's obscurity is attributed, time and again, to a "depth and subtlety" that mere mortals are not equipped to comprehend."

   That sound very far of the mark to me. I studied physics and I never ever heard a professional physicist attribute Bohr's obscurity to depth and subtlety etc. Quite to the contrary: all the physicists I know admitted that they didn't understand a word of Bohr's more esoterical writings and agreed that a good physicist can be a terrible philosopher. The man who thaught me QM once told me: "There's nothing more pitiful than a good scientist who turns into a bad philosopher."

6. **Paul**
   January 17, 2011

   This is kind of off topic, but why is Witten interested in Khovanov homology these days?

7. **Peter Woit**
   January 17, 2011

Paul,

The invariants in Chern-Simons-Witten theory are given by taking the Euler characteristic of Khovanov homology, so it's a generalization of the Chern-Simons story (which Witten won a Fields medal for). There's lots of reasons to be interested in the 3d Chern-Simons theory, and good reason to expect Khovanov homology to appear as part of an interesting 4d TQFT. Lots of people have tried to figure out what is going on here, and Witten has some new ideas, using path integrals over the complexification of the usual space. He ends up using yet another version of N=4 supersymmetric YM, the QFT that appears in geometric Langlands, as well as AdS/CFT. His paper with the details of how he gets Khovanov is not out yet. When it does come out, I'll probably try and spend some time with it, and write about the whole story here.

8. **Peter Woit**
January 17, 2011

Just after writing the above, I see that Witten's paper has appeared on the arXiv this evening. It's 147 pages long, so "spending time with it" may take a while….

See:

http://arxiv.org/abs/1101.3216

9. **Peter Woit**
January 17, 2011

Peter G and others,

Please stick to the Sokal/Berube topic….

10. **Peter Woit**
January 18, 2011

It seems that some unemployed guy in Pilsen who reads this blog thinks Brian Greene is my employer and is upset that Brian is not having me fired. For the record, my position as "Senior Lecturer" in the math department is not tenured, but I have a long-term contract and whether it gets renewed at some point in the distant future will have nothing to do with what Brian thinks about this blog, or with what I think about his books.

Actually, my impression is that if most string theorists could choose one well-known blog dealing with string theory to shut down, it wouldn't be this one…

11. **maros**
January 22, 2011

solve recent witten`s paper problem discussed here http://www.math.columbia.edu/~woit/wordpress/?p=104 ?

12. **Peter Woit**
January 22, 2011

Maros,

Witten' work does give an answer to that problem. Unfortunately it's a rather complicated one, and I'm still far from completely understanding it.

13. **Shantanu**
January 24, 2011

Peter, this maybe a bit off-topic, but have you discussed your concerns about string theory with Brian Greene and does he agree with you?
Also what about other particle theorists at Columbia? (I don't actually
who all work on string theory and who does not). What about Eric Weinberg? Does he agree with your pov?
Thanks

14. **Peter Woit**
January 24, 2011

Shantanu,

Brian and I tend mostly to discuss other things than string theory. If you look closely at what he says publicly and what I say, I think you'll find we don't disagree about any facts, just how we evaluate the likelihood that certain very speculative ideas will turn out to be successful.

I don't remember ever discussing string theory with Erick Weinberg, and don't want to speak for anyone over in the physics department here. But my impression is that it's accurate to characterize the Columbia department on average as not one that has ever been very enthusiastic about string theory.

News from Templeton and FQXi

January 18, 2011
Categories: Uncategorized

The Templeton Foundation has just released their "2010 Capabilities Report", a sort of bi-annual report. It shows that in 2009 they had assets of $1.5 billion, and spent $31.8 million on "Science and the Big Questions". For 2010 two of their funding priorities were Quantum Physics and the Nature of Reality and Foundational Questions in the Mathematical Sciences, but they have yet to report what grants they made in those categories.

The foundation is now being run by Jack Templeton, a surgeon who is devoting his efforts to spending his father's money according to his instructions. For a couple of recent articles explaining what is going on at Templeton these days from two very different perspectives, see God, Science and Philanthropy at the Nation, and Honoring his Father at World magazine. The Nation article reports that the Foundation should soon have $2.5 billion or more to spend as the father's estate is settled, and discusses how Jack Templeton's right-wing politics and the Foundation's goal of bringing science and religion together make many scientists uneasy. At the World on the other hand, they seem concerned that the Foundation is supporting the theory of evolution, for reasons that Jack Templeton spells out:

> Every five years, three independent analysts are to conduct a review to see if Jack Templeton (or his successor) is making grants consistent with Sir John's intent. If they find that Jack is giving 9 percent or more of the grants to causes inconsistent with paternal intent, he has one year to get back into line. If not, Jack and his top two officers will be fired.
>
> Nor can Foundation trustees make changes by themselves or choose new board members. Templeton family members, plus winners of the annual Templeton Prize, plus heads of several organizations Sir John respected (such as the Acton Institute) are honorary members: There are about 75 in all, and 95 percent of them must be in agreement for any substantive change in foundation goals and purposes to be made. Even to change the location of the board's annual meeting requires a 75 percent vote of the honorary members.
>
> The Foundation maintains Sir John's "core funding areas." The lead one, "Science & the Big Questions," includes questions about evolution. Other Templeton core areas are Character Development ("We can determine how to be the masters of our habits"), Exceptional Cognitive Talent & Genius (humans can be "helpers in the acceleration of divine creativity"), and Genetics (the Foundation is not yet accepting unsolicited proposals in that area). Jack Templeton would not discuss any differences from Sir John in those areas: His calling is to do the will of his father.
>
> The son clearly sees things the same way as his father in one other Core Area, Freedom & Free Enterprise. Jack recalls how Sir John "often spoke, year after year about 'people's capitalism' and what it would mean if the overwhelming majority of people in any country were shareholders themselves with the result that they would be much less likely to be envious and instead would focus much more persistently on 'the good of the whole.'

Besides science, Templeton has traditionally funded lots of activities related to religion, as well as ones promoting "Character Development" and "Freedom and Free Enterprise". Another core funding area is "Exceptional Cognitive Talent and Genius", where they try to identify and nurture "young people who demonstrate exceptional talent in mathematics and science." Their newest interest is in genetics, where they've just started to make grants, including one in support of the "Genetics of High Cognitive Abilities Consortium."

One of the Templeton Foundation's biggest grants, featured on the front-page of their web-site, was $8.8 million given to set up FQXi. They list this grant as having an end-date of December 2009, and the plan was for FQXi to get later funding elsewhere. FQXi is still in operation, either with leftover Templeton money or new funds from other sources. They announced today the award of $1.8 million dollars in grants for research into "The Nature of Time", based on this request for proposals, which asked for research "unlikely to be supported by conventional funding sources". The list of grants announced includes quite a few that satisfy that criterion, but winners also include some prominent theorists working on not exactly unconventional topics such as Andy Strominger on AdS space-time, Joe Polchinski on holography and AdS/CFT duality, Hiranya Peiris on analyzing WMAP data, and Berkeley's Raphael Bousso on the Multiverse (along these lines). Maybe the last one does qualify as "unlikely to be supported by conventional funding sources".

In further support of the cause of investigating the Nature of Time, FQXi will pay for an event entitled Setting Time Aright which will take attendees on a chartered cruise from Bergen to Copenhagen late this summer.

   January 19, 2011

   So – setting aside questions of 'is string theory science?' – does Templeton fund grants on Intelligent Design? Apparently not, back in 2007 –

   January 20, 2011

   what are some of the bigger research results to come out of the fqxi research?

3. **larry**
   January 22, 2011

   garrett lisi's e8

4. **larry**
   January 22, 2011

   i meant to write lee smolin's garret lisi juggernaut

5. **Peter Woit**
   January 22, 2011

   QED and larry,

   Garrett's initial work on E8 was done way before he got any funding from FQXi. If his newer work ends up being successful, I suppose FQXi should take some of the credit.

Maybe the relevant question though is to compare the results of FQXi funded research and DOE/NSF funded theoretical physics research. Neither has had much success in recent years, which you could take as due to the problems addressed being too hard, or to both of them funding the wrong things.

One area where FQXi beats DOE/NSF in terms of funding research results is in multiverse studies. In that case there's an argument to be had about whether more and bigger research results is a good thing. Does the world need big, high-impact pseudo-science results?

6. **QED**
January 22, 2011

well, garrett lisi may well be the next einstein as lee smolin proclaimed, and we may well live in a multiverse. both entities represent the pinnacle of fqxi's foundational research. and just like lisi did a lot of his research before the fqxi funds, so too was the multiverse conceived of and set forth before fqxi. 🙂

7. **QED**
January 22, 2011

Dear Peter,

After googlig some items this morning, it seems you are a fan of Garrett Lisi and Ed Witten, while you are not a huge fan of fqxi, the multiverse, and some string theorists' claims of the testability of their theory. Well, Ed Witten supports the the multiverse, and Lisi claims his theory can be tested, even though it cannot. Can you please elaborate on these inconsistencies?

Thanks for your time!

QED 🙂

8. **Peter Woit**
January 22, 2011

QED,

I guess I am a "fan" of Ed Witten's but no, I'm not a "fan" of Garrett Lisi. In any case though, in almost all cases I like some aspects of people's work, and not others.

In Witten's case, some of his work is just completely fantastic and far outclasses anything anyone else in the field has done (see my book for a chapter about this). But I also think he has made a mistake in not giving up in the face of things not working out on an idea (string theory unification) that he had some good reasons to get enthusiastic about back in 1984. He's in good company though, Einstein made the same sort of mistake. About the multiverse, several people have told me that he has been quite critical of the idea in private. His public statements on the subject are typically rather guarded. Recently he sometimes in public talks describes the string theory multiverse idea, then says something about how he's not yet convinced, but it might be true. I'd rather he adopt David Gross's full-throated denunciation.

About Lisi, he's obviously not in the same league as Witten. I'm sympathetic to some of the ideas he is working with and wish him well. What he's trying to do is worthwhile, but I don't think he's yet found a solution to the basic problems of the subject. He should be careful and precise in what he says in any claims of testability of his work. Caveats tend to get lost in the media.

Back to Templeton and FQXi, Witten has nothing to do with them as far as I know. One of my criticisms of the two organizations would be that they don't support research of the sort that Witten has had success with, at the intersection of mathematics and quantum field theory. Lisi's research is about as far as they go in that direction, and he seems to be somewhat of an anomaly in terms of what they support.

9. **Steve Dufourny**
January 31, 2011

Hi all,

Sorry for my english.I am belgian.
I am surprised.First FQXi is a wonderful platform where scientists can speak together in a total transparence.
For example ,I come from Belgium, I work about my theory of spherization, a GUT of spinning spheres.In resume,quantum spheres….cosmological spheres…UNIVERSAL SPHERE.
And FQXi has accepted my posts.There on FQXi you can see this year for ther contest, scientists from all over the world.It's wonderful.These scientists speak together in a total transparence.A real innovant platform, young with a fantastic and wonderful future.This net is revolutionnary indeed.
An other point dear scientists, the strings are purelly falses , a string is divisible, a sphere no.Mr Lisi and Mr Witten are falses simply in the whole and in the details.We can't play as we want with our constants, irreversibilities, coherences,….if you want really knowing FQXi….Read their threads or I have a better idea, you go there and we shall speak in total transparence together with our real name of course.
Dear Mr Woith, come on FQXi you shall be accepted and we shall speak.

On that

Best Regards

Steve

Number 999 or 1000

January 25, 2011
Categories: Uncategorized

According to the WordPress software, this is either post 999 or 1000 on this blog, depending on whether you count one I haven't gotten around to finishing. I'm not sure that number is reliable anyway, since there are various anomalies due to a long-ago transition from Movable Type to WordPress. Some other statistics: 27,089 approved comments since the beginning (March 2004), 84,259 spam comments since the latest spam filter was turned on a couple years ago, 510,530 page hits last month (mostly spam, robots), and 8,842 subscribers at Google Reader.

The blog has turned out to be far more of a success than I ever expected when it was first started. There were few similar blogs back then, with Jacques Distler's Musings having been around for a while, and Sean Carroll's *Preposterous Universe* just starting up. Lubos Motl's Reference Frame quickly followed, I gather somewhat in response to mine. These days, Musings seems to have gone dormant, but Sean and Lubos are still at it. I haven't kept track of physics blogs in general, but there are now quite a few that deal with particle physics in one way or another. For particle phenomenology, Resonaances is a great source of information, for experimental HEP Tommaso Dorigo has a wonderful blog, and Philip Gibbs at *viXra log* does a great job of keeping track of the state of the LHC (for the latest, see here).

There's also now a huge variety of research-level math blogs, including a very active blog by Fields Medalist Terry Tao. The new site Mathblogging.org is an exhaustive source of information and links. The big recent change in the math blogging world is the amazing phenomenon of MathOverflow, which features many of the best young mathematicians around carrying on the sort of conversations about research-level mathematics that traditionally go on in math common rooms. In an odd way, mathematics has often been somewhat of an oral tradition, since the impenetrability of much of the literature often meant that the only way to learn about something was to find an expert and get them to explain it to you. Now you can do this on-line, and this may significantly change how mathematics is done. Just as listening in to common room conversations was a great way to learn things, poking around the links on MathOverflow can provide quite an education. The moderation system somehow maintains a high level of discussion, although sometimes it lets its hair down to allow discussions like the ongoing one about Mathematical "Urban Legends". There one can learn that one's suspicions about string theorists educated at Princeton are correct, with Jeff Harvey contributing the following:

> Since the OP gave a physics example, here is another one, also at Princeton. Why are they always at Princeton? Student finishes his presentation on very mathematical aspects of string theory. An experimentalist on the committee asks him what he knows about the Higgs boson. He hems and haws and finally says "well, it was discovered a few years ago at Fermilab", Experimentalist: "Can you tell me the mass?" Student: "I think around 40 GeV."
>
> This was more than 20 years ago and actually happened. I was there. The student passed, but the next year all Ph.D students working on string theory were required to take a course on the phenomenology of particle physics.

There's now a physics version of mathoverflow starting up, but so far it seems to me much less successful, with far too much in the way of the high-school level topics and uninformed discussion that plagues most internet physics discussion forums. There are some examples of serious questions and well-informed people writing in, so maybe things will improve and it will turn into something very worthwhile, replacing much of what is now going on at blogs.

I'm surprised to still be doing this nearly seven years after starting, but now doesn't seem to be the time to stop. Particle theory has long been a rather intellectually dead topic, but whatever the news is from the LHC, it promises to shake the field up in one way or another, a process that should be interesting to follow. In coming weeks I may try and find time to learn some more about the features of WordPress, adding some features to the blog, or at least refreshing its rather tired look. Don't be surprised if its appearance starts to change, or at least become unstable…

   January 25, 2011

   "Particle theory has long been a rather intellectually dead topic"
   Ha, ha, ha… You mean to say the part of it you actually understand?

   [Initially, I deleted this, but finally decided to leave it. It does represent well part of the experience of blogging these past few years. No way to know who this is, other than that they're at CERN. Maybe it's the Princeton Ph.D. from Jeff Harvey's story….]

2. **Barbara**
   January 25, 2011

   I think you missed a detail. It's not just young mathematicians talking to each other on MathOverflow. In fact, I think its main strength is the range of users, going from grad students to retired professors.
   Other than that, it is totally awesome.

3. **Lee Brown Jr.**
   January 25, 2011

   Congratulations on #1000! Your blog has inspired me. I look forward to reading more.

4. **Chris Austin**
   January 25, 2011

   "In coming weeks I may try and find time to learn some more about the features of WordPress, adding some features to the blog, or at least refreshing its rather tired look."

   I hope it won't become necessary to download megabytes of superfluous data to read a post, as with some blogs. I find N.E.W. a very good source of quick information.

5. **El Cid**
   January 25, 2011

   "*Student finishes his presentation on very mathematical aspects of string theory. An experimentalist on the committee asks him what he knows about the Higgs boson. He hems and haws and finally says "well, it was discovered a few years ago at Fermilab", Experimentalist: "Can you tell me the mass?" Student: "I think around 40 GeV. … The student passed, but the next year all Ph.D students working on string theory were required to take a course on the phenomenology of particle physics."* "

   Peter, really do you think I am stupid? I can't believe it. Maybe, you think Princeton University is like Capillas's School.

6. **Justin Hilburn**
January 25, 2011

There is a proposal for a high level physics site on stack overflow. It would be mathoverflow to physics.SE's math.SE.

http://area51.stackexchange.com/proposals/23848/theoretical-physics

7. **Shantanu**
January 25, 2011

Peter and others, sci.physics.research is still good (even though
most scientists no longer post there).
I learned of many interesting papers and results (Which are usually
ignored in mainstream physics/astrophysics literature) through
that.

8. **D R Lunsford**

10 OPTION BASE 0

So 999=1000 anyway.

Happy anniversary

-drl

9. **nbutsomebody**
January 25, 2011

I agree that discussion of urban legends is a little diluting. However it is extremely entertaining, also for non-mathematicians.

10. **C. J. Mozzochi**
January 26, 2011

Keep up the good work, Peter!

11. **Domenic Denicola**
January 26, 2011

I came here to say exactly what Justin Hilburn said. Hopefully we'll have a good theoretical physics research site soon!

12. **Tim van Beek**
January 26, 2011

> Particle theory has long been a rather intellectually dead topic…

the most depressing feature among severy really depressing ones is – at least for me – that in the 21st century there is a need to discuss – with tenured physicists – what a "test" of a physical theory is, see e.g.

String Theory and the Real World by Gordon Kane.

This resets the whole topic to a pre-aristotelian level. Maybe we should just walk away and never look back…

13. **MO guy**
January 26, 2011

I'll have it known that if questions like the urban legends one become too common (called big-list questions), the NARQ (NotARealQuestion) squad will be there to MOp the floor with their smoldering remains (ooh, a mixed metaphor!).

14. **Chris Oakley**
January 26, 2011

1,000 posts? It seems like just yesterday when this blog and its followers were just a small (but mostly well-educated) group of malcontents and misfits … the days before you started filtering comments (what has happened to Quantoken, I wonder? – no, forget I asked). I thought that the principles of scientific enquiry were generally agreed upon, but a few hundred string theorists have proved me wrong. It is nice to have somewhere on the internet where they are nonetheless taken seriously (along with the basic rules of English grammar).

You were talking about improvements, for which I am grateful, especially since you are not being paid for any of this. One thing is the annoying "1y -12m" showing up in tooltips to express a recent time; another thing is that it would be quite useful if in the sidebar, or something, there was some explanation as to what is possible in terms of mathematical formulae, HTML, etc. in the comments section.

15. **Myke**
January 26, 2011

Peter nice work on reaching 1000, keep it up! Think very carefully before you change your blog's format! It works well and doesn't need fixing. Tired is perhaps a euphemism for lack of confidence, which shouldn't exist in considering your blog…

16. **Michael Gogins**
January 26, 2011

Thanks for your site. I'm not a scientist, but I enjoy reading about it and thinking about it. I've learned a lot from Not Even Wrong.

When I was a teenager, I wondered what would happen when physicists came up with theories so good they would very very hard to test. I had no idea that the Standard

Model, coming into existence at that time, was such a theory. But your blog and those who respond to it make me wonder even more…

What I wonder is this: if there is no practical way to test a theory, does this just sort of automatically turn people who in an earlier age would have been good empirical scientists into theologians and mythologists?

In an institutional and sociological sense, what can be done to enforce intersubjectivity?

Thanks,
Mike

17. **ohwilleke**
January 26, 2011

Congratulations! I particularly commend you for taking the opportunity to recognize other blogs rather than just your own at this milestone. My blog, started in July 2005, recently had its 5000th post and I can't claim to have been as gracious.

Your thousand post count also deserve special attention because you are in the camp of bloggers who post in multiple paragraphs, rather than single sentences or sentence fragments as many of the high post count bloggers do, something that makes your blog worth reading, especially in a relatively arcane field where analysis can add considerable insight.

The fact that your noise to signal ratio in the comments is 3-1 also indicates that a lot of people find this a worthwhile place to want their spam to be (I did a recent purge of years of comment spam and found that about one in ten of my comments was spam.)

Perhaps we should to the analysis of your posting timing that Résonaances did, which seems to indicate that the end of the blog (or maybe the end of the world or the end of particle physics) is due sometime in 2012, per the Mayan calendar. 😉 After all, if it is true at enough physics blogs, the sigma might get low enough to make it publication worthy as a metatheory of physics.

18. **Mean and Anomalous**
January 26, 2011

Thanks for the blog, and thanks for the book; keep it up.

19. **Jeff McGowan**
January 26, 2011

Congrats on the longevity Peter, fun to check in to the physics world once in a while. As for mathoverflow, great resource, funny story. I was at a math conference in the fall, and we were talking about it. One of Thurston's students, very well known person, ton of students etc., was saying how great it was that Thurston had been following/posting on it, but that it got kind of depressing because he would read Thurston's posts and just think "why do I even bother?"

20. **John Baez**
January 26, 2011

Congratulations on your 999.5±0.5th post, Peter!

Michael Goggins wrote:

> What I wonder is this: if there is no practical way to test a theory, does this just sort of automatically turn people who in an earlier age would have been good empirical scientists into theologians and mythologists?

Another option is for them to become mathematical physicists: that is, to study the theory as rigorously as possible. In the absence of experimental evidence, this another way to keep from "playing tennis with the net down". Witten is the most famous example of someone who has taken this tack.

21. **Arun**
January 27, 2011

Congrats on the 1000th post (at the 5sigma confidence level!) Here's to the next 1000! Will the Higgs have been discovered by #2000?

22. **Curious Wavefunction**
January 27, 2011

Thanks for the fish. Your blog and book have been thoroughly enjoyable and I have learnt a lot of interesting facts from them. One thing that I wish you would do more often is write book reviews since I really like them.

23. **Shantanu**
February 5, 2011

Peter and others,
I am still concerned that the only branch of experimental particle physics in which there has been a lot of progress since 1998 (viz neutrino physics) makes absolutely no connection with any theory or hyped extensions to standard model(string theory, ADS/CFT. supersymmetry etc).
See this webpage for quotes by various physicsts (including string theorists such as Pierre Ramond after super-k announced result for non-0 neutrino mass.
Maybe if string theorists are reading this, they could point out what will theta_13 be?

News From Chamonix

January 28, 2011
Categories: Experimental HEP News

The people responsible for the LHC are meeting in Chamonix this week to make plans for the upcoming run, slides of many talks are available here. The results of discussions there are:

- The recommendation will be to run at 3.5 TeV/beam, not increasing to 4 TeV/beam as widely expected.
- The long shutdown to fix splices and allow going to 7 TeV/beam will be delayed until 2013, with 2012 devoted to a physics run. The 2013 shutdown will likely last more than a year.
- Officially, the integrated luminosity goal for 2011 remains at 1 inverse femtobarn. However, unofficially, they expect to be able to do at least twice this, ending up with 2-3 inverse femtobarns by the end of the year

For a discussion of the possible physics that can be done with these parameters, see here. By the end of 2011 the LHC should be able to do better than the Tevatron on the Higgs search over most of the possible mass range, except for the low end of the range, where higher energy isn't much help, and the Tevatron's more than 10 inverse femtobarns and longer experience with the data analysis may give them an edge.

Comments

1. **Anon**
   January 28, 2011

   Particularly noteworthy is the plot on slide 19 of the talk linked above – the first public limits on SUSY from ATLAS, obtained from the same data-taking period as the CMS plot on the previous page. Results from the analysis of other channels still to come …

2. **Tommaso**
   January 28, 2011

   Hi Peter,

   I think CMS and ATLAS will actually win the race even in the range of masses where the Tevatron is advantaged. This stems from the recent re-evaluation of sensitivity performed by the two experiments. Also note that ATLAS and CMS might in principle decide to combine their limits or significances, something that the Tevatron does systematically.

   A few pictures are worth thousands of words: see the CMS expected 3-sigma reach and 95% exclusion reach in 2011 for some scenarios here.

   As you can see, 2/fb at 7 TeV will still allow to reach 3-sigma in a wide range of masses (130 GeV onwards), or to exclude a region down to 120 GeV or so at 95% CL. Combining with ATLAS, which has a similar sensitivity, will do the rest.

   Cheers,
   T.

3. **hg**
   January 31, 2011

   In all the talk about searching for the Higgs at the LHC, what happened to the LEP signal for a Higgs at 114 GeV?

4. **Rhys**
   January 31, 2011

   hg, nothing 'happened to it'. It's still talked about, and many people (especially those of us keen on supersymmetry) think the Higgs is probably quite light, by which I mean in the 110-130 GeV range.

5. **Peter Woit**
   January 31, 2011

   hg,

   I believe that after final analysis, the LEP "Higgs signal" was about 2 sigma, nothing to get excited about. Hopefully though within the next year or two we'll find out whether there was really something there. It's interesting that that Higgs mass is about the worst possible one for the LHC to try and see. Maybe they'll end their 2012 run with a 2 sigma signal….

Is the Multiverse Immoral?

January 29, 2011
Categories: Multiverse Mania

In the last week or so, I've run into two critiques of the currently fashionable multiverse mania that take an unusual angle on the subject, raising the question of the "morality" of the subject. The first of these was from Lee Smolin, who was here in New York last week talking at the Rubin Museum. I probably won't get this quite right, but from what I remember he said that discussions of a multiverse containing infinite numbers of copies of ourselves behaving slightly differently made him uneasy for moral reasons. The worry is that one might be led to stop caring that much about the implications of one's actions. After all, whatever mistake you make, in some other infinite number of universes, you didn't do it.

Over at Scientific American, yesterday they had John Horgan's Is speculation in multiverses as immoral as speculation in subprime mortgages?. There's more about this in a Bloggingheads conversation today with George Johnson, where Horgan describes his current reaction to multiverse mania as "I can't stand this shit."

I'm in agreement with Horgan there, but my own moral concerns about the issue are different than the ones he and Smolin describe. The morality of how people choose to live their everyday lives doesn't seem to me to have much to do with whatever the global structure of the universe might be. The world we are rapidly approaching in which a multiverse is held up as an integral part of the modern scientific world view isn't one in which many people are likely to behave differently than before, so I don't share Smolin's concerns. Horgan's exasperation with seeing the multiverse heavily promoted by famous physicists appears to have more to do with the idea that this is a retreat by physicists from engagement with the real world, something morally obtuse in an era of growing problems that scientists could help address. For what he would like to see instead, I guess a good model would be John Baez's recent decision to turn his talents towards real-world problems facing humanity, see his blog Azimuth for more about this. Personally, I'm not uncomfortable with the fact that many mathematicians and physicists find that they don't feel they are likely to be of much help if they go to work on the technology and science surrounding social problems. Instead, one can reasonably decide that one has some hope of making progress on fundamental issues in mathematics or physics and choose to work on that instead. One can try and justify this by hoping that new breakthroughs will somehow, someday help humanity, although this may be wishful thinking. Or one can argue that working towards a better understanding of the universe is inherently worthwhile, so pursuing this while taking some care to avoid worsening one's local corner of the world is a morally reasonable stance.

My own moral concerns about the multiverse have more to do with worry that pseudo-science is being heavily promoted to the public, leading to the danger that it will ultimately take over from science, first in the field of fundamental physics, then perhaps spreading to others. This concern is somewhat like the one that induced Alan Sokal to engage in his famous hoax. He felt that abandonment by prominent academics of the Enlightenment ideals exemplified by the scientific method threatens a move into a new Dark Ages, where power dominates over truth. Unfortunately, I don't think that revelation of a hoax paper would have much effect in multiverse studies, where some of the literature has already moved beyond the point where parody is possible.

For a while I was trying to keep track of multiverse-promoting books, and writing denunciatory reviews here. They've been appearing regularly for quite a few years now, with increasing frequency. Some typical examples that come to mind are Kaku's Parallel Worlds (2004), Susskind's The Cosmic Landscape (2005), and Vilenkin's Many Worlds in One (2006). Just the past year has seen Sean Carroll's From Eternity to Here, John Gribbin's In Search of the Multiverse, Hawking and Mlodinow's The Grand Design, and Brian Greene's new The Hidden Reality. In a couple weeks there will be Steven Manly's Visions of the Multiverse. Accompanying the flood of books is a much larger number of magazine articles and TV programs.

Several months ago a masochistic publisher sent me a copy of Gribbin's book hoping that I might give it some attention on the blog, but I didn't have the heart to write anything. There's nothing original in such books and thus nothing new to be said about why they are pseudo-science. The increasing number of them is just depressing and discouraging. More depressing still are the often laudatory reviews that these things are getting, often from prominent scientists who should know better. For a recent example, see Weinberg's new review of Hawking/Mlodinow in the New York Review of Books.

While most of the physicists and mathematicians I talk to tend towards the Horgan "I can't stand this shit" point of view on the multiverse, David Gross is about the only prominent theorist I can think of known to publicly take a similar stand. One of the lessons of superstring theory unification is that if a wrong idea is promoted for enough years, it gets into the textbooks and becomes part of the conventional wisdom about how the world works. This process is now well underway with multiverse pseudo-science, as some theorists who should know better choose to heavily promote it, and others abdicate their responsibility to fight pseudo-science as it gains traction in their field.

Comments

1. **Kea**
   January 29, 2011

   After I (the one copy of me) was physically denied entry to a multiverse conference in Oxford in 2009, I had a good laugh about it with a friendly stringer. Then he told me that the conference was secret so that the participants could debate (in secret) whether or not the multiverse was science. It seems they have still not made up their minds …

2. **John Romeo Alpha**
   January 29, 2011

   The universe we inhabit exhibits immorality in a narrow range, defined by the constant I, which is just immoral enough to allow for the possibility of free will, but not so immoral that we annihilated ourselves the moment we gained the technology to do so. Less immoral, and the inhabitants of the universe would bore themselves into petrified non-existence, more immorality, and they vanish in a flash of look-what-we-can-do. I present this as irrefutable evidence that Erdős's SF has planted us in the only or single universe with just the right amount of I to support intelligent life, teetering between determinism and destruction.

3. **Friend**
   January 29, 2011

   I think that multiverses are a misinterpretation of the Path Integral used in QFT, etc. Instead of it predicting the actual existence of alternative paths/universes, it really predicts that it takes ALL possibilities to make just one universe. Thus it is impossible for multiverses to exist.

   However, physics may have something to say about morality. Moral belief systems do consider cause and effect of deeds, which are actual physical events. Perhaps such belief systems can be considered to have some structure and entropy associated with them. Then it might be that maximum entropy limit theorems prevent instant dissipation of those structures so that they do have some physical effect. But then how would one measure belief?

4. **John Baez**
   January 29, 2011

   Maybe a branch of science is ripe for infection by pseudoscience whenever it stops making enough progress to satisfy the people in that field: as a substitute for real progress, they'll be tempted to turn to fake progress. One could expect this tendency to be proportional to the loftiness of the goals the field has set for itself… and to the difficulty its practitioners have in switching to nearby fields that are making more progress.

But is this really true? Does anyone know other examples, beside the current situation in fundamental physics?

5. **Shantanu**
January 29, 2011

Peter, there are many other critics of multi-verse, although they may no be very vocal. some other examples of critics include Steinhardt, Turok, Woodard, Polyakov, Krauss, Turner, Strominger (which you pointed out)

6. **Friend**
January 29, 2011

John Baez, how about the financial market;-) Unsatisfied with economic progress, they've invented extravagant financial theories of prime-lending rates and complicated security instruments. Funny, I've heard that some physicists have found work in the financial industry. Perhaps their theories work in some other universe.

7. **Casey Leedom**
January 30, 2011

I hesitate to offer a serious response here but …

As far as I've heard, all of the promoters of multiverses are using them to explain the "current universe" as just "an" arrangement of a bunch of fundamental parameters of much larger theories. But at the same time, also saying that all of the other universes are beyond our horizon. (The motivation for which seems to be to get out of the hole created by theories which have high degrees of freedom.)

The proposed multiverse models don't appear to offer us any ability to make predictions about this universe. Thus this doesn't give us any more insight into how this universe works.

So beliefe in this multiverse story is at best an amusing diversion along the lines of worrying about the number of angels which can dance on the head of a pin. At worst, that diversion gets in the way of people actually trying to understand what we see around us. Amoral? Meh.

I say: "Where's the beef?"

8. **Andrew L.**
January 30, 2011

This argument shows how desperately insecure these people are from a purely empirical viewpoint. They know there's no more empirical substance to thier grandoise hypotheses then that host of MIT engineering students who famously picketed a science fiction convention with a 200 page mathematical "proof" that Larry Niven's Ringworld was unstable. They HAVE to know-they're PHD's in physics,for heaven's sake! The problem is if they let people look behind the curtain,75% of the current funding in theoretical physics and mathematics in the Western World will vanish in a flash of insight. It's rather sad,truth be told.

9. **Tim van Beek**
January 30, 2011

Peter said:

> For what he would like to see instead, I guess a good model would be John Baez's recent decision to turn his talents towards real-world problems facing humanity…

Well, John switched to "real-world problems" from a topic that was and is seeing a lot of progress (n-categories), the switch from quantum gravity was earlier.

John said:

> Does anyone know other examples, beside the current situation in fundamental physics?

Well there are a lot of topics in fundamental physics that make a lot of progress, even in theoretical high energy physics. Besides that, I do think that the situation in string theory is quite unique:

a) Physicsists that spend their time at their desk, thinking strange thoughts, can become global celebrities, this phenomenon did not exist before the 20th century,

b) the growth of the scientific community led to the formation of a subgroup of a size so big that its members became unable to see beyond it. This, too, is new.

c) There is this unfortunate tendency that at least some physicists think that they are the smartest people on the planet and that everybody who does not appreciate what they do is simply unable to understand it. (Most of these guys are also smart enough to keep these thoughts to themselves, for which I am very thankful.)

To elaborate on the second point: An active researcher monitors the work of his collegues, how many may the average researcher be able to follow? 200? If a research community becomes too big, it usually splits into more specialized subgroups such that its members stand a chance to stay up to date with respect to the work of their collegues, and have time to communicate with their neighbors. It would seem that this did not work well for the string community.

Why do I think this? Because I heard a lot of criticism of string theory way before Peter published his book, from all kind of tenured and not-tenured physicists, both experimentalists and theorists (all outsiders to the string community, of course). Sometimes voiced with very unusual aggression. Yet most members of the string community seemed to be both completely oblivious of this (maybe not anymore), and immune to any criticism from outsiders.

Is there something we can learn from this? I don't know. Maybe funding should be cut in a way that never more than 100 people do research on the very same topic.

10. **Myke**
January 30, 2011

Friend restates Feynman's view, which seems better to me than the multiverse nonsense! Besides, just look up on a clear night and see what is a 'multiverse' of galaxies. The final theory might well show that the mix of galaxies is the 'multiverse' by another description. John's pseudoscience (as judged by his crackpot index) seems to have its epitome in the ramblings of Tomas Campbell, through his big toe, and multiverse mania seems just a small step behind…

11. **Bee**
January 30, 2011

Well, one may like or dislike the multiverse for scientific reasons, but there's no denying it's interesting from a philosophical point of view and it's a fairly new idea, so I don't find it very surprising it's getting its share of attention. Whether that's helpful for physics is a completely different question.

One shouldn't worry about the multimoraliverse, one just has to postulate that our universe is finetuned for moral. It has to be, because otherwise your blog wouldn't be here to discuss the issue 😉

In any case, the question of moral is moot because there's no such thing as free will, and what is moral if your decisions were predetermined already before you were born anyway? Now imagine what's going to happen if that became a popular concept. Then you should be worried…

12. **John Baez**
    January 30, 2011

    I wrote:

    Maybe a branch of science is ripe for infection by pseudoscience whenever it stops making enough progress to satisfy the people in that field But is this really true? Does anyone know other examples, beside the current situation in fundamental physics?

    Friend wrote:

    John Baez, how about the financial market;-)

    That's a nice analogy because it seems to have been caused by a desperate search for "high rates of return".

    But I'd really like examples of branches of science that "sank into pseudoscience" as certain portions of fundamental physics seem to be doing now. Or is this a historic first? That seems hard to believe.

13. **John Baez**
    January 30, 2011

    This just in: Brian Greene is interviewed by Terry Gross on her show "Fresh Air": A physicist explains why parallel universes may exist.

    By the way, just to lay my cards on the table: I think that parallel universes *do* exist. I just don't think they're worth writing papers about.

14. **simplicio**
    January 30, 2011

    Was Smolin discussing the multiverse from Sting Theory or the one from the Many Worlds interpretation? I thought only the latter had the "slightly different versions of yourself making slightly different decisions", but Peter's rant seems directed at the former.

    (also, do people that hold with both ideas think each universe from String Theory has its own near-inifinte set of "Many Worlds" universe. thats a lot of universes! I wonder if William of Occam exists in all of them)

15. **Anton Tykhyy**
    January 30, 2011

    @John Baez 8:45 — good insight!
    As a recent and important example, may I offer paleoclimatology? Also teaching methodology (?) — there are reams of research on how to teach children the three R's, but young adults have been getting progressively worse at them for decades. Philosophy, e.g. philosophy of science, also appears to offer many stellar examples and has been doing so at least since Kant's remark that

    > I do not wish to hide the fact that I can only look with repugnance … upon the puffed-up pretentiousness of all these volumes filled with wisdom, such as are fashionable nowadays. For I am fully satisfied that … the accepted methods must endlessly increase these follies and blunders, and that even the complete annihilation of all these fanciful achievements could not possibly be as harmful as this fictitious science with its accursed fertility.

16. **Peter Woit**
    January 30, 2011

    simplicio,

    I don't actually know which version of the multiverse Smolin had in mind. One of the things that annoys me about the subject is that discussions of it typically involve conflating all sorts of completely different ideas (it's not that Smolin was intentionally doing this, as some do, it's just that's the context in which these discussions are often held).

    You're right that my main problem is with the use of this to avoid the implications of the failure of string theory unification. Unfortunately I think that's the main motivation for some very smart people taking up and promoting a dumb idea.

17. **Giotis**
    January 30, 2011

    This is the main thing I don't like about Brian Greene's new book. He presumably mixes various notions of the multiverse together with some exotic concepts. This I think would obscure the multiverse idea derived from string theory and eternal inflation. This idea has strong theoretical support and it's not some wild ungrounded interpretation of QM. But let's wait to read the book first…

    Regarding Peter's commetns I think he forgets the main motivation for the introduction of the multiverse.

    With the observation of the small CC physicists were facing a big problem with the apparent fine tuning of the universe. It seemed indeed that the universe was fine tuned for life. Trying to make sense of this weird observation they found that the degeneracy of string vacua combined with eternal inflation give rise to the multiverse concept where such a extraordinary fine tuning (and the implied intelligent design) is not necessary. What's wrong with that? People are trying to give a theoretical scientific explanation to an observation. This is what science always does.

18. **Thingumbobesquire**
    January 30, 2011

This question of morality really belongs to the department of metaphysics. Leibniz soundly and cogently rejected the worldview that underlies the multiverse some 300 years ago. The rank pessimism of Voltaire's Candide as a satirical response is echoed by today's widely held "scientific" tenet that the fundamental law of the universe is irrationality. We meet this type of rather flagrant pessimism in this statement from Hawking: "But our genetic code still carries the selfish and aggressive instincts that were of survival advantage in the past."

19. **Peter Woit**
January 30, 2011

Giotis,

I'm not likely to forget the anthropic multiverse explanation of the CC. It's the only "evidence" for the multiverse, explained over and over and over again by those promoting it.

The problem is that I'm just not convinced. The string theory + eternal inflation + anthropic tautology pseudo-scientific ideology makes exactly the same predictions for observable physics as my personal theory of the CC (which is that I have absolutely no idea where it comes from, so its a priori probability distribution is flat).

And to some extent I agree with John Baez. Maybe there are parallel universes. But if you're going to write papers about them and promote the idea to the public as science you need to follow the scientific method. This means having a real theory you can calculate with, one that makes distinctive, falsifiable predictions. Right now, the "theory"being promoted is just a complex mess of failed ideas that "predicts" that a priori any value of the CC is equally likely.

20. **Joel Rice**
January 30, 2011

Giotis indicates that it looks like a Darwinian backlash against an implied 'intelligent design' and thus fine tuning might be irrelevant. But why should fine tuning be assumed due to intelligent design ? Both fine tuning and intelligent design may well be irrelevant. Suppose the design of the world requires the construction of atoms – the association of building blocks – how would one have such a nested hierarchy without the effect looking fine-tuned ? One might ask – do forces explain atoms, or do atomic structures determine the forces ? Normally one thinks forces explain – but maybe we have it all backwards, or upside down.

21. **Frank Quednau**
January 30, 2011

Is there actually an awareness of how we can move on with proper science? Which real world measurable phenomena are currently unexplained and require new models / methods ? What could become / falsifiable possible if we obtain an overarching grand theory?

22. **Emanuel Derman**
January 30, 2011

Re John Baez's post:
Maybe a branch of science is ripe for infection by pseudoscience whenever it stops making enough progress to satisfy the people in that field But is this really true? Does anyone know other examples, beside the current situation in fundamental physics?

The Efficient Market Model and the tendency of financial theory to become irresolutely axiomatic irrespective of whether the axioms describe the world seems a reasonable example.

In physics it used to be fairly easy to tell the crackpots
from the experts by the content of their writings, without having to know their academic pedigrees. In finance, as in nutrition, it's not easy at all. Perhaps physics is going that way too.

23. **Anton Tykhyy**
January 30, 2011

@Frank: that's just the problem. In fundamental physics, there is precious little to chew on — SM has enough free or underconstrained parameters to fit available experimental data; BB cosmology also rehashes the same few datasets — microwave background, elements' abundances etc. It appears that either we have entered the age of diminishing returns on research effort, or (and?) research has self-focused into areas which have rather small measure in the idea space. But whereas 200 years ago it was within the powers of a single individual of independent means to master the available data, theories and methods, come up with new ideas and test them, today it is nearly impossible for multiple interacting reasons.

24. **Arun**
January 30, 2011

In reply to John Baez:

Paul Krugman calls what has befallen on macroeconomics "The Great Ignorance".

http://krugman.blogs.nytimes.com/2009/06/26/a-thought-about-macroeconomics/

Not exactly the same phenomenon as certain portions of fundamental physics. But the lapse into pseudoscience is probably rare enough that the common causes, if any, are hard to perceive.

25. **Peter Woit**
January 30, 2011

Frank,

It's very well understood by people in the field exactly what the open problems are, as well as what a convincing solution to any of them would look like. These problems are hard though and have resisted solution for a long time. One reason for this is that much of the last 25 years the field has been dominated by investigation of one set of speculative ideas that don't work. The continuing problem is that instead of admitting this, prominent physicists go to the public with claims that these ideas do work, it's just that the "multiverse" makes them impossible to test. Thus my shared feelings with John Horgan…

26. **Chris Austin**
January 30, 2011

In my experience, the "moral" impact of taking the Everett-Wheeler "many worlds" picture seriously is the opposite of what Smolin suggests: you start becoming concerned about what happened on other paths. If by chance you narrowly escape a serious accident, you realize, "On another Everett path I got killed just then," which can be a frightening thought. And more generally you find yourself thinking, “What would have happened if … ,” and trying to think through increasing numbers of diverging paths, which can become a serious burden. Nowadays I try to follow a principle, “Make every path, including this one, as good as it possibly can be,” and not to concern myself about other paths.

27. **Low Math, Meekly Interacting**
January 30, 2011

While the observation of putative dark flow, and the proposed observation of evidence of bubble nucleation in the CMB intrigue me, what has been true of multiverse speculation appears to remain true. Specifically, I see no practical evidence that the field depends crucially on empirical observations of any kind, nor that it will do anything but continue indefinitely regardless of whether or not hints of other “universes” are ever seen beyond the chalkboard.

Regardless of what value judgement one puts on this state of affairs (I lean strongly toward the negative), there’s no question it’s a paradigm shift that we’re well in the midst of. “Science”, like it or not, has clearly changed. Whether one wishes to call the new era pre- or post-Baconian, empiricism appears now to be too quaint for a core discipline. It pioneered the scientific and technological successes of the modern era, and now a new course is being charted, for good or ill.

We’re past the point of arguing against it. I find that extremely sobering, to say the least.

28. **Yatima**
January 30, 2011

“Paul Krugman calls what has befallen on macroeconomics … ”

Oh…pullease. Not Paul Krugman; he always reminds me of the poor court alchemist trying to justify why repeated attempts to generate gold out of lesser materials has so far met with complete failure lest the well-funded speaking occasions dry up; sorry I meant to say lest the royal executioner pay a visit.

Keynesianism – Multiverse Theory for the economic profession. And look where it has lead us to.

29. **Peter Woit**
January 30, 2011

Please, informed analogies of economic to physical theory are welcome, but arguments over which economic ideology is best of the same quality as typical arguments over string theory and the multiverse aren’t.

30. **Fred Zarguna**
January 30, 2011

Tipler essentially made this argument going on seventeen years ago in *The Physcis of Immortality* wherein he claimed to have neatly disposed of the Problem of Evil by virtue of the Many Worlds interpretation. Possibly he was correct: unfortunately, if Many Worlds describes actual worlds it also does away with the “Problem of Good,” which most theologins and ethicists never saw as a problem in the first place.

Content yourself with an update to an ancient aphorism: “Sufficient to each path is the evil thereof.”

31. **Bugsy**
January 30, 2011

I am confused by what role a probability distribution is supposed to play (or not) in both of two “multiverse” ideas- the Many Worlds one and the recent CC one. If there is a probability measure on some uncountable set (like the unit interval) then one can think of “all” events (points) occurring, with the one observed (in this case, inhabited by us) distributed in that way- but with the other points also existing. Alternatively, only one occurs (the one we are in). For example, coin-tossing can be modeled by Lebesgue measure on the unit interval with the binary expansion of each point giving a sequence of 0’s and 1’s; alternatively you imagine a single randomly chosen infinite sequence, almost surely with the right statistics. Regarding “MW”, if different worlds are supposed to constantly branch off, then that is severely problematic to model, in either case. One could perhaps imagine branching occurring at all times something like the
direction changes of a Brownian motion path, but with only one path surviving and actually existing, like the coin-toss sample path. Ok, but if it is splitting at every moment at every location…???

And regarding “CC”, if these other universes “actually exist somewhere else” then where? There isn’t enough room in any n-space for uncountably many worlds. So maybe it is envisioned as a
fiber bundle over the probability space. But is any case is sounds very difficult to make any real sense of, to say the least….

32. **Brendan**
January 30, 2011

Peter, don’t discount the degree to which fundamental physics, and our collective understanding of it, inform culture. People do live their lives according to how they see the world. When I was a kid “radical!” was common slang. Today, “random!” is a more common exclamation. I think these are both examples of pop culture tracking science trends. So, I don’t think it’s out of line to consider the moral implications of a particular theory. But it’s an article in Rolling Stone at best. The outcome of considering the possible moral implications of a theory shouldn’t interfere with primary research. But the underlying portrayal and execution of “philosophy of science” is a worry here. I don’t like to think of the message being sent to kids when we have major theories which aren’t subject to much Popperian gravity – just floating around out there in the ether, waiting for the rest of us to have faith that “we’re on the right track, you’ll see. Just keep funding x…”.

I also agree that both finance and physics are “ripe for infection” There’s a lot of energy and diversity of opinion in physics right now. The pent up urst for a true discovery in physics is probably driving some unprotected research. But I’d point to the oft pooh-pooh’ed idea of “the edge of chaos” to suggest that that might not be a bad thing. I think both physics and finance are sailing close to the wind. In sailing terms, you can win the race sailing close to the wind, but sail too high and you luff the sails, you lose the race. Whether I’m comparing science to a boat race, or randy adolescent boys, the importance lies in competition and having a some “grown-ups” around to establish the boundaries.

33. **milkshake**
January 31, 2011

Examples for John Baez: My impression is that wishful thinking and pseudoscience have played an important role in psychiatry, psychology and management theory.

34. **Casey Leedom**
January 31, 2011

Let me be more brief.

I don't care if there are multiple universes or not. I care so little that I'll even grant it to the proponents just to get them to shut up.

And then I say: what about _this_ universes? Now that you've had your fun dodging the hard problems, can we get back to making concrete predictions about what we _can_ see?

35. **Joe Bob**
January 31, 2011

"But is this really true? Does anyone know other examples, beside the current situation in fundamental physics?"

Probably one can see things such as the research fraud committed by Marc Hauser as similar (this related to cognition in monkeys). In the biosciences there is more money and more opportunity for popular exposure, and so the degeneration is even greater, into outright fraud. Or, perhaps, the difference is that the fraud can be debunked, whereas metaphysical quasi-religious speculations are inherently more difficult to counteract.

Looking back to the nineteenth century, perhaps the degeneration into social darwinism was a similar phenomenon.

36. **Bee**
January 31, 2011

Regarding the question what infected economics, you might find this amusing:
http://www.nytimes.com/2011/01/31/opinion/l31atom.html

37. **John Benavides**
January 31, 2011

Dear Peter

It would be interesting to make a post to expose in a detailed way your objections about the multiverse, pointing the difference between the many world interpretation or the consistent histories approach to quantum mechanics (for example I would like to know what do you think about Deutsch's work and Omnès' ideas, where I think there is lot of ideas that should be take seriously), and the inflationary and string theory's multiverse (where I think there is a lot of pseudo science)

38. **Frank Quednau**
January 31, 2011

I think that a popular science book outlining the currently open subjects in physics would be a very nice subject that would be quite refreshing from the bold books that seem to be pouring out these days.

Such a book is obviously subjected to a high risk of becoming obselete quickly, but it would be of great service to the public. Or maybe there is one still accurate enough? Or maybe I am a minority…

39. **SteveB**
January 31, 2011

I listened to Brian Greene's interview on Fresh Air last week. Brian was reasonably fair about mentioning the speculative nature of his arguments and that many disagree with his ideas. What came across was his passion for the beauty of the mathematical outcomes that come from extrapolating from other mathematical theories that come from the Standard Model (QFT) which is itself a mathematical predictive tool that attempts to describe the real world.

And that is where I see the problem. Mathematics is a wonderful, beautiful endeavour. Extending mathematical knowledge is a great and worthy career choice. But as I see it, mathematics in Physics is a tool that is used to try to understand the real world and not an end in itself. While extending the mathematical tools used in Physics can lead to new insights and discoveries, they can also lead to nowhere (in the real world). I think Greene is mistaken that some beautiful mathematical result makes for a plausible theory of physics. Maybe Dirac did it that way once, but that does not prove it to be the best method to use. GR came from the elevator/gravity gedanken experiments and not from the Math.

As others have mentioned, one can argue that the scientific method itself is being abandoned when one goes the routes that have lead to the current multiverse ideas. I do not support that.

40. **Peter Woit**
January 31, 2011

Bee,

Thanks, that's great, I hadn't seen it. Maybe the argument that particle physicists need to be kept busy or they'll bring down the financial system will help get funding for the subject.

John,

As far as I can tell, the string theory multiverse and the many-worlds multiverse have nothing much to do with each other. The string theory multiverse I understand, and it's clearly pseudo-science. QM interpretational issues are something I'm just not expert in (I know basically nothing about the work of Deutsch or Omnes), so mostly try and avoid comment on. To the extent I have tried to follow the subject, there seem to be very interesting issues there, with most writers ignoring them and devoting themselves to arguing about things that are not interesting (at least to me…).

Frank,

Well, I did write a book with a chapter devoted to this (see chapters 8 and 9 of NEW).

SteveB,

I strongly object to blaming the multiverse on the pursuit of mathematical sophistication and beauty in physics. Most multiverse papers use nothing but high-school mathematics. The "string theory vacuum" constructions that motivate this are just hideously complex and ugly beyond belief. Anyone looking for mathematical beauty would give up on this line of research immediately after looking at these things. The "derivation" of these things from some supposedly beautiful "M-theory" suffers from all sorts of problems, not least of which is that no one knows what "M-theory" actually is, making claims for its supposed beauty to be taken with an immense grain of salt.

41. **Paul A. Houle**

January 31, 2011

Physics has been on the wrong side of the rabbit hole since the 1980's or so. The fundamental problem is that there's very little going on physics that grabs the public imagination, so science fiction starts to move in.

(You're just not going to get the public excited about, say, Spin Glasses)

I think of the way the Bell Inequality got popularized in the 1980's. It's real science, but it's a much less profound expression of quantum entanglement than the way that fermion character makes solid matter possible. And if you start taking it too seriously pretty soon you're Jack Safaratti or Clifford Stoll.

In the time I was in grad school, quantum gravity went from a holy grail to an embarrassment of riches: people invent new theories of quantum gravity every day, theories in which it's actually possible to calculate something. Now, "possible to calculate something" means unitarity, and unitarity means "no information loss in a black hole" which means that the 1970's classical picture of a black hole interior is obviously wrong, but on some level the study of black hole interiors is futile since we're never going to send a probe into a black hole that sends back pictures.

Cosmology has always been linked with concerns that are essentially theological. Einstein found an expanding universe distasteful, so he added a cosmological constant to keep it from expanding. Once we learned the universe was expanding, many cosmologists believed in a steady state universe that had neither beginning nor end, rather a process of continuous creation that creates new hydrogen in the spaces between the stars.

Then the CMB was discovered and it became clear that the universe must have been much smaller and very different in the past. Although cosmologists had little evidence that the universe was either closed or open, it seemed like most of them believed that the universe was closed (How could you have a beginning without an end?) until inflation came on the scene, and pointed to a universe that's exactly flat.

Today the multiverse, true or not, reflects a theological preference for 'continuous creation'. It's something that many of us (myself included) find emotionally appealing… in the same sense that some people find it emotionally appealing to believe that God created the world 6000 or so years ago.

42. **Joel Rice**
January 31, 2011

Peter, regarding the idea that it is well understood what the open problems are and what a convincing solution would look like, well, I often wonder if the present situation is not similar to the state physics was in just before Spin finally made sense. There was no lack of ideas, just that none of them actually worked. And Spin was a limited problem. And the answer was in quaternions. It appears that Nature is really good at making a lot with a little. The problem with this is that subtlety can be as big a problem as just being complicated. All of today's ideas might end up like Heisenberg's Core Model, if we are not noticing something that we ought to notice.

43. **Geoff**
January 31, 2011

"None of the so-called "unified theories" are considered in this book, as in our opinion their physical significance is inversely proportional to the number of variants advanced, now more than twenty."

From the preface to Petrov's Einstein Spaces

Perhaps physicists could clear up some of the confusion by not prefacing a chalkboard equation with the statement "Morally speaking, the following should be…."

44. **John Bresnahan**
January 31, 2011

Larry Niven wrote "All the Myriad Ways" with this as it's theme. The original copyright is 1968.

45. **thomas**
January 31, 2011

any reasonable person would do the same thing with or without a non-collapsing wavefunction, since the reasonable thing to do is to maximize your chances of success, and the non-collapsing wavefunction should still respect probability distributions, after all, we observe it to!

I guess what I'm trying to say is that stuff that by definition has no effect on our world might just as well not exist.

Anyway, for a science that has fallen into pseudoscience, we have economics, which Krugman says has been taken over by right-wing ideologues who don't have any awareness of the arguments that people used to have.

Psychology, which started with Freud's brand of pseudoscience, continues to be full of it. That's not a descent into pseudoscience, though.

Medicine maybe? About a decade ago, some people started taking certain alternative medicine theories seriously. That was never really mainstream, though.

It's worth mentioning that neither geology nor biology have fallen into pseudoscience, much as the right wishes it so.

I think that pretty much rounds out our collection of sciences!

46. **John Fro**
January 31, 2011

All cosmologists these days are caught up in the legacy of Einstein and the glorious notion that they can rewrite all of physics with just an idea, even one that is counter-intuitive. This notion is very mistaken. There are no multi-verses because there is no way to produce them. What you have are potentials, but after an event those potentials collapse. Don't try to be the next Einstein. He was solving a very narrow problem with a specifically tailored solution that fit the known facts. While this resulted in predicting unseen phenomena, the goal was not to discover something new, but to solve an old problem. The odds are that you are going to get it wrong.

47. **El Cid**
January 31, 2011

Is the Multiverse Immoral? what is immoral is this post, let me remind you, that your criticising against string theory is for money, too. WTF?

48. **felix**
January 31, 2011

I'm surprised that Greene didn't name the book "The Elegant Multiverse".

49. **Adam F**
January 31, 2011

Biology has certainly not fallen into pseudoscience, but we are running into situations where a disturbingly large proportion of studies (particularly in medicine) turn out to be false. The everyday upshot of this is the constantly changing ideas about what foods and drugs are healthy. It gets very difficult to tease one small cause-effect relationship (say, genes or environmental conditions) from a huge mass of other contributing factors, all of which interact with each other. There are still plenty of areas where relationships are strong and research can be usefully done, though.

50. **Steve Baker**
January 31, 2011

So the multiverse theory must be wrong because it causes immorality? Wow – cogent argument!

We can't prove or disprove the multiverse theory – and there are other alternative theories that we also can't prove or disprove. There is no special reason to believe or discard any of them.

However, the moral issue is a specious one. Would you also condemn the possibility that the universe is infinite on moral grounds? You need to because in an infinite universe, there are also infinite numbers of "parallel earths" in which decisions you make come out differently.

Really, we all need to simply talk about what is possible and what is not – and look for more clues to tell us which is true.

Personally, I'm becoming somewhat impressed by "The Simulation Hypothesis" (look it up on Wikipedia) – it explains an awful lot about some of the seemingly arbitary things about our universe.

However, we can't either prove or disprove that one either.

In the end, all we can do is to fall back on weak guidance from Occam's razor.

51. **Peter Woit**
January 31, 2011

Steve Baker,

I've not claimed either that the multiverse is wrong or that it is immoral or that one implies the other.

What I do claim is that the string theory multiverse is not legitimate science since it is inherently untestable. Note that I don't claim all multiverse theories are untestable, I'm specifically referring to the ones promoted as an implication of string theory. Also note that you need to examine exactly what these theories say to see what their problems are and just how unlikely it is that they can be overcome. This is a complicated subject, but what's not complicated is the current situation: these theories currently make no predictions at all that can be used to test them. It's up to proponents of the idea to come up with a plausible avenue to getting such tests. I don't think they can, and I haven't seen them do it when confronted with the question.

I don't share Smolin or Horgan's particular concerns about morality, I was just reporting them. I do have my own concerns about the morality of how the string theory multiverse is being promoted, but this is not about the "morality of the multiverse", it's a moral question about how science is done.

52. **Clark**
January 31, 2011

The moral argument is weird. It's akin to the argument I've heard some philosophers make that a block universe (i.e. taking GR seriously) must be false as there then isn't the kind of free will many philosophers think is necessary for responsibility. It's an odd kind of reasoning undermined further by the fact, as you note, that in practice no one is probably going to change their behavior anyways.

It's odd Smolin goes so much against the multiverse theory since his own quasi-evolutionary theory doesn't seem *that* different. Although it isn't quite saying that anything goes.

What I don't get is why folks like Greene don't just accept that they are doing philosophy rather than science. I suspect it's a remnant of the anti-philosophical tendency left over from Feynman's influence. But honestly philosophy can be interesting. It can even be rigorous. It just shouldn't be taken as a scientific statements we have relative confidence in.

53. **Brian Knoblauch**
February 1, 2011

While the multiverse theories may not currently (or ever) be able to be experimentally verified/debunked, I don't buy the morality argument. As long as the science being done is still sound, and the multiverse theory is not presented as "knowledge" (merely as speculation), I have not problem with it. Speculating on all kinds of weird and exotic things has been a source of inspiration for others to make REAL discoveries/developments. Dragging morality into it this is pure silliness. If you're doing science the right way, "morality" should not be a concern. It either is right or wrong scientifically, there is no wishy-washy emotional component. By dragging morality into it, you defeat the science.

54. **Peter Woit**
February 1, 2011

Brian,

The problem here is that pseudo-science is being passed off as legitimate science to the public. One reason this is being done is to evade the implications of the scientific failure of string theory unification. This situation seems to me to raise moral issues.

Just to give one example, this is from a recent article on the subject:

"since almost all contemporary physics accepts and even demands the reality of parallel worlds. Love it or hate it, the multiverse is here to stay."

55. **David A. Spitzley**
February 1, 2011

Perhaps I've got the wrong end of the stick here, but is the "multiverse" any different from the Many Worlds interpretation of standard quantum mechanics, which people have been kicking around for decades? If not, how exactly have things gotten any worse in the context of these new books?

56. **Peter Woit**
February 1, 2011

David,

The controversy over the multiverse is about something different, the idea that string theory implies a multitude of completely separate universes with different physical laws. This is quite different than many-worlds, which is an interpretation of standard quantum mechanics, with one fixed set of physical laws. The two very different ideas are getting mixed together often, I'm not sure why.

57. **Nick**
February 1, 2011

Why do they get confused? Even though I have a B.S. in Math and follow science regularly, I didn't know the distinction between multiverse theory and many-world theory until now.

Science journalism for the general public needs an upgrade. Reputable newspapers, etc. have a difficult discerning the legit. from the pseudo science, sometimes degrees in the specific field are required. Any journalist wanting to do serious science reporting should start with a college level statistics course.

58. **Peter Woit**
February 1, 2011

Nick,

I don't think this can be blamed on journalists. The physicists promoting the "multiverse" tend to talk about these things together, without making the distinction, confusing the issues. On the whole I've found that science journalists do a pretty good job of reporting what scientists tell them.

59. **Michael T.**
February 1, 2011

It should come as no surprise to learn that scientists are not immune from self-promotion. The multivese is clearly a metaphysical concept at best but it does sell and the public eats it up big time. You can get a book deal, a few interviews on prime time, maybe even your own TV show. It is the era of the "scilebrity" so why shouldn't they hustle a buck 😉

60. **Tay Owens**
February 1, 2011

Many concepts which are now accepted as scientific fact were once derided as unfalsifiable and hence unscientific. Just because they are unfalsifiable with today's technology and limited knowledge doesn't mean all multiverse theories will always be unfalsifiable, and are therefore pseudoscience. Indeed, Greene takes pains to point out which of the 8 kinds of multiverses he details may be testable in the future (and why) and which most likely will remain unfalsifiable. Perhaps then we can view some multiverse theories as scientific theories, and others as philosophical theories. I rather like that idea, particularly as it brings physics closer to its roots as Natural Philosophy–a heritage to be proud of, not ashamed of.

Indeed, modern physics has often been preoccupied with matters that are perhaps more philosophical than strictly scientific in a Popperian sense–or, at least they seem so until much later when the math or technology or observations finally catch up to the theorizing (philosophizing). The chase after Grand Unified Theories or Theories of Everything or any unification of currently separate physical idioms is as much about producing a philosophically pleasing merge of disjointed models as it is scientific–after all, nothing precludes a universe that obeys multiple sets of laws at differing scales or states; we just don't like the idea on philosophical grounds and seek a more elegant and parsimonious solution. We'll probably find it eventually, at which point it will really be pure science; but until then it's just philosophy in science's clothing. Sounds a lot like multiverse theories to me. Does that make every physicist seeking more unified theories than current models and maths and observations accommodate a pseudoscientist?

61. **srp**
February 3, 2011

I'm a little puzzled by the oft-made claim that the SM is so good at matching the data that theorists have nothing to do. Lederman says that the gap between the observed vacuum energy and what theory says it should be is off by many orders of magnitude. And I seem to recall hearing about some gross anomalies in transverse-spin polarized collisions (Krisch?). Then there's dark matter. So I guess I don't see why everyone chases unification when more tangible prey seems to be available.

62. **Peter Woit**
February 3, 2011

srp,

In the SM the vacuum energy is a free parameter, you can make it anything you want. It's only when you try and work with unified theories of the SM and quantum gravity that the CC can become in principle calculable and you have to find an explanation for why it is so small.

There's no observation at all of dark matter or anything related to it in a laboratory experiment. It's an astrophysical phenomenon. The fact that standard models of cosmology and galactic structure seem to point to some sort of gravitating matter that we don't understand is an interesting hint, but it's not a lot to go on. In any case though, there's a huge concentration of effort by theorists to pursue this hint.

The anomalies in polarized proton collisions are a topic I wish I knew more about. They probably do deserve a lot more attention. Betting though seems to be that they aren't evidence of a problem with the SM, but with the fact that our understanding of how to do non-perturbative calculations in QCD is still quite crude.

63. **Phrustrated Fizix Stoodint**
February 3, 2011

Peter, first thanks for your book and this weblog, it has saved me many hours of not pursuing dead ends.

From your book, I have a quick question. On the last page of your book, you mention two directions that quantum gravity can go in, involving diffeomorphisms. A brief update on progress towards those goals since you wrote the book would be appreciated.

From this weblog and your last reply, we'd be interested in knowing if dark matter phenomenology is still the hottest field in theoretical physics (it was last year, yes?) and whether or not in your humble opinion it would be worthwhile putting effort into it at the present time. I'm not a herd animal and wish to pursue something unique, is why I'm asking. Entering a crowded field is unappealing to me and my friends.

64. **Peter Woit**
February 3, 2011

Phrustrated,

Dark matter is still a very hot subject, but there's a good reason for that: not much else in the way of data that disagrees with the standard model. Everyone is hoping that the LHC will soon change this.

There hasn't much new learned about the problem I mention in the book, how to handle diffeomorphism and gauge symmetries in QFT. Personally I've spent a lot of time learning about how to think of Langlands and geometric Langlands in terms of representation theory, and hope that this might lead somewhere, but that's a long way off.

65. **cormac**
February 5, 2011

Hi Peter, how are things:
my understanding is that,even with ST, the basic concept of the multiverse arises out of cosmic inflaton i.e. the possibity of bubble universes is raised by many of the current models of cosmic inlation.Have I got this wrong?

66. **cormac**
February 5, 2011

ops, that should of read "without ST"

67. **Peter Woit**
February 5, 2011

Hi Cormac, things are good!

Sure, you get bubble universes in some models of inflation. But what's new with string theory is using this as an excuse for not being able to predict anything. People making models of inflation with bubble universes can argue that their model doesn't predict certain things because those things are different in each universe. But they have to predict something to be taken seriously.

String theory is a unified theory, so in principle supposed to explain everything about fundamental physics. It doesn't actually work, but instead of admitting this, string theorists try and use the multiverse to explain why they can't predict anything at all. To me, that's where there's a moral problem…

68. **Stefano**
February 6, 2011

Peter, I enjoyed your book and visit your blog often. Now, not sure this comment belongs to this posting, but anyway… what I don't understand is why you and Lubos are such "enemies". Sure he goes for string theory, but on the other hand he is pretty clear about that other great bs science of day, i.e. "climate change", just like you are about string theory. Now, I have no personal reasons to argue that climate may not be changing or even warming – but what I do see clearly is the bs articles popping up everywhere tying AGW to even the most unrelated topics. It's clear that researchers have understood where the money is and what they need to say to get access to it. New Scientist, Scientific American and even something relatively neutral like sciencedaily.com have become nauseating in that respect. It's just like string theory. Bottom line you and Lubos clearly disagree on a lot of things, but you both can only take so much hypocrisy and bs… I wish the two of you noticed that commonality. (Sorry for the ranting style – I think this is why I commented for this particular post.)

69. **Peter Woit**
February 6, 2011

Stefano,

Actually I do agree with Lubos about a lot. He's not much more in sympathy with the multiverse than I am.

About climate science though, I don't think it's much like string theory at all. Public discussion of the issue is even more politicized and dominated by ideologs than string theory. I'm doing my part to fight this by stopping discussion of the subject here.

70. **chris**
February 10, 2011

"Maybe a branch of science is ripe for infection by pseudoscience whenever it stops making enough progress to satisfy the people in that field But is this really true? Does anyone know other examples, beside the current situation in fundamental physics?"

I don't really know this too well, but astronomy after Ptolemy seems to fit the bill. Or actually Ptolemy can be viewed as part of the decline already.

Another example that pops up in my mind is the scholastic period in the 13th-14th century and the associated mutation of science into comments on Aristotele.

In modern context i'm really tempted to say economics (as a science) and psychology of the Freud and Adler kind. But i don't know how much one can count these as sciences to begin with.

71. **Allan Rosenberg**
February 11, 2011

If multiverse-based theory (or its promotion) is immoral in our universe, does that mean it's immoral in all other universes?

72. **Peter Woit**
February 11, 2011

Allan,

If the laws of physics are different in different parts of the multiverse, I don't see why laws of morality shouldn't vary too…

73. **Allan Rosenberg**
February 11, 2011

Great, we finally have a physical definition of the term "moral landscape." But I think we should reserve judgment on the morality of the multiverse in our universe until the string theorists can at least let us know which of the many universes we inhabit.

74. **Matt**
February 11, 2011

Peter–

I think in your next posting on the multiverse controversy, it might be worth taking a moment to distinguish clearly between the different notions in play. There's the very old notion of the "many worlds" interpretation of quantum mechanics, going back to the work of Everett and DeWitt, in which the different universes are branches of a wave function.

Then there's the more modern notion of a multiverse—the one you're referring to in this post—in which different universes are realized at different locations in physical space. But there are two theoretical underpinnings to the idea, one coming from cosmology and the other from string theory.

Even putting string theory aside, the most successful models of inflation, which are quantitatively consistent with observational evidence from fluctuations in the cosmic microwave background and resolve myriad inconsistencies of the old Big Bang model (horizon problem, flatness, relics, structure, etc.), require at least 60 e-foldings. That essentially inevitably produces a vast, vast space in which our entire observable universe is smaller than an atom in comparison.

There's no string theory here, and this simple consequence of inflationary cosmology that our observable universe really and truly is but a mere speck in a far more immense space immediately raises the question of what the heck else is out there. Is it just empty space, is it stuff that looks pretty much like our own universe, or is it totally different? Given that the early universe exhibited energies far beyond those at which the Standard Model breaks down, there's as much reason to believe the third possibility as there is to believe that ice crystals forming at isolated, separated locations in a giant vat of water will all line up in parallel.

Is it really unscientific to be asking these questions, or thinking about them, or looking for observational signatures (CMB patterns, evidence of bubble collisions, etc.)? What string theory brought to the conversation was merely a candidate theory of quantum gravity that leans to the third possibility, but that possibility is still hanging there whether string theory is correct or not. What do you say to that?

75. **Matt**
February 11, 2011

Typo— should read " … will all line up in different directions."

76. **chris**
February 11, 2011

Matt,

the cosmological "multiverse" you try to construct is really not a multiverse. if you just wait for long enough (and assuming that the pressure to energy ratio of dark energy is at least not <-1) you will see. our horizon is expanding constantly and nothing too shocking is expected to come into view.

why?

because all relevant cosmological transitions are not first order as it seems now. there are no bubbles or cosmic strings as far as we can tell – nothing that would resemble a multiverse at all. so unless the underlying physical laws themselves are spacetime dependent, i guess it is rather boring.

and by the way, what is the scale that the SM breaks down? last time i checked it can be somewhere beyond the Planck scale if the Higgs mass is around 150GeV.

77. **Peter Woit**
February 11, 2011

Matt,

Some of the books I mentioned treat both many-worlds and cosmological multiverses, and the authors seem to thing these two things have something to do with each other. I've never been able to understand this.

I've no problem with people looking for observational signatures of bubble collisions or whatnot in various inflationary models. But it seems unlikely that the size of such effects is exactly such that they're just barely visible in the CMB data, and there's no underlying model that has experimental support that gives any reason to believe this is something reasonable to expect. So, it seems likely that all claims about this have about as much to do with the structure of the universe as does the appearance of Hawking's initials in the data. If people want to do this fine, but they should also be a bit careful about participating in articles in the popular press about about "scientists find evidence for the multiverse."

String theory doesn't "lean to" a multiverse or anything else, it's compatible with essentially anything. Instead of admitting that this means it's a failure, the people backing it have adopted the morally dubious tactic of invoking a multiverse scenario carefully constructed to not predict anything. This is not science, but an attempt to use pseudo-science to prop up a failed enterprise.

78. **Matt**
February 11, 2011

In the interests of clarifying matters, let me ask you a series of questions:

1\. Do you agree with most cosmologists that inflation is the leading candidate for resolving the troubles with the old Big Bang model, and that its quantitative predictions about fluctuations in the CMB have been quite successful?

2\. Do you agree with most cosmologists who say that you generally need 60 e-foldings of inflation for the models to work?

If you say yes to both 1 and 2, then you are basically led to the conclusion that the true universe is really vastly larger than the region we can currently see. You might call this vast expanse the "megaverse."

3\. Now there are two possibilities for this megaverse—it's either empty, or it's not. Do you think it's likely to have lots of other stuff in it?

If you say yes, then you've already accepted that the megaverse is really a kind of a multiverse. Maybe those other regions are filled with matter similar to the stuff in our own observable region—galaxies, planets, etc.—and maybe no two regions are alike. So it's not an "everything"-verse. But if you regard as scientifically acceptable the previous propositions, then you basically accept that we live in some kind of a multiverse.

4. We can go further, of course. Generically, models with inflation never end—inflation is always going on somewhere, because inflationary space expands far faster than patches can freeze out and stop. This is eternal inflation. Where do you stand on this question?

You may or not be on board with that idea, but it would obviously mean that we'll never see most of the multiverse, no longer how long we wait. In that sense, most of it becomes unobservable.

5. Do you regard speaking about those other parts as unscientific and out of bounds?

6. Finally, there's a larger notion of a multiverse where all those hypothetical low-energy vacua of string theory are realized in various places in space. Again, however, this doesn't mean that there's a copy of you where everything possible happens. If the set of possibilities is infinite and unbounded, then even an infinite set of bubbles won't necessarily explore them all.

7. Lastly, there's the idea that every single possibility is literally realized somewhere in some bubble. That's where the multiverse becomes an "all-verse." I definitely know that you regard this last possibility as pseudoscience, and it's what Smolin and others are morally objecting to.

I think it's important not to conflate all these ideas. There are serious scientists who find themselves at various places in this list. Where precisely do you think is too far?

79. **Matt**
February 11, 2011

Peter–

And note that string theory only came up in question 6 on the list. The landscape is not the same thing as the multiverse, as most cosmologists will be very careful to explain.

80. **Cosmonut**
February 11, 2011

@Matt:

2. Do you agree with most cosmologists who say that you generally need 60 e-foldings of inflation for the models to work?

If you say yes to both 1 and 2, then you are basically led to the conclusion that the true universe is really vastly larger than the region we can currently see. You might call this vast expanse the "megaverse.
———————————————–

This is not really true from what I have read.
60 e-foldings during inflation would lead to a homogenous universe of the same size, roughly, as what we see.
That is how the "60 e-folds requirement" is obtained.

Now, number of e-foldings to go beyond 60 — no one knows how many more, because there are dozens of models with no and no idea which is right.

IF that happens, then our "inflationary bubble" could be much larger than the observable universe.

But there's no reason to believe that there would be different laws of physics operating in other parts of the bubble. The default case would be the same laws all through the bubble.

81. **Peter Woit**
February 12, 2011

Matt,

You don't appear to pay any attention to the answers I already gave you, so I don't see why I should spend time answering the same questions again.

82. **Matt**
February 12, 2011

Peter– My point was just to make clear where you stand, but I understand if you no longer wish to discuss the matter.

Cosmonut— No, 60 e-foldings is necessary for our observable region to have the correct properties, such as flatness, but the consequence is that it's then a tiny patch of a far larger space. Think of what you have to do to a balloon to make a tiny surface patch look look very flat–you need to blow up the balloon to a size far more tremendous than that patch.

One piece of advice to you folks that will help you make your case more successfully. (And I'm somewhat sympathetic to that case, by the way.) Critiques of the multiverse would be more convincing if people didn't conflate all the relevant issues, and made more clear exactly what they accept as reasonable and what they don't. Is that asking too much?

Take care everybody.

83. **Emile**
February 12, 2011

Dear Matt,

Science is nothing without the part where we test our hypotheses. There is nothing wrong with starting with observational evidence of the early Universe and trying to figure out the implications. You can then formulate new hypotheses that hopefully will eventually get tested. Until you have figured out how to test those ideas, they are just ideas: call it scientific speculation if you must (but it is speculation). What makes science so powerful is the testing part. I think people are doing damage to its good name when they confuse speculation with science. The lay public is on to us. Look at some comments in newspapers and elsewhere and you'll read sentences like this one:"Modern quantum theory has gone into the never, never land of all theory and no proof, to the point where it's become a religion unto itself, whereby its all based on faith and no fact". That comment was related to a story about religion (I've started to collect these comments). It's unfortunate that quantum theory (think of the anomalous magnetic moment of the electron) is getting dragged into this. I personally think that these ideas about multiverses (even the landscape) are quite likely. But what I think doesn't mean squat. I'll call it science when we have figured out how to test it. And if it is forever untestable, than it will never be science.

84. **Matt**
February 12, 2011

Emile–

Are you a practicing physicist who works in high energy theory and cosmology? I ask not because the opinions of lay persons are inferior in any way–in particular, you make very good points–but that lay persons simply don't get a chance to see what the people who actively work on this stuff actually think about everyday. Peter has a lot of personal bias, as do we all, and he won't tell you.

I can assure you from much professional experience that whatever Hawking or Greene or Susskind or Weinberg (none of whom are very active on the research side any more) say in public, the people who actively study this stuff are absolutely obsessed with observability. Tests are very much on their minds. People are constantly devising schemes to look for signatures from the CMB, or evidence to favor one measure over others for use in making probability statements about features of our observable universe. (See the measure problem.) And that's only scratching the surface.

We are led almost inexorably to many of the central ideas of the multiverse even without invoking string theory, as my list earlier attests, and I can assure you that many researchers were dragged along unwillingly by logic and strong indirect evidence from cosmology, which has become an extremely precise subject in that past decade. (Peter diminishes this fact because it detracts from his belief that string theory is to blame for everything he doesn't like about contemporary high-energy theoretical physics.) Weinberg made his first use of multiverse arguments way back in the eighties when he correctly ballparked the as-yet-unobserved cosmological constant through anthropic reasoning, ten years before it was first measured and without using any string theory. Linde and Vilenkin are not and never were string theorists.

There's an enormous diversity of opinions on even the notion of the multiverse itself, even before connecting it to the landscape of string theory, and top people fall in many different places on my list earlier. I was hoping Peter himself would take a precise stand.

We live in the Internet age now, so you don't have to take my or Peter's word for any of it. Go online and find some videos of research seminars by active people studying this stuff, and it'll give you a real picture of what's on their minds these days.

85. **Peter Woit**
February 12, 2011

Matt,

From the e-mail that "Emile" left, he's a professional high energy physicist. I gather that his opinion is that there may very well be a multiverse, but at the moment it's not a scientific issue, and my impression is that this is probably a majority opinion among working physicists.

Those who work on trying to figure out how to get observational evidence for a multiverse should keep in mind that most trained people in the subject are skeptical about what they are doing. This is not because they are ignorant, but because they've seen nothing much substantive come out of these efforts. There's only so much mileage you can get out of the anthropic argument for the CC. People who want to work on how to turn multiverse speculations into solid science are welcome to, even if the odds of success are long, but until they've made some progress they might want to stop engaging in high-powered hype aimed at the public.

86. **Matt**
February 12, 2011

Peter–

My point is simple, and I think we're talking past each other.

The basic reasons for the multiverse do not come from string theory or the landscape, but from cosmology. Unlike many ideas in contemporary high-energy physics that people are looking for—supersymmetry, small extra dimensions, KK modes, brane-worlds, microscopic black holes, etc.—the basic underpinnings of the idea of a multiverse were not generated in any way by string theory, but from many directions and much indirect evidence (some of which is too technical to make sense to the public, unless they know how differential geometry or Einstein's equation work) in cosmology and inflation.

The cosmic inflation models that we use and that agree excellently with the data generally have as a side-effect the generation of a multiverse of some kind. So writing, even in a public forum, that we're likely living in a giant multiverse is perfectly within the realms of science. That's what the data are telling us.

Where I agree with you is that we don't know very much about what else is in that giant multiverse. Here's where string theory finally comes in: It suggests something about the multiverse, namely, that the multiverse consists of regions that look very, very different from our own region, as they have frozen out into different low-energy solutions with different low-energy particle menus and effective laws of physics.

Some people go even a step further, and claim that the multiverse is an infinitely big space and that every conceivable (and inconceivable) possibility is realized there, with copies of you and me doing and living every possible way imaginable.

Now that's entirely speculative, and we have no evidence to support. If you believe that those speculations are not scientific, then I'm in agreement with you, at least until people find a way to test them.

I worry that you are conflating the entire notion of the multiverse, which has strong backing from many directions in cosmology, with string theory and the landscape, when they're two conceptually different (but connected) ideas. Writing publicly about the cosmic multiverse and how it follows very convincingly from what we know about cosmology (and the search for signatures like bubble collisions, etc.) is perfectly scientific. Inserting string theory and making other metaphysical claims about all possibilities being realized in the multiverse is not.

Is that fair?

87. **Marty**
February 12, 2011

Hi Matt,

(Am not sure if you're the Matt I think you are, but if you recognize my name you probably are. In that case, Hi!)

I'm sympathetic to your interest in hearing Peter's stand on some of your questions to him. I too would be interested… However, in partial defense of his response, I think he probably did state his overall position; it's just that his position kind of preempts your other questions, if I understand his point of view correctly. I *think* where he's coming from is this: It's perfectly legitimate to start with a set of assumptions and use them to make theoretical arguments for a multiverse, bubble collisions, and so on;

but, without feedback from Nature (i.e., unambiguous observations of predicted consequences of those theories), there is no compelling reason to accept that the original assumptions and the theory they imply are correct. Theoretical reasons alone aren't enough… Peter has made it clear over time that his great respect for the Standard Model comes from the huge number of predictions it makes that have been verified, and the lack of predictions it makes that have been observably shown to be false. I think he also finds certain elements of the SM to be elegant as well, but that is secondary. (Peter, if I have misrepresented you here, my apologies.)

If you are "that Matt" 🙂 you know I have done some work with bubble collisions, the unfortunate conclusion being that they probably can't be unambiguously observed except in very "atypical" scenarios. That was enough to discourage me from working further on the problem in any significant way. To me, it just doesn't feel enough like "good science" to rely on theoretical "necessity" and consistency arguments; in the end, there needs to be solid experimental confirmation (as I'm pretty sure you agree), something I'm not optimistic will happen here.

You mention,

> We are led almost inexorably to many of the central ideas of the multiverse even without invoking string theory, as my list earlier attests, and I can assure you that many researchers were dragged along unwillingly by logic and strong indirect evidence from cosmology […]

This seems to be the standard wisdom, but I'm going to give a different take on it. First to state my own position: I personally can't imagine how any process that generated our visible universe wouldn't also generate other "universes," and the number of such occurrences would almost certainly be infinite. Moreover, I find the evidence for an inflation-like era in the very early universe to be very compelling and that the idea is almost certainly correct. But… I personally don't find compelling the argument that the second viewpoint implies the first. It all comes down to a question of theoretical uniqueness: Does an inflation-like era in the early universe *imply* an early de Sitter phase caused by one or more scalar fields tarrying for awhile (e.g. in a local minimum of the potential), or are there alternative pictures that can also yield something that looks like inflation and is fully consistent with all observations? It isn't enough to dismiss this question by noting that no other promising candidates have come forth yet, since both uniqueness of the inflation picture or missing insights (or imagination) can equally well explain the lack of alternatives.

After all, it's not as though the traditional picture of inflation is elegant in its crucial details. You know well that it is extremely hard to come up with an inflaton potential that is at all "natural" (so hard that nobody has figured one out yet, as far as I know) — the ones that are natural don't work, and the ones that work are contrived. (Potentials that rely on the correctness of the idea of a string theory landscape for their existence fall into the "contrived" category, in my opinion.) There's also the issue of the inflaton itself; this particle must be postulated as the driver of inflation, but there is no other evidence for it except that it seems necessary to explain inflation. In fact, given that the search for the Higgs has turned up empty-handed thus far, we don't (yet, anyway) have experimental evidence that *any* fundamental scalar particles exist in Nature. Hence, the reheating phase is also speculative; if we can't observe the inflaton, then we must rely on our speculation that the phase even exists, and further speculate on what a QFT would look like for the inflaton. It seems apparent that none of these problems can be addressed by observation, so it's hard for me to see how there is any inevitability to our current models of inflation or their consequences in terms of an inflation-inspired multiverse.

My own viewpoint is that reliance on an unnatural scalar potential (or set of scalar potentials) to drive inflation in just the right way to give us the CMB we observe, as well as the postulation of scalar particle(s) whose sole purpose and consequence is to drive inflation, are significant conceptual problems. In fact, for the past couple of years or so I've been working hard on an alternative scenario that seems much more "natural" to me; in it, an inflation-like era is an inevitable part of a process of spacetime emergence, ending *because* spacetime becomes sufficiently homogeneous and isotropic and not because of certain characteristics of weird potentials. This blog isn't the appropriate place to discuss that or other alternatives; I only bring it up to make two points. First, it suggests that the current inflation picture isn't unique in the sense I discussed above. Second, questions like those related to the measure problem or "Boltzmann brains" aren't even well-posed questions in the alternative scenario, suggesting that at least some of our current thorny conceptual problems are artifacts of our current (still partly speculative and non-unique) early cosmological picture rather than inevitable difficulties that will arise in any plausible inflation-like scenario.

(Just as I was about to post this, I noticed that Matt responded to Peter. Sorry if what I just wrote doesn't take into account anything Matt just said.)

88. **Peter Woit**
February 13, 2011

Matt,

I mostly agree with your last comment. Hopefully we'll learn more about inflation in coming years, but I'm skeptical we'll learn much relevant to the question of whether inflatiion actually does produce multiple universes. Maybe someday we will, which would be a good time to write popular books on the subject, not now.

Many thanks to Marty. He has thought a lot more about this than me, and taken the time to write out a detailed analysis of reasons to be skeptical about some parts of inflationary theory. His seems to me a better-informed version of my own skepticism about some aspects of the subject.

89. **Matt**
February 13, 2011

Peter–

Who says arguing on the internet can't ever produce agreement? (Or quasi-agreement; I'll take it.)

Just a last point. Evidence for inflation and the more general notion of a multiverse is in a different category from string theory/the landscape. There is no actual physical evidence for the latter, nor does it make any hard predictions, but several pieces of evidence and verified predictions for the former. So the former is not in the same category as the latter, even if it's not on quite the same rigorous footing as the Standard Model. The multiverse is not the landscape, and that's an important thing to make clear. I worry when I hear people like Horgan, who don't seem to make that distinction.

We have evidence that our observable universe is just a small part of a far vaster space, which we call the multiverse, even if we don't know what the rest of it looks like. (And even if we don't yet know exactly how inflation works in detail.)

Would it be fair for a cosmologist to write a popular account of the logic and evidence that has led serious people to that conclusion, as long as they don't veer off into wild speculation about the contents of the rest of that multiverse, and don't make strong claims about the reality of string theory? Is that scientific?

90. **Emile**
February 13, 2011

Hi Matt,

Peter essentially answered for me. My point is also echoed in Marty's post above: "To me, it just doesn't feel enough like "good science" to rely on theoretical "necessity" and consistency arguments; in the end, there needs to be solid experimental confirmation."

91. **Peter Woit**
February 13, 2011

Matt,

If a cosmologist would write a popular book explaining exactly what the evidence relevant to inflation is, as well as what the models people are looking at are (including ones with some sort of multiverse) and how they match the evidence, that would be great, I'd definitely buy a copy. All the ones I've seen though tend to go on at great length about speculative ideas that are supposed to be "exciting", ignoring or minimising their testability problems, and making really dubious arguments in favor of these ideas.

In more technical expository articles aimed at physicists, there's a lot less of this, but still they're often written in a way that makes one feel that one is only being told one half of the story.

92. **Matt**
February 13, 2011

Peter–

Wait, so you're upset that cosmologists who write for the public are taking their more rigorous work as springboards and then also going off in speculative directions they find exciting and inspiring? Why do you think they went into science in the first place? What do you think inspires a lot of the kids to want to do physics and cosmology?

As long as they make very clear what's speculation and what's not, I think it's perfectly fair for them to start with what we're pretty sure about and then talk about exciting future possibilities. There's criticism, and then there's being a grinch. It's a fine line sometimes, but worth keeping in mind.

This is actually a larger problem I have with some of your own public outreach. Science needs criticism, maybe more so than it's been getting. I would certainly concede that, and raise you a nickel. Your points are quite valid.

But too much negativity can be extremely counterproductive, and turns off a lot of young people, not to mention potential allies. It really does. Rather than pointing students in better directions, or brining in people who are sympathetic to your point of view (as I am), it can have the effect of just driving them away from wanting to get involved altogether. (I presume that's not your intent.) I speak from personal experience, by the way. I've seen fellow students react to it while I was coming up through my physics schooling.

That's one reason why I got so upset when I saw this posting on your blog. You seemed to be tossing in a lot of cosmology—some of it speculative—together with your diatribe against string theory. Is there any way you can be a little less negative and vitriolic, a little less broad-brush, and maybe more positive and constructive? In words that are going around a lot these days in other areas of discourse, could you disagree without being so disagreeable?

I mean, you're entitled to your approach and your attitudes. These are just suggestions. Take them under consideration or not.

93. **Peter Woit**
February 13, 2011

Matt,

People can write about speculative ideas they're excited about, I just think that they need to do so in an intellectually honest way. The popular press multiverse stuff I see, string-related or not, contains massive amounts of mis-leading, over-hyped material, aimed at getting people "excited" about some ideas which have very little evidence supporting them. As for the argument that this is the way to get kid interested in physics, I don't accept it. It's a good way to confuse people (of any age) about the difference between science and science fiction, and a good way to drive away people with some ability to think critically, who quickly suspect that someone is selling them a bill of goods.

It's true that I've ended up being critical of cosmologists pushing multiverse ideas independently of string theory. One reason for this is a general distaste for hype in science, although there's plenty of that elsewhere and maybe it should just be ignored. But in this case, cosmologists hyping the multiverse have just about always joined in with string theory pseudo-science, co-promoting it and using it to justify what they are doing. I'm seriously concerned that this is doing a lot of damage to this subject, damage that may be permanent. We're well on our way to having the dominant paradigm of the subject be "string theory is a fantastically wonderful unified theory justified by the deepest mathematics, and it shows we live in a multiverse such that we can never calculate anything beyond what we already understand, and that's just the way the world works."
There are a lot of people pushing this, and a lot of cosmologists signing on for the ride. I think it's worth my time to keep pointing out that there's no evidence for this, that it's an ideology driven by refusal to admit that a certain speculative idea has failed.

94. **Matt**
February 13, 2011

Peter–

I made clear that I consider a lot of your points valid. My point was your delivery, which does you no favors and drives away a lot of people who would probably be sympathetic to your point of view. A lot of people dismiss you out of turn because of your sometimes-overwhelming negativity and the tone of your comments–some of which I've seen you make in person–and that ends up hurting your own cause of making physics better.

Negativity drives people to shore up their defenses and to be less willing to take up alternative viewpoints.

Sometimes when it seems like trends are leading to doomsday, then there's an inclination to believe that all's fair and there's no reason to hold back. What was it Goldwater said, "extremism in the defense of liberty is no vice"? Well, I would have to disagree. I think it can be a vice.

95. **Matt**
February 13, 2011

Woops, looking at those last few sentences again—please don't think I meant to call you an extremist! I was just taking an extreme example. My sincere apologies for seeming to construe otherwise.

96. **Peter Woit**
February 13, 2011

Matt,

I do appreciate the advice and will keep it in mind. Sometimes the thought occurs to me "Oh, no, I'm starting to sound like Lubos!".

The string theory multiverse issue though I find increasingly both depressing and highly frustrating. Before about 5 years or so ago I thought it was possible to have a worthwhile discussion with string theory optimists, since the issues I disagreed with them about could be clarified by discussing the technical problems of the subject. In recent years that's increasingly no longer the case, as the string theory multiverse ideology has been constructed to make the subject immune to the usual sort of scientific challenges. My going on about this has likely gone past the point of being useful.

97. **Matt**
February 13, 2011

Peter–

I adore how you put that.

Sure, I may disagree with how depressed and angry you sometimes sound (even though you're really no cynic), but you aren't even in the same bubble universe (sorry, couldn't help myself) as Lubos. He's beyond Serge Lang territory these days. As long as you retain your evident capacity for self-criticism and introspection, you don't need to worry. I just wish you'd lighten up once in a while!

But, honestly, what can I expect from a leftist feminazi communist university AGW idiot?

🙂

98. **Matt**
February 13, 2011

But, no, seriously, what I find depressing is walking around my department and seeing everybody on his blog. I think the last time I could bring myself to look at it, he was deriding the decision to hold a theoretical physics conference in Mexico, because, as he put it, Mexicans statistically have too low an average IQ to do physics.

Sigh.

99. **Cosmonut**
February 14, 2011

Cosmonut— No, 60 e-foldings is necessary for our observable region to have the correct properties, such as flatness, but the consequence is that it's then a tiny patch of a far larger space. Think of what you have to do to a balloon to make a tiny surface patch look look very flat–you need to blow up the balloon to a size far more tremendous than that patch.
————————————————-

That's what I used to think, but its not true.

60 (or maybe70) e-foldings are the minimum required to give a value of Omega of the *same order of magnitude* as 1.

So, for instance, if we had observed an Omega of 2 – that would indicate a (hyper)spherical universe of about the same size as the observable universe.
But even to explain *this*, we would need to either assume super fine-tuned initial conditions, or an inflation period with at least 60 to 70 e-foldings.

The idea is, that just after inflation ended, the observable horizon would indeed be a tiny patch of the whole universe. But then the horizon would expand until the size of horizon and universe became comparable.
(See Sean Carroll's Spacetime and Geometry for the technical aspects of this.)

Now the point is, it is easy to get *more* than 60 e-foldings in the models, which would lead to the "small patch" effect you mention, even today.

But since we have no idea which model is right, nobody knows if we actually had just only a few more than 60, or billions of e-folds.
The number mentioned in articles is pretty arbitrary and varies widely.

100. **Cosmonut**
February 14, 2011

@Marty:
Does an inflation-like era in the early universe imply an early de Sitter phase caused by one or more scalar fields tarrying for awhile (e.g. in a local minimum of the potential), or are there alternative pictures that can also yield something that looks like inflation and is fully consistent with all observations?
—————————————

There was an interesting post on this a few days back at Cosmic Variance.

http://blogs.discovermagazine.com/cosmicvariance/2011/02/07/do-you-think-inflation-probably-happened/

Sean makes the same point in the comments that while it is observationally clear that some kind of rapid expansion happened early on, we are not sure whether this corresponds to any inflation model currently around.

101. **Cosmonut**
February 14, 2011

@Matt:
Hope I didn't come across as condescending in my last reply. I think you may be a cosmologist yourself from the comments.

Its just that I got really interested in the question of how large our universe is compared to what we can observe.
I had initially thought that if inflation gives us 60 e-foldings, then maybe our universe is at least e^60 times larger than what we can see (a mind boggling thought !).

But then, from further readings, I came to the conclusion I just mentioned.

If you know of any lower bound to the size of our universe from observational evidence, I'd be very interested.

102. **Bugsy**
February 14, 2011

Just want to add my 25 cents… as a mathematician largely ignorant about real physics!…
Matt says (Feb 12):
"Some people go even a step further, and claim that the multiverse is an infinitely big space and that every conceivable (and inconceivable) possibility is realized there,

with copies of you and me doing and living every possible way imaginable.

Now that's entirely speculative, and we have no evidence to support…"

Of the multiverse ideas, this one seems to be the most completely problematic.
Yet to popular writers (and the general public) this is understandably the most attractive, as it can lead to all sorts of wonderful plots for sci-fi stories…There is NOTHING wrong with that, if it stays as sci-fi (it's not just Sheldon, Leonard et al who draw inspiration from wild ideas-many of us got inspiration to study math or physics with well-written, creative sci-fi). I do object to real (ex?)-scientists blurring the distinction, es[ecially if they are using that to sell books, as that does a disservice to the endlessly honest and infinitely deep beauty of reality…

On to the "parallel copies of me" theory, obviously attractive to the ego in each of us…

Maybe this came about partly because of a confusion about the very successful and basic models in probability theory or dynamical systems. To be overly pedantic in the service of having something precise to address, thus an infinite sequence of tosses of a fair coin can be thought of as either a single sequence with certain statistical properties (a "sample path") or as the space of all possible such sequences endowed with a probability measure. There is a standard way to pass from one to the other, due to Kolmogorov combined with the Ergodic Theorem. Ditto for Brownian motion. Additional clarity is added by realizing coin-tossing as the 2x(mod 1) map on the unit interval, with Lebesgue measure, coding points with their binary expansions. Then the infinite random choice of coin flips (made by "Tyche, the goddess of chance" in Billingsley's beautiful explanation), is equivalent to a single random choice (by Tyche!) of a point in the interval, and the dynamics of the map moves us on to the next flip. But though this model is extremely useful, and though the space of all outcomes exists mathematically, no one thinks of all outcomes "actually" existing at the same time except mathematically.

On to the parallel multiverse. Now if in this universe I flip a coin infinitely many times, then presumably in the parallel universes all other sequences are realized, with a probability measure that reflects the Lebesgue measure. But then the
coin-toss model has been realized as a (very very small) factor (i.e. measure-preserving homomorphic image) of the multiverse!

In other words, the advocates of this particular multiverse fantasy have indeed made the mistake of conflating a successful mathematical idea with the "real world". And this makes me question seriously their understanding of either. Here I have been talking only about extremely simple math ideas (which I do however know something about) and if there is that much confusion there, I hate to think how sloppy the thinking must be when the much more sophisticated math needed for partical physics or cosmology is involved….!!!

In short I second Peter's concerns about the necessity and primacy of intellectual honesty. The real world is beautiful and amazing enough
without conflating and inflating it with lazy speculations; it is still wonderful to be able to say, "I don't know!" And with that basis, we can honestly say "what if…!" and again begin to dream…

103. **Allan Rosenberg**
February 17, 2011

Peter,

I think the way you express yourself does do you favors. Science needs informed criticism to progress, and that criticism needs to be most vehement where there is the most hype.

I'm not qualified to evaluate technical issues in string theory, but I can imagine a biologist who submits a paper postulating that lions have sharp canines because there is a multiverse that includes universes with all possible biota, and we happen not to live in a dull-toothed lion universe. I don't think that would pass peer review. Maybe we biologists are just too closed minded.

Don't worry, you don't sound at all like Motl. He has a Czech accent. And you're FAR funnier than he is.

104. **Jon**
February 17, 2011

Well, ether (wrt speed of light) was accepted scientific fact for a long, long time. Likewise various forms of Lamarckism. Likewise Freudian nonsense. All well within the modern era; all had a long run. I guess the new thing with multiverses is the large body of scientists who know it's shit, but don't say so publicly.

105. **Eli Rabett**
February 19, 2011

Well, Eli could make a fair argument that the multiverse kills moral responsibility. If all choices are made, why bother thinking about consequences.

Lest you think such angel counting has no consequences, think about the revolutionary change brought in by the reformation with respect to moral responsibility.

The 4% Universe

January 31, 2011
Categories: Book Reviews

I've written a review of Richard Panek's quite good new book The 4% Universe, which has appeared at the Wall Street Journal. The main topic of the book is the supernova searches that led to what seems to be a non-zero value of the cosmological constant. It also discusses the astronomical evidence for dark matter, as well as on-going searches for a dark matter particle.

One of the most interesting themes of the book is that of the encounter between the two different cultures of particle physics and astronomy. Astronomers have begun to worry not only about a new culture of large collaborations, but about the danger of an over-emphasis on certain specific measurements of fundamental significance. For more about this, see the article by Simon White from a few years ago Fundamentalist Physics: why Dark Energy is bad for Astronomy. Now that cosmologists have their own highly successful Standard Model, they're starting to take a look at what happened after the arrival of the Standard Model in particle physics, and worry that they too may someday become victims of their own success.

Comments

1. **Thomas Larsson**
   January 31, 2011

   Medieval astronomers knew that the universe is a mechanical clockwork with at least 13 epicycles.

   The point is that Nature's answers depend on how the question is posed. If you ask her about epicycles, she will answer with epicycles, even if that has little to do with the correct dynamics. And if you ask her about dark matter and dark energy, she will answer in terms of dark matter and energy. Perhaps this is the right framework. But perhaps it is not.

2. **Noname**
   January 31, 2011

   "Now that cosmologists have their own highly successful Standard Model, they're starting to take a look at what happened after the arrival of the Standard Model in particle physics, and worry that they too may someday become victims of their own success."

   Really? I'd say this is rather your misinterpretation.

3. **Mitch Miller**
   January 31, 2011

   The White article is pretty interesting…. though I imagine some high energy experimentalists will be offended as he basically said that creative and talented people would not go into it.

   It pretty much comes down to the LHC it seems. If only a single Higgs field is found astrophysics could potentially be the only possible experimental input for high energy theorists for the foreseeable future and that will have a large impact on astrophysics whether the current practioners like it or not.

4. **Peter Woit**
   January 31, 2011

   noname,

   You're right, I could be wrong. It's quite possible that astronomers the world over are wetting their pants in anticipation of changing the way they work, on the experimental side joining collaborations of 3000 others to work on a $10 billion dollar piece of equipment that takes 20 years to build, and possibly measuring only one new number, while the more theoretically minded work on mind-numbingly complex and unsuccessful models, in between writing science fiction and trying to pass it off as science.

   Then again, maybe not.

5. **Marcus**
   January 31, 2011

   Peter congratulations on your WSJ book review–and on the broadening of scope it represents. It would be great if you applied your informed intelligence and judgment to a wider range of topics, and would enrich what you have to say on the home topic. I'm just stating the obvious, not news to you!

   This is a good paragraph–saying in concentrated irony what was the overall takeaway message of Simon White's excellent article:

   "…It's quite possible that astronomers the world over are wetting their pants in anticipation of changing the way they work, on the experimental side joining collaborations of 3000 others to work on a $10 billion dollar piece of equipment that takes 20 years to build, and possibly measuring only one new number, while the more theoretically minded work on mind-numbingly complex and unsuccessful models, in between writing science fiction and trying to pass it off as science."

   So congratulations on several things (around the time of NEW #1000) and keep on truckin'

   -Marcus

   PS. I think Nature is more generous and holds more astrophysics surprises than collider, so it mightn't come down to the grinding semi-stall of your ironical vision. But that's not the point.

6. **Peter Woit**
   February 1, 2011

   Thanks Marcus,

   Unfortunately I'm not so optimistic about astronomical evidence helping to solve the fundamental problems of particle physics. The big open issue to me seems to be understanding the origin of electroweak symmetry breaking and I don't see astrophysics helping there. Maybe this will change, but to be clear, right now the difficult path

HEP experimentalists are following seems to me the only viable one.

7. **Noname**
   February 1, 2011

   I can see the point of White but I don't understand your rant about huge collaborations working on very complex experiments. When you consider the LHC, your lack of vision and appreciation is simply astonishing. I wonder why you chose Particle Physics at all. You must have been very confused. If the time comes when Astrophysics is over (not any time soon anyway) too bad for astrophysicists and so much the better for science.

8. **Peter Woit**
   February 1, 2011

   Noname,

   Since you don't understand my "rant", I'll spell it out for you:

   The fantastic success of the Standard Model has made life extremely difficult for particle physics. Improving on the SM is very hard, and the LHC is the only plausible way forward. It's a fantastic project and what people are doing there is great. But I don't think other sciences are looking at what is going on and thinking "gee, I wish my science was in that situation with those constraints and our job was more like theirs".

   Another thing I can assure you about astronomers and others outside particle physics is that they read things like what you write here and think: "My, what a bunch of arrogant nitwits there are in particle physics, thank God my science so far has relatively few people like that."

9. **Noname**
   February 1, 2011

   Thanks for your clarifications. I don't think anybody considers the situation in your terms, though. If there is something people from other sciences might envy of particle physics is the content, not the means.

   Concerning your last remarks, I don't understand why anybody would interpret what I wrote like you did (unless they are affected by some kind of paranoia). I'd write exactly the same as above with astrophysics replaced by any other branch of science, particle physics included. You on the other hand seem to consider that the real use of science is to offer jobs to the scientists.

10. **steve newman**
    February 2, 2011

    i like what Thomas Larsson wrote-

    "Medieval astronomers knew that the universe is a mechanical clockwork with at least 13 epicycles.

    The point is that Nature's answers depend on how the question is posed. If you ask her about epicycles, she will answer with epicycles, even if that has little to do with the correct dynamics. And if you ask her about dark matter and dark energy, she will answer in terms of dark matter and energy. Perhaps this is the right framework. But perhaps it is not. "

    I think his remark is relevant to the the 2 big 'mysteries'- dark matter, dark energy.
    The analogy is Big Bang model = mechanical clockwork with epicycles.

    Dark matter is not mysterious because it is dark, (lots of matter doesnt shine like stars) — but because it is presumed to be non-baryonic. If it were baryonic, it would not be a mystery.
    The gravitational mass of spinning galaxies is deemed non-baryonic only because being baryonic would contradict the limit on baryonic mass imposed by the big bang theory of nucleogenesis.

    So for no other reason but to save the big bang 'standard model' , there needs to be 6 times as much non-baryon mass as ordinary matter..

    Likewise, to save the big bang standard model from its many 'problems' (horizon, flatness,…) requires accepting the Inflation 'Scenario' (scenario,since its not quite a theory).
    This in turn requires the density of the universe to be the 'critical' density (omega=1), and so 73% of the universe mass must be something beyond the 4% baryon and 24% dark stuff.

    so– as Larsson says
    "And if you ask her (nature) about dark matter and dark energy, she will answer in terms of dark matter and energy. Perhaps this is the right framework. But perhaps it is not."

    — — — — –
    Similar remarks about 'cultural' and 'foundational' obstacles to progress in physics and cosmology
    were made by P.M. commenting on your book review of Yau's "inner space".
    PM says:
    September 20, 2010 at 9:23 am
    ….

    best wishes and thanks for your reports and reviews.

11. **neo**
    February 2, 2011

    So what is it? "Wonderful" or "quite good"?

12. **cormac**
    February 4, 2011

    Nice taut review Peter, I must get the book. The only thing I might have done differently is to emphasise why there has been this astonishing convergence of the study of the world of the v large with that of the v small in recent years…but that's cos I love this theme!

IAS 80th Anniversary Talks

February 3, 2011
Categories: Uncategorized

This may be old news, but I just recently noticed that talks given at the IAS in Princeton last fall to celebrate its 80th anniversary are now available on-line [here](). They include talks by Voevodsky on the [foundations of mathematics](), Zaldarriaga on [cosmology](), Wilczek on [supersymmetry and quantum computing](), and Arkani-Hamed on [Fundamental Physics in the 21st Century]().

According to Arkani-Hamed, the 21st century will be all AdS/CFT, all the time, using it to justify:

> the slogan is that string theory/quantum gravity is particle physics…
>
> There is a less interesting but amusing sociological fact associated with this, that since this realization there aren't really different camps in theoretical physics any more. There aren't string theorists and particle theorists, there's one big structure "Good Ideas in Theoretical Physics", OK. That structure has many different facets and you can work on different parts of it, but it's all connected. You can really see it in the way the field developed since the late 90s, we're much, much more one big happy family than was the case in the 1980s. I should say of course there are still people that do bad theoretical physics, but they're not at the Institute. So all good ideas in theoretical physics are combined in one very big structure that no longer is there such a big difference between strings, QFT…

This puts into practice Nati Seiberg's 2005 [prediction]():

> "Most string theorists are very arrogant," says Seiberg with a smile. "If there is something , we will call it string theory."

Both Wilczek and Arkani-Hamed advertise supersymmetry, with Arkani-Hamed making the peculiar claim that physicists need to throw space-time out the window, but for some reason, before doing so it is important that they add supersymmetry to it. Wilczek states definitively that if superpartners don't show up at the LHC, as far as he is concerned the idea will be gone.

The minimal supersymmetric standard model is an important pillar of the "Good Ideas in Theoretical Physics" that those at the Institute cling to, despite efforts to use them to unify physics failing miserably over the last 25 years. If the LHC doesn't see supersymmetry and Wilczek and others give up on the idea, it will be interesting to see if the IAS faculty revise their point of view and start to develop more of an interest in what they now claim is "bad theoretical physics". I suppose though that when they do, they'll call whatever they change over to "string theory".

Update: By the way, for the latest on what initial results from the LHC are saying about extra dimensions and supersymmetry, see [this talk]() given today at CERN by Alessandro Strumia.

Comments

   February 3, 2011

   Crystal ball gazing is a popular pastime, no matter that it has regularly failed. The title of Stephen Hawking's inaugural lecture as Lucasian Professor (1979) was "Is the end in sight for theoretical physics?" (The reason being, of course, the imminent arrival of the Theory of Everything.) So Arkani-Hamed 2010 is no wider off the mark than Hawking 1979. Physics – including "bad theoretical physics" and the Theory of Everything – will move forward on its own merry way.

2. **Geoff**
   February 3, 2011

   I've always wondered whether or not pure mathematicians dismissively refer to string theory as mere applied algebraic geometry.

3. **Peter Woit**
   February 3, 2011

   Geoff,

   No. Mathematicians are well aware that, whatever string theory might be, it's not a subfield of algebraic geometry.

   However, some mathematicians undoubtedly enjoy this xkcd comic:

   Shantanu,

   Unfortunately at the IAS talk he never got to the much more interesting material of the Perimeter colloquium.

7. **neo**
   February 4, 2011

As a non-physicist, I do not understand why adS/CFT generates so much excitement given that the CC is known to be positive, not negative. Is there a simple explanation?

8. **Peter Woit**
February 4, 2011

neo,

Besides that AdS/CFT tells you about gravity with the wrong sign of the CC, you might also want to worry that it tells you about gravity in the wrong dimension…

AdS/CFT is certainly interesting, but I do find the claim that all good theoretical physics is related to it just bizarre.

9. **Yatima**
February 5, 2011

Frank Wilczek's talk (http://video.ias.edu/stream&ref=409) is as usual pretty good. He also talks about aliens straight from a Greg Egan novel!

Is he last man standing who likes Spin(10) GUT?

I wonder why the speakers need to start off at super-low level. What kind of audience do these talks have? Hell, give me an equation in the first minute, amaze me!

10. **John Rennie**
February 5, 2011

Assuming that Arkani-Hamed's talk is the same as the last one I saw, his point (stripped of the propaganda) is that AdS/CFT is a useful mathematical model for describing various physical situations. In fact he explicitly compared it to the simple harmonic oscillator, which (also?) doesn't exist in the real world.

Since he is modelling physics that is experimentally accessible, or at at least much more accessible than the Planck scale, presumably we'll know soon whether AdS/CFT is a useful mathematical model or not.

11. **Bob**
February 5, 2011

In some sense, string theory is a unique way towards the theory of everything if it really exists. There are numerous reasons for that. Here i list some of them.
1 String theorists are smart
2 String theorists are hard-working
3 String theorists are not stubborn, namely always ready to absorb any important insight or development from other desciplines into their toolbox.

On the other hand, just like GR, when you learn AdS/CFT more, you will be intrigued by its beauty and power. With SUSY, AdS/CFT is a very powerful tool at least.

12. **AdSCFTlover**
February 5, 2011

Peter wrote: Besides that AdS/CFT tells you about gravity with the wrong sign of the CC, you might also want to worry that it tells you about gravity in the wrong dimension…

I don't understand why you wrote this.
If you are interested in 4-dimensional AdS space then you need a 3-dimensional CFT. There are plenty of those known, and now we also know that some of them are exactly dual to 4-dimensional AdS times a 7-dimensional Einstein space, like a 7-sphere. They are Chern-Simons theories, so you should like them. There has been lots of work on this since 2008. We also know that the critical 3-dimensional O(N) model is dual to a higher spin theory in AdS_4.

13. **Peter Woit**
February 5, 2011

My main problem with AdS/CFT is that it's an extremely technical subject, with by now about 10,000 papers or so dealing with it. This makes it hard for anyone to understand exactly what the state of the subject is, and this is made much harder by its proponents, who engage in an absurd level of hype. If you believe everything you read or hear, you learn that:

1. It's the modern version of the harmonic oscillator, the central approximation method for solving physical problems that we teach all undergraduates.

2. It contains all good theoretical physics, theoretical physics not related to it is bad theoretical physics. Theorists at top institutions like the IAS are all in agreement about this.

3. It explains heavy-ion physics.

4. It explains high-Tc superconductivity.

5. According to people like Bob, those who work on it are hard-working geniuses, always open to new ideas from all sources. They have found the unique possible route to a theory of everything. It's not their fault that this theory of everything turns out to predict nothing.

6. According to Arkani-Hamed and AdSCFTlover, this solves the problem of a realistic 4d quantum theory of gravity, that's done and over now.

John Rennie has been led to believe that soon we'll have definitive experimental tests of this wonderful subject. But it seems to me that we're now nearly 15 years into this, and I've yet to see anything like a convincing way to confront these ideas with experiment. The most highly developed thing I've seen are the attempts to use AdS/CFT to do approximate calculations in QCD, but here it still looks to me like you have only a very crude approximation with little control of its accuracy.

14. **Bob**
February 5, 2011

To be honest, as to AdS/CFT, i do not think it is a HIGHLY technical object if one is assumed to be familiar with both GR and QFT, two pillars of fundamental physics in 20th century. In particular, the essential underlying idea is remarkably as simple as possible, but not simpler. So i do believe that an idiot can also understand it.

Concerning its contact with experiments, string theorists are trying their best to making it possible. But there is no doubt that this is a tough job. We should be patient with its progress along this direction.

In addition, i am not saying that string players are geniuses although definitely a few of them are.

PS: After i spent some time on studying AdS/CFT, i found there are many misunderstandings about string theory and AdS/CFT in Roger Penrose's Road to Reality book. With this sort of experience, i realize that it is very dangerous to criticize something you are not very familar with.

15. **Peter Woit**
February 5, 2011

Bob,

Sorry, but you're really not changing my opinion that AdS/CFT has a problem with its proponents being fountains of hype.

16. **Bob**
February 5, 2011

Maybe there is some sort of hype in popular scientific articles related to string theory and ads/cft. But similar hype may also happen to other subjects.

But when you read any serious research paper by string theorists,
you will find that none claims that ads/cft has solved QCD problem. On the contrary, they are always saying that there is a long way to go for real QCD….

In addition, I prefer Nima's slogan, namely physics makes progress by radical conservativists rather than conservative radicalists. String theorists belongs to the former.

17. **anon**
February 5, 2011

An example of the bad physics pursued by stupid people is described in hep-ph/0604254 where progress towards over-constraining the CKM parameters via a combination of experimental measurements and lattice QCD calculations is reviewed (no doubt out of date by now). Of course, only ignorant losers could possibly be interested in such an approach to determining new physics beyond the SM.

As usual, if ads/cft geniuses and other geniuses have anything interesting to say about physics, let them go publish it in Physical Review Letters.

Cheers from `amused', after a few too many beers in Taipei. Happy Chinese New Year everyone.

18. **Alex Mikunov**
February 6, 2011

V. Voevodsky's talk is outrageously shallow. He definitely didn't do his homework when analyzing Godel's incompleteness theorems and Gentzen's consistency proof. The fact that the formalized version of 2nd incompleteness theorem is provable in arithmetic itself has far reaching consequences. It led (together with other developments) to an important class of logics called Provability logics (http://en.wikipedia.org/wiki/Provability_logic)
Voevodsky's inability to answer E. Witten's question [about impact on real numbers and the notion of continuum] makes one wonder if he's even aware of the work on independence in set theory. For recent advances see Woodin's review:
http://www.ams.org/notices/200106/fea-woodin.pdf
http://www.ams.org/notices/200107/fea-woodin.pdf

19. **Tim van Beek**
February 6, 2011

> …all good ideas in theoretical physics are combined in one very big structure that no longer is there such a big difference between strings, QFT…

Let's assume that Mr. Arkani-Hamed is aware of the fact that not all theoretical physics is theoretical particle physics, so let's replace "theoretical physics" with "theoretical partical physics".

But then this still means that if you work in theoretical particle physics, you either work on string theory or you're a bad physicist. The way that Mr. Arkani-Hamed made this statement seems to indicate that it is not meant to be a joke.

Well, someone has to tell the non-stringy particle physicists that they'd better switch to string theory, if they are intellecutally capable to do so, that is. Maybe some of them can be redeemed.

20. **joestudent**
February 7, 2011

I have a question about the slides of Alessandro Strumia's talk mentionned in the post: the physics is over my head, but the tone of the last few slides seems to be that SUSY is now very unlikely to be correct.

So I was wondering how much more data is needed to rule it out altogether (e.g. the little green area not yet excluded on slide 16), and whether this could happen before the 2013 shutdown. Thank you…

21. **Peter Woit**
February 7, 2011

joestudent,

The LHC will never be able to completely rule out supersymmetry, since you can always push the masses of superpartners higher. However, if you accept the standard motivation for the subject ("solves the hierarchy problem"), then you get that the supersymmetry breaking scale should be of order 100 GeV. Making other assumptions, Strumia gets a probability distribution peaked there, falling off at higher energies. By this analysis, supersymmetry was already rather an unlikely hypothesis, and the LHC last year removed half of the remaining probability.

I don't have a reference at hand, but talks by Atlas/CMS people projecting the reach of their experiments under various assumptions shouldn't be hard to find. My very rough guess is that they should be able to get gluino mass limits in the range 1-1.5 TeV in the run beginning this year, would need more beam energy and/or a lot more data to get up to 2-3 TeV. Even with this though, there will always be some small amount of probability higher.

It's going to be very interesting over the next few years to see at what point supersymmetry enthusiasts throw in the towel. By Strumia's measure, already half of the possible places for supersymmetry to hide have disappeared. Probably half of the remaining half will vanish in the coming year. Based on my experience with string theory though, I'm wary of making any estimate for how much evidence it takes to convince someone a speculative idea they favor doesn't work.

22. **Rhys**
February 7, 2011

Those plots are for the CMSSM, which is a highly constrained version of the MSSM (although to be fair, the MSSM parameters are already highly constrained by experiment). But weak-scale SUSY does not even have to be the MSSM.

Quite simply, it is way too early to be trying to draw conclusions about the existence of supersymmetry at the weak scale. The next few years will tell. I for one, and I think many other people, will give up on low-energy SUSY if it is not found at the LHC, but the time to give up is not yet upon us!

23. **Peter Woit**
February 7, 2011

Rhys (or any other supersymmetry optimists who care to comment),

You have to make some assumptions on supersymmetry-breaking parameters to even make any understandable statements about this subject, since there are over a hundred of them in the minimal version. If you're not going to be convinced until the LHC nails down bounds on every corner of the parameter space, this could take a while.

What I'm really curious is, at what point would you be willing to give up on supersymmetry if the LHC sees nothing:

1. Late this year (say 3 inverse fb at 7 TeV)
2. Late 2012 (say 5-10 inverse fb at 7 or 8 TeV)
3. 2015? (say 10 inverse fb at 14 TeV)

or later? (will you wait for 100s of inverse fb at 14 TeV, and when nothing is seen then, say then thing to do is to wait for the higher luminosity of the S-LHC, or higher energies from higher field dipoles?).

24. **Eric**
February 7, 2011

Peter,

I think it's only reasonable to wait until after the next two years of running to come close to drawing any conclusions about supersymmetry. As you've said, the expected SUSY spectra are dependent on different models of supersymmetry breaking, and there is currently still a lot of viable parameter space in different models. If supersymmetry is there, it will be found. If not, then there should be some other interesting physics to be discovered. I think it's better to approach things with the optimism and excitement of potential discoveries rather than the pessimism and cynicism that is all too prevalent in your posts.

25. **Peter Woit**
February 7, 2011

Eric,

Well, I'm optimistic that the LHC will tell us something interesting, but think it will be about electroweak symmetry breaking and the Higgs.

Still, I would like to hear from those who expect to see supersymmetry about when (in terms of amount/energy of data) they're expecting to see it.

26. **Eric**
February 7, 2011

Peter,

I'll think we may learn something new about EWSB as well, and I'm very excited to see what is discovered at LHC. I think everyone should try to get past being aligned with and fighting over particular theories and models, as if they were religious doctrines. I do think that supersymmetry plus Higgs is the most likely possibility, however I will rethink this if nothing shows up by the end of 2012.

27. **Rhys**
February 8, 2011

Hi Peter,

I hope your question about when to give up is moot. If the LHC doesn't find sparticles, then I desperately hope it finds some other new dynamics around the TeV scale, otherwise I will probably give up on high energy particle physics altogether.

Eric's comments above are very sensible.

28. **tristes_tigres**
February 9, 2011

Wilczek in his talk presents a graph of 3 coupling constants, that intersect at high energy. To an uninformed person like me, it looked rather persuasive. Is that honest, or did they have to tweak free parameters to get those 3 lines to intersect?

29. **Eric**
February 9, 2011

Hi tristes_tigres,

The gauge coupling unification at high energies happens automatically (within experimental errors) in the minimal supersymmetric Standard Model. Whether or not this is a sign of supersymmetric grand unification or just a coincidence is currently unknown, but many people take it as a circumstantial bit of evidence in favor of TeV-scale SUSY.

30. **Peter Woit**
February 9, 2011

tristes_tigres,

The coupling constant unification argument Wilczek gives is probably the best evidence for supersymmetry, but it is still rather weak evidence. The situation is more complex than the way it is usually advertised, for a detailed explanation, one place to look is

http://www.physics.ohio-state.edu/~raby/pdg.guts.revised05.pdf

My understanding is that things work best in a one-loop calculation, going to a more accurate two-loop calculation makes the agreement less accurate. There are many ways to parametrize the size of the disagreement, Raby gives it as 3 sigma. Note that this kind of calculation typically assumes no new physics between the TeV scale and the GUT scale, which most people find hard to believe.

Wilczek has a personal reason for being enthusiastic about this idea, since he was one of the co-authors of the original calculation of this kind.

31. **chris**
February 10, 2011

"I think it's better to approach things with the optimism and excitement of potential discoveries"

i for once think it has always payed off to approach new theory with extreme scepticism unless they explain all current experimental findings and make definite predictions for future ones.

"I desperately hope it finds some other new dynamics around the TeV scale, otherwise I will probably give up on high energy particle physics altogether."

so you don't follow Churchills advise. that might be really good for you and your future life. i for once am much more interested in how nature works and not so much in some particular theoretical idea. i wouldn't dream of throwing the towel just because an experiment does not confirm my prejudices. but motivations for doing theoretical physics are different i guess.

32. **Rhys**
February 13, 2011

"i for once am much more interested in how nature works and not so much in some particular theoretical idea."

When did I say I was only interested in some particular idea?
If all the data from the LHC can be described perfectly well by the standard model with a fine-tuned Higgs, then it will be very difficult to motivate further experimental or theoretical work in high-energy particle physics.

That's different to saying that there will be nothing to do in theoretical physics…

33. **chris**
February 14, 2011

I think you seriously underestimate human inventiveness 🙂

Celebrity News

February 8, 2011
Categories: Uncategorized

A selection of celebrity math/physics news:

- Jane Fonda's blog has a report on My Meeting With Stephen Hawking. Hawking told her "You were my heart throb", admitting that Barbarella was what he had in mind.
- MIT has put online a video of a lecture given in December by Jim Simons. Simons tells some of the story of his remarkable career and gives some advice about doing math. The financial news this morning reports that Simons's Renaissance Technologies is now down in Brazil doing high-frequency trading. The story is illustrated with a photo of Gisele Bundchen super-imposed on what appears to be Simons lecturing on differential K-theory.
- Someone has come up with an Einstein Index to rank theoretical physicists using a new citation analysis. According to this index, Juan Maldacena outranks Steve Weinberg and Ed Witten by a sizable amount. Further down the list, Sean Carroll and Murray Gell-Mann get the same ranking.
- Brian Greene's new book on the Multiverse is getting a lot of attention, with mostly laudatory reviews. For an alternate take, see the review at Bookforum by Charles Seife.

Comments

1. **milkshake**
   February 8, 2011

   the Seife's review of Greene's book apparently conflates the Landscape multiverse with many-worlds interpretation of QM. I wonder if the distinction is made clear enough in the book.

2. **Steve**
   February 8, 2011

   The Einstein index does not look too bad for comparing young scientist within a subfield of physics. Having said that, there is no index that works when comparing scientists across a timespan of many decades.

   Peter, your Einstein index is a miserable 180. How come? 😉

3. **Peter Woit**
   February 8, 2011

   Steve,

   Well, I guess it's because I'm not the next Einstein…

4. **Cesar Laia**
   February 8, 2011

   PG de Gennes died some years ago…

5. **Rien**
   February 8, 2011

   I'd say that any index that doesn't put Weinberg on top is flawed 😉

6. **Thomas Larsson**
   February 8, 2011

   How would Einstein score on the Einstein index?

7. **Chris Oakley**
   February 8, 2011

   I cannot help thinking that Hawking "blew it" slightly … I mean, there he was, surrounded by gullible actors. He could have said anything he wanted and they would have lapped it up. Instead of these quips about getting out of teaching due to his disability and Hanoi Jane being "hot" in Barbarella (although the latter, I admit, is a perfectly sound observation), he should have spun some yarn about being in contact with beings from the 11th dimension and then started warning them about the compactification that was due if the Earthlings did not spend more money on theoretical physics …

8. **Fabio**
   February 8, 2011

   Ah, the latest silly ranking index. These are always fun. I think the results tell us more about the field itself over time than they do about the individuals being ranked. Clearly you can see citation inflation at work. Also you can see increased herding tendencies in a field starved for good ideas.

9. **noEinstein**
   February 8, 2011

   I don't get it. In making up the ranking, he did not include Weinberg's books, but he included Maldacena's review which is similar to a book. If Weinberg's books our counted, he jumps way ahead of everyone. Clearly, all books and reviews should be excluded from the ranking.

10. **Shantanu**
    February 8, 2011

    Peter, this maybe old news and could be on your website. but the talks of 20th anniversary of INT are
    here
    This includes a talk by Howard Georgi on history of QCD and particle physics from 50s to 80s (sans string theory)

11. **Anony-Mouse**

February 8, 2011

I was recently looking through some classic papers from the 40's and 50's, and one very striking thing is how few references they have. Most of them cite fewer than five other papers total. Nowdays, the norm is to cite anything that is even tangentially related to what you are doing. 50 or more references seems common. I wonder if anyone has studied when and why this change took place.

12. **neo**
February 8, 2011

Anony-Mouse,

Einstein's 1905 special relativity paper cited exactly ZERO papers. Maybe the Einstein index should depend on how few cites an author can accomplish in a published paper.

13. **thomas**
February 9, 2011

I posted this over there, but I'd like to inject into the discussion that one reason people would dislike citation indices is how obviously they get gamed- the pressure to publish, the jokes about the minimal publishable unit, the politics of who gets a cite or a coathorship, the random cites of papers that the authors haven't read or think are viewed as influential just to pad the bibliography- and the concern that taking citation indices seriously would lead to more noisy politics and get in the way of doing science

14. **the Dude**
February 9, 2011

A very interesting ranking of the top theoretical physicists was done in the Discover magazine a few years ago. "With Smolin's aid, DISCOVER has scoured the landscape and found six top candidates who show intriguing signs of that Einsteinian spark. Smolin is too modest to say so, but he might qualify as a seventh;" The results are published here:

http://discovermagazine.com/2008/mar/13-e-nste-n

15. **Chris Oakley**
February 9, 2011

Hi Dude,

Interesting list.

1. Lisi. Unification based on E8. Currently no contact with the real world.
2. Hawking. Radiation of black holes. Not currently measurable.
3. Milgrom. MOdified Newtonian Dynamics. Explains galactic rotation without invoking Dark Matter.
4. Amelino-Camelia. Doubly special relativity. No experimental evidence.
5. Markopoulou-Kalamara. Works on loop QG , for which there is no experimental evidence.
6. Witten. Promotes Superstrings, for which there is no experimental evidence.

It looks to me as though the only one of these who has a theory that actually explains real physical phenomena is Milgrom. Citation counts unfortunately, are a poor substitute for this attribute.

16. **Giotis**
February 9, 2011

Well I'm sorry to say that but putting Witten in the same category with some of the members of this group it's kind of a sacrilege. Some of them will be thrilled if they could just shake his hand.

I wouldn't say that Witten is the next Einstein but that Einstein was the Witten of his time.

He is many classes above anyone we know.

17. **Bugsy**
February 9, 2011

And sometimes a wrong paper is cited many times with all the recent
citations remarking that the proof had been found to be false (as it was based on another false but previously much-cited paper)
…won't name names, to save the guilty from further well-deserved embarassment!

18. **Geoff**
February 9, 2011

How does Randall's coauthor Sundrum not appear as high on the list?

19. **chris**
February 10, 2011

Giotis,

with all due respect, but this should be a list of top physicists. Witten did some pretty good physics, ok. but there are people like Weinberg, Glashow, Wilson, Gell-Mann, 't Hooft – please. What does Witten have to show in terms of physics that would come close to the standard model, the renormalisation group, quarks or the renormalizability proof of nonabelian gauge theories?

20. **El Cid**
February 10, 2011

I don't see John Ellis in the list WTF?

21. **Amber Zee**
February 16, 2011

“Einstein-indices for well-known theoretical physicists and cosmologists. The Einstein index is plotted vertically, and each scientist is listed by the search term used in Google Scholar. Nobel laureates are shown in amber, others are listed in blue.”
So,physics and cosmology blogger Sean Carroll has entered the bottom end of this level which, without any doubt, makes him the physics blogger with the highest Einstein index. At levels above 6,000 we see true giants emerging. Well-known names like Stephen Hawking reside at this level.

22. **anon**
February 17, 2011

Amber, Carroll only made the list because the author forgot to exclude review articles.

Budget News

February 14, 2011
Categories: Uncategorized

Almost five months into FY 2011, the US still has no budget for the year, operating on a continuing resolution that funds the government at FY 2010 levels until March 4. The House Republicans have come up with a proposal for huge budget cuts, which would arrive late in the fiscal year, probably requiring national labs like Fermilab to essentially shutdown for the remainder of the fiscal year. John Conway has more about this here. No one seems to seriously believe this proposal will pass into law.

This morning, the White House announced its budget proposal for FY 2012. The DOE Office of Science would get a healthy increase, to $5.416 billion from $4.964 billion in 2010. Similarly, the NSF would go from $6.873 billion to $7.768. However, the Administration's FY 2011 request ended up being pretty much irrelevant, and it's not clear that this one will fare any better. No information yet on how HEP and mathematics fare specifically in these requests.

So, bottom line is that no one really knows what this year or next year's budget numbers will be, with the House proposal a lower bound for this year, and I suspect the president's proposal will be an upper bound for next year.

Midday tomorrow, Fermilab director Oddone will give an all-hands talk at Fermilab to discuss the implications of all this for the lab.

Update: At the DOE, the FY2012 request for High Energy Physics is $797 million, versus $791 million in FY 2010 (last year at this time, the FY 2011 request was for $829 million). More details here.

Details of the NSF budget request are here. Mathematics research goes from $241 million in FY 2010 to $260 million in FY 2012. Physics from $290 million to $300 million. The NSF has pulled the plug on the DUSEL lab, freeing up $36 million/year, which is repurposed towards what they describe as their three priority areas: physics of the universe, quantum information science and the physics-biology interface.

Comments

1. **Dave Miller**
   February 16, 2011

   Peter,

   What is your take on the NSF priorities: "physics of the universe, quantum information science and the physics-biology interface"?

   My own take is that "physics of the universe" (cosmology, I assume) is pretty interesting, that "quantum information science" is amusing but unlikely to really lead anywhere, and that "the physics-biology interface" sounds really important, except that I am not quite sure what it means.

   Dave Miller in Sacramento.

2. **Peter Woit**
   February 16, 2011

   Dave,

   Well, at least it's "physics of the universe" (whatever that means, presumably astrophysics/cosmology), and not "physics of the multiverse".
   The other two choices for priority are hot topics of this millenium, so not surprising. I don't know enough about research in those areas to have an opinion about how well-justified choice of them is.

   What is more interesting to me is what is now not a priority: accelerator-based high energy physics.

3. **cath**
   February 16, 2011

   "What is more interesting to me is what is now not a priority: accelerator-based high energy physics."

   That is a very astute observation. Robert Wilson, the first director of Fermilab (originally just NAL), explicitly compared the large new synchrotrons to the large cathedrals of medieval Europe. Wilson Hall at Fermilab is intended to resemble a pair of hands in prayer, and inspired by a cathedral in Beauvais, France.
   http://www.nature.com/nature/journal/v404/n6776/full/404350a0.html

   Perhaps the large accelerators will go the way of the old large cathedrals. Constructing cathedrals no longer holds as central place in society as it once did. Cathedrals are still built (and still respected), but built using very different materials and techniques. Perhaps new large accelerators will continue to be built (occasionally?), but with new technologies.

4. **The Cosmist**
   February 16, 2011

   On the issue of accelerator-based HEP, isn't the issue one of severely diminishing returns? I hate to be so practical, but what is the potential impact of this kind of research on human scales? I think the observation about cathedrals is astute, but even theological enterprises have their limits.

   I'm rather dismayed by the fact that, though we can understand mathematically the behavior of elementary particles, model the evolution of the universe almost from its inception and can see galaxies 13 billion light years in the distance, we still haven't found a suitable replacement for burning dead plants to power our civilization! Aren't we guilty of "fiddling while Rome burns", since without energy to power our technology none of the big science required by physics will be possible in the future? I suppose string theory will still be possible in a powered-down post-fossil fuel civilization, but you can forget about any more super-colliders ever again! Maybe physicists need to expend more intellectual energy on applications that can revolutionize life on human scales such as new energy sources, propulsion systems, new modes of industry, computing, communication, etc. – something I haven't seen a lot of in recent decades!

5. **Eric**
   February 16, 2011

   Dear Cosmist,

I think that nuclear/particle physicists gave the world an alternative source of energy to fossil fuels a long time ago, nuclear power. That's what will power the accelerators in the future. Most likely, the LHC already gets most of its electricity from nuclear power plants.

On a different topic, I thought that it was DoE that basically funded the national labs and particle accelerators rather than NSF?

6. **Peter Woit**
   February 16, 2011

   In my comment about NSF priorities, I should have just said "particle physics", not specifying accelerator-based.

   Eric,

   DOE funds Fermilab and much of experimental HEP in the US, but the NSF also funds experimental HEP, through experiments at the LHC and the Tevatron. In the past they have operated accelerator centers (CESR at Cornell), although no longer. They've also just recently pulled out of funding the DUSEL underground lab, which has created a problem.

First LHC Winter Conference Results

February 17, 2011
Categories: Experimental HEP News

This week the Aspen Center for Physics is hosting one of the first of this year's "Winter Conferences" where results from last year's LHC run are being reported. Appropriately, the title of the conference is New Data from the Energy Frontier. The most dramatic result has to do with what is not being seen: any evidence of supersymmetry, with new limits reported today by ATLAS. The new ATLAS results rule out gluino masses up to 7-800 GeV, improving on the first limits of this kind from CMS which were about 600 GeV.

For more detailed discussion courtesy of the blogosphere, see Resonaances and Cosmic Variance. For some indication of what this means for string theory, Michael Dine's lecture notes for his talks on "What LHC might tell us about String Theory" at last summer's TASI summer school are now out, with the title Supersymmetry from the top down. These lecture notes start off with a section very unusual for this kind of thing, entitled "Reasons for Skepticism". and he notes:

> Our enthusiasm for supersymmetry, however, should be tempered by the realization that from existing data – including early LHC data – there are, as we will discuss, reasons for skepticism.

For some historical perspective about what pre-LHC expectations were, I happened to run across today a copy of Witten's lecture notes from a string theory conference at Hangzhou in 2002, where he gives the muon magnetic moment discrepancy as one piece of evidence for supersymmetry, and says:

> Assuming this discrepancy holds up, we would expect to interpret it in terms of new particles, but these are highly constrained; one explanation that does work is supersymmetry, with masses of new particles of order 200 – 300 GeV.

Of course, even the minimal supersymmetric extension of the Standard Model is ferociously complicated, with over a hundred unknown parameters, so all quoted limits make various simplifying assumptions. Relating LHC data to limits on supersymmetry will be a subject keeping many physicists busy for the next few years, for more about this, see this talk at Aspen by Jay Wacker. He doesn't expect this year's run to as dramatically increase limits on gluinos as last year's run did, describing early results as "full coverage up to 300 GeV, reach up to 600 GeV", increasing to "full coverage up to 375 GeV, reach up to 800 GeV" after an inverse femtobarn of data is analyzed (that's the official LHC goal for 2011, although it's hoped they can double or triple that).

The last sentence of his last slide refers to something that I've always worried about, but am not expert enough to know whether such a worry is serious. He describes the web-site http://LHCNewPhysics.org where simplified models based on supersymmetry and other BSM ideas are given, and notes:

> ATLAS studying 10 Simplified Models from 0 in August. Changing their triggers.

The worry I'm not so sure about is to what extent the LHC detector triggers are being optimized to look for supersymmetry, potentially missing un-expected non-Standard Model physics. Since there were always reasons to be skeptical of LHC-scale supersymmetry, and these have now become so compelling that even Michael Dine is writing about them, one hopes that the trigger designers will keep that in mind.

Meanwhile, back at the LHC, powering tests are finished, the ring is closed and will be put through full tests of its operational cycle the next couple of days. Official start of beams for this year is planned for Monday.

Update: More details about the latest on this at Resonannces.

Update: More from Tommaso Dorigo (LHC Excludes SUSY Theories, Theorists Clinch Hands), and a Physics World article by Kate McAlpine here. Tommaso links to a 2008 posting by Ben Allanach that discusses predictions for SUSY masses made (using various assumptions one can read about there) around that time. One of these, by a large group including John Ellis, predicted that 50 inverse picobarns at 10 TeV would be enough to explore most of the region they expected SUSY masses to be in, at 68% confidence level. The latest data, which is about that luminosity but at 7 TeV, does rule out much of that region, with the most likely SUSY mass right around the boundary of the region ruled out by ATLAS (although the tan(beta) values are different). According to the Physics World article:

> John Ellis of CERN and King's College London disagrees that the LHC results cause any new problems for supersymmetry. Because the LHC collides strongly interacting quarks and gluons inside the protons, it can most easily produce their strongly interacting counterparts, the squarks and gluinos. However, in many models the supersymmetric partners of the electrons, muons and photons are lighter, and their masses could still be near the electroweak scale, he says.

Comments

1. **Thomas Larsson**
   February 17, 2011

   If even Michael Dine admits that there are reasons for skepticism, the reasons must be very strong indeed. Now we are only waiting for Gordon Kane…

2. **DB**
   February 18, 2011

   When the LHC fails to find supersymmetry, then Split Supersymmetry will be invoked to explain this away. Just as the Multiverse is now used to explain away the Landscape Problem of String Theory.

   Fundamental theoretical physics has never been in such a parlous state as it is today. It looks increasingly less like science, and more like a branch of metaphysical speculation.

3. **An Ominous**
   February 18, 2011

   However, after SUSY particles start to be detected at the LHC, Supersymmetry will be considered the holy grail of Theoretical Physics and another jewel in the crown of theoretical speculation and ingenuity, a la par with General Relativity. And then you should feel ashamed, but that's petty and unimportant.

4. **Peter Woit**
   February 18, 2011

   DB,

In split supersymmetry, the gluinos are still supposed to be at a mass accessible to the LHC. To explain away a failure to see them, you have to invoke super split supersymmetry,

http://arxiv.org/abs/hep-th/0503249

5. **Giotis**
   February 18, 2011

   There are two sides of the story.

   If Low SUSY is ruled out then someone could see it as a failure of the SUSY idea (and thus String theory) but others as another triumph of anthropic reasoning and the landscape. Indeed such failure will leave EWSB unexplained (like CC) and thus susceptible to anthropic interpretation (like CC).

   The rule is that the more phenomena are left unexplained the more the landscape idea gains validity.

6. **lun**
   February 18, 2011

   Peter, the "trigger bias" is a huge issue.

   Experiments were always theory-laden, but this used to be compensated by an ensemble of experiments to match the ensemble of theories.
   In era where each experiment costs billions of dollars, and you can cound the number of experiments on the fingers of one hand, biases built in the experiment can literally set phenomenology back for decades.

   A "toy scenario" example relevant for SUSY would be if unitarity at the EW breaking scale was restored by a slight decrease in multi-particle processes, rather then a resonance (this is exactly how unitarity is restored in high energy QCD, via Froissart's bound. We do not know exactly how to derive in terms of partons, but we know its associated to low Bjorken x strongly coupled physics).
   If this was the case, the only way to get a grip on the new physics would be to precisely cound how many multi-W, multi-Z and multi-top events there are, and compare with expectation. Can ATLAS and CMS do this, given the trigger bias? Perhaps, but its a good question.

   Experimental timescale to adapt to changes in phenomenology has already had big consequences in heavy ion collisions: When the LHC experiments were being designed, the consensus was that most interesting physics indicating deconfinement would be hidden in correlations of very low momentum particles (the technical name is HBT interferometry), and jet physics, for example,such would have little or no relevance.
   Nowadays the consensus is entirely reversed, few people care about HBT and jets are where the physics is at. Because of this, "particle-optimized detectors" (CMS and ATLAS) actually might have a better shot at intesting physics than the detector optimized for heavy ion collisions (ALICE), at least if this consensus lasts and is justified. So its not a "worry". It happened already.

7. **Tristes_tigres**
   February 18, 2011

   Lun,

   Thank you for info on the subject I have wondered about for some time.

   To what extent the raw data from finished experiments is archived and available for re-analysis, in case someone later comes up with a new idea?

8. **Peter Woit**
   February 18, 2011

   Tristes_tigres,

   The data collected is archived, but the issue with "trigger bias" is much more serious. Data that doesn't pass the trigger is not collected at all. In these experiments, the detector is producing data far more quickly than it can be collected, so an elaborate trigger is necessary to decide which data to collect.

9. **Tristes_tigres**
   February 18, 2011

   Don't they ever consider collecting some amount of randomly sampled events? I suspect it could help to debug and validate the trigger, in addition to enabling tests for alternative theories.

10. **trig**
    February 18, 2011

    They do all sorts of tests and checks. Control expts to quantify backgrounds, tests to quantify cosmic ray events which decay in the detector, lots of things. Why not ask someone on a big HEP collaboration? It does not have to be LHC, the same is/was done at the Tevatron and LEP, SLC, B-factories, etc.

11. **Michael**
    February 18, 2011

    Hi,

    concerning Tristes_tigres' comment: yes, we devote a small fraction of the trigger bandwidth to recording min-bias and even zero-bias data, precisely for its value in calibration and checks of detector performance. Such data are also extremely useful for tuning models of the underlying event (ie, extra tracks and energy not directly related to the main interaction) which can spoil the construction of an "interesting" high-pT event. Aside from the zero- and min-bias data, we collect events with relaxed trigger requirements, in order to verify the main triggers. These so-called "monitoring" triggers are pre-scaled, which means we save some fraction 1/N of them, so as to keep the trigger rate under control.

    People sometimes propose to look for new physics in these auxiliary triggers. The problem is that they have been heavily prescaled, so that the effective luminosity will be really very low. The new physics signal would have to have a large cross section in order to be discovered this way, which is why we experimentalists work so hard to devise a wide variety of triggers to collect relevant, rather than irrelevant, events.

    regards,
    Michael

12. **Bernhard**
February 18, 2011

I think it´s pretty soon to make claims about supersymmetry not being seen, as the luminosity is still very low. But in any case, the complicated plots showed by ATLAS and CMS showing some new parameter space region being excluded must be handled with caution. Normally a constrained model like minimal supergravity is used to set those limits and it´s not clear at all e.g. if light gluinos are really being excluded… I think that best thing you can say is that light gluinos are being disfavored but the evidence is circumstantial in the sense that if they were there, sure you could have detected them. On the other hand SUSY models have so many parameters that I can really see already some new paper coming up saving light gluinos again. Eventually they will have to give up but although you can exclude more regions, the theory is poorly falsifiable with such low statistics.

In any case I believe also that one thing that should not be forgotten, ever, is that even if SUSY is found and string people will be delighted, we should never miss the point that we are still talking about point particle theory (even with Michio Kaku lying to children on TV saying he works with string theory, THE theory that predicts s-particles).

13. **ss**
February 18, 2011

Supersymmetry will never be disproved. Phlogiston and the luminiferous ether were never disproved. Instead something else came along which could do a better job of explaiing the facts. But the point is "the facts" — HEP is really hurting for expt data beyond the Standard Model. In the 1950s and 60s there was plenty of unexplained data, and new discoveries every year. This just isn't happening now. A "particle desert" at the LHC will make the futire of expt HEP really bleak. People will not give up on supersymmetry or string theory jusy becaise no sparticles are found. Something needs to be FOUND, and then we shall see how well the various theiries explain it.

14. **Claver**
February 19, 2011

Dear Peter,

You might find the book 'Laboratory Life' by Latour and Woolgar interesting.

I say this because I understand your 'worry' to mean that you are concerned that experiment is being used to construct facts rather than observe them. Something the authors discuss.

Perhaps in this case you feel that the process is overly constructive of facts by means of excessive selection of data.

Anway, my goal was to point out the literature and show its relation to the present discussion. I cannot possibly make a qualified comment.

15. **Claver**
February 19, 2011

Perhaps this link may be helpful (Cormac O'Raifeartaigh) http://coraifeartaigh.wordpress.com/

16. **Michael**
February 19, 2011

Let's not forget what has been pointed out many times already, namely, that a signal in CMS or ATLAS for physics beyond the standard model will be difficult or even impossible to ascribe to SUSY per se. The reconstruction of the final states is difficult and it will take a while before any pattern points to SUSY as opposed to extra dimensions or Little Higgs models, among others. Some versions of low-energy SUSY might be more-or-less ruled out by CMS and ATLAS, but they cannot be unambiguously discovered.

17. **tristes_tigres**
February 19, 2011

Michael –

I have no doubt that HE experimental teams are thoughtful and know what they are doing. What I was concerned with is the possibility that motivation to get results ASAP gets in the way of testing alternative physics ideas by some outsider later. If we indeed hit the "particle desert", I hope they will store some minimally filtered data, just in case. Although, I imagine, someone not involved with detector designers won't find it easy to make use of the raw data.

18. **Peter Woit**
February 19, 2011

Michael,

Thanks for the explanations. You make clear the problem: almost certainly not enough possible luminosity in "unbiased" data to find evidence for something new.

Claver,

Thanks, but I should make clear that the "selection of data" effect here is not "excessive", it's forced upon the experimentalists by the overall limits on how much data they can collect. They're well aware of the problem and devote a lot of effort to figuring out how to deal with this. I'm not expert in this subject, so I don't understand all the choices they're making or their implications. My "worry" is just that these choices may be being overly influenced by theoretical models (supersymmetry and large extra dimensions) that have gotten a lot more attention than they deserve.

tristes_tigres,

There's been some debate in the past about whether these kinds of experiments should make their data public for others to try and analyze. Given the complexities involved, I'm rather dubious that outsiders could do this in any reliable way. In any case, my guess is that the LHC is going to be the only experiment of this kind for a very long time, and also will run (with upgrades) for a very long time. The groups working there are extremely large and will be doing this for many, many years. After the first few years, unless they've got some very exciting new physics already to analyze, I'm pretty sure that many of the physicists there will be quite interested in pursuing any new ideas about how to find something unexpected in the data.

19. **nnn**
February 20, 2011

This just appeared on CNN

http://news.blogs.cnn.com/2011/02/20/early-universe-revealed-at-4-billion-degrees/?hpt=C2

I suppose the nattering nabobs of negativism will complain about the statement near the end "finding … the Higgs boson … would explain gravity" or that the scientists said they would be happier if the Higgs is not found (?). But really, it is an effort to convey what is happening in modern science (expt HEP anyway). The stuff about 4 trillion degrees (Celsius or Fahrenheit doesn't matter) and primordial soup/early Universe is not bad at all.

20. **Geoff**
    February 22, 2011

    I've always wondered – to what extent does Witten's proof of the positive mass theorem depend on supersymmetry being realized in the physical world?

21. **Peter Woit**
    February 22, 2011

    Geoff,

    The great thing about mathematical proofs is that they don't depend at all on the physical world. Witten's argument about the positive mass theorem has nothing to do with whether a supersymmetric theory describes nature.

    More generally, if the MSSM doesn't appear at the LHC, this doesn't affect in the slightest any of the many interesting mathematical applications of supersymmetry.

22. **Claver**
    February 28, 2011

    Thank you for your response Peter.

This Week's Hype

February 21, 2011
Categories: This Week's Hype

A session on results from the LHC at last week's AAAS meeting has generated some news reports about results from the heavy ion run, see here and here. Under the heading "String theory supported", MSNBC reports:

> Previous experiments conducted at another particle accelerator, the Relativistic Heavy-Ion Collider in New York, showed that quark-gluon plasma took on the form of a liquid. Some scientists expected the plasma to go to a gaseous state at the higher temperatures achieved by ALICE, but it didn't. Instead, it was a "perfect liquid, which flows without resistance and is completely opaque," Schutz said.
>
> That in itself was a big surprise. But Schutz told me that the results were consistent with what had been predicted by a particular variant of string theory known as AdS/CFT correspondence, which also addresses such mysteries as quantum gravity and extra dimensions. "I'm surprised that they can make a prediction and that it matches what we measured," Schutz said.
>
> String theory is a long-debated conception of the subatomic world that envisions matter as being composed of incredibly tiny strings or membranes that vibrate in an 11-dimensional universe. Skeptics have criticized the concept as being untestable and unfalsifiable, but if findings from the LHC can confirm some hypotheses and falsify others, that could increase string theory's acceptance.

The campaign to deal with the failure of string theory unification by confusing it with AdS/CFT as an approximate calculational method continues. No matter how successful or unsuccessful AdS/CFT is at describing heavy-ion collisions, this has nothing to do with string theory as a unified theory of gravity and the Standard Model. I am curious though about the question of how well AdS/CFT does work as an approximation for describing heavy-ion physics. Can anyone point me to distinctive AdS/CFT predictions about what the LHC should see that are now being tested? The news reports just seem to refer to evidence that at LHC energies the quark-gluon plasma seems to continue to exhibit the perfect liquid behavior seen at RHIC.

Update: See the comment section for an extensive discussion by someone expert in the field (Hans Juergen Pirner) relevant to the question I was raising.

Comments

1. **El Cid**
   February 21, 2011

   Peter,

   String Theory is the best paradigm to build a theory of quantum gravity. I don't know why, like you, but what I've read about ST, I can say, she has the potential to solve the unification problem in physics. ST models can unify the gravity force with the other three fundamental forces in an only consistent framework, namely, ST is the way to build the Theory of Everything. ST is the natural heir of quantum field theory. So far, ST is just a paradigm. A paradigm with the adequate features to describe all known fundamental forces. A paradigm that is compatible with special relativity and quantum mechanics. A paradigm where you can quantize the Einstein field and to obtain consistent results with the calculations. Theoretical Physicists who are working in string theory are also discovering new math tools useful in other branches of physics. How time do you think is enough to complete the TOE? I think a hundred of years would be optimistic ;-). By now I just can say, ST is spectacular.

2. **Peter Woit**
   February 21, 2011

   El Cid,

   Even if one were inclined to swallow all of your hype, that wouldn't change the fact that the data about heavy ion collisions collected by ALICE has nothing to do with it.

3. **Amused**
   February 21, 2011

   Peter,

   I think these results about the quark-gluon plasma rather behaving like a fluid than a gas are not new but discovered and reported about last year already…

   So, it seems that Your google alert works not perfectly well sometimes :-P, ha ha …

4. **Peter Woit**
   February 21, 2011

   Amused,

   The relevant LHC ALICE results may not be new (I first mentioned them here), but the MSNBC hype is fresh this week.

5. **Brathmore**
   February 21, 2011

   (Note: I'm a big fan of the blog and appreciate the often lonely battle you've waged against string theory hype.)

   Peter,

   I went to a popular talk about string theory today by Brian Greene, expecting that all I would hear was unabashed hype. To my surprise and delight, at several points in the talk he specifically said that string theory was speculative in the sense that it didn't yet have experimental support. I find it encouraging that, due to just criticism from people like you, some of the greatest popularizers of string theory (e.g., Brian Greene) have started conveying some of the theory's difficulties. For instance, he mentioned the 10^500 possible geometries, and said that some people had taken the "justifiable step" of quitting work on string theory, that some were still trying to figure out a way to make it unique, and that others had resorted to the multiverse interpretation, which he openly acknowledged was very speculative and controversial. On the subject of AdS/CFT, he mentioned the recent Relativistic Heavy-Ion Collider result as being an "encouraging" result for string theory, but he certainly didn't tout it as being proof that the theory is correct.

I don't mean to make this about any one popularizer of string theory, but I think it shows that your critiques are having an impact, and that the public might be beginning to get a more balanced view of the theory from some of its popularizers. Good work!

(Side note – given the lack of progress in string theory, I for one would love to hear any news you might have about progress of other approaches…non-commutative geometry, loop quantum gravity, etc. Thanks!)

February 22, 2011

Reg. heavy ion physics at LHC & AdS/CFT, here's one paper I know of

Di-Jet Conical Correlations Associated with Heavy Quark Jets in anti–de Sitter Space/Conformal Field Theory Correspondence
Jorge Noronha, Miklos Gyulassy, Giorgio Torrieri

http://arxiv.org/abs/0807.1038

Abstract: "We show that far zone Mach and diffusion wake "holograms" produced by supersonic strings in anti–de Sitter space/conformal field theory (AdS/CFT) correspondence do not lead to observable conical angular correlations in the strict $N_c\to\infty$ supergravity limit if Cooper-Frye hadronization is assumed. However, a special {\em nonequilibrium} "neck" zone near the jet is shown to produce an apparent sonic boom azimuthal angle distribution that is roughly independent of the heavy quark's velocity. Our results indicate that a measurement of the dependence of the away-side correlations on the velocity of associated identified heavy quark jets at the BNL Relativistic Heavy Ion Collider and CERN LHC will provide a direct test of the nonperturbative dynamics involved in the coupling between jets and the strongly-coupled Quark-Gluon Plasma (sQGP) implied by AdS/CFT correspondence."

There was also something about jet quenching and elliptic flow, but can't recall the details. Maybe this paper: http://arxiv.org/abs/1009.2286

7. **Chris Oakley**
February 22, 2011

Brathmore,

It is of course a good thing that (e.g.) Brian Greene is prepared to be honest about the failure of String Theory; what is retarded is that the conclusion of all of this seems not to be that one should give up on it and try something else.

8. **piscator**
February 22, 2011

I heard an AdS/CFT talk recently which claimed that the thermalisation time of the QGP should depend on the boost factor of the heavy ion (I forget the precise dependence, 1/gamma?), so there was an effective prediction for the functional dependence of the thermalisation time on the centre of mass energy of the initial state.

Not an expert so don't know to what extent this is correct, a particular feature of AdS/CFT, or a particular feature of the model used. It remains the case that N=4 SYM in the N_c -> infinity limit is not a systematic approximation to QCD.

9. **AdS/QCDnik**
February 22, 2011

Some proposed predictions by Casalderrey-Solana et al
http://arxiv.org/abs/0912.3717
http://arxiv.org/abs/0907.4012

Iancu, Mueller and Collaborators have come with a picture for energy loss and momentum broadening at strong coupling.

All this builds strongly on the work of Gubser and collaborators, to mention just another prominent name.

10. **neo**
February 22, 2011

I am currently reading Brian Greene's new book. In it, as in the talk Brathmore attended, he candidly admits there is no evidence for string theory, as yet. However, he still asserts that the evidence is around the corner at LHC. His view remains that string theory is a huge success on all fronts, except for that little matter of experimental evidence…

11. **Sam**
February 22, 2011

The fact that ADS/CFT has some fairly strong qualitative resembelance to nuclear physics seems remarkable to me. I don't understand why you insist that S.T. must provide a cannonical explanation of such a compicated interaction before it can at least be admitted that the correspondence provides some level of evidence that the theory is on the right track.

12. **Peter Woit**
February 22, 2011

Brathmore,

Thanks for the encouragement. I should point out that Brian has always taken pains to make sure to acknowledge the lack of experimental support for string theory. Unfortunately his caveats often get dropped in stories that make it into the press. My main disagreement with him has always been on the issue of whether optimism about this situation changing is justified.

Unfortunately I don't know of any news about anything promising coming out of non-commutative geometry or loop quantum gravity. Personally I'm excited by some ideas about representation theory coming out of the Langlands program that I think might go somewhere, but I'm still a ways away from understanding this well enough to start promoting these ideas here. Maybe soon though…

13. **Peter Woit**
February 22, 2011

Sam,

I don't insist string theory provide a canonical explanation of nuclear physics. I'm quite willing to believe that it provides a useful approximation scheme in this field. However, the ferocious level of hype in this subject is pretty discouraging and makes it very hard for a non-expert to figure out exactly what works and what doesn't work. Again, it would be very interesting to see exactly what AdS/CFT based approximations predicted about what the LHC would see and compare to what the experiments are finding. Maybe such a comparison is out there, but I haven't seen it.

All of this though has nothing at all to do with string theory's failure as an idea about unification. Arguments otherwise seem to me to be nothing more than attempts to mislead people and avoid owning up to this failure.

14. **hv**
February 22, 2011

PW, you keep bashing string theory for its failure to provide a unified model for gravity plus the gauge forces. Why don't you post an explanation of how, in your opinion, the correct model to describe such an unified reality is *excluded* from the scope of string theory?

15. **Peter Woit**
February 22, 2011

hv,

Because no one knows precisely what "string theory" is, you can't prove that there is no way it can lead to a successful unified theory. However, you can look carefully at what is understood about it, what the problems are keeping it from success so far, and what the history of attempts to overcome those problems is, and make an educated judgment based on those facts. That's what I've tried to do in the book I wrote and in many of the blog entries here.

If they want to, people are always going to be able to come up with some reason to hope that string theory's problems will be overcome, no matter how bad things look.

16. **Bernhard**
February 22, 2011

These claims about ADS/CFT predicting anything in these experiments sound very suspicious. Where are the monte carlo/detector simulations showing that? Does one really want to use vague or qualitative arguments to support this? Or did I miss the point? I doubt very much any studies on this direction exists at all.

17. **hv**
February 23, 2011

I'm sorry, but when you say that 'no one knows precisely what "string theory" is', you're wanting an exact and rigorous nonperturbative definition of string theory. However, you know exactly how that unknown theory looks like in several perturbative limits. In addition, duality relations between those limits confirm that the they are different points of view of the same physical formalism. But even if that wasn't the case, each perturbative limit of string theory is known and well-defined.

So, reformulating my question, how would you argue that a realistic 'gravity + standard model' model is *excluded* as a vacuum of any one of these perturbative string theories?

While you say that 'you can't prove that there is no way it can lead to a successful unified theory', I say that it is strong enough to show that no perturbative vacuum of the theory contains 'gravity + standard model' as a low energy limit. If you fail to prove this, it means that there is a possibility that the opposite statement is true. There's also the possibility that it is false. Our inability for technically proving an assertion or its negation is not synonymous of unprovability.

18. **Peter Woit**
February 23, 2011

hv,

You can't show that a realistic unified theory is excluded as a solution of string theory for two reasons:

1. Even if you assume that couplings are small and you're in a region where a perturbative expansion about some hopefully consistent background works, you can't actually compute what you want, since the number of such things is exponentially large, and each individual computation is too difficult (you need to be able to do things like have explicit Calabi-Yau metrics).

2. Assuming you can solve 1, you still would not have shown that a realistic solution to string theory is excluded, because you don't know what the theory is outside of limiting cases. If the realistic solution is not in a region close to one of these limits, you don't even know what it is you are supposed to compute.

19. **hv**
February 23, 2011

If perturbative string theories are quantum and consistently contain both gravity and gauge forces (as they do), and if, as you argued, one cannot exclude that they may contain a realistic unified model, that means that they *potentially* harbor one valid complete description of reality. And that's enough motivation to continue doing research in string theory. You only listed the technical difficulties in dealing with the theory. Difficulties that warrant a continued research program, not its abandonment.

IMO, the necessary condition for a valid realistic unified theory is to contain gravitational and gauge forces in one consistent framework. String theory does that. The sufficient condition is for it to contain at least one specific model that is consistent with the low-energy reality and is consistent with new experimental high-energy results.

Other proposals, like loop quantum gravity, fail already at the level of the necessary condition, let alone the sufficient condition. Which is why string theory is the only framework on the table to a complete description of reality.

Theorists are yet to find a realistic unified model within string theory, yes, but that only means that it is premature to ask for experimental predictions. But the fact that no one has ever found one realistic model doesn't mean that none is there. It might not be there, true. But potentially it is. And that's what matters.

For example, Yang-Mills theories are a good framework to describe non-gravitational forces. But it is only a framework, just like string theory is. The match with reality in Yang-Mills theory resides in choosing the correct gauge group that describes reality. Luckily, there aren't as many Lie groups as there are Calabi-Yaus, so it was relatively easy to figure out that SU(3) describes the strong interactions, for example.

20. **Peter Woit**
February 23, 2011

hv,

You're just repeating standard hype. The facts of the matter are that thousands of people have worked for more than a quarter century trying to do what you suggest, and what they have learned is that:

1. They can't extract any specific predictions out of this framework. Not one. Nada. Zip.

2. There are clear reasons why this is true (see my earlier comment), and no one has any reason other than wishful thinking to believe that these reasons will disappear and the theory will become predictive.

Comparing this situation to that of the Standard Model is just silly.

21. **hv**
February 23, 2011

PW, if I'm repeating anything, it is standard LORE, not HYPE. With respect to the predictability of string theory, I think you are mistaken:

1. A theory is *wrong* if it is predictive but at least one of its predictions does not fit experimental data.

2. A theory is *incomplete* if the prediction for some physical phenomenon that could/should be in its scope is empty.

3. A theory is *non-predictive* if the prediction for some physical phenomenon is multivalued.

Unless you can demonstrate any these points, you can't dismiss any theory! And since no one, including you, has ever shown the multivaluedness or emptyness of the generic predictions of string theory (on any vacuum of the theory, toy or realistic), you can't dismiss it as wrong. Nor as non-predictive. Nor as incomplete.

One thing is certain: the theory may be technically hard, but none of the points above is undecidable. And that's why research continues.

22. **Peter Woit**
February 23, 2011

hv,

Your definition of "non-predictive", predicts multiple things, is what I would call "inconsistent". My definition of "non-predictive" is that it's a vacuous idea that can't now be used to predict anything, and such that there are good arguments that it never will. String theory fits this definition well. There are lots and lots of vacuous speculative ideas out there that don't and can't lead to a predictive theory. String theory is just one more.

23. **Hans J. Pirner**
February 24, 2011

Dear Dr. Woit

You have asking for information on Ads/CFT and QCD. I have been following with our research the Ads/QCD and AdS/CFT debate. My preliminary conclusions are as follows:(Hopefully this is not too long)

It is very difficult to model AdS/QCD breaking conformal symmetry in such a way that it reproduces the equation of state of Lattice QCD and the Debye Mass as a function of temperature. We have tried with a dynamical dlilaton in a 5-d two-derivative gravity action and with a Nambu-Goto action for the string to reproduce QCD as accurately as possible. See our reference "Trouble finding the optimal Ads/QCD (Veschgini, Megias,Pirner) Phys Lett B 696: 495-498,2011, see also very extensive work by Kiritsis et al. before us.

In this paper we also describe further work on the optimization program. (See the papersQCD-Thermodynamics using 5-d gravity and Thermodynamics of Ads/QCD within the 5-d dilaton-gravity model)

Concerning the heavy ion physics there are two aspects to be investigated further:
1)low energy flow (parameter v2) which documents the strongly interacting Quark gluon plasma according to most theoreticians

2)Jet quenching which should also indicate the strong interaction of the parton with the plasma

We only worked on the second topic there is a paper in review
"Jet Evolution in the Quark Gluon Plasma from RHIC to LHC" by Domdey, Kopeliovich and Pirner where we calculate two scenarios:
1)A conventional QCD parton cross section with the plasma particles which adds to the DGLAP evolution and then at the critical cross over temperature an absorption mechanism for the freshly formed prehadrons in the resonance gas.
2)An enhanced (K-factor =8, purely hypothetical) cross section (a la strongly interacting plasma) and no final state prehadronic cross section

Note, however, perturbative QCD has a problem to choose the coupling scale, since the shower virtuality is high , but the temperature in the plasma is low. We can fit with both scenarios RHIC data. But at LHC scenario 1 is favoured. In our prediction we cannot reproduce the strong transverse momentum dependence seen in the ALICE data between 5 GeV and 20 GeV. Our prediction for pion suppression is above the data for charged particles between 5-10 GeV. In our opinion this necessitates a more careful absorption calculation. Our conclusion would be: from jet quenching there is no strong indication for an ADS/CFT like strongly interacting plasma with the partons. Anyhow AdS/QCD is so bad an approximation to QCD concerning the running coupling and the string tension and the equation of state and the Debye mass that in our opinion it is not worth to be discussed seriously.

One definitely needs to break conformal invariance. Further progrees depends on coupling the world sheet to the dilaton and perhaps increase the number of derivatives in the gravity dilaton action. In total I think low energy QCD up to 10 GeV is a really good candidate for string theory and 5 dimensions may help to do a good job as Polyakov already pointed out very early. The arguments for this theory have to bottom up and at the moment not so much top down, but more work on the relation between a nonconformal string theory and the corresponding gravity is urgently needed.

Best regards

Hans Juergen Pirner

Implications of Initial LHC Searches for Supersymmetry

February 22, 2011
Categories: Experimental HEP News

There's a new paper out this evening from a large collaboration entitled Implications of Initial LHC Searches for Supersymmetry. Instead of just adding it to the bottom of my recent posting, I thought it would be a good idea to start a new one, and add a bit more explanation of what is going on.

For a good news story from today by Kate McAlpine, see this at Physics World. For excellent more technical explanations, see the latest blog postings at Tommaso Dorigo's blog (today) and at Resonaances (yesterday). Physics World, Tommaso and the new arXiv preprint discuss published results from CMS and ATLAS, while Resonaances discusses even more stringent preliminary limits on SUSY from ATLAS made public last week at Aspen.

Tommaso also refers to a 2008 guest blog posting by Ben Allanach explaining how statistical predictions for SUSY masses were being made, adopting various simplifying assumptions (CMSSM) and assuming supersymmetry solves the problems it is advertised as solving (muon g-2 anomaly, dark matter, etc.). Allanach discusses the 2008 version of this kind of calculation by the same group that has just put out a new, 2/22/2011 version this evening.

The usual model for how science is done is that theorists make predictions before an experiment is done, then when the experimental results come in, they get compared to the predictions. That's not quite what is going on here, where as far as I can tell, the new paper doesn't directly compare the 2008 predictions to the new experimental results. Instead, the new experimental results are used to make new predictions. Since a large part of the parameter space favored in the 2008 predictions has now been ruled out, the new ones move the favored part of parameter space up to higher particle masses. The authors do make clear what is going on, showing on their plots a "snowflake" where the 2008 best-fit value was, and "stars" for where the new best-fit values are based on data from the two experiments. Note that the paper does not include the latest, stronger results from ATLAS announced last week, which presumably would move the "stars" up to even higher mass.

While the question this paper addresses about where supersymmetry might be given that it hasn't been seen yet is interesting, it leaves unaddressed the more conventional question: do the LHC experimental results show that the theoretical predictions about supersymmetry made in 2008 before the machine was turned on were wrong? This is a statistical question, so should have a statistical answer. Assuming that the LHC continues to not see supersymmetry as it collects more data, I'm interested in the question of how the experimental data will falsify the theory. Will its proponents just keep calculating statistical predictions of higher and higher masses as lower ones get ruled out? Most will undoubtedly at some point throw in the towel, although there will be some who will never, never, never, never give up (see here):

> SUSY may still be there even if it remains invisible to the LHC, indeed. And yes, I don't hide that I will be convinced that SUSY is there even if the LHC doesn't find it. The LHC will only confirm or exclude effects at particular regimes – usually low energy but it's not quite accurate a description of the regime that may be excluded.
>
> What I have been scared for several years is the pseudoscientific propaganda of your kind trying to claim – without any justification – that not seeing SUSY at the LHC should imply that physicists shouldn't be allowed to work on SUSY or believe that it is a key feature of our Universe. There are many reasons to think it's the case and theorists whom I consider any good will continue to treat SUSY as an essential feature whether or not it shows up at the LHC.

Update: See figure 1 of this evening's What if the LHC does not find supersymmetry in the sqrt(s)=7 TeV run? to see how how much of the predicted region of superpartner masses was ruled out by initial LHC results, and how much of the rest is likely to be ruled out during by the 2011-2 7 TeV run.

Update: There's a very new up-to-the-minute survey of LHC results concentrating on supersymmetry by John Ellis here. Unfortunately no figures that superimpose CMS/ATLAS exclusion regions on the statistically favored regions for supersymmetry that are discussed (based on assuming supersymmetry explains dark matter and the muon g-2 anomaly). It does look like this year's data should be able to convincingly rule out the idea that supersymmetry explains both of these phenomena.

Update: The ATLAS results providing the strongest limits so far on SUSY are now out, see the paper here.

Comments

1. **DB**
   February 23, 2011

   At this rate Tommaso will soon be able to lodge his bet as triple A rated security. It certainly looks a lot more solid than what most banks have in their vaults.

2. **Bernhard**
   February 23, 2011

   "The usual model for how science is done is that theorists make predictions before an experiment is done, then when the experimental results come in, they get compared to the predictions. "

   Although I agree things are getting ugly for SUSY you have to admit that the SM was completely tuned to data for each we have absolutely no idea from where parameters are coming from. So, whatever the beyond standard model will be, SUSY or not, it appears the same procedure will happen, so people tunning SUSY models to data are doing nothing new and if it was good for the SM I don't see why this should be a problem if it's BSM. I am not advocating anything for SUSY but your arguments this time sound less convincing.

   My point: was the SM proven right or wrong? You can make a case for predicting W's and Z (so in a sense it was proven right) but in the end it uses a "minimal particle content". If any SUSY model will someday fit data better than the SM that would be an amazing achievement no matter how high the masses turn out to be, if that's what Nature wants. If it indeed what it wants it's THE question and I agree we should abandon SUSY (or regard it as unfavoured candidate as opposed to mainstream subject) if it does not show at the LHC at all.

3. **Peter Woit**
   February 23, 2011

   Bernhard,

   The SM case was quite different, with no free parameters available to significantly change the W and Z mass predictions made before the SPS started looking for them. If the W and Z hadn't been found, you wouldn't have had a group publishing a paper about how this changed the probability distribution for where the W and Z were. Instead, everyone would have just acknowledged that the SM was wrong and moved on to figuring out a better theory.

   In this case, all we have are statistical predictions of superpartner masses. I'm curious to see some measure of how the new experimental results compare to those predictions (e.g., what fraction of the original probability distribution is now ruled out). There's no way you can completely rule out supersymmetry the way the SM could have been ruled out, but you can quantify what new results say about predictions made before the machine was turned on.

4. **piscator**
February 23, 2011

Peter,

This isn't a completely accurate historical account of the development of the SM. For example there was a developed history of topless models to account for the repeated non-observation of the top quark. After all, the top quark was a basic prediction of the Standard Model which wasn't observed – and wasn't observed again – and wasn't observed again….

Sometimes the right response to an expected discovery that doesn't show up is to go to higher energies, where it will. We don't know whether the LHC will discover SUSY or not, but what is surely clear is that finally after many many years there is a machine capable of probing the TeV scale fully.

5. **Peter Woit**
February 23, 2011

piscator,

The top (like the Higgs) is an example of something not tightly constrained by the model before the experiments that went looking for it. My point was just that the SM did make dramatic, tightly constrained predictions that could not be evaded (the W and Z masses). This is very different than supersymmetry.

6. **Thomas Larsson**
February 23, 2011

I liked the first sentence in the collaboration paper.

"The results of experiments at the LHC will be make-or-break for supersymmetry."

Something to quote in 2015.

7. **Bernhard**
February 23, 2011

Peter,

I agree the SM was way more robust than SUSY in providing evidence that could not be evaded. My point was that both models however share the fact that some aspects can adapted. The SM has a minimal particle content solution, which naturally makes the necessity of things not constrained by the model much lower. The price is to leave lots of things unexplained.

The prediction SUSY makes that should not be evaded, even if shared by other BSM scenarios are particles TeV scale accessible, reason I said one should abandon it the same way they would have done it if the W and the Z were not there, as you said. The question of model determination will be very hard but in the end this is the price for a hadron collider as opposed to a linear collider.

I would also like to see a probability distribution for spartner masses, guess the best way to get this is to bet with SUSY theorists they are not capable of doing that (joke).

8. **UnderlyingEvent**
February 23, 2011

It's an interesting question – should we ditch SUSY if no hints of it are seen at the LHC? The problem is that supersymmetry appears to be a very important concept in quantum field theory – and the Standard Model is a QFT. To my mind, it would be perverse of nature not to be supersymmetric in some sense.

On the other hand, it is, to say the least, unconvincing to just dismiss lack of evidence for superpartners by saying "they must be at higher energy". It's a perfectly true statement, but where does this leave us?

I don't think the null results so far are too much of a problem for susy though. But if nothing is found in 2-3 years, it will be very interesting indeed to see how the people working in the field react. It's times like this I'm glad I work in QCD – because we know for sure that exists!

9. **Roger**
February 23, 2011

> Bernhard says: I agree the SM was way more robust than SUSY …

This is like saying that Newtonian mechanics is more robust than astrology. SM has always had huge amounts of quantitative agreement with experiment. SUSY makes no quantitative predictions, and no aspect of it has ever had any confirmation.

10. **Anonymous**
February 23, 2011

On-shell N=4 SYM: recursively solved to all orders:
http://motls.blogspot.com/2010/08/on-shell-n4-sym-recursively-solved-to.html
There's no other 4d QFT that is understood so well analytically.
This alone will guarantee that SUSY remains one of the most important ideas in theoretical physics even if a Planck-energy collider fails to find it.

11. **UnderlyingEvent**
February 23, 2011

Roger: "SUSY makes no quantitative predictions"

What do you think the LHC results are being compared to? Maybe you are thinking of string theory.

12. **A.J.**
February 23, 2011

Eh, Lubos is right on this one.

The hypothesis the LHC might disprove is that particle physics at the TeV scale is well-described by a supersymmetric theory. If LHC doesn't find evidence for a supersymmetric theory, people will continue to wonder if physics at higher scales is supersymmetric. That's their right, until someone actually does an experiment. Other people will no doubt speculate along other lines.

I doubt the idea of susy will ever go away entirely. If nothing else, it's easy to imagine a QFT class 50 years from now starting with the professor saying, 'Well, these theories aren't realistic, but it's useful to study them first, because they behave like the SubStandard Model in some respects but are easier to understand.'

13. **Roger**
February 23, 2011

> UnderlyingEvent says: What do you think the LHC results are being compared to?

They are being compared to the SM. And successfully too, as far as we know. SUSY does predict new particles, without saying much about their properties. That is a qualitative prediction, not a quantitative prediction.

14. **Eric**
February 23, 2011

Roger,

The only detailed property of the superpartners that SUSY-theories do not predict is the exact mass spectrum. This is because the mechanism of SUSY-breaking is not understood in detail. However, the masses are expected to be TeV-scale if supersymmetry is responsible for stabilizing the electroweak scale. If the superpartners are found, it will be considered a tour de force of theoretical reasoning. If not, then there is likely some other other new physics such as technicolor which will be found. The thing that must be kept in mind is that nothing will show up until the energy is raised high enough and/or enough data is collected. It is extremely foolish to draw any conclusions until these criteria have been met.

15. **chris**
February 24, 2011

"If not, then there is likely some other other new physics"

the key word here is likely. likely as judged by arguments such as naturalness.

in the case of the W and Z that were mentioned above there was no "likely". something needed to be there to make the S-matrix unitary. The SM however can provide for unitarity far beyond the Planck scale provided the Higgs mass is in the correct region.

i'd say it's a really tough call. colliders of any currently imaginable size might just not give us any new particles. we'll see.

16. **Sven**
February 24, 2011

Hi there,
two things:
1) The SM is already experimentally ruled out by the observation
(by several independent experiments) of Dark Matter – which on the other hand is automatically explained by SUSY (if R-parity is conserved).
2) SUSY, well, let's better talk about the MSSM to be specific, does indeed not make any prediction for the SUSY mass scales. However,
2a) there are firm predictions for the mass of the lightest Higgs boson. If there is no Higgs below 135 GeV the MSSM can be considered as ruled out.
2b) there are predictions using the existing experimental data. Exactly these kind of predictions, as made in the paper that Peter discussed in the beginning of this blog (and of which I am co-author), tell us that we should expect relatively low SUSY mass scales. Consequently, the new bounds by CMS and ATLAS not only move up the best-fit points, but also in the case of ATLAS worsen the fit probabilities slightly. The chi^2/d.o.f. will be an interesting measure in the future for these theories.

However, one should also keep in mind that the GUT-based versions of the MSSM under investigation right now (CMSSM, NUHM1, VCMSSM and mSUGRA) are only one special subclass of the MSSM. Other realizations might look completely different. This has hardly been analyzed so far.

17. **Bernhard**
February 24, 2011

"Dark Matter – which on the other hand is automatically explained by SUSY (if R-parity is conserved)."

Strictly speaking even if R-parity conserving SUSY is discovered that would be strong circumstantial evidence of (one of the, maybe) the origin of dark matter, but not a proof.

18. **Peter Woit**
February 24, 2011

Sven,

Thanks for the interesting comment. Given though that there's no evidence that dark matter is actually a WIMP, that's a pretty weak argument for adding a huge number of new particles and 120 or more new parameters to the SM.

Any evidence of a Higgs sector will definitely be the big news coming out of the LHC. If it contains no evidence for supersymmetry and the limits on strongly interacting superpartners continue to move up, covering almost all of the pre-LHC predicted region, I find it hard to believe that many people will continue to find the MSSM or its extensions very interesting.

19. **Peter Woit**
February 24, 2011

AJ,

I don't think Lubos's concern that theorists won't be allowed to think about supersymmetry anymore will be justified. While there are a lot of interesting aspects of supersymmetry, and supersymmetric qfts worth thinking about, the MSSM and its extensions don't seem to me to qualify. The world might be better off in a future where students aren't encouraged to spend a lot of time learning how to do calculations in this particular framework. It's quite a bit harder than in the SM, not easier.

20. **chris**
February 24, 2011

Sven,

I agree that there is a huge consensus that your arguemnt 1 is true, but it is a bit formal. strictly speaking the SM was disproven by neutrino oscilations. now for DM there is e.g. the axion possibility that carries no further implications for higher energies. if you want to make a case for the SM to be really disproven in the sense that at higher energies some new physics will show up i think the strongest point is matter-antimatter asymmetry and the associated need for B-L violation.

21. **King Ray**
February 24, 2011

Bad theories never die. They just fade away to higher energies.

22. **bad**
February 24, 2011

Bad theories indeed never die. They get ignored because alternative theories come along which can explain the facts better (and make successful testable/falsifiable predictions). Then they "die". That is what happened with phlogiston, for example. People simply lost interest.

23. **neo**
February 24, 2011

SUSY won't die, at least not easily. Here is a theory that doubled the number of possible particles, without one of them detected at pre-LHC energies. Only one thing can make physicists consider such a theory–an enormous aesthetic appeal. That appeal will keep it in the race a while yet.

24. **KD**
February 25, 2011

Anonymous:

"On-shell N=4 SYM: recursively solved to all orders:" is nice.

The question is "what theory describes the universe", not "what theory can be solved to all orders".

KD

25. **Paolo Valtancoli**
February 25, 2011

I am an expert of 2+1 gravity, which is an exactly solvable model. But unfortunately we live in 3+1 gravity… I think the same is for the idea of supersymmetry, which enhances the integrability of the model. But it is not warranted that Nature is an integrable model, and I suspect that it isn't.

Very interesting what's going on with this experimental data. Puts a lot of current grad students into a bind when deciding which area of mathematical physics to pursue…

28. **Peter Woit**
February 25, 2011

Geometrick,

If graduate students have been making their career choices based on assuming low-energy supersymmetry would be seen at the LHC, they've been making a mistake. I don't think this issue puts them much in a bind, they can pretty safely assume that the LHC won't be seeing superpartners. There never was a good reason to believe this, and this should just become more and more clear as results come in.

29. **Eric**
February 25, 2011

"…they can pretty safely assume that the LHC won't be seeing superpartners. There never was a good reason to believe this, and this should just become more and more clear as results come in."

I look forward to seeing you eat your words in a couple of years.

30. **Sakura-chan**
February 25, 2011

"I look forward to seeing you eat your words in a couple of years."

Peter has a good track record of admitting when he's wrong, something SUSY proponents seem to lack…

31. **Eric**
February 25, 2011

Dear Sakura-chan,

If SUSY is not discovered after the LHC has run for 1 or 2 years at maximum energy, I think that most proponents would admit that it is not relevant to the TeV-scale. However, this is far from the case at the present. There is a lot of parameter space available for the LHC to explore, and only very foolish people are willing to jump to conclusions. It is not possible to rule out anything yet, including ideas which are alternatives to SUSY for which data has apparently not shown up either, such as technicolor etc… For that matter, the last piece of the Standard Model has not been found yet either.

32. **Anonymous**
February 25, 2011

"If graduate students have been making their career choices based on assuming low-energy supersymmetry would be seen at the LHC, they've been making a mistake."

If based on the least optimistic assumption that LHC would find nothing significant beyond the SM, graduate students in particle physics should seriously consider alternative options, because particle physics would become a dead field, more dead than now. At least you should be mentally prepared to switch research fields in case funding for particle physics drains in future. However, this mainly applies to the phenomenology. People working on the mathematically interesting aspects of SUSY and strings would be less affected. But keep in mind that mathematical physics is always a niche in the physics department.

33. **P.**
February 25, 2011

Dear Peter,

concerning your last update, within the context of the MSSM it is no problem to accommodate neutralino dark matter and the muon g-2, and at the same time have a very heavy spectrum with TeV scale squarks and gluinos. I don't think TeV scale supersymmetry will be ruled out anytime soon. More predictive models like Msugra or the CMSSM are easier to constrain and rule out however.

In general, the results of the LEP experiments and of the Tevatron have made it clear that new physics is most likely at or close to the TeV scale, with only certain weakly interacting particles (e.g. neutralinos, sleptons) still allowed to have smaller masses. This not only applies to the MSSM but also to other models that attempt to solve the hierarchy problem and have a dark matter candidate, like composite and little Higgs models, walking technicolor, 5D gauge Higgs unification and so on. For most of these models it is somewhat challenging to find regions of parameter space that are easily accessible at the LHC and not yet ruled out either by precision constraints or Tevatron searches.

34. **Peter Woit**
February 25, 2011

P.

Thanks! My comment about muon g-2 was based on Figure 5. of the new Ellis paper that I linked to, where he shows as a pink band the region favored by the g-2 measurement. I really wish Ellis had superimposed on that figure the latest CMS/ATLAS results, but my attempt to eyeball it (and guess that the difference in tan(beta) isn't important) indicated that much of the pink region is now excluded. It's quite possible I've got this wrong. I really would love to see the pre-LHC plots of regions favored by assumptions about supersymmetry superimposed on the data.

35. **Shantanu**
February 26, 2011

Sven,
the Dark matter -> supersymmetry or vice-versa argument has been oversold. (WIMP miracle etc)
some facts :
if you assume dark matter is a non-thermal relic you can essentialy get any mass or cross-sections in order to be a dark matter candidate (axions to wimpzillas)
Also DM could be primordial black holes which also has almost nothing to do with particle physics.
Although this is not a watertightargument I claim that simple vanilla WIMP dark matter is almost close to been ruled out, given that DD experiments are reaching limits close to 10^{-43} cm^2 (which is precisly the cross-section for a particle to be weakly interacting)

36. **Sven**
February 26, 2011

Shantanu,
your arguments could be right if one would invoke SUSY just to explain DM.
However, SUSY was 'invented' for particle physics for completely different reasons, and it has many virtues. The fact that DM is easily explained, is just a free bonus.
Concerning the DD limits, also this has been analyzed in the context of the fits and those GUT based models, see, for instance, fig. 20 in http://arxiv.org/abs/0907.5568 or figs. 6,7 in http://arxiv.org/abs/1102.4585.
One can see that DD limits will be challenging in the near future, but are not very restrictive nowadays.
Another advantage of the models: they make clear and falsifiable 🙂 predictions.

37. **Bernhard**
February 26, 2011

Sven,

SUSY was invented in the framework of a theory that so far has nothing to do with reality (strings). The other big advantage it could have, i.e. to solve the hierarchy problem was killed by LEP, so the best one can say today is that it ameliorates it. This is an embarrassment for the theory, not an advantage.

The bonus of DM is very weak, as Peter pointed out.

I´m not sure about other advantages. I admit its falsifiable only if one takes the position that one has to find TeV scale particles in order to stabilize the electroweak scale. But there is no hard requirement on that too, reason why many proponents are already saying that will not give it up even if the LHC finds no clue of SUSY.

Did I forget something?

38. **Eric**

February 26, 2011

"The other big advantage it could have, i.e. to solve the hierarchy problem was killed by LEP.."

This is completely false statement.

39. **Eric**
February 26, 2011

Bernhard, I think you may be confusing the gauge hierarchy problem and the so-called little hierarchy problem. The LEP results in no way whatsoever killed the possibility of supersymmetry being responsible for stabilizing the electroweak scale, nor due the present results from LHC. However, the range of allowed Higgs mass from LEP is such that it creates a small amount of fine-tuning in the SUSY mass spectra.

40. **Bernhard**
February 26, 2011

I´m not confusing anything. The fact that LEP killed the possibility that s-particles could have the same mas as its SM cousins requires that SUSY must be broken. That introduced the little hierarchy problem which is the same thing as to say that the hierarchy problem cannot be solved, i.e., that although the electroweak scale can be stabilized (you misinterpreted me here, as I never said it could not, quite the contrary) it must do it by a little bit of fine tuning. So, that´s why I repeat. SUSY does not solve the hierarchy problem, it ameliorates it. You can call this the micro hierarchy problem if you will, but still a problem. If the theory were so great it should solve the problem by zero fine tuning not by a small amount.

41. **Eric**
February 26, 2011

Bernhard,

The hierarchy problem as I understand is equivalent to the problem of stabilizing the electroweak scale, in other words, preventing the Higgs mass from receiving large quantum corrections which push it to the Planck scale. The little hierarchy problem is due to the fact that LEP has constrained the mass of the Higgs to be > 114 GeV, whereas it has a more natural value of around 90 GeV. This causes there to be a small amount of fine-tuning in the SUSY mass spectra, but this amount of fine-tuning is not really a problem. In fact, if there ends up being a fourth-generation of fermions, the Higgs mass should be heavier.

42. **Bernhard**
February 26, 2011

Yes, I have a problem with this consensus that it is allowed to say you solve a problem by introducing a little one. I´m aware of this "understanding" people have, which for me it´s just cheating. But fine, this is polarizing into semantics not physics, since I agree with what you said. But contrary from you I believe that introducing a little bit of fine tuning for answering a problem of large fine tuning is far from great. Let´s forget how one calls it. My point: can SUSY stabilize the electroweak scale by no fine tuning and no fine tuning at all? If the answer for this is "yes", than I would retreat and admit I was wrong as this is not the information I have. If however the answer for this is "no" or "kinda", than sorry, stop calling this the little hierarchy problem and just admit the theory failed in solving the dam thing.

43. **Eric**
February 26, 2011

Bernhard,

The hierarchy between the TeV-scale and the Planck scale is sixteen order of magnitude. A model with TeV-scale SUSY cancels corrections to the Higgs mass of this order. You are complaining if the Higgs mass is roughly 25 GeV larger than the mass of the Z-boson. This seems extremely unreasonable to me. I don't know about you, but I think that a mass difference of the order of the Plack scale is much larger than 25 GeV. Just sayin'….

Equally unreasonable is Peter's claim that a theory should be able to predict the exact masses of unknown particle ahead of time, something which has almost never happened in the history of particle physics.

44. **Bernhard**
February 27, 2011

Eric,

That´s why I acknowledged SUSY ameliorates the problem (by a great deal, I can even add that if makes you happy), but if we are talking about a solution, than the 25 GeV difference is enough for complaining. You cannot expect someone to say a theory is great because it is off by only 25 GeV. What I would like to see is a real solution, something that solves the problem and afterwards you have the clear "aha" feeling that it was unavoidable. That´s not what´s happening here and everything you said, to my mind, reinforces that.

Of course there is still hope. If TeV scale SUSY is found than loop corrections to the Higgs mass will be saved almost naturally. Almost. But a real natural solution was discarded by LEP, my original point. Furthermore if on the other hand the LHC still does not find any signs of SUSY I really see not point on insisting with this theory.

45. **Peter Woit**
February 27, 2011

Eric,

The problem with the motivation for SUSY that it "stabilizes the weak scale" is that the weak scale is around 100 GeV, and the limits on superpartner masses and thus the supersymmetry breaking scale are getting close to 1 TeV. So, there's an order of magnitude problem here. This shows up in the Higgs mass as a requirement of of significant fine-tuning to get a mass above the LEP limit. I forget what the numbers are (ten percent, one percent?), but they're much larger than just 25 GeV/Higgs mass.

46. **Sven**
February 27, 2011

Fine-tuning can easily be regarded as ill-defined, since there is no measure on the parameter space. Yes, precise measurements require precise values of input parameters. This is called 'measurement'. 🙂

That the MSSM even in its most simple realizations (like the CMSSM) can easily produce a Higgs mass value high enough, was shown (again) in the paper discussed in the original post (and many others). To me it is really amazing that such simple models are in agreement with *all* experimental measurements, including (g-2)_mu and

DM.

Another good point for SUSY: in its most simple realizations (GUT based models such as the CMSSM) it correctly predicted the top quark mass many years before its discovery. The requirement of correct electroweak symmetry breaking placed m_top between 150 and 200 GeV, which is exactly correct as we know now. 🙂

47. **chris**
February 27, 2011

Sven,

"Fine-tuning can easily be regarded as ill-defined, since there is no measure on the parameter space."

how right you are! and now please tell us again why it is so great that SUSY is supposed to solve the fine tuning problem of the Higgs mass?

48. **Eric**
February 27, 2011

Peter,

If you look in any elementary textbook, you will see that the electroweak scale is stabilized by SUSY so long as the splitting between the SM particles and the superpartners is of the order of a TeV or less. Thus, your above argument is completely ill-informed and spurious. I suggest you do a better job of educating yourself on the subject.

Best,

Eric

49. **Peter Woit**
February 27, 2011

Eric,

One of many places I've learned about this is one that I went back to recently, Arkani-Hamed's talk at Strings 2005 on "HEP Circa 2010".

http://www.fields.utoronto.ca/audio/05-06/strings/arkani-hamed/

I suggest you listen to it, especially the part starting around 21 minutes in, where he discusses supersymmetry and the "little hierarchy problem". He explicitly states that the problem is that one expects the superpartner spectrum to be at LEP energies, not TeV energies.

By the way, he was expecting first collisions summer 07- winter 08 and arguing that by the end of 2008 one would certainly know if supersymmetry had any relevance to the hierarchy problem, claiming that only weeks or months of data would be needed to see squarks and gluinos if they were there and relevant to the hierarchy issue. He was far too much of an optimist about the LHC initial energy and luminosity, but still.

I suggest you contact Nima and explain to him why he's full of it and needs to better educate himself…

50. **Peter Woit**
February 27, 2011

Sven,

Interesting to see that you're abandoning the naturalness argument for supersymmetry. Arguing that it's remarkable that by doubling the number of degrees of freedom and adding 120 new parameters one can fit some conjectured new physics isn't exactly convincing.

Will your group put out a new analysis soon using the latest ATLAS paper, and showing how their results compare to your 2008 CMSSM predictions? It seems to me that your argument that CMSSM explains muon g-2 AND dark matter has likely already been blown out of the water by ATLAS. But maybe more data is needed, I'd love to see an appropriate plot.

51. **Arun**
February 27, 2011

Arkani-Hamed slides on "Approaches to the Hierarchy Problem" (PDF file, best I can tell, it is from July 2004)
http://www.sns.ias.edu/~arkani/pdfs/HierarchyAppr.pdf

52. **Sven**
February 27, 2011

Peter,
our simple realizations of the MSSM have 3 or four new parameters, not more.
Consequently, the chi^2/dof is excellent.
Our latest paper (the one that you discussed) includes already the latest official
ATLAS results (although not the one that will appear only next week 😉

53. **Peter Woit**
February 27, 2011

Sven,

The latest ATLAS paper is out this weekend, see the link I added to the posting. Get to work….

54. **Bernhard**
February 27, 2011

Sven,

You have a very selective way of arguing.

The test of a good theory is whether it can predicts. The only semi convincing point you gave in the earlier post was the prediction of the top-quark mass, but this is a half merit since the particle itself was predicted by the SM.

The cherry on top is abandoning naturalness and at the same time brag that the model can “easily produce a Higgs mass value high enough”.

55. **Eric**
February 28, 2011

Peter and Bernhard,

The current constraint on the Higgs mass in three-generation SUSY models is that it should be less than 130 GeV. A Higgs mass of around 120 GeV is well within this range, and so I believe it is completely incorrect to claim that this somehow makes a SUSY solution to the hierarchy problem unnatural. If the experimental Higgs mass limit ends up being pushed above 130 GeV, then perhaps this will be the case, but until then I think it would be a good idea for you to stop exaggerating the issue.

As for Arkani-Hamed, I believe that he was also exaggerating the problem in the talk you mentioned in order to sell his own alternative models. Other theorists such as Ellis would disagree with him, as do I.

56. **M. Wang**
February 28, 2011

I am a financial statistician. Just want to point out a problem in Sven’s latest comment here.

You seem to be saying that your latest model has only 3 or 4 parameters and therefore can produce quite decent statistical significance. This is actually a common folly in the trading business. People spend months looking for the “right” model that gives high R^2. They forget that their own efforts at excluding unsuccessful models should be taken into account. This is called the data-mining problem. Even in a theoretical framework with zero predictive power, careful structuring of the model can always generate nominal statistical significance to any degree you want, as long as you look hard enough.

57. **Anonymouse**
March 5, 2011

Sven,

You might not want to go too far down the path of arguing against naturalness considerations. The fact that (as you yourself argued above) even the MSSM has an upper limit on the Higgs mass is only because someone like you has chosen to apply an upper limit to the stop masses.

Make the stop masses the GUT scale, and you can get essentially any Higgs mass you like (within reason of a perturbative quartic). Then your favorite “prediction” of the MSSM fades away.

58. **Jaykov Foukzon**
March 5, 2011

SUSY has no reliable and clear physical motive. It has arisen only from desire some mad Russian mathematicians
http://ufn.ru/en/articles/2001/9/f/
to expand a class of renormalizable models of canonical QFT. But mathematic does not work if basic physics idea Not Even Wrong.

59. **Christopher Lester**
March 7, 2011

There are some comments in this blog asking to see the effect of the lastest ATLAS 0-lep susy exclusion data on the CMSSM fit … if you are still interested, see the first paper on that topic here:

http://arxiv.org/abs/1103.0969

(btw – I should declare a self interest as an author in the above)

60. **Peter Woit**
March 8, 2011

Thanks Christopher,

If I’m not mistaken, figure 3a in your paper answers the question I’ve been asking about comparing the ATLAS exclusion results to earlier estimates of SUSY parameters. It looks like very roughly half of the probability-weighted parameter space is now excluded (although a much smaller fraction of the size of parameter space). Presumably over the next year or so we’ll see results that cover much of the rest…

61. **purple**
March 8, 2011

Thanks for taking the time to discuss and share this with us

62. **Jaykov Foukzon**
March 11, 2011

Physicists joke again:

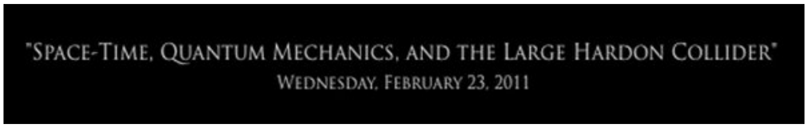
Extra dimensions of space, for instance, which are predicted in many forms of string theory (a variant called M theory requires 10 spatial dimensions rather than the familiar three), could be accessible at the Large Hadron Collider (LHC), said Barnard College physicist Janna Levin. In the LHC’s unprecedentedly high-energy experiments, some products of particle collisions could go missing, having vanished into those extra dimensions.

http://www.scientificamerican.com/ar…SA_DD_20110310

Space-time, Quantum Mechanics and the Large Hardon Collider

February 28, 2011
Categories: Favorite Old Posts, Uncategorized

The title of the posting is that of Nima Arkani-Hamed's public lecture last week at the IAS, with the spelling that of the title at the beginning of the video (available here, lower resolution version here).



The bulk of the talk is devoted to expounding the idea that the central problems of fundamental physics are two hierarchy problems, that of the CC (why isn't it at the Planck scale?) and that of the Higgs mass (why isn't it also at the Planck scale?). Given that we don't understand quantum gravity, and don't know that the Higgs phenomenon is due to an elementary scalar, it's not clear to me that these are yet real problems. In any case, Arkani-Hamed gives the anthropic multiverse argument for the CC problem, and claims that if the LHC doesn't see supersymmetry or large extra dimensions, then we're stuck with the anthropic multiverse argument also for the electroweak scale.

The LHC only puts in an appearance in the last fifteen minutes of an hour and a half talk. Back in 2005 (see his talk at Strings 2005) Arkani-Hamed claimed that we would know whether supersymmetry solves the hierarchy problem within a year or so of first collisions at the LHC (then scheduled for summer 2007). Now that initial results from the LHC are in, showing no evidence of supersymmetry, his estimate is:

> We're going to have answers one way or another to this question on the time scale of 2020.

One of his slides estimates production of 1 squark/minute given 1 billion collisions/sec, which would mean about 50 squarks already produced in each detector. While it's true that the LHC won't be running at full energy until 2014, no explanation is given for why we need to wait until 2020 to find out about supersymmetry. Back in 2005, before the machine was turned on, enthusiastic predictions of quick results were being made. Now that the data is coming in, the story seems to have changed.

Update: Nature News has a new article up by Geoff Brumfiel: Beautiful theory collides with smashing particle data (also available here). While Arkani-Hamed is arguing that one will have to wait until 2020 (the sLHC perhaps?) before knowing whether supersymmetry is at LHC energies, John Ellis appears willing to give up much earlier, maybe the end of next year:

> "I'm wouldn't say I'm concerned," says John Ellis, a theorist at CERN, Europe's particle-physics lab near Geneva, who has worked on supersymmetry for decades. He says that he will wait until the end of 2012–once more runs at high energy have been completed–before abandoning SUSY. Falkowski, a long-time critic of the theory, thinks that the lack of detections already suggest that SUSY is dead.
>
> "Privately, a lot of people think that the situation is not good for SUSY," says Alessandro Strumia, a theorist at the University of Pisa in Italy, who recently produced a paper about the impact of the LHC's latest results on the fine-tuning problem. "This is a big political issue in our field," he adds. "For some great physicists, it is the difference between getting a Nobel prize and admitting they spent their lives on the wrong track." Ellis agrees: "I've been working on it for almost 30 years now, and I can imagine that some people might get a little bit nervous."

The article ends with a very sensible quote from experimentalist Chris Lester, who evidently doesn't share Arkani-Hamed's view that it's SUSY or the Multiverse:

> "Plenty of things will change if we fail to discover SUSY," says Lester. Theoretical physicists will have to go back to the drawing board and find an alternative way to solve the problems with the standard model. That's not necessarily a bad thing, he adds: "For particle physics as a whole it will be really exciting."

Update: It seems that the video files have been temporarily removed, presumably for editing. I fear that some poor tech person is having a bad morning…

Update: New video files with typo fixed are now available.

Comments

1. **Kea**
   February 28, 2011

   AAAARRRGH! Nima of all people should be taking the twistor geometry message seriously: ie. the right spaces for calculating twistor amplitudes depend on particle number and holographic principles, NOT on an a priori local spacetime with fairy fields attached.

2. **Chris Oakley**
   February 28, 2011

   Right – at first I thought that there was a Large Hardon Collider that fulfils all Nima's dreams/fantasies. Now I realise that it is probably a mis-spelling.

3. **anon**
   February 28, 2011

   Much in the same way that God implanted fake dinosaur bones in the ground as a test of faith, so too has SUSY arranged to trap the unfaithful. The likes of Ellis will abandon hope over the next few years, and will be left behind when the super-Rapture arrives in 2020.

4. **Thomas**
   February 28, 2011

   So SUSY or nothing for Arkani-Hamed?
   How many more physicists will give up on their field if there is no SUSY?
   What a waste of talent and experience it is, to just throw up your hands like that.
   What a perverse way of saying that you are wrong; to say that there is no answer.
   And what an arrogant way to do physics; to claim the unknown and call it yours.

5. **realistic**

February 28, 2011

Let's not get carried away with `Hardon'. Tim Bishop, a Congressman for Long Island, NY, USA, is fighting against budget cuts which might cost 930 jobs at BNL. He speaks of the negative impact this would have on the "Realistic" Heavy Ion Collider.

http://northshoresun.timesreview.com/2011/02/6698/breaking-news-bishop-says-gop-budget-cuts-would-cost-bnl-1000-jobs/

"It could also result in BNL shutting the doors on the National Synchrotron Light Source (NSLS) and Realistic Heavy Ion Collider (RHIC) machines, world class research facilities," according to a Bishop press release.

One can laugh, or scoff, but that will be small comfort to the 930 jobless at BNL. Even smaller comfort of you're one of them. And it *will* be a real loss for science, realistic or not.

6. **Peter Woit**
   February 28, 2011

   realistic,

   I'll try and write something here about the current situation of the US federal budget when it becomes a bit clearer what the implications for science are, and suggest comments on this topic should wait until then. At the moment, as far as I can tell, no one knows what will happen, with the extreme House budget presumably DOA, and legislators fighting over government funding not for next year or next month, but for this weekend. Strange way to run a society…

7. **Shantanu**
   March 1, 2011

   Peter or others, what about other implications for models such as technicolor, Little higgs models etc based on current LHC data?

8. **Geoff**
   March 1, 2011

   Shantanu, many little Higgs models predict W' and Z' bosons, and they have been ruled out up to fairly large mass values.

   The experimental situation is simply that there is no deviation from the standard model at all, whereas all theoretical models predict such deviations.

   Both the Higgs and supersymmetry were predicted because the standard model cannot be all there is. Now experiments are showing the opposite. The only thing one can do, if really nothing is found, is to go back to these predictions and check whether they are water-tight.

   In a sense, this is what Peter is doing, especially when he criticizes the supersymmetry fans.

9. **csrster**
   March 1, 2011

   In case anybody is interested:
   http://www.googlefight.com/index.php?lang=en_GB&word1=large+hadron+collider&word2=large+hardon+collider

10. **Bernhard**
    March 1, 2011

    Peter,

    Thanks for the news and the video. One thing I find worth discussing is Alessandro's comment "This is a big political issue in our field,"

    It's a interesting point because many people in power right now are SUSY or string proponents and I just hope more people will be willing to take Ellis's example and throw the towel if SUSY is not found at the LHC.

    At the same time what gives me really high hopes is that eventually these people will go into pension and the new generation will not swallow theories so experimentally discredited (if that really happens, of course). This is the same problem of the multiverse "revolution", a movement of old theorists giving up altogether to impose that if they couldn't make it than the answer is likely that there is no answer.

11. **Bernhard**
    March 1, 2011

    Shantanu,

    I think nothing really conclusive (at least not new) can yet be said about these models. Differently from SUSY, 35 pb-1 are not enough to improve limits in a significant way:

    Have a look:

    http://arxiv.org/abs/hep-ph/0402037

    http://cdsweb.cern.ch/record/1259930/files/

12. **fatdog@yale.edu**
    March 1, 2011

    Very smart people whose main concern is winning a Nobel Prize usually finish their unimaginative careers as deans.

13. **SUSY**
    March 1, 2011

    The news of my death have been greatly exaggerated.

14. **Giotis**
    March 1, 2011

It’s not a coincidence that both explanations (SUSY, anthropic) are provided by String theory. This is because String theory is currently the only consistent theoretical framework with enough explanatory power to provide potential answers to such deep questions.

15. **Jens**
March 1, 2011

Giotis,

Or perhaps String Theory has so little explanatory power that it’s consistent with anything.

16. **Tom**
March 1, 2011

I amnot a SUSY advocate & have worked on many BSM ideas over the years so will claim to be an agnostic as to what new physics exists beyond the SM. However it is fair to point out that SUSY is NOT mSUGRA (or even the MSSM). If you give up on the very simple mSUGRA idea there is plenty of parameter space still available where sparticles can be light & missed (so far) by the LHC. The problem is that (the 4-parameter) mSUGRA has been pushed so hard for so long by advocates that people forget about this.

17. **Peter Woit**
March 1, 2011

Tom,

The initial data has ruled out only a part of even the CMSSM region in parameter space promoted as most likely, so it’s certainly too early to announce the death of SUSY. But, presumably over the next couple years we’ll see much of the rest ruled out, as well as other parts of parameter space.

Since the MSSM parameter space is so large (and extensions of it even bigger), SUSY diehards will be free in coming years to keep pointing out that possible places for it to hide remain. While this is going on, it seems to me a good idea to look at what the same people were saying before LHC turn-on. I found the difference between Arkani-Hamed 2005 (answer 1 year after first collisions) and Arkani-Hamed 2011 (answer 10 years after first collisions) quite striking, and not fully explicable by the fact that the initial run is at half energy and luminosity is ramping up more slowly than some might have expected.

18. **chris**
March 1, 2011

the tension is mounting not because susy is under scrutiny – our understanding of physics is. regardless of what it might be, we did not see any sign of new physics at LHC yet – safe for some high multiplicity and heavy ion stuff.

the news is not so much that susy is still not found but that it takes a pretty darn large stick to beat old standard model dead at the energy frontier.

19. **SUSY**
March 1, 2011

People get a bit impacient, don’t they? SUSY is dead with this little integrated luminosity? Gimme a break!

20. **Bernhard**
March 1, 2011

I didn´t save Nima´s talk. Can someone share?

21. **Somdatta**
March 1, 2011

Susy will most definitely be found.

22. **Peter Woit**
March 1, 2011

Bernhard,

Sorry, but I don’t think I should use this blog to provide or exchange info about bootleg copies of something belonging to the IAS. I’m assuming that they’ll soon provide the full video again themselves, after a very small amount of editing…

23. **Bernhard**
March 1, 2011

I understand, Peter.

24. **Giotis**
March 1, 2011

If somebody is interested in the anthropic alternative (a la Bousso-Polchinski) to low SUSY for solving the hierarchy problem, Higgs mass etc, he could check this original paper by Silverstein http://arxiv.org/abs/hep-th/0407202. It is well known that low SUSY was never a prediction of String theory. It is just a reasonable hypothesis; a bonus if you like. SUSY could break at String scale for example as the paper explains.

25. **Bernhard**
March 1, 2011

Giotis,

If low SUSY was never a prediction from String it´s even worse. SUSY is a testable theory by the prediction of TeV scale particles. If you are not a fanatic neither pro or against it, one can even say that it can be ruled out. Part of the problem Peter is trying to draw attention to, I believe, is regarding the sudden efforts by some of its leaders to change their minds about this. But that´s point particle theoryl, where one can discuss, agree, disagree and make bets but in the and it will be up to the LHC to define, if SUSY, technicolor or something else.

With Strings there are no tests to be made, since the theory cannot be falsified. You can get any answer you want. If SUSY is there, good for Strings, if SUSY is not there good for Strings too.

26. **Chris Austin**
March 1, 2011

chris,

"safe for some high multiplicity … stuff"

Are you thinking of the right-hand graphs on pages 8 and 9 of [ATLAS-CONF-2010-088](), or is there something else at high multiplicity? And if so, where?

Thanks in advance

27. **Peter Woit**
March 1, 2011

Giotis/Bernhard,

For a while 6 or more years ago, Susskind, Douglas, Dine and others were quite excited about the idea that string theory could predict the SUSY breaking scale statistically: you count "string vacua" and take into account anthropics. It quickly became clear this doesn't work, see for example

http://www.math.columbia.edu/~woit/wordpress/?p=182

Like everything else, the SUSY breaking scale can be absolutely anything at all in string theory, with no way to decide among the possibilities. There is one thing predictable here though: if susy does show up at LHC energies string theorists will claim this was a prediction of string theory, but if it doesn't they'll claim that string theory made no such prediction.

28. **chris**
March 2, 2011

Chris Austin,

i was thinking about the CMS observation – it is e.g. the first reference in a paper by Shuryak arXiv:1009.4635.

most likely it is the first observation of a QGP in pp colissions, so nothing too exciting, but kind of new physics in some sense.

29. **Chris Austin**
March 2, 2011

Thanks

30. **Roger**
March 2, 2011

> Geoff says: Both the Higgs and supersymmetry were predicted because the standard model cannot be all there is.

That is true about Higgs, but not supersymmetry. Supersymmetry was predicted for entirely aesthetic reasons, and not because of any standard model shortcoming.

31. **Eric**
March 2, 2011

Roger,

Supersymmetry is predicted because it provides a solution to a big problem in the Higgs sector of the Standard Model. A Higgs which is a fundamental scalar receives large loop corrections which should push its mass to the Planck scale. These corrections may be cancelled by introducing supersymmetry partners. This is called the hierarchy problem and is one of the main topics mentioned in this post.

32. **Roger**
March 2, 2011

Yes, the post talks about the hierarchy problem, and beliefs that people have about it. But it is not a problem with the SM or with any experimental outcomes. It is only a problem with the beliefs that some people have. If I am wrong, please point me to something that shows that I am wrong.

33. **Eric**
March 3, 2011

Roger,

No, the hierarchy problem is not about belief. It is quantifiable, mathematical problem with the Standard Model + Higgs. SUSY provides one way of solving this problem. It is not the only solution, just the one that has been considered most likely. I think what you may be trying to say is that it is a theoretical problem rather than a problem with experiment.

34. **Roger**
March 3, 2011

I am not sure why you would rather call it a theoretical problem than a problem about beliefs. It is not even a theoretical problem unless you have certain unverified beliefs about how things ought to be. At any rate, I guess that you are agreeing that it is not a problem with any observed physics.

35. **Bernhard**
March 3, 2011

Eric,

As you already know some people disagree that SUSY offers a solution to the hierarchy problem, and as you also know I include myself among them. But in any case let's not go there, as we know each others arguments (but I believe you agree with me this is a clear object of dispute).

In any case: “not the only solution, just the one that has been considered most likely.”

Likely by whom? Are you talking about Ellis, Arkani-Hamed et al? Sure. Or are you talking about particle physics community? Then, not so sure.

By the way, what is the likelihood of this “solution” being right given the already amount of fine tuning needed? 10%? 50%? 90%?

Let me know, since you see this as a clear “quantifiable, mathematical problem”…

36. **Eric**
March 3, 2011

Bernhard,

Yes, I would assert that supersymmetry has long been considered by the particle physics community as a whole as the most likely solution to the hierarchy problem since at least the 1980’s. The only other serious contender is technicolor, but it has had problems satisfying precision electroweak measurements, as well as other issues. More recently, there have been solutions involving warped extra dimensions, and there is always the possibility of (drastic) fine-tuning with just the SM.

The degree of fine-tuning in minimal supersymmetric models required at present is rather mild, of the order of 10%. It is still very easy for SUSY models to satisfy all experimental constraints and produce a Higgs mass ~115 GeV. If there happens to be additional couplings which are ignored in the minimal models, even the 10% degree of fine-tuning can go away.

37. **Peter Woit**
March 3, 2011

What I’ve found surprising, for about 30 years now, is that the “hierarchy problem” has been considered something especially significant. It’s only a problem if you have a unified theory you believe in, with quantum gravity at the Planck scale, and electroweak symmetry breaking due to the dynamics of an elementary scalar at the 100 GeV scale. If you don’t think you understand quantum gravity and how it unifies with the SM, or if you think electroweak symmetry breaking may be due to something more interesting than an elementary scalar, there’s no problem. Put differently, if you don’t think you understand what is responsible for the electroweak scale or the Planck scale, that they’re very different is not a “problem”, it’s just part of what you don’t understand.

38. **Eric**
March 3, 2011

Peter,

The hierarchy problem is a problem in QFT with the Higgs being an elementary scalar. If this is the case, then the Higgs mass will receive large quantum corrections, regardless of whether or not we understand anything about quantum gravity. Unless there is some low-energy scale at which these corrections are cut-off, then there is no reason why the electroweak scale should be ~100 GeV, rather than some arbitrarily high energy.

39. **Peter Woit**
March 3, 2011

Eric,

Sure, the whole set-up of electroweak symmetry breaking via an elementary Higgs field, with weak-couplings that make perturbation theory valid, has a fine-tuning problem. This just seems to me an argument that probably something more interesting is causing electroweak symmetry breaking. Hopefully the LHC will soon start giving us hints about this.

40. **Seesaw**
March 3, 2011

A simple seesaw already shows clearly the hierarchy problem. No need of quantum gravity or GUTs.

41. **Peter Woit**
March 3, 2011

Seesaw,

Again, that’s a hierarchy problem you’ve introduced by introducing some speculative new physics at a speculative new energy scale. Until we have some better evidence for that new physics, it seems to me the “hierarchy problem” is with your speculation, not with the physics we know about.

42. **Bernhard**
March 3, 2011

“Supersymmetry
The most popular model beyond the Standard Model
is unquestionably supersymmetry. Its motivation is to
ameliorate, not solve, the gauge hierarchy problem.”

This is from Frampton in 1997:

http://arxiv.org/PS_cache/hep-ph/pdf/9706/9706237v1.pdf

I think that opinions changed drastically after LEP, so I strongly disagree with your vision about what people in general think about SUSY solving or not the hierarchy problem. But OK, this is not a very solid thing to discuss.

But Peter has as point. This is a problem only if you are sure that electroweak symmetry breaking is caused by some scalar field, that by the way, unless you are talking about bound states, was never seen in nature at all.

You create a solution to a problem (hierarchy), that solutions has another problem (large quantum corrections to the particle that its essential for your solution (Higgs) and to solve this you create a trick that should solve everything (supersymmetry). If the trick is true you should see evidence of it, but you don´t. So you accept the fact that the trick is not perfect (little hierarchy problem) and go on.

One begins to wonder if your original solution to the electroweak breaking was correct in the first place. Perhaps there is something else that you missed and makes the need for constantly repairing the theory unnecessary. I don´t have this solution (unfortunately) but it´s conceivable that the LHC data will gives us a good hint.

43. **Roger**
March 3, 2011

I looked at the above Frampton paper. He explicitly says that the motivation for susy is “not from the physics end. It does seem, on aesthetic grounds, that supersymmetry is likely to be used by Nature in Her fundamental theory.” From this I conclude that susy is only likely if you have certain mystical beliefs. If I am wrong, I would like to see the paper showing that I am wrong.

44. **Bernhard**
March 3, 2011

Roger,

I believe what Eric was trying to say is that if you assume that the cause of electroweak symmetry breaking is a scalar field, then you have a mathematical problem, for you expect a number and you get another one that is way larger than this expectation. This is not a mystical belief. It´s to solve this discrepancy that people invented supersymmetry and if it´s elegant or not, well depends who is looking at. Now, if you should assume that the origin of the electroweak symmetry breaking is indeed this scalar field in the first place is a whole different story, as this might well be the wrong assumption. But this assumption is not mystical in nature.

If you want to see mystical assumptions in physics talk with String theorists since their best argument seems to be a mystical feeling that the theory is right and that non believers in Witten are infidels 😀 .

45. **Eric**
March 3, 2011

Bernhard,

Yes, I agree with you that the argument that SUSY solves the hierarchy problem is on less solid ground since LEP and also with the latest results from the LHC. This undoubtedly causes some people to worry, probably more than they should at this point. My point is that SUSY still can solve the hierarchy problem, though not as naturally as before. However, it is still the best and most likely solution to the hierarchy problem.

You and Peter are absolutely correct that the hierarchy problem arises only if the Higgs is a fundamental scalar. Technicolor models attempt to avoid this by having the Higgs be a composite state of some strongly coupled sector. Other variants of this idea are top condensates.

I should also say that there is no requirement that SUSY must solve the hierarchy problem in a completely natural way. The important thing is that it can get the job done.

46. **Seesaw**
March 4, 2011

Eric says “From this I conclude that susy is only likely if you have certain mystical beliefs.” What you call mystical beliefs other people call beauty and theoretical ingenuity. It can fail but it can also bring glory. Examples abound and they should be familiar to all the readers of this blog.

47. **Seesaw**
March 4, 2011

Sorry Eric, I meant Roger!

48. **Seesaw**
March 4, 2011

By the way, it would be good that those impatient people who want to prematurely exclude SUSY remember the long story of failed expectations regarding the top mass value. Of course the theoretical need for the existence of the top affects the picture. Take that need out and many people would have considered the top as a purely mythical belief and bla bla bla. History repeats itself.

49. **Emile**
March 4, 2011

Hi Peter,

There is something I don’t get about what you wrote: “Again, that’s a hierarchy problem you’ve introduced by introducing some speculative new physics at a speculative new energy scale. Until we have some better evidence for that new physics, it seems to me the “hierarchy problem” is with your speculation, not with the physics we know about.”

Maybe it is just some distinction between the hierarchy problem and the naturalness problem.

As you know, the SM, something we’ve tested quite well, includes a scalar field. If we don’t find that scalar field, the SM is wrong. You also know that the corrections to its self-energy increase in proportion to the energy cutoff you use. I don’t need to introduce speculative new physics or hierarchies for this statement to be true. Nothing in the SM prevents me from doing calculations at high energies. Nothing in the SM says that I can only use it below 1 TeV or 100 TeV or whatever. So the SM has a theoretical problem in that the Higgs’ mass is “unnaturally” small. It could be that this is just the way the Univserse rolls… Of course, anthropic arguments will immediately explain the fine tuning 🙂

50. **Peter Woit**
March 4, 2011

Emile,

I’m not sure what your question is…

One point is that the “naturalness” problem is just one of several reasons to be unhappy with an elementary scalar Higgs (others are the renormalization group behavior of its couplings, and the way Yukawa couplings are arbitrary). It might be a good idea to wait and see if the LHC shows the Higgs to be an elementary scalar at TeV energies, or gives us a hint about something more interesting. If it still looks like an elementary scalar, I’ll still be unhappy about the state of the theory, with “naturalness” not the most serious problem to my mind.

If you instead want to look at the problem as a "hierarchy problem", i.e. why are two hugely different energy scales kept separate, you first need to be sure there's a second energy scale (i.e. we have no actual evidence for GUT or Planck scale physics).

51. **Bernhard**
March 4, 2011

"If we don't find that scalar field, the SM is wrong."

Emile,

That´s not true. Would mean only that we got wrong this specific sector of the model. It ´s like having U(1)-q X SU(WRONG). If SU(WRONG) is wrong does it mean that QED is wrong? Of course not. So of course it is conceivable to have the SM with another origin for electroweak symmetry breaking.

52. **Emile**
March 4, 2011

Bernhard,

I guess we have a different definition of what is commonly referred to as the Standard Model. Take most (any?) text books and what constitutes the SM is clearly defined: SU(3)xSU(2)LxU(1)Y, has 3 generations of fermions, a Higgs boson etc. If you want to extend this definition to the point where we can get the the gauge groups wrong, and still call it the SM then I guess it is up to you. Not finding the Higgs would mean that many text books would need to be revised… I really like the fact that the SM (according to my definition of what the SM is) has a scalar field in it and that I can go and look for it and possibly exclude it. That you could still say that the SM is alive and well even if we don't find the Higgs is precisely what I don't like about certain theories. You can't kill them…

53. **Emile**
March 4, 2011

Peter: I guess I was trying to make the point that there are theoretical issues with the SM even without the need to speculate about new physics or other energy scales. I thought what you wrote sounded as though we only ran into problems with the SM if we assumed physics beyond the SM.

54. **Bernhard**
March 4, 2011

Sigh..

I was really hoping here that you would not come with this "argument".. If you want to discuss the label SM fine. Then you are saying that if I come up if a model that has exactly the same fermion, quark, group sector, everything and has a different mechanism of electroweak symmetry breaking that actually INVALIDATES, i.e., makes it wrong (if you want to be picky about wording here it goes too) that other model identical to the first one in every single aspect but this sector? OK, then with this twisted way of seeing things and with a precious caution about how you name it and nothing else in mind but this, then I guess you´re right. My bad.

55. **Eric**
March 4, 2011

Dear Bernhard,

It might help if you actually specified the alternative to the Higgs mechanism that you are thinking about and said something about whether or not this can be fit into the minimal SM as is. Also, please enlighten us as to whether or not your alternative mechanism can do completely the same job as a fundamental scalar and still satisfy experimental constraints.

56. **Giotis**
March 4, 2011

Peter really, what do you mean when you say "speculative new physics at a speculative new energy scale"?

I don't suppose you imply that maybe the SM is all there is? Do you?Regularization is not a trick, is the admission of the SM that it holds up to a certain energy scale. Without this admission it wouldn't make any sense.

57. **Peter Woit**
March 4, 2011

Giotis,

My problem is with arguments like: "we must explain why the electroweak breaking scale is so much smaller than the GUT scale!" or "we must explain why the electroweak breaking scale is so much smaller than the Planck scale". We have no evidence at all for what physics is like at those scales, just speculation about their significance. Claiming that you've identified one of the most important problems in fundamental physics, but basing it on some purely speculative sector of the theory that you have no evidence for seems to me unconvincing.

The question of how high in energy we can extrapolate the SM before running into various problems is certainly interesting, but seems to me different than the usual "hierarchy problem".

58. **Bernhard**
March 4, 2011

Eric,

The SM is a model composed of parts, parts that fit together but even the anomaly cancellation is "trivial" (in the sense that they are applied separately for each family) and the Higss sector appears as an almost plug-in accessory that sophisticated and clever as it is, might be incorrect. I really don´t think that it is correct to affirm that not finding the Higgs makes all the success in explaining every single experiment so far a failure, because statements like "if we don´t find the Higgs the SM is automatically wrong" pass this idea. I think it is conceivable that this specific mechanism could be clever but wrong, and my original discussion with you was the need for SUSY, a theory with problems of its own, to correct it. So the SM Higgs create something already begging for physics BSM, and I´m just saying that this might be actually a longer shot away from the SM that is actually needed, but of course I don´t know that, SUSY, Higgs and cia might all be there and and if that happens to be confirmed by experimental evidence I will happily acknowledge it. I however I´m not so much without imagination to think that an alternative is impossible and even if it happens to be a solution less simpler than the Higgs I will not have a sudden epiphany that the SM is completely wrong since its precious Higgs was not found.

59. **Eric**
March 4, 2011

Hi Bernhard,

I certainly agree with you that there are alternatives to the simple Higgs mechanism which don't involve a fundamental scalar. The problem with these, generally, is they also introduce a lot of BSM physics which introduces problems of their own. For the most part, these problems are much more severe than a SUSY + Fundamental Higgs scalar solution. However, it is not at all impossible that LHC will find technifermions or something similar which will point directly to something besides SUSY. Personally, my opinion is that if the simplest ideas with a three generation SM + fundamental Higgs + SUSY doesn't pan out, then the most likely possibility is that in addition to the above there is a fourth generation. Because of the large Yukawa couplings required for the fourth generation, the fourth generation quarks become strongly coupled and can play a role in EWSB. In any case, what we know is that it's extremely unlikely that the SM is all there is, unless things are just extremely fine-tuned.

60. **Bernhard**
March 4, 2011

Eric,

"In any case, what we know is that it's extremely unlikely that the SM is all there is"

Agreed 100%!!! 🙂

61. **Roger**
March 4, 2011

Seesaw says that what I call mystical beliefs, other people call beauty and theoretical ingenuity. Maybe so, but I don't see any good reason to doubt that the SM is all there is.

62. **Anonymouse**
March 5, 2011

The Standard Model includes the Higgs. Like it or not, that is the definition. No Higgs means no Standard Model.

The hierarchy problem is nothing more than fine tuning. As Peter correctly has stated, it is not a problem unless there is some kind of high scale physics beyond the Standard Model. I personally think it is likely something like that exists, but there is no evidence as of yet.

The Standard Model includes exactly one dimensionful parameter, which is the Higgs mass parameter (or alternately, the VEV which determines the Z and W masses). There are no large quantum corrections to it. What you call large quantum corrections are just the renormalization required to move from an unphysical number in a Lagrangian to a physically measurable quantity (such as any of the masses listed above).

Even perturbative gravity is soft, and does not correct the Higgs mass parameter by a positive power of M_Planck. (Gravitational couplings are negative powers of M_Planck). Of course, there may be non-perturbative gravitational phenomena which upset this, so the best we can do is to say that there is no obvious contribution to the Higgs mass from quantum gravity. Without a verified quantum theory of gravity at small distance scales, there isn't much more one can say.

But once there is new physics with massive particles, such as super-particles, stringy states, GUT bosons, right-handed neutrinos for a seesaw, or anything else with a relevant interaction with the Higgs, the hierarchy problem exists. So it is fair to say that SUSY must first create the problem before it solves it.

If we see some clear sign of heavy physics, any at all, this situation will change. Neutrino masses don't work because there need not be any heavy new degrees of freedom.

63. **Bernhard**
March 5, 2011

Anonymous,

I agree with your point. I was imprecise to exclude the Higgs in the framework of the SM so I take it back. Emile, I acknowledge you also had a point. I guess I just wanted to say I didn´t want to have a pointless discussion about naming, since if want really to be picky neutrinos oscillations, even if they don´t include new degrees of freedom are enough to say we have physics BSM and that neither this nor an absence of a Higss sudden turn the

64. **Bernhard**
March 5, 2011

(sorry, sent too early)

SM wrong. I agree however that the absence of the Higgs would require solving a much harder puzzle to maintain the SM minimally affected. That is, a new mechanism of electroweak symmetry breaking that does not destroy the current structure is a a tough problem.

65. **Bernhard**
March 5, 2011

…and a just extending a little bit the last thing I want to say about this, neutrino oscillations for example already require a significant change in the SM since something that was supposed to be conserved (lepton family number) was violated. One can require total family number still to be conserved but that´s characteristic already of many BSM models, like the 331 model.

66. **OhDear**
March 5, 2011

"something that was supposed to be conserved (lepton family number) was violated"

Sure, but what do you mean by "supposed to be" ? Before we found neutrino oscillations it just happened to be true that lepton family number was conserved. Then it turned out it wasn't true, and I'm tempted to say "big deal". The essence of the standard model is the gauge group, the specification of the matter particles, and the higgs mechanism. All else is just detail. Neutrino masses can be accomodated in the same way as quark masses. Mind you, nobody really believes that the SM way of giving fermions masses is correct.

And to Roger, who sees no reason why the SM cannot be all there is – what about gravity? There is no gravity in the SM.

67. **Bernhard**
March 5, 2011

ohdear,

you should have followed the discussion, not my isolated comment before trying to be clever…

Sure I also don´t give a dime for lepton family conservation, but if you want to be precise about how the SM was DEFINED, then it was defined with a massless neutrino and a massive neutrino represents a violation of this definition. If it is to be precise and consistent I can agree, but then let´s be consistent to what the model defined not matter what.

68. **Bernhard**
March 5, 2011

and by the way, not giving a dime to lepton family number conservation can be very significant depending on the how you see it. If for example the decay "mu–> e + gamma" were to be observed you are forced to say you STILL haven´t seen any violation of the SM since you suddenly changed your mind that this principle can easily be thrown out of the window. I think most experimentalists would disagree with you on that.

69. **OhDear**
March 5, 2011

Bernhard, my point was that the SM is *not* defined to include lepton family number conservation. But you make a good point about "mu–> e + gamma". That would be a big result, but wouldn't violate my (perhaps too narrow) definition of the SM.

Short Items

March 6, 2011
Categories: Uncategorized

- There's a wonderful interview at the Notices with last year's Abel Prize winner John Tate (video here). He blames the fact that his name is on so many mathematical results and concepts on Serge Lang. The 2011 Abel Prize winner will be announced on March 23rd.
- Sir Michael Atiyah's February 1 talk at the College de France titled *A Geometer Explores the Universe* is now on-line.
- Through the intervention of mathoverflow.net, Barry Mazur managed to retrieve a copy of his 1963/64 unpublished paper that first promoted the idea of an analogy between prime numbers and knots in a 3d space.

> In 1963 or 1964 I wrote an article Remarks on the Alexander Polynomial) about the analogy between knots in the three-dimensional sphere and prime numbers (and, correspondingly, the relationship between the Alexander polynomial and Iwasawa Theory). I distributed some copies of my article but never published it, and I misplaced my own copy. In subsequent years I have had many requests for my article and would often try to search through my files to find it, but never did. A few weeks ago Minh-Tri Do asked me for my article, and when I said I had none, he very kindly went on the web and magically found a scanned copy of it. I'm extremely grateful to Minh-Tri Do for his efforts (and many thanks, too, to David Feldman who provided the lead).

For more about this fascinating topic, see a summary by Lieven le Bruyn here.

- LHC beam commissioning is now in progress, it is supposed to start colliding beams for physics again in another week or so.
- In the Dark Matter world, all eyes are on Xenon100, waiting to see what their results will be. Nature News has an update here. Next week Elena Aprile will be speaking at NEUTEL11 (which has a blog here) and revelations may occur.
- This year's Asimov debate is on the topic of string theory and whether there's any hope for a unified theory. I'll have to miss this, I'll be at local bookstore Book Culture introducing Richard Panek who is giving a talk there that evening about his recent book that I wrote a review of for the Wall Street Journal. I'll be curious though to hear from anyone who does go to the debate what they thought of it.
- Blogging may become more sporadic over the next couple weeks. If so it's because I'm on Spring Break in Paris.
- Things don't seem to have gone well for Raja of Invincible America John Hagelin and his Global Financial Capital of New York down on Wall Street. He has given up the mansion/headquarters building at 70 Broad Street, sold to a Chinese construction company. Nowadays he is President of the David Lynch Foundation and working on a much more conventional way to make a living, offering an on-line course on Quantum Field Theory, Superstring Theory, Inflationary Cosmology, and Higher States of Consciousness, $1400 if you take it for credit, $600 otherwise.

Update: A podcast of the Asimov debate is available here.

Comments

1. **Yatima**
   March 6, 2011

   QFT and Higher States of Consciousness?

   Do we really need a repeat of Scientology…

   What's with people trying to link that barely adequate debugging tool called "consciousness" to quantum whatever and claim that there are 'higher states'. For some reason consciousness being thrown overboard whole through meditation or laudanum is assigned to it being in a "higher state". It makes me nauseous.

2. **Yatima**
   March 7, 2011

   And while we are doing the laundry list:

   http://spectrum.ieee.org/aerospace/astrophysics/string-theory-made-easy

   "String Theory Made Easy: Two books tackle one of the most complex theories known to man — with surprisingly satisfactory results"

3. **pos**
   March 7, 2011

   Surely it is not necessary to focus only on the negative. I had not heard of the Asimov debates until now. Thanks to PW for bringing them to my attention. So this year's debate is about string theory (so what?) … looking at the list of debate topics in years past, there are some fascinating choices (and I missed them all, of course, and seats for this year are sold out). But anyway, Xenon100 is physics at its best, tackling a really difficult problem on the cutting edge of research, it will be fascinating to see how it all works out. My best to them.

4. **Shantanu**
   March 7, 2011

   If somone knows of a link to the webcast of the event, maybe they
   can point it out. At times I like this I wish was in NYC

5. **Bugsy**
   March 8, 2011

   I just listened to a bit of Hagelin on You Tube and find it very hard to take… it's to me unfortunate that he seems to find it necessary to forcibly "unify" two of his personal interests (physics and TM meditation), the effect of which could be to bring both into some ridicule. Physics and math are infinitely beautiful and so is human consciousness. So what? The fact that we use our reason and our intuition, our logic and our dreams, and that there are so many very different kinds of minds successfully pursuing science is fascinating. On the other hand meditation can be a valid practice for gaining deep insights into oneself or into life, and that can have profound beneficial effects for individuals who happen to find that such a practice fits them. And that could naturally include scientists (as well as artists, writers and dish washers). Why not? Poetry is also inspiring, so is listening to a bird sing or
   Brad Mehldau play the piano. But that doesn't mean we need to claim that string theory explains why Brad's or the bird's song is beautiful or why
   a proof of John Tate's is. Mashing these things together diminishes all of them, and misses the surprise of the smile that can be hidden in a line of prose, or the mystically marvelous taste of an apple pie, which could provide a wonderful moment to prove a truly new theorem, whether not not we happen to be levitating at the time.…Oh well.…

6. **Steven Colyer**
March 9, 2011

Clara Moskowitz, in her 3/8/11 article on the 3/7/11 11th Asimov Debate:

When filtered through the lens of string theory, general relativity and quantum mechanics can be made to get along.

From the article:

"The progress [in string theory] over the last 10 years has only solidified my confidence that this is a worthwhile direction to pursue."
… Brian Greene

"Are you [string theorists] chasing a ghost or is the collection of you just too stupid to figure this out?" Neil deGrasse Tyson teased, beginning a friendly banter that would continue throughout the night.

deGrasse Tyson later says if you're making progress, keep pursuing it.

7. **Peter Woit**
March 9, 2011

Thanks Steven,

I'd be curious to know what these "string theory predictions"are about large dimensions at the LHC and about structure in the CMB. As far as I know there are no such predictions, and for Freese to claim that they exist is intentionally misleading. Presumably what's involved are things that stretch the term "prediction" far away from its conventional usage.

I suspect that when Brian is referring to progress in string theory, he's thinking of things like AdS/CFT, not string theory unification. As far as unification goes, progress in the last decade has been negative (the landscape is not progress, quite the opposite).

It's funny that it looks like the organizers were only able to come up with one person willing to argue that the extra dimensions lead to deadly problems, and that's Jim Gates, who is a string theorist.

It also looks like the previously fashionable argument that "string theory predicts supersymmetry" has now vanished down the memory hole.

8. **Steven Colyer**
March 9, 2011

You're more than welcome Peter but is is we who thank you for a frank weblog about these important topics.

We have a second article up on the event, also very frank and not overstretching in the least, by participant Marcelo Gleiser at NPR Blogs: here.

9. **Geometrick**
March 9, 2011

As much as I love David Lynch, I'm a bit uncomfortable when spiritualists try to invoke quantum mechanics. I believe that Rhonda Byrne tried to use quantum physics in "The Secret." I would say more about her and her ilk, but I don't want to slander her.

10. **Peter Woit**
March 9, 2011

Steve,

Thanks again. I wrote a posting last year about Gleiser's recent book about this.

http://www.math.columbia.edu/~woit/wordpress/?p=2865

11. **Bernhard**
March 9, 2011

Peter,

Perhaps not exactly what you´re looking for but I saw a talk in Boston (SUSY 09) on "Strings at the LHC" that could interest you (if you don´t already know it):

http://nuweb.neu.edu/susy09/talks/Talk_599-L%C3%BCst.pdf

I remember Lüst said in the end "we could see something only if we are very very lucky".

Lüst has by the way some articles on the subject:

http://arxiv.org/abs/0807.3333

http://onlinelibrary.wiley.com/doi/10.1002/prop.201000024/abstract

And you can find more in hep-th.

12. **Peter Woit**
March 9, 2011

Bernhard,

I have seen that work, but I don't think anyone has ever taken it (the idea of strings with a TeV string scale) seriously or promoted it as a string "prediction" for the LHC.

13. **Coin**
March 9, 2011

Way back in 2000 when John Hagelin was running for President, the Natural Law Party campaign website had this absolutely mind-boggling diagram on it that– I am not sure I am remembering this exactly correctly– had “SUBATOMIC PARTICLES” at the bottom and “HUMAN RIGHTS” at the top. The diagram was built like a pyramid where somehow constitutional law rested on top of quantum field theory, or… something. Alas, I didn’t bother to save this masterpiece of incoherence when I first saw it, and I’ve been trying to locate a copy ever since to no avail. (The Natural Law Party website does not appear to have updated since about 2003, but somehow that diagram doesn’t seem to still be on it…)

14. **Bernhard**
March 10, 2011

Here more on the dabate:

http://www.scientificamerican.com/article.cfm?id=string-theory-debate

15. **@ Coin**
March 10, 2011

Not exactly the one you mentioned, but nearly equally hilarious (also with some Natural Law Party affiliation):

16. **Nigel**
March 11, 2011

“… working on a much more conventional way to make a living, offering an on-line course on Quantum Field Theory, Superstring Theory, Inflationary Cosmology, and Higher States of Consciousness, $1400 if you take it for credit, $600 otherwise.”

Just curious, but do you see stringy theory continuing its trip into pseudoscience if it fails at the LHC, just as the S-matrix continued with *The tao of physics* eastern mysticism after it was superseded by the standard model?

17. **Coin**
March 11, 2011

@: OMG, there may have been more layers in the version I saw, but that is so totally it! Except I don’t remember it being INVINCIBLE before.

18. **Shantanu**
March 12, 2011

The podcast is
http://www.amnh.org/news/tag/isaac-asimov-memorial-debate/

Peter: what do you think?

19. **Peter Woit**
March 12, 2011

Thanks Shantanu,

I’m on vacation right now, which seems like a good excuse for not listening to this at the moment…

20. **Peter Woit**
March 12, 2011

Nigel,

I think the string theorists who have gone down the route of anthropic multiverse pseudo-science are already on thin ice in terms of retaining any credibility with their colleagues. They’ll concentrate on trying to ahore up this situation by promoting the multiverse, and won’t engage in obvious nonsense like the consciousness stuff. This is not new for Hagelin, he’s been doing this for 25 years now.

21. **Giotis**
March 13, 2011

When somebody from the audience asked Marcello Gleiser about which experiment in his opinion would help most in the quest of a unification theory, he replied the detection of gravitons.

I completely agree.

There is a lot of speculation that gravity might not be a fundamental force but some emergent collective phenomenon. If this is true everything changes regarding unification and Quantum gravity.

If somehow we could verify that gravitons exist as mediators of the gravitational force then our confidence to String theory where gravitons find their natural place would increase substantially.

On the other hand if you could verify somehow that gravitons don’t exist you kill String theory automatically.

22. **Peter Woit**
March 13, 2011

Giotis,

The problem is that you can give a good order of magnitude estimate of the probability of detecting a graviton, using any kind of apparatus conceivable in you, my or our great-grandchildren’s lifetime. It’s essentially zero, so string theory remains immune from this “test” like all others. In any case, I disagree that detection of a graviton would be evidence for string theory, but that’s irrelevant since we know it’s not going to happen, whether or not they’re there.

23. **Anonymous**

March 13, 2011

Only 3 days to go before Xenon100 announces SUSY WIMP!

24. **Coin**
March 14, 2011

…dumb question… Given the kind of data produced by Xenon100/XMASS/whatever, if they got a signal would they actually be able to distinguish a SUSY/superpartner WIMP from a normal WIMP? If so, how?

25. **Shantanu**
March 14, 2011

Coin, no you cannot.
All you get from dd experiments is the mass and WIMP-nucleon cross-section.
The result is agnostic to whatever BSM theory produces this mass and
coupling constant

26. **martibal**
March 14, 2011

Peter,

why are you so pessimistic on graviton detection ? What about the detection of gravitational wave (several experiments are going on on that matter): couldn't it be related to the existence of graviton ? Or say differently, if gravity is an "emergent phenomenon" (whatever its means, I am still not sure I understand what people intend by that), would it mean that there is no gravitational wave ? Or simply that there are classical gravitational wave with no corresponding quanta ?

27. **Peter Woit**
March 14, 2011

martibal,

Classical GR effects, including classical gravitational waves, are certainly measurable, and experiments likely will see them. But seeing the quanta of any quantization of a theory with classical gravitational waves is a very different story.

28. **Paul**
March 21, 2011

Smolin's point was never really addressed in the debate. He said spacetime is dynamical, so any extra dimensions have to be dynamical too, but this leads to the extra dimensions blowing up to spacetime-size. Does anybody know how this is dealt with?

29. **Giotis**
March 21, 2011

Paul,

The overall size (volume) of the compactified dimensions is a modulus from 4D point of view i.e. a massless scalar field. This modulus is stabilized in small values by various techniques. In general a potential is obtained in 4D for the volume modulus which is then minimized in a stable/metastable vacuum and thus the field acquires an expectation value (a small size in this case). There are many geometric and other moduli in String theory compactifications; it is a very large subject called moduli stabilization.

This Week’s Hype

March 14, 2011
Categories: Experimental HEP News, This Week's Hype

The LHC is back in business, producing stable colliding beams for the first time this year, although still with a small number of bunches and thus a low luminosity. The number of bunches and luminosity will increase over the next couple weeks.

Reuters explains the significance of this, based on quotes from CERN scientists: they expect to find evidence of the multiverse as predicted in Stephen Hawking and Brian Greene’s books.

> Oliver Buchmueller, a leading physicist on the $10 billion project, said top priority in 2011 and 2012 would be finding evidence of super-symmetry, extra dimensions, dark matter, black hole production and the elusive Higgs boson.
>
> These concepts and ideas are at the new frontiers of science research as it pushes into the realms of what was once science fiction, giving a new impulse to cosmology and theorizing on whether the known universe is alone, or one of many.
>
> Cosmologists, like Briton Steven Hawking and U.S. physicist and mathematician Brian Greene, are looking to the LHC to turn up at least strong signs that there was another universe before the Big Bang or that others exist in parallel to our own

There’s no word on exactly how LHC data is going to provide evidence for the multiverse, I guess we’ll just have to wait and see.

Comments

1. **King Ray**
   March 14, 2011

   String theory is a Zombie Theory that won’t die, and keeps eating the brains of those silly enough to believe in it.

2. **UnderlyingEvent**
   March 14, 2011

   Hi Peter, Where exactly do you get your latest LHC news from? Like the fact that beams are colliding now, and what the luminosity is.

3. **Glenn**
   March 14, 2011

   Perhaps John G. Cramer’s prediction will come true after all?

   http://en.wikipedia.org/wiki/Einstein%27s_Bridge_(book)

   Of course, in that case, the proof would exist on a world-line inaccessible to any living observer.

4. **Gerrid Hargors**
   March 14, 2011

   is there a chance that the LHC might find absolutely nothing?

   when would we see this?

5. **Sakura-chan**
   March 14, 2011

   Even if it finds nothing that’s still something.

6. **Christian Takacs**
   March 15, 2011

   It is very possible to write a brilliant, internally consistant, story in the english language which is incredibly detailed and resembles reality in some ways, but only so much as the author desires and has the skill to imagine and impart. We call this body of work a fiction or fantasy, and no one seems surprised it is quite possible to make things up which don’t exist but have aspects of realism.

   It is very possible to write a brilliant, internally consistant speculation in the language of mathematics which is incredibly detailed and resembles reality in some ways, but only so much as the mathematician or physicist desires and has the skill to imagine and impart. It appears many in the mathematics and physics community are confused about what to call this growing ‘speculative body of work’, while others seem quite surprised (and unwilling) to consider it is quite possible to make things up which don’t exist but have aspects of realism…even in mathematics.

7. **DB**
   March 15, 2011

   I expect that your colleague Brian Greene will quickly and vocally distance himself from this nonsense. Right?
   After all, surely he doesn’t want to be remembered as the mass peddler of pseudo-scientific quackery.

8. **Peter Woit**
   March 15, 2011

   UnderlyingEvent,

   At some point I started not linking to LHC info at CERN, since they were making private previously public sources when they were linked to. But it now looks like they made a long-term decision to keep public these:

LHC vistars (see Page 1, Coordination and Operation)
http://op-webtools.web.cern.ch/op-webtools/vistar/vistars.php

Latest news from daily commissioning meetings:
http://lhc-commissioning.web.cern.ch/lhc-commissioning/news-2011/LHC-latest-news.html

Philip Gibbs does a good job of summarizing the situation at
http://blog.vixra.org/

9. **Peter Woit**
March 15, 2011

Gerrid,

The supersymmetry, extra dimensions, etc. is all a side show,these are not well-motivated ideas and they will just get slowly ruled out to higher and higher energy levels. The serious thing to watch is the Higgs. Either it will be found, or our understanding of electroweak symmetry breaking is wrong, and presumably some sort of evidence will be found for what the right theory is. This should start later this year…

10. **Peter Woit**
March 15, 2011

DB,

Brian does seem to often take pains to claim he's not a proponent of these multiverse ideas, but that generally gets lost.

More importantly, I think the CERN PR people should think twice about having those who speak publicly for them heavily promoting extra dimensions, etc., and encourage them to stick to real physics

11. **pr**
March 15, 2011

The PR office has to say *something*, and it can't be simply "the LHC is looking for the Higgs boson". The PR office *has* to say "the LHC is searching for new physics, beyond current knowledge" ~ and what is there to say? It can only be phrased in terms of the prevailing ideas/fashions of the day. That's not the fault of the PR office. SPEAR was not built to search for quarks. The AGS was not built to search for quarks (or CP violation) either. They were all built to explore the unkown, which turned out to be quite a bit different from the expectations of the day. It is a pity that nothing has been found (by accelerators) beyond the SM for 30-odd years, and perhaps the LHC will be the same, but the PR office can and must speak in terms of the ideas of the times. No matter if history shows that this is a very poor guide to successful predictions.

12. **Michael**
March 15, 2011

pr has a point. The easiest and most effective way to justify the LHC now is with these speculative theoretical ideas. However, doing so is also dangerous since the speculations cannot all be right and a malicious journalist could always write a lead article "CERN scientists fail to find Supersymmetry again!" or something like that. So the hype does cost us in the long term and makes our community seem unserious or even silly. Which we are not.

Oliver Buchmüller is a serious scientist and I regret that his words were twisted by Reuters. He is a leading figure in CMS and contributes at many levels. Don't judge him by this one twisted quote.

13. **Rhys**
March 15, 2011

I agree with both pr and Michael. Of course there *are* searches for black hole production, extra dimensions etc. being performed by the LHC experimental groups, but nobody would argue that they are the "top priority", and I'll bet that Buchmueller didn't say so.

14. **dir**
March 15, 2011

if lhc finds just the standard model higgs, and nothing else, then the best understanding of the stability of the weak scale is anthropic idea, this is especially the case if the higgs mass is 143 \pm 5 gev which implies a high scale susy breaking.

15. **Giotis**
March 15, 2011

I think there is a misunderstanding here. The article explains later the line of reasoning behind this assertion, that is if SUSY is discovered this would backup String theory and String theory offers backup for the multiverse idea. In fact this is consistent with Brian Greene's book which promotes the same thing i.e. that if we could estimate by circumstantial evidences (e.g. SUSY) that String theory is on the right path then the multiverse will gain validity and a concrete theoretical justification.

Also I'm not sure if this is an actual quotation of Oliver Buchmueller; maybe only the first paragraph is his.

PS. Peter the link is faulty…

16. **Mike**
March 15, 2011

Peter,

This is off-topic so feel free to delete.

The Japan Society has created a disaster relief fund to aid victims in Japan. 100% of your generous tax-deductible contributions will go to organization(s) that directly help victims recover from the devastating effects of the earthquake and tsunami that struck Japan on March 11, 2011.

See: http://www.japansociety.org

17. **neo**

March 15, 2011

I just finished reading Greene's multiverse book. He may not be a proponent, but he is far from agnostic about it. He is very sympathetic, and most of the book is an extended defense of his view that the multiverse (he considers NINE types) is science, not pseudo-science. No where does he claim, however, that the LHC will provide evidence for it, except indirectly, such as finding SUSY particles, which he argues would weakly affirm string theory, which would (even more weakly) affirm the landscape multiverse.

18. **Roger**
March 15, 2011

> Brian does seem to often take pains to claim he's not a proponent of these multiverse ideas, but that generally gets lost.

Greene just wrote a book that consists entirely of a promotion of nine different types of multiverses. He is out giving TV interviews promoting the multiverse. It appears to me that he is more of a proponent of multiverse ideas than anyone else. Where does he take pains to deny it?

19. **Thingumbobesquire**
March 16, 2011

I guess these types never weary of peddling this kind of dross: "Large Hadron Collider could be world's first time machine"

20. **rhofmann**
March 16, 2011

Some very personal thoughts on the LHC situation: The healthy part of the electroweak (ew) part of the SM, namely an SU(2)x(effective)U(1) gauge structure, which was confirmed so many times by LEP and predecessor machines, will be reconfirmed by LHC. The ugly part – the entire Higgs sector with its implications for all sorts s of model building – will go away to eventually make room for a much more fundamental understanding of ew symmetry breaking, fermion-mass emergence and effective chirality of the weak interactions, the grasp of the latter providing an EXPLANATION for the effective anomaly cancellation in the SM. This will require a sharp break with the perturbative approach to gauge theories, and we will have to go a long cumbersome way to reach the same level of SM accuracy that was confirmed by past ew precision experiments. Apart from not seeing the Higgs the LHC may provide hints in low-energy secondaries (multiplicities) and possibly by seeing additional heavy vector triplets.

21. **Susy WIMP**
March 16, 2011

What did Xenon100 announce this morning? They haven't made anything available online yet.

22. **Peter Woit**
March 16, 2011

Susy WIMP,

See the Neutel11 blog for info on this. Xenon100 announced only that their data is not yet unblinded. Nothing yet….

This Week’s Hype II

March 16, 2011
Categories: This Week's Hype

LHC-related hype is coming fast and furious this week during my vacation, with Vanderbilt University yesterday issuing a press release headlined Large Hadron Collider could be world’s first time machine. It’s based on this paper, and the Vanderbilt press release explains:

> Weiler and Ho’s theory is based on M-theory, a “theory of everything.”

The press release has been picked up by lots of other media outlets, including CBS News and UPI.

It’s rather impressive that these tests of M-theory at the LHC will not only provide evidence for other universes, but allow time travel in this one.

Comments

1. **causality**
   March 16, 2011

   “Causality-Violating … (anything)”. Oh dear, if you can violate causality then you can probably work your way around the Second Law of Thermodynamics. Make a perpetuum mobile!

2. **anonymous**
   March 16, 2011

   I bet there are a lot of people who would like to go back in time and change their theories right now. Maybe the Multiverse folks can use the LHC to go back in time and uninvent this concept (and if they are real generous, maybe they can plant some papers in a few journals detailing how mathematically ridiculous it is).

3. **David Bailey**
   March 17, 2011

   This is an example of the scourge of image consultants! God particles, recreation of the big bang, and now time machines!

   Non scientists are not stupid, and they know that vast amounts of money are spent on these projects, and that less and less comes out of them except hype!

   The science community should realise that resorting to image consultants is like taking cocaine – a short term ‘solution’, but a long term disaster. Think for a moment about people’s current disillusionment with politicians in general – part of this is because politicians have overdosed on image consultancy!

4. **Peter Woit**
   March 17, 2011

   Dave Bailey,

   I don’t think the multiverse or outrageous claims about the LHC are the fault of image consultants. It’s physicists themselves who have gotten used to getting attention for spouting nonsense and are happy to do it themselves without any need for encouragement. The press will always lap this stuff up if physicists are willing to provide it.

5. **Michael**
   March 17, 2011

   Peter,

   it depends on which physicists you are talking about. Speaking for at least a segment of the HEP experimental community, it is extremely frustrating when some outspoken colleagues try to grab some glamor by making inflated and extravagant claims. The rest of us who are more sober and less addicted to the limelight can only suffer these fools. The cocaine analogy is a good one – some people want a high but everyone pays the consequences.

   Another example is all the hype expounded a decade ago for the ILC. The result was a proposed machine that would not have delivered the physics needed and therefore would have led to the death of the field. Instead, we suffered the embarrassment of a project that was not supported by the whole community because many people resisted the hype and did not jump on the bandwagon led a noisy and boisterous subset of the community.

   Michael

6. **Peter Woit**
   March 17, 2011

   Michael,

   I had in mind theorists, too many of whom seem to think it’s a good idea to issue press releases promoting absurdly unlikely speculative ideas. This isn’t something that I’ve seen experimentalists engage in.

7. **cf**
   March 17, 2011

   I had in mind theorists, too many of whom seem to think it’s a good idea to issue press releases promoting absurdly unlikely speculative ideas. This isn’t something that I’ve seen experimentalists engage in.

   Cold fusion?

8. **TedUnger**
   March 17, 2011

   We have been promised Earth-consuming black holes, a new Big Bang, marauding aliens from another dimension, and enough antimatter to build our own USS Enterprise

– but there's been nothing from these CERN scientists except some lousy boring data on physics! They better at least give us some time travel or else!

You know that is what Joe Public is thinking.

9. **David Bailey**
March 17, 2011

I'd say the problem is wider than high energy physics. Terms like "quantum teleportation" seem pretty absurd, when compared to the Star Trek version, and even the term "quantum computer" makes me feel a little uncomfortable, because it is far from clear if there is a realistic chance of scaling the idea up to anything resembling a computer – certainly I'd be happier if they reserved the term for something with >1000 (say) q-bits coupled together. Then of course there is the invisibility cloak…..

10. **Roger**
March 17, 2011

Michael, can you tell me some names of these sober physicists, so I can credit them? Are they willing to be quoted? As far as I can see, they all make silly and extravagent claims.

11. **Joe Public**
March 17, 2011

I have no scientific background, but this is what bothers me. 3-Dimensionality is a model for understanding our "spacial reality". I don't have a problem with claiming some newly discovered plane to be the "4th dimension" (discounting time, obviously)- what bothers me is using mathematical models with no empirical basis to make such wild and ubiquitous claims about x many new dimensions, and then the even more specious subsequent claims that spew forth…time travel, parallel universes etc. Not just claims that properly belong in science fiction, but claims that seem to be forming the basis for some new scientific religion. A very lucrative mythology for those who profit from it.

Brian Greene and friends seem to be giving "realism" its most outrageous treatment since Plato. Btw- I'm all for science, and I believe it is the best tool we have to collectively model and understand our material reality, but…why can't they see how horribly they're abusing their own concepts?

12. **csrster**
March 18, 2011

"Large Hadron Collider could be world's first time machine"

or maybe it already has been! Did they think of that?

13. **TedUnger**
March 18, 2011

I know a lot of scientists have neither the skills nor the interest in sharing their findings and knowledge with the unwashed masses. But someone has to. After all, don't you want to inspire that next great scientist? Don't you want the public to at least appreciate and understand a bit of what you are doing?

The public may be ignorant and superstitious, but guess who foots the bill for most science, and guess who takes it away when they don't get what the guys in the white lab coats are doing up in their ivory towers. Brian Greene and Carl Sagan were are treated like lepers by many of their peers for daring to reveal some of the mysteries to the people.

Apollo and SSC went away in large part because the public did not see their value. How about some of you stop whining about the publicity machine and start doing something about it? Otherwise hello new Dark Age.

14. **Allan Rosenberg**
March 18, 2011

If Weiler and Ho are right, then future string theorists will no doubt use the effect to send messages with the experimental proof of string theory back in time. Once we have that data (and who knows, maybe we already have it), nobody will need to actually perform those experiments. So much for Woit's claim that we need experiments to justify string theory.

15. **Michael**
March 18, 2011

Hi Roger,

sure – you can look at the blogs written at US LHC, for example. There is the famous blog by Tommaso Dorigo, the one by Gordon Watts, John Conway at Cosmic Variance, and perhaps even my own obscure blog.

Hi Ted,

none of us is whining about the need to promote science. I agree that it is our duty and it should be our pleasure to share our positive and privileged experiences with non-experts. I don't look down on the public nor do any of my friends in HEP. On the contrary, efforts at genuine outreach increase every year and are far, far better than anything I saw as a student. My teenage interest in science stems from popular science articles like those in Scientific American and from science instruction in school, not from Star Trek or other entertaining but purely fictional productions. It never serves science to bait with science fiction and I would resist any tendency to do so, at CERN, at Fermilab or at my own university.

regards,
Michael

16. **Bugsy**
March 18, 2011

Michael writes:
My teenage interest in science stems from popular science articles like those in Scientific American and from science instruction in school, not from Star Trek or other entertaining but purely fictional productions.

I completely agree; while I found written sci fi inspiring (not so much the
watered-down movie or tv versions, with few exceptions) it needed to be backed up with the "real thing" or I never would have gotten interested in math and science. But

back then, Sci Am was far better than now:
meatier, without the fancy graphics and sensationalism, and with the incomparable Martin Gardner in every issue.

17. **Paul**
March 18, 2011

When a physics department issues a press release, don't a bunch of physicists in the department have to sign off on it?

How many physicists would have signed off on this time-travel release?

18. **jpd**
March 18, 2011

"Large Hadron Collider could be world's first time machine"

or maybe it already will have been! Will they thunk of that?

19. **Peter Woit**
March 19, 2011

Paul,

No, in American universities, typically tenured faculty members do this sort of thing without any involvement of their colleagues. It's between them and the university administration, which typically is very interested in seeing research of its faculty promoted in the media.

20. **nonstupid layman**
March 19, 2011

Everybody knows that one of the purposes of the LHC is to "look back in time"; meaning to investigate the state of the universe (note: no plural s here !) shortly after the big bang. And it is well known too that the media reporting about different subjects (politics, economy, science, …) tend to exagerate and amplify what they are told more and more these days to sell their stories.

It is just unfair and incomprehensible of You, Peter, to take the fact that the media make "time-travel" of things like "looking backward in time" as another pretext to get started again about scientist working in the fields (note: here is a plural s) You hate. Be sure that apart from certain exceptions the scientists feel uncomfortable too watching the media reporting claims which are neither scientifically true nor pronounced in this way by them.

Du You really think that we laymen are that stupid such that we are not capable of distinguishing a silly and exagerated headline and just laugh about it by ourselfs? It is really not necessary that You point out and term every bit of science knews You dont like (independent of it being exagerated or not, true or not true, etc) as a Hype!

You are getting more and more unfair, destructive, fanatic and obsessed by what You obviously think is Your "holy crusade" to protect the poor innocent laymen against the demonic scientists You see everywhere in Your hallucinations.

Get well soon!

21. **Roger Schlafly**
March 19, 2011

Michael, thanks for your suggestions. I did not immediately see any sober assessments of the "inflated and extravagant claims" that you complain about. On your own blog, you seem to avoid making such claims, but you don't comment on such claims either. I would suggest that if the fools really frustrate you so much, then you criticize them on your blog.

22. **Cents**
March 19, 2011

To nonstupid layman:

I am sorry that you feel Peter is not providing a useful service in pointing out the BS and hype that is part of today's magazines business model. Besides providing interesting and timely insight as to what is going on in various areas of Math and HEP he is acting as communicator to the lay public – getting current science info out and and pointing the speculation aspect to the stupid laymen (do you think everyone is just like you). There is no shortage of speculation out there as that what sells magazines. I have been lurking here for a couple years (since reading Greene, Randall, Hawking and Smolin's books that discuss multiuniverses and string theory and other speculative views), and really appreciate the service that Peter provides pointing out what is on the fringe versus what has solid experimental evidence. If I wanted speculative BS I would follow Michio Kaku or similar sci-fi-ish authors. Normally I would just keep lurking but I felt the comments by nonstupid were completely unfair. Since I won't comment again, I just want to thank Peter for his blog and ask when and if you will write another layman book. Your writing style is extremely approachable and I would enjoy reading any new layman related science book that you care to write. (Yes I admit I am a fanboy).
Nonstupid, no one is forcing you to read Peter's blog so if you don't like what he writes look for your Math/Physics fix somewhere else.

23. **Peter Woit**
March 19, 2011

Cents,

Thanks a lot! Providing a more accurate source of information about subjects I care about is certainly one thing I hope I'm doing, and glad to hear it's appreciated. No plans anytime soon for writing another book for layman. There are some expository writing projects I'd like to work on, but they would be at a more advanced level.

nonstupid layman,

You've completely misunderstood what this is about. The LHC as "looking backward in time" to the big bang is the usual kind of hype which isn't worth making too much of. This is about something different, a claim that using extra dimensions and M-theory, signals can literally travel backwards in time, in a fashion observable at the LHC. This kind of M-theory inspired nonsense, spread by university press offices, is the kind of thing "This Week's Hype" tries to point out. I think it's worth doing, and no one else is doing it. I'll be glad to stop when someone else starts (or, better, physicists stop doing this or tolerating it when their colleagues do it).

24. **PWfan**
March 19, 2011

"I think it's worth doing, and no one else is doing it. I'll be glad to stop when someone else starts (or, better, physicists stop doing this or tolerating it when their colleagues do it)."

You're a hero! 🙂

Thanks!

25. **Yatima**
March 20, 2011

Backwards-in-Time signalling would make the NP complexity class accessible. Weakly godlike computational power at your fingertips, even if backed by Big Science? I'm all for it!

http://www.scottaaronson.com/democritus/lec19.html:

"Yes. Once we set up the CTC [Closed Timelinke Curve Computer], its evolution has to be causally consistent to avoid grandfather paradoxes. But that means Nature has to solve a hard computational problem to make it consistent! That's the key idea that we're exploiting."

26. **nemo**
March 20, 2011

Peter,

did you see this:

http://today.msnbc.msn.com/id/41974768/ns/today-today_tech/

?

27. **Paul**
March 20, 2011

Peter, you might be very interested in the recent string debate at

http://www.amnh.org/news/tag/isaac-asimov-memorial-debate/

It's got Greene, Smolin, Freese, Gates, Levin, Gleiser, and Tyson debating.

28. **Bernhard**
March 20, 2011

There should be some kind of political action against these clowns, really. Society is paying for this time-travel garbage which has no chance of explaining fundamental theory, is not science, not even good sci-fi. Even when people promoting this are competent in their fields, something should be done do punish them. Perhaps go tell on them to some piss-off congressman who knows nothing about science and willing to not see tax-money spent on this crap. Than after one or too time loosing funding perhaps the Universities would consider themselves not allow this kind of crap to be promoted.

29. **Bernhard**
March 20, 2011

… anyway, this sounds a bit extreme, and it is I admit, but it pisses me off no end, see this kind of things on the papers. I see no reason why this people have so much power and recognition but in the end what´s really worse is that these are the people with job deciding powers (on the theoretical side)!

30. **Peter Woit**
March 20, 2011

Nemo and Paul,

See previous mention of this in "Short Items" posting.

Bernhard,

In this case and others, I think the people and institutions putting out dubious press releases don't have much influence in the field. Consider it just evidence of the odd nature of the 21st century American university (50 years ago, if one of a university's faculty members was working on time travel, the administration would probably not issue a press release about it).

It would be helpful if prominent physicists contacted by journalists about stories like this would be willing to make forceful and colorful statements. In this case though, I guess the stories were just based on the press release, with no real reporting. Also a sign of the times….

31. **CarlH**
March 21, 2011

While Peter and others should never give up the good fight, keep in mind that you are up against something that has gone on for a long time.

When Percival Lowell was using his wealth and influence to promote intelligent canal-building beings on Mars over a century ago, there were plenty of professional scientists who showed why there could be no such thing on the Red Planet.

Take a wild guess who the media focused on and gave disproportionate amount of publicity to. Plus, Lowell apparently gave some very enthralling lectures and was a very good popular writer. I have read two of Lowell's books on Mars and I have to admit, I can see how he could convince a lot of people there were ETI one planet over.

I think we are going to have to wait for the human species to become a different and more educated creature before we can expect the majority of people to logically gravitate towards views such as those being espoused here. It's going to be a long wait.

32. **Shantanu**
March 22, 2011

Peter, am still eagerly waiting for your comments on ASimov debate which btw is on youtube

33. **Peter Woit**
March 22, 2011

Shantanu,

I just got back from vacation, and there's a long list of things I need/want to do that seem a lot more appealing than watching the Asimov debate. Maybe I'll get around to it, maybe not. I'm much more interested in what other people think about it.

Also, I pretty much know what the debaters each are likely to say on the topic, and readers of this blog probably know what I'm likely to say about what they say. So the marginal utility of me watching and writing about it may not be very high…

34. **Zathras**
March 22, 2011

If the goal of this blog is to take down the massive amounts of science hype out there, the proper course is to do more than just a blog. How do movements get started in science? By articles and conference proceedings. Are there any articles on the arXiv that lay out the problem of hype in science? How about a session at an APS meeting which goes through what is hype and why it hurts science. With just a blog the believers will nod their heads, the trolls will troll, and everyone else will never get the message.

35. **Shantanu**
March 22, 2011

Peter the session was quite interesting and I did learn something new from the discussions and worth a look.
Jim Gates (JG) does not believe in extra dimensions. He was contradictied by Brian Greene who said that extra dimensions are instrinstic to string theory.
JG also said that this nobel prize winner found applications of string theory in graphene. He also said that everything is a matrix (which I don't think anyone else including Brian understood). Marcelo Gleiser pointed that he is skeptical about grand unifcation and even things like unification of electricity and magnetism works only in a limited sense (that is in vaccuum in absence of sources) and
he doesn't think electro weak theory is a true unification of electricity & magnetism.
Katie Freese pointed out that LHC and dark experiments may provide evidence for super-symmetry which might pave the way for string theory. At the end of the debate Neil Tyson (who btw did an excellent job in moderating the debate) grilled Brian a bit as to why "string theory has not made much progress". Brian's reply was that the questions we are addressing are much more profound and insisted that there had been progress(he mentioned applications to RHIC etc)
I think that's a short summary from my side.

36. **thanksgod**
March 22, 2011

Thanks god that in Europe all is well in contrast to what is going on in the US as it seems.
Evereybodyhere can investigate what he wants and what he is interested in, including quantum gravity or other fundamental questions, without being threatend by religious fanatics who want at any cost to eradicate certain research directions. Sorry but it is really insane what is going on and what some people are saying here …

37. **Peter Woit**
March 22, 2011

thanksgod,

Sorry to have to tell you this, but, based on the e-mail addresses they leave and the IP addresses they are coming from, as many as half of the more vocal commentators here come from Europe, including the "religious fanatics who want at any cost to eradicate certain research directions".

However, both in Europe and the US, I don't think there's any danger that those who comment on this blog or others will eradicate any particular line of research. Physicists issuing ridiculous press releases promoting their line of research might manage though to convince some of their colleagues that what they do is not to be taken seriously.

38. **Peter Woit**
March 22, 2011

Shantanu,

Jim Gates and I were once invited together to debate string theory, but disappointed our hosts by agreeing on most things. He (and others, e.g. Warren Siegel) don't think string theories in 10d give viable unification, they're interested in making sense of "non-critical" string theories in 4d. So far this doesn't give viable theories either, but you can argue it's a more promising thing to work on than 10d strings, which have been a failure.

It would have been interesting if Tyson had asked Freese whether, since supersymmetry at the LHC was evidence for string theory, wouldn't no supersymmetry at the LHC be evidence against it? And at what combination of luminosity/beam energy would she give up on supersymmetry if it wasn't seen by then? For Brian an interesting question would be whether he thinks there has been progress in the area of string theory unification. This raises the interesting issue: is the landscape progress or not?

39. **Shantanu**
March 22, 2011

Peter,
I think Marcelo pointed out that some early LHC results already rule out a lot of parameter space in SUSY, but K.Freese didn't quite agree. People also talked about the anticpated PLANCK results. but it was not obvious to me what that rules out or not.

40. **Shantanu**
March 22, 2011

a typo in my prev. posting
"he doesn't think electro weak theory is a true unification of electricity & magnetism".
I meant
"he doesn't think electro weak theory is a true unification of weak nuclear force and electromagnetism" , since both weak nuclear force and electromagnetism retain their individual identities.
also one interesting question asked by Neil was whether people worked on extra time dimensions and the answer was yes (I couldn't catch the name of the person who worked this, but apparently this is complicated). No one mentioned neutrino experiments anywhere in the debate.

41. **supsym**
March 22, 2011

The “establishment” will not give up on supersymmetry just because it is not found, at the LHC or anywhere else. People did not give up on the luminiferous aether just because it was “not found”. Instead they invented more and more contrived explanations. Remember that Lorentz-FitzGerald length contraction was actually invented to accomodate the null result of the Michelson-Morley expt. The aether theory was NOT abandoned, it was **modified**.

What really killed the aether theory was that Albert Einstein could explain all the observed phenomena with a simpler alternative scheme which was demonstrably more successful. New observations fitted well with relativity, **without** the need to tinker with the foundations of relativity.

So … bottom line … people just lost interest in the aether. The same happened with phlogiston — people just lost interest because there was a better alternative explanation for things.

Supersymmetry will only go away when “something else” comes along which can do a better job of explaining known things, and can explain new things without revision of its foundations. But that requires “new things” to be found (new particles at the LHC). The “non-finding” of superpartners is neither here nor there.

42. **younghun park**
March 23, 2011

supsym
good! I feel what you said is good, very good.

The problem we have is not that SUSY is wrong, but, there is not the alternative theory, the other creative idea against SUSY and String theory to explain the experiment.

43. **Bernhard**
March 23, 2011

thanksgod,

I do research in Europe and have certainly no problem with people investigating quantum gravity. It’s a really interesting subject. Actually even time-travel per-se as an (highly) theoretical speculative direction can has its value, like guys like Kip Thorne demonstrated. Asking the question on how much the laws of nature are allowed to be bent is part of the fun. On the other hand as a direction of research String Theory offers nothing. It failed in every single problem which aimed to solve and makes absolutely no prediciton. Of course if someone is willing to embark in such a sinking boat I have personally also nothing against it. But scientists must be responsible and not make really retarded public claims like leaving someone thinking that M-theory at the LHC will provide evidence for other universes and or time travel, which is complete crap. For this kind of think I have no patience or sympathy.

44. **Nathalie**
March 23, 2011

I wouldn’t worry about the Ho-Weiler paper. The LHC physicists can’t even imagine how they could experimentally observe that the secondary vertex appeared before the primary one.

supsym
I agree with your main message that people tend to lose interest … However, your historical account is not correct. Michelson didn’t know that he had proven the non-existence of the aether. If he was sure of having made such a great discovery he would have at least mentioned it in his Nobel lecture 1907. The great Lorentz believed in aether when he gave his Nobel lecture in 1902 (15 years after the Michelson-Morley experiment). For him the fact the “atoms” of aether were smaller than the ordinary atoms was not such a big deal.
It is never easy to abandon an idea that has fascinated you for years just because it happens to be wrong.

45. **mm**
March 23, 2011

Michelson (and Morley) never claimed to demonstrate the non-existence of the aether. They could not. They could only test a hypothesis and report a null result. MM performed many versions of their expt (rotating mirrors) to test (and rule out) various hypotheses. But it was up to the theorists to explain the data using the aether, or something else.
http://en.wikipedia.org/wiki/Michelson%E2%80%93Morley_experiment

The LHC, for its part, can only report null results of searches, but not that “supersymmetry does not exist”. But note the following:

a) The aether theory made concrete predictions (“solar wind”). These were tested (MM) and null results were found.
b) MSSM in that respect does not make any specific predictions. If LHC does not find superpartners, MSSM is not “ruled out”.
c) Things will only change if the LHC (or ILC or whatever) **finds something**, then the theorists will have to explain it. A continuation of “not finding anything” will not change the status quo. The more new physics found, the better. But even if new stuff is found, it is only if and when a competing explanation can do a better job, then MSSM will go away. And if MSSM explains the data … hah!

46. **Chris Austin**
March 23, 2011

shantanu,

“also one interesting question asked by Neil was whether people worked on extra time dimensions and the answer was yes (I couldn’t catch the name of the person who worked this, but apparently this is complicated).”

Two-time physics is developed by Cumrun Vafa in the context of F theory, which is something like type IIB string theory oxidized to 10 space dimensions and 2 time dimensions. F theory is being vigorously developed by Jonathan Heckman, who has published or co-authored 19 articles on it in the past 3 years. There is a separate development of “two-time physics” by Itzhak Bars.

47. **Kenneth Vatz**
March 25, 2011

For whatever it’s worth, I reviewed Brian Greene’s latest book, “The Hidden Reality….,” on Amazon, and it is easily found there under “one star reviews” of the book. What I said is entirely derivative, since I am not a physicist, and is based mainly upon the books I cited at the top of the review, including, most importantly, “Not Even Wrong.”

More people than not have found the review "helpful," although I did get one rather nasty comment calling it a "crank review," to which I responded as objectively and dispassionately as I could. Well, maybe I could have been nicer…. 🙂

In this review I was really expressing my own disappointment at having had the idea of string theory, multidimensionality, and parallel universes taken away from me after all these years of assuming this would be the ultimate GTE once it was proven experimentally. I guess it all has to do with the natural human desire and need for intellectual closure, even when it can't be achieved.

BA-ZING!

Things That Deserve (but won't get) Longer Blog Postings

March 23, 2011
Categories: Experimental HEP News, Langlands, Uncategorized

Here's a selection of news that deserves longer blog postings that, for one reason or another, I'm unable or unwilling to provide…

- This year's Abel Prize goes to John Milnor. With an excellent blog posting about this from Fields Medalist Tim Gowers, why should I try and compete?
- I've been waiting for the US budget situation to clarify before writing about its implications for physics and math research, but it looks like that isn't going to happen anytime soon. The US Congress is now engaged in a bizarre and irresponsible exercise of trying to run the country by each week fighting over not next year's budget, not next quarter's, not next month's, but next week's. At the moment there's a budget for the next week and a half, but no one seems to know what will happen after this. The president has issued a proposed FY2012 budget, but there's no reason to believe it will have anything to do with whatever the reality of funding later this year turns out to be. Trying to make plans and run a large laboratory like Fermilab under these conditions must be a nightmare. Last week there was a HEPAP meeting in Washington, with presentations that explain the current situation. A good excuse for not writing more about the future implications of federal funding decisions is that no one is actually making such decisions.
- Last week Langlands supposedly gave a talk at the IAS, On Functoriality; on the Correspondence; and on Their Relation, Part I (I'm not sure if or when there will be a Part II). I wasn't able to attend, but perhaps video will someday be available. Langlands provides a link to a document of "work in progress" entitled Functoriality and Reciprocity. In it, he gives his reflections on the current state of attempts to precisely formulate and understand the conjectures generally referred to as "Langlands functoriality" and the "Langlands Correspondence" (or "Langlands reciprocity"). These conjectures come in versions for algebraic number fields, function fields, and so-called "geometric Langlands" over the complex numbers, in each case in local and global versions.

Much of the document consists of Langland's description of his struggle to understand some issues in the geometric Langlands story, including the work of Witten and collaborators relating this to 4 and 6d quantum field theories. Another topic is that of the Abelian theory, and attempts to understand it locally. A very good reason to not write more about this is that I don't understand it very well, although, paradoxically, I find Langlands writing about what confuses him rather easier to follow than when he writes about what he has completely understood. Another good reason is that I'm busily learning more about some of this, and maybe someday I'll be less confused and able to write something more sensible here.

- Also from the IAS, there's video of a talk by Arkani-Hamed to the mathematicians available here, about work on scattering amplitudes. I'm curious to know what they made of it.
- Also on the Langlands front, again in a category of things I don't understand well enough to write more about, see this new Seminaire Bourbaki report on the Fundamental Lemma from Thomas Hales.

Update: There's a Newsday story about Milnor here, unfortunately only the first bit is free. He explains what he is going to do with the million bucks: buy more leg-room on airplane flights (he's 6'3″).

Comments

1. **fatdog**
   March 25, 2011

   A semi-serious meta-mathematical question: is it possible to write more pompously than Langlands does? Is Langlands as pompous and condescending in person as he is in print? While he somehow manages to write clearly, and he clearly writes deeply, his tone almost makes the readable intolerable. It's like a movie caricature of a self-important professor.

2. **dogfat**
   March 25, 2011

   Pomposity is a point of view. I am sure the perspective is different if one is offering the benefit of one's years of hard-won accumulated wisdom to the unwashed masses.

   I see that this post has undergone numerous deletions of comments. Add this and previous the list … asap!

3. **Peter Woit**
   March 25, 2011

   fatdog/dogfat,

   I've deleted various off-topic comments, these are at least on-topic, although I really don't like the use of anonymous comments to personally criticize people, and this comes awfully close to that. I probably should delete the exchange, but I do think the question of Langlands's somewhat unusual writing style is an interesting one.

   I don't think "pompous and condescending" are accurate descriptions of this. He often is giving opinions, in ways that are not conventional for mathematical writing. Usual standards require this sort of thing to be rigorously suppressed, for good reasons: in a scientific paper you want facts, not opinions. But Langlands has got the track record to make his opinions worth hearing, no matter how they come off.

   I've no personal experience interacting with him, and sometimes found his writing style odd, but not really off-putting. The one thing he does I find hard to justify is his choice to sometimes write not in his native language (he has quite a few papers written in French, and German, and is also known to write in Turkish). I found his extensive autobiographical comments you can find here

   http://publications.ias.edu/sites/default/files/ubc.pdf

   quite fascinating, and they also give some insight into how he came to love erudition and thus explain a bit of the style and use of other languages.

4. **Jeff**
   March 25, 2011

   Well, as a data point, I was once informed by the chair of a Research I math department that he had read a number of recommendation letters from Langlands, and in each of them the only thing Langlands talked about was how the applicant had contributed or not to the Langlands program. No general discussion of their mathematical ability at all.

5. **Kea**
   March 25, 2011

Well, I actually met Langlands once, some years ago now, and I thought he was interesting and friendly.

6. **Bugsy**
March 25, 2011

Peter, thanks as usual for all the links and observations. I have to say I found fatdog's comments equally stupid and offensive. Being not at all in Langland's area, I began with the autobiographical interview and proceeded to
the recent paper, skimming both, just to get an impression. What is that? Of a thoughtful, erudite, creative and intellectually curious mind, who is genuinely trying to communicate something of value.
I didn't pick up a mote of arrogance or condescension, to the contrary I found the style refreshingly literate for a mathematician. Just because someone (in this case from an older generation) does know how to use the English language doesn't mean we should feel bound to insult them. In other cultures age and concomitant deep experience are met with respect: our eyes open wider, and shine from the privilege of the encounter….

7. **Shantanu**
March 28, 2011

Peter or others, have you heard any assessment of reports on how the earthquake in Japan is going to affect ongoing HEP(mainly neutrino) experiments in Japan and implications for near term future?

8. **lun**
March 28, 2011

I would be very interested in your opinion of the colloqium today at Columbia University, if you happened to attend it.

It seems to concern several of the issues you most often write about in a very succint way

9. **Peter Woit**
March 28, 2011

lun,

Yes, I was there (Arkani-Hamed colloquium on scattering amplitudes here at Columbia, somewhat like the IAS talk mentioned in this posting).

Personally, I found it a mixed bag: about an hour of very interesting results and ideas about scattering amplitudes in N=4 super Yang-Mills, explained well, prefaced by a tedious half an hour of unconvincing arguments and ridiculous hype. He seemed to have planned to give at least an hour and a half talk, even though it was scheduled for an hour, which struck me as rather rude, especially since skipping the first half-hour would have improved the talk a lot.

As he said at the beginning, this is work in progress. This has been an active area of research for several years, and it's not clear where it's going. That will be really interesting to see in the future. The impressive results he described are only about N=4 SYM in the planar approximation. One question is how widely these techniques can be applied to other theories, the other is whether they will lead to a fundamentally different theory, and if so, what it will look like. I'm a fan of twistor geometry, and I think it's great to see people doing something new with it.

On the other hand, I don't see how this yet shows any signs of solving any of the fundamental problems of how to get beyond the standard model and how to unify it with gravity. What's there now, impressive as it is, just didn't seem to me to support the grandiose hype that made up a big part of the talk.

Change of Direction

April 1, 2011
Categories: Uncategorized

It probably won't surprise my regular readers to hear that recently I've been getting rather tired of the usual topics of this blog. String theory has been intellectually dead for a very long time now, and continuing to point this out is becoming more and more tedious. About the multiverse, surely no one takes that seriously anymore, so, the less said, the better. Recently, John Baez decided to move away from abstract mathematical physics to write about topics of more relevance to the real world, see his blog Azimuth. Like him, I think it's time to move on to subjects of wider interest. In the past I've very much restricted the topics I write about on this blog, but now have decided that I should share my views on a wide array of topics not just with my friends and colleagues, but with the wider world. This blog will be one way of doing this, but in the next days and weeks I'll also be entering the world of Web 2.0 in a big way. There's now a twitter feed, with much more to come.

As part of this new order, I intend to stop my previous somewhat fascist policy of deleting a large fraction of comments on various ill-defined grounds. I now encourage interaction with my readers, feel free to write about whatever's on your mind!

Comments

1. **Dave**
   April 1, 2011

   As a reader for a long time, I won't say the prior topics of the blog won't be missed, they surely will. However much luck and enjoyment on the new direction, judging by the politics post, still a blog of interest to follow. Thanks for all the hard work and time leading up to this.

   p.s. Is there a good book/blog that you can recommend that deals with refuting the multiverse?

2. **Matti Pitkanen**
   April 1, 2011

   April first joke?

3. **abbyyorker**
   April 1, 2011

   A welcome break from your whining. Of course, this opinion only lasts 24 hours.

4. **Robert Smart**
   April 1, 2011

   If, after studying the issue for 1000 years, we determine that the probability of intelligent life arising in this universe (the bit we're in causal contact with) is very low, then it seems that it will be impossible to distinguish between 3 ways of looking at it: (a) Our existence causes the universe to have had some fortuitous events in the past; (b) We are actually just a simulation in a higher being's computer and they fudged it to get us; (c) There are multiple "universes" and naturally we are in one that happens to have intelligent life. Which will you prefer on aesthetic grounds (it being agreed that Science can't distinguish)?

5. **Casey Leedom**
   April 1, 2011

   Wow. I _Really_ Should_, as per always, read my email — blogs comments — in reverse order. I'm Very Sorry Peter for not having done that tonight.

   My personal belief: High Energy Particle Physics is both dead and boring in the current world. I hope that some day we'll have the ___DATA___ to generate some new and interesting theories. But right now, not so much.

   So, it's time to focus on more productive paths. And I'm sorry, but physics isn't part of that. My own personal view is that: if I were a young person trying to figure out what's "interesting", "likely to mean something", etc. … it would be biology. I think that there's a very real possibility of making a large number of people's lives better. The data is there and growing. It's going to take people with strong mathematical skills to process, integrate into good models, and help develop new takes on things.

   Let's give this "Unified Field Theory" stuff a rest and try working in a domain that's actually interesting …

6. **chris**
   April 1, 2011

   april 1st?

7. **Peter Woit**
   April 1, 2011

   This is me posting from a parallel universe and I'm _very_ annoyed at me in this universe for giving up the good fight!

   A change to more interesting directions would be desirble …

9. **joke**
   April 1, 2011

   … and a stop of the randomly and absolutely unpredictible disappearance of posted comments into … 😛 (the Nirvana ?) would be a god thing too …

   But Alas! …

Happy April 1st :-/

10. **Frank Quednau**
April 1, 2011

Well, the bit about the Twitter account is true, April Fool's or not, why not? "Not even wrong" applies to so many areas in our modern life, that you'd never run out of subjects in line with the blog title.

11. **Shantanu**
April 1, 2011

Peter, I shall miss the science and physics posts from you (as well as related comments from the readers). hope you continue blogging about particle physics.

12. **Giotis**
April 1, 2011

Good decision; if you can't beat them, ignore them…

13. **alt**
April 1, 2011

"About the multiverse, surely no one takes that seriously anymore, so, the less said, the better."

what about Briane Greene "The Hidden Reality: Parallel Universes and the Deep Laws of the Cosmos" Jan 25, 2011 release date. Have you read it and do you have a review of it?

from Publisher's Weekly

But string theory opened up a new can of worms, hinting at the possible existence of multiple universes and other strange entities. The possibility of other universes existing alongside our own like holes in "a gigantic block of Swiss cheese" seems more likely every day. Beginning with relativity theory, the Big Bang, and our expanding universe, Greene introduces first the mind-blowing multiplicity of forms those parallel universes might take, from patchwork quilts or stretchy "branes" to landscapes and holograms riddled with black holes.

14. **Sung Lee**
April 1, 2011

Was NEW hacked by string proponents?, or Peter just went nuts? Hope it is really an April 1st joke and the site goes back to the way it has been tomorrow. This site has really been a great source of information on mathematics and theoretical physics, and I am shocked and appalled by what I am seeing now. Is this a sign that mathematics and theoretical physics are hitting a dead end?

Sorry, this is your blog but as a long-term reader of your blog, I am very disappointed if this is not a joke.

15. **Anonymous**
April 1, 2011

"String theory has been intellectually dead for a very long time now."
Particle phenomenology is a much more intellectually stimulating. It's all about supersymmetry, supersymmetry, supersymmetry… and thousands of non-SM Higgs models.

16. **The Cosmist**
April 1, 2011

Mark my words, the future of physics and cosmology is turtleverse theory!

17. **SieveMaria Lucianus**
April 1, 2011

April 1st right ?

18. **D R Lunsford**
April 2, 2011

Peter, it was a heroic effort and did enormous good. I was utterly depressed about the state of science when I stumbled across your manifesto on arxiv a long time and another city ago. I was immediately cheered and took up physics again with a renewed effort. So this may be Aprils Fools day, but I do detect some sincerity in your screed here. You can still write about physics and desserts and New York all at once. I like to see some "then and now" photography from the city, maybe some architecture tours – that'll give you some excuses for biking around.

-drl

19. **John Baez**
April 15, 2011

Grrr…

20. **Peter Woit**
April 15, 2011

I guess not everyone is amused by getting brought into my practical jokes…

21. **donald klein**
April 16, 2011

I appreciate your thoughtful dehyping book Since you intend to march on to other
super-hyped areas you might look at "personalized medicine" and
the need to complete every biological finding with the promise of new therapeutic horizons.
This all falls under the rubric of translational medicine.
Please un-translate using scalpel of predictive validity.

22. **John Baez**
April 17, 2011

That was supposed to be a somewhat ironic "Grrr…", but it's hard to convey tone of voice in this medium.

Obama Worse Than Bush

April 1, 2011
Categories: Uncategorized

I voted for Obama in the Democratic primary, because I figured Hillary Clinton was more likely to expand the war in Afghanistan and otherwise engage in the sort of misguided military adventure favored by the shrub. Look what happened. He appointed Clinton Secretary of State, and then sent even more troops into Afghanistan than Bush Jr. would have dared consider. Don't even get me started about his Mideast policy and spineless cave-in on Israeli settlements. Remember Guantanamo? He's commander-in-chief, could shut this illegal abomination down whenever he wants to, instead he intends to keep it open indefinitely. Again, W would have closed the place by now and moved on. The fact that Obama was given a Nobel Peace Prize is some sort of sick joke.

On the domestic front, let's face it: Obama has been a disaster for the country, moving it farther to the right than it has been at any time since perhaps a period of a few years sometime back in the 19th century. He has pursued policies more or less in line with those of Bush, confusing and neutering moderates and progressives (who don't dare criticize him). Based on his inspiring speeches, they thought they had elected a community organizer, but are slowly realizing that they've been had, with the White House now in the hands of a Bush clone interested not in fighting powerful interests but in playing golf with them. By doing this, he has pushed the Republican opposition so far to the right that they've descended into lunacy, and ensured that he'll should have no trouble winning re-election in 2012. The only threat to him is that of the rise of a populist/fascist movement, motivated by blind hatred and the (accurate) feeling that they are being driven into poverty by a ruthless Ivy-league-educated establishment with a lock on the political and financial system of the country. At the Harvard Club in midtown there's a huge new portrait of him set in a prominent place as you enter the building. The establishment lawyers and financial types who congregate there know that he's their man.

The military budget is now significantly higher than during the Bush years, and taxes on the wealthy even lower (taxes on large estates are lower than under Bush). While Bush expanded Medicare significantly to cover prescription drugs, Obama's health plan was written in partnership with those responsible for the problem (high costs): doctors, insurance and pharmaceutical companies. The great innovation seems to be to expand access to medical care by forcing people who can't afford it to buy insurance from rapacious insurance companies. Obama's choice for Fed Chairman: same guy as the one Bush had running his Council of Economic Advisers, before moving on to the Fed and presiding over the worst financial crisis since the Great Depression. If there's any difference between Obama's treasury secretary (Geithner) and Bush's (Paulson), I'm unable to see it and haven't met anyone who can. Geithner is now in charge of gutting the few minor reforms that were passed in the aftermath of the crisis, while institutionalizing a system of government backing for too-big-to-fail financial firms of sizes expanded since the Bush years. The organized looting of these firms by their employees that brought on the mess of 2008 is now back in full-swing.

Next year's presidential campaign is predicted to cost a billion dollars, which Obama has already started raising from the financial industry and other interest groups. He faces no progressive or moderate opposition at all, with the only question to be resolved that of exactly how extreme his Republican opponent will be. I'll be covering all this here on the blog, but on days when I don't get around to giving you my thoughts on what is happening, two other places you might want to consult are FireDogLake and Naked Capitalism

Comments

   April 1, 2011

   the prime axiom of neoclassical economics, and much else besides: when the rich are happy, great things happen. Corollary: when the poor wallow in misery, wonders never cease. I bet all the theorems of that other body of theory that is "not even wrong" are based on the prime axiom. Adam Smith himself called it the "vile maxim" of the "masters of mankind." There are clear parallels between string theory and neoclassical economics. Might make for an interesting research paper.

2. **Mikhail Obamachev**
   April 1, 2011

   April Fool, none of this actually happened… right?

3. **Casey Leedom**
   April 1, 2011

   Okay, sorry, moving my way through your posts in reverse order. My bad.

   Breath. Really and seriously. Politics is "The Art of the Possible." It's weird and absurdly true. As a Died-In-The-Freaking-Wool liberal I have many dashed hopes in this game. But as a Died-In-The-Wool realist, eehhh, I'm open to what comes next. It really is better than what came before. Really.

   And by the way, if you are ever in the South Bay, drop me a line. I'll organize a bike ride/hike and a party and we'll all have a grand time.

   In the mean time, yeah, we've all got to try to influence things in reasonable directions.

4. **Cliff**
   April 1, 2011

   I think I am a much bigger fan of Peter Woit the political commentator than Peter Woit the physics commentator ;D

   Seriously, you're right in just about everything you say here. I voted for Obama also. Nothing wrong with embracing the mistake. What I really can't stand is the completely irrational unwillingness of Obama supporters to realize that his nice-guy facade is a complete lie. People desperately want to believe he's some victim of the establishment rather than a part of it. Grow up people, you were deceived by a bunch of empty PR. Now we have to figure out what to do about it.

5. **chris**
   April 1, 2011

   very well said. i never thought that you political views would be so absolutely congruent with my own ones – although the tone of your budgetary comments was hinting at it.

   why did you not become a journalist, really? you 've got talent for it.

6. **Nigel**
   April 1, 2011

   Look on the bright side, Peter. At least President Obama has got America firing its cruise missiles and dropping its bombs in the Libyan Civil War. So it's not all bad news.

7. **eldavojohn**
April 1, 2011

OMG!!!1!1! I LUV you're knew blog format! Like, I had gotten really sick and tired of you're "blah blah blah string theory blah blah blah like math …" and that shit is hard! It's about time you switched to something worthwhile and I'm glad I stayed and kept reading.

This is such a HUGE coincidence. Just the other day, me and my one friend LaShawnda, were talking about how there just isn't enough like politic blogs on the 'Net. SRSLY! You can't find anything like this anywhere! I even searched on AOL and you're like the only person with enough balls to diss the president.

And you totally changed my mind. I used to be some sort of Obama parrot but after reading your blog post, it really made me think. And after I thought I had like this revelation and then I totally agree with you now.

8. **tomate**
April 1, 2011

I see this as refined mock of aggressive and vague political writing, raging over the internet. No surprise that more than one commentator liked it: for the information standards today, this is high journalism!

But jokes sometimes are a good way to say what one really thinks… is that so?

9. **Desperate scientis**
April 1, 2011

Well, I think you can relax because there is no way Obama will win over Palin in 2012. So our next president will be even better.

10. **chris**
April 1, 2011

if a president is not able to locate a country on a world map, does that imply that (s)he will not send troops there?

if this is so, i am all for palin.

11. **SieveMaria Lucianus**
April 1, 2011

Do you think really that Obama is his own man ? That he has any power ? I think no and thought then that he is a straw man and he is afraid. Where did he come from – who put him there ? clearly he is someone who obedient to the powers that be.
I was one of 300.000 who voted for Ralph.

12. **steve newman**
April 1, 2011

hi peter-
i've been coming regularly for the physics, but i like the new format.
i consider string theory, standard model cosmology (and probably a lot of the math, which i don't understand), a total dead end.
just like the political scene, its depressing that the wrong way is in
power and squashes any opposition. a miniature version of the wrongness of things, is your aricle about the police war on bicyclists!
I agree with the commenter who said that your new blog direction is probably an admission of (hopefully) temporary defeat in the physics wars.
i'm less enthusiastic about the food reviews, especially in the context of all the grim stuff. finally, i agree completely with your assessment of Obama.
looking forward to seeing how your blog develops. maybe you should rename it to "More than Even Wrong".

13. **Roger**
April 1, 2011

I think I get the joke. You've written a parody of an anti-Lubos blog!

14. **Claver**
April 1, 2011

If the wise play the fool, still the fool remains more foolish indeed!

Nice one Mr Woit.

15. **S. Molnar**
April 1, 2011

Satire or not, I agree with almost everything you have said in your 1 April posts. I differ in the matter of BBQ – I refrain from eating land animals so that my atmospheric methane contribution will be of the direct kind only – and I have one example of the Obama administration being better than Dubya's. The Transportation Secretary, who is an open Republican, unlike the crypto-Republican Obama, has actually done a respectable job of promoting cycling infrastructure, pedestrian access, and public transportation. He clearly comes from an alternative universe.

16. **anonymous**
April 1, 2011

This may be a great time to mention the new element that is speculated to be the bearer of all political mass in the universe:
Govermentium (Gov). Govermentium is normally stable and does not change under most circumstances (including new election cycles), has a transient state where it spews a great deal of negatively charged taxions. Governmentium has 1 neutron, 12 assistant neutrons, 75 deputy neutrons, and 224 assistant deputy neutrons, giving it an atomic mass of 312. These 312 particles are held together by forces called morons, which are surrounded by vast quantities of lepton-like particles called peons. Since governmentium has no electrons, it is inert. However, it can be detected as it impedes every reaction with which it comes into contact. A minute amount of governmentium causes one reaction to take over four days to complete when it would normally take less than a second. Governmentium has a normal half-life of three years; it does not decay, but instead undergoes a reorganization in which a portion of the assistant neutrons and deputy neutrons exchange places. In fact, governmentium's mass will actually increase over time, since each reorganization will cause some morons to become neutrons, forming isodopes.

17. **SieveMaria Lucianus**

April 1, 2011

The real worry is the brute hammer of censorship – good choices are not made with missing information. An educated, well informed public is imperative for the survival of democracy – We have now at this very moment in the internet an amazing tool for the freedom of information – or in a parallel world – a twinkling of the eye it is gone and more and more you will be finding we are living in a totalitarian regime. If you want to control people just make them feel stupid or better yet shut the book stores, control the web. In a few years most everyone will forget how to survive.

18. **Bobito**
April 2, 2011

Right on the money, so to speak.

19. **Josuah Chamberlain**
April 4, 2011

Glad to see that you come to your senses. Isn't being able to think independently,that is to say, being able to think for yourself a wonderfull thing!!!!

Being president of the US for Barack and Michelle Obama is all about being the coolest kid in the class….scaled up big time. That it requires the destruction of human beings in the Muslim world and the destruction of American teenagers economically coerced into carrying out imperial policy in the Middle East is of no consequence to these two sociopaths and the previous two socoipaths-Bush W and Bill Clinton…all three working on behalf of the oil companies and the hedge funds. It is all going to end very badly and in tears.

20. **Andrew L.**
April 5, 2011

I agree with most of this post except that he's worse then Bush. Bush's administration INSTITUTED most of the most horrific polices you complain about. The problem with Obama is that he's gone along with them after BSing the nation. He's not a real Democrat,as I've said many times. He's a corporate token. But the really frightening part is how the Corporations have decided to use his weakness to eliminate the middleman entirely and return us to the 18th century of gilded age psuedodemocracy and legalized slavery of non-wealthy people. They've done this by a sustained 2-pronged attack through the subversion of the Supreme Court that now is systematically handing the country over to them piece by piece beginning with the Citizens United decision-and the shift of the Republican party into lunatic policies that are almost comically pro-wealthy and anti-middle/lower class.The local attack on labor is the centerpiece of the latter. All is not completely bleak, though.The plutocrats' huge mistake was directly attacking the rights of workers in such a heavy handed and overt manner and not even bothering to conceal thier contempt for the suffering working poor. People are ANGRY and they see through the scam now.They tell me, "oh,the mindless rabble will forget this in a few years." I don't think so, this was too direct and vicious. Taking away workers rights,demonizing them and cutting thier pay while laughing is pretty hard to spin effectively. That was thier mistake-they're usually a lot more subtle then this. Right now,that anger is locally directed-it may take a few more years before that anger is directed upwards towards Washington. The real breakthrough will come when they see that Obama and "bluedogs" like him aren't just the "lesser of the two evils"-they're as big a part of the problem as the Conservatives are. Personally-I'm seriously considering moving to Canada when I get my PHD.

21. **william C wesley**
April 5, 2011

OK progressives/liberals time to give a culinary review, how was the crow? Hope you liked it because you'll be eating that almost exclusively for most of the foreseeable future. You thought that because your weapon is individual honesty you were immune to this, that this dish could only be for the Republicans who's main weapon is shared illusion. Nope. Anyone can be wrong, anyone can be had. Liberals are had when the truth is falsely employed while conservatives are had when illusion is falsely employed. Bush was a wolf in wolfs clothing while Obama is a wolf is sheep's clothing, and so yes, he's worse. I don't mind when obnoxious ignorance does the wrong thing compared to when supposed compassionate wisdom does the wrong thing. I can understand when denial and illusion turns out to be denial and illusion but I can't forgive when honesty and knowledge turns out to be illusion
Bush never claimed to be on the side of the powerless, unlike the current occupant who did. WE HAVE BEEN HAD. In the next election VOTE INDEPENDENT! Who? Whomever most represents the attitude that creativity and liberty will solve our problems because ONLY RESPECT FOR THE INDIVIDUAL WILL. Nothing of any value was ever invented by a committee, and it maters not whether the committee that rules us is a government committee or a corporate committee it is rule by closed committee that must end. Return the patent/copyright office to INDIVIDUALS and take it out of the hands of the MOBS THAT NOW RULE OUR LIVES whether they be the Ivy league gangs or the crime boss gangs the government gangs or the corporate gangs, educate children to be EMPLOYERS NOT EMPLOYEES, CREATIVE PRODUCERS NOT PASSIVE CONSUMERS. If we continue to rely on gangs to get us out of what only individual initiative can overcome WE ARE DOOMED

22. **Chris W.**
April 6, 2011

…educate children to be EMPLOYERS NOT EMPLOYEES, CREATIVE PRODUCERS NOT PASSIVE CONSUMERS.

Uh, excuse me for asking this, but who will these employers employ, and who will consume what these creative producers produce? Just wondering…

23. **Tim R**
April 9, 2011

Hilarious.

I used to be sorta naive too, back in grad school. At least I never had a lapse in judgement as large as yours.

24. **Dave Miller**
April 17, 2011

Peter,

I realize that this is a bit of an April Fools' spoof and should be taken with a grain of salt…

But, in my experience, most intelligent liberals AND conservatives would agree with most of what you wrote here. The two things we could reasonably hope for from Obama were an end to the senseless wars and an end to the bailouts of the fat cats.

I was never an Obamaniac, but I too thought Obama would be better than Hillary and hoped he would be better than McCain.

I now think we elected Hillary W. McCain in '08.

Dave Miller in Sacramento

25. **Matt**
April 18, 2011

Nothing is more offensive than a naive person who claims that everyone else is naive.

Where to begin? First, Afghanistan. Obama campaigned on increasing the fight in Afghanistan. He talked about it repeatedly, especially in the debates. That you are surprised of his decision to increase troop levels in Afghanistan is rather strange. Did you think he was lying about his AfPak policy during his campaign?

And Guantanamo. Okay, let's say President Obama, the Commander-in-Chief, unilaterally declares that he's closing Guantanamo. What happens to all the prisoners? Where do they go? No state will try them–just look at the fiasco in NYC when Holder attempted to hold the trial for one of the 9/11 conspirators there. Ten years later, they eventually just gave up.

And no state will agree to hold the prisoners, either. Nor any foreign non-torturing country. None of our European allies have agreed to take them in. So what is Obama supposed to do with all these people? If he releases them all, and one of them commits another major act of terrorism, the blowback would be far more devastating to the liberal cause than Guantanamo's existence. If you can think of a way for Obama to somehow make state or local American politicians have a spine and take in Guantanamo prisoners, please tell me. The mere fact that you think it's just as simple as the Commander-in-Chief declaring the end of Guantanamo (what, in some sort of executive order?) is preposterous. How do you physically carry out that policy?

And on it goes. Health Care Reform? The model is a carbon copy of the system we have here in Massachusetts, and you know that if Ted Kennedy were alive when the national plan had been passed, he'd have been jumping with joy. Here in MA, 98% of adults have health insurance today, and 99.7% of children. Have you seen the national rates? How can you possibly argue that nationalizing the MA plan wouldn't be a staggering improvement, especially considering that the national plan, unlike the MA, also includes countless additional trial programs for actually making health care delivery less expensive over time, like bundling, ACOs, revised payment schemes inspired by the Mayo Clinic, computerization, etc. If you or Jane Hamsher or Howard Dean had your way, we'd be stuck with the status quo, just like the GOP wanted. So tell me, do you really think a national version of the MA plan is worse than the status quo?

This whole making-the-perfect-the-enemy-of-the-good thing is what makes me so disgusted with the hard left. Do you know what the original incarnation of Social Security looked like, and how long it took before the program took its modern form? Would you have demanded that FDR veto the original Social Security plan?

The choice between the Dems and the GOP has become the choice between Coca-Cola and arsenic. On the one hand you have an ideologically blurry party with liberals, moderates, and conservatives represented, and on the other hand you have a party that's basically the John Birch society. If it hadn't been for the GOP's massive federal tax cuts, two decadal unfunded wars, and a Medicare prescription plan bigger than Obama's health care bill, all put entirely on the national credit card, there would be no short-term or medium-term debt crisis right now. And you think Obama is worse than Bush? Who would Bush have replaced Souter and Stevens with on the Supreme Court?

As for the Fed, the best possible thing the Fed could be doing is a massive quantitative easing program that pours a huge amount of money into the system. And that's precisely what they finally decided to do, and they're keeping at it, despite many right-wingers demanding that it's going to lead to too much inflation. You think another term of Bush would have them doing monetary stimulus on that scale?

Your post is ridiculous, pie-in-the-sky whining. Politics is very, very hard, and it's for grown-ups who have a grip on the real world. You fight hard and take what you can get. But this attitude of declaring that it's all a big sell-out and you're just going to take your marbles and go home is childish and immensely counter-productive. You think if Gore had won in 2000 we would have had Iraq and those massive tax cuts, let alone Alito and Roberts on the Supreme Court, who are responsible for Citizens United?

Here's a good idea: Find a way to eliminate filibusters and other anti-majoritarian parliamentary rules in the Senate. Nancy Pelosi and Obama got everything you wanted through the House, including a public option, cap and trade, a much bigger stimulus package, and over two hundred other bills. But they all died in the Senate. Was that Obama's fault too?

I'd like to see the Peter Woit plan. Compaining is easy, but productive suggestions are much more difficult.

26. **Marty**
April 18, 2011

Matt's comment is a good example of why I'm glad Peter avoids political commentary in his postings (except for April Fool's Day…). Why the *ad hominem* attacks? They add nothing useful or interesting. There seems to be something about political views, religion, and sports team rivalries that can bring out some of the worst in people. Well reasoned discussions that avoid ideology and strong emotions are enjoyable and thought provoking, but it seems too hard for some people to keep the discussion at that level…

27. **Peter Woit**
April 18, 2011

Thanks Marty,

You're quite right, Matt's comment does an excellent job of showing why I don't allow political discussions here except on April 1. The internet unleashes too many of people's worst characteristics, including that of vilifying anyone who disagrees with them. Only a self-destructive idiot would choose to spend his time moderating such discussions.

For the record, no, I don't think that "if Gore had won in 2000 we would have had Iraq and those massive tax cuts, let alone Alito and Roberts on the Supreme Court, who are responsible for Citizens United?" I actually was quite a fan of the Clinton/Gore administration, something which now seems to make me, according to Matt and other Obamaites, a member of the "hard left". My problem is just with Obama, and the collapse of moderate/progressive politics in the US that he has been (partly) responsible for enabling.

28. **Matt**
April 18, 2011

Perhaps you would be willing to tell me what specific things a hypothetical Bill Clinton 2008 presidency would have done differently? Clinton failed to pass health care reform, enacted Don't Ask Don't Tell and the Defense of Marriage Act, and shut down much of welfare, not to mention presided over most of the financial deregulation that led to the financial collapse of 2007.

It was much easier for Clinton to look good when the economy was roaring along. But Obama inherited the worst financial picture since the Great Depression. He somehow got nearly a trillion dollars in fiscal stimulus through (you should read through the list of separate items in that bill, which also included a huge boost to science research funding), plus at least as much monetary stimulus through the Fed. He saved the American auto industry and with it millions of working-class jobs. He finally ended the banking middle-men in student loans and the insurance middle-men in Medicare Advantage. He finally got DADT ended, got a federal hate crimes bill and the Lily Ledbetter act through, and dropped the federal defense of DOMA. He ended the global gag rule on foreign aid groups providing family planning services, too. And, refusing to give in to GOP demands, he is refusing to send ground forces into Libya, and letting the Europeans do the job (poorly, as we're now seeing). And he replaced two Supreme Court justices with liberals.

Please tell me how Bush would have handled all this. I just don't understand. Please explain it for everyone.

29. **Peter Woit**
April 18, 2011

Sorry Matt,

I don't do rants about how politicians I approve of do everything right, and ones about how politicians I disapprove of do everything wrong I only do on April Fool's Day. The world is very complicated, and it's also quite different than in the 1990s: militarism and inequality between the rich and the poor in the US has increased dramatically. Progressives and moderates should be holding Obama accountable for his failure to do anything about these problems, not making excuses for him about how it's impossible.

30. **Matt**
April 18, 2011

I notice that you're not willing to give specifics. I know you're disappointed, but please tell me concretely what you would have Obama physically be doing differently.

How does he get a bolder agenda through the buzz saw of the Senate, given the filibuster and other procedural roadblocks there? Look at all the bills they got through the House but that failed to get through the Senate, from a public option to cap and trade to a much bigger stimulus bill, etc.

How would Obama have gotten around that? I mean, look at what they had to do to get the health care bill through the Senate—they needed to do all kinds of crazy workarounds and loopholes, and even then it barely squeaked through after nearly a year of constant effort.

31. **Matt**
April 18, 2011

And, for goodness sake, Bush brought us Dick Cheney as VP, Donald Rumsfeld as Defense Secretary, and John Bolton as UN ambassador, just to name a few. These were all raging sociopaths. Was there ever a group of more horrible human beings in top US posts than these guys, who did more domestic and global damage? Were Obama's picks of Joe Biden, Bob Gates, and Susan Rice really worse?

I just don't understand.

32. **Peter Woit**
April 18, 2011

Matt,

I did give specifics in this posting:

1. Expansion of the war in Afghanistan. He's Commander-in-Chief.

2. Failure to close Guantanamo as promised. The place is a disgraceful violation of international law. He's Commander-in-Chief, personally directly responsible for the place, and could have flown its inmates to a legal military prison in the US.

3. If he wanted to decrease military spending, he could have proposed this, and vetoed legislation that increased such spending.

4. It was his choice to veto the UN resolution on illegal Israeli settlement activity.

5. Appointment and Reappointment of those responsible for the financial crisis (Bernanke + Geithner).

6. Bonus points for what he has done recently concerning the treatment of Bradley Manning.

You can argue back and forth about whether Obama could have gotten better legislation through the Senate (and now his problem is not the Senate, but that he and the Democrats politically did such a bad job during his first two years that they lost the House), but the record is clear on what he has done on his own.

About Bush Jr.: Yes, he and the people around him were awful and did a huge amount of damage to this country. The question now is whether Obama is going to fix any of it or continue along the same lines. Under Bush Jr., most Democrats were appalled by what was going on, now they're defending it.

33. **Matt**
April 18, 2011

>2. Failure to close Guantanamo as promised. The place is a disgraceful violation of international law. He's Commander-in-Chief, personally directly responsible for the place, and could have flown its inmates to a legal military prison in the US.

In what state? He needed Congressional approval and state approval to move them. Don't you remember all that wrangling going on in his first year, all the crazy US and state legislators screaming that these Guantanamo prisoners were supervillains who couldn't be contained even in supermax facilities, and refusing to vote to allow the prisoners to come in? Don't you remember all the jokes by Jon Stewart about how foolish those legislators were, given that we had man-eating serial killers in these prisons?

In the abstract, it all seems so simple. But the president doesn't have a magic wand. He's got the veto pen, the state of the union address, and he's commander of the armed forces. He doesn't get to vote in Congress, and he can't overturn Supreme Court decisions. Do you know of any off-mainland military prisons other than Gitmo where he could have sent the prisoners, and, importantly, that he could get Senate approval for?

The rest I basically agree with. But that's all small potatoes compared to what Bush did. The Israel UN vote? Who cares? Bradley Manning? Criminal treatment, but come on! Bush would have waterboarded him to death. Bush invaded Iraq for no good reason, and Obama has finally wound it down. Bush presided over the biggest economic collapse in modern history, and Obama turned it around. Bush tortured hundreds of innocent prisoners to death, and Obama's contribution was to keep those photos from getting out. Coca-Cola versus arsenic, again. But perhaps the McCain-Palin ticket would have been more to your liking.

The fact is that Bush was a reckless man, and Obama is not, and that's probably the single most important reason why Bush was far, far worse. And that's more generally true of the GOP versus the Democrats. So the lesson is never, ever to elect the GOP, because they'll put in place all kinds of horrible, horrible policies that the Democrats are too cautious to sharply reverse as soon as they get back into office. The lesson is not to say that the Democrats are worse than the GOP, and that nobody should care if the GOP wins the next election. I'm sure the Paul Ryan budget plan would not be to your liking.

34. **Matt**
April 18, 2011

I'm not making this up. Here are the results of a simple Google search on "guantanamo house vote":

"U.S. House votes to block Guantanamo transfer"
http://www.reuters.com/article/2009/10/01/us-usa-guantanamo-idUSTRE5905EQ20091001

"House votes to prohibit moving Gitmo detainees"
http://articles.chicagotribune.com/2010-05-30/news/ct-met-house-vote-gitmo-05-30-20100528_1_democrats-split-gitmo-center-in-guantanamo-bay

Here's a sampling, from http://entertainment.xin.msn.com/en/radio/938live/headlinesnews.aspx?cp-documentid=4510680

>>The US House of Representatives has approved legislation to stop the moving of terrorism suspects from Guantanamo Bay to American soil

It prevents the transfer of prisoners by prohibiting the government from spending any money to do so.

The vote is a blow to US President Barack Obama's efforts to prosecute prisoners in America.

The spending ban makes it impossible for Mr Obama to follow through on his campaign pledge to close the prison by re-locating the prisoners.

The Obama administration has condemned the tighter restriction.

It argued that Congress should not direct how the administration prosecutes such cases.

There are still 174 detainees at Guantanamo prison.
—

So Peter, what should Obama do about it?

35. **Matt**
April 18, 2011

What drives me most crazy about the Guantanamo fiasco is that Obama is getting it from both sides. The right wing is calling him a terrorist-loving, America-apologizing, naive Marxist for trying to close it down, and the left wing is calling him a capitulating, lying, worthless scum bag for keeping for being unable to get its closure through Congress. If you have any concrete ideas for how to get closure of Gitmo through Congress, please let me know.

36. **Peter Woit**
April 18, 2011

Matt,

One reason for emphasizing the Guantanamo story is that it's the clearest case where Obama had the power to do something and refused to use it. When he came into office, he clearly had the authority as commander-in-chief to issue orders to the military to shut the Guantanamo prison, send transports down there, pick up the prisoners, and fly them back to military prisons in the US. Had he had done this, I seriously doubt that Congress or the States could have gotten a court to issue an enforceable order that the prisoners be sent back to Guantanamo. This might be a bit trickier now due to the Congressional legislation, but I still think he should do this and suspect he would do very well in court making the case that this is not up to Congress, but up to the Commander-in-Chief. Do you really think a court is going to rule that a President leading a nation at war does not have the power to hold captured enemy soldiers on US soil if necessary?

In any case, looking at how he has handled the Manning case and continued a large number of other Bush-era violations of civil rights on national security grounds, it's pretty clear that the reason he didn't do this is that he just doesn't see the issue very differently than Bush did. Again, if we had Bush still as President, I strongly suspect that he would have emptied Guantanamo by now, through one means or another, and if he hadn't, the Democrats would be putting heavy pressure on him to do so. Instead they're rolling over and supporting Obama's disgraceful and illegal behavior on this issue.

As for the politics of it, he has caved in to the far-right and done what they want, but they're never going to love and support him. The "far-left" of people who believe in following conventional legal and ethical standards are not happy with him, but see no alternatives. So he's not making many people happy, but he is pursuing what will probably be a successful political strategy: govern like Bush, driving Republican opposition to the loony extreme right, while making sure no challenger from the center or the left emerges. To make this work he just needs to convince most people that it's not his fault that moderate or progressive policies are not being pursued. So far, this is working quite well for him.

37. **Matt**
April 18, 2011

Actually, Article I, Section 8 of the Constitution declares that only Congress shall have the power to "make Rules concerning Captures on Land and Water." To the extent that Bush made these sorts of decisions unilaterally, he was acting in an extrajudicial–illegal–way. Perhaps Obama should do so as well, but I sort of like the fact that he has decided not to keep breaking the law. Perhaps he was stupid to try to get Congress to act, but that was the legal approach. And his inability to get it done has nothing to do with his desire to get it done. Bush wanted to create Guantanamo, and Obama wants to get rid of it. And yet Obama is worse than Bush?

The Manning case is a travesty. But Bush did not do a single good thing for the country in his entire eight year presidency. (His only positive accomplishment was PEPFAR, but that was in Africa.) Every decision Bush made was a catastrophe and a screw-up that made our lives incalculably worse. He added literally trillions to the debt, and the cost was strangling many of the good things liberals wanted to get done when he left.

Has Obama really done nothing good in his two years in office so far? I listed a huge number. Saving us from total financial collapse has to go up on that list. So was the nearly a trillion dollars in stimulus. You should really read the contents of that bill in detail. It's apparent magnitude seems small only because it all got into one single bill. Read its Wikipedia page:

http://en.wikipedia.org/wiki/American_Recovery_and_Reinvestment_Act_of_2009

The unemployment rate had a major inflection point just when the stimulus package started:

http://en.wikipedia.org/wiki/File:Recovery-JobLossGain.png

Then came the year-long struggle to pass a health care bill, nationalizing the MA plan so that 30 million more people get access to health insurance. And he actually paid for the damn thing, despite having to raise all kinds of taxes and cut Medicare Advantage.

The financial bill was too weak, but at least it wasn't more de-regulation, like Bush favored. Obama saved the American auto industry, despite enormous criticism at the time and calls to let the auto makers collapse. (And take millions of jobs with them.) He ended DADT and stopped defending DOMA. If it hadn't been for the filibuster, he would have gotten cap and trade passed, too, as well as a public option and much more stimulus.

I also mentioned before the Lily Ledbetter Act, the new federal hate crimes bill, and the two Supreme Court replacements. Bush didn't do anything helpful, and Obama did many helpful things. The few bad things Obama has done (AfPak, Manning, etc.) are as bad as what Bush did, but Bush had nothing to balance that out. To say that four more years of Bush would have been better is just difficult to understand. Are you also saying we should all sit out the 2012 election and not vote for Obama?

38. **Peter Woit**
April 18, 2011

Matt,

Since Guantanamo is illegal, Obama is in violation of the law by keeping it open. Saying he is going to keep doing this in order to more carefully follow the law than Bush is just absurdism.

I'm not saying people should sit out the 2012 election. They should make clear that Obama's cave-to-the-right tactics are not acceptable, work to get a better Democratic candidate and vote for him or her in the primary. If this fails, barring some miraculous decision of the Republicans to nominate someone sensible, people won't have any choice and will have to vote for Obama, at least if they live in swing states.

39. **Matt**
April 18, 2011

Oh. That actually sounds like a pretty good plan. Why do you have to be so damn reasonable?

40. **chris**
April 19, 2011

Matt,

you make it sound like Obama is a string theorist. He does not produce results but excuses.

Looking at it from the outside it is just plain disappointing that with both chambers on his side he could get so little done in the first 2 years.

41. **Matt**
April 19, 2011

Chris, in the American system we have this thing called the filibuster. Look it up. Unless you have 60/100 seats in the Senate, there's no advantage in having a majority.

42. **Matt**
April 19, 2011

Again, to get a truer sense of what Obama and the Dems were trying to accomplish, look at what made it through the House. Unfortunately, except for a brief period after Spector switched parties, the Dems didn't have enough votes in the Senate to overcome the filibuster. It's a frustrating peculiarity of the American political system.

43. **chris**
April 20, 2011

matt,

if someone is too cowardly to bring in an initiative just because a stupid loophole would in principle allow to veto it is not really convincing.

i always hear a filibuster as an excuse by the dems, never have i heard of them threatening to do it against the other side. i would guess that after 2 years of constant filibusters voters might grow weary of such strategies, but all of the us seem to accept this extreme measure as bussiness as usual – like a nuke, that does not need to be employed, just its existence blocks change of any sort.

44. **Matt**
April 20, 2011

Voters do not "grow weary," because the vast, vast majority of voters have no idea what the filibuster is. Instead they just blame whoever has the majority.

To get a sense of the scale of this massive institutional problem, see

http://voices.washingtonpost.com/ezra-klein/2010/12/breaking_the_filibuster_in_one.html

Most of people's gripes with particular political parties are really problems with the system itself, problems that are insanely difficult to fix. (And outside the president's powers to fix, by the way.)

45. **jpd**
April 20, 2011

@Matt for historical accuracy, when Ted Kennedy was alive
the Dems had 60 (same number as with dem spector)

46. **vorpal**
April 20, 2011

@matt,

Obama didn't hesitate to skirt the Constitution when initiating a war in Libya, yet when it came to Gitmo he followed, and continues to follow, the "law" to a T.

I think the contrast in attitude Obama has shown in the above two policies shows where his heart lies.

47. **Matt**
April 20, 2011

jpd- As I said very clearly, the Dems had 60 votes in the Senate only for a very brief period, a few months, after Spector switched parties and before Ted Kennedy died and was replaced by Scott Brown. (Here I'm treating Lieberman as a quasi-Dem, which is frankly questionable.) But nothing can move through the Senate that fast, because of cloture votes, holds, and other parliamentary delaying tactics that the GOP gleefully employed.

Given your blatant error being brought to your attention, I'm sure you'll revisit your opinions, right? (Ha!)

vorpal- So far the president refused to declare war on Libya, despite both Dems like Kerry and Republicans like McCain pushing him to do so, and has sent no troops over, both acts that would have required Congressional approval. So far he's made menacing gestures and fired missiles, but left the heavy lifting in Europe's limp-wristed hands. As a NATO treay signatory, Article 6 of the Constitution makes certain demands of us.

Let me know when Obama changes his mind and decides to invade. Given his (and his Sec Def's) blatant distaste for getting involved in another Middle-Eastern conflict, I'm not holding my breath.

48. **Matt**
April 20, 2011

Indeed, without a declaration of war, the legal status of presidential authority in matters of no-fly zones is rather murky, especially when there's a situation of acute humanitarian crisis and UN approval (such as Libya, or Clinton's intervention in Kosovo, although the UN probably would have approved intervention in Rwanda and Darfur if Western powers had pushed for it).

See Wikipedia's entry on the War Powers Resolution of 1973, especially the section on its constitutionality:

http://en.wikipedia.org/wiki/War_Powers_Resolution

See also as this piece specifically on the Libyan no-fly zone by Michael Kelly, president of the U.S. National Chapter of L'association International du Droit Penal:

http://jurist.org/forum/2011/03/the-president-does-not-need-congressional-approval-for-libya-no-fly-zone-yet.php

Whether you approve of the Libyan intervention or not, Clinton's intervention in Kosovo was certainly as significant, so Obama is hardly an outlier among Democratic presidents on this one. Inasmuch as this is a debate over whether Obama is worse than Bush, who actually invaded two Middle Easter countries at a cost of trillions of dollars and thousands of American lives, I'm afraid I can't concede this point.

49. **Matt**
April 20, 2011

These last few comments really typify why this belly-aching gets on my nerves so much. These criticisms are mostly based on profound misunderstandings and ignorance about presidential powers and the basic structure of American's political institutions.

The system itself really sucks. It's poorly designed, to a large extent because the founders didn't understand the sociology of party politics. Hell, they thought the Senate was going to be a nonpartisan body of elders! (And the Senate is probably the single dumbest part of our system.)

The president exists inside this highly constrained, frustratingly obstacle-ridden system, and criticisms should be deployed with all these factors in mind. It's far, far easier for a reckless president to be destructive than for a cautious president to clean up the mess. That's the breaks, unless you all can figure out a concrete, well-though-out way to change the system.

Any ideas?

50. **jpd**
April 21, 2011

whoa, "blatant error"? i wasn't even involved in your discussion, just pointing out the Spector count was the same as the Kennedy count.
but now that you bring it up, why is it so easy for obama to invade yet another country but ie not close guantanimo?

51. **jpd**
April 21, 2011

rhetorical question, dont bother answering

52. **Matt**
April 21, 2011

Because the American political system makes it far easier to fire missiles than to relocate military prisoners. There needs to be a place that agrees to take the hundreds of them in. If you'll recall, Obama was pushing hard for several states and European countries to take them, but without much success. For a while Yemen was taking prisoners of Yemeni nationality, until the Yemeni Christmas underwear bomber fiasco made that untenable. Obama also found a place for the Uighurs.

I'm not going to repeat my arguments again. Read my previous comments. But it's clear Obama wants to close Gitmo, and has put much effort into doing so, no thanks to Congress or state governments or Europe. There's no simple solution. The lesson here is not to let the GOP come to power in the first place.

By the way, they just agreed to move Manning out of the hell hole he was in. We'll see what happens.

53. **vorpal**
April 21, 2011

@matt,

So Pearl Harbor was not an act of war since Japan didn't commit ground troops?

If Libya "just" shot missiles at Gitmo (to help protect the detainees), that would not be interpreted by the US as an initiation of war? Or do I have a profound misunderstanding of America's political institutions?

54. **Matt**
April 21, 2011

I didn't say act of war, I said declaration of war. You can drive a truck through that legal loophole.

Putting legal issues aside, if you can't see a moral distinction between Libya and Pearl Harbor, I'm not going to try to explain it you.

55. **Politically naive**
April 21, 2011

Clearly people who are not allowed to return to their home country count as refugees and thus eligible for specific treatment under treaties to which the US is a signatory? There are clear legal procedures for such an occasion.

As for Pearl Harbor vs. Odyssey Dawn, indeed, those are very different: the first was a miscalculated military response to an economic blockade as part of the maneuvering between two imperial powers, the other is an intervention in a foreign civil war for the purpose of maintaining secure access to cheap oil.

56. **Matt**
April 21, 2011

What treaties to which the US is a signatory would they be covered under?

And, oh, how original! A claim that it's a war for oil. You're quite a genius! Please shower us with more of your rarified wisdom.

Such lazy thinking. Thank you for reminding me why I could never find myself at home with the Left. (If only the Right weren't crazier…)

Given that there's obviously no way to prove a negative, I'll just say that letting the genocidal madman Qaddafi crush the rebel movement would be a far cheaper and more reliable way to keep Libya's oil flowing to the West. Turning against Qaddafi, with whom the US formerly had a stable relationship, and supporting the rebels in an indefinitely-long conflict would be the last thing you'd do if oil was the priority.

And Obama and Bob Gates resisted getting involved for weeks, almost till it was too late. You can read plenty of in-depth reporting online that got inside the White House during the crazy time when all the deliberations were going on. It was Hillary Clinton, Susan Rice, and Samantha Power who are most responsible for US backing of the UN resolution and US intervention. (And who's a more blood-thirsty imperialist hound for oil than Samantha Power, right?) Nobody wantes this to be another Rwanda; they were all hoping for Kosovo.

Do some reading, and then you can speak without looking foolish.

57. **Matt**
April 21, 2011

And I'll let slide your typical left-wing moral equivalency between Imperial Japan and the isolationist US in WWII.

58. **Matt**
April 21, 2011

You know what? There's no point in further discussing any of this with all of you. You've all made up your minds already, and no amount of further evidence is going to change any of your minds.

What I will say is that if you any of you think Obama is as bad as any of the current GOP contenders, and that your voting in 2012 is meaningless, then you're sadly misguided.

Obama/Biden 2012. Peace out.

59. **Politically naive**
April 21, 2011

As to refugees, there is
http://en.wikipedia.org/wiki/Convention_Relating_to_the_Status_of_Refugees
to the Protocol of which (the version which extends outside of Europe) the US is a signatory. Under that, a refugee is defined as

"A person who owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear, is unwilling to return to it.."

If those countries refuse to accept the detainees or if there is a real fear that they will be persecuted in their countries of origin, they seem to be covered by this convention. They will not be the first or only refugees living in the US, where in most cases the US is not directly responsible for them having become refugees. That is definitely no excuse to bar them from their basic human rights.

As for Libya, that truly sounds very noble until you look around the Middle East and note that the US does not even deign to pressure regimes with which it is in much closer contact when they butcher their civilians for protesting the government, e.g. in Yemen or Bahrain. It is clear that nobility has nothing to do with it; the danger of a civil war resulting in a conclusion that is bad for US and European oil interests in Libya seems a much likelier impetus, especially in light of other "comrades" already being deposed or removed.

Nevertheless, I am open to other suggestions; unfortunately, you have left the stage after bombarding us with further abuse and ad hominems which are presumably based on a background respect for the humanistic tendencies of particular members of the administration, as if that mattered. Finally you conclude with a campaign sticker. Marvelous.

New York, New York

April 1, 2011
Categories: Uncategorized

Another topic I hope to write about extensively is that of New York City, including discussing the wide range of cultural events going on, as well as the amazing restaurants. On the subject of food, I should give a plug for my friend Nathan Myhrvold's new book Modernist Cuisine. It's been getting rave reviews, and the first printing has sold out. I've been promised a copy from the second printing, and Nathan tells me that, "while it's not a coffee-table book, you could use it as a coffee table…" I'll report once the book arrives.

I've been in and out of New York City since the earliest times I can remember, which were in a suburb 25 miles north. My mother was born here and my father came here by himself as a 17-year old after the war. The place has changed quite a bit over the years, and some of the changes of the past few years are quite remarkable. These days, most of Manhattan is filled with new or renovated architecture, everything fixed up to a high level of gloss, and virtually crime-free. With one bedroom apartments going for a million dollars in many neighborhoods, if you trip on your shoelace you're likely to take down a couple millionaires. These people are not going to mug you, and any outsiders who might think of this are deterred by the intense police presence, especially since 9/11. The only exception is bicycle theft, which is rampant, and doesn't much interest the police. Last summer I came out of a store on Broadway mid Sunday afternoon to find a group of guys with bolt cutters freeing my bicycle from its chains. No one seemed to find their activities unusual or worth doing anything about.

Back in the 1980s there was a lot of talk of "gentrification", as poor people were displaced by well-educated young middle-class people. These days a new word is needed to describe what is going on, perhaps "plutocracification". Someone who lives in Tribeca described to me how 20 years ago the neighborhood changed as lawyers and doctors moved in, and artists moved out. Nowadays, the lawyers and doctors are getting pushed out as the hedge-funders and investment bankers arrive. It's hard to overstate the effect of the financial industry in Manhattan, where supposedly it provides half the personal income, with much of the rest of the economy based on catering to this new wealth. Bank branches are everywhere, often taking up four corners of an intersection, with long swathes of expensive commercial street frontage devoted to cubicles for not very well-paid bank employees, most of which are normally empty.

In late 2008, there was a blip there for a moment, and I even saw one bank branch get closed. That didn't last long though: apartments are selling again at high prices, new bank branches are opening, and you can't get a reservation at a long list of popular expensive restaurants. Midtown streets are impassible, filled with fleets of massive black SUVs, their bullet-proof windows tinted dark. Used to be that the rich favored limos, but no longer. No one knows how long this will last, but the city is partying like it's 2011. Huge cuts to the budgets for schools and the city university system have just been announced, but most Manhattanites are unconcerned, since they would never have their children educated in public institutions.

One side effect of having a lot of rich people from many different countries is that the restaurants in Manhattan tend to be spectacularly good. Some are trendy and rather expensive, but for not a ridiculous amount of money you can get a fantastic meal, and you have to go out of your way to find a bad one. I'll be writing extensively about some of my culinary obsessions, one of which is barbecue. At this point I might argue that New York has better barbecue than just about anywhere else in the world. Just down the street from here (108th and Broadway), Rack and Soul has some of the best ribs I've ever eaten. On 26th St., Hill Country has taken the best sausage and brisket available in Texas (Kreutz's in Lockhart), stolen it and brought it here to the city. Over in Williamsburg, you can get great barbecue with the best pork and beans I've ever seen at Fette Sau. The list goes on and on….

Recently opened near here just off 125th St. is Marcus Samuelson's Red Rooster Harlem, where I recently had a wonderful lunch. Getting a dinner reservation is not easy, and some days the restaurant is packed with the power elite. Last week Obama took over the place for a $31,000/head dinner with his friends from the hedge funds. Here's the menu. This is a typical story of the new New York. In what used to be pretty much a slum, now there's a beautiful restaurant with some of the world's best food. The wealthy may sometimes monopolize it, but if you're a New Yorker and play your cards right, you too can participate in the fun and get a fantastic meal in a gorgeous place, at a not unreasonable price.

Comments

1. **JSE**
   April 1, 2011

   Come now — NYC has a glorious array of great restaurants, but you hardly "have to go out of your way to find a bad one." In fact, I think the median is pretty bad. New York has tons of people who never cook, so mediocre restaurants can stay in business there in a way they never would in smaller cities.

2. **Casey Leedom**
   April 1, 2011

   And I'll offer that NYC is hardly, even close to Great BBQ. I do better here in Palo Alto. And if I take you to Flint's in Oakland, you're in trouble. And if we heads on down south, well, you gets whats you deserve.

   It's not that the "interpretations" of BBQ in NYC are bad. They're not. They are in fact Great and even Spectacular. But, in the end of the day, they're really simply "different," interesting, etc.

   When you hear Jimmy Hendrix's cover of Bob Dylan's All Along the Watchtower, it's not that's he's devalued what Bob did. He's just offered a completely different take. In the end of the day, there's still the validity of the original.

   And speaking of which, I feel a big desire to cook some BBQ this Saturday. And that ain't no April Fools Day joke!

3. **Looking for BBQ**
   April 1, 2011

   Casey,

   Where in Palo Alto?

4. **milkshake**
   April 1, 2011

   this reminds me of an excellent documentary "Cocaine Cowboys" about late 70s and 80s – half of the Miami downtown was built with drug money. Hedge fund gangsters at least wont spray you with bullets.

5. **Deane**

April 1, 2011

I agree with JSE that most New York restaurants are mediocre or worse. It was easier to find good food in Houston. The neighborhood around Columbia has very little to offer in good food. My family and I have tried Rack and Soul, but have never been extremely impressed. I'll have to try Hill Country some time, because I really miss good Texas barbecue. I was, however, very impressed by the food at Smoke Joint in Fort Greene (about two blocks from BAM), both the meat and the sides.

6. **John**
   April 2, 2011

   Just a factual note: those black vehicles in midtown are Lincoln Towncars, and I've never seen one that was bulletproofed.

   If you wanted to see armored black SUVs, Obama's motorcade on 5th ave a day or two ago was the place to be.

7. **frank**
   April 2, 2011

   I too have been disappointed trying to find good authentic BBQed Texas brisket in NYC or anywhere else outside of the Texas. Unless you are lucky enough to be a guest on a Texas ranch that slow smokes over mesquite for 8 to 12 hours briskets from 5 to 10 year old steers that have never tasted any grain and have a nice thick layer of fat then you should just 'forgetaboutit'! Real Texas BBQ does not involve sauce. The flavor comes from the fat and the smoke. The skill and patience of the cook turns the toughness of the brisket with its associated gristle into tender gold. With its omega3/6 ratio exceeding one, its fat is as healthy and nutritious as it is delicious.

Biking in New York

April 1, 2011
Categories: Uncategorized

I've been biking in and around New York City for many years, recently doing several thousand miles a year, and this should provide many topics for the blog. Look forward to, for example, an explanation of how to best get across the Passaic River to Newark on bike. Biking in Manhattan has always been a challenge, but things have gotten exciting recently. A few years ago the city started painting lines on some of the streets, announcing that these were "bike lanes". They're generally filled with double-parked cars or trucks, and pedestrians hailing cabs or waiting for a break to run between the traffic. The width is carefully chosen to coincide with the width of a car door, so if you ride inside the lane you're guaranteed to properly get "doored" by people leaving their parked cars. The act of painting the line has the added feature of making it illegal for bicyclists to ride outside of it, at a safe distance from the cars.

The latest news is that a few special, protected lanes have been created, with cars parked outside the lane. These lanes go for a few blocks, and are heavily favored by delivery people to store what they're working with, tourists taking pictures of each other, parents changing their baby's diapers, or basically any activity that pedestrians would complain about if it was done on the sidewalk. The new lanes have enraged some powerful New Yorkers, who are now on a "bikelash" campaign to get them removed. They've managed to enlist the police, who have a long history in Manhattan of fighting with bicyclists, and have started up a serious campaign of legal harassment.

I used to ride regularly in Central Park, which has a 6 mile long road winding through it, most of the time closed to traffic. A couple months ago the police started issuing $270 tickets to bicyclists for not stopping at any of the 50 or so traffic lights (it seems that when traffic is not allowed, bicyclists must obey the traffic lights anyway, runners or pedestrians no). This caused almost all bicyclists to stop riding in the park, but a few kept on anyway. The police then decided that the speed limit should be 15 mph for bicyclists, and set up a speed trap at the bottom of a hill early one morning, ticketing quite a few people. Later they changed their mind about this, and decided the law really was 25 mph. Teams of armed police were dispatched to appear at homes of the 15-25 mph ticketees in the evening and tell them a mistake was made, while continuing to make clear that if they didn't stop at traffic lights when there was no traffic, they would still be ticketed. And if they were going faster than 25 mph at the bottom of a hill, there would be trouble. I'm sure they found this very reassuring. Personally, I've stopped riding in the park. It turns out though that there's a platoon of undercover police throughout the city in unmarked cars waiting to start up sirens and go after any bicyclist who violates any rule in the hundreds of pages of regulations governing not just bicycles, but motor vehicles (their slogan: a bike is the same as a car!). Recently I ran afoul of one of these due to rolling very safely and slowly through an intersection, which got me not one, but two \$270 tickets. I'll appear in court on these charges some day soon, and I'm sure my readers will want to hear all the details of how this works out.

Update: A commenter correctly points out that I got the Passaic and Hackensack Rivers confused, it's the Hackensack that is difficult to cross by bike down around Newark.

Comments

1. **Casey Leedom**
   April 1, 2011

   Dude. I'm sure you've seen this already but, whatever. If you're a bicyclist in NYC, this is _mandatory_:

   http://www.youtube.com/watch?v=6nQs7u3fDXc

   That aside, I've been focused on getting back into biking shape recently so if you're ever in the San Francisco South Bay, drop me a line and I'll schedule a ride. Currently I'm focusing on getting in shape enough to do "The Coast Ride" again this summer (~62 miles, ~6,200 feet vertical elevation gain). It's more a question of perseverance than capability … 🙂 But it _is_ beautiful. And there's the "Terminator" on Stage Road between 84 and Highway 1 …

2. **Chris Oakley**
   April 1, 2011

   Peter, this change of tack of your blog is only going to viewed as a surrender in view of the announcements this morning, namely that Motl has been re-appointed – this time as a full professor – to Harvard, and that Distler has been nominated for the 2011 Nobel Prize in physics ("for contributions in showing the world that surf bums are surf bums, and will never be anything more").

3. **Agent314**
   April 1, 2011

   Even foolish April cyclists are welcome in San Francisco. Peter, why don't you move out west to our fair city of SF?

4. **Blaaaaaack Ice**
   April 1, 2011

   I'm tired, soooooo tired, of taking that long uphill walk to the methadome clinic. There's got to be an easier way. Now I suggest to you it takes 5 seconds, just fiiiiiiiive seconds, to put a morphine suppository all the way inside. Yeah!

5. **Christian Takacs**
   April 2, 2011

   The problem with riding a bicycle anywhere is that it will make you two tired.

6. **John Romeo Alpha**
   April 2, 2011

   Blog symmetry is preserved, as I have recently decided to become a cranky physicist.

7. **Ed**
   April 2, 2011

   A sophomoric pot shot at Clifford Johnson? That's pretty low.

8. **Peter Woit**
   April 3, 2011

   Ed,

????

I disagree with Clifford about string theory, not about biking.

9. **Ed**
   April 3, 2011

   So, you're telling me that your April 1st incursions into the world of inane bike and food related commentary were in no way spoofs of Asymptotia? My apologies then.

10. **Peter Woit**
    April 3, 2011

    Ed,

    Inane? Those were honestly my heart-felt opinions about bikes and food. I don't personally think it's a good idea to go on about them on my blog under usual circumstances, but the great thing about blogging is that everyone's blog is different. And the virtue of blog posts you're not interested in is that you can not read them…

11. **AL**
    April 4, 2011

    Contrary to the yelps from those who find this post unphysic(s)al, it seems to me quite relevant to any enlightened theoretical mindset and interesting to all who share the joys of bike riding in NYC, given that a bicycle is second only to the wok as a peak of the engineering of a tool's form to its use ie it is one of the simplest arrangements of simple components -basically two wheels and a frame, handlebars, pedals, chain and a saddle – to achieve maximum payoff in terms of usefulness and other benefits such as outdoors, sunlight, ability to get off and on anywhere instead of official locations, exercise of lower body muscles, etc. In other words, a physics problem (urban transport for the individual) perfectly solved.

    Be that as it may, one has to admit that the riders on the recommended video are foolishly ignoring the fact that most cars weigh enough to kill them in a collision and in New York City are usually driven as if they were beds and the drivers half asleep, at least to what is happening on either side of them towards the rear, for the reason US automobiles are very hard to see from, and anyone who cuts right through the narrow passage between two buses is asking for disaster. So one doubts that they are trained in elementary physics.

    But actually I came to comment mainly to make the point that the complainers are underresearched in the matter of whether blogs should stray from their primary topic. If they pick up a copy of this weeks New Yorker (April 11 2011) they will find that James Surowiecki their excellent Economics columnist quotes many studies which have shown that if you distract people from the main task they will perform better at it ie if you let them have the Internet at work they will do more and better work. The link is http://www.newyorker.com/talk/financial/2011/04/11/110411ta_talk_surowiecki). So blogging actually should be alleviated by wandering from the main topic from time to time, because it will increase the quality of everybody's attention when it gets back to it.

    Anyhow biking in New York is a very great cause which should be promoted until cars are largely replaced. The fact that it has such distinguished support is important news in its own right.

12. **jensph**
    April 5, 2011

    Too bad this topic was just an April Fool's diversion, because I was all set to explain that it's not the Passaic River that's difficult to cross on bike, it's the Hackensack River…

13. **Peter Woit**
    April 5, 2011

    jensph,

    Of course you're right, I got those confused, will fix. I've tried this once on Lincoln Highway (Rt. 9), once on Newark Turnpike (Rt. 7), neither of which was an experience I'd like to repeat (getting a flat in the middle of the Rt. 9 one didn't help..). Final conclusion was that one really has to go all the way North up to around the Teterboro airport to make this crossing sensibly.

14. **AL**
    April 5, 2011

    May I add that I for one am agog to hear how your $270 x 2 ticket fighting goes, though I suspect you will be let off. If it is any encouragement, a speed trap on the path crossing Central Park at 97st last autumn at 5pm ie at twilight caught me (actually it didn't, but the cop said "Oh no, we saw you get off the bike after you rode twenty feet into the path to talk to your friend who was warning you we were here!" That was when I walked up to them and asked how many tickets they had given out so far. They immediately added me to the list!

    As it turned out when I got to the court's payment windows downtown to say I was innocent they said Don't worry about it! the ticket had been cancelled! That was a relief, especially when I learned that it cost more to proceed with a second court date to have a hearing than it would to pay the $50 fine.

    Your stories sound as if they have ratcheted up the irationality since then, however.

15. **jensph**
    April 6, 2011

    Peter,

    I have also tried the Rt 7 and 9 crossings once. The Rt 7 bridge is particularly bad since you have to climb over the guard rail… Never again. There really is no safe crossing south of Teterboro. The only safe option is to take your bike on the PATH.

    There is talk of adding a bicycle crossing to the designs for the new Portal Bridge (which is the NE Corridor train crossing) just north of Rt 7. But I haven't heard much on that over the last year.

Dessert

April 1, 2011
Categories: Uncategorized

Another important topic that this blog will cover is that of baked goods. While every street-corner in Paris has a wonderful bakery, they're hard to find in the US. Luckily for me, there's Silver Moon at 105rd St. and Broadway, which could be the best bakery in the city, and often is the place where I start my day. Another related fine source of sugary goodness is the Wafels and Dinges food truck that spends Monday near Columbia, providing a wide array of waffle possibilities.

Until recently, a sad fact about life in New York City was that you couldn't get a religieuse. This situation has now been rectified, with La Bergamote at 20th St. and 9th Avenue an excellent source. On my last trip to Paris I was introduced to a French pastry treat I'd never had before, a Breton specialty called a Kouign Amann, which is available quite a few places there. Unfortunately, as far as I can tell, such a thing is not for sale in New York. I hope that this shocking situation will be rectified soon, and will report on any progress.

   It sure must be where you are!! 🙂

3. **Kea**
   April 1, 2011

   So which post is the April Fool's joke? They all sound pretty depressing to me – this one because I can't often afford to indulge in delectable pastries.

4. **Crackpotl**
   April 1, 2011

   I always love your April Fool's jokes.

5. **martibal**
   April 1, 2011

   Shame on me… being french (but not Breton), I do not know what a Kouig Amann is. Could you explain ?

6. **Casey Leedom**
   April 1, 2011

   Okay, when I was 19 — and many eons ago — I lived with a "sugar-holic" in a "retro-converted" Community Hospital building. E.g. Condemned in any other universe. So I was 19 and devoid of any free will other than that offered to me by the external universe. I.e. I ate what my house-mate ate without any questions. After five months of eating Chips-Ahoy-Chocolate Chip Cookies, Mountain Dew and Dinty Moore Beef Stew I've never been able to face sugar in the same way since. I now _hate_ all of the above and struggle to cope with anything even vaguely sugary.

   These days, I'm with an old friend of mine: another [savory] main dish would be my favorite dessert.

   And by the way, since we _are_ talking about NYC, I'm thinking Katz's and Peter Luger's.

7. **Casey Leedom**
   April 1, 2011

   So I've processed your posts in reverse chronological order as per my typically stupid email response pattern. But, that aside, here's my overall view:

   Life is great, NYC is … something unique that we're all "blessed" to have available … and, I repeat, go to Katz Deli, get [your favorite sandwich], grab a beer, sit out on the sidewalk and watch The People drift by. We may not be — and probably aren't — Special Creatures, but our lives are wonderful.

8. **JAC**
   April 1, 2011

   The dessert of God is threads of spun sugar vibrating in 10 dimensional spacetime.

9. **Breton from Paris**
   April 1, 2011

   The kouign-amann (kouign with an N) is indeed a delicious specialty

   Not very light, though -in breton language, kouign=cake and amann=butter- it is literally a "butter cake" 🙂

10. **Peter Woit**
    April 1, 2011

Thanks Breton and others, typos fixed: Kouign has its n back, and Silver Moon is at 105th St.

11. **Pablo**
April 1, 2011

Are you gonna also change the blog's name to 'not even wafles' or whatever? You got me in this one!! Thanks for the good laugh.

12. **wrep**
April 1, 2011

Perhaps the `Woit Report' ~ "We're On It Totally"? (The definition of `it' being subject to loose interpretation …)

13. **Peter Orland**
April 1, 2011

Oh good, a physics topic. Imagine my relief. What about that dessert between the standard model scale and the aptly-named GUT scale? Perhaps the LHC will find lots of particles (instead of the dessert) beyond the berryons, such as croutons or raisons.

14. **Tommaso**
April 1, 2011

Silver Moon – I think it's the one we went to last September, right Peter ? I confirm, delicious pastry!

Your April fool is much less dramatic than mine. I suggest to first read mine and then yours, to overcome the depression with some sugary thought.

cheers,
T.

15. **Deane**
April 1, 2011

Peter, I agree that Silver Moon is a great bakery. Even the bread is great. I love their rustic baguettes, which compare well against the better baguettes in Paris. We're very lucky to have it in our neighborhood, which otherwise has mostly rather mediocre food.

16. **Tom W.**
April 1, 2011

With three minutes left in April 1, maybe it's safe to add:

Eat, drink and be merry, for tomorrow we may diet.

20. **Yoshi**
April 2, 2011

The best bakery ever is located in Montreal, 322 av Mont Royal, and it is called "Kouign Amman". They have Kouign Amman, and their croissants and their pains-au-chocolat are even better than in France !!

21. **MathPhys**
April 2, 2011

When a friend of mine, on a visit to some place in Florida, asked "Is there a place where one can get a serious espresso in this town?", he was told "No, but you can open one".

So, Peter, you want a serious French bakery? you can open one. You've probably discovered a hole in the market.

22. **John**
April 2, 2011

There are occasionally serious French bakeries in Manhattan, but they tend not to survive. Fauchon used to do an excellent kouign-amann.

Bouley makes something they call by that name, but it would be unrecognizable to a Breton.

Back to the Usual

April 2, 2011
Categories: Uncategorized

Since April 1 is over, choice of blog topics will revert to the usual, and at some point I'll get around to reverting the logo. There are plenty of other blogs covering desserts, biking, and what's wrong with Obama, so I think I better stick to my market niche.

In Langlands/String Theory/Media news, the last episode of The Big Bang Theory (The Zarnecki Incursion) starts off with a scene where the white-board in the background has a central object in Langlands theory. It's the representation of the upper-half-plane modulo SL(2,Z) as an adelic double coset, with a picture of a tree for the prime p=2. Next week, my colleague Brian Greene will make a guest appearance. For more Big Bang coverage, see Lubos, who really does seem to think that he's Sheldon.

Later today I'll post the usual tedious new review of a book about the multiverse. But, first I need to get breakfast at Silver Moon, and the weather is great for a bike ride…

    You don't realize how close I came to deleting the bookmark for this site. Good one!

Multivers: Mondes Possible de l'Astrophysique, de la Philosophie, et de l'Imaginaire

April 3, 2011
Categories: Book Reviews, Multiverse Mania

While I was in Paris recently I picked up several French books that aren't readily available in the US. One of these is entitled [Multivers: Mondes Possible de l'Astrophysique, de la Philosophie, et de l'Imaginaire](), and it takes the form of a conversation between theoretical physicists Aurélien Barrau and Jean-Philippe Uzan, as well as historian of science fiction Patrick Gyger and philosopher Max Kistler. Astrophysicist Isabelle Joncour acts as moderator. The conversation is often dominated by the provocative philosophical flights of fancy of physicist Barrau, with philosopher Kistler playing the role of providing sobriety and down-to-earth arguments.

The contrast with the typical Multiverse Mania books of the Anglo-Saxon world is striking. French intellectuals are seriously educated in philosophy, and think it natural to carry on arguments invoking the ideas of a wide range of philosophers, even in contexts such that similar Americans wouldn't see the point of raising philosophical issues. In this case, some of the discussion revolves around the ideas of American philosophers David Lewis and Nelson Goodman about "possible worlds". It's amusing to note that it would probably be extremely difficult to get together for a discussion a group of American physicists who had even heard of these two of their countrymen, much less be capable of seriously discussing their ideas. Maybe that's just as well though, as professional philosopher Kistler makes a good case that the "possible worlds" at issue in this sort of philosophy don't really have anything to do with the multiverse.

Barrau takes a position refreshingly agnostic about string theory and LQG, deploring the ideological warfare between them. Unlike most physicists though, who were interested in string theory when it might have predicted something and are now losing interest, he claims that the fact that it can't predict things is what got him to really like string theory:

> la theorie des cordes commence à m'intéresser à partir du moment où, précisément, elle prend ce tournant où l'on ne sait plus très bien où on va et où on change les règles du jeu au milieu de la partie. Ca devient très motivant!
>
> string theory starts to interest me precisely from the moment where it takes this turn; one doesn't much know where one is going and one changes the rules in the middle of the game. This starts to become appealing!

For Barrau, it's just when string theory starts to turn into pseudo-science that it interests him. In brief, he agrees that the string theory multiverse moves the field from physics into metaphysics, but thinks that's a *good* thing. He's in love with the idea of finally being free from many of the conventional constraints physicists labor under as they try to do science and the possibility of taking up again the overlap of some French philosophy with science that Alan Sokal very successfully made a joke of. He starts out:

> En philosophie francaise, je pense à Deleuze et à son rhizome, au "plus d'un" de Derrida, au(x) toucher(s) chez Nancy, au nominalisme de Foucault, a l'ontologie du multiple de Badiou…

and immediately realizes that the question of Sokal must be addressed if you're going to go on like that:

> Je crains que l'on soit encore dans une sorte de timidité généralisée qui est peut-être issue des contrecoups de la triste affaire Sokal. Il est tout à fait souhaitable d'enjoindre les gens a ne pas dire n'importe quoi. Cela ne se discute pas. Mais il serait dommage que cet excès de précaution leur interdise tout simplement de penser à partir des constructions scientifiques. La physique d'aujourdhui me semble fabuleusement propice à philosopher, il faut oser.
>
> I fear that we're still in a kind of generalized timidity that may have come about as a consequence of the sad Sokal business. It's completely desirable to insist that people not say just anything, that's not up for discussion. But it would be a shame if too much caution keeps them from thinking starting with scientific constructions. Contemporary physics seems to me fabulously propitious for philosophizing. One must be daring.

There's much abuse directed towards Popper, falsifiability, and of crude attempts to separate science from non-science. Barrau is very happy with the idea of not having any way of distinguishing the two, while Kistler tries to remind him that, tricky as it may be, there's an important distinction involved. What seems important to me here is maybe more of a sociological than philosophical point, and it's a bit like the one that motivated Sokal. If you don't have any standard at all for what is science and what isn't, you lose control of the powerful role of science in how we see the world, and put yourself at the mercy of socially stronger forces who will be happy to take on this role and grab control and power away from those who have disarmed themselves. In the specific local area of fundamental physics, if there's no way to recognize that ideas have failed, those with a vested interest in a set of failed ideas will never give up their control of the discourse. Instead of the philosophers listed by Barrau, someone like Michel Foucault might be more relevant…

Comments

1. **Kea**
   April 3, 2011

   A courageous, but futile new direction for NEW. It's not like the French only discovered philosophical rationalism yesterday. They have been mocking this kind of Anglo-Saxon idiocy since the revolution, which is probably why they are blind to the good neo-Popperian arguments.

2. **Dr. Philip Carey**
   April 3, 2011

   Peter, your comments regarding the familiarity of American physics professors with modern philosophy are wholly inconsistent with my experiences at several large American research universities. In my current department, for example, lively and sustained conversations about philosophy and physics are a daily treat, both with grad students and with faculty. Indeed, a number of professors in my department have masters in philosophy; one has a doctorate. Please avoid making such generalizations in the future!

3. **The Cosmist**
   April 3, 2011

   Doesn't the "philosophication" of physics represent the decline and fall of the field? Aren't you be back to the days of Zeno and Aristotle contemplating the universe abstractly without contact with reality? And to philosophize a bit myself, will anyone care about the laws of physics in a post-Singularity world of infinite reality simulations and arbitrary physical laws in the Dyson sphere computronium hive-mind of the future? 😉

4. **Peter Woit**
   April 3, 2011

   Philip Carey,

   American academia is a huge and wonderful place, and I don't doubt that somewhere it includes physicists able and willing to knowledgeably discuss David Lewis and

Nelson Goodman. But personally I don't seem to have run across these people. It is true that I spend less time amongst physicists than I used to, and maybe since the advent of the multiverse, such discussions of "possible worlds" now are common in American physics departments, who knows…

5. **Aaron**
April 3, 2011

Really? You've never met them?

http://scienceblogs.com/principles/2007/08/alone_in_the_multiverse_1.php

6. **Peter Woit**
April 3, 2011

Aaron,

OK, I have to admit I was wrong about this. It was kind of a mistaken attempt though to defend the honor of American theoretical physics. I should have known better.

7. **Bee**
April 4, 2011

That's interesting, thanks. I was wondering the other day what's the history of the multiverse-idea? I mean, most modern ideas turn out to have been touched upon much earlier. Is there anything in the books about it?

8. **Aurelien Barrau**
April 4, 2011

Dear Peter,
Thanks for your interest in our book. This is much appreciated.
If I can allow a few comments, I have not said that "string theory is a pseudo-science", nor that it is "metaphysics". What I think is that it is both impossible and uninteresting to try to define the borders of science. Which does not mean that "everything is the same", of course. Clearly, string theory plays with the limits of physics and I indeed find this interesting.
However, on this specific string theory point, I would like to emphasize that one can work on Loop Quantum Cosmology (this is the case for me) but still highly respect string theory and consider this approach as beautiful and meaningful. The World is highly diversified and so are our models !
Best regards,
Aurelien Barrau

9. **peterg**
April 4, 2011

"I think is that there is both impossible and uninteresting to try to define the borders of science."

The first part probably is correct, but I respectfully disagree with the second part. Maybe I'm missing the point, but it is as if you're saying that morality is not grounded in rational thought (I agree) and that therefore rational discussions about morality are uninteresting (wrong, in my view).

A long time ago I collaborated with physics researchers. I lost track of most of them, but I'm certain one of them (a mathematical physicist) has asked "Yes, it's nice, but is it physics?" when he learned about the more esoteric domains of string theory.

Perhaps more scientists should have asked that question, even if there is no straight answer.

10. **Peter Woit**
April 4, 2011

Aurelien,

Thanks for the clarifications. I should have made clear that the use of "pseudo-science" was my own editorializing, and shouldn't have been attributed to you.

The Bogdanov Equation

April 3, 2011
Categories: Book Reviews

Another book that I picked up in Paris is Lubos Motl's L'Équation Bogdanov: Le secret de l'origine de l'Univers?. It's a rather weird document, a mish-mash of defense of the Bogdanovs (partly by comparing their ideas favorably to loop quantum gravity), generalities about cosmology, and promotional material about string theory. Among the odd features of a book entitled "The Bogdanov Equation" is that there is no "Bogdanov Equation" in the book (or anywhere else, as far as I know). In a comment on his blog posting about the book Lubos writes

> If there is an equation written by the twins that can be shown to explain the origin of the Universe, you will read about it in the book. If there is none, you won't find such big statements. But I can't tell you and others the punch line here. Wink

I don't think it's hard to guess which alternative is the right one…

One of the great mysteries of the book is that of its authorship. Supposedly it was written by Lubos in English, then translated into French. I don't doubt that large parts of it were written by him, although in a style somewhat different from his blog, and then passed through the filter of translation. Some parts of it though, especially some of the details of the endless defense of the Bogdanovs I can't believe were written by him. For instance, pages 187-189 are taken up with a translation into French of this internet mailing list posting by "Osher Doctorow Ph.D.", and the author is described as "Professor Osher Doctorow, mathematician at the California State University", which appears to be misinformation of a Bogdanovian rather than Lubosian sort.

Another commenter on the same blog posting by Lubos gives a long and detailed list of dubious things in the book and states that "To make it short, I have the impression that you are not the sole author of the book.", asking him to clarify this issue. The response is

> Sorry but I have neither time, nor desire, not the full rights to answer ten kilobytes of such questions, some of which are well-informed observations but most of which are not.
>
> The book is created not only as a blog but also to satisfy a contract with the publisher. So I was okaying some proposals from the publisher. It is essentially good if you can identify these places.

Theoretical physics in recent years has produced some very odd things, this book is one of the most bizarre.

Comments

1. **Roger**
   April 3, 2011

   It is getting harder to separate the hoaxes from the non-hoaxes. This seems to be a serious post about a hoax book. Or maybe Lubos got tricked by some hoax research. Or maybe Lubos was trying retaliate against a publisher somehow in order to get out of a contractual obligation to deliver a book. Or maybe the Bogdanovs have discovered the secret to the universe.

2. **Mike**
   April 4, 2011

   what about this one?

   http://novel-theservant.blogspot.com

3. **Emanuel Derman**
   April 4, 2011

   One of the things that everyone wants, even in academic life, is to have their cake and eat it. If someone puts his name to something you should give him credit where credit is due and blame correspondingly. It doesn't seem right to get the upside and put the downside on someone else unnamed. (No more bailouts.)

4. **Nono**
   April 4, 2011

   I have not read the entire book, just some excerpts on the internet. Why not tell the truth about it, if everyone already knows it? It's a lot of bullshit.

   But I think you're being unfair to its author. I don't see why there should be any doubt that this book is exactly what its author wanted it to be, and exactly what he is capable of writing, no more and no less.

   The choice of topic, the crappy smokescreens to hide the fact that the book is completely empty and devoid of substance, the inclusion of ancillary material written by third persons (the Bogdanov brothers themselves, of course, who else?) just to fill pages. All that is what the author wanted it to be and nothing else.

   After all, if there was some kind of contractual agreement to be fulfilled, the author could have done a completely different thing. Just write a popularizing introduction to string theory, or to the many different approaches to quantum gravity, or to the history of those subjects. Or whatever that's not just useless rubbish like this book. But, as it happened, Motl chose to write this and nothing else.

5. **Peter Woit**
   April 4, 2011

   In case I wasn't clear enough. Yes, this book is a lot of bullshit. However, it is also an extremely weird example of bullshit…

6. **cormac**
   April 4, 2011

   BS is one thing, plagiarism in order to meet a publishing deadline quite another

7. **Peter Woit**
   April 4, 2011

cormac,

It’s not plagiarism, since “Osher Doctorow, Ph.D.” is properly quoted. However, this seems to me too weird even for Lubos. I don’t have conclusive evidence, but if I had to guess I’d say that parts of the book were written not by him but by the Bogdanovs. That’s not really plagiarism, more like a weird variant of ghost-writing.

8. **Chris Oakley**
April 4, 2011

People wonder about the motivation of the brothers, but I have had them figured them out for some time. Their aims are very similar to yours, Peter – to expose modern “fundamental physics” for the sham it really is. Getting theses they know to be bullshit passed, and, what’s more, published in a respectable journal; getting a former Harvard professor to endorse their “work” in a popular science book. They are lying low at the moment because they want to net a bigger fish – a Weinberg or a Witten, maybe. Once they have done that, or at least established that they cannot, then the public denunciations will begin in earnest.

9. **milkshake**
April 4, 2011

Nothing weird about this partnership. Lubos wants to write pop-sci books that reach wide audience. He would be delighted to be on TV. Re-opening the Bogdanov controversy works well with media. The brothers can help him: he provides them vindication, they introduce him in showbiz. And they flatter his genius. From the starting position that the brothers were unfairly treated by anti-string crusaders, and that they were basically on the right track (even if they were not the brightest contributors to ST – he reserves this place for someone else), he can then plug in any of his own favorite topics. Without Bogdanovs, his tirades would not get the interest of a publisher.

10. **chris**
April 5, 2011

“Osher Doctorow, Ph.D.” – this name alone is about enough to gauge thew IQ of the Bogdanoff brothers.

11. **Bobito**
April 5, 2011

The explanation for this weird book is simple, and gets to the true commitment to science that lies behind it: money.

12. **J.F. Moore**
April 5, 2011

Chris,

If that’s true, they’re playing a very long game with almost no leverage, since they’ve already been ‘exposed’. It seems much more likely that they’re just self-deluded.

Milkshake,

Good analysis, but I’d still call it weird or bizarre, even if there is some underlying reason involved.

13. **FrediFizzx**
April 6, 2011

Osher Doctorow is the handle of a person that posts a regular series of messages on the sci.physics.* UseNet newsgroups that no one really ever responds to. Some of what they post is quite involved and very bizzare sometimes. Do a googlegroup search if interested.

14. **YBM**
April 6, 2011

Did you know that *even* the forewords from Clovis de Matos (which is NOT a physicist as the book pretends) have been deeply rewritten by the Bogdanov’s ?

Précision: Science & Vie et l’équation Bogdanov.

> A moins que le préfacier de l’ouvrage, un dénommé Clovis de Matos, présenté comme ayant soutenu un doctorat sur la théorie des cordes bosoniques et physicien théoricien à l’Agence spatiale européenne (Esa), nous en apprenne davantage. Interrogé lui aussi par nos soins, il a surtout tenu a signaler, manifestement gêné, qu’il n’était pas docteur en physique (il a une maîtrise) et que l’Esa n’avait rien à voir avec sa préface. Quant au ton dithyrambique de son intervention, il serait le fait d’une profonde réécriture de son manuscrit, sans que les épreuves ne lui aient été envoyées pour relecture. Drôle d’équation !

About the book book itself, an interesting article : L’equation Bogdanov: The Salvador Dali school of physics.

Meanwhile, the two fraudsters are now sueing the french magazine Marianne (which published the CoNRS report in last october), asking for not less than… 750 000 € !

15. **Yatima**
April 6, 2011

Tout ça commence à bien faire!

16. **publius**
April 7, 2011

LOL at Chris Oakley theory.

It could be true! I did not realize until now the bogdanoff’s are fighting the good fight too! they are just doing it the french way, maybe subtler but also effective, while Peter is doing it the american-estonian way.

2011 Templeton Prize

April 6, 2011
Categories: Multiverse Mania

This years $1.6 million dollar Templeton Prize has been awarded to astronomer and cosmologist Sir Martin Rees. The Templeton Foundation has traditionally been largely devoted to promoting the intersection of science and religion, so one surprising aspect of this choice is that, while Rees is a very accomplished scientist, he doesn't believe in God (although he likes the music and architecture in churches):

> In fact, Rees has no religious beliefs, but considers himself a product of Christian culture and ethics, explaining, "I grew up in the traditions of the Anglican Church and those are 'the customs of my tribe.' I'm privileged to be embedded in its wonderful aesthetic and musical traditions and I want to do all I can to preserve and strengthen them."

Rees does seem to believe in something that the Templeton people are willing to take as a replacement for belief in God: belief in the Multiverse. He has been one of the leading figures promoting the Multiverse and anthropic explanations, even before the recent string theory landscape pseudo-science made this so popular. For more about his views, see a 2003 interview In the Matrix, which leads off with:

> All these multiverse ideas lead to a remarkable synthesis between cosmology and physics…But they also lead to the extraordinary consequence that we may not be the deepest reality, we may be a simulation. The possibility that we are creations of some supreme, or super-being, blurs the boundary between physics and idealist philosophy, between the natural and the supernatural, and between the relation of mind and multiverse and the possibility that we're in the matrix rather than the physics itself.

Something for future Templeton candidates to keep in mind: no need now to believe in a Christian God, belief in "The Matrix" is good enough.

Comments

1. **CarlH**
   April 6, 2011

   If this world is the ultimate reality, then I am all for finding an alternate universe and getting the heck out of here! Plus I admire Rees' honesty regarding religion. Almost everyone is a product of their culture which includes religion, so why pretend to be a stout atheist when we've all been indoctrinated since birth about the Big Man Upstairs and His Kid who we tortured and killed.

   BTW, go back to taking about physics. Bike riding in NYC isn't why I come here. There's enough of those kinds of blogs anyway. Do you want to hear about what I had for breakfast this morning? Neither do I.

2. **Bobby**
   April 6, 2011

   Peter, why not put a lid on the negativity and simply congratulate Rees on his achievement? Imagine how you'd feel if you just won 1.6 million dollars and some blogger was sniping at you from across the pond. Not cool. If you want to take on the substance of Rees views at an appropriate time and place then go ahead. But what you're doing now is not much different than slagging off a colleague at his funeral.

3. **Peter Woit**
   April 6, 2011

   Bobby,

   If you read the posting, my description of Rees was "a very accomplished scientist". His accomplishments as a scientist deserve recognition, but the Templeton Prize is not a prize given for scientific accomplishment. It's given for "an exceptional contribution to affirming life's spiritual dimension, whether through insight, discovery, or practical works." I do find it remarkable that Templeton is now giving this prize to atheist scientists, as far as I can tell that's the first time they've done this. If they turn it into a prize for purely scientific achievement that will be great. In the past it was a prize for bringing God into science, which personally I think is a bad thing, not worth encouraging. Replacing the God part though with the Matrix isn't an improvement.

   I don't see the analogy to "slagging off a colleague at his funeral". He's not my colleague, and getting $1.6 million dumped on you is not really like a funeral. Amidst all the adulatory praise and all the money he's getting this morning, I don't think a bit of sniping from a blogger across the pond is going to ruin his day.

4. **The Cosmist**
   April 6, 2011

   I don't understand your equating of "the Matrix" with monothestic notions of God — I certainly consider a multiversal Matrix of simulations an improvement over an omnipotent bearded guy in the clouds who takes a personal interest in human beings! And it's just strange enough that might even be true…

5. **DB**
   April 6, 2011

   I think Rees is a particularly good example of what happens when a top-flight physicist goes off the boil and enters his dotage. For reasons not very well understood, it tends to happen rather early in life to theoreticians, usually by the age of 45.

   They lose their hard edge and begin to wallow in intellectual mush. Giving out to them is like criticising granpa for his senior moments. They really can' t help it.

6. **Peter Woit**
   April 6, 2011

   The Cosmist,

   My interest in either the bearded guy or a "multiversal Matrix of simulations" is pretty much nonexistent. I just wish people would keep them out of science I care about, instead of encouraging bringing them into it with large cash prizes.

7. **Allan Rosenberg**

April 6, 2011

CarlH,

I live in New York, too, so I'm always looking for recommendations for good bakeries. BTW, if you ever visit, you have to try the cupcakes from Baked by Melissa, they're awesome. Seriously, these are the best cupcakes you'll ever eat. Keep the NYC blog entries coming, Peter!

8. **Peter Woit**
April 6, 2011

Allan/CarlH,

The postings about bikes and bakeries were a local April 1 phenomenon. No more. At least not in this particular branch of the multiverse…

9. **Roger Aune**
April 7, 2011

Congratulations. Thanks for getting some of our money back! M theory and similar science are certainly welcome compared to the unfunny joke that is religion. The fact that the templeton group is is honoring this is very suspect, though. Enjoy the $ indeed!

10. **Guillaume**
April 7, 2011

I went to a talk Martin Rees gave just a couple of weeks ago in London. The traditional Ouroboros cosmological kind of talk, nothing original but I remember being very annoyed by its distinctive Kantian flavour, which fits nicely within the Templeton framework. I find it sad that Rees does not have enough common sense to reject such an "honour"…

11. **honour**
April 7, 2011

Wait till someone slaps you in the face with a wad of unmarked $100 bills (or sterling) with random serial numbers to the tune of > $1M, and then see what you do!

12. **Bobito**
April 8, 2011

"Peter, why not put a lid on the negativity and simply congratulate Rees on his achievement? Imagine how you'd feel if you just won 1.6 million dollars and some blogger was sniping at you from across the pond. Not cool. If you want to take on the substance of Rees views at an appropriate time and place then go ahead. But what you're doing now is not much different than slagging off a colleague at his funeral."

This is wrong-headed in so many ways.
1. Winning a prize is not an 'achievement'. Perhaps some 'achievement' led to the prize being awarded, but let's not confuse the two.
2. What is 'not cool' about criticizing someone who just won 1.6 millions dollars? What would be 'not cool' would be criticizing some guy publishing ridiculous things that no one paid attention to, ever. It's not at all like 'slagging off a colleague at his funeral' – there's not a good analogy between dying and winning the lottery (which is, to some extent, what winning such a prize is).
3. The misuse of millions of dollars is something that merits criticism. It's reasonable to debate whether this is a misuse, but if it is, it certainly merits criticism, because the misuse of millions of dollars is socially indefensible. The libertarian sort will say – it's their money, they can do what they want with it – but beside being an indefensibly self-centered anti-communitarian point of view – that's just oblivious to the social context of money.

13. **miss use**
April 8, 2011

Will it be a misuse if Rees endows a scholarship(s), for example?

14. **oracle**
April 8, 2011

You Guys here are just unbelievable, really!

While it is obvious that the US Governement ist just giving up on all science like particla physics, cosmology, space research and other more fundamental than applied stuff (Fermilab will close, LISA canceled and surely more such good news will follow soon…) people on this blog are complaining about a non-governemental organization giving some money to a scientist!

There`s no need for being that impatient and trying to accelerate the process of dissipation of science. If all goes well, the US will continue to put all their money into war games pulling it out from science in particular and hopfully Europe and the rest of the world will follow their example as they usually do …

Be assured that You Peter, and all the others here, will soon be put out of the misery to smash everything down that is going on in particle physics and related subjects while pretending to care in the slightest for or being interested in science.

The april 1. change of direction of this blog was indeed a unusually wise and very clear-sighted moment. It seems time has come to look out for other things; soon there will be nothing left for You to fight. So why not write about things like politics, culture, food, cycling, etc …?

Have fun and enjoy youself as long as You can

cheers

15. **Paul**
April 8, 2011

There are some similarities between the status of monks and priests in the past, and the status of professors of fields that use technical jargon today. They have a claim to be purveyors of truth. But what is exactly the extent of this claim?

16. **Peter Woit**
April 8, 2011

oracle,

Please note that (unlike other blogs, e.g. Cosmic Variance and Pharyngula, have you written to them?) I'm not complaining about Templeton giving money to Rees, or him taking it. If I were him, I'd take the money, and it's their money, they can give it to whoever they feel like. I'm just reporting that they did it, and offering some commentary on how their choices seem to be changing (belief in God no longer necessary). We report, you decide… In this new world order where particle theory is more and more going to be funded by private sources, I don't see why I shouldn't point out that one side-effect is that going on about Multiverse pseudo-science is the sort of thing some private funding sources really love.

Sorry, I don't feel any personal responsibility for Nasa's budget problems that led to the cancellation of LISA, or the shutting down of the Tevatron. As you might have noticed from an April 1 posting, I share your opinions about the dreadful current state of the US government and its budgetary priorities. If this blog instead were devoted to how wonderful the multiverse idea is and how well string theory is doing, that would have no effect on those issues.

17. **oracle**
April 9, 2011

Ok, Peter

yes You just reported it, maybe I`ve overdone it a bit yesterday 😉

But I agree with Bobby that it would be god if You could hold yourself back a bit and stay generally more fair than is often the case.

These are really dreadful times for particle physics and all of the other sciences not providing results which can be turned immediately into money or weapons…
In principle we have the knowledge and technology to make progress in our scientific understanding as never before but it is all in vain as it seems now 🙁

It would just be cool to see that You can avoid kicking (almost) dead horses lying on the floor already

On the other side it would be interesting if You could invest more time into understanding the mathematicel topics You announced to not report about some time ago than in "dead-horse-kicking" which is uncool 🙂

best wishes

18. **Tim van Beek**
April 9, 2011

oracle wrote (with a hint of sarcasm):

> …hopfully Europe and the rest of the world will follow their example as they usually do…

There is no indication that European countries will cut the funding of CERN, DESY or other projects. There have been no cuts to funding of universites, no cuts of tenured positions either. Business as usual, for both string theorists and people interested in different approaches. While there are many controversial topics discussed in European politics, cutting funding to science, education, universieties etc. is not one of them.

19. **Giotis**
April 9, 2011

I wrote the following to another blog but I repeat it here because I think it fits perfectly with Rees' quotation in Peter's post too.

I wonder, why whenever the multiverse is discussed people start talking weird all of a sudden mixing various philosophical/metaphysical Mumbo Jumbo? There are so many beautiful physical concepts within the multiverse that someone could discuss; from quantum cosmology, eternal inflation and the dynamics of the landscape to the properties of the underlying fundamental theory. Why not focusing on these concepts for a change? The conditions for the appearance of the multiverse/landscape and its ability to explain measurements in *our* universe are highly non trivial with hard physics at their core.

Of course I understand that Peter choose the above excerpt to discredit the multiverse idea but still Rees should have known better.

PS. I bought Greene's book but I skipped all the "crazy" stuff regarding computer simulations etc. I'm only interested in the physics of the landscape/multiverse which is quite elegant, robust, theoretical motivated, mathematical consistent and with enormous explanatory power. These are enough I think to take the framework seriously. Regarding experimental (even circumstantial) evidence; well you never know where research, technological breakthroughs and the deeper theoretical understanding of these concepts may lead you in 10, 50 or 100 years from now. Even tomorrow some clever guy may come up with an extraordinary proposal that could put some of these ideas to the test.

20. **oracle**
April 10, 2011

Goitis,

would it not be better to constrain the number of solutions of the hard physical core further mathematically and physically to a reasonable value?
To just say now we have a multiverse gives one a good giggle; but to stop at this point and being happy with that looks like some kind of a lazybones-approach 😛

21. **Peter Woit**
April 10, 2011

Sorry Giotis, but you're just putting forward over-the-top hype and wishful thinking. Many people thought the initial 1984 models for string theory unification were elegant, hardly anyone thinks that about the complicated mess you get out of a conjectural anthropic string theory multiverse. "Enormous explanatory power" doesn't really go with "can't predict a single f—ing thing"….

22. **Phil**
April 10, 2011

I think it is a mistake to rely on the Big Bang or anthropic coincidence or any particular theory of physics as "proof" for the existence of God. In the same way, it would be foolish to use the multiverse theory as "proof" against God. While the Big Bang or anthropic coincidence may offer something like a hint about God's existence, the philosophical argument about God's existence is much older than those findings. The proper idea is not that God just started the big bang and moved on to something else. In this sense, perhaps the idea of a "first cause" is misleading. In Christian theology(Catholic theology, anyway), God is the underlying cause of the creation and the

continued existence of all things, regardless of whatever physical theory happens to be true. St. Thomas Aquinas famously argued that the universe would still need an ultimate cause even if it had no temporal beginning. The debate about all this will continue, but it would be more helpful if people on both sides framed it in a better context.
Christian belief is not dependent on the Big Bang.

23. **milkshake**
April 12, 2011

A large cash prize given to famous senior people is probably harmless. I would be concerned about Templeton directly-sponsored research – even modest grants can induce people in fledgling groups to spend their time on explaining how their research connects to mystic-friendly universe…

Suspicious Bump

April 6, 2011
Categories: Experimental HEP News

Last night a new preprint from CDF appeared at the arXiv, discussing a signal observed in their data, at about 3 sigma significance, that could in principle correspond to a new particle not seen or predicted before. This morning's New York Times has an article about this here. The Times does a pretty good job of getting quotes from relevant experts and explaining the situation, which is basically "if it's real that's very exciting, but it probably isn't".

I went to check Tommaso Dorigo's blog only to find that he had a short posting up explaining that a more detailed one was embargoed until the public talk this afternoon at Fermilab (live stream at 1600 CDT here). This seemed rather odd since the Times had clearly been given the story a few days ago, embargoed only until last midnight. He now has a full posting up, and you should go there for a detailed and authoritative look at what this all means (most likely not much, modeling the huge background you have to subtract is hard).

Update: For other blog postings about this well worth reading, try Michael Schmitt, Resonaances, Gordon Watts and Flip Tanedo.

Update: Took about 21 minutes from the time of release of this data to submission of a paper explaining it.

Comments

1. **Tommaso**
   April 6, 2011

   Thanks for the link and the kind words Peter. Indeed, I had promised somebody in CDF that I would not blog on this until it was public.
   What do I know… First of all Viviana Cavaliere's thesis contains all the information of the paper -actually ten times more, and that one is public since a while ago (note that it caused a theoretical paper hypothesizing a Z' signal in CDF to be produced by April 1st).
   Second, the NYT piece. And third, the paper is in the arxiv but the seminar hasn't started yet. Oh well.

   So, this is no higgs. This might be the Z', but it is orders of magnitude more likely a JES problem mixed in with a W+jets background simulation mismodeling…

   Yet it is nice that CDF is not afraid to publish these kinds of signals any more – ten years ago they would rather sit on such a thing and die than publish it.

   Cheers,
   T.

   Cheers,
   T.

2. **Michael**
   April 6, 2011

   Hi,

   I also applaud the CDF Collaboration for bringing this out reasonably quickly. It is not shody work, and so other collaborations (D0, CMS, ATLAS) should be motivated to check for a corresponding signal. Good since, for sure.

   In my opinion, if it is not real, then it is a statistical fluctuation rather than a problem with modeling the background or with the jet energy scale.

   Michael

3. **Kea**
   April 6, 2011

   Well, the 21 minute paper has an abstract quoting the 2010 thesis sigma of 3.2, as opposed to the new paper sigma of 3.3. This suggests that the paper was already prepared, and rushed onto the arxiv to beat competitors.

4. **lcs**
   April 6, 2011

   I would be more convinced if both electron and muon Mjj distributions showed equally convincing bumps. At least in Fig. 7.1 of Cavaliere's thesis this is not the case.

5. **abbyyorker**
   April 7, 2011

   Negative spin would say that it is hype driven by the imminent shutdown. Rather a nasty thing to say, I admit.

6. **AR**
   April 7, 2011

   The paper you cite was not the first paper explaining the data. There were two theory papers even before the CDF paper came out (arXiv:1103.6035 and arXiv:1104.0243). The analysis had already been published in a thesis.

7. **jo**
   April 10, 2011

   Off-topic: there's a pretty pompous-looking string theory conference next may at IHES, invoking "three generations" http://www.ihes.fr/jsp/site/Portal.jsp?page_id=62

   No Witten nor Maldacena though: it would be interesting to know if they can't attend, or don't want to attend…

8. **Peter Woit**
   April 10, 2011

jo,

I don't know about "pompous", lots of those people have done very interesting things, many of them with nothing to do with string theory, and if I wanted an excuse to go back to Paris, there's plenty of talks by that group I'd like to hear.

What is kind of funny is the "three generations" thing. If one wanted to, I suppose you could start with the people who first worked on string theory circa 1970, find their students, their student's student's etc, and have a conference on "six generations of string theory". Pretty impressive for an idea that doesn't work…

9. **Jurgis Rudkus**
   April 10, 2011

   Hey Peter, have you watched the wonderfully combative interview Brian Greene recntly did with Amir Aczel? http://www.booktv.org/Watch/12292/The+Hidden+Reality+Parallel+Universes+and+the+Deep+Laws+of+the+Cosmos.aspx Greene fared quite well, though he had to work for the win. In fact, Greene dispensed with most of the objections you've raised on your blog in a lucid, congenial, and complete fashion. I haven't felt this good about the multi-verse in years. Check it out!

10. **Peter Woit**
    April 10, 2011

    Jurgis,

    No, I hadn't seen that, thanks for pointing it out to anyone who wants to follow it. I have to admit though that I think I'm pretty well conversant with the arguments of Brian and other multiverse proponents (I've read about half a dozen books on the subject now, including his…). So, I'll skip this. If someone who does watch it hears a new argument not gone over endlessly already, let me know…

11. **Shantanu**
    April 11, 2011

    Peter, I thought you said Brian and you agree on most things.
    (looks like multiverse is not one of them)

12. **Peter Woit**
    April 11, 2011

    Shantanu,

    I don't think I disagree with Brian and most string theorists about what the actual state of the subject is, when you get down to precise questions. I've always disagreed with them about the likelihood of the kind of future progress needed to overcome the well-know problems they have. When it comes to the multiverse, this is even more true, and I suspect that actually the majority of string theorists are skeptical that the obvious problems with it can be overcome.

    But, enough about the multiverse here, surely a posting where it is more relevant will come along soon…

13. **kelly**
    April 12, 2011

    Now that the major media has taken this report and run with it (and oh what a run!..) all the good physics blogs have gone silent! Common guys, lets hear some follow up! Don't be afraid, the ball is already rolling, you can blame Tomaso, let's hear some speculation on what confirmation of a new boson or force could mean! And I don't mean technicolor strings!

14. **Peter Woit**
    April 12, 2011

    kelly,

    I'm not sure what follow-up is needed to reporting that there's almost surely nothing here. As a follow-up though, it still looks very likely there's nothing here…

15. **James**
    April 13, 2011

    Peter: I enjoy your blog and I'm reading "N.E.W." now. I wonder, is this article at all relevant to the Fermilab "bump"?

    http://arxiv.org/PS_cache/hep-ph/pdf/0002/0002292v2.pdf

16. **Peter Woit**
    April 13, 2011

    James,

    Glad you enjoy the blog. Looking at that paper, it "predicts" that the mass of such a Z' is above 30 TeV, beyond even the scale accessible at the LHC. So, the Tevatron bump can't be it.

More on Scattering Amplitudes

April 10, 2011
Categories: Uncategorized

Last week was the beginning of a program at the Santa Barbara KITP entitled [The Harmony of Scattering Amplitudes] which will focus on topics including recent advances in computing N=4 super Yang-Mills scattering amplitudes. Talks are available on-line [here]. There's a full schedule of talks in the program and related talks [here]. On Thursday, Nima Arkani-Hamed will give a talk on "The planar integrand of N=4 super-Yang-Mills theory", which some wag has scheduled as lasting from 1:30pm to 5am.

For a survey of some of these recent developments, a correspondent points me to the thesis of Arkani-Hamed's student Jacob Bourjaily, which has just appeared online [here].

Comments

1. **Kea**
   April 10, 2011

   Interesting that the Spradlin talk mentions motives and Hopf algebras in passing, since he has been working with the mathematician Goncharov (et al) to obtain a short expression for the 2 loop 6 pt amplitude in N=4 SYM. There was a bit too much talk about being in a 'cult' though.

2. **Anonymous**
   April 11, 2011

   The linked article says in the first paragraph "With the imminent arrival of the Large Hadron Collider (LHC) at CERN, it is clear that in the coming years scattering amplitudes and cross-sections will take on an even more prominent role in particle physics."

   I have a hard time believing their work on N=4 SYM and N=8 SUGRA would shed much light on QCD processes at LHC. Can someone explain to me to what extend will this be true?

3. **Anonymous**
   April 11, 2011

   Oops, there's no such thing as "imminent arrival". The LHC *has* arrived for some time.

4. **Kea**
   April 12, 2011

   Anon, as explained in the first (technical) talk, the original Parke Taylor MHV (tree) amplitude is just as valid for QCD as for N=4 SYM. For this reason alone N=4 SYM is worth pursuing, and one might also note that SUSY aspects are rather easy to separate out from the other degrees of freedom. That is, there is every reason to believe that real QCD has a similar non local formulation in terms of motivic Galois theory (whatever that is).

5. **¡Viva la twistor revolución!**
   April 12, 2011

   Remember that even the original Parke-Taylor QCD calculation was done by using susy arguments.

6. **Rhys**
   April 12, 2011

   I'm also skeptical about the application of all this stuff to theories with less SUSY. For example, a simple argument shows that (+++…+) and (-++…+) amplitudes vanish to all orders in N=4 SYM, but this is not true for theories with less supersymmetry. I saw Nima give a talk recently, and this was one of many crucial points which seemed to rely heavily on having N=4.

7. **Susy WIMP**
   April 13, 2011

   XENON 100 announces the result!
   http://arxiv.org/abs/1104.2549

8. **Proudmemberofthecult**
   April 14, 2011

   @anonymous #1,

   There are several ways in which information from amplitudes in supersymmetric theories can be used in practical QCD calculations up to one-loop. Let me mention three

   – At tree level susy and non-susy theories are not that different: fermion lines do not show up in the diagrams of purely bosonic amplitudes. There is a story for what happens to tree amplitudes with quarks (bottomline: you can extract the QCD quark amplitudes from the N=4 ones).

   – Tree amplitudes appear in unitarity cuts of one loop amplitudes, also in QCD. There are known ways to use this information to calculate the full loop amplitudes. This includes the amplitudes with helicity +++…+ configuration for instance.

   – last but not least: people write actual numerical code for calculating QCD amplitudes using methods inspired by all the N=4 type stuff (BLACKHAT, ROCKET, etc, etc).

- For a while now the situation with this year's budget for science in the US has been very unclear, with threats being made of huge cuts to be instituted in the middle of the fiscal year, requiring shutdowns of labs, etc. The recently negotiated budget agreement turns out to involve only relatively small cuts for both the NSF and the DOE Office of Science, more here and here. Details still have to be determined and the legislation has to be passed, but it looks like most physics and math research will escape any serious immediate cuts. The new fiscal year starts October 1, and fighting over that budget has not even begun. From the hearings already held, it looks like math and physics research has bipartisan support, but in the new environment of significant budget-cutting, focused on discretionary non-military spending, I'd guess that budget levels for the next few years will be flat at best.
- There's an interesting interview with Dennis Overbye of the New York Times here. He's noticed a problem with string theory:

> One pet peeve is press releases about papers that show that string theory is about to be experimentally tested. When you read the fine print that's never true. There was a press release that the large hadron collider was going to test string theory. It was kind of embarassing for them.
>
> Scientists and science journalists just take these shortcuts And I think they become enshrined as truth in the public mind.

He also has some comments about blogs:

> Science journalism is in a very interesting, very turbulent state I think. We still have newspapers. Some newspapers still have science reporters, like the Times. I feel like the blogs have risen up to become huge force in the coverage of science. I think the readership now is very fragmented. I think a lot of people get their information from blogs, where people can be more casual or more arcane if they want to be. I think even at my newspaper there's a difference between people who read the science times and the font page. There are a lot of these different layers of coverage going on.

- In the category of "string theory about to be experimentally tested" nonsense that Overbye refers to, no press releases this week, but we do have a special section of Science News with an array of over-hyped stories about Cosmic Questions, with the one on string theory assuring us that:

> Even then, the LHC will be far from powerful enough to re-create the single, unified force that physicists believe existed for a fraction of a second after the Big Bang — you'd need a collider as big as the universe itself for that. But the LHC might be able to test some of the predictions made by the leading theory that joins gravity and the other forces.

- In the category of something I just put on my list to try and find time to listen to, there's a Science Friday program featuring a discussion about Science and Art between Cormac McCarthy, Werner Herzog and Lawrence Krauss.
- In the category of talks I'd like to hear but can't, Graeme Segal will be giving the Felix Klein lectures in Bonn next month, on the topic of Three Roles of Quantum Field Theory.

Update: Two more

- According to a new preprint, CDF's observed suspicious bump that made the New York Times "is a generic feature of low mass string theory". No word yet on whether there's going to be a press release. I guess this also means that if D0 doesn't see the bump, that pretty much rules out low mass string theory since its generic feature is not observed, right?
- Langlands has written a very interesting review for Mathematical Reviews of Ngo's paper proving the fundamental lemma.

   April 13, 2011

   "you'd need a collider as big as the universe itself for that"
   Last time I read that I believe the collider was as big as the Milky way. Just out of curiosity, does anybody know of an estimate for that?

2. **chris**
   April 13, 2011

   i remember a seminar on planck scale colliders where the conclusion was that they can't be built. the thing that came closest was the Unruh collider – it consisted of two orbiting black holes. so i guess it is a bit up to your fantasy and to what you call a collider, but i doubt any serious size estimate can be given at all.

3. **petergreat**
   April 13, 2011

   When will D0 have enough data to confirm or disprove the CDF finding?

4. **Paolo Valtancoli**
   April 13, 2011

   I think that CDF bump reveals that physicists are only a bunch of fools.

5. **Peter Woit**
   April 13, 2011

   Bee,

   Assuming similar magnets, collider energy scales linearly with size. So, very roughly saying the Tevatron is 1km in radius and gives collision energies of 1TeV=10^3 GeV, you need a factor of 10^16 to get to the Planck Scale. If I believe Wikipedia the Milky Way is 10^17km or so in radius, so a Planck scale collider would fit nicely.

   One other problem is luminosity, since interesting cross-sections fall off quickly with energy. It might not be possible to get sufficient luminosity to produce a useful number of events. Then there's the minor problem that string theory doesn't actually predict anything about what will happen if you built such a machine…

6. **neo**
   April 13, 2011

One thing that gets ignored when people talk about milky way sized (or larger!) colliders is that it would take at least 300K years for a beam to circulate, so in our reference frame the data would be very slow coming in even if we were somehow to have one.

7. **neo**
   April 13, 2011

   Scratch that–I guess you could have a very large number of detectors.

8. **Yatima**
   April 13, 2011

   Well, I wonder what the business end of the collider (the thingamabob that corresponds to the Schroedinger Cat) would have to look like for Planck-Scale events to be detectable. Calorimeters made of thin slices of neutronium?

9. **A.J.**
   April 13, 2011

   Calorimeters made of thin slices of neutronium?

   You're also going to have to work pretty hard to shield the detector from background effects, like the occasional gamma ray burst. You think the TGV caused calibration problems…

10. **Yatima**
    April 14, 2011

    Under "believe it or not", Michio Kaku is being interviewed about the striken Fukushima 1 plant and manages to be even more catastrophist as the Japanese governement. It's very bizarre and unfortunately rather unhinged:

    http://www.alternet.org/story/150599/fukushima_reactors_are_a_%22ticking_time_bomb%2C%22_japanese_govt_in_denial

11. **Peter Woit**
    April 14, 2011

    Yatima,

    A quick read of what Kaku has to say doesn't seem to me that unreasonable. Accurate information about what is going on at that reactor seems to be hard to come by, and the Japanese government has every reason to minimize the dangers to stop panic. Kaku quite possibly is maximizing the dangers, for his own reasons. I wish it was clear that he had gone way beyond the realm of plausibility. If someone knows an authoritative source that shows this convincingly, that would be reassuring.

No WIMPs

April 13, 2011
Categories: Experimental HEP News

A commenter points to the long-awaited release of a preprint from the XENON100 experiment giving results from a 100-day run last year. This is the most sensitive dark matter experiment that has released data. The result: with an expected background of 1.8 +/- .6 events, they see 3 events (i.e. about what you'd expect if there's nothing there). For a WIMP mass of 50 GeV, this allows them to exclude certain WIMP cross-sections at the level of 7.0 x 10^{-45}cm^2. This pretty conclusively kills off some other claims by dark matter experiments to have seen something, especially the CDMS result from late 2009 (see here).

One motivation for supersymmetry has always been that it can provide a WIMP with the right properties to explain astrophysical dark matter observations. This new data rules out some (if you use the SUSY expectations plotted in the new paper), or most (if you use the expectations plotted in the CDMS paper, see here and here) of the possible parameter space where such a particle is expected, providing yet another nail in the SUSY coffin.

Update: More details available at Resonaances and Tommaso Dorigo's blog.

Update: For a detailed analysis of the implications of the XENON100 result for supersymmetry models, see here.

Comments

1. **Kea**
   April 13, 2011

   There may be many nails in Susy's coffin, but Susy is still running around, terrorising people as a zombie.

2. **Susy WIMP**
   April 14, 2011

   The New York Times reports the finding, with some collaborators posing for a photo:
   Particle Hunt Nets Almost Nothing; the Hunters Are Almost Thrilled

3. **Georges**
   April 14, 2011

   This is excellent news for all those theories that predict the absence of supersymmetry. That is only a tiny fraction of all candidate theories, but it is an important step that tells us where to continue searching. What a great day.

   And compliments for being faster than Resonaances on this news item!

   Peter, is there an overview of candidate theories that do not contain supersymmetry somewhere?

4. **Holycow**
   April 14, 2011

   Your take on this is really a disgrace. The result is not bad for SUSY and the most important point is that no WIMP of any kind is there (yet), SUSY or non-SUSY. To intrepret this just as "another nail in the SUSY coffin" is only another instance of your legendary theoretical shortsightedness. Paraphrasing the classics, "the dead that you kill, are in excellent health".

5. **Peter Woit**
   April 14, 2011

   Holycow,

   What's a disgrace is the refusal of SUSY proponents to admit that there is such a thing as experimental evidence against their pet idea. Imagine that XENON100 had seen a signal. You can be sure that SUSY advocates would be loudly proclaiming that this was exactly what they expected, that evidence for SUSY had been found.

   More specifically, the John Conway and Tommaso Dorigo 2008 postings that I linked to argued that the data then was already starting to cut deeply into the region favored by SUSY. Now that the limits have been moved down more than an order of magnitude, wiping out the "favored region" on the plot they show, why is this not evidence against SUSY?

6. **DB**
   April 14, 2011

   Peter,

   Susy is like Count Dracula. It will take more than a few nails in the coffin to put paid to him. He already has a few exit routes mapped out. But he is definitely on the run.

   I expect Tommaso Dorigo's credit rating to be upgraded by Moody's any day now.

7. **Georges**
   April 14, 2011

   Holycow,

   you come close to say that nothing can be bad for SUSY, which would mean that SUSY is not science. But I am sure you do not want to say that.

   So please tell us what else would be bad for SUSY – we are all listening.

8. **Rien**
   April 14, 2011

Actually, CDMS did not claim to have seen anything. They had two candidate events, but this was not significant.

9. **Peter Woit**
   April 14, 2011

   Rien,

   Many people did at the time interpret the CDMS two events as "seeing something", although not conclusively. One example from the many news stories at the time:

   From http://news.sciencemag.org/sciencenow/2009/12/17-01.html

   "Even so, Joseph Lykken, a theorist at Fermilab, says he's relieved that CDMS has finally seen something. WIMPs are predicted to exist by theories involving a principle called supersymmetry, which posits a heavy partner for every particle currently known. Had CDMS continued to see nothing, the results would have undermined those theories. So seeing something is better than seeing nothing, Lykken says."

10. **Holycow**
    April 14, 2011

    Clarification. What I find annoying in this post is that Peter seems to be so happy about the loss of another chunk of SUSY parameter space that forgets being worried by the absence of a positiva signal, of any kind (Or do you believe that WIMPs and SUSY are equivalent?). And that's the most important fact. You should get your priorities right.

    Then, SUSY can be disproved by LHC with more luminosity
    (certainly not with 35/pb).

11. **Rien**
    April 14, 2011

    Peter: yes, this is true, but it was over-eager theorists, not the experiment themselves that thought they were real. They even went back to check those two candidates again, IIRC, and concluded they were background.

12. **Paul Wells**
    April 14, 2011

    Dear Holycow,

    What Luninosity at what energy would be sufficient to disprove SUSY ? 1 fb at 7 Tev ?

    Thanks
    Paul

13. **Peter Woit**
    April 14, 2011

    Holycow,

    I'm happy that the XENON100 experiment is a success, accomplishing what it is supposed to do. That they get a null result tells us something new and non-trivial, which is great. A positive result would have been Nobel prize-worthy and revolutionized the field, but it's hard to call a null result very disappointing, since it's the one that seemed far and away the most likely.

    That the null result makes one of the main arguments for SUSY less compelling is just a fact that I'm reporting.

14. **Holycow**
    April 14, 2011

    Peter, can you also report on how Xenon results affect the very possible and relevant SUSY idea of gravitinos as DM? Or explain to other readers how it is enough to exclude some chunck of parameter space to be ready to give up on the best theoretical idea we've had in the last 30 years?

    Paul, say 30/fb at 7TeV should be quite good. Of course for you it would be much simpler: as soon as SUSY particles start to pop up you can join the celebration (and no problem with that).

15. **chris**
    April 14, 2011

    "What I find annoying in this post is that Peter seems to be so happy about the loss of another chunk of SUSY parameter space"

    i for once am very happy. but that might be due to the fact that i am in the business of cutting parameter spaces for SM extensions myself.

    the best thing you can get is evidence for new physics. the second best thing is a good weeding of obsolete theories.

16. **Eric**
    April 14, 2011

    I think what needs to be pointed out here is that SUSY can still be observed at low energies without the dark matter actually being a SUSY WIMP. First, the LSP is only stable if R-parity is conserved, which doesn't necessarily have to be so. Also, even if R-parity is conserved, the resulting relic density can be vanishingly small, or the LSP could be a gravitino. So, these direct detect experiments only constrain the hypothesis that dark matter is a SUSY WIMP. Superpartners could still be observed at the LHC without also needing to explain the dark matter.

17. **Peter Woit**
    April 14, 2011

    Holycow,

    OK, here's a report on what XENON100 has to say about the idea that, since the neutralino idea didn't work, let's save SUSY by postulating the gravitino as DM:

Nada, Zip, Nothing. This is an idea you can't test with this kind of experiment.

As for your description of supersymmetric extensions of the SM as "the best theoretical idea we've had in the last 30 years", I'm afraid I think it's more accurate to describe it as "a not very good idea that has done huge damage to the field for 30 years by dominating the attention of theorists, for no good reason".

18. **Holycow**
April 14, 2011

Dear Peter,

if you have proof that "the neutralino idea doesn't work" you better publish it as many people would be interested in knowing. If the lack of a signal in some region of parameter space is enough for you to give up on some idea, then this just goes to show you are a bad scientist (bad theorist and would also be a bad experimentalist) and that you let your prejudices rule over logic.

You write a blog that journalists read and you should be more careful with the way you project your prejudices (and personal frustrations) on your reports.

"Since the neutralino idea didn't work, let's save SUSY by postulating the gravitino as DM". Your naive simplistic point of view is wrong again. This idea has been circulating for years and has its own appeal. The point you fail to appreciate is that it is damn difficult to guess what the theory of nature is without experimental guidance. By your comments you also fail in discriminating the sensible theoretical ideas.

"Nada, Zip, Nothing. This is an idea you can't test with this kind of experiment." Correct, so your claim about coffins and nails is pure hot air.

"a not very good idea that has done huge damage to the field for 30 years by dominating the attention of theorists, for no good reason". Which as Lubos would say just goes to show your limitations as a theoretical physicist.

19. **Peter Woit**
April 14, 2011

Holycow,

I happen to think that the scientific accuracy of what I write here is quite a bit higher that that of what well-known theorists promoting SUSY/extra dimensions/string theory have to say to the press. To the extent journalists do pay any attention to this blog, that's one reason.

If a low opinion of SUSY extensions of the SM makes one a bad theoretical physicist, yes, I'm a bad theoretical physicist.

20. **Georges**
April 14, 2011

Holycow,

SUSY is by far not "best theoretical idea we've had in the last 30 years". I do not like string theory too much, but it is clear that strings themselves are a much better idea than supersymmetry. Strings were much more successful than supersymmetry by any measure you might want to use. And strings are not the best idea either, as Peter consistently showed.

Fact is that supersymmetry is wrong. Go back to the drawing board. And better be quick – better ideas, which agree with data, are already on the market.

21. **Anon**
April 14, 2011

Wow.

I highly advise anyone who is actually trying to learn about physics by reading this blog, to look briefly into the differences between gauge mediated and gravity mediated supersymmetry breaking. That will teach you a lot more about what susy does or does not predict, than reading oversimplified statements here will.

These distinctions became clear in the early 80s and are not a response to any recent experiment, as a brief perusal of the many thousands of papers will teach you.

22. **Holycow**
April 14, 2011

Georges, agreed, string theory is even better. I was just thinking of the TeV scale and the LHC.

"Fact is that supersymmetry is wrong."
Fact probably has a different meaning for you than for the rest of scientists.
Fact is, it's pretty hard work to come up with good theoretical ideas and even harder to find new stuff experimentally. You should show a bit more respect for this enterprise and present a more serious perspective of what this is all about. It's OK if you have your personal preferences for whatever you expect to show up at the LHC but don't misrepresent the meaning of experimental results for the theories you dislike. Be honest. I think that's a minimum to ask.

"better ideas, which agree with data, are already on the market." Really? Like what?

23. **Mike**
April 14, 2011

Anon,

As a laymen, I have some questions. Could you please say (simply please) what SUSY does predict? Then, could you please explain what experimental results would falsify such predictions? Finally, could you please state whether, in your opinion, current experimental set-ups, if any, are capable of falsifying such predictions? Thanks.

24. **Peter Woit**
April 14, 2011

To be clear, I don't agree with Georges that good ideas about how to get beyond the SM that agree with data exist.

Mike asks an excellent question, and I'm curious to hear what SUSY advocates have to say about this now, as well as to look at the record and see what they were saying earlier. So far the reaction I've seen to null results from the LHC and dark matter experiments has been "that's no problem at all for SUSY, although if it had come out the other way, it would have been strong evidence for SUSY", which strikes me as less than honest. Or, if SUSY is going to be pursued scientifically by the new standards developed to deal with the failure of string theory (experiment can never provide evidence against the idea, only evidence for it), that should be made explicit.

25. **Holycow**
April 14, 2011

So, even Peter should be able to understand this allegory: you go pick up your friends who went for a long walk in the forest and in your way to meet them you lose your car keys. You discover this when you find them, explain the situation and then you start your search. As time passes and no keys are found, your friend Peter starts ranting that there were no keys at all and that the null result of your search just proves it. Well, you know that this simply means you haven't covered the whole path. But then somebody comes along with a brand new metal detector and you continue your search much faster and happier. You cover 1/4 of the whole path you walked in no time and here comes Peter repeating again and again there are no keys because the whole idea is preposterous and there are no such things as keys in the world. The best you could do is to ignore him and patiently continue your search, till you find the keys, or some gold coin or nothing, because somebody took them and you'll be faced with a different problem to solve. As you see the analogy is not perfect, but really captures well the role of the chorus of naysayers in this business: Just a bloody pain in the ass.

26. **Mike**
April 14, 2011

I was asking a serious question, and perhaps my lack of grounding in the subject is why I don't follow your "allegory."

So, you lost your keys, you know already that you lost your keys –they're just misplaced.

However, unless I'm missing something, even those who think SUSY exists (I'm agnostic on this — I simply don't know), don't know for sure that it exists — they haven't "lost" it anywhere. What's the connection?

Perhaps you could help me understand. What SUSY does predict? What experimental results would falsify such predictions? In your opinion, are current experimental set-ups, if any, capable of falsifying such predictions? If not, what more is needed, other than time to keep searching? Thanks.

27. **Georges**
April 14, 2011

Peter, Holycow,

there are several ideas on the market that state that there is simply *nothing* beyond the standard model plus Higgs. Such ideas agree with all data. These ideas then have to explain the shortcomings of the standard model in a way or another; but when they do, they have fewer assumptions than all those ideas that use supersymmetry or higher dimensions.

28. **Math Student**
April 14, 2011

Mike,

A better analogy could be something like SETI. Everybody would agree that extraterrestrial intelligent life (or SUSY) exists with very little positive data but falsyfying it could require close to an infinite amount of data, and is thus impossible.

29. **Geometrick**
April 14, 2011

As a math PhD student myself, the previous commenter is way off the mark. The analogy they used is actually a horrendous analogy. It needs to be pointed out.

30. **Holycow**
April 14, 2011

Sorry, my analogy was devised to explain the chorus, not the search.

31. **Holycow**
April 14, 2011

Mike: one basic prediction of SUSY is that for every type of particle we know there is another with the same quantum numbers but different statistics (boson fermion) and mass. So LHC should find strongly interacting partners of the known quarks and gluons, among other things.

SUSY theories do more than this and help solve some of the problems of the Standard Model. For such solutions to be natural the mass scale of these new particles cannot be much higher than the TeV scale, which is the range that will get covered by LHC. If the limits on such masses are pushed well in the few TeV
regime then one should give up on this idea. But talking about the demise of SUSY now, is plain stupid.

32. **Mike**
April 14, 2011

Math Student,

Thanks, that does seem like a more apt analogy.

I'm agnostic on that question as well — but I admit to a bias that extraterrestrial life should exist, all based on my limited understanding of the nature of the physics and the scope of space and time.

One possible difference I see is that the answer to the ET question is either yes or no — in the sense that there is no other possibility. And, although the answer to the SUSY question is also yes or no –there may well be other competing possibilities (at least in theory) for answering the questions at hand regarding what, if anything, extends beyond the SM, and any such theory has some realistic hope of being falsified in some reasonable period of time.

On the other hand, perhaps that's a distinction without a difference — and I'm just moving the goal post in the middle of the game.

If so, rather than drop what I see to be an important aspect in the progress of science and the growth of knowledge — at least some hope of falsifiability — I suppose I would in the end have to say that SETI is a great and useful "hobby" for humans to undertake, but perhaps not "science" as such.

Thanks again.

33. **Mike**
April 14, 2011

Holycow,

Thanks for your comment as well.

I take it then, within current experimental design limits, if the LHC fails to observe strongly interacting partners of the known quarks and gluons, among other things, and absent any other new discoveries that would put it back in play, at least in your mind SUSY would be effectively falsified. Is that correct?

Thanks again for your comment. I appreciate people trying to deal seriously with my necessarily naive questions.

34. **Peter Woit**
April 14, 2011

Holycow,

As others pointed out, your extended analogy was rather bizarre. You have never seen the keys in question.

I take your answer to Mike to be that you'll give up on SUSY once limits on superpartners are "well in the few TeV" regime. Hopefully the ultimate reach of the LHC will be sufficient to satisfy you. Personally I don't see why you have to go all the way up into the few TeV regime to falsify the idea that supersymmetry explains the stabilization of the weak scale at around 100 GeV.

I don't expect SUSY proponents to be conclusively giving up now, but they might want to admit that these experimental results are not encouraging. For a long time, SUSY phenomenologists have been playing the game of producing elaborate plots showing what are supposedly the most likely ranges of SUSY parameters. As experiments start to rule out large sections of these ranges, the reaction seems to be to not admit that one's predictions are starting to fail, but to produce new predictions.

35. **Tommaso**
April 14, 2011

Hi all,

indeed, in 2008 the searches were over one order of magnitude less sensitive to the presence of SUSY wimps. Still, they were already clipping out regions of phase space for SUSY theories. What was true back then, is even more so now. A neutralino may be there -and I would be quite happy if we found it at the LHC, or even if one of these sit-and-wait experiments found it- but we are Bayesians by nature, at least somewhere close to our amygdala. And if the prior belief in SUSY was what it was four years ago, we have to acknowledge that it has shrunk quite sizably now.

As for my bet, those 1000$ will be invested in a party in a suitable place. The losers of the bet (Watts and Distler) will of course be invited. Reservations are open, RSVP.

Cheers,
T.

36. **The Cosmist**
April 14, 2011

If you don't mind another layman's (meta-)question, mine is this: how would you characterize the state of theoretical physics today? From the outside it sounds like there is huge disagreement and confusion about basic questions, as if the whole field is in disarray like never before. It's strange to hear physicists arguing about experimental results and interpreting them so differently. WTF is going on with physics these days?

37. **Mike**
April 14, 2011

The Cosmist,

"WTF is going on with physics these days?"

A layman's answer to a layman's question. Being an optimist and assuming, as I do, that new fundamental scientific explanations are almost always surprising in many ways, I would judge the current disorder as a good sign — for surely it is now just a matter of time (short I would hope) until a better fundamental explanation emerges.

Of course, this will only give rise to new and better questions, but that's the name of the game.

38. **Giotis**
April 14, 2011

There is a clear distinction between SUSY as a fundamental property of nature and its breaking scale. Low energy SUSY which LHC tries to find is just a convenient estimation of this breaking scale engineered to help people solve some SM problems; nothing more. It may well be that these problems may not be solved by Low SUSY after all but that doesn't mean SUSY doesn't exist as a fundamental property of nature. There are models where SUSY's breaking scale reaches the string scale. So SUSY cannot be falsified by LHC or any similar experiments.

39. **Mike**
April 14, 2011

Giotis,

Question: Do the models where SUSY's breaking scale reaches the string scale encompass and purport to solve the SM problems?

40. **Giotis**
April 14, 2011

Yes in some cases but by other means. These models are constructed by String theorists not particle/field theorists and String theorists have other alternatives (not just Low SUSY) to solve these problems. LoW SUSY is the most obvious way but not the only one.

41. **Mike**
April 14, 2011

Giotis,

Thanks. I assume that experiments at the string scale are far beyond our current and reasonably foreseeable capability. If that's the case, maybe Math Student's analogy to SETI is more apt than I imagined.

42. **Peter Woit**
April 14, 2011

The Cosmist,

The fundamental situation in particle physics these days is that we have an extremely successful theory, the SM, with only one sector of the theory untested. This is the Higgs sector, and it's the source of a lot of the less satisfying aspects of the theory. The thing to be excited about is that later this year we should start getting experimental data relevant to this, seeing a Higgs if it is there. This could get very interesting, less so if the Higgs exists and behaves as predicted by the SM.

Things like SUSY/strings/black holes/extra dimensions are a sideshow. These have never given any convincing explanation of anything about the SM or any serious reason to believe they exist. All that's going to happen on that front is that over the next few years there will be a lot of null results coming from the LHC and other experiments. Sooner or later some of the partisans of these ideas will give up on them, other ones will keep the faith, but no one else will take them seriously. The collapse of some speculative research programs that have been around for decades may be of sociological interest to watch, but there's not much of scientific interest there.

Mike: if the SUSY breaking scale is much higher than the 100 GeV electroweak scale, SUSY does nothing at all to solve problems of the SM, all it does is introduce new ones.

43. **Paul Wells**
April 14, 2011

Peter,

As you know there aren't that many valid ways to build a point particle Quantum Field Theory- and supersymmetry is one of them. It may or may not exist but isn't a search justified from a pure phenomenology point of view? I am thinking of the situation with Dark Energy a few years ago….

Paul Wells

44. **Peter Woit**
April 14, 2011

Paul,

I've nothing against people investigating supersymmetric QFTs. Actually, there is some fascinating mathematics behind the general idea of supersymmetry, and I wouldn't be surprised if it somehow turns out to be of fundamental importance.

The problem is that the supersymmetric extensions of the Standard Model that are known, once one includes supersymmetry breaking to agree with experiment, become quite complicated and don't actually explain anything that the SM doesn't. People like to go on about how SUSY relates fermions and bosons, but it doesn't relate any known fermion to any known boson. It relates fermions to unknown bosons and bosons to unknown fermions. This isn't convincing at all. But, sure, the LHC should look for it anyway, who knows what will be found?

45. **GradStudent**
April 14, 2011

The Cosmist,
"From the outside it sounds like there is huge disagreement and confusion about basic questions, as if the whole field is in disarray like never before."

Yes.

46. **imho**
April 14, 2011

chuckle… me thinks HolyCow is a first year grad student 🙂

These results and discussions are all signs of a healthy field, and as a cond mat guy I think this is all great. My question is where are the discussions about technicolor and its incipient resurgence???

47. **No Black Holes?**
April 14, 2011

Peter,

"Things like … black holes … These have never …. any serious reason to believe they exist."

Am I understanding correctly that you're saying there's no serious reason to believe that black holes exist?

48. **milkshake**
April 14, 2011

Another layman question: How likely is that LHC will miss new physics? My understanding is that LHC detectors have to perform extensive data filtering, which in turn depends on how the triggers are set. So, my question is, would they be able to notice unexplained collisions against the high background, especially if signs of new physics were subtle ? Thanks

49. **SpearMarktheSecond**
April 14, 2011

Wimps don't need SUSY, that dark matter has a weak interaction is sufficient. The existing ratio of dm to luminous matter is consistent with a weak interaction and thermal equilibrium in the big bang, but there are other solutions too. In any case mundane issues like hadronic uncertainties in the wimp-nucleon cross section are about an order of magnitude.

50. **Shantanu**
April 14, 2011

Peter, I know several people (including my former colleagues) who still
believe proton decay exists and continue to do thesis projects and searches for it, despite 30 years of null results. So don't expect people to stop believing in supersymmetry for weak-scale interaction strength based dark matter even if LHC or NLC finds nothing.

51. **Peter Woit**
April 14, 2011

NBH,

This is about the LHC. Sure, there's a black hole in the center of the galaxy, but none are going to be made in Geneva.

milkshake,

It's possible to come up with scenarios where there would be new physics missed by the LHC because of the detector triggers. I have no idea how to assign a probability to this. If the experimentalists are doing their job well, it should be low.

Shantanu,

I think people should keep searching, both for WIMPs and for proton decay, as long as they are able to keep increasing the sensitivity of these experiments. Doesn't really matter if the main motivation is misguided, you still should look where you've never looked before to see if something unexpected turns up.

By the way, I haven't followed that story recently, but last I heard, proton decay experiments were getting to the point where they too could start putting nails in the SUSY coffin…

52. **D R Lunsford**
April 14, 2011

Hey, UCLA is being positive

http://newsroom.ucla.edu/portal/ucla/dark-matter-search-one-step-closer-200546.aspx

"Now that we know there are no unicorns in Chicago, we are that much closer to finding them."

-drl

53. **Susy WIMP**
April 14, 2011

I've heard an interesting take on this. Since we are looking for dark matter interacting via Higgs exchange, could it be that the result is evidence against a single scaler Higgs, rather than against supersymmetry?
Does anyone know the status of Xenon-1t, XMass etc.? Are we expecting another order of magnitude increase in sensitivity within the next one or two years?

54. **M. Wang**
April 15, 2011

Tommaso,

"we are Bayesians by nature, at least somewhere close to our amygdala. And if the prior belief in SUSY was what it was four years ago, we have to acknowledge that it has shrunk quite sizably now."
This is the best comment from a physicist that I have read in years, and how relevant it is here! I wish more scientists could have the broad knowledge and common sense you demonstrated in one sentence. It is sad to see so many confusing narrow technical expertise with true understanding of a subject.

Mike,

"I would judge the current disorder as a good sign — for surely it is now just a matter of time (short I would hope) until a better fundamental explanation emerges."

I cannot share your sanguinity. In 30 years of wild goose chase, the majority of the institutions studying theoretical particle physics have been staffed mostly with worshipers of the false faith. Here I don't mean false theories but an entire system of anti-scientific attitude. Witness the total inability for someone like Holycow to appreciate the relevance of the failure of their previous predictions. People don't accept failure easily, particularly not when they are in their 40's or 50's and had their entire careers built on not just the failed ideas but also the false methodology. On top of this, they are many. Tommaso may be able to point out more specific research regarding how crowd psychology induces greater variations from rational behaviors.

Take the investment banking industry for example. For years, they spouted all kinds of theories that purported to show their great contributions to the efficient markets and therefore to the economy as the justification for looting the nation's wealth. The great recession proved them false, but have they stopped doing what they were doing? Once the regulators chose rescue over closure, their jobs were secure and they promptly went back to the old business of ripping off the nation. When the senate questioned Goldman Sachs regarding its behavior, the CEO simply lied and got away with it, even though now some senators publicly acknowledge that they have been lied to. The moral is, if you don't clean out the scums, don't expect them to behave differently if given a second chance just because they had created a big mess the first time around. Last time I check, most of the physics institutions still follow the tenure system…

55. **Thomas Larsson**
April 15, 2011

So crackpots don't care about the experimental verdict. What else is new?

56. **chris**
April 15, 2011

Mike,

if no Higgs is found below say 150GeV SUSY will start drifting into the fringe science direction and slowly die off similar to -say -the steady state model in the '70s and '80s.

57. **Holycow**
April 15, 2011

"if no Higgs is found below say 150GeV SUSY will start drifting into the fringe science direction and slowly die off similar to -say -the steady state model in the '70s and '80s." Wrong. A light Higgs is a prediction of the minimal versions of SUSY.

58. **Holycow**
April 15, 2011

M. Wang

"This is the best comment from a physicist that I have read in years". You have to read more.

"Witness the total inability for someone like Holycow to appreciate the relevance of the failure of their previous predictions." What is astonishing is the inability of some to understand the very basic fact that in the road to discovery your limits will be pushed up and chunks of parameter space will be discarded. How on earth can it be otherwise? I have no problem at all in giving up on a theory if it doesn't have anything to do with nature. (By the way, I'm not like Georgi who once wrote a paper titled "Why I would be sad if a Higgs boson is found".)
But I will not give up until it has been put in a hole by experiment, which is not the case for SUSY. (Not even close). If you think otherwise, that's your problem, but respect the work of others who still have to collect much more luminosity searching for this jewel.

You would have given up in the search for the top when the lower limit was at 90 GeV. (Don't reply saying this case it's not the same, because we knew it had to be there. I know. What I critize is the attitude of people putting down others worthier than them simply because they fail to understand the issues involved or because of their personal prejudices).

59. **ShrugOffNaysayers**
April 15, 2011

It seems that everyone here would get very happy if nothing is found. That's the difference to actual scientists.

60. **Rhys**
April 15, 2011

The WIMP miracle is a remarkable theoretical fact which now looks less and less likely to be the way nature actually works. This is completely logically independent of supersymmetry, but some SUSY models naturally provide stable WIMPs. So this is really only evidence against certain realisations of supersymmetry; there is plenty of scope for gravitino or axion dark matter, for example. (I have personally written exactly one paper about low-scale SUSY, and our model doesn't have stable WIMPs).

I agree with chris that the absence of a light Higgs would be much stronger evidence against SUSY. Of course, by the time a light Higgs can be ruled out, we should have found some superpartners anyway! If we haven't, I will probably already have given up on weak-scale SUSY.

Susy WIMP:
Somebody may correct me, but I don't believe the direct detection experiments have yet begun probing Higgs-exchange cross-sections.

imho:
In my opinion, 'realistic' technicolour models are a lot uglier than low-scale SUSY models (which are themselves rather messy).

61. **chris**
April 15, 2011

holycow asys:

"if no Higgs is found below say 150GeV SUSY will start drifting into the fringe science direction and slowly die off similar to -say -the steady state model in the '70s and '80s." Wrong. A light Higgs is a prediction of the minimal versions of SUSY.

that was exactly my point ^_^

62. **Holycow**
April 15, 2011

Chris, it's important to give the right message. If you say SUSY *predicts* a Higgs below 150 GeV you are misleading people. That prediction is not universal and can be violated. SUSY does predict superpartners and that's the key search, not the Higgs.

Rhys, thanks for your post. It's good to read reasonable people from time to time.

63. **Thomas Larsson**
April 15, 2011

Speaking about nails, how are the searches for permanent electric dipole moment going? In 2005, Chad Orzel wrote: "Experiments currently in production should lower that limit by another 2-4 orders of magnitude, which would either find a non-zero EDM, or rule out pretty much every theory now on the books. I'm told that the theorists who deal with this stuff are starting to sweat a little… "

But I guess the silence speaks for itself…

64. **chris**
April 15, 2011

"If you say SUSY *predicts* a Higgs below 150 GeV you are misleading people."

sure you would, i fully agree with you. it would be equally misleading as e.g. saying that SUSY is a fact of nature.

65. **Holycow**
April 15, 2011

"It would be equally misleading as e.g. saying that SUSY is a fact of nature." Not really. This might be true (we don't know yet). We know already that SUSY does not predict a Higgs below 150 GeV.

66. **Georges**
April 15, 2011

Supersymmetry is a fact of nature. At lest according to Warren Siegel, who writes since many years: “Thus, particle theory predicts supersymmetry.” (See his page http://insti.physics.sunysb.edu/~siegel/vs.html)

Siegel obviously has a special view of nature, one that many others do not share. But if you want to make a career in particle physics, you better follow Siegel and Motl instead of those many others who prefer fact to fiction.

67. **Holycow**
April 15, 2011

Time will tell what’s fiction and what’s fact. And the future will be of the daring. Zwicky’s name will be remembered and those who opposed his ideas are already forgotten.

68. **joke**
April 15, 2011

Ha ha,

is Siegel’ s whole homepage not just a joke-page?
He does not mean any stuff he writes there serious or does he?!

The joke-papers on it are really funny and give one a good laugh 🙂

69. **edg**
April 15, 2011

Maybe the dark halo is very different to the standard one.
See http://arxiv.org/abs/1103.6091: a WIMP with mass in the TeV range and a rotating dark disk could be a viable solution for DAMA and the recoils measured by the other experiments.

70. **Geometrick**
April 15, 2011

Supersymmetry is not a fact until we discover those predicted particles. That is the objective truth.

71. **M. Wang**
April 15, 2011

Holycow,

It is difficult to have a logical discussion with you because you consistently employ counterproductive debate tactics, but I will give it one last attempt.

Claiming the others are trying to stop research into SUSY is a plain straw man attack, because I have not seen anyone here making that argument. What everyone here is saying is, instead, that previous SUSY predictions have been largely ruled out, and therefore Bayesian logic dictates that SUSY should be treated as a far-out idea unlikely to have relevance to this universe. Research into such ideas is still part of science, but they should certainly not considered mainstream.

“You have to read more.””Your take on this is really a disgrace.””So, even Peter should be able to understand this allegory” These are all ad hominem attacks that serve only to degenerate the discussion into name calling.

And finally, when you are not using these attack tactics, I find your logic impossible to discern. For example, “‘It would be equally misleading as e.g. saying that SUSY is a fact of nature.’ Not really. This might be true (we don’t know yet).” How does “might-be-true” leads to “not really” on a statement like “misleading…saying that SUSY is a fact of nature”, regardless of its true merits? If it is not misleading saying that SUSY is a fact of nature, then there is no might, could, would or any uncertainty.

72. **Eric**
April 15, 2011

M. Wang,

The statement that SUSY has been mostly ruled out (even in the Bayesian sense) is completely false. I believe that what irritates Holy Cow is that yours and Peter’s statements are highly misleading in this regards. Obviously, this is related to your own biases and opinions, but I’m sure also it is related to fundamental ignorance about how science works.

73. **Peter Orland**
April 15, 2011

“Obviously, this is related to your own biases and opinions, but I’m sure also it is related to fundamental ignorance about how science works”.

No, such statements are what betray fundamental ignorance. Remarks like this remind of what is said of professional tennis players. They have to be smart enough to play tennis, but just dumb enough to think it really matters.

74. **Shantanu**
April 16, 2011

Peter, If you have a multi-purpose experiment with different physics goals (such a Super-K), then sure if you have some people working on proton decay
it is fine. But beyond a point, I am not sure its worth investing in building dedicated proton decay experiments, esp. if most well motivated theories continue to be ruled out
in the 80’s building a dedicated magnetic monopole search experiment would make sense, but not now.

75. **KD**
April 16, 2011

Just to state the obvious. SUSY is a general idea with many specific incarnations. Those specific incarnations (and those only) can be falsified experimentally.

Once a stage is reached where most popular incarnations are falsified one may start to doubt the general idea.

KD

76. **felix**
April 16, 2011

Among all the envisioned possibilities at LHC, SUSY and large extra dimensions are the few outcomes that will bring a paradigm shift to physics. Most other speculations are merely mundane QFT theories built upon the old paradigm of gauge theory and spontaneous symmetry breaking. They are nothing but simple generalizations within the good old SM framework. I dare say that if the new physics that's discovered is among this boring category, then the theorists behind it wouldn't even get a Nobel prize.

77. **Bobito**
April 16, 2011

Too many take too seriously the idea that what is science is what can be experimentally falsified.

What is science is what can be justified by experiments. This involves falsification, but there is more to it.

The ether was a good idea that did not correpsond to reality.

Right now there is not much (if any) experimental evidence that suggests that SUSY, in any form, is true (in the platonic sense). It's simply a bad scientific attitude to say that what has not been ruled out is still credible. What confirmed general relativity in the minds of professionals wasn't that it couldn't be falsified (that's not even clear yet). Rather it was that the predictions it made related to Mercury's orbit coincided with observation (not even yet experiment – that came later). The acceptance of the theory was based on positive confirmation – and it didn't come after years of null results.

The success of such mathematical theories as general relativity or the standard model has ruined a lot of physicists educated in recent decades. Those working in the 50's and 60's mostly had some direct experience in engineering type activities in a war, and were able to distinguish between theory for its own sake and theory that grapples with real physical questions. That's been lost to some extent. The success in mathematics of some theorists, e.g. Witten, has further confused the scene. However, as much as the geometrical-topological theory of higher dimensional manifolds is beautiful and deep, it has yet to find any (!) really deep application in genuine physics. Better to levitate a frog.

78. **Mitchell Porter**
April 16, 2011

felix says: "a paradigm shift to physics"

You can see a paradigm shift in theory happening at the KITP program discussed in a previous post:

http://www.math.columbia.edu/~woit/wordpress/?p=3611

There is an extraordinary convergence among gauge theory, string theory, and twistor theory taking place. It's as if they are all different ways of expressing the same thing. It's being understood first for highly supersymmetric field theories, but there's every reason to think that these new perspectives will extend all the way to the standard model, which is after all a gauge theory.

Even without the LHC, then, big things would be happening, but all this is happening at the same time that we're going to get the facts on electroweak symmetry breaking. But the point I would emphasize is that, even if neither Higgs nor supersymmetry is revealed at the LHC, even if every single beyond-standard-model phenomenological theory ever proposed is wrong, all the years of theory since mid-1970s have not been wasted, because they were indispensible in bringing us to this new convergence of mathematical perspectives, in which theories known for decades are proving to contain all these hidden properties.

AdS/CFT and the twistor string were the breakthrough ideas, and as Arkani-Hamed mentions in his talk, now connections are being made to a great body of mathematics which had not previously played a part in physics, such as the theory of motives. With respect to string theory, what may be happening is that strings and branes are showing up as universal structures in quantum field theory, with compact extra dimensions corresponding to the moduli space of degenerate ground states. (That's how it works in AdS/CFT.) It may turn out, not that string theory picks out a unique field theory as the theory of everything, nor that string theory has nothing to do with reality, but that string theory is one of several equivalent pictures available for a very large class of field theories, one of which describes our world.

79. **Peter Woit**
April 16, 2011

KD,

The problem I'm trying to point out is that what's a "popular incarnation" of SUSY keeps changing. For instance, it used to be that for a choice of SUSY parameters to be popular, it had to have a viable WIMP candidate to explain dark matter. Since a couple days ago, that may no longer be true. I'm sure that SUSY phenomenologists are hard at work on new plots of "favored" regions of parameter space, different than the old ones, since the old ones have been at least partly ruled out by XENON100.

80. **Peter Woit**
April 16, 2011

Mitchell Porter,

That's just nearly pure unadulterated hype. String theory has a long history of taking a very complex theoretical situation and claiming much more for it than there's any evidence for. It seems that nothing has been learned from the results of that.

81. **Benito Callas**
April 16, 2011

> SUSY and large extra dimensions are the few outcomes that will bring a paradigm shift to physics.

Well, no. There could be experimental results that do not fit into any known theoretical framework that force a paradigm shift. In that case the Nobel you mention would go not to theorists but to experimentalists.

On the other hand, I don't see how SUSY could possibly be considered a paradigm shift, since it has been the de-facto paradigm for the last three decades.

82. **Holycow**
April 16, 2011

M. Wang,

I don't even know what "counterproductive debate tactics" means. But I sure agree with you that it is very difficult to have a logical discussion with some of the people here.

I don't think I claimed there are people trying to stop research on SUSY. I'm not paranoid. I'm just sick of bloggers saying SUSY is dead, or nearly so, when they should know better, especially thinking of what journalist can make of it. Why I feel strongly about this?: first because I happen to think SUSY is the best BSM idea in the market. Second, because I hate inconsistent crappy logic. I said it before and I'll repeat it: experimental searches are bloody difficult, even when you know that the particle should be there. Remember the top. When the lower limit on its mass kept increasing and increasing who thought the top was a far out idea? There was a range for it to be found, we knew it should be below 200 GeV, and till the limit reached that point the idea was pretty much alive. So, Bayesian logic, my ass.

The same holds for the statuts of SUSY searches (only much more difficult this time). Till the limits reach into the few TeV masses the search is on, the idea is alive and it's in fact the most relevant goal for LHC besides the Higgs. If you don't like it, too bad, but don't discharge your frustration on the logic of scientific research.

"These are all ad hominem attacks that serve only to degenerate the discussion into name calling." Agreed.

"""It would be equally misleading as e.g. saying that SUSY is a fact of nature.' Not really. This might be true (we don't know yet)." How does "might-be-true" leads to "not really" on a statement like "misleading…saying that SUSY is a fact of nature", regardless of its true merits? If it is not misleading saying that SUSY is a fact of nature, then there is no might, could, would or any uncertainty."

OK. I didn't say I support the claim that SUSY is a fact of nature. What I wanted to say is that "SUSY predicts a Higgs below 150 GeV" is a false statement, while we don't know yet if "SUSY is a fact of nature" is true or false. Is that clear enough?

83. **Holycow**
April 16, 2011

Peter, you spend a lot of time fighting "hype" but then you fall into the hype-logic yourself. If some people wanted to promote their SUSY models or preferred regions of parameter space this shouldn't fool you into thinking they are right. You do well in fighting such hype, but fight the hyppers, not the theory.

I don't care what the "popular incarnation" of SUSY is.
Do you think somebody really thinks the CMSSM is the true BSM theory? It just serves a useful purpose to tune the experimental searches and the needed triggers, but SUSY is not over if some particular incarnations of it are ruled out. They have to be ruled out before we get to the real model.

But in your mind, SUSY doesn't exist, and I have the feeling that no amount of arguing will ever convince you that the discovery of SUSY is a logical possibility not ruled out at all.

84. **Peter Woit**
April 16, 2011

Holycow,

To make clear what I think (and continually specifying that here SUSY=any of the known SUSY extensions of the SM, not something more general).

1. The discovery of SUSY is a logical possibility not ruled out at all. But the world is full of implausible ideas that are logical possibilities, not ruled out.

2. From the beginning SUSY was not a very compelling idea, since it doesn't really explain anything about the SM.

3. The continuing lack of any evidence for SUSY at LEP, in precision electroweak results, proton decay searches, dark matter searches makes the idea quite implausible.

4. The last hope for SUSY is the LHC, which has already ruled out a lot of possible parameter space. There was some hope that dark matter searches would find a SUSY WIMP, but that had started to become unlikely, became even less so last week.

5. Over the next few years better dark matter experiments will put even tighter constraints on SUSY WIMPS, and the LHC will rule out more parameter space. Each time these new results come out, SUSY advocates will produce new plots showing that it's likely to be just around the corner, just a bit past the latest limits. I and other bloggers will accurately describe the situation as more and more nails firmly closing the coffin on SUSY. One notable exception to this will be Lubos.

6. Anonymous commenters here will attribute skepticism about SUSY to ignorance. A large part of the particle theory establishment will go to its grave still convinced that SUSY is a wonderful, beautiful idea, with experimental confirmation just around the corner, and will promote this idea to anyone who will listen. As years go by, fewer and fewer will listen.

85. **Holycow**
April 16, 2011

Good enough. I'll keep a copy of this for future reference. 🙂

One simple reply, as I'm tired:

#1 For you, everything is equally likely? Cultivate your taste.

2. The existence of a third generation doesn't solve any problem. Or does it? SUSY has the potential of solving several problems and explaining puzzles of nature. Go read some textbook on the subject.

Do you know of any other BSM scenario at the TeV scale for which the lack of experimental evidence is less strong than for SUSY?
#3. down

#4. SUSY WIMPs are still a healthy possibility. Just in case, study gravitinos as DM candidates, if you wantyour claims to be as strong as you say. And, sorry, experiments exclude things before discovery. It would be nice if you just turned the experiment up and lots of new exciting stuff would pop up. Maybe in a different universe. If you don't like this one, go somewhere else!

Do you have a sorcerer's ball? #5 irrelevant.

#6 what's the point?

86. **Peter Woit**

April 16, 2011

Holycow,

Where did I say all things are equally likely? I definitely have my tastes, although you don't like them. SUSY is more likely than some, less likely than others. On an absolute scale, I happen to think it's pretty unlikely. Maybe more likely than black hole production at the LHC…

I'm very well aware what the arguments are for SUSY, about which problems and puzzles of nature it is supposed to solve. I just happen to think those arguments are weak. If you can't find those arguments here, a large part of a chapter of the book I wrote deals with the issue. The "you should read a basic textbook on the subject" argument is just juvenile, I've noticed it's a favorite of those who don't have a real scientific argument of their own.

Sure, the best argument for SUSY is the lack of other good ideas. Doesn't mean it's a good one though.

#6 The point is that I'm showing off my predictive powers, successfully it seems…

87. **Georges**
April 17, 2011

Peter, here your efforts ("there is no susy!") are compared to those of El Baradei ("there are no weapons of mass destruction!") :
http://physicswithoutideology.blogspot.com/2011/04/woit-and-elbaradei-weapons-and-standard.html

All the best to you!

88. **Holycow**
April 17, 2011

Peter,

So, what do you think LHC will find besides the Higgs?

"If you can't find those arguments here, a large part of a chapter of the book I wrote deals with the issue."
Thanks, maybe I can find your book in some library. I'm not buying it 🙂

"The "you should read a basic textbook on the subject" argument is just juvenile, I've noticed it's a favorite of those who don't have a real scientific argument of their own." It's rather being tired of repeating the same well known arguments.

"Sure, the best argument for SUSY is the lack of other good ideas. Doesn't mean it's a good one though."

That's a matter of taste and in the end nature will tell. Coming back to Georgi's boutade ("Why I would be sad if a Higgs boson is found"), I'll be happy with whatever LHC brings up. I'm more interested in finding out how nature works than proving my option is realized in nature. Can you say the same? Would you be happy if SUSY turns out to be the way nature is?

89. **Yatima**
April 17, 2011

"So, what do you think LHC will find besides the Higgs?"

How about

"So, what do you think LHC will not find besides not the Higgs?"

Seriously, this is getting tiresome. I though popularity contests where for Italian Saturday Night TV.

90. **Peter Woit**
April 17, 2011

Holycow,

My general point of view is that the SM is a fantastically beautiful and compelling structure, with the most problematic part of it the electroweak symmetry breaking mechanism. So, if I get to choose, I'd like the LHC to find not a scalar Higgs with the expected properties, but some unexpected evidence that leads to finding a better electroweak symmetry breaking mechanism. Of course I don't get to choose, and will be very interested in whatever the LHC does find, even if it is SUSY. Actually I suppose I'd rather have some form of SUSY than the all too possible result that may come out of the LHC, a Higgs exactly as predicted and nothing else. Now, that's going to be depressing…

91. **Holycow**
April 17, 2011

Cheer up! It's gonna be SUSY all over the place! 🙂

92. **Georges**
April 18, 2011

Susy all over the place?

– Monopoles?
– Proton decay?
– Large electric dipole moments?
– Sparticles?
– Many Higgses?

In fact, even the wikipedia entry on supersymmetry does not list any experimental prediction. One gets the impression that the supersymmetry crowd is going the way of the string crowd, with the statement:

"We do not make predictions, but we know that we are right."

93. **Holycow**
April 18, 2011

Well, if the wikipedia doesn't list any prediction I should consider seriously giving up on SUSY. 🙂

94. **Younghun Park**
April 18, 2011

The gravitational wave is not found, but, no one gives up the general relativity. When will it be found? We don't know.
The gerneral relativity is perfect? No!

We can't give up SUSY and String theory even if that is not found in experiment. Some concepts in SUSY and String theory are useful, very useful to make the better physics.

We must not give up the all of SUSY and string theory.
We must use the some usefulness in SUSY and string theory
for the next advanced physics.

What is useful in SUSY and String theroy?
It' up to you!

95. **Peter Woit**
April 18, 2011

Yonghun Park,

One difference is that there actually is quite a lot of evidence for GR, while there is zero evidence for SUSY/string theory. Even on gravitational waves, the GR predictions have been indirectly tested (pulsars).

Theories that never pass experimental tests or predict nothing should be abandoned, ones that pass experimental tests are the ones you know are worth trying to build upon.

96. **Bernhard**
April 18, 2011

Peter,

I think one should not give the impression SUSY and Strings are the same thing. Of course you know that, but when you say "zero evidence for SUSY/string", someone could get the wrong idea.

Now I think the worst thing about SUSY is something I already discussed in this blog is that since LEP and with the LHC going to new parameters space, one of the most advertised things about SUSY, the "solution" to the hierarchy problem is looking less and less a "solution". But of course there is still some room for it. So I agree with those who say we should wait.

After 2012, as far as I know the situation should change. I am involved in an LHC experiment searching for SUSY or not SUSY. If SUSY is not there I want to be one of the people to rule it out.

In any case the absence of a WIMP is bad, but for people working with R-parity breaking SUSY perhaps not a big surprise.

In any case, SUSY is not dead at all, just looking less likely. The difference between the top quark history is that the heavier the sparticles the worse is the solution to the main motivation for SUSY exiting in the first place. The top quark could not have been too heavy but being light or heavy did not affect the motivation for its existence.

97. **on the way out**
April 18, 2011

SUSY will be abandoned only when something else comes along that does a better job of explaining things (and making successful falsifiable predictions). Just as the ether was abandoned only when relativity came along and did a better job of explaining things and making successful testable predictions. But for SUSY to be abandoned, the accelerators must find *something* BSM (suspicious bump? it will need more than one bump), and (i) SUSY must fail to explain it satisfactorily, and (ii) a "new theory" must do a better job of explaining things, and (iii) don't forget the testable falsifiable predictions, the new theory will win only when it passes this step. But SUSY per se will never be abandoned, it will get displaced. So it was with the ether.

Consider also the J/psi and other peaks (psi'). The quark model could explain all the peaks in a natural way (and predict the chi states and D mesons their properties ~ decays, selection rules, etc). Other models (S-matrix) could not do such a good job. One needs new bumps.

98. **Bobito**
April 19, 2011

Mitchell Porter:

It's very difficult to take seriously as physics any discussion that involves motives. This is taking something from the deepest reaches of number theory and algebraic geometry and imposing it on the physical world. It's the same error that macroeconomists made when they took dynamical models from physics and tried to use them to interpret economic markets.

Knowing too much can be a terrible impediment to understanding.

99. **Peter Woit**
April 19, 2011

Bobito and Mitchell Porter,

When Arkani-Hamed spoke at Columbia, he mentioned the connection to motives, referring to discussions with Goncharov. He also stated quite clearly that he had no idea what a motive is.

100. **physicsrob**
April 21, 2011

Regarding SUSY parameter priors, there are generally two categories:

1. Priors based off of theoretical or philosophical motivation

2. Priors chosen by/for experimentalists so that they have sensitivity

Okay, so #2 is not a prior, but it could be easily misinterpreted as such. Experimentalists choose to study theories that their experiment might have sensitivity to (not theories that they consider to be likely). If one were to misinterpret their choice of parameters as some sort of bayesian preference one would come to the misguided conclusion that the preferred versions of SUSY have been excluded. But that's nonsense.

If, however, the motivation for SUSY requires a certain choice of parameters and those parameters have been excluded that would be a strong case to abandon it at as plausible theory. But is that really the case? (I'm not a theorist so I don't have much to say about this)

Personally I have a completely flat prior for SUSY parameters (or its existence in the first place), so the whole argument that SUSY should be considered a fringe theory simply because a small set of parameter space has been excluded seems a bit ludicrous to me.

101. **Mark**
April 24, 2011

Check out the title of this post-Xenon100 talk by Dan Hooper: http://www.phys.psu.edu/seminars/index.html?event_id=2232;event_type_ids=0;span=
That said, I won't be terribly surprised if someone like Weiner, Hooper or Zurek will put out another paper in a few weeks, where they tweak a few parameters in one of their pet models and produce another "consistent" scenario 🙂

102. **Shantanu**
April 25, 2011

Peter, what do you think of this paper by 'Hooft?
http://arxiv.org/pdf/1104.4543v1

103. **felix**
April 26, 2011

My bold prediction: even if LHC finds new physics that is something other than susy, the new physics will cause new naturalness problems, which will be curable by susy. At that point, susy will regain momentum.

104. **Seb**
April 26, 2011

@Shantanu

I'm also curious about this paper by Hooft. Peter, will you write something?

105. **Peter Woit**
April 26, 2011

Well, first I have to find time to read and understand it. Too busy with other things right now, we'll see. From a very quick glance all I can tell is it's quite far from anything I've ever though much about.

This Week's Hype

April 18, 2011
Categories: This Week's Hype

This week's string theory hype is brought to you by a press release headlined Dark Matter and String Theory? from the Institut Laue-Langevin in Grenoble, and another one from the Vienna University of Technology. These have led to a BBC News report which is getting wide distribution, claiming that Neutrons could test Newton's gravity and string theory. According to the BBC, this is going to allow a search for:

> supersymmetric particles, part of some formulations of string theory that suggest that many extra dimensions exist over tiny length scales, which would require the precision that is only now possible with the team's approach.

The actual physics here is described in this paper. You'll need to find an atomic physicist to explain exactly what this is about, but the claim is that the author's new techniques in resonance spectroscopy can potentially be applied to measuring the gravitational potential at micrometer distance scales. This hasn't actually been done yet. As for what string theory predicts about how the gravitational potential will deviate from the Newtonian value at these distances, the story is the usual: no predictions at all one way or another. Such violations would be very interesting, but say nothing one way or another about string theory.

Update: The folks at Slashdot have started to get a clue, stripping the nonsense about string theory from this story before posting about it here.

Comments

1. **ucn**
   April 18, 2011

   Experiments with UCN (ultracold neutrons) have already reached the point where the change in gravitational potential energy of the neutrons makes a detectable change to the de Broglie wavelength of the neutrons. Yes, the neutrons are going so slow that they really do fall down measurably as they traverse a detector! I believe some Berry's phase experiments have been done but I am not sure of that. So now they can probe gravity down to micrometer length scales? Well done, I say. If the motivation to do this is to test dark matter and string theory, well that's too bad, but it is good physics in its own right.

2. **Peter Woit**
   April 18, 2011

   Thanks ucn,

   I am curious if anyone expert in this area can tell whether this really is likely to lead to a method for measuring the gravitational potential at short distance scales, and if so, what the limits on this technique would ultimately be. I don't see anything in the paper addressing this.

3. **Giotis**
   April 18, 2011

   When they say:

   "part of some formulations of string theory that suggest that many extra dimensions exist over tiny length scales…"

   they mean most probably the ADD paradigm of large extra dimensions which is not considered part of String theory per se.

   The title is misleading of course but such titles are common practice for the vast majority of journalists; so no surprise there.

4. **Peter Woit**
   April 18, 2011

   Giotis,

   As I keep pointing out in these cases, the misleading nonsense is not something the journalists came up with. It's in the press releases given to them, and in the actual Nature paper:

   "The experiments are linked to current ideas in string theories…"

   This can't be blamed on inept journalists, it's physicists who are putting this out since they think it will draw more attention to their research.

5. **Giotis**
   April 18, 2011

   Even so Peter don't you think there is a big difference between the above excerpt and BBC's title?

6. **Peter Woit**
   April 18, 2011

   Giotis,

   If you're a physicist who decides to participate in issuing a press release with a title making a misleading claim about the relation of your research to string theory, I don't see how you can complain when a journalist writes a story based on the press release and uses a misleading title involving string theory.

7. **Pawl**
   April 18, 2011

   I wonder if the physicists approved the title of the press release. (I know journalists don't generally get to choose their stories' titles.)

   It might be good for scientists, university and institute press/publicity offices, and media covering science stories to adopt some standards in these matters.

8. **tittle**

April 18, 2011

Curious isn't it, that everyone can only comment on the title, and nobody can find anything to say about the physics? Has anyone attempted to contact the authors, and/or friends at ILL (say), to ask about the science as opposed to the title?

9. **Bernhard**
April 19, 2011

Anything to do with experiments cannot, by definition, have anything to do with string theory.

10. **Bee**
April 19, 2011

I presently don't have access to Nature, so have only read the abstract. It sounds related to the experiments with bouncing neutrons in the gravitational field that we discussed on our blog some years back. Yes, one can get down to distances of some micrometers, yet I'm not sure how sensitive one is at this distance to Newton's law. For that I suppose one would have to actually read the paper. Needless to say, the connection to string theory is vague. Also, if one wanted to test extra-dimensional scenarios with that, those with a lowered Planck scale around a TeV, one would only test d=2 or maybe 3, and these are strongly disfavored by astrophysical measurements already. Details are in the Particle Data Book.

11. **Proudmemberofthecult**
April 19, 2011

One can discuss the phrasing of the press release but it should be obvious that any measurement of a deviation of Newton's law is indicative of radically new physics beyond what is presently known. If you were writing the press release though you would also put in something about what this would mean. The layman does not know ADD, but does know the word string theory, so this is what they write.

Big deal.

Although logically disconnected, any measured deviation *would* strongly favour string theory types of scenario. Even this blog's owner might agree with that.

Of course I do not believe they will find anything, but it's an interesting proposal for which they should get credit.

12. **Bernhard**
April 19, 2011

"Although logically disconnected, any measured deviation *would* strongly favour string theory types of scenario. Even this blog's owner might agree with that. "

This is no way true. Really far from it. It would indicate new physics. There is no way on this Earth this would favour a string scenario. Only if you accept Seiberg's claim that whatever new thing that appears you call it string theory. This is by the way likely to happen also with whatever new thing we find at the LHC. Somehow it will support string theory, but this is completely dishonest.

13. **Proudmemberofthecult**
April 19, 2011

Dear Bernhard, which other consistent physical theories do you know which support large extra dimensions? That is, theories which do not have a string theory (-inspired) description? Hence the 'favour'.

Note it's the same kind of 'favour' which fancies susy solutions to the hierarchy problem. Or inflation as a solution to cosmology problems. For both of these the 'generic' mechanism works although figuring out the exact one is beyond current understanding (how many xxxxxx-inflation type models exist, where the x's are some word?).

I tried to be careful to say that measuring deviations does not *prove* string theory in any sense, shape or form. Not with the current state of it. It would erect a huge sign in the sky pointing at string theory saying "look here".

14. **Peter Woit**
April 19, 2011

No, the blog owner doesn't believe that an observation of a violation of Newton's law would favor "string theory types of scenario" or "string theory (-inspired) descriptions". Just because string theory has turned out to be an empty idea you can use to get anything doesn't mean it's the thing to turn to if you observe something unexpected.

I'm somewhat amused by the way string theory partisans have adopted various favored weasel-words. A translation table to keep in mind would be:

"string theory description": almost anything
"string theory-inspired description": everything else

15. **Proudmemberofthecult**
April 19, 2011

If deviations of Newton's laws are observed at these scales and no explanation can be found within the known laws of physics, what would *your* explanation be?

Please note I am being careful with my words because I wanted to avoid being too 'partisan'… sorry to note I failed.

– string theory description: arises naturally as a well-defined low energy limit of a string theory setup (modulo all the usual things we do not understand about string theory (time-dependence, non-perturbative behavior, vacuum selection)).

– string theory-inspired description: incorporates some elements natural in string theory (extra dimensions, supersymmetry, grand unification, etc, etc.), but not all. Usually some form of effective action where the string theory inspiration bit provides some constraint to limit parameter space (usually also rather arbitrarily).

16. **Peter Woit**
April 19, 2011

If evidence is found for new physics at a distance scale of 10^-6 meters, I don't have any good ideas about what that physics might be. However, in terms of places to start looking, a theory based on new physics appearing at 10^{-35} meters wouldn't be an obvious place to begin.

17. **Eric**
April 19, 2011

Peter,

You've missed the entire point regarding large extra dimensions in string theory. If the extra dimensions are large, this lowers the string scale so that the new physics appears at larger distance scales than 10^{-35} meters. This is exactly why black holes could be produced at the LHC in models with large extra dimensions.

18. **Zathras**
April 19, 2011

Proudmemberofthecult,

Care to explain the logical leap between "radically new physics beyond what is presently known" and "which support large extra dimensions?" There's been a lot of radically new physics done in the past without inventing extra dimensions out of thin air.

19. **Peter Woit**
April 19, 2011

Eric,

I realize you can make "string theory-inspired" models (such as ADD) with observable effects an any distance scale you want. This doesn't seem to me a point in their favor. I'm just pointing out that the conventional thing to do when faced with new phenomena at a certain distance scale is start by looking for models where that specific distance scale appears naturally for some reason.

20. **Proudmemberofthecult**
April 19, 2011

Zathras,

If any deviations from Newton's law are measured this would be unexpected to say the least. You are right I should have stressed more I'm presuming these measurements would conform to the large extra dimensions scenario. As this is the only known class of physical theories accommodating such deviations in a natural way as far as I know (correct me if I'm wrong!), this is not such a big assumption.

Hence IF some non-trivial effect is measured it's a fair bet it will support large extra dimensions. This in turn would favour (not prove) a very specific type of background in string theory.

Let me stress again that I don't believe in this scenario, basically for the same reason as Peter W. mentioned. For me though it's not `natural' in string theory :). Not 'natural' does not mean impossible though: improving bounds by orders of magnitude as is proposed in the press release is a good thing.

21. **Higgs?**
April 21, 2011

Internal Note
Report number ATL-COM-PHYS-2011-415
Title Observation of a γγ resonance at a mass in the vicinity of 115 GeV/c2 at ATLAS and its Higgs interpretation
Author(s) Fang, Y (-) ; Flores Castillo, L R (-) ; Wang, H (-) ; Wu, S L (University of Wisconsin-Madison)
Imprint 21 Apr 2011. – mult. p.
Subject category Detectors and Experimental Techniques
Accelerator/Facility, Experiment CERN LHC ; ATLAS
Free keywords Diphoton ; Resonance ; EWEAK ; HIGGS ; SUSY ; EXOTICS ; EGAMMA
Abstract Motivated by the result of the Higgs boson candidates at LEP with a mass of about 115~GeV/c2, the observation given in ATLAS note ATL-COM-PHYS-2010-935 (November 18, 2010) and the publication "Production of isolated Higgs particle at the Large Hadron Collider Physics" (Letters B 683 2010 354-357), we studied the γγ invariant mass distribution over the range of 80 to 150 GeV/c2. With 37.5~pb–1 data from 2010 and 26.0~pb–1 from 2011, we observe a γγ resonance around 115~GeV/c2 with a significance of 4σ. The event rate for this resonance is about thirty times larger than the expectation from Higgs to γγ in the standard model. This channel H→γγ is of great importance because the presence of new heavy particles can enhance strongly both the Higgs production cross section and the decay branching ratio. This large enhancement over the standard model rate implies that the present result is the first definitive observation of physics beyond the standard model. Exciting new physics, including new particles, may be expected to be found in the very near future.

See: http://cdsweb.cern.ch/record/1346326?

22. **Brathmore**
April 21, 2011

Peter,

Quick questions from someone who is not a physicist but enjoys reading this blog: What is the state of the experimental evidence saying that gravity is quantized? Is the BBC correct when it says that in 2002, "gravity's quantum nature was proven"? How strong is this evidence? (I had thought– perhaps erroneously–that the quest to find a quantum theory of gravity was motivated largely by theoretical concerns).

Thanks

23. **Peter Woit**
April 21, 2011

Higgs?

That looks very, very interesting! It looks like one can't yet get a copy of the paper without a CERN login. If anyone can provide this or more information, that would be great.

24. **McNicholl**
April 21, 2011

After a quick read of the article: a sensitive resonance measurement of the energy levels of slow neutrons due to the gravitation potential from the earth (among other boundary interactions). The results agree at the current level of precision with a classical treatment of the gravitational potential. The authors propose to improve precision with a technique analogous to a well known resonant technique (separated oscillatory fields). Now I am not a theoretician so up to you guys but, for what it is worth: (1) this is not a high precision measurement of graviation per se–the precision is required due to the small mass of the neutrons; (2) much of the misleading hype (not sure how much due to the paper itself) comes from the misleading juxtaposition of the words “quantum states” and gravitation; (3) though the vertical (transverse) dimensional scale of the experiment is ~ 20 microns, one is not measuring graviational effects between two objects of this scale (a la Cavendish balls)–one of the objects is indeed the earth.

25. **Peter Woit**
April 21, 2011

Brathmore,

What’s observed is the effect of the classical gravitational potential on the wavefunction of a particle. This isn’t really “quantum gravity”, by which one normally means quantization of the gravitational degrees of freedom (e.g. the metric), which would show up as new phenomena such as a graviton (quantized excitation of the gravitational field). If this method works out, you would get more information about classical gravity at shorter distances, but still nothing about whether and how gravity gets quantized.

26. **McNicholl**
April 21, 2011

Still questionable that it provides information on classical gravity at small scales…if I intrpet scale as the range we are always inverting. I.e., the effective range we know from 101 is ~ radius of the earth.

27. **Arun**
April 21, 2011

Assuming Higgs? is not spoofing us:
http://arxiv.org/abs/1103.0631

Quoting from the abstract: “…the di-photon Higgs signal $pp->h->\gamma\gamma$ is a sensitive probe for new physics…….(i) In the MSSM the signal rate for the SM-like Higgs boson (the lightest CP-even Higgs boson) is suppressed compared to the SM prediction, and for many survived parameter samples the suppression can be over one order; (ii) For the SM-like Higgs boson in the NMSSM the signal rate can be either suppressed or enhanced by one order, depending on the parameter space; (iii) For the SM-like Higgs boson in the nMSSM the signal rate is much suppressed.”

28. **OhDear**
April 21, 2011

“Higgs?” more information please…

Why are only a few authors listed, and not the whole collaboration? Also I wouldn’t expect the abstract of an experimental paper to gush about new physics like that. So I’m a little sceptical and think you might be pulling our collective leg.

29. **Amos**
April 21, 2011

@OhDear:

Re “Why are only a few authors listed”? That seems to be how Atlas organizes its papers. See http://www-wisconsin.cern.ch/physics/papers.html .

And its the right names. But it still doesn’t feel right.

30. **Anonymous (but PW can see my details anyway)**
April 21, 2011

Higgs? is not pulling any leg, the paper is there. Of course the reason there are only few authors and such a strong claim is the same – it’s still an internal publication. And there seems to be some room for discussion about the photon identification methods, but after all that’s why internal notes are internal.

This Week's Rumor

April 21, 2011
Categories: Experimental HEP News, Favorite Old Posts

A commenter on the previous posting has helpfully given us the abstract of an internal ATLAS note claiming observation of a resonance at 115 GeV. It's the sort of thing you would expect to see if there were a Higgs at that mass, but the number of events seen is about 30 times more than the standard model would predict. Best guess seems to be that this is either a hoax, or something that will disappear on further analysis. But, since spreading well-sourced rumors is more or less in the mission statement of this blog, I think I'll promote this to its own posting. Here it is:

> Internal Note
> Report number ATL-COM-PHYS-2011-415
> Title Observation of a γγ resonance at a mass in the vicinity of 115 GeV/c2 at ATLAS and its Higgs interpretation
> Author(s) Fang, Y (-) ; Flores Castillo, L R (-) ; Wang, H (-) ; Wu, S L (University of Wisconsin-Madison)
> Imprint 21 Apr 2011. – mult. p.

Exciting new physics, including new particles, may be expected to be found in the very near future.
>
> See: http://cdsweb.cern.ch/record/1346326?

Update: Jester is up late with some comments here.

Update: Tommaso is skeptical here.

Update: It should be made clear that, while members of ATLAS work here at Columbia, I have no connection at all to them, and they had nothing to do with this. The source of the abstract posted here anonymously as a comment is completely unknown to me. The question has been raised of whether I should allow this kind of material to be posted to this blog and I think it's a serious one that I have mixed feelings about. On the one hand, ATLAS has legitimate reasons for keeping this kind of information private, on the other, it's the kind of information that traditionally has sooner or later circulated outside a collaboration in one form or another. As an example, in my graduate student days back in the early 80s, I remember Carlo Rubbia telling a large group of people at the departmental tea about how his experiment had the top quark "in the bag" (actually, they didn't…).

I've generally taken the point of view that it's not my job to stop rumors, but rather to put out accurate information about them when available to me. But blogs do raise all sorts of issues, and they're likely to keep coming up. I'm curious to hear if my readers have any wisdom to share about them.

Update: Via Slashdot, some more comment about this, including disclosure of another vector of information transfer out of ATLAS:

> Someone left a copy of the note on the printer in my office building. (I work on CDF at Fermilab, but there are others in the building who work on ATLAS at CERN.) The gist of the article is that they found a bump in the diphoton mass spectrum at a mass of ~115 GeV. If the Higgs exists, it is expected to produce a bump in that spectrum, and 115 GeV is a very probable value for the mass of the Higgs. (Experiments at LEP ruled out masses up to 114 GeV, but a mass as low as possible above that fits best with other measurements.)
>
> Now, the inconsistencies: The bump that they found is ~30 times as large as the Higgs mass peak is expected to be. However, due to field theory that I don't want to get into here, the Higgs peak in this spectrum could be larger than expected if there exist new, heavy particles that we haven't discovered yet. The latest published result from CDF sets a limit of about 30 times the expected rate at 115 GeV in the diphoton channel. (Yes, this means that, if you're optimistic enough, there's just enough wiggle room to fit a Higgs in there while accommodating both measurements.)
>
> The internal note is very preliminary and uses a crude background estimate; I'll have to see a more thorough analysis before I make any judgment on it. We shouldn't have to wait very long; I expect that after this leak, they'll be working overtime to push out a full published result as soon as possible.

Update: Since I don't traffic in rumors of dubious source, you'll have to go here to get the latest rumors from someone younger who knows about this whole Twitter kind of thingy…

Comments

1. **GJ Philip**
   April 21, 2011

   The note says that a revolutionary new particle will appear soon, something that happens maybe once every 20 years. It also says that the the standard Model is about to be superseded, something that has been touted for 20 years too.

   It's like saying "The world will end next week!" or "A new continent will be found in the Pacific Ocean tomorrow!"

   The flavour of it is similar to a pep-talk at a political rally just before an election.

2. **OhDear**
   April 21, 2011

   If someone has access to the note, perhaps they could send the pdf to peter and he can make it public via this blog.

3. **Yatima**
   April 21, 2011

   Harold Camping [http://en.wikipedia.org/wiki/Harold_Camping] predicts End Of The World Through Rapture for in exactly one month [21st May].

Coincidence? I think not!

4. **Peter Woit**
April 21, 2011

A question for experts: is this kind of signal consistent with Tevatron data? Looking at

http://moriond.in2p3.fr/QCD/2011/MondayMorning/Cooke.pdf

I see an overall combined limit at 115 GeV of 1.5 times SM, and in the specific channel mentioned here (115 GeV Higgs to gamma-gamma) independent limits of about 20 times SM from D0 and CDF. Can a higher production cross-section at LHC than at the Tevatron explain this?

5. **Sumar Ongi**
April 21, 2011

This is probably an April 21st fool's joke…

6. **Eric**
April 21, 2011

If it's true, it likely means that there is a fourth generation.

7. **lun**
April 21, 2011

Lets draft a press release that this is an experimental test for string theory! 🙂

8. **Tom**
April 21, 2011

I can't swear but I believe that when the different final states are combined to quote 'The SM Higgs Bound' the SM branching fraction weights are used. If for some reason the Higgs were SM-like except for the gamma-gamma final state (which I think is non-trivial especially as the glu-glu channel cannot be too much changed) then one needs to look only at the search in the specific gamma-gamma search channel. As Peter points out the bounds from Moriond for masses near 115 GeV are ~20x the SM value.
A Tevatron/LHC experimenter should comment further.

9. **OhDear**
April 21, 2011

Peter, according to the abstract the search is along the lines of that proposed in "Production of isolated Higgs particle at the Large Hadron Collider Physics" (Letters B 683 2010 354-357), which is "semi-exclusive" Higgs production. This is quite different from the searches so far at the Tevatron, which are inclusive, i.e they search for ppbar -> H + X, where X is anything. So this could explain why the previous exlusion limits do not apply.

Of course, we have no real details of the search or analysis…

10. **Peter Woit**
April 21, 2011

OhDear,

I'm no expert, but that paper they refer to strikes me as odd on several counts, including its promotion of the idea of "considering the LHC as a Pomeron collider", and the fact that it looks like it was never posted to the arXiv.

From the abstract, it certainly sounds like all they're doing is looking for two photons and plotting their invariant mass. If so, that's comparable to the Tevatron searches, right?

11. **Paul Wells**
April 21, 2011

If it coupled so strongly to gamma gamma wouldn't it have been seen at LEP ? Is this size signal consistent with the Higgs "hint" seen at LEP ?

I am afraid I think this is a cruel hoax.

Paul Wells

12. **Tim Tait**
April 21, 2011

Four generations aren't enough for a factor of 20. One could do it with five, but that would require something else as well to take care of the precision Electroweak measurements.

13. **Peter Woit**
April 21, 2011

Paul,

Good question. They're claiming to be at 115 GeV, not far at all above the LEP limit.

14. **Tom**
April 21, 2011

Tim: even 5 isn't enough as the Hgg coupling increases BUT there is a destructive interference with the WW contribution in the gamma gamma case shrinking it!

15. **Spencer Chang**

April 21, 2011

I'll fuel the controversy a little bit.

Looking at the Moriond talk by Markus Schumacher (ATLAS), it says that they have a limit of 40 times the expected Standard Model rate (see figure on bottom right of slide number 4). This is with the the 2010 data of 37.6 pb^-1.

http://indico.in2p3.fr/getFile.py/access?contribId=76&sessionId=1&resId=0&materialId=slides&confId=4403

However, if you look at the data (bottom left plot), it is much flatter than what they predict. So what they could be doing in a reanalysis is using a sideband, where you would estimate by extrapolating from outside the peak that the two bins around 115 should have 10 background events each (20 total). That leaves roughly 14 signal events which would give a significance of 14/sqrt(20) = 3.13. With the additional luminosity of 27 pb^-1, scaling up these numbers would give a significance that goes to sqrt(1+27/37.6) = 4.1, very close to the 4sigma the note claims.

16. **Tom**
April 21, 2011

Thanks for the quick analysis Spencer…I showed the same panel to a VERY famous , prize-winning experimenter some time ago 7 HE thought there was a bump there in the 35 pb^-1 data set

17. **Amos**
April 21, 2011

Assuming that it's right, what does this do for SUSY?

18. **Eric**
April 21, 2011

Amos,

It would be a big confirmation for SUSY, but might also imply the existence of additional matter besides the superpartners.

19. **JoAnne**
April 21, 2011

IF this is right, all it says is that there is a bump in the gamma gamma channel at ~115 GeV. It says nothing about SUSY and seems difficult to explain with a Higgs since the production rate is so high.

20. **Eric**
April 21, 2011

IF the bump is the Higgs, then it does say a great deal about SUSY since this is exactly where SUSY says it should be. The high production rate can be explained if there are extra heavy states which also couple to the Higgs.

21. **Alexey Petrov**
April 21, 2011

If it is a Higgs, the enhanced production cross section could just be an upward fluctuation. If I remember it correctly, top quark production cross section was also too high initially…

22. **Tom**
April 21, 2011

Well, MSSM SUSY needs the Higgs below ~130 GeV. If there really are a bunch of extra states (like a 4th generation or more) then this limit no long applies & one can't say that SUSY predicts ~115 GeV. Also the additional states would change the EW fits so that a light Higgs would then also not necessarily be prefered by the data.

23. **JoAnne**
April 21, 2011

@Eric: The problem is that CDF/D0 already limit the glu-glu-Higgs couplings from their searches in the WW* mode. You can't add extra heavy states willy-nilly without screwing this up.

And I contend that a potential observation of a light Higgs does not confirm SUSY. Could be a coincidence. The observation of a sparticle (and the precise measurements of the terms in the underlying Lagranian) confirm SUSY.

24. **Eric**
April 21, 2011

So, if there's a fourth generation, am I right in remembering that the enhanced production rate is about a factor of ~9 for 300-400 GeV fourth-generation quarks?

25. **JoAnne**
April 21, 2011

You get a factor of ~9 enhancement in glu-glu-Higgs with a 4th generation, but then you also get a factor of ~2 suppression in gamma-gamma-Higgs coupling.

26. **Daniel**
April 21, 2011

This is an internal, un-vetted, un-reviewed ATLAS document. It hasn't been released for public consumption precisely because it hasn't been reviewed or vetted.

You're wasting your time spinning your theoretical wheels on such tripe, and it doesn't serve any purpose other than the blogger's desire for hits.

27. **Peter Woit**
April 21, 2011

Daniel,

This blogger actually isn't very interested in hits, this isn't a commercial site. Rumor-mongering has its own rewards though, and this sort has a certain educational value (I learned some things about Higgs searches in general this evening).

I'm shocked to hear that ATLAS internal documents contain tripe!

28. **Daniel**
April 21, 2011

Like all internal, un-vetted documents, there is the significant possibility for errors. I imagine if I ruffled through a theorist's unfinished work I'd find some shocking results which turn out later to be wrong…

I'm all for openness, but then we need to be consistent, so you'd see how often ATLAS sees wiggles in the data which appear to be interesting, but are then quickly understood to be run-of-the-mill errors in background calculations….

29. **DonManuel**
April 22, 2011

Madame Wu is the best scientist in the world, and one of the most influent women in USA.
She discovered already twice the Higgs in LEP in ALEPH.
Her famous words when anybody tried to argue on the consistency of arguments and data were:
"What do you prefer, to have a signal or not?"
So she is now simply rediscovering her Higgs at 115 (that was 10x what expected also at that time).

30. **Steven**
April 22, 2011

Peter,
you rightly chide others for blogs and press releases which allow others to gain a distorted view of research findings. Given that this "Higgs discovery" seems based on an internal ATLAS note and that it is not an approved and well checked result, you're as guilty of hype dissemination as those you criticise.

Experiments spend a huge amount of time and effort in getting results right. They have the right to announce a result only after they've performed due diligence. Circumventing this with rumours needlessly damages their hard-earned reputations and does nothing for the advancement of science.

31. **Tommaso**
April 22, 2011

Hi all,

just to mention that I also covered this in my blog too, after reading Peter's post above. See
http://www.science20.com/quantum_diaries_survivor/did_atlas_just_see_higgs-78316 .

In any case, I think the signal is a fluctuation. Their significance is overblown by tuning cuts, and their estimated look-elsewhere effect (the trials factor due to not knowing in advance what to search for and where) is much smaller than what it actually is.

I also want to comment on the use of these "rumors". I think they are valuable for attracting the attention of outsiders. However, insiders should not be attracted into this game too much…

Cheers,
T.

32. **Visitor**
April 22, 2011

This is likely trigger effect. If the have any trigger cuts around 110-120 GeV, this is threshold behaviour of not very well simulated trigger. ATLAS is famous for its approximations in MC, when they are using average efficiencies for various kinds of particles across large eta-phi areas instead of full detailed MC. So, it is possible to gain whatever bump you want in the areas near the trigger thresholds – they just didn't simulate them properly.

33. **Chris Austin**
April 22, 2011

Tim: "Four generations aren't enough for a factor of 20."

Tom: "even 5 isn't enough"

Is this specifically for 300-400 GeV fourth-generation quarks? What if the 4th generation was heavier, e.g. 600 GeV?

34. **Steven**
April 22, 2011

@Visitor
Can you point me towards an ATLAS physics publication in which a detailed trigger simulation isn't used ?

@Tommaso
I don't share your view that this is all good publicity. The field has suffered from a number of hyped up non-discoveries in recent times, eg WIMP dark matter, dubious resonances etc. The public may well be getting sick of the particle physics community crying wolf. I certainly am.

35. **Tom**
April 22, 2011

Chris: Once the mass for the chiral quark is larger than of the top quark's, then to a good approximation the explicit value doesn't matter so 300 or 600 GeV makes little difference here. However, there is a perturbativity bound on the couplings of these heavy objects so they cannot be heavier than ~600 GeV.

36. **Anon-ish**
April 22, 2011

@Visitor: Oh please. ATLAS is, if anything, famous for using (slow) full simulation for everything. Perhaps you are confusing "efficiency" with "efficiency systematic uncertainty".

I find this discussion rather distasteful: publicizing a collaboration's internal documents, *with absolutely no context*, is a profoundly unprofessional thing to do – we're here to deliver quality science, not to entertain people with exciting rumors. Shockingly, while initially exploring and considering the data, we may use looser terms and standards when talking to each other than we would use for an external publication.

37. **Peter Woit**
April 22, 2011

Steven,

To "hype" something, you have to put out misleading information about it. My goal has been to provide accurate information about topics of interest, and I think that's what I did here, with the posting and subsequent discussion providing to anyone interested a pretty accurate picture of what is going on.

The question of what I should do with different categories of information that either gets sent to me or posted on my blog is a legitimate one. This may be a borderline case, but I don't think the problem here is "hype" as long as the information made available is accurate.

38. **Simplicio**
April 22, 2011

I think I'm "pro-rumor". As you say, they're educational, and it gives us something to discuss during the current drought of actual discoveries. If the rumor turns out to be bunk, I don't really see any harm done.

39. **Maxime**
April 22, 2011

I've seen the note. It is clear that they see something with cross sections largely above what is expected in SM. It is also clear that there is no tengible proof shown that this is not a fluctuation of the QCD background. The QCD with 2 prompt photons is not well known area. The estimations of the background is purely data driven based on the side bands estimation.

What is nice is that the analysis is quite simple, no Neural Network, no complicated cuts and games.

40. **Paul Wells**
April 22, 2011

I think as a taxpayer I have a right to know what is going on at an early stage. Peter and others are doing a valuable service that arguably should be done by CERN itself being more open. This type of blog shows that science is an exciting, risky, and difficult human activity where mistakes are often made. What is the big problem with that ? Please credit us taxpayers credit with enough intelligence to filter out the gold nuggets from the crud.

Paul

41. **Tommaso**
April 22, 2011

I would agree it's a "simple" analysis, but the devil is in the details. If they grew enamoured with the fluke they saw in 2010 data, they probably played around with cuts enough to get something out of nothing.

As for the bigger issue of whether this is good or bad, and despicable or reasonable, I have written at length on the topic, but let me point out that in this case indeed we are talking as if this was an atlas result when it really looks like the work of four people working in isolation. At least that is the impression I got.
I must say that if I were in ATLAS, I would not be very happy of the way things have turned out… But I would never blame the bloggers, who do nothing but report what is already out there. They should blame their own collaborators for leaking the material.

Best,
T.

42. **Steven**
April 22, 2011

@Paul Wells

As a taxpayer you have a right to the best science and value for money. Why does this mean that you need to read internal documentation and look at results as they are being produced/disarded/prepared for publication ? Don't you think that scientists should be allowed to have private discussions during data analysis ? To the best of my knowledge there has never been a climategate-style scandal in particle physics. There are no "secrets" but scientists rather like the right to talk openly at work without the world listening in. Furthermore, collaborations are usually in healthy competition with each other. They wish to develop their own techniques to, eg, suppress backgrounds to steal and edge on the opposition. There won't be too much of that in the true "open access model" which you propose.

43. **Steven**
April 22, 2011

Peter,

you put out information which suggests that ATLAS has found the Higgs and hosted the subsequent discussion/speculation. That pretty much fulfills the definition of hype:
"excessive publicity and the ensuing commotion".

44. **Chris Austin**
April 22, 2011

Tom, thanks.

45. **RealScientist@ATLAS**
April 22, 2011

This is NOT a PUBLISHED PAPER. It's a COM note.

Anything, especially garbage, can be published as a COM note. It's internal to the ATLAS collaboration, NOT REVIEWED by anyone, NOT APPROVED.

An approved result is signed by the entire collaboration, namely more than 2000 people.

Seeing this on a blog is a shame. The person who releases this paper is not worth being called a scientist. Makes me sick.

46. **Peter Woit**
April 22, 2011

Steven,

Read what I wrote introducing the topic:

"Best guess seems to be that this is either a hoax, or something that will disappear on further analysis."

I partly agree with your response to Paul Wells: scientists should largely be allowed to do their data analysis in peace, without the world looking over their shoulder. People need to have some privacy to make mistakes. But I don't buy the argument that scientists won't come up with better experimental methods if the competition is going to immediately get access. A better argument for secrecy would be that leakage of information between two experimental groups makes their results not completely independent, whereas that's a very desirable characteristic.

One thing that occurs to me is that the scale of the LHC experiments is something new. If everyone in ATLAS has access to this note, you're talking about 3000 people, no? Maybe a third of the world-wide experimental HEP community? If you've already got 3000 people looking over your shoulder, you're not exactly able to make mistakes in private. I'm not well-informed about ATLAS procedures, so it surprised me to hear that results from a small group of 4 people were being immediately broadcast to the entire collaboration, before a smaller, more specialized group had done some vetting.

47. **Steven**
April 22, 2011

As was mentioned earlier, anyone can write a com note and send it to the collaboration. A com note is unreviewed and is a very good way to quickly transmit ideas and techniques within the collaboration. A com note is not a result by any stretch of the imagination. Any ATLAS member can write a com note claiming anything.

I agree with "real scientist", whoever passed this on should be ashamed of themselves. Collaborations have internal peer review procedures for a reason.

48. **Nathalie**
April 22, 2011

A historical note: Sau Lan Wu and her collaborators had V-V events in their data while working in the ALEPH Collaboration at LEP (Large Electron Positron) Accelerator. In those days, the events were not considered to be significant. That was indeed ages ago as LEP was closed in the year 2000.

49. **Low Math, Meekly Interacting**
April 22, 2011

There's going to be a lot of this for the next few years, isn't there.

50. **AS**
April 22, 2011

keeping secret the work of 2000 persons in the age of internet is just impossible.

51. **Paul Wells**
April 22, 2011

I don't want to start a flame war so I will summarize my position then shut up.

I paid for this work so I think I should have free access to-

1. All Raw Data
2. Programs required to interpret raw data.
3. Project documentation to interpret 1. and 2.
4. Final publications WITHOUT having to pay for journal.

Agreed though that IF this was leaked without the author's permission it was wrong.

Thanks
Paul

52. **Peter Woit**
April 22, 2011

Paul,

What you're bringing up are issues not really related to the question at hand, that of information getting to the public about incomplete results that have not yet been fully checked. The people who designed and built this experiment have a legitimate interest in seeing that the data from it is responsibly analyzed and interpreted.

53. **Also a real scientist @ ATLAS**
April 22, 2011

The first commenter is correct. This cannot be considered an official result of the ATLAS experiment. It has not been reviewed by even a single internal reviewer. COM notes are, as noted by others, used to communicate information to the whole collaboration. The subject of such notes is information all collaboration members have access to already, but usually written in such a way that it is well-explained for members that don't necessarily participate in a given analysis. It's a 3000 person collaboration; without something like COM notes, it would be difficult to follow everything that goes on. You certainly can't go to all the meetings.

Here is a link (publicly available) explaining the categories of ATLAS documentation that can be found on the CERN document server (CDS): https://twiki.cern.ch/twiki/bin/viewauth/Atlas/CdsCategories

"ATLAS Communications (ATLAS-COM-*): ATLAS communications – no approval or vetting by ATLAS; also used as "discussion category" for documents to be approved (Proceedings, Slides, INT and PUB notes)"

54. **Peter Woit**
April 22, 2011

Thanks for the information about ATLAS documents, although the link you provide requires a CERN login when I try it.

I don't know if anyone from ATLAS or CMS is willing to discuss this, but I for one would be interested in hearing an outline of how things are supposed to work for searches like this one. This case seems anomalous. Surely the standard procedure can't be to have everyone off looking for whatever they think might be interesting, then when they think they see something writing a draft of a paper about how physics has just been revolutionized and putting it up for 3000 people to look at and discuss.

55. **OhDear**
April 22, 2011

yes yes, we all appreciate that this is not an official statement from the Atlas collaboration, and has in no way been vetted by anyone apart from those who produced it.

The question is, how often do sensational com notes like this one get circulated internally? How likely is it that the authors of this note have done something silly in the analysis? They are professional experimental physicists, and are members of Atlas, so they know what they are doing. Of course we all make mistakes, but I assume they would have checked this analysis quite thoroughly, to avoid looking silly in front of the rest of the collaboration.

I also wonder if/how the Atlas heirarchy are going to try to discover the source of the leak. I guess only a limited number of people would have clicked on the link to this document, and their identities may be available. (note that to access the document you need to login using your CERN login.)

56. **mark**
April 22, 2011

Paul,

All LHC publications are available from CERN CDS or arxiv free of charge (unlike most other scientific fields which require you to pay for expensive journals).

I suggest you read the talks and papers on the topic of (1)-(3) (google it) – its far from trivial to do due to various technical software reasons (what happens when the computers the computer code ran on cease to exist – think of a program on a 5 inch floppy disk from 30 years ago – what on earth would you do with it now if you wanted to use the programs and data on it….computer hardware does not last forever, and noone builds any device that could read it anymore), though I believe e.g. ALEPH has attempted this in recent years and lots of people spend lots of time thinking about how best to do this to preserve the data for future generations (obviously given the expense you cannot rerun these experiments easily if you lose the data).

57. **Anonymous**
April 22, 2011

Paul,

If everyone has access to all raw data immediately, what makes you think anyone would actually build these experiments? Just let someone else do the hard work and wait around to do an analysis.

As a former member of ATLAS I can tell you that the only reason most physicists work on these experiments is to have access to the data.

If anyone could do any analysis on any experiment's data then no experiment would actually get built.

58. **Also a real scientist @ ATLAS**
April 22, 2011

Sorry, I thought the link should be publicly available as I got to it from the public page. The important part is the definition of a COM note, which I anyway listed.

>yes yes, we all appreciate that this is not an official statement from the Atlas collaboration, and has in no way been vetted by anyone apart from those who produced it.

Good! 🙂

>The question is, how often do sensational com notes like this one get circulated internally?

I don't want to say "never"; the thing is, we have not been taking data that long…and how can you have a note making truly sensational claims with Monte Carlo simulation? I will say that I have seen some worthless COM notes, documenting studies that are not well done and are clearly not going anywhere. Sometimes a student is going to graduate, or a person is going to need to search for jobs, and they need to just document their work, put an internal number on it, and it looks like they accomplished something. Funding agencies also seem to like it when you can show that you have produced many of these notes. I'm not saying that's the motivation with this incident. But I have seen several throw-away COM notes that fit that bill.

>How likely is it that the authors of this note have done something silly in the analysis? They are professional experimental physicists, and are members of Atlas, so they know what they are doing. Of course we all make mistakes, but I assume they would have checked this analysis quite thoroughly, to avoid looking silly in front of the rest of the collaboration.

Here's the thing: most of the time when an important analysis–let's use a less controversial example, like the measurement of the Z cross section–is documented by a COM note, it is not a situation like this one. These analyses are very complicated and have many pieces. There is an entire working group, of usually around 30 people, behind the note. Each aspect of the analysis is carefully studied. In the case of the Z cross section, there were probably 2-3 people working on the electron identification criteria for that analysis. They presented their results to the working group, and those were discussed. After several iterations of this the group agreed on the criteria that seems to work the best. We went through this for other parts of the analysis…QCD background determination, electron efficiency measurements, etc. When the group has a complete analysis, it is written as a COM note. This is to document and communicate the work that has been done so far. The collaboration offers comments etc., which is helpful but does not count as review. An internal review board is assigned to the note, and only after this board signs off, and all comments from the collaboration have been addressed, can the document be made public.

In this path, the original, un-approved COM note, although not an "official" result, was stringently validated due to the work of many people in the working group and is probably not far off from the final approved version. The authors of the note behind the leaked abstract did not take this path, so while it is not guaranteed that their results or their approach are wrong, but a mistake somewhere is also much more likely.

As far as wanting to avoid looking silly in front of one's colleagues…Even when you are considering people who are professionals, wanting very badly for something to be true, really BELIEVING that something is true, can cloud one's judgement. Also consider: what does Sau Lan Wu have to lose? She has a position with tenure at a nice university. She has a proven track record of success and will continue to be able to get funding for the immediate future. If she makes sensational claims to the collaboration, people will roll their eyes, scrutinize the work, but if it's wrong it doesn't really cost her anything in the end. As for the graduate student and post-docs, I don't know if they have much of a choice whether to be listed as authors or not. I guess they could refuse, but that's tricky since they certainly are the ones who did the work.

>I also wonder if/how the Atlas heirarchy are going to try to discover the source of the leak. I guess only a limited number of people would have clicked on the link to this document, and their identities may be available. (note that to access the document you need to login using your CERN login.)

I am sure that almost everyone in ATLAS has read this document. Seeing who clicked on the link would not be a viable way of finding the leak. I've heard (completely unfounded) rumors that email tracing may be done, but my understanding is that the leak happened via a comment on a blog (this one?). In this case, I guess that the only way to find out would be if the blog owner could be persuaded to give the information. Even in that case, if I were going to leak it that way (and I didn't), I would use a fake email address. So probably we're not going to find out who did it.

59. **OhDear**
April 22, 2011

Hi "Also a real scientist @ ATLAS " – thanks for your detailed reply! Very interesting to see how large collaborations like this work. Us theorists are of course only working in small groups.

Regarding finding the leak, I had in mind that the timestamps of the requests for the document might be available. The culprit would likely be one of the first few to access it. Of course, by now everyone else will have accessed it, but these will all be at later times.

60. **asymptotea**
April 22, 2011

Peter, Here is some press for you.

http://www.wired.com/wiredscience/2011/04/higgs-rumor/

61. **Emile**
April 22, 2011

The tax payer argument does not work. That public funding pays for these experiments does not entitle everyone to listen in to private conversations, read private emails exchanged by colleagues, or get
to go inside the control and start to play with buttons. You don't get access to all internal documents produced by civil servants either (think of lawyers working on behalf of governments or internal documents written by public officials). Similarly, publicly funded artists should not be required to provide you with all their private recordings or sketches or everything that's unfinished or perhaps not yet good enough.
What you pay for is for good science to be performed. This involves necessary internal discussions and studies where scientists, who are experts on different aspects of the detector, trigger, and software, come to a consensus and are willing to stand behind the result. You pay for science to get done properly and releasing results that have not been checked and approved is not good for anybody. It's bad science. Results should be released when the experimentalists are satisfied that the results are scientifically sound. I'm disappointed that internal documentation of a scientific collaboration was posted on this site.
This is tabloid science. Hyping theories gets you into print and similarly, jumping on every bump will get you some attention too. But, given the trials factor associated with these large experiments, you'll
cry wolf often enough that people will not take you seriously. All
this also leads to armchair guessing about a result. This is speculation. It's not serious science. Taxpayers deserve better value for their tax money.

62. **barry taylor**
April 22, 2011

It is difficult to keep a secret in today's World. Some of us simple folks think this is all pretty exciting given the news from the Chicago area collider a few weeks back. A large public excitement over the GOD particle might generate enough interest to get more $$$ for the science bunch. The U.S. is in desperate need of some good news. Let the rumor run, and let's all have a good time and pay up if they don't gots it yet. More $, more research. More interest, more money.

63. **Jay**
April 22, 2011

The taxpayer argument works. There exists freedom of information legislation in over 85 countries. Additionally there are open meeting laws enacted in many countries. It would be interesting to be a fly on the wall in your HEP experiment meetings. The taxpayers who sponsor these experiments have a legal right to see the process that leads up to the good science that is produced.

In astronomy, there are many instrument builders who take great pride in their work. They are especially celebrated when astronomers use the data produced by their instruments to gain profound insights into nature.

64. **Steven**
April 23, 2011

@Jay
I'm sure that one could attempt to use FOI information to get hold of all sort of internal information. However, I have a suspicion that, since the LHC experiments are CERN-based and since CERN is an international organisation in a country which offers such organisations privileged status, I'm not altogether sure such information would eventually become available.

Also, I'm at a loss to see how science would improve even if the cupboard doors were flung open and every internal document was made available. If all techniques and all numbers (eg calorimeter scale uncertainties) were available as soon as they were calculated and documented then why should a country bother to take part in the experiment and do the messy bits i.e. build and maintain the detector. All the information anyway becomes available for free. Great news for science until the science stops happening. Its also not so great news for the PhD student who is measuring, eg, jet production but who also has spend much of their time making sure their bit of the detector works while another PhD student enjoys the fruit of the first student's labour by reading all the documentation on jets and publishing first.

Also, we should at the same time be making available theorists' early numbers. That theorist who has spent a year updating his/her Monte Carlo program in collaboration with a couple of others should be prepared to give it up to others to use before they have the chance to write their own publications with it.

Particle physics has been at the forefront of efforts to make freely available research findings through an open access model. Similarly, a lot of work is going on in making sure that experiments are able to document their data and techniques such that future analyses will be possible (and open to all). One can throw a spanner in the works with FOI requests (knocking down things is easy, building them up is hard) but I'm far from convinced that this would lead to better science being performed.

65. **Ryan**
April 23, 2011

I don't see what the big deal is with leaking this?

This is similar to a conference paper! A bit of info pre-publication. If it turns out to untrue, who cares! Some more publicity for the scientists. If it's true we get a sneak peak before it's on the cover of Nature.

66. **physicsrob**
April 23, 2011

@Steven
Exactly — But I think you should take it a step further. The analogy would be that theorists should open up their notebooks and share any incomplete idea they are working on.

@Jay
The analogy with telescopes doesn't completely work. ATLAS has roughly 3000 physicists. Every single one of them is required to complete "service work" to be a member of collaboration. If completing this work was not a requirement for analyzing the data then literally half of the physicists (more, actually) wouldn't bother being members of the collaboration or doing any of the necessary work.

67. **Also a real scientist @ ATLAS**
April 23, 2011

@Ryan:

>This is similar to a conference paper!

No it is *not*. That is precisely what all the fuss is about. This paper has not gone anywhere NEAR the level of internal checks that we do before putting something out as a conference paper.

>A bit of info pre-publication.

It is not necessarily info, it is quite possibly trash. The result has not been checked by the collaboration as is necessary to ensure that the analysis was properly done. As far as publication, this is not anywhere near being pre-publication. Others have indicated they understand this, but I feel I must emphasize it again for your benefit: this is *not* an official result of the ATLAS experiment, and you should not expect to see this any time soon as a publication.

>If it turns out to untrue, who cares! Some more publicity for the scientists. If it's true we get a sneak peak before it's on the cover of Nature.

You don't care I guess, but as a member of the collaboration I do. I feel that it reflects badly on me and my colleagues that this has been leaked. A large fraction of the general public seems to believe that this is a result that has been reached and approved after our usual rigorous checks…that it's just almost a result we can all stand behind, but not quite. You very much imply that you think that's exactly the case, but it couldn't be further from the truth.

As far as the authors, they may gain publicity, but I don't think I'd want it in 3 of their cases. Wu won't suffer, I think. She's too well established. The other 3 are a grad student and 2 post-docs. It's a small field. How are their job prospects, as you say, "if this turns out to be untrue?"

68. **Ryan**
April 23, 2011

@ Also a real scientist:

Hang on – you peer review your conference papers? Get real.

Not one organization of respect is claiming this as fact. Everyone has claimed this as just what it is – a rumor. If your worried about the morons in the general public taking this the wrong way you have bigger issues to worry about. And don't flatter yourself – the vast majority of the worlds population don't understand nor care what you are doing. I care – and understand some – but I'm in a minority.

As for the phd students – again, get real. As a recent phd graduate, if they drop the name of where they did their thesis studies the whole field will open their doors to them.

For a scientist, you are awfully melodramatic.

69. **Giotis**
April 23, 2011

Real scientists, I think you are exaggerating. An internal note about the Higgs hunt was leaked. So what? This kind of research does not have any impacts on society (like a prognosis of an upcoming earthquake or the cure of a disease would have for example) so I don't see any harm done. On the contrary such results often trigger public discussions which are always good and informative for many people. Also I don't see why you should worry about the reputation of the people involved and of ATLAS collaboration. Don't you think people are smart enough to understand that this (as stressed by Peter and others) is just an unvetted internal note?

70. **Steven**
April 23, 2011

@Ryan
Yes, referees are appointed for all conference contributions and they are rigorously reviewed. This is the true for all of the major collaborations.

Neither I nor "real scientist" are being particularly melodramatic.
The fact is that the LHC was built primarily to find the Standard Model Higgs or to disprove its existence. A lot of people have spent a lot of time making sure that the

ATLAS detector works and that results are sound and definitive. Circumventing a well structured review chain to spread rumours about unchecked results on a Higgs search is annoying and unscientific.

71. **Steven**
April 23, 2011

@Giotis

Over the past few years there have been a few "discoveries", eg hints for WIMP dark matter and various new particles. Unfortunately, these discoveries have tended to vanish upon receipt of more data.

It does the field little credit to continuously have rumours washing around but no actual verified discoveries.

72. **Also a real scientist @ ATLAS**
April 23, 2011

Thanks Steven, for articulating very well exactly what I also think about this.

@Ryan: As Steven said, yes we do internally peer review our conference notes. So do CMS and CDF and D0. Furthermore, we internally review a class of internal notes as well, known as INT notes. COM notes really are the furthest thing down on the ladder of peer review, a ladder that we take very seriously…they are the ONLY class of ATLAS documents on CDS that is not reviewed. This includes the actual slides shown at conferences, which must also be signed off on.

I don't think that people outside of my field are morons. I do realize that they provide my funding via taxes. That funding is for research that I'm convinced has a noble purpose, even if there is no immediately practical application. That noble purpose is the pursuit of further knowledge, just for the sake of it, conducted in a scientific manner. Leaks like this severely undermine that, and that is especially the case if the work is not rigorous enough to stand up to scrutiny. With that said, I actually do not have more important things to worry about. If this is what the general public grows to expect of us, we are going to be out of business.

As for my "melodrama" regarding the future job searches of the post-docs and grad student, I would venture to guess that you are not a part of this field. It really is a valid concern, especially for the post-docs. It may be of interest of you to see where Sau Lan's grad students end up: http://www-wisconsin.cern.ch/~wus/achievements.html Notice the trend towards grad students staying at Wisconsin for post-doc positions, something considered unusual and not particularly desirable in this field, or going onto less prestigious positions than earlier in her career. She paints a very rosy picture to the outside world, but is not as highly thought of within HEP as her website and interviews with the press would have you believe.

@Giotis: I guess you see no harm done because it probably doesn't impact your life as much as it does mine. Quite frankly, it is just *annoying* on one level. From what I've seen on message boards and blog comments, many people don't understand that this is not on behalf of the whole collaboration. It's annoying to have my name attached to that note in any way. It's annoying that if we do really discover the Higgs later, the result will be viewed by the public with sort of a contempt…many would question the discovery even if that result would be scrutinized to the highest level possible, just because we "cried wolf" earlier. Aside from the annoyance, I do also see it as harmful for the reason I told Ryan. There is already a large sort of mistrust towards scientist, and a reluctance to give us funding. Things like this just make that worse.

73. **Non-HEP PhD**
April 23, 2011

Not even wrong is my all time favorite phrase of condescension ;). Go Peter! …. I disagree with the writer who asserts rights to early access to data. … I hope for all concerned that this is a hoax

74. **David**
April 23, 2011

3 questions come to mind:
1- who has interest in leaking this info?
2- why did the leaker prefer the Columbia Uni site?
3-what will be gained or destroyed with this leak?

No matter what the answers are, this leak shows that there are some internal problems within the Atlas collaboration.

[*personal attack deleted*]

New people, but well connected to the management, can be appointed to key positions in ATLAS even before doing any service work for the collaboration. This has certainly got many people angry, and some of them have simply left ATLAS.

All the physics leaders are appointed by the management and the collaboration has no say. Yes, powerful people with a lot of $ certainly get involved in the process, but everything is done behind the scenes. Is this right in HEP? no idea? will this model work in a collaboration with 3,000 people? I don't know….

I Think CERN has to take this leak seriously and should try to understand why people are unhappy. Perhaps the solution will be to fire this management and appoint a new management which will encourage the creativity of people instead of shooting up everybody who does not belong to the close circle of the Queen. This may explain why ATLAS is always behind CMS. I think this leak is a wake-up call for CERN and will expose all the dirty-political games going on in ATLAS. Unhappy people do unpopular things.

Now coming back to the leak, my view is that the leaker is an enemy of Dr. Wu? atlas physicists should have some names…..but as I said, this is not the real issue. The real problem is the atlas management.

75. **Peter Woit**
April 23, 2011

David,

Please do not use this blog for anonymous attacks on people, that's really problematic.

I have no idea at all who posted the abstract, have seen suggestions both that it was an ally of Dr. Wu or that it was an enemy of hers. It seems even more likely to me that it was just some random ATLAS member who thought this was exciting news that deserved wide discussion, enough so that they were willing to break ATLAS policy on this. The choice of my blog was probably just due to the fact that it has quite a few readers interested in the topic.

76. **BBBShrewHarpy**
April 23, 2011

@giottis:
In addition to the problems of credibility for science in general and ATLAS in particular referred to by the real scientist@ATLAS, this leaking has serious implications for the continued effectiveness of the collaboration. I am not part of ATLAS, but I am part of a large collaboration, with rules that aim to ensure effective work practices and equitable rewards for those who perform the work and follow the rules. There is a lot of background slogging that goes on in large experiments, and as much close work that goes into evaluating results. Not all of this work receives press, or results in presentations at conferences, but all of it is vital for the running of the experiment. The tension between those who perform the hard work without recognition and those who receive the flashy rewards exists even when the rules are followed, but when the system breaks down, all the grievances and frustrations can cause severe problems for the working of the collaboration. Much of this is a matter of personalities and human nature, and conflict is inevitable, though we would all love to believe that our love for science is pure and our expectation of worldly rewards nonexistent. This facade can hold only if those of us who are mostly drudges and worker bees are not pushed beyond a certain limit by the queen bee and her attendants. In my view the rights of the people who are attempting to live within the strictures of the collaboration trump the vicarious thrill the rest of us are experiencing from the breakdown of the system.

77. **scientistOnCMS**
April 23, 2011

I'm a collaborator on CMS. I can tell you that notes that are unreviewed by the collaboration never see the light of day, and for good reason, on every major HEP collaboration. Thousands of scientists have reputations that rely on the results that come out of the experiment. So there's a peer review process for even single plots to be shown at APS section meetings. Nothing particularly prestigious about those meetings, but the results must be approved nonetheless.

As for people claiming rights to the data because they paid taxes? Give me a break. First, CERN is an international collaboration, and the bulk of funding comes from European countries. But even ignoring that, I could give you the raw data, and you wouldnt' be able to do a thing with it. You certainly don't have rights to our software. And even if you did, what would you do with it? Do you understand the physics you'd be looking for? If not, it's useless to you. Regardless, keeping the data confidential (even from scientists on rival experiments) is a very good idea from a science point of view. It keeps everybody honest. If one experiment finds something, the other can then look in their own dataset to find a confirmation of the effect. Independent collaborations are a good thing.

78. **physicsrob**
April 23, 2011

@scientistOnCMS
Very well put. I think many non-experimentalist underestimate just how much effort goes into taking the raw data and generating for example a diphoton mass plot.

79. **sciing**
April 23, 2011

What are you talking about? There are some rumors about the a discovery. Nice to know. No one takes it as real. But its nice for all the fans of HEP. And no one else is really interessted.
I have more concerns about the way CDF is working right now.
I think a note like this is not destroying the reputation of the particle scientiest but all the stuff that comes out right now from CDF (per reviewed from the whole collaboration). I get they feeling they make 1000 analysis and claim everything a hit thats probability to be nothing is less than a thousands. Is this science? CDF does not only claiming the results but also begins to speculate about new forces and so on. What is the motivation? At the end of the year LHC will get enough data to answer al this question. So why they can't wait?
On the other hand is it science if the carrier of young graduate is detroyed just for starting a disscussion of a new "result", observation?
That these note is leaked is a problem of ATLAS not the graduates.

80. **Peter Chase**
April 23, 2011

Much uncertainty. Can we say ATLAS shrugged?

(Gad, that was cheap.)

81. **Berger**
April 23, 2011

@ "David" :

> No matter what the answers are, this leak shows that there are some internal problems within the Atlas collaboration.

> All the physics leaders are appointed by the management and the collaboration has no say.

This statement is factually wrong. "Physics Leaders" (by which I assume you mean physics group conveners) are elected by the collaboration.

The rest of the post probably qualifies as "Not even wrong".

82. **NoNaMe**
April 24, 2011

To Paul Wells, who wrote
"I paid for this work so I think I should have free access to- 1. All Raw Data
2. Programs required to interpret raw data.
3. Project documentation to interpret 1. and 2.
4. Final publications WITHOUT having to pay for journal."
Wow. I guess with the amount of money *you* paid, you should be given access to a couple of events, five lines of code and a commemorative ball-pen.

83. **Georges**
April 24, 2011

@David: well written.

@Berger:

Your statement about physics conveners is wrong and David is right. The collaboration has no say. There is a call for nomination by the collaboration. The management makes the selection. There is no shortlist that is communicated to the collaboration, there is no discussion within the collaboration and the voices of the collaboration have always been ignored. People without (or not enough) service work and/or inactive people became physics leaders from nowhere. However they are good servant of the

Queen!

84. **woit**
April 24, 2011

I’m shutting off comments for now. The fraction of informed comments relevant to the posting has gone to almost zero, and dealing with the large number of other ones is wasting too much of my time.

Short Items

April 27, 2011
Categories: Experimental HEP News, Multiverse Mania

- Progress on increasing luminosity at the LHC has been going extremely well, with peak luminosity a few moments ago over $7\times10^{32}cm^{-2}s^{-1}$. So far integrated luminosity is over 200 pb^{-1}, well on the way to the extremely conservative nominal goal for the year of 1000 pb^{-1}. By fall, with the shutdown of the Tevatron at the end of FY 2011, the LHC experiments should be in a position to start overtaking the Tevatron and seeing evidence of a standard model Higgs if it is there.
- It's still very early to know how Fermilab will do in the US FY2012 budget, other than that the Tevatron will definitely not be there. However, the Obama administration is supportive in its budget proposal, and this document from the Republicans running the relevant House committee is encouraging for HEP research. Democrats and Republicans seem to agree that science research is a good thing in general, and HEP research is not one of the categories that annoys Republicans and that they suggest cutting (applied research that could be done by private companies, climate science research, environmental research, ITER). One member of the committee is freshman Republican Randy Hultgren, who represents the district that includes Fermilab, and he added his own addendum to the report, emphasizing support for HEP research. Hopefully the Republicans will want to help re-elect him by getting him anything he asks for…

With the bizarre US budgeting process of recent years though, whatever the appropriate Congressional Committee decides may turn out to be irrelevant, with last minute budget cuts appearing from mysterious sources to get things under whatever numbers end up being agreed to.

- The New Yorker has a profile this week of David Deutsch. I still can't figure out what his argument is that if a quantum computer works, that means there are multiple universes.
- Lots of people are asking me what I think of 't Hooft's new paper. The answer so far is just that I don't understand it. He's doing something unusual with how he handles conformal symmetry, and I think one needs an expert on that to weigh in.
- Mathoverflow continues to amaze me, providing the sort of high-quality discussion that the internet was always supposed to provide, but rarely did. For example, see this recent question, which asks about the relationship between two different ways of encoding the geometry of a manifold. One way to do this is to choose a metric, the other is to choose a connection on the frame bundle. For arbitrary bundles, there's an infinity of possible connections and they have nothing to do with the metric, but the frame bundle carries extra structure (the vierbeins, in physicist's language). Given a metric, this extra structure can be used to pick out a unique connection (called the Levi-Civita connection), which satisfies two conditions: orthogonality and zero torsion. The question asked is about whether one can go the other way: given a connection, is there a unique metric for which it is the Levi-Civita connection?

The answers given include one by Fields Medalist Bill Thurston, whose comments reflects his background as a topologist, another is by MSRI director Robert Bryant, whose answer is that of a geometer, one who has delved deeply into the subject, including its roots in the work of Elié Cartan. The fact of the matter is that the relationship between these two structures is not one-to-one, for reasons that are well explained. This may be of interest to physicists thinking about the quantization of gravity. In that subject, one basic question is that of which fundamental variable to pick to "quantize", and the conventional choice is the metric, even though in non-gravitational physics, the conventional choice is the connection. Philosophically though, the gauge symmetry involved in gravity is something like local translation symmetry, and the right analogy of a Yang-Mills connection might be not a connection on the frame bundle, but something like the vierbein, but that's a whole other story….

Comments

1. **Deane**
   April 27, 2011

   I'd like to echo how amazing and wonderful it is to see answers by Bill Thurston and Robert Bryant to a question on MathOverflow, not only because each one is a world class mathematician but because each brings a completely different perspective to the same question. It allows the rest of us, especially students, to see how differently the same question can be approached by different mathematicians.

2. **anon**
   April 27, 2011

   Support the new site: http://physics.stackexchange.com/
   The community has quite a few experts on hep, including a persistent criticizer of this blog.

3. **das higgs**
   April 27, 2011

   The author thanks ….R. Bousso, …P. Mannheim, … for discussions.
   huh.

   I can tell you it's going to be a controversial and not seriously taken paper without even reading it

4. **also anon**
   April 28, 2011

   @anon: so math has Fields medalists and phys has Lubos.
   Kind of sums up the sorry state of physics if you ask me.

5. **Octoploid**
   April 28, 2011

   Regarding 't Hooft's new paper:
   I always thought that this (local conformal symmetry)
   is the only direction in which further progress could be
   made on the theory side. (The whole mass/higgs and
   hierarchy problems are closely related to this)
   It's nice that he's working on that topic.

6. **Tim van Beek**
   April 28, 2011

   The physics stackexchange site allows homework level questions, too, and should rather be compared to the math stackexchange site than to math overflow. The success of math overflow can be attributed to the strict moderation, allowing high quality questions only – and of course the existence of a consensus about the meaning of "high quality" in the global math community in the first place. Is there a similar consensus in the physics community or even in the hep-th community? I don't thinkt so…

7. **John Baez**
   April 28, 2011

   If you support a certain glamorously worded version of the many-worlds interpretation of quantum mechanics, the ability for a quantum computer to put itself in a superposition of a bunch of states, do interesting things in each of those states, and then 'recombine' and cough up the answer to a problem would be evidence for 'many universes'. But so would various simpler applications of the superposition principle. I don't think it's really that big a deal. It's just a way of talking.

   If you don't like this way of talking, you can just translate it into an interpretation that you like better – if you do it right, you'll never disagree on any observed phenomena. That means you can argue endlessly about which way of talking is 'right' and never reach a conclusion. But it also means you don't have to.

8. **Moshe**
   April 28, 2011

   For various reasons the physics stack exchange site is not likely to ever have the same quality as Mathoverflow (I don't think it's the level of questions, but the quality of the answers which is the issue, but that's for another place). There is a proposal to have higher quality physics site devoted mainly to research questions here:

   http://area51.stackexchange.com/proposals/23848/theoretical-physics

   Once it has enough supporters we'll see exactly what is needed to have high quality discussion, but I understand the intention is to aggressively pursue something like the MO model. I suspect it won't be easy…

9. **Mike**
   April 28, 2011

   In a short interview Deutsch was once ask:

   "How does quantum computation shed light on the existence of many worlds?"

   He responded as follows:

   "Say we decide to factorise a 10,000-digit integer, the product of two very large primes. That number cannot be expressed as a product of factors by any conceivable classical computer. Even if you took all the matter in the observable universe and turned it into a computer and then ran that computer for the age of the universe, it wouldn't come close to scratching the surface of factorising that number. But a quantum computer could factorise that easily in seconds or minutes. How can that happen?

   Anyone who isn't a solipsist has to say the answer was produced by some physical process. We know there isn't enough computing power in this universe to obtain the answer, so something more is going on than what we can directly see. At that point, logically, we have already accepted the many-worlds structure. The way the quantum computer works is: the universe differentiates itself into multiple universes and each one performs a different sub-computation. The number of sub-computations is vastly more than the number of atoms in the visible universe. Then they pool their results to get the answer. Anyone who denies the existence of parallel universes has to explain how the factorisation process works."

   This was a simple response to a complicated question in the popular press. Of course, he goes into greater detail in his work, and especially in his two books.

   That may not satisfy you — but it gives a pretty good outline of how his argument runs.

10. **dan**
    April 28, 2011

    "Anyone who isn't a solipsist has to say the answer was produced by some physical process. " You know, like, maybe, the schrodinger equation in the observable universe?

    Not including quantum mechanics in your definition of "computing power" seems a little restrictive. Is there a precise definition/reason for sticking to classical physics?

11. **Peter Woit**
    April 28, 2011

    Mike,

    I did read that argument in the article, and it made no sense to me, still doesn't. All it seems to give is that there is more to the universe than classical physics, not that there are other universes.

12. **Moshe**
    April 28, 2011

    While I am here, seems to me the basic flaw in Deutsch argument is that it suggests a speedup in quantum computing far beyond what is actually attained. It is also strange that the argument does not need or make reference to decoherence, which is a necessary ingredient in any "many-world" view.

13. **Klil Neori**
    April 28, 2011

    @Mike:
    Deutsch's argument is fallacious. They key term is "classical computer." There do, in fact, exist physical processes working within this universe that can accomplish what he is stating: they are part of quantum mechanics. Unless you believe quantum mechanics requires multiple universes, this isn't a proof. It is circular reasoning.

    Moreover, he is forgetting that prime factorization has not been proven to be above polynomial – it is just that the asymptotically most efficient algorithm known is not polynomial. He would best stick to a fact that is well known, that simulation of a quantum system by a classical computer is, in fact, exponential in the number of quantum states.

    As for the article: from the abstract (I don't have access to the paper itself), I object to a few claims made in the New Yorker article itself. For example, "With one millionth of the hardware of an ordinary laptop, a quantum computer could store as many bits of information as there are particles in the universe." That requires a very odd definition of storage. Storage usually implies retrieval. You cannot retrieve more than N classical bits out of an N-qubit system. Or "Tells how Deutsch came to propose a universal computer based on quantum physics, which would have calculating powers that Turing's computer (even in theory) could not simulate." This is kind of sloppy, since in theory a Turing machine could in fact simulate any quantum system – it may just take more than the age of the universe/more than the matter available in the universe to do so.

Of course, these could be just mistakes by the writer rather than by Deutsch himself.

14. **Mike**
April 28, 2011

Peter,

I know you've seen at least part of the following as well. I think it's informative, but of course, if you wish to delete it I understand and am not interested in cluttering up your blog.

Dan,

The the Schrodinger equation, as applied to a quantum computer, certainly "predicts" the right results, yes — but it doesn't "explain" how they arise.

Deutsch has addressed this distinction by analogy to Einstein's general theory of relativity:

"Our best theory of planetary motions is Einstein's general theory of relativity, which, in the early twentieth century, superseded Newton's theories of gravity and motion. It correctly predicts, in principle, not only all planetary motions but also all other effects of gravity to the limits of accuracy of our best measurements. For a theory to predict something "in principle" means that as a matter of logic the predictions follow from the theory, even if in practice the amount of computation that would be needed to generate some of the predictions is too large to be technologically feasible, or even too large to be physically possible in the universe as we find it.

Being able to predict things, or to describe them, however accurately, is not at all the same thing as understanding them. Predictions and descriptions in physics are often expressed as mathematical formulae. Suppose that I memorise the formula from which I could, if I had the time and inclination, calculate any planetary position that has been recorded in the astronomical archives. What exactly have I gained, compared with memorising those archives directly? The formula is easier to remember – but then, looking a number up in the archives may be even easier than calculating it from the formula. The real advantage of the formula is that it can be used in an infinity of cases beyond the archived data, for instance to predict the results of future observations. It may also state the historical positions of the planets more accurately, because the archives contain observational errors. Yet, even though the formula summarises infinitely more facts than the archives do, it expresses no more understanding of the motions of the planets. Facts cannot be understood just by being summarised in a formula, any more than by being listed on paper or memorised in a brain. They can be understood only by being explained. Fortunately, our best theories contain deep explanations as well as accurate predictions. For example, the general theory of relativity explains gravity in terms of a new, four-dimensional geometry of curved space and time. It explains how, precisely and in complete generality, this geometry affects and is affected by matter. That explanation is the entire content of the theory. Predictions about planetary motions are merely some of the consequences that we can deduce from the explanation.

Moreover, what makes the general theory of relativity so important is not that it can predict planetary motions a shade more accurately than Newton's theory can. It is that it reveals and explains previously unsuspected aspects of reality, such as the curvature of space and time. This is typical of scientific explanation. Scientific theories explain the objects and phenomena of our experience in terms of an underlying reality which we do not experience directly. But the ability of a theory to explain what we experience is not its most valuable attribute. Its most valuable attribute is that it explains the fabric of reality itself. As we shall see, one of the most valuable, significant and also useful attributes of human thought generally, is its ability to reveal and explain the fabric of reality.

Yet some philosophers, and even some scientists, disparage the role of explanation in science. To them, the basic purpose of a scientific theory is not to explain anything, but to predict the outcomes of experiments: its entire content lies in its predictive formulae. They consider any consistent explanation that a theory may give for its predictions to be as good as any other, or as good as no explanation at all, so long as the predictions are true. This view is called instrumentalism (because it says that a theory is no more than an "instrument" for making predictions). To instrumentalists, the idea that science can enable us to understand the underlying reality that accounts for our observations, is a fallacy and a conceit. They do not see how anything that a scientific theory may say beyond predicting the outcomes of experiments can be more than empty words. Explanations, in particular, they regard as mere psychological props: a sort of fiction which we incorporate in theories to make them more memorable and entertaining. The Nobel prize-winning physicist Steven Weinberg was in an instrumentalist mood when he made the following extraordinary comment about Einstein's explanation of gravity:

"The important thing is to be able to make predictions about images on the astronomers' photographic plates, frequencies of spectral lines, and so on, and it simply doesn't matter whether we ascribe these predictions to the physical effects of gravitational fields on the motion of planets and photons [as in pre-Einsteinian physics] or to a curvature of space and time."

Weinberg and the other instrumentalists are mistaken. It does matter what we ascribe the images on astronomers' photographic plates to. And it matters not only to theoretical physicists like myself, whose very motivation for formulating and studying theories is the desire to understand the world better. (I am sure that this is Weinberg's motivation too: he is not really driven by an urge to predict images and spectra!) For even in purely practical applications, the explanatory power of a theory is paramount, and its predictive power only supplementary. If this seems surprising, imagine that an extraterrestrial scientist has visited the Earth and given us an ultra-high-technology "oracle" which can predict the outcome of any possible experiment but provides no explanations. According to the instrumentalists, once we had that oracle we should have no further use for scientific theories, except as a means of entertaining ourselves. But is that true? How would the oracle be used in practice? In some sense it would contain the knowledge necessary to build, say, an interstellar spaceship. But how exactly would that help us to build one? Or to build another oracle of the same kind? Or even a better mousetrap? The oracle only predicts the outcomes of experiments. Therefore, in order to use it at all, we must first know what experiments to ask it about. If we gave it the design of a spaceship, and the details of a proposed test flight, it could tell us how the spaceship would perform on such a flight. But it could not design the spaceship for us in the first place. And if it predicted that the spaceship we had designed would explode on takeoff, it could not tell us how to prevent such an explosion. That would still be for us to work out. And before we could work it out, before we could even begin to improve the design in any way, we should have to understand, among other things, how the spaceship was supposed to work. Only then could we have any chance of discovering what might cause an explosion on takeoff. Prediction – even perfect, universal prediction – is simply no substitute for explanation."

April 28, 2011

Mike,

I don't buy that either. Quantum mechanics "explains" what is going on perfectly well in this case, it's a compelling model of physics, far more powerful and successful than the classical model. Insisting that anything that counts as an explanation must retain features of the classical model seems unreasonable. To me, multiple universes actually "explain" nothing in this case. They provide a way to look at things that some people might find attractive, but as far as I can tell they just introduce a lot of extraneous structure that raises more questions than it solves.

16. **Mike**
April 28, 2011

Peter,

I understand your view — I guess we just disagree on what consitutes a good “explanation”. Thanks for the chance to discuss.

17. **Klil Neori**
April 28, 2011

I think there is a false dichotomy here: it’s not “instrumentalists” vs. “many worlds interpreters”. It’s “many worlds interpreters” vs. people who do not find it compelling for whatever reason. It is disingenuous to present “many worlds” as the only viable interpretation or world-view.

18. **Mike**
April 28, 2011

“It is disingenuous to present “many worlds” as the only viable interpretation or world-view.”

No it isn’t. It might ultimately be wrong. But it’s certainly not disingenuous to compare the philosophical basis of the MWI to instrumentalism (only predictions are important) or solipsism (the calculations just happen in an abstract “black box” unrelated to any explanation of the actual physical entities and processes taking place).

I promise Peter — that will be my last comment on this point 🙂 Thanks again for allowing it to continue, probably much longer than you would like.

19. **Klil Neori**
April 28, 2011

You concede that it might ultimately be wrong, yet you persist in denying that there are other interpretations that do not fall into instrumentalism or solipsism: consistent histories, pilot wave, stochastic mechanics, objective collapse, etc. All have their faults (the latter actually makes predictions that have been falsified), but they are not all less viable than many worlds, nor are they all less established than many worlds in the foundations of physics community, and it is therefore disingenuous of you (as it is for Deutsch) to present many worlds as the only world view.

20. **Physicsphile**
April 28, 2011

I realize Peter does not want the comment section to turn into a debate on the interpretation of QM. But I can’t resist mentioning my own take on this. The many worlds interpretation seems to me to be to be the most direct way of interpreting the mathematical formalism of QM. As far as I understand it is just saying the ultimate reality is a wave function on configuration space. It is not adding anything new to the QM formalism it is just saying what it is. While pilot wave, stochastic mechanics, etc seems to me to be adding new physics which is not motivated by experiment.

21. **Peter Woit**
April 28, 2011

Physicsphile (and others),

Yes, unless it’s interesting and about David Deutsch, please don’t continue here with the usual sort of discussion of QM interpretational issues. Personally I find this kind of discussion just depressing, tedious and unenlightening. There are interesting issues here, but people seem devoted instead to over-simplified sloganeering. Enough.

22. **outside_math**
April 29, 2011

Moshe,

From my perspective as an outsider to both fields, there is a very large cultural difference between math and theoretical physics. Several Field’s medalists not only contribute to mathoverflow but blog about technical mathematics as well. There is nothing comparable in the physics world, heck you can’t even get physicists to comment with their real names on blogs! My guess is that a physicsoverflow site will not work until physicists at the very top level of research are willing to actively participate. It’s a shame, because I think that such a site would be very useful.

23. **also anon**
April 29, 2011

@outside_math I am pretty sure MathOverflow would not have worked well during the Grundlagenstreit with Hilbert and Brouwer going after each other.

And PhysOverflow will not work well as long as the community disagrees if string theory is physics or wishful thinking.
As long as you have Lubos and others behave the way they do, any sane person will either stay away from such websites or not post with their good name.

24. **Yatima**
April 29, 2011

If anyone of the quantum-computing-interested gentlemen or ladies is at CMU on April 29th at 1630 EDT (I won’t):

http://www.cmu.edu/mcs/news/pressreleases/2011/4_25_Buhl2011.html

MIT’s Scott Aaronson to Present 2011 Buhl Lecture – “Quantum Computing and the Limits of the Efficiently Computable”.

Should be interesting.

25. **Scott Aaronson**
April 29, 2011

Yatima: Thanks for the publicity! 🙂

I’ve been working on my own blog post about the New Yorker piece, but briefly: I agree with Peter that quantum computing has no *direct* implication for the Many-Worlds debate. (Ironically, Deutsch also agrees: he thinks that Many-Worlds is already an experimentally-established fact, regardless of whether quantum computers are built.)

Assuming the plausible conjecture that quantum computers can’t be efficiently simulated by classical ones (i.e., P≠BQP), a scalable quantum computer would show that Nature has “computing resources” that exponentially exceed anything described by classical physics in certain respects. But there’s then the further question of whether you want to describe those computing resources in terms of “parallel universes.”

(Incidentally, it's not just factoring that's not known to be hard for classical computers, but also simulating quantum mechanics in general.)

26. **Dave Miller**
    May 1, 2011

    Peter,

    I used to be on an e-mail list of David Deutsch's followers, to which the Big Man occasionally contributed himself. Most of his followers are, of course, non-physicists, and they did not much appreciate questions being raised about whether or not his views on physics can be justified.

    I eventually got bored, but it was sociologically interesting to see a physicist who had real, live, and *very* intense followers!

    I've also followed David's work on MWI for many years. At one point in his career he explicitly recognized some of the technical problems with MWI: e.g., the "preferred-basis" problem and the "probability-measure" problem. He eventually decided that these were not problems, after all, though I was never able to understand his published reasons as to why he changed his mind.

    Deutsch has written widely on politics, child-rearing (!), and, of course, various areas of science, and often has interesting, insightful comments on many of those subjects. However, I found myself a bit turned off by the constant implication that David had found the final answer to every question, answers that should not be questioned.

    Anyway, if the "String Wars" ever end, and you find yourself drawn to further explorations in the side-lanes and by-ways of the sociology of physics, you will find much to explore in the Deutsch phenomena.

    Dave Miller in Sacramento

27. **rrtucci**
    May 1, 2011

    Does "The New Yorker" magazine make you dumber?

    Yes. The article rhapsodic about Deutsch's views proves it.

28. **McNicholl**
    May 1, 2011

    (1) The multiverse implications of the capabilities of a quantum computer makes no sense…since the latter relies on (essentially) nothing that Bohr did not know, and (2) (the short subject that you all ignore) it is navel-looking (if not hypocritical) to hope for a Fermi-lab district congressman to save HEP funding. Where is Aristophanes when we need him?

29. **vorpal**
    May 2, 2011

    Thanks for the link to the discussion on connection coefficients. I really do wonder what the "right" quantity to quantize is.

This Week's Hype

April 28, 2011
Categories: This Week's Hype

This week's hype comes from an unusual source, John Baez and his ex-student John Huerta, who have a new article in Scientific American entitled [The Strangest Numbers in String Theory](#).

The expository article about octonions by John (Baez) that appeared in the AMS Bulletin (copy [here](#), a web-site [here](#)) is one of the best pieces of mathematical exposition that I have ever seen. The octonions can be thought of as a system of numbers generalizing the quaternions. As with the quaternions, multiplication does not commute, and things are even worse, it's not associative either. So, probably best not to try and think of these as "numbers", but they do give a very remarkable exotic algebraic structure, one that explains all sorts of other exotic structures occurring in different areas of mathematics. The article beautifully explains a lot of the intricate story of how octonions connect up surprising phenomena in algebra, geometry, group theory and topology.

If you're a mathematical physics mystic like myself, you're susceptible to the belief that anything this mathematically deep, showing up in seemingly unrelated places, must somehow have something to do with physics. The story of octonions is closely related to the story of Clifford algebras, which are definitely a crucial part of physics, but it seems to me we're still a long ways from truly understanding the role in physics of Clifford algebras, much less the more esoteric octonions. One thing that is fairly well understood is that the sequence of division algebras explains some of the structure of low-dimensional spin groups in Minkowski signature, through the isomorphisms:
SL(2,**R**)=Spin(2,1)
SL(2,**C**)=Spin(3,1)
SL(2,**H**)=Spin(5,1)
The octonion story is supposed to be the next in line, involving Spin(9,1), but made much trickier by the fact that SL(2,**O**) doesn't really exist, since the octonions are non-associative.

Back in 1982, a very nice paper by Kugo and Townsend, [Supersymmetry and the Division Algebras](#), explained some of this, ending up with some comments on the relation of octonions to d=10 super Yang-Mills and d=11 super-gravity. Baez and Huerta in 2009 wrote the very clear [Division Algebras and Supersymmetry I](#), which explains how the existence of supersymmetry relies on algebraic identities that follow from the existence of the division algebras. Kugo-Townsend don't mention string theory at all, and Baez-Huerta refers to superstrings just in passing, only really discussing supersymmetric QFT. There's also [Division Algebras and Supersymmetry II](#) by Baez and Huerta from last year, with intriguing speculation about Lie n-algebras and what these might have to do with relations between octonions and 10 and 11 dimensional supergravity. For a nice expository paper about this stuff, see their [An Invitation to Higher Gauge Theory](#).

In contrast to the tenuous or highly-speculative connections to string theory that appear in these sources, the Scientific American article engages in the all-too-familiar hype pattern. The headline argument is that octonions are important and interesting because they're "The Strangest Numbers in String Theory", even though they play only a minor role in the subject. It wouldn't surprise me at all if octonions someday do end up playing an important role in a unified theory, but the rather obscure connection to the calculation of the critical dimension of the superstring that seems to be the main point of the Scientific American article isn't a very convincing argument for such a role.

Somehow I suspect that those string theorists who were upset by Scientific American's decision to publish speculation by Garrett Lisi about E8 and [wrote in to complain](#), won't be similarly upset to find this highly speculative material about the octonions appearing in the magazine.

Comments

1. **Eric Weinstein**
   April 28, 2011

   Hi Peter,

   I don't think it is sporting to say that octonions have played only a minor role in string theory. Any area where maximal supersymmetry, large exceptional Lie-Groups (F_4 and E_6-8), triality, G_2, Exceptional Jordan algebra or a host of other constructs have cropped up is, in essence, an octonionic branch of mathematical or physical theory. Even Bott periodicity uses the octonions (in disguise) to cycle through the other three division algebras.

   While hardly a supporter of the string triumphalist movement, I think that string theorists have been at their best in calling the attention of the mathematics and traditional physics communities to the possibility of integrating octonionic mathematics with core geometric and physical theory.

   Octonionic mathematics used to be on the 'down low' but has now made the leap out of the closet and into mainstream research.

   So: Two cheers for string theory!

   Join me, won't you?

   Eric

2. **Peter Woit**
   April 28, 2011

   Hi Eric,

   It's kind of like with E8: I've got mixed feelings about all these exotic structures, feeling I can't be sure what's a beautiful, fundamental structure, and what's a complex piece of mathematical junk that managed to just barely hold on to some interesting structure for kind of random reasons. The string theorists also did a great publicity job for E8, although they seem to have lost interest in it.

   At least with Garrett's SciAm article on E8, you didn't have to put up with a sales job implying string theory was the reason to take an interest in the subject.

   I really did love John's expository article on Octonions. It lays out beautifully the attractive part of the mathematics and how it hangs together. If that could be connected to physics, I'd be interested, but the only connection advertised in the SciAm piece is the rather obscure one about getting the supersymmetry algebra to work out a certain way in a certain dimension. It's not even clear to me that this is what explains why 10 is the critical dimension, which is the claim repeatedly hammered home in the article.

3. **King Ray**
   April 28, 2011

Corinne Manogue, Tevian Dray, and others wrote some very illuminating papers where they spell out the properties of octonions and postulate about their applications to physics:

http://arxiv.org/find/all/1/all:+AND+manogue+octonion/0/1/0/all/0/1

The one below by Manogue and Schray was especially enlightening. They even define structure matrices for the octonions in Appendix A:

http://arxiv.org/abs/hep-th/9302044

4. **Thomas Larsson**
April 28, 2011

I never understood the big deal with octonions. Sure, it is the last division algebra, but if you relax your axioms a little the Cayley-Dickson construction gives an infinite tower of increasingly uninteresting algebras:
n=1: Reals.
n=2: Complex numbers.
n=4: Quaternions, not commutative.
n=8: Octonions, not associative.
n=16: Sedenions, not alternative but power associative.
n=32: 32-ions?
…
I can see why you need to give up commutativity – things can be done in different order – but why is the division algebra property important? There might be a reason that octonions have not made it into physics in 150 years.

5. **John Baez**
April 28, 2011

Peter wrote:

> The octonion story is supposed to be the next in line, involving Spin(9,1), but made much trickier by the fact that SL(2,O) doesn't really exist, since the octonions are non-associative.

PSL(2,O) does exist: you just have to be careful about it. The octonions aren't associative, but the subalgebra generated by any two octonions is. So, you just need to avoid recklessly multiplying lots of numbers when you don't really need to.

You can define the octonionic projective line and the group PSL(2,O) acting on it. You can even go ahead and define the octonionic projective plane and PSL(3,O), which turns out to be a certain real form of E6. But then the show stops: to define PSL(4,O) we'd really need the associative law. It's fun to see how one "hits the wall" here.

This is explained in my octonions paper, though I could make it all much clearer now.

> but the only connection advertised in the SciAm piece is the rather obscure one about getting the supersymmetry algebra to work out a certain way in a certain dimension.

It's not at all "obscure" — within the narrow confines of string theory at least — that classical superstring Lagrangians rely for their supersymmetry on a magical identity that holds only in spacetimes of dimensions 3, 4, 6 and 10. It's explained in Green, Schwarz and Witten's textbook, for example.

And it's been known for quite some time that these special dimensions are 2 more than the dimensions of the reals, complexes, quaternions and octonions. And in fact this is no coincidence: the existence of these number systems is the simplest explanation of what's going on here.

So, don't try to make it sound like an obscure yawn-inducing technicality about "some supersymmetry algebra working out a certain way in a certain dimension". It's a shocking and bizarre fact, which hits you in the face as soon as you start trying to learn about superstrings. It's a fact that I'd been curious about for years. So when John Huerta finally made it really clear, it seemed worth explaining — in detail in some math papers, and in a popularized way in *Scientific American*.

But of course, none of this has anything to do with whether superstring theory is *right* as a theory of physics. The article says quite clearly that superstring theory makes no testable predictions:

> At this point we should emphasize that string theory and M-theory have as of yet made no experimentally testable predictions. They are beautiful dreams — but so far only dreams. The universe we live in does not look 10- or 11-dimensional, and we have not seen any symmetry between matter and force particles. David Gross, one of the world's leading experts on string theory, currently puts the odds of seeing some evidence for supersymmetry at CERN's Large Hadron Collider at 50 percent. Skeptics say they are much less. Only time will tell.

I thought you'd quote that part. Oh well.

By way, I just won a case of scotch from Dave Ring: I'd bet him that the LHC wouldn't discover "strong evidence for supersymmetry" in its first year of operation.

> It's not even clear to me that this is what explains why 10 is the critical dimension, which is the claim repeatedly hammered home in the article.

I don't think the octonions explain why 10 dimensions is the critical dimension – at least, not now. It would be cool if they did. But so far, all I know is that classical superstrings favor dimensions 3, 4, 6 and 10, thanks to the four normed division algebras. Other considerations pick out the 10-dimensional case, which happens to be the octonionic one.

It's a bit odd to say we "repeatedly hammer home" something about the critical dimension – that was certainly not our intention, and we never even use the phrase "critical dimension". But maybe I can guess how you'd get that impression. It's probably worth comparing what John Huerta and I originally wrote, to what came out in the final version.

We originally wrote:

> For strings, when the number of extra directions is 1, 2, 4, or 8, we get supersymmetry. Why? Because then its vibrations can be described using numbers in a division algebra. But the total number of dimensions of space and time is 2 more than the number of extra dimensions. So, we get supersymmetry when the total number of dimensions is 3, 4, 6, or 10. One of these dimensions is time; the rest are space.
>
> Curiously, when we fully take quantum mechanics into account, it appears that only the 10-dimensional theory is consistent. This is the theory that uses octonions. So, if string theory is right, the octonions are not a useless curiosity: on the contrary, they play a fundamental role in understanding spacetime, matter, and the forces of nature!

Here it's pretty clear, I hope, that quantum considerations pick out the 10-dimensional theory—not some special fact about octonions. The "curiously" makes it clear that we don't understand the connection to the octonions.

The final version says:

> At any moment in time a string is a one-dimensional thing, like a curve or line. But this string traces out a two-dimensional surface as time passes. This evolution changes the dimensions in which supersymmetry naturally arises, by adding two — one for the string and one for time. Instead of supersymmetry in dimension one, two, four or eight, we get supersymmetry in dimension three, four, six or 10.
>
> Coincidentally string theorists have for years been saying that only 10-dimensional versions of the theory are self-consistent. The rest suffer from glitches called anomalies, where computing the same thing in two different ways gives different answers. In anything other than 10 dimensions, string theory breaks down. But 10-dimensional string theory is, as we have just seen, the version of the theory that uses octonions. So if string theory is right, the octonions are not a useless curiosity: on the contrary, they provide the deep reason why the universe must have 10 dimensions: in 10 dimensions, matter and force particles are embodied in the same type of numbers—the octonions.

This "provide the deep reason why the universe must have 10 dimensions" makes it sound as if some special fact about octonions explains why the universe has 10 dimensions. So yeah, that's bad. But if you read the beginning of the paragraph you'll see that's *not* what's going on: it's quantum considerations that pick out the number 10. And the "coincidentally" makes it clear that we don't understand the connection.

If you saw how much editing and counter-editing were involved in, perhaps you'll forgive us for letting that phrase slip past. I also don't like the title, but I couldn't think of a better one. I had to admit that our original proposed title, "The Octonions", would to most readers be about as appealing as "The Metaphraxis" or "The Sexadent".

Of course, it would be cool if we could find a link between the calculation that singles out the number 10 and the fact that the normed division algebras give an identity that lets you write down supersymmetric string theory Lagrangians in dimensions 3, 4, 6 and 10. It's hard to find real "coincidence" of this magnitude in math. So, I suspect it's just a matter of time before someone finds a deeper link. I've made some nice progress on this but not enough to talk about.

By the way, I have permission to put the Sci Am article on my website about a month after it comes out, and I'll also put up the various drafts, just for the amusement of people who wonder how this sort of editing process works.

6. **John Baez**
   April 29, 2011

   Thomas wrote:

   > … but why is the division algebra property important?

   The division algebra property is not important. What's important are two things.

   First, you get a *normed* division algebra in dimension n if and only if you can find an n-dimensional spinor representation of Spin(n). This starts the interplay between spinors and vectors, which provides the special features of Lorentzian geometry in dimension n+2: namely, dimensions 3, 4, 6 and 10.

   Second, a normed division algebra is *alternative*. The alternative law gives the spinor identity that makes supersymmetry work for super-Yang-Mills theory and classical superstrings in dimensions 3, 4, 6 and 10. It also gives the Jacobi identity for the exceptional Lie algebras F4, E6, E7 and E8 — which *contain* the Lorentz Lie algebras for dimensions 3, 4, 6 and 10. It also gives a 3-cocycle on the superPoincare groups in these special dimensions, which let John Huerta build 'categorified' Lie supergroups relevant to describing superstring theory as a higher gauge theory.

   So, a lot of math interacts in a marvelous way when you have a normed division algebra.

   None of this stuff works anymore when we move further up the Cayley-Dickson tower. I bet something interesting *does* work, and I'd love to know what it is, but I don't know and nobody seems to be working on it.

   Needless to say, I'm not talking about whether any of this stuff is useful for physics. I'm talking about math.

7. **John Baez**
   April 29, 2011

   By the way, John Huerta is not my "ex-student". His thesis defense is Wednesday May 18th and he should be working on his thesis *right now* — not wasting his time reading blogs.

8. **also anon**
   April 29, 2011

   @baez

   you wrote "The universe we live in does not look 10- or 11-dimensional"

   so what do octonions tell us about 11 and the M?

9. **kneemo**
   April 29, 2011

   The split-octonions have already been used by Ferrara and Duff et al. in the description of black hole and string charge vectors in toroidally compactified M-theory (N=8 supergravity). See [arXiv:1002.4223 [hep-th]](arXiv:1002.4223)

10. **Peter Woit**
    April 29, 2011

    John,

    Thanks a lot for the detailed explanations. I should have made clear that this is a quite different case than the usual editions of "This Week's Hype", which just about always involve a claim that "we've found a way to test string theory". Thankfully, there's nothing at all like that here, and the material in the article about the relationship of string theory/supersymmetry to the real world was accurate.

11. **neo**

April 29, 2011

I read the article and enjoyed it. From the SA headlines, it sounded hypey, but the article itself was not. I am guessing Baez and Huerta don't control how SA chooses to headline the story, which of course will be done in a way that catches the most attention.

12. **chris bolger**
April 29, 2011

I have done some reading of octonions, and I read John's paper on it. It is very good, but technical to me. From what I understand about octonions is that they are anti-associative for three oconions that are different (excluding a real scaling factor). Since, the ORDER of the octonions determines the value, has anyone tried to make a consistent theory of spacetime using octonions? The order would determine different possible outcomes, but nature would only choose one. Also since the order does determine output, this gives a before and after quality if we build a length of time by successive octonion multiplication.

13. **John Baez**
April 29, 2011

also anon wrote:

> so what do octonions tell us about 11 and the M?

Maybe you can try my blog article here… it's a bit technical, but a lot less technical than our actual paper.

But here's something really quick: the real numbers, complex numbers, quaternions and octonions don't just let you write down the (classical) theories of supersymmetric strings in 3, 4, 6, and 10 – they also let you write down (classical) theories of supersymmetric 2-branes in dimensions 4, 6, 7 and 11! And the 11-dimensional octonionic case is believed to be relevant to "M-theory", whatever that is.

Once you hear this, you should wonder about 3-branes in dimensions 5, 7, 8 and 12. But if you look at the old "brane scan" picture on that blog entry I'm pointing you to, you'll see it doesn't quite work as smoothly as that. In particular, John Huerta has done a bunch of calculations showing that the trick relating octonions to strings in 10 dimensions and 2-branes in 11 dimensions does not continue to work one dimension higher. Apparently the nonassociativity messes things up!

(It's long been known by string theorists that something "ends" at dimension 11. However, we are focusing on a limited portion of the math, not the whole story physicists are interested in. So, the calculations John Huerta did may be new, or at least a little different than the usual story.)

By the way, John Huerta has gotten a postdoc position with Peter Bouwknegt at Australian National University in Canberra. That's 'close' to where I'm working here in Singapore – meaning, only about a 12-hour flight. (In fact Australia isn't close to anything.) So, I hope to continue doing a bit of work with him on octonionic puzzles. There are not many people with a good intuition for the octonions, and he's one.

14. **Casey Leedom**
April 30, 2011

Okay, I know this is trite (and liable to get deleted) but I haven't found the answer after a bit of survey. So how is "octonions" pronounced? Is it "Oc-'tone-ions" or is it "'oct-'ung-ions"? (As in the In-and-Out: do you want a _lot_ of onions with that?)

15. **John Baez**
April 30, 2011

Everyone I know says "Oc-'tone-ions". I'm assuming that little accent thing means the second syllable is accented – that's what everyone does.

This is like "quaternions", which also has the second syllable accented.

But the really evil people, who need to be brutally mocked, are the ones who write "octonian", often in the same sentence as "quaternion". I have no idea why.

16. **Giotis**
April 30, 2011

Peter wrote:

"The string theorists also did a great publicity job for E8, although they seem to have lost interest in it."

This has nothing to do with the E8 per se as a mathematical structure. They were forced to focus on Heterotic E8 since at that time it was the only road connecting String theory to phenomenology. With the advent of D-branes and flux compactifications though they were able to construct realistic string vacua in IIB/F-theory with all the moduli stabilized and even to connect these models to cosmology i.e. dS vacua (via KKLT), or warped D-Brane inflation (via KKLMMT) etc. On the other hand Heterotic has some know problems with respect to moduli stabilization and wasn't able to compete with IIB/F-theory on all these fronts of phenomenology.

Of course this doesn't really matter since as is well know all these theories are connected via dualities. There is only one String theory.

17. **someone**
May 1, 2011

just heard from colleagues that Quillen is no more.

18. **Thomas**

(Posted here because answering is disabled in: http://www.math.columbia.edu/~woit/wordpress/?p=942)
H. Hironaka speaks about news on resolution of singularities in positive characteristics http://www.mpim-bonn.mpg.de/node/3357 in ca. two weeks.

19. **Zathras**
May 3, 2011

"If you're a mathematical physics mystic like myself, you're susceptible to the belief that anything this mathematically deep, showing up in seemingly unrelated places, must somehow have something to do with physics."

This point of view is absolutely pervasive with particle/GUT theorists right now. There is an absolute disdain for non-rigorous mathematics in theory. The problem is that non-rigorous mathematics has often been the tool to advance theory in the first instance. Newton's theories depended on a very non-rigorous theory of calculus. Advancements in quantum mechanics were made for decades before renormalization could be rigorously handled. Feynman's initial methods for QED were an absolute mess of ad hoc rules and tricks. Only later were the rules formalized.

To make better theory, we don't need better mathematics. We need better Physics. Sort out the math later.

20. **Peter Woit**
May 3, 2011

Zathras,

This has nothing to do with rigorous vs. non-rigorous. The theories being studied by particle/GUT theorists are not rigorously well-defined, and there's nothing wrong with that.

Many physicists believe that whatever mathematicians are working on, it's irrelevant to them: they just need the right "physical idea", with the only math needed maybe something like PDEs. Newton was not so foolish. He was at the cutting edge of developing both new mathematics and new physics, well aware that the kind of new ideas about mathematics being developed by Leibniz and others were going to be required to express the new ideas about physics that he was developing. If he had taken the attitude that "all these new-fangled ideas about math can't be needed for physics", surely the dynamics of particles can be expressed using basic algebra and the theory of functions (e.g. today's high school pre-calculus math), he would not have gotten far.

The problem with what has come out of string theory is not that it is based on too much abstract mathematics, but that it is based on a physical idea that turned out to be wrong.

21. **Zathras**
May 3, 2011

"The problem with what has come out of string theory is not that it is based on too much abstract mathematics, but that it is based on a physical idea that turned out to be wrong."

No, that *was* the problem with string theory. The problem *now* is that the people doing string theory are so raptured with the beauty of the mathematics in string theory, that they think the theory must be correct. Which brings us back to your quote. People have stopped looking for other physical analogies because they think their rigorous math has to be correct.

22. **Peter Woit**
May 3, 2011

Zathras,

String theory is not based on rigorous mathematics. No one has a consistent definition of the theory, even at a non-rigorous level. What people won't give up on is not a piece of rigorous mathematics, but a physical idea: space-time has 10/11 dimensions and strings/M-theory branes unify particle physics and gravity.

Some interesting mathematics has come out of string theory (e.g. mirror symmetry), but this happened not by physicists coming up with rigorous mathematics, but by physicists coming up with non-rigorous, conjectural ideas about mathematics, which mathematicians then used as inspiration to come up with rigorous versions (of small parts of the original ideas).

23. **younghun park**
May 3, 2011

Peter
Very good! I agree to your thought. I think you are right.
As you said, many physicists and mathematicians won't give up string theory right now because that gives the inspiration to them, especially mathematicians.

I think you too don't give up the string theory as mathematician
because that you and your people in mathematics can obtain the conjectural ideas from string theory.

Even if string theory is not good physics, it is good for mathematicians to long for getting conjectural ideas.

24. **Frank**
May 7, 2011

@Peter: To me it seems increasingly likely that string theory is the physics equivalent of what in markets we call a "speculative episode". I think theoretical physics has suffered from badly exagerated expected returns on investment of time in string theory. And as usual those who are stuck in the investment till their necks will not be the first ones to blow the whistle that a market correction is coming. But I think for the rest of us … we might start to think about how we're going to bail our colleagues out …

This Week’s Leak

May 4, 2011
Categories: Experimental HEP News

Recently there was a bit of a kerfuffle triggered by someone leaking here the abstract of an internal ATLAS document claiming to have found a Higgs signal as a bump in the gamma-gamma invariant mass distribution. After some initial discussion of this, I wrote:

> Best guess seems to be that this is either a hoax, or something that will disappear on further analysis.

It quickly became clear this was not a hoax, but now there’s a new leak, this one from CMS to New Scientist, which indicates that “disappear on further analysis” is where this is going:

> Now physicists working on the LHC’s other main detector, CMS, have come up empty in an initial search for a similar bump in their data, according to a document shown to New Scientist. So ATLAS’s bump may not be due to Higgs particles, after all, but instead down to something mundane, such as an error in the analysis.
>
> The internal CMS document has not been released to the public, so the result is still preliminary, as was the news of the original ATLAS bump, for that matter, which was leaked before it was reviewed or endorsed by the ATLAS collaboration.

Well, maybe first news of the Higgs won’t show up on a blog, but at a more standard journalistic outlet…

Update: Curiouser and curiouser. It seems that there are questions about the existence of the supposed CMS document leaked to New Scientist. In other rumors floating around, while there may not be such a CMS document shooting down this signal, there really is an ATLAS one, soon to see the light of day. In any case, there are no rumors I’m aware of that there’s any confirmation of the original signal.

Comments

1. **tulpoeid**
   May 4, 2011

   Ahem, http://resonaances.blogspot.com/2011/04/atlas-shrugged.html

2. **Peter Woit**
   May 4, 2011

   tulpoeid,

   Yes, but that was just a rumor, this is a leak…

3. **Mike**
   May 4, 2011

   Peter,

   The link in the update you’ve added “This Week’s Rumour” does not work

4. **Peter Woit**
   May 4, 2011

   Thanks Mike, fixed.

   That was a link to the Resonaances posting mentioned here by tulpoeid.

5. **tulpoeid**
   May 5, 2011

   Peter:
   Oh ok, to be honest I didn’t realize at first they claimed to have seen an official document. Now that it’s clear, I still believe it’s a rumor.

6. **Bernhard**
   May 5, 2011

   It seems nobody in CMS is willing to comment on this. I think it’s likely that either the journalist made it up or what he claims to be a “document” is not even a CMS memo, just a piece of paper that someone in CMS have showed to him, (if one wants to believe he is not being dishonest).

7. **DB**
   May 5, 2011

   Dorigo doesn’t pull any punches. He states: “I think that the New Scientist reporter made this up. Yep, that’s what I think, and I challenge him to prove otherwise.”

   As Dorigo is a member of CMS, that carries some weight.

8. **lun**
   May 5, 2011

   There is a very nice blog-post about this whole matter, and physics leaks in general. Unfortunately, it is in Italian, but perhaps google translate does an acceptable job:

   http://www.borborigmi.org/2011/04/27/integrita-scientifica/

9. **rummy**
   May 5, 2011

This is all really a pathetic display of how everybody and his pet dog has to report rumours and counter-rumours or else get left out of the feeding frenzy. Honest scientists painstakingly working on a difficult analysis cannot do their work properly without everyone peering over their shoulders and gossiping.

Like me.

10. **Peter Woit**
May 5, 2011

rummy,

Consider the feeding frenzy just as evidence that people are very interested in what you're doing, so it must be worthwhile. Much of the world goes to work every day and does difficult, painstaking things that no one cares about. So, enjoy it while it lasts….

11. **Shantanu**
May 5, 2011

Peter something else to blog about is the COGENT result present at the STSCI symposium (which I am watching live now) and it will soon be archived on the web. what do you and others think?

12. **Peter Woit**
May 5, 2011

Shantanu,

My impression is that the COGENT results are just marginally statistically significant, and possibly inconsistent with CDMS/XENON100, so not worth getting excited about. But I'm not a dark matter expert, so to get an informed opinion about this, best to go elsewhere. The people at Science magazine just told me about a a program by Adrian Cho talking to dark matter experts this afternoon, which might be interesting, see here:

http://news.sciencemag.org/sciencenow/2011/04/live-chat-unraveling-the-mysteri.html?ref=topst

13. **nessuno**
May 6, 2011

Could it be that the CMS document is too atrocious to be made public?

14. **chris**
May 6, 2011

Peter, I think rummy indicated that he is gosipping, not doing the hard work 🙂

15. **Bernhard**
May 6, 2011

In the meantime, Fermilab is willing to die fighting:

http://www.voanews.com/english/news/science-technology/At-FermiLab-end-of-Search-for-God-Particle-Nears-121350499.html

"As we look at these huge data sets that we've acquired over the 10 years, we're now putting out things that we've learned about that data," he said. "And so what you're seeing here is evidence for perhaps a new particle and there will be other things that will come out over the coming months that will be just as interesting as this."

I´m puzzled what evidence Roser is refering to (perhaps the 3-sigma CDF paper?).

16. **Valerie Jamieson**
May 6, 2011

New Scientist was sent a 46-page powerpoint presentation by the CMS Higgs group outlining the search for a Higgs to gamma gamma decay that was conducted 21-27 April.
Valerie Jamieson, New Scientist deputy features editor

17. **Bernhard**
May 6, 2011

Meaning the "document" was indeed NOT even a CMS memo, just an internal presentation, not reviewed nor endorsed by CMS, since we can assume this was not a public presentation. But OK, a genuine leak then.

18. **Valerie Jamieson**
May 6, 2011

I should clarify my comment above. The presentation by the CMS Higgs group was sent anonymously to New Scientist, and not by the CMS Higgs group.

19. **tommaso**
May 6, 2011

By writing
"The internal CMS document has not been released to the public"
in their piece, NS made it look like it was a paper draft. If these are powerpoint slides the matter is different. Although their stating in more detail what they were sent does not prove anything, I will admit that it makes them more credible, especially since the author is now backed up by the editor.

In the end, I am only concerned that now nobody will take my $1000 bet, alas.

Cheers,
T.

Not a Leak

May 8, 2011
Categories: Experimental HEP News

ATLAS this weekend has finally released their latest analysis of the gamma-gamma invariant mass spectrum, carried out in response to claims from within their collaboration that a 4 sigma Higgs signal had been observed in this channel. The result? Nada:

> The dominant background components are measured and found to be in agreement with the Standard Model predictions, both in terms of overall yield and invariant mass distribution. No excess is observed.

Comments

1. **ruomur**
   May 8, 2011

   Oh dear. What would happen if it took > 1y to do the full analysis to say the rumour was unfounded and there was no excess beyond SM? There would be a dozen published PRL, all the way from MSSM to 'rigorous evidence of the existence of the Multiverse'. It's a nuthouse.

This Week's Hype

May 8, 2011
Categories: This Week's Hype

Philip Gibbs points to an impressive piece of string theory hype from British Channel 4 news.

If you watch the clip, you get the latest news about string theory and the LHC: people were getting discouraged about string theory, but now some of its predictions are being confirmed by the LHC. For the extra dimensions to appear, we may have to wait a couple years for when the machine runs at design energy.

Not clear at all where they got this nonsense from.

Update: The source for this seems to be a story by Jonathan Leake in The Sunday Times, entitled Stand by, we may soon enter a new universe (subscription required, but a syndicated version is freely available here). The story has David Evans of Alice trying to promote his experiment with:

> The Alice experiment may soon be able to make experimental measurements which, for the first time, can be modelled using the techniques of string theory.
>
> Although the experimental results will not prove string theory to be correct, an accurate prediction would certainly show that the techniques work, could distinguish between different versions of the theory, and perhaps even show whether the theory is going in the right direction.

Given this kind of quote, one can see why the writer completely mixes up string theory unification and string theory as approximate calculational method in heavy-ion physics:

> The researchers, at Cern, the European centre for particle physics near Geneva, say results from the Large Hadron Collider suggest it could offer the first experimental test for some aspects of string theory.
>
> Formulated in the 1960s, this theory attempts to describe how all the fundamental forces of nature, such as gravity and electromagnetism, interact with matter.
>
> On paper, the theory has been highly successful, resolving many mathematical problems.
>
> In practice, however, there is no experimental evidence to support its predictions, including the idea that there could be as many as 11 dimensions – the three physical dimensions, time and seven others as yet undiscovered.
>
> At Cern, there are now hopes the LHC may be able to break this impasse.

Then, as usual, the headline writer takes things a step further:

> SCIENTISTS have devised the first experiment capable of giving insight into one of the universe's greatest mysteries: could there be more dimensions than we know about?

So, out-of-control promotional efforts for ALICE are at the bottom of this one.

Comments

1. **ch4qgp**
   May 8, 2011

   Umm … it wasn't as bad as all that, really. There was a reference to expt data at the ALICE detector of collisions of lead ions and the quark-gluon plasma. But others have been talking about 'applications of string theory' (or AdS-CFT?) to the QGP for a while. There was a clear statement that string theory has been worked on for years and has made no predictions at all, and this has prompted some scientists (hmm …?) to claim that string theory does not work. There was a statement by the interviewed physicist that 'if a theory cannot predict anything then it's not really physics, it's … (shrug) … philosophy' (gasp!!). There was quite a bit of 'data from the LHC may be on to something' with regard to string theory. It did say towards the end that when the LHC cranks up to top energy then perhaps some evidence for the extra dimensions may be observed (didn't say what that evidence would be). However, it is indeed not clear why Ch4 would choose to run such a news item now. There was no statement of any new or recent discovery. ALICE/QGP has been around for a while. It may be (speculating here!) a fallout from the ATLAS-CMS rumours that 'something is afoot at CERN, with the LHC'.

2. **Chris Oakley**
   May 9, 2011

   A theory that cannot even get the number of spacetime dimensions right is not generally in good shape, and consequently the only reason for mentioning String Theory when reporting on a scientific experiment is as a sociological phenomenon amongst theorists. The public will eventually realise that they have been misled and what worries me is that then *all* theorists – not just the String partisan who advised on this piece – will be tarred with the "bullshitter" brush.

3. **DB**
   May 9, 2011

   Probably the source is the most vocal, and prominent of string theory hypesters, your colleague, Brian Greene. In a recent interview (Jan 24) on NPR he gushes:

   "You almost can't avoid having some version of the multiverse in your studies if you push deeply enough in the mathematical descriptions of the physical universe," he says. "There are many of us thinking of one version of parallel universe theory or another. If it's all a lot of nonsense, then it's a lot of wasted effort going into this far-out idea. But if this idea is correct, it is a fantastic upheaval in our understanding."

   "There are a couple of multiverses that come out of our study of string theory," Greene says. "Within string theory, the strings that we're talking about are not the only entities that this theory allows. It also allows objects that look like large flying carpets, or membranes, which are two dimensional surfaces. And what that means, within string theory, is that we may be living on one of those gigantic surfaces, and there can be other surfaces floating out there in space."

   "If we are living on one of these giant membranes, then the following can happen: When you slam particles together — which is what happens at the LHC — some debris from those collisions can be ejected off of our membrane and be ejected into the greater cosmos in which our membrane floats," he says. "If that happens, that debris will take away some energy. So if we measure the amount of energy just before the protons collide and compare it with the amount of energy just after they collide, if there's a little less after — and it's less in just the right way — it would indicate that some had flown off, indicating that this membrane picture is correct."

4. **Peter Woit**

May 9, 2011

DB,

Brian has recently been the source of a lot of multiverse hype, but this is a somewhat different category. I've identified the source here, see update to posting, and it's not Brian.

5. **neo**
May 9, 2011

You should have titled this as "This Week's Leake".

6. **Bernhard**
May 9, 2011

Hi Peter,

I remember you excused experimentalists some time ago for not engaging in the string, multiverse and likes nonsense, but clearly this is not the case anymore. Experimentalists too, talk all kinds of nonsense to get attention. Just depressing. This is much worse than any false rumor.

7. **DGP**
May 10, 2011

I doubt if you have identified the source correctly. There just doesn't seem to be time for one reporter (I think that Channel 4 have precisely one science reporter) to have produced a 2 minute magazine article from scratch, even though other journalists probably saw the Sunday Times at 23:00 on Saturday.

It's more likely that this was picked up from the CERN Courier piece on May 3rd which probably had a parallel Press Release (or David Evans sent out his own Press Release, which seems likely if he is a bit of a self-publicist).

My media advisor says that the lead-in (the voice-over on the stock LHC film) was probably written by a sub-editor to link to previous LHC coverage, so it would mention things said previously. Since the public preception is that LHC is meant to find "Higgs" and "Strings" it's not surprising it was mainly about strings.

Overall, I thought it was fairly constructive. Clearly, some experimentalists think that string theories are now testable to some extent and Evans was clear about the priority of experiment over speculation in physics (although he offended my wife by implying that String Theory would be philosophy if it wasn't verified: she is a philosopher).

I chance to recollect that one of the more fully worked out string theories makes some predictions for the QGP which I think this experiment may well be at variance with.

So it looks like "Game On" for the experimentalists. If my recollection of being a theorist amongst experimentalists is accurate, many experimentalists will take great pleasure in kicking down any theoretical edifice. Looking in Particle Data Tables "Cross Sections" suggests that some people have been working hard at trying to extract testable predicitons from a variety of String theories.

Happy Days! I wish I was there.

8. **Bernhard**
May 10, 2011

DGP,

"Clearly, some experimentalists think that string theories are now testable to some extent and Evans was clear about the priority of experiment over speculation in physics"

If there are experimentalists thinking that, too bad for them. There is no such thing as testing String Theory at all.

9. **Peter Woit**
May 10, 2011

DGP,

The "public perception" that the LHC is meant to find "Strings" is the problem, since this is simply not true. Claims that heavy-ion physics experiments at the LHC will "test string theory" are heavily over-blown, and part of an effort to mislead the public by generating exactly this sort of completely false story in the press. The supposed application of AdS/CFT approximation methods to certain phenomena in heavy-ion physics has nothing at all to do with string theory unification. The physicists involved here are well aware of this, but happily help generate false news stories like this one.

It's too much of a waste of time to keep rewriting this same point every time a new bogus press story like this one appears. For some idea of the scale of the problem, click on my blog category "This Week's Hype" to get an idea of how long and intensively this dishonest campaign has been going on.

10. **Giotis**
May 10, 2011

"The supposed application of AdS/CFT approximation methods to certain phenomena in heavy-ion physics has nothing at all to do with string theory unification"

More importand ST is a theory of Quantum Gravity and AdS/CFT via ST is closely related to Quantum Gravity.

So AdS/CFT and it's verification is very important for ST as a theory of QG.

QGP is just another application…

11. **qpg**
May 10, 2011

"QGP is just another application…" — how many other applications are there?

It appears that this news item is an attempt by ALICE to gain a share of the spotlight. Rumours have circulated that ATLAS has "seen something" (and CMS is checking its data to confirm) and every false lead gets reported or blogged to fever pitch (yes?). And (horror!) if the "thing" should prove to be true, then ATLAS/CMS/CERN will grab ALL of the headlines. Possibly also all of the LHC beam time. Alice will traipse in Wonderland totally unnoticed. So better to call some attention to oneself. And so to string theory … who in the taxpaying public cares about turning lead ions into pancakes? It appears now that the current rumour from ATLAS is not true … there will be others.

12. **Bernhard**
May 10, 2011

Giotis,

the point is if AdS/CFT cannot make ST explain anything for its own, it´s a test of equivalence. It´s like if Einstein came with the theory of relativity and said that the only experimental test he has is that in particular cases his theory is equivalent to Newton´s… This is the same thing, so NOT a experimental test. A test would be something that QFT cannot make it and ST can but this is something by definition AdS/CFT will never be able to make it. So, the story so far is the same.

13. **Peter Woit**
May 10, 2011

Giotis,

To supplement Bernhard's comment:

We are pretty sure we know what the theory is that governs heavy-ion physics, QCD. Claims that ALICE is "testing" some theory aren't about testing the underlying theory, but about testing whether some string theory-AdS/CFT inspired model reproduces QCD approximately in some specific situation or not. If ALICE doesn't find agreement with the predictions of a particular string theory-AdS/CFT based model, it doesn't mean QCD is wrong, it doesn't mean string theory is wrong, and it doesn't even mean the AdS/CFT correspondence is wrong. This is not a "test of string theory". All it means is that, for the specific phenomenon checked, the model turns out to be useful (to some approximation), or not.

Claiming that you can get from this situation to using the LHC to test the idea of 11 dimensions and string theory unification, which has nothing to do with any of the above, is just absurd.

14. **Mike Reeves**
May 10, 2011

Why all of the hush, hush. I would think they would post everything there learning and attempting real time! It not like anyone else has the equipment to outdo or discover something first. Science is for all mankind.

15. **Peter Woit**
May 10, 2011

Mike Reeves,

I think you're referring to an earlier posting. But one thing to keep in mind is that there is a competition here. ATLAS is only one of two big general purpose detectors, very much in competition with the other one. One reason for keeping their internal documents out of the public eye is to keep their competitors from reading them. This competition is scientifically valuable since it means that they are under pressure both to get a result as soon as they can, AND to get it right.

16. **chris**
May 11, 2011

Mike,

all of the LHC experiments and all accelerator based experiments are under extreme pressure to discover *something*. because if they don't, LHC is probably the last of its kind and even running it to the end will be questionable.

it has become a multi-billion $ business and that is generally not healthy.

17. **Giotis**
May 11, 2011

Peter and Bernhard,

Nobody talks about testing string theory in the strict sense.

People are talking about circumstantial evidence from different areas of ST which in time could pile up and boost our confidence to the general framework.

I think the article has been written in this spirit. You could tell this from the title which is rather conservative.

I quote: 'SCIENTISTS have devised the first experiment capable of giving insight…'

This is quite an honest statement I think especially for a headline .

18. **Bernhard**
May 11, 2011

Giotis,

You remind me of Polchinski defending ST by saying that "String theorists have a strong sense that they are discovering something, not inventing it".

I'm sorry to say I am very much not convinced by string theorists feelings, nor do I agree with you that one gets ANY insight that there could be 11 dimensions because of a particular string theory-AdS/CFT based model might agree with QCD. I think there is no logical conclusion one can draw from this.

On the other hand, if you get such an insight, whatever you mean by that, than I guess we could spread the news that if this "test" fails you will get the insight that there is no such thing as 11 dimensions, right?

19. **Peter Woit**
May 11, 2011

chris,

It’s true that the LHC experiments are under a lot of pressure to discover something new. It’s also true that they’re under just as much pressure to not make a mistake, with the competition between detectors ensuring that possible mistakes will be vigorously pursued by someone with a huge interest in showing them wrong.

20. **Peter Woit**
May 11, 2011

It is true though that the pressures to find funding for these experiments might explain why the string theory hype campaigns sometimes conducted on their behalf.

21. **srp**
May 11, 2011

I heard one of the CERN management guys say that he hopes they find the Higgs, because he promised the politicians that they would. But it seems that not finding it would be bigger news–kind of a null Michelson-Morley-type result that would blow up everything. So I don’t think they should worry too much about anything but inconclusive findings.

Pricey Strings

May 11, 2011
Categories: Uncategorized

In recent years most of the conferences I've attended have been mathematics and mathematical physics ones, and I had noticed that, while modest registration fees were often a feature many years ago, these days most such conferences, especially in the US, have no registration fee at all. It seems that mathematicians tend to organize conferences at rather modest cost, and mathematics research is very well supported by the NSF, universities and private foundations. This morning I'd been idly considering the idea of taking a day-trip down to Philadelphia next month to visit friends and maybe attend a couple talks at String-Math 2011, which has a promising list of speakers, but not yet a schedule of talks. I noticed though that registration is $200, which is a bit high as a price to attend a couple talks, whatever source I might find to pay for it.

As one moves from mathematics topics to physics ones, it seems that things get a lot pricier. You might think that string theory not working out as hoped would lead to the availability and market-value of string theory talks heading downwards, but the opposite seems to be true. The big string theory conference this summer is Strings 2011 in Uppsala, where registration will cost you 5625 Swedish Krona (about \$900) . For that you get the talks, coffee, lunch and a reception. If you want to go to the conference dinner, that's \$112 extra. The conference series is advertised as "gathering more than 500 researchers in string theory", although in recent years, attendance at Strings 20XX conferences has been a bit lower. Last year's was anomalous, held in March (when academics often can't travel) in College Station, Texas (not exactly a major tourist destination), it attracted only 193 participants, despite a relatively low registration fee of only $350. For Strings 2011, they've got 208 people registered already. The list of speakers is here. There's an associated program of Public Lectures which seem likely to have little to do with string theory, instead concentrating on "mind-boggling questions" about the multiverse and the Big Bang. Those at least seem to be free.

I haven't added up the total cost, but if you've got significant funds available from a grant, university research support, or private wealth, you can spend pretty much the entire summer attending not just string theory talks, but even string phenomenology talks (see a list here). There's the String Vacuum Project meeting in Philadelphia starting May 23, from which one could head to String Phenomenology at Nordita from May 30 to June 25, then Strings 2011 in Uppsala until July 2, a workshop and conference in Spain from July 3-29, Les Houches for most of August, then String Phenomenology in Madison August 22-26 and SUSY11 at Fermilab keeping you busy until Labor Day.

Update: The hot topic these days is not string theory, but gauge theory amplitudes, using twistors. If you can't afford strings, the price of the twistor talks is still low: a correspondent points out to me that for a registration fee of 15 pounds, you can attend Twistors, Geometry and Physics, a meeting this summer in honor of Penrose's 80th birthday.

Comments

1. **Bee**
   May 11, 2011

   And we all know why the fees are so high. Because you pay for the flights of the invited speakers.

2. **chris**
   May 11, 2011

   curious – i always have to pay my own trip even as an "invited speaker".

3. **lun**
   May 11, 2011

   This is true for physics conferences in general: cost of upcoming Quark Matter conference, 600 Euro.

   From what I understand (Anyone correct me if I am wrong, I heard this from participants), the string conference series is invited speakers only.
   In practice, this and the number of attendants translate into an exercise of celebrities talking to each other and everybody else listening and hoping to get a word to someone edgewise.

   If this is true (see disclaimer in previous paragraph), I would not attend such a conference, for a whole slew of reasons, summarized in the equation conference!=oscars. 🙂

4. **confs**
   May 11, 2011

   Lots of confs, not just on strings, are pricey. And if you look beyond physics, to medical or financial confs, you may have to pay USD 900 just for a one-day meeting. Phys/math confs are pertty cheap by comparison. If 200 bucks gives you pause, you probably can't affort to gamble at the casinos and chug the cocktails either. What will the hookers think of you?

   Invited speakers may or may not have to pay their own way. A friend of mine was invited to speak at a conf, but had to pay his own airfare (and registration fee!). But I invited him to stay at my home, and took him around ~ tourism, which persuaded him to accept the invitation. On the other hand, I was invited to an overseas conf and all my expenses were paid.

   Numerous prestigious confs have invited speakers only. That does not detract from their quality.

5. **15p**
   May 11, 2011

   If the Penrose b'day registration fee is 15 pounds I doubt the tea, coffee and sandwiches will be any good.

6. **Henry Walloon**
   May 11, 2011

   Peter,

   Conference attendance costs amongst professional scientists?…Pity the amatuer who, arxiq aside, struggles to even read the typical academic paper for less than twenty dollars per download…

   Henry

7. **nbutsomebody**
May 11, 2011

It is quite pointless to participate in the Strings. Most talks will possibly be available online. On a generic ground it is hard to understand what one may gain by paying $900. There is not so many new results in string theory, I wonder who is going to attend this conference and for what reason ?

8. **Peter Woit**
May 11, 2011

nbutsomebody,

Like most conferences, the main reason to go is to get a chance to meet up with other people in your field and talk to them. I suspect that very few people will be paying the \$900 themselves, with it being covered in some cases by the conference organizers, in many cases by research grants and other funds available from one's home institution for this purpose. So, if there's the possibility of a summer trip to Sweden, with someone else paying the bill, and you'll get to hang out with friends and colleagues you haven't seen in a while, why not go? If there's money from some source to cover your flight and hotel, it will probably also cover the registration fee, even if it is \$900.

Finding 500 string theorists with this happy financial situation though might be a bit of a challenge, but maybe not. At least in the US, the budgetary situation for mathematicians and theoretical physicists has been pretty good recently (partly due to "stimulus" funding). Then there's an increasing amount of private foundation money available, for example the Simons Foundation has
https://simonsfoundation.org/funding-guidelines/current-funding-opportunities/collaboration-grants-for-mathematicians

9. **In Hell's Kitchen (NYC)**
May 11, 2011

I'll take 3 kilos of strings for $9.99…

You should see the registration fees in Applied Math and Engineering conferences…in the stratosphere !

10. **Jeff**
May 11, 2011

Wow, you physics types really get jerked, unless you get paid a lot more than us mathematicians. Even the big yearly AMS meeting is much cheaper than this, and targeted conferences often don't really have a registration. I ran a CBMS conference two summers ago, big name main speaker, bunch of well known invited talks, we were going to charge \$25 but ended up just forgetting about it. The banquet was less than \$50, wine included, at a really good restaurant.

11. **King Ray**
May 11, 2011

The truth is free, but falsehoods are usually charged for.

12. **Peter Woit**
May 11, 2011

Jeff,

Traditionally, particle theory groups are quite a bit better funded than mathematicians, with significantly more money available for things like paying conference fees.

13. **Jeff**
May 11, 2011

Peter,

Kind of figured that was the story, just moving the money around I guess. I mean, when you're spending millions on equipment, what's a few thousand on conference fees? The biggest expense for most mathematicians is probably a Mathematica license, or MathSciNet fees, peanuts in the particle physics community. I guess the fact that invited speakers have to pay there own way is for the same reason? For any sort of major speaker that would never happen in the math world – I mean if you're giving a talk at a session at an AMS meeting you probably pay your own way, but if you're one of the "invited speakers" you won't, and if you're giving a talk at a seminar somewhere you won't pay you're own way either usually.

14. **nbutsomebody**
May 11, 2011

Peter,

Thanks for the reply. Yes, it is indeed nice to meet friends and colleagues. For some people this is the motivation, however I do not think these kind of conference are good place to start new scientific collaborations. The reason being that young researchers do not talk in such conferences. Even if there is 3-5 min sessions for less well known people then it may be worth to go. One may talk to people personally but it is difficult to know beforehand who may be interested. Similarly it is difficult to know whose work I may be interested in.

Not to mention the fact, with the current situation of string theory, it is a clear wastage of time to fill ones ear with mostly useless talks and a fair-share of gibberish and promotions. Frankly it is difficult to see the point of arranging a global conference each year, there are not simply so many new results! A five yearly thing would possibly be more appropriate. So I am not going even if I have some NSF money.

15. **sanjay sood**
May 12, 2011

You are right about the hype being generated about ALICE with a likely boost by ALICE people. But one could try to understand their point of view as well.
Gauge/gravity duality or AdS5/CFT4 duality does have some relevance to the properties of quark gluon plasma even though it's a tenuous one. While QGP has neither the supersymmetry nor conformal symmetry, these two are essential in AdS5/CFT4 duality. On the other hand QGP has asymptotic freedom and running of gauge coupling which are missing in AdS5/CFT4 duality. Despite these major differences, AdS5/CFT4 has had some modest success in explaining the properties of QGP, especially the ratio of viscosity to entropy density bound.
One key component of AdS5/CFT4 duality is, by its very nature, a correspondence between a 4+1 dimensional space(AdS5) and a 3+1 space(Euclidean space). Since string theory is in fact the most important part of this duality(closed strings giving rise to quantum gravity in the AdS5 bulk) one could perhaps argue that this duality does in fact explains how space comes into existence. In other words how extra spatial dimensions come into being.

So even though one must be wary of any purported claim of string theory being able to unify all 4 forces, one could at least agree that string theory or Ads5/CFT4 duality has opened a new door that may lead to a new and very deep understanding of the nature of space.

16. **Bernhard**
May 12, 2011

Uau, there's a conference on String "phenomenology"? And from Monday to Friday?

Talking about what???

17. **Peter Woit**
May 12, 2011

sanjay sood,

I'm not seeing how a "tenuous" relation to gravity in AdS5 has anything much to do with gravity in 4d and unification, other than providing an opportunity to mislead people.

18. **Rien**
May 12, 2011

The high price of the Strings conference may have to do with the banana republic-ness of the dollar… Recently you'd get about 6 SEK per USD, while a few years ago, you'd get almost 9. That's quite a drop.

19. **Joe Minahan**
May 12, 2011

Peter,

Thanks for providing a link to the Strings2011 conference for which I am one of the organizers.

However, I would like to correct some of the misconceptions about the costs involved. The registration fee you quote, while technically correct, applies only for same day registrants. Those who register in advance pay 3500 SEK +VAT, which corresponds to 700 USD. We are the first to admit that this is still a lot of money, but this is mainly due to circumstances beyond our control. These are: 1) The weak dollar. Today it is 6.25 crowns per dollar, 2 years ago when we agreed to host the conference the exchange was more than 8 crowns per dollar. 2) The strong Swedish crown. Not only has the crown risen against the dollar, but it has also increased substantially against the euro. Since the majority of the participants will be coming from Europe, this will affect them fairly severely. 3) The VAT. Starting in 2010 the Swedish government instituted a mandatory VAT on conference fees paid by participants coming from outside of Sweden. We, nor any other potential conference host in Sweden saw this coming in 2009. And there seems to be no way to get around it. 4) Not much outside funding. Vetenskapraadet (the Swedish equivalent of the NSF) and KVA (The royal scientific academy, the group responsible for choosing the Nobel prize winners) have generously contributed the maximum amount they are allowed to fund conferences. But this still does not come close to covering our costs.

Let me now say what the conference fee pays for. 1) Local costs for invited speakers. This is a long tradition of the Strings 19xx and 20xx conferences. However, despite what Sabine wrote in her comment, we do not pay for the speakers airfare. 2) The lecture hall and accompanying personnel. This also includes the technical facilities so that you and others can watch the proceedings live (or taped if you are not normally up at 4am). 3) Subsidizing the costs for students. On the registration page you will notice that PhD students pay half price. This money has to come from somewhere. 4) As you mentioned, coffee, lunches and a reception are provided.

Let me add a remark on having invited speakers. It is true that many of them are "celebrities", but they are celebrities for a reason. I can almost guarantee that the most well attended talks will be by Maldacena and Witten, and they will surely give very interesting and exciting talks. Other speakers were chosen depending on their field and recent contributions. Many suggestions came from our International Advisory committee and we tried to round things out as best we could. Nevertheless, there are many deserving people who were regrettably not invited to speak because we did not have room.

Finally, while the number of participants is lower than in past years, we are still expecting to have a very exciting conference. This is the second strings conference I have helped organize. The first was the 1995 USC conference which only had 150 participants, and I think that one turned out okay.

Best Regards,
Joe Minahan

20. **Peter Woit**
May 12, 2011

Joe,

Thanks for the corrections and detailed explanations about the conference costs and funding. I certainly hope Witten or someone else has something up their sleeve that will match the 1995 USC conference, and look forward to free-loading by remotely watching some of the talks. Good luck with the conference!

21. **lun**
May 12, 2011

I do not doubt the ability of the celebrity speakers to give excellent and inspiring talks. But as peter seems to say, if this is all there is to a conference, why should someone (especially a student!) pay the fee rather than just watch the conference from home.
If the only talks are invited than, by definition, the conference will be about presenting results that there is a consensus are interesting, rather than discussing and deciding WHICH results are interesting and thought-provoking. The separation between talking celebrities and listening students will make it very difficult for a student to meaningfully participate in the discussion.

That might well work out for the best. However, sometimes the most interesting result of that year is one everyone on various international advisory committees would have happened to have missed. And in a less formal (in an organizing sense) conference where there are more submitted talks, such results might emerge and stimulate further work and discussion.

In the off-chance that this happens, I generally prefer smaller workshops to big conferences, for this reason.

22. **Amos**
May 12, 2011

The science of economics offers an explanation for the high cost of string theory workshops: rent seekng.

An economic rent is the ability to earn money without expending effort, like the way a landowner can (simplified, of course) sit back and receive a revenue stream by renting out his land.

"Rent seeking behavior" is the tendency of people to overspend in chasing rents, leading to a net economic loss. For example there must be ten thousand barristas in Los Angeles who could be starting productive careers but instead hope to become famous.

Tenure is also a rent. So is an academic reputation with salary-command potential. The great efforts spent to obatin these things, in which most contenders lose out, is economically wasteful rent seeking.

As the number of available string theory rents declines, rent-seekers will increase their expenditures in the hopes of obtaining the last few.

23. **conf_student**
May 12, 2011

I got my first job after graduation by going to a conference. My thesis supervisor did not attend, but he told me "Go speak to people, tell them that you are writing your thesis and expect to graduate in a few months, and are looking for a postdoc job, do they have any openings?" I was utterly terrified at this bare-faced way of doing things. (I later found out this is called "cold-calling" and it is a recognized technique and studies show that it is successful.) But anyway I took my life in my hands and approached some strange professor whom I had never heard of and made my pitch. As soon as I saw the big smile on his face and he put his friendly hand on my shoulder I knew that all would be ok. He didn't have a job opening, but he pointed me to someone who did. I went to that person and he scheduled an interview, and I got my first job. There's more to a conf than listening to talks via streaming video. Conferences are job fairs, too. And (some?) professors do not object to being approached by unknown grad students. I made many friends at that conf, friendships which have lasted many years. So I got my money's worth from my registration fee (which was paid by a grant, of course).

24. **Peter Woit**
May 12, 2011

Amos,

The problem with your argument is that no one here is making a profit or collecting rent. The money that comes in from registration fees goes back out to cover the expenses of organizing the conference. This is not something you do to make money, and it's a huge hassle. The rewards are intangible ones.

Joe Minahan did a good job of explaining here why their conference has pretty high fees. Most small math conferences I know about have many fewer people attending, and a quite healthy contribution from the NSF and some other sources. The small size means the organizational work can be done by the organizers themselves, and getting a venue at the university is easy and cheap. For a big conference you need staff and a large venue, and without a correspondingly larger financial contribution from grants, registration fees have to cover the difference.

25. **Peter Woit**
May 12, 2011

conf_student,

Thanks for the excellent explanation of why attending a conference is important for young scientists, even if they get nothing out of the talks. Conference organizers are well aware of this, it's one reason that they offer much lower registration fees for students.

26. **Christine**
May 12, 2011

For what is worth, in Brazil a postdoc position is not considered a job at all. It is even amusing for us to imagine it seen as a "job".

27. **pdoc**
May 12, 2011

Does a postdoc position (a non-job) pay a salary? Does a postdoc have to pay income taxes on that salary? (If yes, is "income" not correlated with "job"?) Is the postdoc expected to put in (regular?) office hours, if the position is not a job?

28. **Christine**
May 12, 2011

@pdoc: In Brazil, the answer is no to all your questions. Postdocs receive a fellowship (sort of) and are seen mostly as trainees. See e.g.: http://www.fapesp.br/en/5427

29. **Mitchell Porter**
May 15, 2011

Peter wrote:

"The hot topic these days is not string theory, but gauge theory amplitudes, using twistors."

But these aren't separate topics! It started with Witten's twistor string, and the theories being studied have string duals in AdS space.

30. **Bugsy**
May 15, 2011

Christine- a postdoc grant of 5,000 reais per month tax-free I suppose is not so bad in Brazil, for a single person. In a weird move, the Brazilian govt is trying to make up for abysmal primary/high school education by expanding the universities enormously, so if the person ends up wanting to stay in Brazil, it appears there are at the moment lots of open positions at new federal universities throughout Brazil, in math or physics, at which a posdoc who learns Portuguese has a good shot. So rarely in today's world, there are jobs. Now whether this is a good career move is a different question- you might "end up" in a small town someplace, with a nontrivial teaching load, or in a big city choked with cars like Sao Paulo or Rio.

31. **Peter Woit**
May 15, 2011

Mitchell Porter,

Just because you can find some connection between a topic and string theory, that doesn't mean the topic is string theory.

Nati Seiberg of course predicted this years ago, when he said that no matter what replaced string theory, string theorists would “call it string theory”.

32. **Mitchell Porter**
May 15, 2011

Peter – d=4 N=4 Yang-Mills theory, which is at the center of the twistor/gauge enthusiasm, is *equivalent* to Type IIB superstring theory on a certain background. (Or if, against all the evidence, it *is* inequivalent, then it is so close that the difference consists of a very subtle deformation.) And Type IIB is, uncontroversially, old-school string theory, it’s not some new topic which has been adventitiously appropriated by string theorists in order to remain relevant. So string theory was rediscovered in an unexpected place.

It *is* remotely conceivable that the string description will recede into the background conceptually, and people will prefer to think in terms of twistors, but I doubt it. A more reasonable question might be, does this mean that strings “mean” something different to what people thought in the 1980s? What I mean is that from the d=4 field-theoretic perspective, the AdS dimension, the compact dimensions, and the extended objects (strings and branes) all emerge from renormalization group flow and the structure of moduli space. It might be argued that strings and branes should therefore be conceived as abstract in some way, and one might wish to reserve the notion of physicality proper for the fields in four dimensions. I think *that* is a debate with a future. But if string theory is truly irrelevant to reality, then so is the twistor/gauge revolution.

33. **Peter Woit**
May 15, 2011

Mitchell,

As far as I can tell, the reasons twistors are useful in studying perturbative gauge theory amplitudes have little to nothing to do with string theory. But it’s an evolving story, we’ll see what the final result is when people really understand how to formulate these theories in twistor space. Maybe strings will play a central role, we’ll see. Until then, I think continually hyping the importance of strings in cases where they aren’t the center of attention is PR, not science.

34. **Christine**
May 16, 2011

@Bugsy: I didn’t say to be a postdoc in Brazil was *bad* (in terms of temporary earning), only that it is not seen as a *job*. The notion of job is simply different here. There are openings (jobs!) in federal universities/institutes, but they require disputed contests. I had to win over 86 candidates to get a permanent position in a related area (not my primary area) in a military institute, considering at the time personal constraints (city, family, etc). What I have *is* a job, but as you say, not the best career move. But I guess you’re right: there are probably more opportunities now in Brazil than in the USA/EU, and I wouldn’t want to live anywhere else anyway.

In any case there are no guarantees that a postdoc will end up exactly where she/he planned, in terms of career and city. That is why a postdoc is seen here as a trainee with a temporary grant, and for us this is not exactly a “real job”.

35. **Shantanu**
May 17, 2011

conf_student, I wish it is as rosy as you point out. I wanted to switch fields after ph.d and my thesis advisor and people who wrote letters for me did not know anyone among the jobs I applied and none of the conferences I went to ever helped me.

Recent NSF Grants

May 11, 2011
Categories: Multiverse Mania

In responding to a comment on the previous posting, I was curious if one could easily get some data on relative sizes of grants in mathematics and physics, so started to do a quick search on nsf.gov. Among the first few NSF grants that turned up, I noticed a couple rather odd things:

- Award 1056580 for a postdoc in "Dark Energy, Fine-Tuning, and the Multiverse: Testing Theories in Modern Cosmology" drew my eye, since my impression was that NSF physics panels weren't so likely to support Multiverse Mania research. Taking a look at the details of the award gave the explanation: this one is being funded not by the physics division (PHY) at NSF, but by the sociologists (SES, Division of Social and Economic Studies). So, now it seems that multiverse studies are part of sociology, which is much more appropriate than physics, and has the added advantage of opening up new funding opportunities.
- Trying to pick a typical theory group grant, I took a look at Award 0969020, for the string theorists at UT Austin. I was pleased to see that blogging is now a selling point on NSF grants:

> Professor Distler authors a blog which discusses and elucidates many of the important research papers which appear on the daily arXiv listings, and he plans to continue his activity.

The abstract was the usual sort of string theory promotional verbiage, beginning:

> For the past two decades, string theory has been one of the most intensely investigated areas of theoretical high-energy physics. This is true chiefly because string theory offers what is currently the most successful method of unifying gravity with the other fundamental forces (strong, weak, and electromagnetic).

The next one I took a look at was Award 1001296 to theorists at UPenn, whose abstract sounded kind of familiar, beginning:

> For the past two decades, string theory has been one of the most intensely investigated areas of theoretical high-energy physics. This is true chiefly because string theory offers what is currently the most successful method of unifying gravity with the other fundamental forces (strong, weak, and electromagnetic).

Comments

1. **Shecky R.**
   May 11, 2011

   Well, this is all sort of funny… or, NOT! (or maybe by mistake you just logged into the National Sociological Foundation grants and didn't realize it).

2. **JSE**
   May 11, 2011

   Re the first grant: studying the battles touched off by string theory over the philosophical question "what constitutes evidence for a theory?" seems to me a very interesting and important question in the philosophy and sociology of science. It seems especially suited to somebody like the PI, David Kaiser, a historian who holds Ph.Ds in both history and physics. He gave a very illuminating physics colloquium here last month about the history of Bell's theorem outside academic physics in the 1970s. Good granting, as far as I'm concerned.

3. **Peter Woit**
   May 11, 2011

   JSE,

   The multiverse business is certainly an interesting issue in sociology and philosophy of science, and I've no problem with it being studied as such. The funny thing is how much their abstract reads just like those of people claiming to be doing conventional physics these days.

   By the way, Kaiser has an interesting book about to appear on the topic you mention, called "How the Hippies Saved Physics". I've written a review of it for American Scientist, soon to appear, at which point I'll write something on that topic here.

4. **DLS**
   May 11, 2011

   Regarding the last two quotes, I've seen that sort of thing before. My understanding is that NSF program officers can sometimes insert a sentence or two in award descriptions that they feel need a little extra non-technical context, and these get re-used. So while it's possible that the PIs borrowed from each other, you can't take it to the bank.

5. **Peter Woit**
   May 11, 2011

   DLS,

   Since the awards were made at the same time, the hypothesis that someone at the NSF is responsible for this seems reasonable. Perhaps they'll save people some work from now on by just reusing the same hype on all grants in the field. Just imagine the amount of time that has been wasted over the past 25 years by thousands of physicists trying to come up with some new way of saying the same thing. Enough's enough.

6. **Marc**
   May 12, 2011

   The funny side is that Distler has not discussed physics or arxiv papers in months on his blog, but only posts about his bizarre software packages. His blog has become completely narcissistic and useless.

7. **Tim van Beek**
   May 12, 2011

   Peter said:

> The multiverse business is certainly an interesting issue in sociology and philosophy of science…

Yes, definitely! Someone could start to investigate the redefinition of *"successful"* in statements like

> …string theory offers what is currently the most *successful*method of unifying gravity with the other fundamental forces…

Also, I'm surprised that the fact that

> …string theory has been one of the most intensely investigated areas…

is supposed to be an argument **pro** more research. When I was a graduate student in Heidelberg, I remember a discussion about someone not getting funding for more solid state physics research, because the Heidelberg factulty already had a fair share of solid state physicists. (And these are people who produce tangible results every year.)

8. **JSE**
May 12, 2011

By the way, you can find mention of my blog in my latest grant, too:

http://www.nsf.gov/awardsearch/showAward.do?AwardNumber=1101267

I'm with Peter — blogging is "broader impact," and if you blog you should say so in your proposal.

9. **Mikhail shifman**
May 12, 2011

Excellent observation!

10. **Roman Oliynyk**
May 12, 2011

My first post here, although enjoyed reading the blog for a couple of months.
Excellent and sad observations. Will be interesting to see 5 years from now, hopefully the trend will change by then. Provided string theorists can find a different line of work and enough integrity to go a different way, when CERN and other experimental results will show no evidence of supersymmetry as stated and no heavy particles.
Well, I am preaching to the choir masters…

11. **Roman Oliynyk**
May 12, 2011

On second thought, one already have done it. Lubos Motl 🙂

12. **anon**
May 12, 2011

If SUSY is not found, SUSY experts will be among the first to figure out whatever new theory that is to be established. They have the formidable mathematical and theoretical skills that are needed for such tasks.

13. **ysus**
May 12, 2011

If SUSY is not found at the LHC, then SUSY will get modified, that is all. When experimental data showed there was no aether drag, the aether theory was not abandoned. Instead it was modified: the Lorentz-FitzGerald length contraction was invented. The aether theory was only abandoned when Einstein came up with a better alternative theory (= special relativity). (And as events showed, relativity incorporated the Lorentz-FitzGerald length contraction in a natural way.) SUSY will only be abandoned when something better comes along. But first there will need to be some data, which SUSY cannot explain easily. "No data" (at the LHC) is not a disproof. There is no other clearly superior alternative theory, and "no data" doesn't point the way to a better theory.

14. **Peter Woit**
May 13, 2011

anon and ysus,

Sometimes I just can't tell whether comments here are parodies or not.

There is a better, more powerful and simpler theory than SUSY. It's called the Standard Model.

15. **anon**
May 13, 2011

I don't totally disagree, but worshiping the standard model is really an activity for the 1970s. SUSY is proven to be the only possible extension of Poincare symmetry of the S-matrix, so its experimental discovery would be on par with special relativity. Given that GR exists in nature, the discovery of SUSY would automatically imply the existence of SUGRA, which may be the low energy limit of string theory. Even if SUGRA is to have a UV completion other than string theory, we are already half-way at finding a quantum theory of gravity. Besides, SUSY would guarantee the precise unification of gauge coupling constants, which would constitute the strongest evidence towards GUTs which are natural and appealing models.
Even though people are well aware that SUSY is too speculative, the potential pay-off is simply too big, so they can't resist the temptation to work on it. Why haven't criticizers come up with something that is more exciting and more addictive?

16. **chris**
May 13, 2011

"Given that GR exists in nature, the discovery of SUSY would automatically imply the existence of SUGRA, which may be the low energy limit of string theory."

do you really mean imply? not hint at or provide evidence in favor of?

i mean, we have no clue yet how to quantize gravity. there are some indications that some sugra models are preturbatively renormalizable (or even superrenormalizable), but they have a host of other difficulties.

in addition, we know for a fact that at least the vacuum state breaks susy. this is quite a bit different than in the case of the Poincare group. and just because we know how to promote this symmetry to a local one in the classical case does not at all imply that we can do the same with a spontaneously broken extension in the quantum case.

it is exactly this kind of sloppy thinking that poisons hep-theory these days. finding a vague analogy is often a good starting point, but unless you can establish every single argument in your chain of reasoning, consider a conjecture a conjecture and not more.

17. **Peter Woit**
May 13, 2011

Please all, enough of the SUSY arguing, please stick to the topic of the posting.

18. **Bertrand Gray**
May 13, 2011

I wonder how many times that NSF abstract is used in other multiverses?

Probably billions upon billions?

19. **Bertrand Gray**
May 13, 2011

Or, NSF could claim that the duplicate abstract in this universe is proof that not only does the multiverse exist, but chosen entities pass back and forth between them!

Also–am I reading DLS right? He writes, “Regarding the last two quotes, I’ve seen that sort of thing before. My understanding is that NSF program officers can sometimes insert a sentence or two in award descriptions that they feel need a little extra non-technical context, and these get re-used. So while it’s possible that the PIs borrowed from each other, you can’t take it to the bank.”

What? Really? Then what is the purpose of abstracts? Is he saying that the National SCIENCE Foundation is striving to be non-technical? For who? Aren’t the folks applying for grants and receiving them–the folks reading NSF Bulletins–the most technical folks in the world?

And is it not possible to be non-technical without repeating verbatim an abstract? Or is there only one non-technical abstract for all of string theory?

DLS’s ho-hum nonchalance and flippancy is as astounding as the identical abstracts! If not moreso! It’s like a vast car pileup/accident or big building going up in flames and someone standing on the street corner going, “nothing of interest here. Move along now.”

One must wonder how often Bohr, Einstein, and Heisenberg submitted IDENTICAL abstracts. lol!

20. **Peter Woit**
May 13, 2011

Bertrand Gray,

In general, the abstracts that appear on the NSF web-site are not necessarily the original ones written for the grant application, but may have been partially rewritten by someone at the NSF, with the goal of explaining what the grant is about to as many people (taxpayers, congresspersons, etc) as possible. So, in this case it’s not what it might originally appear to be (someone plagiarizing someone else’s language, which is a big No-No in academia), but someone at the NSF maybe self-plagiarizing and re-using language of their own.

Coming up with sensible language explaining why string theory research needs to be funded is not so easy to do once these days, having to do it dozens of times, year after year, is quite a task.

21. **cormac**
May 13, 2011

Hi Peter, I too am pleased to see that first award. Prof Kaiser is both an excellent physicist and historian. I’ve sat in on many of his lectures on the history of 20th century physics at MIT this year and they are superb.
More importantly, I’ve studied quite a few sociological studies of physics by academics who know a lot about sociology but less about physics, and they can reach some very strange conclusions indeed. I think studies like this one, by academics who walk in both worlds, are to be strongly encouraged.

22. **Bertrand Gray**
May 13, 2011

Thanks Peter,

Yes–I was just at my local Tea Party meeting, and thanks to the duplicate abstracts which were authored for us laymen, I think we all finally grasped the beauty and promise of string theory. Some people just need to hear things twice is all, and I think we’ll all be voting for more string theory funding now. 🙂

23. **anon2**
May 14, 2011

The highlights from the long interview by John Horgan which you gave in five years ago for *Not Even Wrong* are now on youtube: http://www.youtube.com/watch?v=ukNbQEq4kEE

24. **David Brown**
May 14, 2011

I have 2 questions about the academic sociology of string theory: Approximately how many string theorists are there? Approximately how many academic positions are there for string theorists?

25. **Roman Oliynyk**
May 14, 2011

Peter, just curious about your opinion on John Moffat’s Modified Gravity. This is one of many attempts on cosmological solution. But it does not pretend to be a theory of everything, and at current level of experimental data it feels to me like one that does not over-reach into wild fantasy land (string theory). Any comments?

Anon, I don't agree with the statement that 'SUSY experts will be among the first to figure out whatever new theory that is to be established'. They sure exercised in esoteric mathematics a lot, but your statement would be correct only if the new theory math was closely related to string theory, which is unlikely.

26. **Peter Woit**
May 14, 2011

David,

As a very rough guess at number of string theorists, about 500 or so have tended to show up at the big annual conference, and that's a sizable percentage of the total. A total number of 2000 is probably at least the right order of magnitude. One problem with this question is that it's often rather unclear these days what it means to be a "string theorist".

Someday I'll write about the latest data, but in recent years in the US very few string theorists have been getting tenure track positions. There are however quite a few postdocs in string theory, but these are temporary jobs. As far as permanent positions goes, I suspect the situation is better in Europe, where hiring is traditionally not so trendy (in the US, string theory is not the trend these days).

27. **Peter Woit**
May 14, 2011

Roman,

In general I'm not that interested in or expert about gravity questions. No opinion at all about Moffat's gravity theory.

There was a time when susy was the hot new mathematical idea and the smartest young theorists were the ones all over it. That was about 30 years ago though. By now, it's an extremely old, very conventional (but not successful) idea that is worked out in detail in all the textbooks. Becoming a "SUSY expert" just requires having spent some time with grad-student level material at some point during the last 30 years. This isn't necessarily an indication that you're going to be an innovator…

28. **Peter Woit**
May 14, 2011

anon2,

Thanks. I pretty much can't stand watching myself or listening to myself, but anyone who wants to hear me say the usual things, at a time of the height of the "String Wars", might want to take a look.

Much more interesting video is now available though, since a correpondent tells me that Graeme Segal lecturing on QFT at Bonn is starting to be available on video. I hope to find time soon to watch and may write more about this after that:

http://www.mpim-bonn.mpg.de/node/3365

29. **Shantanu**
May 17, 2011

BTW I looked at the NSF grants in theoretical gravitat and almost all of them are on binary black hole or black-neutron star simulations along with a few more on LQG.

The Big Bang

May 15, 2011
Categories: Film Reviews

There's a new film out this weekend with a particle physics theme (no string theory), called The Big Bang, starring Antonio Banderas. I figured that it's my duty to cover this kind of popular culture use of particle physics, so went to see the film last night. It took some effort to identify the one screen in New York where it was showing, and the theater contained about 10 people at the Saturday night 8:20 show. If it's showing in your area (only New York and LA I think) and you want to see it on a big screen, better go very soon.

I was going to write a review, and mention as many as possible of the various physics inside jokes that appear, but this has been done better here, where the film is aptly described as belonging to the genre "nerd noir", with a "particle physics fetish" sex scene. The film features an LHC-lookalike built underground in New Mexico, designed to search for the Higgs (God Particle). The sex scene mentioned in the review pairs Banderas with a woman with a bubble chamber event and uncertainty principle tatoos. In the throes of passion she discusses Heisenberg uncertainty, entanglement, and the Standard Model.

There's more about the film here, and Lubos has his take here. Rex Reed really didn't like it, and it's hard to disagree, unless you're a great fan of particle physics camp in movies.

Presumably this will be going more or less straight to DVD in a rather short time.

Comments

1. **Yatima**
   May 15, 2011

   I haven't seen it nor do I plan to but this is a pretty good review, sounds like something straight out of Michael Weldon's "Psychotronic Video Guide".

   [Explanation for that obscure term is here: http://en.wikipedia.org/wiki/Psychotronic_Video%5D

2. **Bernhard**
   May 16, 2011

   Hi Peter,

   Sorry norry really related to Antonio Banderas, but have a look at this:

   http://www.guardian.co.uk/science/2011/may/15/stephen-hawking-interview-there-is-no-heaven

   It contains a heavy amount of hype, multiverse mania, boosted with the traditional misleading statemenets like:

   "Evidence in support of M-theory might also come from the Large Hadron Collider (LHC) at Cern, the European particle physics laboratory near Geneva.

   One possibility predicted by M-theory is supersymmetry, an idea that says fundamental particles have heavy – and as yet undiscovered – twins, with curious names such as selectrons and squarks."

3. **Bernhard**
   May 16, 2011

   sorry, *not really*

4. **Syksy Räsänen**
   May 16, 2011

   Maybe you should add a tag for "Pop culture".

5. **milkshake**
   May 16, 2011

   No tarantino was observed in this experiment.

6. **Peter Woit**
   May 16, 2011

   Bernhard,

   Maybe it's a sign of the times that you can get more accurate information about fundamental physics from a naked young waitress with impressive tattoos while she is having sex than from one of the most famous theoretical physicists of our era.

7. **Bernhard**
   May 16, 2011

   🙂

   And in the meantime the guy is trying to dig some deeper meaning between the lines:

   http://www.guardian.co.uk/science/blog/2011/may/16/hawking-physics

   "To me, it feels as though he is referring to the idea that there are many possible universes and that we can use Darwinian ideas of natural selection to work out which might be most hospitable to life as we know it, and because they are habitable in some sense we value them more highly. That's my best guess, but I have minimal confidence in it being right."

8. **Low Math, Meekly Interacting**
   May 16, 2011

   Duty? Given the reviews, “cover(ing) this kind of popular culture use of particle physics” was apparently the aesthetic equivalent of taking a bullet for us.

9. **Orre**
   May 16, 2011

   Actors, actresses and directors do not age gracefully. They just decay.

   I remember the pain of seen giants like De Niro and Hoffmann in “Meet the Fokkers”, and great Al Pacino and Coppola making fools of themselves in “The Godfather III”.

   I guess a minor talent like Banderas must be in bad need of cash to co-star a movie with the SM… He’s definitely on the way out.

10. **Giotis**
    May 16, 2011

    Ok Hawking makes various controversial statements to attract attention most probably but you have to wonder why the elite of physicists thinks that String-M/theory is the most promising framework of unification and of Quantum Gravity? Hawking has no obligation or personal interest to support M-theory, he didn’t work on the field and has no significant contributions to it; on the contrary judging by his research history you would expect to support other ideas closer to the canonical quantization of GR.

11. **Peter Woit**
    May 16, 2011

    Giotis,

    There are plenty of the “elite of physicists” who don’t think string/M-theory is the most promising path to unification, and even those who say this often only mean that no one has a good idea, with string theory just the least bad.

    I certainly do wonder why Hawking and other very smart physicists have signed on to M-theory multiverse mania. Then again, some smart people do and say stupid things. I’m encouraged that the waitress with the tattoos at least seemed to have the sense to ignore this stuff…

12. **bjm**
    May 16, 2011

    @Orre
    Re: “…Banderas must be in bad need of cash to co-star a movie with the SM…”

    Trying to milk a commercial success (your first two examples) is a lot different than taking a chance with an original, independent production. Maybe the film didn’t work, but there’s no way to know without trying. Thank goodness for those who try.

Hawking and the Google Zeitgeist

May 16, 2011
Categories: Multiverse Mania

Today is the first day of this year's Google Zeitgeist gathering of high-powered world leaders and thinkers (described here, it seems that Google either doesn't believe in having a web presence, or it's a secret one. Anyway, my attempts to Google it have failed). One of the headline speakers is Stephen Hawking, and the Guardian reports that:

> His talk will focus on M-theory, a broad mathematical framework that encompasses string theory, which is regarded by many physicists as the best hope yet of developing a theory of everything.
>
> M-theory demands a universe with 11 dimensions, including a dimension of time and the three familiar spatial dimensions. The rest are curled up too small for us to see.
>
> Evidence in support of M-theory might also come from the Large Hadron Collider (LHC) at Cern, the European particle physics laboratory near Geneva.
>
> One possibility predicted by M-theory is supersymmetry, an idea that says fundamental particles have heavy – and as yet undiscovered – twins, with curious names such as selectrons and squarks.
>
> Confirmation of supersymmetry would be a shot in the arm for M-theory and help physicists explain how each force at work in the universe arose from one super-force at the dawn of time.

They got him to respond to some questions posed in advance, and one of them has the Guardian's Ian Sample puzzled. Hawking's answer to "What is the value in knowing "Why are we here?"" was:

> The universe is governed by science. But science tells us that we can't solve the equations, directly in the abstract. We need to use the effective theory of Darwinian natural selection of those societies most likely to survive. We assign them higher value.

Sample's reaction to this:

> On reading it I had one of those familiar, sinking moments of realisation that my brain is so spectacularly inferior to the interviewee's that all I can do is hold up my hands and say: "Huh?"
>
> At best I might have an inkling of what this means, but I am by no means sure. In this situation, it might take a while to clarify the answer, but other bright minds out there might well be able to unravel it for me and anyone else who might be interested. If you can help, post your thoughts below and put me out of my misery.
>
> To me, it feels as though he is referring to the idea that there are many possible universes and that we can use Darwinian ideas of natural selection to work out which might be most hospitable to life as we know it, and because they are habitable in some sense we value them more highly. That's my best guess, but I have minimal confidence in it being right.
>
> I will do my best to clarify the answer this week.

My contribution to explaining this is that I see two possibilities:

1. Hawking has signed on to Lee's Smolin's ideas about cosmological natural selection.

2. Hawking has realized that once you've decided to trade in science for pseudo-science and head down the Multiverse Mania path, there's no longer any point in worrying about whether what you say makes sense or not, and is behaving appropriately.

Comments

1. **Thomas Barton, JD**
   May 16, 2011

   Perhaps he is prepping in his mind for a laudatory speech to EU bankers and Eurozone types who believe they will survive their own self-inflicted wounds like some Darwinian super-beast. The man may be experiencing the onset of the structural changes in the brains of some elderly men which explains their rapid and vapid and vigorously angry old codger syndrome. I personally think he has been deified for so long that perhaps he believes his eternal consciousness resides in some supermassive black hole.

2. **Bernhard**
   May 16, 2011

   I think option number 2 is more likely. Hawking has thrown in the towel, probably has given up that someone will ever detect his radiation that (according to him) would presumably make him win a Nobel prize. What´s left is make misleading public statements about multiverses and M-"theory"as if they were traditional science. He is responsible for a huge scientific disservice, as people like Sample really think he still has something to say. Pathetic to say the least.

3. **DB**
   May 16, 2011

   History teaches us that spent theoretical physicists, i.e. virtually all over the age of 45 – engaging in speculative musings are rarely worth listening to. They may sell popular books to bamboozle an already bewildered public, but for science, their value for all practical purposes is nil. Indeed they are often Worse Than Useless, since they undermine their own prestige and that of the field they are undermining when they should be providing valuable and inspirational mentoring service to up-and-coming young talent – from where new discoveries invariably emerge.

   Although never as egregious example of this phenomenon as many String Theorists, Hawking has been slithering down the road towards WTU status for some years now.

4. **Chris Oakley**
   May 16, 2011

   I must admit, I cannot see what Sample's problem is. Hawking is losing it, going senile, going off the rails, losing his grip, losing the plot … whatever. What further explanation does he require?

5. **Jeff**
May 16, 2011

Well, my take on this when I read it in the Guardian was initially that option 2 was correct, but rereading it I think it parses like this – sentence 2 refers to "equations" that cannot be solved, I take this to be Hawking saying that science can't tell you why we are here, the equations describing the human condition cannot be solved. Sentence 3 about natural selection is referring to selection between different human societies. Sentence 4 says that people value societies that survive the most, hence those might somehow be the "answer" to why we are here.

Now, even parsed this way it's not like it makes much sense, and it's said in such a way as to make it impossible to tell anyway, so in some sense we're back to option 2.

6. **MarkoB**
May 16, 2011

What Hawking says makes perfect sense. He is talking about natural selection and evolution of human societies. Why are most countries around the world compelled to adopt "the Washington consensus?" One reason is because those who adopt social democratic policies get out competed by more lean and mean free market societies. That kinda remins me of natural selection. I don't see what the multiverse has to do with this quote specifically.

7. **Carlos**
May 16, 2011

Why we are here, in the google's zeitgeist? The universe is governed by science. Read: The universe is governed by scientists, us. But science tells us that we can't solve the equations, directly in the abstract. Read: But we can't solve your problems, directly in the abstract, we want cash. We need to use the effective theory of Darwinian natural selection of those societies most likely to survive. We assign them higher value. Read: The dollar is going the dinosaurs way, give us gold coins. We assign them higher value.

8. **Yaakov Baruch**
May 16, 2011

Carlos – that was funny!

9. **Anonymouse**
May 16, 2011

DB, that statement is worse than idiotic.

Theoretical physicists taken as a whole have had breakthroughs at all points in their careers. Your ageism is simply indefensible and senseless. I hope whatever field you belong to decides to treat its elder members better than you would seem to do, at least by the time you are one of them.

10. **Bourgeois Nerd**
May 16, 2011

Well, I suppose there is option 3: his voice synthesizer had a meltdown.

11. **Peter Woit**
May 16, 2011

To be fair to Hawking, the difficult nature of communication for him surely explains why no one seems able to figure out what he was trying to say in this case (was it about the multiverse, about the nature of human society?). If he could easily write more sentences, that would help disambiguate.

This doesn't explain though why he thinks it's a good idea to use his limited abilities to communicate to give talks to business and government leaders about how the answer to our fundamental questions about physics is the pseudo-science of the M-theory anthropic landscape.

12. **marrakesh**
May 16, 2011

I agree that Prof. Hawking has to be very concise in his answers, and that may make them rather cryptic at times.

On the other hand, it's clear that chemistry, and biology are effective theories of the underlying fundamental theory. Evolution theory could probably be considered as an effective theory of, say, molecular biology.

Obviously, trying to explain chemistry, biology or evolution directly from the SM would be impossible, so we use those effective theories instead.

So, the answer to "why are we here?" should be sought for in evolution theory, not the underlying fundamental theory. I think Hawking's point is pretty obvious.

He probably was trying to say something more about societies, rather than individuals, which seems to me to involve moving up one more rung in the effective theory ladder (maybe sociology is an effective theory of evolution theory?).

But I think that part was partly lost to the mandatory conciseness. Probably just formulating that simple answer took him a good half-hour.

13. **Harry Johnston**
May 16, 2011

The question is so vague as to be pretty much meaningless anyway. If we knew how he had interpreted it, perhaps we'd understand his answer. 🙂

14. **Kurt**
May 16, 2011

It should be obvious from the first sentence of his reply – "The universe is governed by science" – that he is way out of his depth on such subject matter. The universe isn't governed by science, science is our study and resulting knowledge of the universe.

Wasn't it made clear some time ago when Hawking started pontificating on things like aliens and theology that when answering questions outside of physics he has no idea what he's talking about?

15. **Bernhard**

May 17, 2011

Peter,

I think excusing Hawking for his communication limitation is a big problem. He's receiving much of attention and every single word he types has a direct influence on society and this is a responsibility. One could say is difficult for him to express himself clearly but if we assume this, we have to take from him this right of being someone people look up to or as an authority on science matters. If on the other hand we accept he is capable of making meaningful statements via his computer we have to right and to criticize him for what he says as anybody else. No excuses, and I think we even show him more respect doing so. If I believe the following is more or less accurate:

"In the talk, he will argue that tiny quantum fluctuations in the very early universe became the seeds from which galaxies, stars, and ultimately human life emerged. "Science predicts that many different kinds of universe will be spontaneously created out of nothing. It is a matter of chance which we are in," he said."

then I repeat, he's down the road. If he can use his limited speech capability to say such a thing (m-"theory" might predict multiverses, science certainly does not) I have no desire in trying to find any deep meaning in what he's saying. From the very beginning is clear he embarked in the pseudo-science journey, so farewell.

16. **John Baez**
May 17, 2011

I like this quote:

> One possibility predicted by M-theory is supersymmetry, an idea that says fundamental particles have heavy – and as yet undiscovered – twins, with curious names such as selectrons and squarks.

So M-theory makes a prediction after all! It predicts that these heavy and as yet undiscovered particles will have curious names.

17. **chris**
May 17, 2011

the universe is governed by science?

huh???

18. **zomarz**
May 17, 2011

I suppose Hawking is just reasoning in effective theory sense. I think he meant that it doesn't make sense to use particle physics to describe life (too complicate equations with too many variables), but rather one has to use the "effective theory" of Darwinism. In other terms, he found a new way out of the question "about (the meaning of) life?" a scientist is often asked, that cannot be asked within science itself.

And yes, the universe is ruled by science, because it tells you "how", while not "why".

19. **Bernhard**
May 17, 2011

At least now m-"theorists" are discussing in the proper arena (i.e. far away from physics):

http://www.irishcentral.com/news/Christians-angered-by-Stephen-Hawkings-heaven-is-a-fairy-story-comments-121991594.html

"Hawking is happy to discuss the M-theory, in which the universe is said to have 11 dimensions, why then could the universe not have a 12th spiritual dimension?'

This guy seems to be an advanced m-"theorist".

20. **chris**
May 17, 2011

"And yes, the universe is ruled by science"

yeah, about as much as the surface of earth is ruled by google maps.

21. **fairy story**
May 17, 2011

SWH is on CNN now "Heaven is a fairy story", reported by the CNN Religion Editor, no less.

http://religion.blogs.cnn.com/2011/05/17/heaven-is-a-fairy-story-scientist-stephen-hawking-says/?hpt=T2

Then again, back in the 19C, Napoleon Bonaparte famously inquired of the Marquis Pierre Simon de Laplace (who had presented the Emperor a copy of his book on Celestial Mechanics) that Laplace's book nowhere mentioned the Almighty. Laplace equally famously replied "Je n'avais pas besoin de cette hypothese". (I had no need of that hypothesis.)

22. **Peter Woit**
May 17, 2011

fairy story,

I guess it's a good thing that Hawking has decided to go on about religion. Everyone then just pays attention to this and ignores the business about M-theory.

23. **Bernhard**
May 17, 2011

Ignore the business of m-string-theory is unfortunately not going to happen soon. It seems now, ST is an alternative to the Higgs or something like that:

"Theories have been suggested as alternatives to the Standard Model that do not require a Higgs boson.

One of the leading ideas is string theory, which proposes that elementary particles are not 'points' but 'strings' with curled up higher dimensions."

http://www.dailymail.co.uk/sciencetech/article-1388086/God-particle-likely-end-year.html?ITO=1490

24. **Claudio Corbetta**
May 17, 2011

I was at the Zeitgeist this afternoon and listened to Professor Hawking presentation. I had not read his latest book in advance and it came quite as a shock/surprise to see that he unmistakenly said "I believe we have a final answer, it is M-Theory and I believe this theory is right". I am quite familiar with Lee Smolin's ideas and there was definitely no hint whatsoever to cosmological natural selection. By the way, by the sounds in the audience it was quite clear that there was more compassion than attention or interest in what Professor Hawking had to say. On the positive side there he praised data driven cosmology!

Professor Hawking video is not up yet but if the organisers publish it it will be found here http://www.youtube.com/user/zeitgeistminds

25. **Peter Woit**
May 17, 2011

Claudio,

Thanks, although that's rather depressing news.

While some string theorists embrace the M-theory anthropic landscape as an excuse for not admitting failure, I can't help thinking that in Hawking's case the unconscious motivation is that he wants to feel that he has found a final theory before he passes away. This is the ultimate final theory, it says that the laws of our universe are essentially random artifacts of an array of solutions so complicated we can't really analyze them and compare the results to what we see. Signing on to this is doing what David Gross accurately described quite a few years ago when this started: giving up. Maybe someone should read Churchill's speech to Hawking to give him some inspiration…

26. **imagine**
May 17, 2011

What did John Lennon/Imagine say? Who needs heaven?

"Imagine there's no Heaven
It's easy if you try
No hell below us
Above us only sky
Imagine all the people
Living for today "

27. **Cosmonut**
May 17, 2011

I agree with Claudio.

After two decades of making grandiose proclamations about being on the verge of "complete understanding of the Universe", Hawking seems to be having trouble digesting the fact that the unified theory is nowhere in sight, and when its found, his name won't be on the discovery.
So, he keeps pretending that it has either already been discovered, or it never will be.

Hawking's latest popular book, "The Grand Design" is a good example.

He starts off by saying that there *is* no unified theory – only multiple observer-dependent theories (whatever that means).
Then he contradicts himself by saying that
M-theory is the unified theory (never mind that nobody knows what M-theory really is).

Then he muddies the waters even further by saying that M-theory predicts that the Universe can spontaneously appear from Nothing
(No way. M-theory hasn't made a single testable prediction. The spontaneously appearing Universe is a pure speculation based on quantum field theory)

That, of course, allows him to bring in God, and make headlines, and also pretend that he has "Explained Everything".

With all due respect, I'd say its time to relegate Hawking to his rightful position of scientific museum relic.

28. **Paul**
May 18, 2011

When was the last time Hawking published a paper?

29. **Bernhard**
May 18, 2011

I just saw this:

http://www.telegraph.co.uk/technology/google/8520033/Stephen-Hawking-tells-Google-philosophy-is-dead.html

"Speaking to Google's Zeitgeist Conference in Hertfordshire, the author of 'A Brief History of Time' said that fundamental questions about the nature of the universe could not be resolved without hard data such as that currently being derived from the Large Hadron Collider and space research."

and at the same time:

"In a 40-minute speech, Prof Hawking said that the new "M Theory" of the universe was the "unified theory Einstein was hoping to find". He compared the idea to the computer programme Google Earth, saying it was a "map" of theories, but added that a new, bigger Hadron Collider the size of the Milky Way was needed to collect more data to prove it. "

So, at the same time that we need hard data and that philosophy is dead (here he's probably excused for not really knowing what he's talking about anyway) what comes to the rescue is a theory that makes no predictions and that we have no idea to extract anything meaningful or to get any of the hard data he himself claims is needed.

Hawking must be really sad to see he will die not knowing the truth but this way out is really depressing.

30. **Amateur Scientist**
May 18, 2011

Paul,

The last publication of Stephen Hawking was written by J. Hartle and T. Herzog, and it came out on the 8th Apr. this year, in PRL 106 141302 (2011).

31. **Amateur Scientist**
May 18, 2011

Oops! I meant, of course, that the paper was written WITH Hartle and Herzog, not "by" them. Sorry!

32. **tate**
May 18, 2011

i don't know m-theory from animal magnetism; on the other hand, i find the statements about using science to assign differential "value" to different societies to be extremely creepy. some here have suggested that there is a level of unrepresented nuance to his statement or that he is being imprecise, but i don't see any indication why we shouldn't take him at his word that he believes his own statement (except for wishful thinking). why should anyone read this as anything other than an explicit endorsement of eugenics?

also, if science was vested with the exclusive right to "value" certain societies over other societies or certain individuals over other individuals–based on whether they are "likely to survive"–would we have had a stephen hawking in the first place?

and does no one else here see the problem with hawking making such statements to elite members of government and the private sector?

33. **Nabla**
May 18, 2011

No.

Just wrong key. Hawking sent his answer number two, to Ian's question number three.

34. **ObsessiveMathsFreak**
May 18, 2011

Has anyone considered the possibility that Hawking is not in fact "writing" these speeches at all? He's 69 and in pretty bad shape anyway. There have been several cases of carers of highly disabled people effectively writing their words for them. I know nothing about the professors current condition, but the paragraph quoted seems too incoherent to be written by someone with or without their faculties.

35. **speeches**
May 19, 2011

Even if someone else writes the speeches, Hawking has to approve them. One can hardly proclaim "Heaven is a fairy story" to an international audience and not realize that it will grab headlines.

36. **Claudio Corbetta**
May 19, 2011

Hi again,

by the way the original video has been uploaded, so you can all see by yourself the presentation and the speech

http://www.youtube.com/watch?v=r4TO1iLZmcw&feature=player_embedded#at=124

Regards

Claudio

37. **Peter Woit**
May 19, 2011

Thanks Claudio,

I'm watching the video, it really is appalling. Hawking attacks philosophers as not knowing anything about modern science, then goes on to aggressively promote pseudo-science and make misleading claims about testing M-theory about at the LHC. Very sad.

38. **Peter Woit**
May 19, 2011

Just finished watching the video, and, as the video showed the audience I noticed something about the Google Zeitgeist: women aren't part of it. Besides the woman in charge of taking care of Hawking it looked there were just a handful of women in a room of a couple hundred people, with none of them in the front rows.

39. **Giotis**
May 19, 2011

Be careful Peter, by using the word appalling some may think that you refer to his physical appearance which I don't think is the case.

40. **Fallen Angel**
May 19, 2011

I don't know what's the big deal. Everybody know that heaven actually IS a fairy tale.

Now, are they going to forbid Hawking from entering the US like they did with Bertrand Russell ?

41. **spirit of russell**

May 19, 2011

When was Bertrand Russell denied entry to the USA? Russell was resident in the USA during WW2, and was appointed as a professor at City College in New York in 1940, but it was annulled on the grounds that he was "morally unfit". Look it up, it's a famous case.
Russell also participated an anti-Vietnam war marches in the 1960's. He was in his nineties when he did that.

Paul Erdos was denied a reentry visa to the USA.

42. **lun**
May 19, 2011

Actually, the M-theory multiverse, together with Poncaire cycles, makes the existence of the after-life inevitable precisely because our branes are computers with a finite amount of degrees of freedom.

All string theory needs to become a true religion is an afterlife, and Hawking might be trying to fill gaps 😀

43. **cycles**
May 19, 2011

If the Multiverse is indeed ruled by Poincare' cycles, then surely we must all return to our origins, and be reborn in eternal cycles? So Hawking may indeed be correct that "Heaven is a fairy story". Is Hawking also a Hindu?

44. **D R Lunsford**
May 19, 2011

Attacking philosophy this way was patented by Feynman, but apparently the patent has expired.

And you are right Peter – the only word is appalling. Any sympathy one feels is erased by contempt for the disservice done to what once was called "natural philosophy".

-drl

45. **Peter Woit**
May 19, 2011

drl,

If you've just discovered how to make sense of QED and do calculations in it, you quite reasonably could taunt philosophers for not keeping up with you. If on the other hand, you've just announced that an empty bit of pseudo-science is the grand-unified theory of everything, you might want to not abuse philosophers, who could teach you a thing or two.

46. **bonk**
May 19, 2011

To Hawking's credit, his Brief History of Time is much worth reading than any of latest books by Greene or Sussikind. It has a wide range of topics, with only the last 4 chapters being complete speculation (which still presents a very physical picture).

47. **willi**
May 28, 2011

I think it's bad if one of either stientist has more importance in science than other scientists. It's nothing bad done by Hawking, but it's not good for science. He can be manipulated. People look up to him and too much importance is given to his speech. Every word which is left from his mouth can change air in science world. For example Einstein has done great theories of relativity / and Hawking has made a lot of good theories too. Einstein "has a very forceful word" in science in that time as Hawking now. Einstein thought Quantum Theory is wrong and now it's one of the best teories we have. Hawking can do the mistake too and can be inteligent how you want…. Some people think that everything what Hawking said is holy right….that's bad!

48. **Anon**
May 29, 2011

Willi, Einstein did not say that Quantum Mechanics was "wrong". His objections regarding QM were way subtler than that, and really have never received a satisfactory answer. The best we have collectively been able to do so far, to quote Feynman, has been to admit that "…nobody understands quantum mechanics". To Einstein this state of affairs was, quite rightly, unsatisfactory, and any thinking Physicist today in his right mind would consider that to be to Einstein's credit. It is only certain science journalists who have no deeper understanding of the issue continue to criticize Einstein for it.

49. **willi**
May 29, 2011

Ok. Maybe I used a wrong parable, but my opinions on Hawking and his strong word in science still stay. Do you agree?

Particle Theory Job Market 2011

May 19, 2011
Categories: Uncategorized

By now the hiring season for tenure-track jobs is pretty much over, and for the field of particle theory some idea of the results is available at the Theoretical Particle Physics Jobs Rumor Mill. As has been usual for the last few years, most jobs are going to phenomenologists. Remarkably, it seems that no jobs at all are going to string theorists so far this year. The final number of jobs is yet to be determined, with ten people so far getting job offers. It looks like the total number of jobs in the field will remain at the low level typical of the last three years since the recession hit in 2008.

Erich Poppitz has been compiling statistics based on the Rumor Mill data, and has the results through 2010 here. Job numbers rose to a level of 20-25 jobs/year from 2000-2007, from a low level of 10 jobs/year back in the 1990s. This phenomenon is generally attributed to jobs becoming available as the generation that was tenured during the huge expansion of universities in the 1960s finally started to retire. The recession has brought those numbers down to 15 (2008), 9 (2009) and 14 (2010). In recent years (since about 2004) he counts about a fifth of the jobs as going to string theorists. If that number does go to zero this year, that would be the first time this has happened since the numbers became available, and I would guess all the way back to shortly after string theory first became popular in 1984-5.

Comments

1. **bonk**
   May 19, 2011

   Is it just my institution? Graduate students here are dying to do string theory rather than phenomenology. I hope the trends are not as misrepresented in other places.

2. **Peter Woit**
   May 19, 2011

   bonk,

   String theory has always been much more popular than phenomenology. Given the choice of working on the theory that unifies all physics and explains the big bang or computing grungy things about parton distribution functions, it's easy to see why this is. At least for the moment though, those willing to work on phenomenology have much brighter job prospects than the string theorists.

3. **phenom**
   May 19, 2011

   Actually almost *anything* (not only ST) is more exciting than phenomenology. Back in the days when I was looking for a PhD thesis topic, the exciting stuff was the magnetic monopole (which is NOT string theory). Phenomenology is (widely perceived, falsely or not) as bread-and-butter work. It's not the path to choose, to stick one's nose in the air and show the world that one is "exploring the unknown" on a "search and discovery" voyage.

   Even if ST is indeed all bunk. All that glitters may not be gold, but at least it glitters.

   FWIW I did not do a thesis on the monopole.

4. **Jeff Murugan**
   May 20, 2011

   http://inspirebeta.net/search?p=find+a+Bringoltz%2C+B

5. **Peter Woit**
   May 20, 2011

   Jeff,

   Yes, Bringoltz is a lattice gauge theorist.

6. **piscator**
   May 20, 2011

   A lot of 'phenomenology' hiring is model building hiring. Proposing sexed-up models of new weak scale physics is not remotely the same as studing PDFs or calculating NNLO processes. Physics where you get to invent the rules ain't grungy. Most of the recent hiring, at least in the US, seems to be in the former than the latter.

7. **nbutsomebody**
   May 20, 2011

   Peter,

   Let me thank you heartily for the job you are doing. Physics in general, high energy in particular, badly needed somebody like you who will expose, explain and highlight various soci-policitc-economic-al dynamics of the field. That's helpful to both physicists and lay people/tax payers equally. Regular journalism is not of much help, as somebody with a fine understanding of scientific issues is needed.

   Sorry for a very general comment !

8. **human mathematics**
   May 20, 2011

   Wow. I'm so glad I didn't go to grad school. TEN jobs?! It seems like every other person I know is trying to go to grad school. Because you can just do quantitative finance or something if you don't get an academic job. Except that's not really true (according to the people who know http://www.nuclearphynance.com/Show%20Post.aspx?PostIDKey=147527) either. It seems the only truth worth knowing for a twenty-something as far as this Big Decision is concerned is that grad school is a treadmill you run to benefit someone else.

9. **Anonymous**

May 20, 2011

I have to say, I agree (more, not completely) with piscator and disagree with nbutsomebody. Almost all of the hires in the last 10 years in the area of "phenomenology" have been "beyond-the-standard model general phenomenology", meaning that the BSM is the common denominator, but the actual expertise in phenomena ranges from collider to astroparticle/dark matter. Sure, Erich's data aren't sorted this way, but if you just peruse the archives of the rumor mill, it is evident.

Piscator is absolutely right that there is nothing very grungy, and certainly nothing bread and butter about the BSM enterprise. I think for many students, catching the LHC wave and being the bright young theorist who "figured out the LHC discoveries" is pretty sexy. Now if we would just make some of those…

10. **else where**
May 20, 2011

You are only looking at the US rumor mill..
if you look at the UK rumor mill, you'll find at least two people who are string theorists with jobs: franco and wecht.

http://pyweb.swan.ac.uk/~pybl/rumours/

11. **Shantanu**
May 20, 2011

Here is a very nice talk which every particle physicist grad student/postdoc must watch. This is heared towards astrophysics/cosmology, but same advice applies to particle physics
http://online.kitp.ucsb.edu/online/colloq/loeb1/

12. **bonk**
May 20, 2011

For a flavor about how current BSM research works, look at this recent comprehensive paper:
http://arxiv.org/PS_cache/arxiv/pdf/1105/1105.2838v1.pdf
Just look at the table of contents. 46 models, mostly highly speculative, are awaiting the verdict from the LHC.

13. **surikata**
May 21, 2011

> Phenomenology is (widely perceived, falsely or not) as bread-and-butter work. It's not the path to choose, to stick one's nose in the air and show the world that one is "exploring the unknown" on a "search and discovery" voyage.

And who says string theory is not bread-and-butter work? Especially after three decades of furious activity on it.

These days working in ST is more or less the same thing as working in any other well-established branch of physics: doing small variations on results already available in the literature.

14. **Physicsphile**
May 22, 2011

Shantanu, thanks for that link to Loeb's talk. It one of the best talks I have ever seen.

15. **Anon**
May 25, 2011

A word in support of what is being called here 'grungy physics' – i.e. Standard Model phenomenology.

It has been commented that

"…. catching the LHC wave and being the bright young theorist who "figured out the LHC discoveries" is pretty sexy. Now if we would just make some of those…"

Quite how anyone thinks we make any of those discoveries without relying on the PDFs and NNLO processes that people seem to find so boring is beyond me.

Look at it another way – as a 'grungy' phenomenologist you get to see your work used by and quoted in all the major experimental papers developing our understanding of the Standard Model and possibly discovering New Physics. BSM model builders however have to develop increasingly exotic models to get noticed, with a vanishingly small probability of being observed. They also have to become expert self-publicists.

Of course they can try the scatter gun approach (publicise lots of models in the hope that one will bear some relation to reality) or they can start ambulance-chasing the experimentalists – either way its not what I would call the makings of a satisfying or useful career. So you have to balance a guarantee of making a big impact on the field as a whole, against a tiny probability of winning a Nobel Prize. Of course if you have sufficient arrogance you will probably make the wrong choice ….

16. **grungy**
May 25, 2011

BSM, phenomenology, grungy, sexy etc ~ these are holdovers from the 70's and 80's. (Approx ~ one can make a case that the attitudes go back much further.) But back when the SM was brand-new, when it had just been put together and shown to be renormalizable, etc, and spectacular experimental confirmation of weak neutral currents, quarkonium, W and Z bosons etc were pouring in, there was tremendous optimism that high-energy physicists knew the way forward. The buzzword was 'unification' (the 'Theory of Everything'). For a graduate student searching for a thesis topic, BSM ideas abounded, and it was sexy to work on any one of them, and there was optimism and respect that one of those ideas might lead to the TOE. Phenomenology, by contrast, was verification of a model (SM) that was already accepted as correct in all its essentials. Not a glamorous path to follow for a thesis. And HEP was basking in (well-earned) glory in those days. There really was a feeling that the 'big breakthrough' (whatever it might be) was just around the corner. So SWH gave his famous inaugural lecture as Lucasian Professor "Is the End in Sight for Theoretical Physics?" ST was part of that wave of enthusiasm. Today, 30 or so years later, the attitudes or prejudices persist, even if the justification wears increasingly thin.

17. **Shantanu**
May 25, 2011

Peter or anyone else,
are there good blogs which discuss most interesting hep-th or hep-ph papers?
Most of the blogs linked on Peter 's blog (by high energy theorists) hardly discuss hep papers anymore. cosmicvariance once upon a time was good. but there are almost

no paper discussions.

18. **Peter Woit**
May 26, 2011

Shantanu,

It does seem odd to me that some of the blogs that used to discuss hep theory papers now rarely do (e.g. Distler, Cosmic Variance). The best that I know of is Resonaances. One suspects that the lack of anything very interesting happening to talk about may have something to do with this.

One blog specifically devoted to arXiv papers is here:

http://www.technologyreview.com/blog/arxiv/

but I have no idea who is writing it (they hide behind the name "KentuckyFC"), and the coverage of hep-th does things like take seriously Bousso-Susskind, see

http://www.technologyreview.com/blog/arxiv/26787/

19. **Tim van Beek**
May 26, 2011

Sometimes it's hard to tell if a post about hep-th is a hoax, a satire, or not. For example, having Peter Woit recommending a blog where people write this about the BS-paper:

> Still, what this new approach does have is a satisfying simplicity– it's neat and elegant that the many worlds and the multiverse are equivalent. William of Ockham would certainly be pleased and no doubt, many modern physicists will be too.

20. **Peter Woit**
May 26, 2011

Tim van Beek,

My comment wasn't really a recommendation, since I don't know anything about the blog author, and their taste in hep-th papers is pretty dubious. I found that blog and the posting I linked to from an arXiv trackback, so the blog is approved by the arXiv moderators, for what that's worth…

21. **rrtucci**
May 26, 2011

I think Susskind is also interested in complexity theory. It's only a matter of time before he extends his theorem from
Thm
multiverse=many worlds
to
Thm
(a)multiverse = many worlds
(b)(multiverse = many world) iff P!=NP

Cosmological Interpretations of Quantum Mechanics

May 19, 2011
Categories: Multiverse Mania

It seems that there's now a new burgeoning field bringing together multiverse studies and interpretational issues in quantum mechanics. Last year Aguirre, Tegmark and Layzer came out with with Born in an Infinite Universe: a Cosmological Interpretation of Quantum Mechanics, which claimed:

> This analysis unifies the classical and quantum levels of parallel universes that have been discussed in the literature, and has implications for several issues in quantum measurement theory… the analysis suggests a "cosmological interpretation" of quantum theory in which the wave function describes the actual spatial collection of identical quantum systems, and quantum uncertainty is attributable to the observer's inability to self-locate in this collection.

Last month there was Nomura's Physical Theories, Eternal Inflation, and Quantum Universe where "a picture that the entire multiverse is a fluctuation in the stationary, fractal "mega-multiverse," in which an infinite sequence of multiverse productions occurs" is invoked and:

> Our framework provides a fully unified treatment of quantum measurement processes and the multiverse. We conclude that the eternally inflating multiverse and many worlds in quantum mechanics are the same.

Most recently, tonight's arXiv listing has Bousso and Susskind's The Multiverse Interpretation of Quantum Mechanics:

> We argue that the many-worlds of quantum mechanics and the many worlds of the multiverse are the same thing, and that the multiverse is necessary to give exact operational meaning to probabilistic predictions from quantum mechanics.

I confess that I'm having trouble making sense of any of these papers. According to Bousso and Susskind, if I want to understand how quantum mechanics describes some simple, local physical system and what happens when I do measurements of it, I need to sign on to the theory of eternal inflation and the multiverse:

> We will offer some principles that we believe are necessary for a consistent interpretation of quantum mechanics, and we will argue that eternal inflation is the only cosmology which satisfies those principles.

In the case of many string theory papers, one's problems understanding their claims could often be attributed to the highly complex and sophisticated mathematical framework involved. These papers are mostly long sections of verbiage, sometimes with pictures. My inability to make sense of them must have some other source…

Update: Lubos has an explanation of the Bousso-Susskind paper: "they're on crack".

Update: I suppose one could have guessed that Sean Carroll would be a fan of this. In his book he argues that the way to understand the second law of thermodynamics and the arrow of time is to invoke cosmology and the multiverse, now he seems happy to do the same thing with the interpretation of quantum mechanics. The ideas seems to be that to understand some local quantum mechanical phenomenon, you need to use cosmology and think about the horizon that is part of the deSitter geometry. I don't find this argument any more plausible than the arrow of time one.

It does seem like this is now being promoted as the hot topic in theoretical physics, with Sean and others organizing a conference partially devoted to this at Perimeter this summer.

Comments

1. **hutom**
   May 19, 2011

   If you quote them correctly, you are lying about the universe.

2. **DT**
   May 19, 2011

   Interesting.

   In an inflationary multiverse, each universe is separated spatially (albeit over a very large distance) so this still theoretically allows one to travel from one bubble universe to another.

   Now since the many-worlds contains the ensemble of all possible scenarios, it is possible that there is a bubble universe where an advanced alien civilization exists and that has the technology to travel betwen bubble universes.

   Let's also assume that their leader is the abducted Elvis Presley. Theoretically Possible.

   Since anything is possible as long as consistent with physics, we should anticipate this alien civilization to travel to the milkyway and start an inter-bubble war that will soon involve planet earth triggering armageddon.

   Of course, one will argue that we may belong to the universe within the ensemble which the aliens never invaded. But since infinite quantities are now allowed in physics, nevermind everyone confuse quantity with the limit theorem, without a doubt this alien civilization will have the ability to replicate itself infinitely to invade all the infinite number of universes within the ensemble.

   But since this will assign a 100% probability to the invasion scenario, this is a complete violation of the ensemble wave function. A case of inifinity over infinity.

   Wow. The things that are revealed to us by the double-slit experiment.

3. **Bertrand Gray**
   May 19, 2011

   Where do I get the feeling that the Wall Street hedge funds funding fqxi are using the same logic, reason, and math as the folks at fqxi?

4. **DT**
   May 19, 2011

Now, with regards to unifying quantum measurement processes and the multiverse, its understanding is a simple derivation of the reformulated Schroedinger Cat.

Imagine an astronaut who is asleep in orbit around planet Earth, which is in a verge of annihilation care-of an anti-matter death-ray using quantum mechanical effects as trigger.

Since there is now a superposition of Earth-still-there, and Earth-blasted-into-smithereens, there is a superposition of gravity as well – a case of gravity being there and NOT there at the same time, which shouldn't confuse the austronaut since he is asleep and unconscious. But since this is not possible (gravity and no-gravity superposition), the gravity wave function will collapse even without direct observation.

This simple analogy with complex mathematical implications tells us that gravity, including quantum gravity is immune to quantum observational effects. Such a brilliant concept is now being applied to inflation theory.

Only Physicists who are confused by the mathematics, like Woit, won't figure this out.

5. **Anon**
May 19, 2011

The real tragedy is that these blathering idiots are occupying the resources that could be so much better spent on the many worthy young physicists who don't have jobs.

6. **also anon**
May 20, 2011

>> when I do measurements of it, I need to sign on to the theory of eternal inflation and the multiverse

as we have learned from Sean Carroll: if you scramble an egg you are a cosmologist.
and as we have learned from Lewis Carroll: We're all mad here.

7. **Guillaume**
May 20, 2011

And you could also mention the would-be modern Aristotle, crackpot David Deutsch and his multiverse-parallelized quantum computer… Seriously, I've just started his latest book (The Beginning of Infinity), it's quite something. And he blames sceptical physicists for having a "bad philosophy"! Hopefully you can find some time to write a review, Peter.

8. **Francis Cornish**
May 20, 2011

Peter, when are you going to review Penrose's fascinating new book, "Cycles of Time"?

9. **Tim van Beek**
May 20, 2011

I'd like to know if there is some consent in the String theory community about the Bousso-Susskind paper: How important is it and what should be done with it?

A kind of review at the nearing end of a long academic career, the kind I understand and really like to read, is this:

* Rudolf Haag: Questions in quantum physics: a personal view

10. **Christian Takacs**
May 20, 2011

I believe there should be a new classification of fallacy in math and physics called "Appeal to Complexity". The way it works is, an argument or theory is proposed that is so complicated that you can't understand it, but since you don't want to look stupid in front of your peers, you nod your head and say solemnly "hmmm, very interesting, very sophisticated, might be possible" which will cover your ass from actually making a judgement you can be accountable for, while at the same time presenting the pretense that you actually understand the argument, thus making you look clever. The only weakness of an "Appeal to Complexity" argument is if someone not ruled by his peer's favor (or a small child) does a sniff test and says "hmmm, It smells like bullshit".

11. **enc**
May 20, 2011

@Christian Takacs: "The Emperor's New Clothes". The story goes exactly as you say and the hero was indeed a small child, who uttered the famous line "The Emperor has no clothes".

12. **anon**
May 20, 2011

If the Lenny from 20 or 30 years ago could travel forward in time, I'm sure he'd tear the modern "multiverse" Lenny to shreds.

13. **Anon**
May 20, 2011

I think it deserves serious consideration whether someone like Susskind wouldn't be a better fit for a humanities department.

14. **Peter Woit**
May 20, 2011

Anon,

I think you're being unfair to humanists. Relatively few of them are on crack.

Francis Cornish,

I've written a review for a popular publication, will write something here when it appears.

15. **Bernhard**

May 20, 2011

I wonder if it bothers these guys at all they´re not doing physcis anymore. “the multiverse is necessary to give exact operational meaning to probabilistic predictions from quantum mechanics.” ???? Really, what is this? I certainly don´t need to know math as good as them to smell bullshit.

This kind of curiosity should not be put together with physics and I think anything related to these multiverses should start having their own space, their on arxiV… And leave the LHC and measurable things for “narrow minded” people who just want to make science in the old experimental fashion way… This is all going too far and I hope the new generations entering physics will understand that what these guys are doing is not bold and forward. Is just not science.

16. **Paul Wells**
May 20, 2011

I think the key question is if this idea makes any new predictions.

If, for example, there was a connection between the cosmological constant and a time-varying behavior of the fine-structure constant that would be interesting. Otherwise I think it is philosophy.

17. **Peter Woit**
May 20, 2011

Tim van Beek,

I suspect that Lubos’s “they’re on crack” reflects the attitude of much of the string theory community. They thank Witten (among others) for discussions about this, I’d be curious to know what he thinks.

18. **maciej**
May 20, 2011

Even in the Everett many world idea the “worlds” have the same physical laws and constants, e.g. the fine structure constant is the same in every “world” of Everett’s concept.

However in the multiverse concept one imagines that the separate “worlds” may have different constants.

Do they comment on that? (sorry for my ignorance not having read their paper).

19. **Mitchell Porter**
May 20, 2011

Bousso and Susskind’s paper became much more comprehensible to me once I arrived at Figure 13 (page 40). I don’t agree with any of these “cosmological interpretations of quantum mechanics”, but at least I can now understand something of how B & S’s cosmology is organized. In Figure 13, you have a big causal diamond on the left, which corresponds to a stable supersymmetric vacuum state in a flat space which lasts forever. Then you have all the little causal diamonds on the right, which correspond to metastable de Sitter geometries in which supersymmetry is broken, and which decay to the supersymmetric ground state in finite time. And the idea is that there is a novel holographic duality (“FRW/CFT”, see 0908.3844) connecting spacelike slices of the eternal supersymmetric geometry with entire histories in the de Sitter patches. So the formula for this paper is “FRW/CFT eternal-inflation cosmology + the dubious philosophy that QM has no meaning unless every experiment occurs infinitely often”.

20. **Anon**
May 21, 2011

Shall this be called “The BS interpretation of Quantum Mechanics”? 🙂

21. **anonymous**
May 21, 2011

It may now be an open question of whether the authors on arxiv write better fiction than those on vixra – it used to be a no brainer to decide this. I guess crack helps in writing fiction..

22. **Crackpotl**
May 21, 2011

Come on, they’re obviously not on crack. That’s a ghetto drug. More likely some sort of organically grown hashish.

23. **srp**
May 21, 2011

I’ve become more and more unhappy with the new marriage of physics and cosmology. They used to serve as a check on one another, but now it seems like whenever people get stuck on one side they pull something bizarre out of the other to move ahead. Trouble with the Big Bang flatness problem? Invent an inflaton field! Trouble with the time reversibility of physical law and the Second Law of Thermodynamics? Appeal to the low-entropy early universe!

24. **bonk**
May 21, 2011

That’s true. Inflation also serves as the solution to the “monopole problem”, a non-existent problem from particle physics.

25. **Zed's dead**
May 22, 2011

> They thank Witten (among others) for discussions about this, I’d be curious to know what he thinks.

Zed’s dead, baby.

26. **Hansi**
    May 22, 2011

    Arxiv should have some filter that papers with a certain number of words versus number of formuas ratio are automatically given to an administrator for refereeing or are automatically rejected.

    Typically, only crackpots publish dozents of pages without even one single, or only very few mathematical formulas.

    It is a typical criteria for crackpot papers not to contain interesting calculations.

    It is a shame, that people like Suesskind are publishing stuff like this.

27. **the next einstein**
    May 22, 2011

    Dear Hansi,

    The notebooks of Faraday and Bohr contained page after page of words, thoughts, and ideas, with nary an equation. Are you calling Bohr and Faraday crackpots?

28. **the next einstein**
    May 22, 2011

    p.s. I do agree that the current crop of Aguirre, Tegmark and Layzeritus papers constitute crackpottery, but it is because the ideas are completely crankish with no physical basis.

    On the other hand, Bohr and Faraday's words reflected a true, deeper physical reality.

    Einstein had a picture of Faraday hanging in his office, next to one of Newton and Maxwell, so Einstein held Faraday in high esteem.

29. **Hansi**
    May 22, 2011

    Certainly, many of the papers of Faraday and Bohr contained only words. And, according to modern science standards, these would be certainly not be mathematical physics papers.

    Remember: the section where postet their nonsense is

    High Energy Physics – Theory

    But a theory does at least imply some degree of mathematisation.

    If they would have postet their nonsense in physics/general or some private homepage, I would not care, because I do not read physics general.

    What Suesskind is doing here is simply to spam the hep/th archive with off topic nonsense..

30. **Anon**
    May 22, 2011

    I don't like the direction this discussion has taken. I think censoring the arxiv would be a very dangerous and unfortunate path to choose.

    I think it is good that this paper was hosted in hep-th. It just makes their embarrassment more public and humiliating in the circles where it counts, which ultimately will serve the interests of real Physics.

31. **Yatima**
    May 22, 2011

    @srp

    "Trouble with the time reversibility of physical law and the Second Law of Thermodynamics? Appeal to the low-entropy early universe!"

    Err… what?

    If you accuse someone of having to "appeal" to a low-entropy early universe you might as well accuse people of "appealing" to the heat pump if they find their fridge in a markedly off-equilibrium temperature upon opening it.

    And who has trouble with the "time reversibility of physical law" which clearly ain't … is this 1910 or what?

32. **Bernhard**
    May 23, 2011

    Anon,

    You have a point and this applies specially for someone like Süsskind who is already famous and one can say used to be a physicist. But I wonder if we want to allow any sort of crakpotish paper in the arXiv with no moderation. Going around the internet you find so many "awesome" theories that is hard to see that physics have anything to gain with all of them populating the arXiv…

33. **chris**
    May 23, 2011

    His name is Susskind.

34. **Anon**
    May 23, 2011

    There is already moderation.

35. **Bernhard**
May 23, 2011

Anon,

that there is already moderation was exactly my point. So hopefully the level of nonsense will not raise even more, otherwise it will start to be difficult to separate the usual nonsense from the sophisticated string nonsense.

36. **Cosmonut**
May 23, 2011

String theorists have long been trying to piggyback on eternal inflation by saying that the many bubble universes predicted by inflation correspond to string theory vacua. As far as I can see, the landscape of and multiverse are quite independent of each other.
The attitude seems to be “the multiverse can’t be osberved, and neither can the string landscape, so they must be the same”.

Now they are trying to go one step further and claim that the landscape, multiverse and many worlds of QM are one.
I can see an attempt at “unification” going on here – just very different from the unification that was promised in the 80’s !! 😉

Agree with Lubos that these guys are on crack. I think they mostly have been for the last decade or so.
The quest to unify physics is increasingly turning into a farce.

37. **Peter Woit**
May 24, 2011

Anon, Bernhard,

Susskind is one of the few respectable physicists I know who has had an arXiv submission rejected on grounds of sheer looniness, see

http://www.math.columbia.edu/~woit/wordpress/?p=63

In general though, if journals are publishing this stuff, prominent people are doing it and endorsing it, and it is the public face of the field (next month Bousso and Susskind are on a program at the World Science Festival here, funded by Templeton), the arXiv can’t reject such things. They reflect the standards of the field, can’t institute higher standards.

Note that one place where they are doing multiverse-related censorship is that they are censoring links to this blog, a policy that seems to have had something to do with me saying mean things about a Bousso/Polchinski article in Scientific American promoting the landscape.

38. **Anon**
May 24, 2011

Peter, that is exactly why discretionary censorship of the arxiv is a bad thing. Those who exercise this discretion have in various known instances shown themselves incapable of controlling their baser political urges. The dictatorial behavior of the emperor of the arxiv is already bad enough. We don’t need more of that kind of thing.

39. **Bernhard**
May 24, 2011

Anon, Peter

Agreed. Maybe the arXiv could create a new category for these kind of papers, because I still think hep-th does not apply. Perhaps hep-mv (for multiverse), since hep-non (for nonsense) would probably offend someone.

40. **Albert Zweistein**
May 24, 2011

How about hep-ut, for untestable. Or maybe hep-ps for pseudo-science? Or hep-pc for Platonic?

41. **oaf**
May 24, 2011

What makes anyone on this blog think hep has a monopoly on silliness?

42. **Albert Zweistein**
May 24, 2011

Of course hep does not, but the offerings at hep sure make the competition look stodgy.

43. **Guillaume**
May 25, 2011

What I find most disturbing is that arxiv seems to have become a substitute to publishing in decent peer-reviewed journals, which is not what it was supposed to be. Maybe it would be a good idea to only accept on arxiv papers that have already been submitted for publication somewhere? I’m sure a lot of garbage would immediately disappear…

44. **chris**
May 25, 2011

Guillaume,

at least in my field (hep-lat) this is not true. preprints with an arXiv number older than 2 years and no journal reference are generally frowned upon and regarded as proven junk. arXiv is very effective and useful just as it is in giving the community a chance to ‘referee’ a paper before it is submitted to a journal.

45. **ark**
May 25, 2011

The arXiv is supposed to be ‘preprints’ so articles are posted before submission to any journal. So one cannot insist that a post has already been submitted to a journal. But it is also true that in some cases the publishers **want** people to also post on the arXiv. For example the proceedings of the Rencontres de Moriond (or will you call them crackpots?). For example for the 2010 Electroweak meeting, the instructions to contributors state in part:

May we also suggest that you submit your contribution to the proceedings as an eprint to the arXiv.org repository.
http://arxiv.org/
This will ensure a long-term web persistence of your paper. Inform us of the submission number to AirXiv, by sending a mail to the secretary (specify that your proceedings are for the Moriond 2010 EW session)

See this link
http://indico.in2p3.fr/internalPage.py?pageId=2&confId=2065

46. **joenobody**
May 25, 2011

Off-topic: perhaps you’ve noticed it already, but there’s a recent paper in Nature about the measurement of the electron which appears to rule out some supersymmetric theories and, according to its authors, could conclusively rule in or out SUSY in general within the next few years, see this
http://www.guardian.co.uk/science/2011/may/25/electrons-round-cosmos

47. **Paul**
May 25, 2011

“Our formal argument hinges on properties of what we term the quantum confusion operator…”

There’s no way THAT could go wrong.

48. **Bernhard**
May 25, 2011

joenobody,

That´s interesting. I would really like to know how much this experiment can disfavor SUSY (and how much it already did), because I find it hard to believe it can “pretty conclusively rule in or out supersymmetry”.

49. **edm**
May 25, 2011

The paper is really about a measurement (or upper limit) of the electric dipole moment (EDM) of the electron. (There seem to be many ongoing or proposed EDM searches.) Many BSM theories yield much larger values for the EDM than the SM value. (Indeed the SM is almost unique in yielding very small values for EDMs of elementary particles.) Many theories of CP violation yield much larger values for EDMs than the SM, and many models were ruled out in the 1982 review by Norman Ramsey
http://iopscience.iop.org/0034-4885/45/1/003

So almost 30 years later, the search for EDMs continues, and the ruling out of BSM models continues. Of course, for SUSY one can tweak the SUSY parameters. But that will also constrain other things (sparticle masses?).

50. **edm**
May 26, 2011

A more precise statement is that the SM is almost unique in that it predicts nonzero CP violation and also small values for EDMs of fundamental particles. Most other models of CP violation also yield much larger EDMs. Experimental searches for nonzero EDMs have ruled out many such models.

51. **Bernhard**
May 27, 2011

I spent my morning trying to digest Sean’s post. Seems the universe is an inverse black-hole like place where light far away can not reach us (or whatever place you take as “central”) and that defines a cosmological horizon. With this you define a notion of “in and out” of this say pocket universe and just like in a black hole to have a complete description you need to know what’s actually inside the observable universe and this has to includes an amplitude for being in various possible states. Now why and how this possible states becomes the many worlds of quantum mechanics I have no idea. He then asks what the consequences are for cosmological initial conditions and the arrow of time. What I on the other hand would like to know is what would be the consequences of this for experimental cosmology, if any. A pure philosophical discussion with very little chances of becoming a discussion of physics.

52. **somebody**
May 27, 2011

“A pure philosophical discussion with very little chances of becoming a discussion of physics.”

The point however is that these are the ONLY chances we have for making progress in fundamental physics. So I would take them, even if they are slim.

Since this seems to be a popular objection to a lot of what goes for as high energy physics (including string theory), let me just clarify a point that I have often seen the proverbial “layman” to miss. This is not necessarily addressed to the author of the quote.

These questions are only “purlely philosophical” in as far as we are NOT able to do experiemnts/observations at high enough energies like the GUT or Planck scale. If we could (for example) do direct observations of gravitational waves from before big bang many of these questions/theories/models will have immediate answers. Even including things like multiverse. So these are possibly physical, yet at the current time technologically inaccessible (at least if we don’t get lucky), questions. You might be not interested in this distinction, but they do exist. If we had a Planck scale collider of course, these questions are DEFINITELY physical questions, but building one is likely technologically impossible at ANY time.

Finally, ANY fundamental question that we are puzzled by at this point in history, is BOUND to be open to this criticism. We understand the understood Universe amazingly well (this is lost oftenh on many people), so what is to be understood is going to quite difficult to experimentally reach! Despite the statements made on this blog, I am not sure there is a much better way to go about unraveling the remaining mysteris of the Universe than our current ones. We are all a bit frustrated we are not living in the haydays of quantum field theory in the late sixties or so when experiments were still accessible, but we got to keep trying.

Our best shot after LHC (Last High-energy Collider?) will be cosmology.

53. **Bernhard**
May 27, 2011

somebody,

I agree with the fact that such discussions have have a certain value, but I repeat that as of today they remain a philosophical discussion, and there is nothing wrong with that. This fact could change and multiverses could even become part of physics, but more than having the experimental apparatus would be needed in order to change this. The problem is not how crazy or not this all sounds. I'm sure when Einstein started to talk about curved space this was taken as crakpot talk by many. The difference is that GR made genuine predictions that could be tested. It's up to the proponents of a theory to suggest how can be tested or falsified.

I ask, even with the galactic collider or even with cosmology, how would anything Susskind and Bousso claim be falsifiable and become as you say a physical discussion? I cannot see how this would be possible, but maybe a just missed it. I'm open to hear the contrary and I it would be exciting to be wrong.

Also, I disagree with you that this is the only way to make progress. Progess will be made by people collecting data, making plots and theorists struggling to understand it. The hope is of course to see some real SM deviations at the LHC and this would be real progress in fundamental theory. I understand some people just can't wait for experiments to reach they favorite physics scenario but with no predictions, no experiments or even suggestions of a test, it remains a discussion beyond physics. The some physics can potentially emerge from this someday, I can't deny, but right now, this is something entirely different.

54. **Christine**
May 27, 2011

There is a simple, but fundamental detail. It is called the "scientifc method".

As a method, it consists of several items to proceed. One of them is experimental verification. The scientist should provide concrete statements on how to prove that a proposed theory will correctly describe observed data or predict certain phenomena. If that is so, the theory can be regarded as a scientific one. Otherwise, it is not a scientific theory. It is called "speculation". The end.

Now, there are only 2 possibilities: 1- people deliberately want to dismiss the scientific method altogether in order to promote their speculative endeavors as some kind of new "science". 2- They do not know what the scientific method is.

Either possibility is disturbing. Specially if they teach to the younger generation.

55. **Anon**
May 27, 2011

It is clear that Bousso and Susskind do not understand the relative state (many-worlds) interpretation. They do not appear to understand the purpose of it, and they /clearly/ do not understand its technicalities. I doubt they even bothered to read the original Everett paper.

56. **Christian Takacs**
May 27, 2011

May I propose that the problem with the Bousso and Susskind (known hereafter as B.S.) model is not of a philosophical kind, it is actually of a logical nature. By demonstration ; A is true because of B. B is not measureable, testible, or predictable until C. C is when a miracle occurs OR some unknown discovery at some unknown time allows B to be measureable, OR when pigs fly. Logic clearly shows that the B.S. model suffers from premature speculation without any kind of verification, and should be given the sniff test before further consideration.

57. **Anon**
May 27, 2011

Are we sure this paper is not a parody? It reminds me of this classic paper by V. Gates et al., maybe from 1985:

http://insti.physics.sunysb.edu/~siegel/parodies/sgs.html

58. **Peter Woit**
May 27, 2011

Anon,

It's more like this one:

http://insti.physics.sunysb.edu/~siegel/parodies/misanthrope.html

I'm pretty sure though that these papers are not parodies. For one thing, they're not funny…

59. **Jeffrey Dunham**
May 27, 2011

http://news.yahoo.com/s/afp/20110527/sc_afp/australiaastrophysicsscience – is this missing matter that is not part of dark matter, or is it saying they found the matter that dark matter was suppose to account for?

60. **Peter Woit**
May 27, 2011

As far as I know this has nothing to do with dark matter. But you really should consult an astrophysicist, not me.

61. **Cosmonut**
May 31, 2011

This seems to be part of a general pseudoscience principle:
X can't be observed/explained, neither can Y.

Hence, X is the same as Y, or X explains Y.

I hereby propose that the multiverse is the same as the many worlds of QM which is also the same as the various spirit worlds proposed by the religions of the world.

Cycles of Time

May 27, 2011
Categories: Book Reviews

Today's Wall Street Journal has a review I wrote of Sir Roger Penrose's new book Cycles of Time. The review is aimed at a much wider audience than this blog, and is the product of substantial editing to get its length down and make it as readable as possible for as many people as possible, so here are some supplementary remarks.

I should make it clear that I'm not at all convinced by what Penrose is proposing. He needs the distant future of the universe to be conformally invariant, and this requires all particles to be massless. As far as we know the electron is completely stable, with unchanging mass, and this will always ruin conformal invariance. Penrose himself notes the problem. For this to be overcome, whatever our ultimate understanding is of how particles get mass must change so that these masses go to zero in the future. It's also seems to me that the conformal anomaly of QCD will always be a problem, with quantization and the renormalization group always breaking conformal invariance and giving a mass scale, indefinitely far into the future.

The other main problem is the one shared by most "pre-big-bang" ideas: how do you ever test them? Penrose and a collaborator last year created a stir by claiming to see in the CMB patterns of the sort he argues might be expected from black hole decays late in an era before the Big Bang, but it's not clear there's a real prediction here, and others who have redone this analysis say they see nothing.

Attempts to get a Big Bang in our future as well as our past generally strike me as motivated by a very human desire to see in the global structure of the universe the same cyclic pattern of death and rebirth that govern human existence. To me though, deeper understanding of the universe leads to unexpected structures, fascinating precisely because of how alien they are to human concerns and experience. Just because we might find a cold, empty universe an unappealing future doesn't mean that that's not where things are headed.

The book is in many ways an unusual document. It includes an extensive appendix working out some of the details of the mathematics of his proposal. In some sense he has managed to get a trade publisher to put out a highly technical discussion of a speculative idea inside the covers of a popular book, instead of going the usual route of publishing this in a refereed journal. The only references I can find to other places where he has written some of this up are to chapters in this book and this one, as well as this contribution to a conference proceeding. The technical idea behind this, that the hypothesis of the vanishing of the Weyl curvature in the early universe leads to possible cosmological models that can be extended past the Big Bang singularity he attributes to this paper of K.P. Tod. There's a nice recent exposition of this by Tod here.

So, I'm not convinced by the speculation about the far future, and for an evaluation of the ideas about extending back through the big bang singularity you'll need someone more expert about cosmology than me. These topics are very clearly labeled in the book as speculative, without support from other physicists or any experimental evidence. The bulk of the book though is other material providing a background and context for the speculation, and it is this which I think makes it most valuable as a popular book. Penrose is a wonderful, elegant and clear writer, and he covers a lot of ground about physics beautifully here. Most remarkable are the illustrations, by far the best visual representations of a range of important ideas that I know of. Physicists and mathematicians work with lots of internal pictures in their minds representing important aspects of the concepts they are investigating, but very rarely do they have the technical skill to grasp some of the essence of these pictures and get them down on paper. Even more rarely do they make it into wide distribution in print, so I'm glad to see that happen here.

Comments

1. **manyoso**
   May 27, 2011

   Thanks for the review! This will definitely be going on my reading list!

2. **Rich C**
   May 27, 2011

   Penrose makes another testable prediction in the book though, doesn't he? He argues that the correlations in the microwave background should not extend past 60 degrees, for reasons that I sort of thought I understood when reading the book but can't articulate now. As there is a wealth of new data on the CMB coming in now and expected in the near future, wouldn't this also potentially provide either falsification or support for his speculations?

3. **Philip Gibbs**
   May 27, 2011

   I don't see why there would be electrons left. Negative and positive charges are perfectly balanced in the universe as far as we can tell, so if the electron and positron are the only stable charged particles then eventually they will come together and annihilate.

   The theory may have other problems, such as those you mention, but I think it is right for physicists to speculate in this way. It is only by thinking along the lines of such crazy ideas and seeing where they lead that we can figure out what are the consistent possibilities.

4. **Peter Woit**
   May 27, 2011

   Philip,

   First you have to get all your protons to decay, then, in an expanding universe I don't see why all electrons and positrons have to find each other. And, if they're just one electron left over, you're not conformally invariant. Besides, the same argument could be made with neutrinos.

   To make this work, it seems to me you need that whatever gives mass to fermions does so in a fashion that goes to zero at long times. Since we don't understand really the origin of these mass terms, in principle it's possible, but it doesn't seem likely.

5. **Yatima**
   May 27, 2011

   From a layperson's perspective, this review hits the mark.

   Public Service Announcement: Well-grounded discussions about what the universe is, is doing or will be doing shall have to be postponed for an indefinite time, though it's always fun to speculate.

6. **D R Lunsford**

May 27, 2011

Peter said “He needs the distant future of the universe to be conformally invariant, and this requires all particles to be massless. As far as we know the electron is completely stable, with unchanging mass, and this will always ruin conformal invariance.”

Well I think the idea is that is gets close enough to conformal invariance that the remaining masses are comparable to fluctuations in the conformal vacuum. It’s almost a way of realizing Mach’s principle. The fluctuation could be thought of as a new Big Bang. I don’t know if this is what Penrose intends, but that was how I rationalized it to myself.

-drl

7. **D R Lunsford**
May 27, 2011

The other aspect of this, is that at the time scales involved, there is not enough happening to define the scale (that’s the conformal scale) without it being disturbed by fluctuations.

-drl

8. **the next einstein**
May 27, 2011

^^^^
“Penrose is a wonderful, elegant and clear writer, and he covers a lot of ground about physics beautifully here. Most remarkable are the illustrations, by far the best visual representations of a range of important ideas that I know of. ”

“There is nothing worse than a sharp image of a fuzzy concept.”
— Ansel Adams

9. **abomb**
May 28, 2011

How it can it be hard to buy the concept that electrons aren’t infinitely stable, .i.e they are only “meta-stable”. We’re already trying to cope with quadratic renormalization problems with theories like super symmetry. How it can be that electrons are genuinely believed to infinitely stable?

Regardless, given infinite amounts of time, are these electrons really a problem?

10. **ZZZ**
May 28, 2011

I find Penrose’s idea interesting. If the lambda-CDM model holds, each remaining electron positron or neutrino would become isolated in its own private observable universe and the total volume of the universe will become exponentially dominated by voids with no matter. Since physical laws and statements are accurate to only finite number of digits, at some point the universe will become empty, i.e. can be described by models with no particles. So I don’t see the electron that would not die as the fatal flaw in this idea. Rather I don’t know whether vacuum fluctuations continue to supply a time scale. The problem with setting the clock by the vacuum is, what’s that clock for?

Also Lunsford makes a valid point in that, if the universe is finally cold, i.e. nothing happens any more, then what defines time? If the time between particle interactions increase exponentially as things fly apart and cool down, then the total number of interactions is finite. So then the universe really does have a rather definitive end. Or is the ticking of the clock really a counter of interactions because a clock must have physical reality? Then, provided that the cooling down happens faster than the flying apart, distances would actually seem to shrink, and the universe would collapse at the final tick.

11. **Chris Oakley**
May 28, 2011

The lack of conformal invariance of the real world is also the reason that Penrose’s Twistors have not made serious inroads into physics. The twistor is a fundamental vector in SU(2,2), a double cover of C(3,1), the conformal group in 3+1 dimensions. Interesting mathematically – and more so than the ISO(3,1) subgroup – but the latter, the Poincare Group is at least a known symmetry of nature.

12. **Marius Buliga**
May 28, 2011

“Physicists and mathematicians work with lots of internal pictures in their minds representing important aspects of the concepts they are investigating, but very rarely do they have the technical skill to grasp some of the essence of these pictures and get them down on paper.”

Almost any paper by Louis Kauffman (btw, one of the first mathematicians exploring topological quantum computing) is amazing in this respect. See
http://www.math.uic.edu/~kauffman/

Another excellent communicator is Jean-Marie Souriau (geometric quantization and many others), see his latest book “Grammaire de la Nature” (in french) here
http://www.jmsouriau.com/

13. **apostolos syropoulos**
May 28, 2011

Intriguing review of an intriguing book!

14. **Rael**
May 28, 2011

But even if electrons completely annihilated with positrons (what positrons, by the way?), as long as there is a gluon field in the vacuum, wouldn’t its dynamics (also known as QCD) dynamically set a mass scale?

We don’t need to have protons in order to have a natural mass scale of ~1 GeV, only gluons and massless quarks are enough for that.

15. **GeorgeDorn**

May 28, 2011

Hi Peter. Could you comment on this perhaps?

http://arxiv.org/abs/1105.5283

16. **cormac**
May 28, 2011

Nice review Peter, just the right balance.
Here's a morsel of trivia: Mum claims that Penrose seriously considered a permanent position at DIAS in the 1970s. He came over, took on look at Dublin traffic and decided no thanks!

17. **Anon**
May 28, 2011

This book perhaps says more about humans than the universe, specifically our panic, as social primates, at the desolation and loneliness of a wound-down universe.

To avoid this prediction, we will do what we can to try to force a square peg into a round hole, which is unfortunately what this looks like to me. Something like Kepler's attempt to relate the orbits of the planets to the platonic solids.

18. **bjm**
May 28, 2011

@Rael: (what positrons, by the way?)

The ones that would come from proton decay. (See Peter's post above).

19. **jpd, MD,PhD,MfA,**
May 28, 2011

its not a sphere, the electric dipole moment was found to be very
very small. for some reason many articles describe this as "spherical electrons"

20. **Philip Gibbs**
May 29, 2011

Peter, Rael, even if the proton is stable at the GUT scale, it is predicted to be unstable through the non-perturbative effects of the sphaleron solution in electro-weak theory. We are talking about very long timescales so any instability is relevant. Another mechanism is the proton falling into a blackhole and any excess charge being reradiated with electrons and positrons most favoured. By whatever means protons will ultimately decay into positrons in equal number of the electrons and the vast majority (if not all) will pair off and annihilate. I think most (or all) neutrinos will be captured in black holes too.

It is true that electrons could become isolated in regions separated from positrons due to the horizon effect of the cosmological constant. This will be rare because once the particles slow down they will tend to attract. Isolated regions will be quite large with a scale determined by the cosmological constant. In this case there will still eventually be other isolated regions of this size in which there is nothing massive, not-even a neutrino.

Does the Penrose theory really require the whole universe to be absent of massive particles or is a causally disconnected region sufficient?

21. **Markus Maute**
May 29, 2011

What do you think about the following statement by Lenny Susskind:

"One of the deepest lessons that we have learned over the past decade is that there is no fundamental difference between elementary particles and black holes. As repeatedly emphasized by 't Hooft, black holes are the natural extension of the elementary particle spectrum."

Doesn't that point to a possible resolution of the problem of the "decay of all masses" ?

22. **Peter Woit**
May 29, 2011

George Dorn,

Looks like the dozens of other bogus "We've found a way to test string theory!" papers chronicled here in "This Week's Hype". I'll be interested to see if the media pick it up, in this case it looks like the author's institutions at least haven't so far issued press releases. My impression is that science journalists mostly now realize that they've been had far too many times by these claims and may now start just ignoring them. Perhaps that's the best thing to do here too…

23. **Yatima**
May 29, 2011

>Does the Penrose theory really require the whole universe to be absent of massive particles or is a causally disconnected region sufficient?

Well, the new C^3 universe doesn't "take off" at the exact moment everything is living on the light-cone. The new C^3 universe is "just" a remapping of the extremely large, fast-expanding and empty old one. If I understand correctly, once only conformally mappable fields living on the light-cone remain the remapping makes *mathematical* sense, but in effect the current universe, right now is already the next one moving towards its Big Bang. So ok, this idea needs some work.

24. **july**
May 30, 2011

A quick question for anyone understanding Penrose's idea. Why does the space is remapped but not the time? In other words, for what reason does Penrose stipulates a series of eons instead of single recycling eon?

25. **Rael**
May 30, 2011

bjm, phillips, OK, there are enough positrons then. I have no trouble with that.

(I'm not sure sphalerons transitions would play a role in a very cold universe, though. They may have played a role in baryogenesis when the temperature was of the order of the electroweak scale or higher, but as the universe cools down they become irrelevant.)

But even if there are no particles left, besides very cold photons getting even colder as the universe expands, the electron mass and the QCD scale are still present in vacuum fluctuations and they would be important at the very low energies involved in a very cold universe. In other words, QED and QCD are far from scale invariant at low energies.

26. **Jess Riedel**
May 31, 2011

I really don't think it's fair to attribute interest in cyclic universes to "a very human desire to see in the global structure of the universe the same cyclic pattern of death and rebirth that govern human existence," any more than it's fair to attribute interest in big-bang-big-crunch universes to, say, ' a desire to see in the global structure of the universe the creation and ultimate destruction of existence as suggested in the bible'. (If you have actual evidence for any non-scientific motivations of Penrose or others, please share it.) I have no particular fondness for any cyclic universe model, but in the abstract they are pleasing simply for the chance that they could remove mathematical discontinuities/singularities.

27. **lun**
May 31, 2011

For your next book review, I highly recommend
"Higher Speculations: Grand Theories and Failed Revolutions in Physics and Cosmology" by Helge Kragh

It is right up your alley, plus a historical dimension; eg, at the turn of the20th century we also had a "theory of everything" which everyone considered correct because it sort of managed to include all observed forces and objects of the world (from electromagnetism to atomic spectra) and was highly mathematically elegant (helping the development of knot theory): The theory of atoms as ether vortices.

28. **Peter Woit**
May 31, 2011

Jess,

"If you have actual evidence for any non-scientific motivations of Penrose or others, please share it."

Actually, all the scientists I've ever met are human beings and have non-scientific motivations of all sorts.

Removing singularities doesn't have anything to do with cyclicity. If you turn the Big Bang into a Big Bounce to avoid a singularity, that doesn't imply the universe will recontract and do it again.

lun,

Many thanks for the suggestion. I'd read his book on Dirac long ago, which was quite good, and look forward to reading this new one.

29. **Jess Riedel**
May 31, 2011

Peter,

Thanks for the response.

"Actually, all the scientists I've ever met are human beings and have non-scientific motivations of all sorts."

Yes, of course. What I mean is: do you have good reason to believe that cyclic-universe proponents are *significantly more* swayed by such motivations than proponents of mainstream cosmologies…other than just the fact that cyclic models aren't the dominant paradigm?

"Removing singularities doesn't have anything to do with cyclicity. If you turn the Big Bang into a Big Bounce to avoid a singularity, that doesn't imply the universe will recontract and do it again."

Well, fine, cyclic cosmologies are a subset of those which avoid big-bang singularities through a big bounce. How's this for a cyclic-specific benefit: cyclic universe may remove singularities *without* producing infinite spacetime volumes (by making time periodic), thereby avoiding problems choosing measures with which to compute observation probabilities.

Again, I'm not arguing for cyclic models. I'm just offering off-the-cuff reasons why someone might reasonably prefer cyclicity to a big bang.

30. **Peter Woit**
May 31, 2011

Jess,

My comment about the aesthetic appeal of cyclic models was really nothing more than that, an observation that many people seem to find them aesthetically appealing (from what I remember, Bojowald's recent book had some explicit discussion of this). This isn't an argument for or against such models (including Penrose's), or a claim that some people are subject to unscientific behavior and others aren't.

31. **Allan Rosenberg**
May 31, 2011

Peter,

I thought the way you suggested that Sir Roger has, perhaps, progressed past his use by date was very well done. Anyway, I don't blame him for the wild speculation, I blame the microtubules in his brain.

32. **july**
May 31, 2011

>A quick question for anyone understanding Penrose's idea

It seems no one here fits the description. ^^

33. **Lee Flight**
May 31, 2011

Penrose covered much of the material in the book in a recent talk at the PI: http://pirsa.org/11040063/

I saw him give much the same talk live a few weeks ago, he was very open about some of the issues with his approach, the fate of matter fields "you can take it or leave it". There is also his willingness to lose information in black holes which seemed a bit odd to me as a main driver in his book was to reflect on the second law of thermodynamics and it seemed like the evolution of the left-hand side of the Boltzmann entropy formula (S) was of paramount importance to his thinking and yet the right-hand side (logW) not so much. Any how I thought the book worth the price just to read him on conformal diagrams.

34. **Peter Woit**
May 31, 2011

Allan,

I'm sorry to hear that you interpreted my review that way, it's not at all what I think or intended to convey. The idea put forward in Penrose's book is quite speculative and has problems, and he says as much himself. But it's far more lucid and sensible than the kind of speculative nonsense involving multiverses that is is now highly popular among prominent physicists less than half Penrose's age. If I wanted to classify books about fundamental physics aimed at the public in recent years by degree of apparent brain damage of the author, Penrose's is definitely on the low end of the neurological problem scale.

35. **Anon**
May 31, 2011

Just to add into this conversation, Penrose also ties his CCC ideas into his Orch-OR ideas in his latest paper on consciousness with Hameroff:

http://journalofcosmology.com/Consciousness160.html

From towards the end:

"The recently proposed cosmological scheme of conformal cyclic cosmology (CCC) (Penrose 2010) also has some relevance to these issues. CCC posits that what we presently regard as the entire history of our universe, from its Big-Bang origin (but without inflation) to its indefinitely expanding future, is but one aeon in an unending succession of similar such aeons, where the infinite future of each matches to the big bang of the next via an infinite change of scale. A question arises whether the dimensionless constants of the aeon prior to ours, in the CCC scheme, are the same as those in our own aeon, and this relates to the question of whether sentient life could exist in that aeon as well as in our own. These questions are in principle answerable by observation, and again they would have a bearing on the extent or validity of the Orch OR proposal. If Orch OR turns out to be correct, in it essentials, as a physical basis for consciousness, then it opens up the possibility that many questions may become answerable, such as whether life could have come about in an aeon prior to our own, that would have previously seemed to be far beyond the reaches of science.

Moreover, Orch OR places the phenomenon of consciousness at a very central place in the physical nature of our universe, whether or not this 'universe' includes aeons other than just our own. It is our belief that, quite apart from detailed aspects of the physical mechanisms that are involved in the production of consciousness in human brains, quantum mechanics is an incomplete theory. Some completion is needed, and the DP proposal for an OR scheme underlying quantum theory's R-process would be a definite possibility. If such a scheme as this is indeed respected by Nature, then there is a fundamental additional ingredient to our presently understood laws of Nature which plays an important role at the Planck-scale level of space-time structure. The Orch OR proposal takes advantage of this, suggesting that conscious experience itself plays such a role in the operation of the laws of the universe."

36. **Peter Woit**
May 31, 2011

Anon,

Thanks, that journal looks pretty peculiar and crank-ridden. I've no idea what Penrose is up to with getting involved with them or what his current ideas about consciousness are, he keeps that quite separate from his cosmology work. I don't recall seeing anything at all about any of this in either his book or the talk on the subject I attended a while back.

37. **ArchBishopofCanterbury**
June 1, 2011

You are the first to report about all the negative things, reports about the alleged rise of string dictatorship etc etc etc. However, when there is anything interesting going on the field like the fermi lab anomaly you dont have much concrete to say. This makes me really sad and also suspicious of you. I wonder if you really have anything to say about anything that matters.

38. **Peter Woit**
June 1, 2011

ABC,

Well, I'm right in the middle of writing a new posting, and was just writing about the CDF news. Not to get anyone's hopes up, mainly I was just pointing to the postings by Jester and Tommaso Dorigo. In general, when a topic is being well covered by other bloggers, I don't see much point in my going on about the same thing. Very often, on the latest news about some experimental data, the two of them do an excellent job of covering the topic from both the experimentalist and particle theory phenomenologist point of view. I wish I could compete and provide something better than them, but that's rarely the case.

39. **John Baez**
June 2, 2011

Jess wrote:

(If you have actual evidence for any non-scientific motivations of Penrose or others, please share it.)

Since nobody else is doing so, I'll come out and admit that the idea of a cyclic universe always appealed to me, just because it seems depressing to think the universe will just fizzle out in a heat death. The idea of a phoenix-like "death followed by rebirth", and another chance at a universe with no Sarah Palin, seems a lot more pleasing.

However, like plenty of scientists, I'm sensible enough to recognize that the universe isn't necessarily the way we'd like. Right now the evidence seems to favor an eternal and increasingly boring and chilly future – a scenario I explore in my page on [The End of the Universe](). Anyone who places a lot of stock in perpetual progress, or the notion that the future makes our present actions worthwhile, has got to think about this scenario and consider recalibrating their value system.

However, it's also important to remember that there's a lot we don't know about physics, and predictions of what will happen in, say, 10^(10^26) years are incredibly un-robust: changes in our understanding, or even more careful calculations based on the physics we already know, could change these predictions dramatically.

(10^(10^26) years is one estimate I've seen for how long it will take for the Earth to quantum-tunnel into becoming a black hole.)

So, besides avoiding a value system where the worth of our actions today depends heavily on their consequences in the far future, it's probably also good to avoid a value system where the worth of our actions depends heavily on calculations that could easily be wrong.

40. **Rael**
June 2, 2011

> (10^(10^26) years is one estimate I've seen for how long it will take for the Earth to quantum-tunnel into becoming a black hole.)

But, by then, the Earth will have long ceased existing.

> Anyone who places a lot of stock in perpetual progress, or the notion that the future makes our present actions worthwhile, has got to think about this scenario and consider recalibrating their value system.

I think you're mixing two completely different time scales. Our values are based on a human time scale (decades, centuries, or even a few milennia), and that's as it must be. The notion that we should recallibrate our values because the Universe will be cold and lonely in 10^(whatever>9) years seems to me a form of millenialism.

41. **John Baez**
June 6, 2011

Rael wrote:

Some people seem to think that it's important that things keep getting better *forever*. I'm saying that there's no reason to think that, so we should avoid a value system where the worth of our actions today depends heavily on their consequences in the very far future.

Maybe I should give you an example of the people I'm talking about. To take an extreme case, there's [Frank Tipler]():

> According to Tipler's Omega Point cosmology, for the known laws of physics to be mutually consistent it is required that intelligent life take over all matter in the universe and eventually force the collapse of the universe.

42. **Rael**
June 6, 2011

Oh well, in that context your point seems perfectly sensible to me. But, boy, what a context!!

43. **Tony Smith**
June 6, 2011

John Baez said
"… we should avoid a value system where the worth of our actions today depends heavily on their consequences in the very far future …"

which reminds me of the "corporate finance" guy who, when evaluating projects for building civilization, asked
"… what is the net present value of these projects? …"

in Abstruse Goose at abstrusegoose.com/363

Tony

44. **John Baez**
June 7, 2011

Hi, Tony. it's interesting to think about the whole idea of how the future matters less and less to us as it recedes into the distance… and how what counts as the "far future" depends on who you're talking to. For some "corporate finance guys", the far future might be 5 years from now. But for me, if I had to pick, I'd say it begins when the human race is about twice as old as it is now. We should at least try to do things to make it likely that we'll be around as long as we've *been* around.

The idea of [hyperbolic discounting]() is one attempt to inject some sanity into discussions of how much we value the future.

Quick Links

June 1, 2011
Categories: Experimental HEP News, Uncategorized

- The big news of the past couple days has been the release of more data by CDF which continues to show a bump in the invariant mass of two jets produced with a W. Resonaances gives an excellent description of this and its possible significance. Tommaso Dorigo remains a skeptic.

  I can't do better than the two of them on this story, but here's my summary take on the situation:

  With the new data, this can no longer be written off as a statistical fluke. 3 sigma you can argue away as such a fluke, but not 5 sigma.

  The main reason to be skeptical though hasn't been the statistical significance, but the possibility that this is due to bad modeling of the background. The signal is being extracted from a huge background, so a small misunderstanding of the background could be its cause. If this is the case, the new data changes nothing, you expect to continue to see the effect as more data is analyzed.

  The fact that Tommaso is a skeptic carries a lot of weight, since he works on the CDF experiment and understands the problems well. In general, experimentalists want the experiments they work on to make great discoveries, so tend to be optimists about their own results. When someone is skeptical about a result of their own experiment, that should give one pause.

  What would really make the case for new physics here more compelling would be if the result is confirmed by one of the other experiments (DO at Fermilab, CMS or ATLAS at the LHC) that should be able to see the same effect if it is there. These groups have a certain motivation to not just confirm their competition's discovery (raising the question of why they didn't find this first), but to convincingly shoot it down. This posting by Pauline Gagnon of ATLAS says that they see nothing in their 2010 data. One expects that D0 is hard at work and should soon release whatever they have found. ATLAS and CMS should also be hard at work looking at the much larger 2011 data samples. We'll know soon the results, but the public comments of Dorigo and Gagnon don't sound to me like those they would be making if they knew their experiments had preliminary confidential results confirming the CDF anomaly.

  Finally, while there are lots of theory papers out already with supposed models explaining this, none are really compelling. This is not an experimental result with an obviously attractive theoretical explanation.

- Abstruse Goose has commentary on SUSY here.
- In gossip of the mathematics world, it looks like Princeton (the IAS) has stolen away number theorist Richard Taylor from Harvard.
- Video of Graeme Segal's Felix Klein lectures this spring at Bonn on quantum field theory are now available, and well worth watching.
- Other interesting video available is Greg Moore's lectures on geometry, topology and QFT at Rutgers last fall.
- For pictures from this years Physics of the Universe Summit, see here. Any info beyond the transparencies caught in the pictures seems to be private.
- The journal Foundations of Physics will be putting out an issue on "Forty Years of String Theory". So far articles intended for this have appeared on the arXiv from Dean Rickles, Steven Gubser, and, last night, Steven Giddings. The Giddings contribution is entitled Is string theory a theory of quantum gravity?, and provides an unusually hype-free discussion of the relevance of gauge/gravity duality to hopes to use string theory to understand quantum gravity, writing:

  > While string theory addresses some problems of quantum gravity, its ability to resolve these remains unclear. Answers may require new mechanisms and constructs, whether within string theory, or in another framework.

Comments

1. **X**
   June 1, 2011

   I'm not following the phenomenology too closely, but I liked the technirho: http://arxiv.org/abs/1104.0976 Do you know what the major criticisms of that suggestion are that make it not "an obviously attractive theoretical explanation"? It would also explain the absence of the Higgs and presence of EWSB in terms of (relatively) known mechanisms.

2. **Peter Woit**
   June 1, 2011

   X,

   I'm no expert on this, would love to hear from someone who is. In particular, I'm curious to know if this kind of technicolor signature is something that was investigated before the CDF result. My uninformed impression is that this wasn't an obvious thing to expect to see with this kind of cross-section.

3. **P.**
   June 1, 2011

   Well, such technicolor inspired resonances are being searched for. They have their own entries in PDG, and also on p. 138 in Viviana Cavaliere's thesis you can find a related plot. I think Peter is right in that one would expect somewhat smaller cross sections for this channel (actually the cross section obtained in 1104.0976 is on the lower end of what is compatible with the CDF excess).

   One reason technicolor is not considered an "obviously attractive theoretical explanation" is that technicolor models tend to be in conflict with a lot of other experimental constraints, in particular flavor physics and electroweak precision tests. But many of these things are very hard to actually calculate, so maybe it does work.

   Cheers

4. **anon.**
   June 2, 2011

   I think that if you had asked technicolor advocates, at almost any point in the last 10 years, at what mass scale they would expect techni-resonances to show up, they would have tended to give you answers much larger than 150 GeV. Even if this state is supposed to be lighter because it's a techni-pion, it would be coming from something at 300 GeV or so, which is *still* lighter than any TC advocate would have expected. This scenario — an s-channel resonance decaying to a W plus another resonance — would definitely be a "who ordered that?" moment for the field.

   Electroweak precision and precision flavor physics results are still incredibly difficult to reconcile with technicolor, and most attempts to do so amount to putting lipstick on a pig. Even if the result holds up and proves to be a new s-channel resonance, interpreting it as being related to technicolor would be a real stretch, one not (so far) justified in any way by the data itself.

5. **Bernhard**
   June 2, 2011

   Peter,

   About Giddings article… One sentence on the very beginning caught my attention:

   “Specifically, string theory naturally regulates the infinite proliferation of ultraviolet divergences in the loop expansion, and, order-by-order in perturbation theory, apparently gives UV finite scattering amplitudes.”

   I´m interested in the “apparently”… Do you know how certain anyone is of this claim? It´s hard to believe one can get “nice”cross-sections out of ST, but perhaps I´m wrong…

6. **Peter Woit**
   June 2, 2011

   Bernhard,

   The situation with finiteness of multi-loop superstring amplitudes is kind of murky, and during the “String Wars” for some reason I ended up getting into long arguments about it, which you could probably find on my blog, Jacques Distler’s or Clifford Johnson’s. One of my colleagues at Columbia, Phong, is one of the experts in the subject. He and Eric d’Hoker (who I went to grad school with) have shown finiteness at two-loops, in a calculational tour-de-force. The technicalities involved are fearsome. As far as I know, neither they nor anyone else has conclusively shown finiteness at 3 loops or above. One reason this story is complicated is that there are several different possible formalisms to use in the superstring quantization, with different technical problems. The claims made from the early days that string had to be finite at any number of loops could be described perhaps as plausibility arguments.

   To be fair to string theory, you certainly can compute amplitudes perturbatively at the first couple of orders, with very pretty and interesting results (which have little to do with HEP as far as we know…). Of course, the full perturbation series is divergent, you need some non-perturbative formulation to get something fully consistent.

   In any case, what Giddings is claiming is that this is all irrelevant, that the real problem is not UV finiteness of perturbation theory, but the infrared and non-perturbative behavior.

7. **Igor Khavkine**
   June 2, 2011

   Question for anyone who has watched Graeme Segal’s lectures. Is there anything particular in his lectures that is worth paying attention to? For instance, which, if any, of his comments are particularly new or particularly clear summaries of what’s already known? For the record, having watched the lectures, I found it hard to figure out an answer to these questions. I do have to admit a certain bias in my theoretical interests, which have so far stayed clear of 2-dimensional, topological, Euclidean QFTs, which might have been a drawback.

8. **Peter Woit**
   June 2, 2011

   Igor,

   One thing worth paying attention to is Segal’s treatment of the relation between the Minkowski and Euclidean formalisms of QFT (he treats this by doing analytic continuation on a space of metrics, not in physical or momentum space as is conventional). Even if you think you’ve never deal with Euclidean QFTs, you probably have, since in order to make calculations well-defined you generally have to do this. This is a fundamental issue about QFTs, and Segal is one of the few people I know who has tried to think it through clearly.

This Week's Hype

June 1, 2011
Categories: Multiverse Mania, This Week's Hype

The latest New Scientist has a much larger dose of M-theory/multiverse hype than I've seen in one place in quite a while. There's a four-part series on M-theory (here, here, here and here) by Mike Duff. It tells the story of the progress of modern physics over the past century according to the dominant ideology: general relativity, Kaluza-Klein extra dimensions, super-symmetry, superstrings, branes, ending in the apotheosis of M-theory more than fifteen years ago. For the current state of affairs, Duff describes his "M-theory" predictions about the real world (that 4 qubits can be entangled 31 different ways, something discussed here). He ends with the M-theory multiverse and the following comments on whether this can ever be tested:

> So is M-theory the final theory of everything? In common with rival attempts, falsifiable predictions are hard to come by. Some generic features such as supersymmetry or extra dimensions might show up at collider experiments or in astrophysical observations, but the variety of possibilities offered by the multiverse makes precise predictions difficult.
>
> Are all the laws of nature we observe derivable from fundamental theory? Or are some mere accidents? The jury is still out.
>
> In my opinion, many of the key issues will remain unresolved for quite some time. Finding a theory of everything is perhaps the most ambitious scientific undertaking in history. No one said it would be easy.

Here he makes it clear that, at least while he's still around and enjoying academic prominence because of M-theory, there's no danger it will face any sort of test it might fail. He answers critics of M-theory by claiming that its failures don't matter. It's the dominant paradigm, and will reign as such until someone comes up with a different theory of everything that isn't a failure.

Elsewhere in the magazine, there's a fawning article about the recent Bousso-Susskind paper (see here):

> TWO of the strangest ideas in modern physics – that the cosmos constantly splits into parallel universes in which every conceivable outcome of every event happens, and the notion that our universe is part of a larger multiverse – have been unified into a single theory. This solves a bizarre but fundamental problem in cosmology and has set physics circles buzzing with excitement, as well as some bewilderment.

No critics of the idea were located by the writer, with the discussion on blogs described as:

> The paper has caused flurry of excitement on physics blogs and in the broader physics community. "It's a very interesting paper that puts forward a lot of new ideas," says Don Page, a theoretical physicist at the University of Alberta in Edmonton, Canada. Sean Carroll, a cosmologist at the California Institute of Technology in Pasadena and author of the Cosmic Variance blog, thinks the idea has some merit. "I've gone from a confused skeptic to a tentative believer," he wrote on his blog. "I realized that these ideas fit very well with other ideas I've been thinking about myself!"

Somehow Lubos's "they're on crack" take on the subject was missed.

Finally, the significance of all of this is summarized in an editorial which argues that Bousso-Susskind finally pulls the plug on religion and replaces it with science:

> Cosmologists can now begin to take God seriously, precisely because they can explain him (or her) away.

Comments

1. **Anon**
   June 1, 2011

   I think you mean Bousso-Susskind, not Bousso-Polchinski.

2. **Peter Woit**
   June 1, 2011

   Anon,

   Oops, many thanks for the correction, now fixed. My apologies to Polchinski…

3. **Bernhard**
   June 1, 2011

   There was also some little hype here: http://bigthink.com/ideas/38684 (not surprising though, since this is a hype specialized blog).

   I wonder if this new wave of hype is just related to Buosso-Susskind´s paper.

   And I´m surprised nobody yet suggested their paper "predictions" will also be tested at the LHC…

4. **Peter Woit**
   June 1, 2011

   Bernhard,

   It's not completely hype-specialized since they have an interview with me on their site…

   That seems to just be a link to a not-very-good article by an author who got the nonsense from popular science writer Amir Aczel, who got it from physicists who should know better (those promoting the usual "string theory can be tested since there are string theory models with extra dimensions visible at the LHC" hype which has been around since the dawn of time).

5. **Bernhard**
   June 1, 2011

   Really? OK, didn't know that. I got this impression because I often see things like this: http://bigthink.com/ideas/38513

But good to know it was just my bad luck.

6. **Cosmonut**
June 1, 2011

I wonder why they always keep claiming that the multiverse explains God away.
After all if there's an unobservable multiverse out there, there can also be an unobservable God who creates the entire multiverse and keeps creating more !

7. **Peter Woit**
June 1, 2011

Cosmonut,

What I can't figure out is why people who want to fight the science/religion war on the side of science think that giving up on the scientific method and promoting an untestable pseudo-scientific unified theory of the "multiverse" is the way to do it. The behavior of many of these physicists looks every bit as irrational as that of the most fervent religious believer. I don't see how you make a convincing argument to someone that they should trade in their Bible for Bousso-Susskind.

8. **Eric habegger**
June 1, 2011

This newest hype is just another good reason to vote with your wallet and discontinue one's subscription to NS when it comes up for renewal. I did and I've never looked back, plus my blood pressure has been lower ever since. I feel sorry for you Peter that you have to read it just to keep up with the zeitgeist of physics in popular culture.

9. **Allan Rosenberg**
June 1, 2011

Very cute, Bernhard. No doubt their predictions will be tested in some eigenLHC in some eigenuniverse. We just don't know which one it will be.

10. **Peter Woit**
June 1, 2011

Eric,

Stopping having anything to do with popular science media that features multiverse nonsense would mean dropping pretty much all of it. Might be a good idea, but I do need things to write about on the blog.

The bulk of the hype in the latest New Scientist isn't written by them or by any journalist, but by one of the leading British academics in the field. Can't blame journalism for this…

11. **Sean Strange**
June 1, 2011

Thank you Peter Woit. It's nice to hear a physicist point out the crazy hubris of these mathematical theologians. They seem to be trying a little too hard to discredit religion, and the way they pull new theories out of their heads and treat them as scientific facts strikes me as pure mysticism. A true skeptic should reject any group which attempts to be the self-appointed arbiters of truth without evidence, and that includes these multiverse mystics of the scientific priesthood. I don't have a problem with wild speculations about multiverses, as long as they don't call it science or insist that any of it is true!

12. **Anon**
June 1, 2011

What really bothers me is that friends and family members who are laypeople but interested in science keep wanting to talk to me about these "great new multiverse findings", and then I have to be the bad guy and burst the bubble on their sense of wonder.

Oh for the good old days when I was a kid and we had Carl Sagan. We had it good then. We didn't know just how good we had it.

13. **Bee**
June 2, 2011

Ah, but you can now have LQG with SUSY and extra dimensions too: http://arxiv.org/abs/1105.3709

14. **M. Wang**
June 2, 2011

I, too, have noticed the declining quality of popular science media, but I cannot discount the possibility that they have always been filled with Hypes; we may simply have grown old and acquired enough knowledge and wisdom to tell the difference.

Take the latest issue of Scientific American for example. The article, "Planning for the Black Swan" by Adam Piore, claims that the Westinghouse's AP1000 is a Gen III+ design like the pebble bed reactors and will be immune to a Fukushima-type disaster. This is pure baloney. AP1000 is a Gen III reactor, which is basically a Gen II (like the Fukushima) with additional cooling back-up that gives additional 3 days of grace period under blackout before a meltdown. Pebble beds, on the other hand, is a true Gen IV reactor, which is totally immune to melt-down even in principle. Mr. Piore is probably a paid consultant to Westinghouse, but ten years ago I did not know enough to tell. In fact, ten years ago, I probably would have read all the multiverse propaganda with just the faintest unease. Woit's and Smolin's books make all the difference.

15. **Guillaume**
June 2, 2011

So the Busso-Susskind paper has just hit the arxiv, hasn't been published in a journal yet, hasn't even been properly reviewed, but the media are nonetheless showcasing it like it's going to be the next Nobel Prize… Somehow the Rapture craziness doesn't seem so crazy now…

16. **Guillaume**
June 2, 2011

NS "report that cosmologists claim to have found a way to rid themselves of the need for a God-like observer."

Well that's a false problem anyway, as long as you replace the metaphysics of Copenhagen by a materialist interpretation of QM like Bohm/de Broglie/Bell's pilot wave theory.

17. **Aleksandar Mikovic**
June 2, 2011

The reason why many reputable scientist use “unscientific” methods in order to explain everything is due to the fact that scientific method is not sufficient for obtaining/explaining all the features of reality. Simply, there are truths which we obtain without science, and mathematics is the most familiar example. The domain of science are the phenomena which can be tested by experimental tools, and it is clear that this domain is limited, unless you are diehard scientific fundamentalist. The history of the scientific approach to the Universe was to postulate a theory and then to try to test it, but as the domain of the theory grew larger, it was more difficult to test it. Eventually one is forced to use the theories where most of the features cannot be experimentally tested, but this is OK for me, since one is entering in the metaphysics domain, which philosophers have been exploring since Plato.

18. **Anon**
June 2, 2011

You should stop bashing these magazines. They publish hype because hype sells. They are in business and their goal is to make mucho dinero. In any event, real pragmatic scientists like WOit here have not produced any science worth writing about in a long time. The last discovery was the top quark in 1994, I believe. So produce new stuff or shut up. By your reasoning all these mags should have been out of business for the last 16 years or so.

19. **Christine**
June 2, 2011

The history of the scientific approach to the Universe was to postulate a theory and then to try to test it

History shows the contrary.

From *observed* phenomena, elaborate a theory that correctly describes the phenomena. Eventually, the theory may lead to the prediction of new phenomena.

The only theory that I know of which predicted something unobserved until then, from pure thought, was Dirac’s.

Quantum gravity goes in that same direction, though, since it originates from the pure theoretical need to conciliate quantum field theory with gravity.

Nevertheless, any proposed theory in this area should provide means to be tested, at least in principle. Otherwise, it is a speculation and any honest scientist would label it accordingly.

20. **SteveB**
June 2, 2011

Concerning the popular scientific publications. I was once a simultaneous subscriber to Science News, New Scientist, and Scientific American.

I dropped SA because many of the articles were nothing more than thinly veiled advertisements for some product or company. I do miss Mirsky and “100 years ago”, though.

I dropped SN because its content became weaker and NS had the same current news with more details.

I am keeping NS because the writing is excellent, and the coverage is very good. I don’t always agree with each article, but you may get an opposite point of view in the next issue. It doesn’t seem like their staff has too many agendas they are promoting. The worst thing about NS is that their editors leave subtle British slang in many articles which is difficult for an American to translate.

21. **Bernhard**
June 2, 2011

Anon,

Bashing these magazines and newspapers and comment the latest hypes is what I believe is part of the mission of this blog and the reason many of us like to read it. This is not just to simply mock string theorists for no reason. What society gets convinced is important can ultimately even affect our funding. All the crap that is published everyday needs some balance and I have to say I feel kind of a relief when after seeing some ridiculous article about Susskind latest crackpot paper I can read Peter shooting it down merciless.

22. **cormac**
June 2, 2011

I don’t agree with Anon at all. I think NS in particular has become quire sloppy in its physics coverage (can’t judge the rest), mainly because it does not delineate clearly between relatively well-established science and speculation.
I have thought this for some time, so I was interested to observe during the year that NS is not admired amongst the rather prominent physicists I have met at Harvard and MIT – to put it mildly.

23. **milkshake**
June 2, 2011

I don’t know if its is relevant, but I remember reading pop sci articles about multiverse in 80s that were not all that different from what one finds in New Scientist these days. It really helped me during a dreaded oral exam in marxism-leninism philosophy, in 1988, which of course was a mandatory part of the university curriculum in Eastern Europe. So I sailed from historic materialism to anthropic principle and multiverse, and finally I disposed with God. The stern marxism professor was visibly delighted, she even asked me for article reference so that she could use it in her class, and she did not molest me during the following year. (We had several semesters of this stuff). So you can see that multiverse has a practical explanatory power and can become useful if you are cornered by a merciless marxist.

24. **Peter Woit**
June 2, 2011

cormac,

I’m also curious what those you met in Cambridge thought of the sources of the New Scientist stories. New Scientist isn’t just making up this multiverse stuff themselves…

milkshake,

The great thing is that you can use the multiverse to justify either atheism or theism. You made good use of it, but see here for someone who is making good use of it to get paid from religious hedge fund source:

http://www.oxfordtempletonfellows.com/winners201112.html

"Professor Kraay hopes to develop and defend the view that if theism is true, the world God selects for actualization is a multiverse comprising all and only those universes worthy of being created and sustained by God. He further hopes to show that, if theism is true, this multiverse is the only possible world. He will explore the consequences of these views for theism, and will consider the connections between these views and various multiverse theories in contemporary physics and cosmology."

25. **the next einstein**
June 3, 2011

didn't ed witten start the whole m-theory thing?

and isn't brian greene hyping the multiverse?

is not new scientist just following the lead of prominent physicists?

26. **chris**
June 3, 2011

"In any event, real pragmatic scientists like WOit here have not produced any science worth writing about in a long time. The last discovery was the top quark in 1994, I believe. yea, right. you missed the CC? CMB anomalies? neutrino masses and mixings?

and if you want speculation, there is plenty of good one. just this week, heard of the Wjj CDF anomaly?
or, also recenly featured, PAMELA and all other DM searches? The ALICE bumps in high multiplicity events?

lots and lots of new, genuinely interesting stuff. all of which was totally unforseen by the prevalent ToE of today.

27. **Jim**
June 3, 2011

Bernhard,

Thank you for your comparison of the science magazines. I too have subscribed to all three in the past. However I remain faithful to SA. It's like a family faith tradition for me because I began reading my dad's subscription while I was a child-like object. Like every other source, they require critical analysis, only more so.

Thanks also for your mention of Big Think and for eliciting Dr. Woit's reply. From its name I might well have suspected it to be as hype-driven as you were suggesting. Then I found this: Peter Woit interview at http://bigthink.com/peterwoit
It is a video interview with our good Dr. Woit telling it like it is And it is excellently done. Thank you Dr. Woit! I get to hear how to say his name correctly, too.

I believe I can now rank Big Think above New Scientist.
(Please forgive my clumsy attempt at html.)(no bold text was intended)

28. **Jim**
June 3, 2011

my apologies :

I was agreeing with SteveB's assessments of the mags.
I do agree with Bernhard's valuation of this web log.

29. **David Bailey**
June 3, 2011

I used to love reading NS as a kid in the 1960's. The articles were written in an authoritative style without hype, and included such things as relevant chemical formulae, which pushed me into reading more chemistry. NS must have helped to push many kids into science.

Now, I only buy the occasional copy of NS if there is an exceptional article. Far too many articles seem to be hype of one kind or another , or to be written by journalists who have little understanding of the subject matter.

Does hype about infinitely bifurcating universes (a concept which surely goes back to Everett in the 1950's) really sell magazines – maybe, but I'll bet it doesn't encourage many kids to actually enter science!

30. **Cosmonut**
June 3, 2011

@Peter:
I don't see how you make a convincing argument to someone that they should trade in their Bible for Bousso-Susskind
————————-

Well, Hindu cosmology has a beautiful story about how an infinite number of universes are continually emanating from the mind of Brahman.
So, if people are getting tired of evidence-based science, we have a much better deal for them than the Bousso-Russkind multiverse.
No convoluted math jargon, just pleasant Sanskrit shlokas. 🙂

31. **Cosmonut**
June 3, 2011

But honestly, I think the whole landscape/multiverse fiasco shows that the dream of unifying physics purely through mathematical consistency – much hyped by Stephen Hawking – is dead.

Mathematical consistency is not strong enough to give us a unique theory unifying GR and the standard model. We need more data.

32. **Nige Cook**
June 4, 2011

> It's the dominant paradigm, and will reign as such until someone comes up with a different theory of everything that isn't a failure.

The different theory will be a failure until it is developed far enough to not be a theory. String theory, like weeds, will starve off any new born alternative ideas long before they can be developed to the stage of providing a serious challenge to string theory. The intimidation (fear of abuse from string theorists) will in fact probably deter anybody from working on alternatives.

The reason why a lot of progress occurred very fast in quantum mechanics in the mid and late 1920s was because people could make progress *quickly*, without being bogged down in something speculative for decades! String theory is the exact opposite: attracting the opposite kind of people, who want long term stability in their careers. Non-falsifiability is turned to a career advantage, offering stability to physics.

33. **grad_student**
June 4, 2011

@Cosmonut
"But honestly, I think the whole landscape/multiverse fiasco shows that the dream of unifying physics purely through mathematical consistency – much hyped by Stephen Hawking – is dead."

This is the same thing as saying string theory is the 'only game in town'. How do you know that unification based on pure mathematical consistency is dead because of one failed attempt?

34. **Peter Woit**
June 4, 2011

Blaming the multiverse on putting too much faith in mathematical consistency is completely backwards. If you look at papers like Bousso-Susskind, or anything from Hawking in recent years, you find very little mathematics, just a lot of verbiage and a few trivial equations. This is what you get when you ignore the lessons of the deep connections between physics and sophisticated mathematics, and decide that you are going to pursue "physical ideas" uninformed by mathematics.

The reason string theory failed was not that it used too much mathematics, but that it was a wrong physical idea about fundamental physics.

35. **Cosmonut**
June 4, 2011

@Peter, @grad_student

Blaming the multiverse on putting too much faith in mathematical consistency is completely backwards.
——————————————

Ok, here's my understanding of the situation.

In the 1980's, the big hope – much hyped by the likes of Stephen Hawking – was that unifying GR and QFT would prove to be so mathematically stringent, that we would get one unique Theory of Everything which would predict the values of the fundamental constants, predict the masses of the particles (and know the Mind of God as a bonus 🙂).

But now, string theory claims to already be a quantum theory of gravity (see my question here: http://physics.stackexchange.com/questions/10754/is-string-theory-a-quantum-theory-of-gravity), which is consistent with both GR and QFT.

Yet, it allows 10^500 solutions at least, leading to the multiverse nonsense.

Hence, my claim that mathematical consistency with GR and QFT is not strong enough to give us an unique theory.
If string theorists are to be believed, there are 10^500 "theories" consistent with both !

Am I missing something here ?
For instance, is string theory not actually consistent with GR and QFT ?

36. **Cosmonut**
June 4, 2011

Just to clarify, I am not saying that mathematical consistency can never lead to an unified theory.

Its just that the string theory flop show suggests to me that our attempts at this point may be premature (just like Einstein's attempts were).

Maybe we need to create a few more layers of sub-theories using the old fashioned experiment-observation-theory route before purely mathematical constraints can give us the TOE.

37. **Bernhard**
June 4, 2011

Cosmonut,

The proper marriage of QM and GR, when it happens, should lead to a profound understanding of fundamental theory and when it happens I bet with you is going to be old fashioned in terms of mathematical rigor. The problem with ST, as Peter said, is that it is based on the wrong physical idea. The mathematical nonsenses coming out of the theory should actually serve as an alert that this is the case, but on the contrary, it made the proponents to abandon math and start the pseudo-science multiverse campaign. With this kind of attitude you can build any theory you want, since when you get in trouble you can advocate that, the crap solutions you´re getting out of your math, are in other universes.

38. **David Rod**
June 6, 2011

Highly recommend the recent book by Helge Kragh – Higher Speculations: Grand Theories and Failed Revolutions in Physics and Cosmology (Oxford University Press, 2011). It has excellent chapters covering many of the ideas expressed above.

39. **Zathras**
June 6, 2011

I second David's recommendation of Kragh's book. It really puts the ST enterprise, the multiverse, and anthropic principles in their proper historical perspective.

40. **John Baez**
June 7, 2011

I hope Peter writes a review of Kragh's book. I'm too cheap to fork over $63 for it right now, but I've long dreamt of *writing* a book about the history of "grand theories", and I hope this book covers the ground well enough so I can drop that ambition. For example, I hope it talks about Schrodinger's attempt at a grand unified theory, and also Einstein's various attempts. It would be nice to have a detailed analysis of these.

41. **Tim van Beek**
June 7, 2011

John wrote:

> I'm too cheap to fork over $63 for it right now, but I've long dreamt of writing a book about the history of "grand theories", and I hope this book covers the ground well enough so I can drop that ambition.

Until someone writes a review of the book, there is an article covering the period of 1914 – 1933 here:

Hubert Goenner: On the History of Unified Field Theories, living reviews.

42. **Greg Egan**
June 7, 2011

The Amazon page for Kragh's book has a look-inside function that enables you to browse the index and table of contents. There are certainly entries in the index for both Einstein and Schrödinger.

43. **Shantanu**
June 8, 2011

So john, you don't think proton decay will ever be detected?

44. **Bernhard**
June 8, 2011

Peter,

Did you review this book already?

http://www.theglobeandmail.com/news/arts/books/the-hidden-reality-parallel-universes-and-the-deep-laws-of-the-cosmos-by-brian-greene/article2050835/

45. **Peter Woit**
June 8, 2011

Bernhard,

I wrote a little bit about it here:

http://www.math.columbia.edu/~woit/wordpress/?p=3389

based on looking at the extensive "technical notes" available free on Amazon, and then took a bit more of a look at it when it came out. Capsule review: the usual pseudo-science and lack of any possible way to test it as every other one of the endless number of multiverse books, but better writing and presentation.

I haven't read Brian's book (or some of the other recent such book like Gribbin's and Manly's) carefully and written a detailed review partly because I'm too bored and discouraged by these things to put more time into thinking or writing something substantive about them. By now I've repeated time and again the same obvious arguments about why these things are problematic pseudo-science, for a recent example, mentioning the book, see here:

http://www.math.columbia.edu/~woit/wordpress/?p=3419

There's another similar book coming out soon, Barrow's "The Book of Universes". When I see a copy of that one, maybe I'll write something, maybe not.

These things are atrocious, but one consolation is that I think the whole "multiverse" thing is now getting over-exposed. Publishers want to sell something "new" and this stuff is getting old fast.

46. **DGP**
June 9, 2011

This is rather belated I know, but I wasn't going to read the NS "Instant Expert" item about String Theory until I saw the comments about Duff's rather polemical last page. I am surprised NS let that through since "Instant Expert" is supposed to be informative not controversial.

I asked a mathematician friend for his opinion. He said he had stopped reading papers and articles about String Theory. He did take a look, however, and here is his reply:
http://xkcd.com/171/
Outside the string coterie, there seems to be increased cynicism about their claims.

Duff seems to have reverted to full adherence to the String Party line recently. His opinions seem to have been more tolerant of criticism. In September 2010, in an article on his work on entanglement he said:
"We have nothing to say about whether string theory is the theory of everything." (From http://www.sciencenews.org/
Home / News / September 25th, 2010; Vol.178 #7 / Article String theory entangled .)
Admittedly, that was in the particular context. Even so, the change of tone is remarkable.

DGP.

47. **John Baez**
June 11, 2011

Tim wrote:

Yes, I really liked this article. I should reread it! For people who have followed the recent struggles to find a unified theory of physics, it's very thought-provoking to look back at these earlier attempts. For example, the problems with media hype today remind me of Einstein's criticism of the premature publicity Schrödinger engaged in. I'm not finding the exact quote now, but it was quite biting. I'm only finding this:

> In January 1947 he believed he had made a major breakthrough in Unified Field Theory. He read a paper at the Royal Irish Academy on 27 January entitled The Final Affine Laws. Schrödinger presented it to the Academy and to the Irish press as an epoch-making advance. The Irish Times carried an interview with Schrödinger the next day in which he said:-
>
>> This is the generalization. Now the Einstein Theory becomes simply a special case… I believe I am right, I shall look an awful fool if I am wrong.
>
> Einstein, however, realised immediately that there was nothing of merit in Schrödinger's 'new theory'
>
> Before he received Einstein's opinion, he was attempting to offer an explanation for the 'exaggerated' newspaper reports. Soon afterwards, Einstein stopped corresponding on the subject and no communication between the two was made at all for three years.

Shantanu wrote:

> So john, you don't think proton decay will ever be detected?

I have no idea. I wish something like the SO(10) GUT would turn out to be true, because it so neatly packages all the fermions in each generation into a single irrep. But I'll be happy if people make *any* sort of significant progress on understanding elementary particles.

The Quantum Story

June 8, 2011
Categories: Book Reviews

Jim Baggott's The Quantum Story: A History in 40 Moments is now out here and I've been starting to see it in bookstores. I read most of it a year or two ago when he sent me a draft of the manuscript asking if I'd take a look at it, and very much enjoyed getting the chance to see it then. If you're looking for an excellent popular level physics book to read, I highly recommend that you consider this one, which should be accessible to just about anyone, no matter what their background.

The topic of the book is the story of quantum physics in general, told historically with a structure of 40 vignettes. The first three chapters cover mainly events of the dramatic period of the mid-1920s to early-1930s during which physicists uncovered the basic structures of quantum theory and struggled to make some sense of them. The next two take on the late-40s to mid-70s during which a long succession of discoveries about elementary particle physics drove theoretical progress on quantum field theory and gauge theory, culminating in the Standard Model falling into place in 1973. The material Baggott works with here has been the topic of many other books, but he does a wonderful job of putting it together in a fast-paced but very clear and entertaining narrative. Along the way, the individual stories he tells often contain fascinating details I'd never heard before, even though I thought this was a subject I knew all too well.

The next to last chapter starts with the 1950s and David Bohm, picking up the thread of later debates and discoveries related to the general problem of the interpretation of quantum mechanics. It brings this story up to date, explaining some of the current questions that are still being debated. The final chapter gives an appropriately short discussion of speculative ideas in quantum gravity and string theory that have dominated theoretical research for the past few decades, making clear that they're a long ways yet from the solid science that's the main topic of the book.

The LHC and the search for the Higgs make up a final epilogue or 41st vignette, accurately describing the high expectations and drama that surrounds the final period of the long wait for new data that is finally coming to an end this year. The story of quantum theory is not a finished one, and we all hope that very soon we'll get some clues as to where it will go next.

Comments

1. **Steve**
   June 11, 2011

   Thank you for recommending this book!

2. **Eric habegger**
   June 13, 2011

   This is a sensational book and i'm about 2/3s through it right now. Even though it doesn't focus in and concentrate on narrow subject matter within the history of quantum physics it still describes those individual discoveries better than 90 percent of more narrow focus books. One really comes away with the feeling of an author who not only writes well but also knows how physics well.

3. **Andrew Daw**
   June 28, 2011

   Having read Jim Baggott's excellent *Beyond Measure: Modern Physics, Philosophy and the Meaning of Quantum Theory* I'd better read this one too.

   (Long live the nonlocal real world revolution!)

This Week's Rumor

June 8, 2011
Categories: Experimental HEP News

A couple months ago CDF made the New York Times by releasing results claiming to see a resonance in the invariant mass spectrum of two jets produced together with a W. Last week they released a new analysis with twice as much data, claiming the signal was still there, now at a statistical significance of nearly 5 sigma.

I recently wrote about this here, explaining the reasons for being skeptical, despite the high statistical significance. One very good reason for being a skeptic is that CDF's Tommaso Dorigo doesn't believe this is real, going so far as to put his money where his mouth is, offering a $100 wager to back up his arguments. The crucial question in everyone's mind has been whether D0, CDF's competition and sister detector at Fermilab, would see the same thing in its data. If there's really something there, D0 should see it.

This Friday there will be a Wine and Cheese talk at Fermilab, where the D0 results will be unveiled, and you can watch this as a live video stream here. But, as one might expect, now that the D0 result is ready to be revealed, people do things like leave print jobs on printers, etc., causing well-sourced rumors to spread. Blogs such as this one seem to be a place where such information tends to end up, so I can report a rumor (based on excellent sources) that Tommaso is right. D0 will report on Friday that there's nothing there, that they find no evidence for a dijet resonance in the region from 110-170 GeV. They reject the CDF hypothesis of a resonance with a cross section of 4 pb at a significance level of over 4 sigma.

In other news, the LHC is running very well, with the official goal of this week being to reach an integrated luminosity of 1 fb^{-1}, something that had been the official goal for the entire year (although, unofficially, 2-3 fb^{-1} is more like it). Right now, they're around .8 fb^{-1}. This sort of luminosity should finally start to allow in coming months results that either rule out a Higgs in the region it is expected or see first indications if it is there.

At the KITP, this week marks the start of a program on The First Year of the LHC. Unfortunately for theorists, the only result of data from the first year of the LHC has been to shoot down some of their favorite models, ruling out for instance a large amount of the parameter space where supersymmetry was expected to be found, making the most popular theoretical idea of the last thirty years significantly less popular. The first talk held at the KITP program was this afternoon, and it dealt not with the LHC data, but with the supposed CDF resonance (it appears that news of the D0 result hadn't yet made it to Santa Barbara).

Update: The KITP talk is now available here.

Update: The D0 PRL submission that has been circulating privately for the past few days is supposed to be available at 9am Friday Fermilab time here. See here for other material to be released publicly today.

Update: Now that the D0 results are officially out, as usual your best bet for informed explanation is to check out what Jester and Tommaso have to say.

Comments

1. **Anonymous**
   June 9, 2011

   As always, the devil will be in the details. When D0 concludes no resonance, one should ask compared to what. An interesting D0 thesis on W+2 jets is http://www.slac.stanford.edu/spires/find/hep/www?r=fermilab-thesis-2010-48.
   Same luminosity as in D0 talk on friday, different cuts.
   Starting at pg 101, a procedure called reweighting the theory prediction is explained. Of particular interest is fig 44 (the dijet invariant mass before and after reweighting). The crucial thing to look for during Friday's D0 talk is how does the dijet mass distribution compares to background estimates (theory prediction+detector simulation) before reweighting. Only then do we compare apples to apples. Everything after that, including reweighing, is interpretation and will be open to discussion…..

2. **anon.**
   June 9, 2011

   The first talk held at the KITP program was this afternoon, and it dealt not with the LHC data, but with the supposed CDF resonance (it appears that news of the D0 result hadn't yet made it to Santa Barbara).

   Everyone expects D0 will say they see nothing. This doesn't mean we shouldn't be talking about the CDF resonance. It's raised a lot of questions — how do we know when to believe signals that come from jet physics? How can you successfully make a case that a peak is real if it's a wiggle on a steeply falling background? What can we do to convince ourselves something is new physics, if even high statistical significance isn't a good guide? (See also: pentaquarks.) Even if D0 rules it out so decisively that everyone is convinced, we'll still have the puzzle of what went wrong in the CDF analysis, and how to keep it from going wrong again. None of the potential mismodeling explanations seem entirely convincing.

   The LHC is doing amazing work slicing away parameter space using missing ET or leptons, but if new physics shows up in very jetty channels, the same issues raised by the CDF analysis are going to be important. Whether or not the CDF bump is real (and even the most rumor-happy phenomenologists in the world tend to think it isn't), getting theorists and experimentalists to talk seriously (hopefully to each other) about jets is an important thing.

   Having watched the video of the KITP talk, it's very much in the vein of "let's try to figure out what the data are saying and what could be causing this," not a premature celebration of new physics.

3. **factotum**
   June 9, 2011

   CDF measurement has been scrutinized for 2 months. Why should we take D0's word as final without subjecting it to the same level of scrutiny?

4. **anon2**
   June 9, 2011

   @factotum

   The D0 analysis is not new. They have been looking at this data as long as CDF has. This is, at least, what I've heard from a D0 member directly involved in this analysis.

   @Anonymous

CDF does not need to tweak the Monte Carlo generator knobs to match the data control distributions because they make more strict kinematics cuts than D0. If D0 presents the results with an analysis strategy similar to CDF's, the effect of the so-called "reweighing" (which is a really bad name) will be negligible.

5. **Anonymous**
   June 9, 2011

   @anon2: then let's hope D0 leaves the kinematic adjustment (=reweighing) issue out of this analysis. This will give us a clean comparison between CDF and D0.

6. **Bernhard**
   June 9, 2011

   @ anon.

   "What can we do to convince ourselves something is new physics, if even high statistical significance isn't a good guide?"

   Now that D0 is refuting the peak, I see two possibilities on the table. Either D0 screwed it up and is not seeing the peak because it overestimated the systematics and erased the signal in a sensitive high-background region or CDF is suffering from a subtle detector effect, so a subtle systematic effect that D0 does not suffer from and so does not see the peak. Either way, there is no chance (or a extremely tiny one) that the much better ATLAS and CMS detectors with better resolution eta coverage etc will suffer from both. Given enough data, it will be clear if there is something there, but to be sure this will take more than 1fb-1 I'm afraid. And imagine that both ATLAS and CMS could suffer from the same supposed systematic effect that CDF could be suffering from at the same time is very unlikely. So if they both see the peak, case closed. The apocalyptic scenario would be ATLAS seeing the peak and CMS not but I see no reason to imagine that such a bizarre scenario like that would happen.

7. **tommaso**
   June 9, 2011

   I like a lot this thread -very informed. Interesting points are raised. In particular, the reweighting technique is indeed the crucial point IMO.

   Now all please stop and think. What do we do when we put a Monte Carlo simulation under our data ? We are comparing previously tuned simulations to newer data, nothing else. The parton shower simulation that is used to go from matrix element calculations to final state observables contains knobs that are turned to match the simulation output to large datasets of well-understood physics processes. Every time something matches poorly, one asks oneself if NP is the cause or a mismodeling issue; once the NP interpretation is disproven, the simulation receives a further tuning.

   In this case, what I think I can say is that W+jets production is a rather well-known and well-understood process, but its detailed kinematics had not been tested to this level of statistical precision before. So we are in a regime where mismodeling issues may arise. And they do. If a reweighting appears to be all what's required to match the data, Occam's razor comes a-slashing the pet signal that CDF published.

   Peter, thanks for the mention of the bet -but I guess that by now nobody else will take it. On the other hand, it is not a single $100 bet: I made available 20 tickets. 19 are still there, so if you believe the CDF signal will eventually survive, take one. Say so in my blog.

   Cheers,
   T.

8. **Bernhard**
   June 9, 2011

   Tommaso,

   If this is the case, one should expect different mismodeling effects from different Monte Carlos, don't you agree? I mean even if you have all generators needing some reweighting in that region to fit the SM one could expect the tunings not to be the same. And the shape and even how much the peak is pronounced would probably be generator dependent as well, right?

   Also, I'm not sure I understand for example how could CDF and D0 apply such a different reweighting… The reweighting factors should be taken from a control region (not where the peak is or is not) where one would expect both detectors to agree very well so the final tuning (for each generator) would be similar. How can this, in the end cause, such a dramatic difference? Is hard to believe CDF would make such a fuzz on something that can be corrected by a simple reweight factor. What they are claiming is a genuine peak, something that cannot be corrected by scaling some curve up. So, a subtle detector effect seems more likely IMHO.

   What did I miss?

9. **Ken Lie**
   June 9, 2011

   I want to share with you a rumor which is discussed in an informal way in Munich. The source of this information is in the theory group of CERN.
   The LHC has seen a particle of energy 150 GEV which is not Higgs (!!)
   Apparently, the result will be confirmed in 2-3 weeks.

10. **Bernhard**
    June 9, 2011

    Ken Lie,

    "The LHC" didn't see anything .

    Which experiment?

11. **DGP**
    June 9, 2011

    I used to think I knew something about experiment design but I am awed by the difficulty of the background subtractions involved in these latest experiments.

    I assume that all proper precautions have been taken to avoid a systematic error in the background: I know that more than one Monte Carlo code was used but are the algorithms and especially the pseudorandom number algrothims fully independent? And what dependence is there on assumptions about QCD? QCD is very good but it's not quite as solid as QED.

    I will be watching the contributions from the other experiments with great interest.

DGP.

12. **Walter**
June 9, 2011

@tommaso: exactly! However, at this point the question is not new physics or not.
Understanding this potential mismodeling in terms of the theory predictions will extend beyond CDF and D0. After all ATLAS and CMS use the same tools.
This point was very well made in anon's first comment. If the deviations from the theory expectation are subtle, how can we conclude there is new physics? The CDF bump, no matter its origin, is a perfect case against which this can be discussed.

13. **chris**
June 9, 2011

DGP,

random number generators have matured substantially over the last 2 decades. with all the modelling of e.g. hadronization in there, RNGs are the last thing i would be concerned about.

14. **DGP**
June 9, 2011

Chris,

Thanks. I know RNGs have moved on since I modelled scattering but there was always a tendency for everyone to use the best, i.e. latest, RNG so independence was always an issue. I thought that might still happen.

I assume that by "hadronization" modelling you mean the sort of consideration I meant when I referred to the assumptions in QCD.

Regards,

DGP

15. **Peter Woit**
June 9, 2011

anon.,

I didn't intend to suggest that phenomenologists at the KITP or elsewhere were optimistic about the CDF signal, just thought it was an interesting sign of the times (the times being this month…) that at a workshop supposedly devoted to the LHC results, the hot topic was a Tevatron topic. I did listen to some of the talk last night, and noticed that if the speaker or those in the audience knew what the D0 result was about to be, they were keeping quiet about it…

Ken Lie,

Are you sure this isn't a garbled version of the Tevatron story about a supposed 150 GeV state discussed here? I haven't heard any rumors about either of the LHC experiments seeing a 150 GeV state. If there are more details though, pray tell…

16. **factotum**
June 9, 2011

@anon2: CDF looked internally for over a year, then their result has been subject to 2 months of public scrutiny

Sure, D0 may have had the internal studies for a long time. But they should be subject to the same questioning and testing from the broader community, just as CDF has, and not just be taken immediately at their word..

17. **Philip Gibbs**
June 9, 2011

Peter, the new LHC results are being presented at PLHC2011 this week. There are ten talks from ATLAS and one from CMS that cover new results using 2011 data. All the plots appeared in conference notes last week so we already know they just show new exclusions, not new physics. D0 are also presenting Wjj there on Saturday.

18. **tommaso**
June 9, 2011

Dear Bernhard,
not necessarily different MC would give different outputs. If you take Alpgen matrix element calculations and add a Herwig parton shower evolution, and then take Sherpa and add a Herwig parton shower evolution, the parton shower is the same.
Further, the reweighting issue involves quite a few choices that require craftmanship. Experimentalists are proud of this part of their job, which is in fact what distinguishes them from a piece of computer code (a simulation of the typical particle experimentalist is not so hard to write, anyway). I think this is enough to understand why different experiments can see and do different things.
As for a detector artifact, I doubt it. The detectors are very, very well understood by now.
Cheers,
T.

19. **Peter Woit**
June 9, 2011

Philip,

I noticed that the most interesting of these talks, the Friday ones with some results from 2011 data, have now been posted, see

http://indico.cern.ch/conferenceOtherViews.py?view=standard&confId=100963

The bottom line: SUSY and extra dimensions are in even more trouble. No hint of the Higgs yet, but they're getting closer. If it's there it could easily start to show up in the data they're analyzing now, trying to get ready for conferences in late July.

20. **Bernhard**
June 10, 2011

Dear Tommaso,

Thanks. I agree with you that if one has the same parton shower, the output can be almost the same.

As for reweighting, you are probably talking about something more sophisticated than I thought. I naively thought you were just talking about the procedure of choosing a control region (let´s say a dijet QCD region for a final state with no leptons) that you know well the MC should reproduce it and if the data gives say 100 events and your MC just 85, one multiplies this MC and all other curves by a factor of 1.17… This should be fairly simple to do…

As for the detector effect, you maybe right, but we never know for sure… 🙂

21. **anon**
June 10, 2011

to ken lie :
i can say that there are quite a lot analyses which have some sort of large disagreement with expectation. mc modeling sometimes is not reliable which people might not realize in some special cases. 2 or 3 sigma is easy to see, what's interesting is if this is a modeling problem, people would see significance growing as more data come in, which resembles what people expect if there's a real signal. if this happens to a *benchmark* analysis, rumor may spread easily.

22. **model and sim**
June 10, 2011

I was curious, for the modellers out there, as the means and distributions are changed in the monte carlo model, I assume that someone is recording those changes in assumptions. Has anyone done analysis on those changes as part of a dual solution check?

23. **M**
June 10, 2011

there is a new rumor from LHC…

24. **Anon**
June 11, 2011

Tomasso says: Further, the reweighting issue involves quite a few choices that require craftmanship. Experimentalists are proud of this part of their job, which is in fact what distinguishes them from a piece of computer code (a simulation of the typical particle experimentalist is not so hard to write, anyway). I think this is enough to understand why different experiments can see and do different things.

Hmm, as a theoretician reading the last sentence, it doesn't sound like something to be that proud of 🙂

25. **Peter Woit**
June 11, 2011

M,

I'm hoping there's finally enough luminosity for rumors to start about seeing something with a plausible cross-section to actually be the Higgs. Or, at least there should be a supersymmetry signal rumor, I'm surprised there haven't been any of those yet. Let's hear some more details…

26. **tulpoeid**
June 12, 2011

Oooooh, this is starting to border begging, guys…

27. **d0 compared to cdf**
June 16, 2011

This is still a little prelimary, but after pulling apart the distributions, the principle reason why cdf sees a particle and d0 does not appears to be correlated with cdf favorings top quark events over w events. Because the top event distribution has a different peak than the w event distribution, the difference in proportionality appears to cause a deficit in the region were cdf claims to see a new particle. There also appears to be a shift in distributions related to choice of bin size which is also having a lesser effect.

The underlying distributions for the different types of events appear to be largely in agreement between the two teams, but CDF definitely appears to favors more events as being top quark events as compared to D0

28. **Peter Woit**
June 16, 2011

d0 compared to cdf,

Thanks for the informative comment. People interested in this should also look at Michael Schmitt's blog entry here

http://muon.wordpress.com/2011/06/12/top-background-shapes-and-the-cdf-mjj-anomaly/

29. **d0 compared to cdf**
June 16, 2011

Thanks,
One of the things I am hoping to figure out is why there is a deficit at 65 GeV in the D0 analysis that appears to have harmonics. One can enhance the harmonics and transform into the t-domain and see two distinct events each half cycle. The same deficit at 65 GeV is apparent in the CDF data, but the CDF error interferes with the harmonics. If I can isolate the nature of the error, it might be possible to see if the harmonics where actually enhanced in the 7.3 fb^-1 data.
I am sure there is a logical explanation for the harmonics, it could just be a fluke.

New Look

June 9, 2011
Categories: Uncategorized

I've updated the blog a bit, to a newer, widgetized theme. Functionality should be the same as before. The only issue I'm aware of now is that the "Archives" widget adds an annoying character below its header which I can't get rid of. This widget may also be the source of problems some people are having (due to some combination of Javascript and incompatibility with latest WordPress version), it may get replaced…

Please let me know of any other issues.

Comments

1. **Anon**
   June 9, 2011

   Slick! I like it.

2. **Mike**
   June 9, 2011

   Like the new look!

3. **Chris Austin**
   June 9, 2011

   What is meant to be below the Archives header? I am using Konqueror in KDE 3.5 (Debian Lenny), admittedly a bit dated now, and there is just a short vertical line under the left of the A, and then nothing until the Links header, just below that.

4. **Peter Woit**
   June 9, 2011

   Chris,

   You should be seeing links to old postings, by year. I just changed the settings so that this should work if you don't have javascript, does it work now?

5. **Chris Austin**
   June 9, 2011

   No, it's still the same, (after several refreshes). However I can see the links to the archives in Iceweasel, with nice + boxes to click on to expand the menus. And the menus correctly hide again when you click the – boxes in Iceweasel. I shouldn't worry about the issue with Konqueror, which still has some Javascript issues in KDE 3.5. I had similar issues trying to get a similar show / hide effect to work in Konqueror with Javascript on a website. Getting it to work in Konqueror requires arranging the Javascript code in very particular ways that should not be required according to the Javascript definition. The Javascript implementation in Iceweasel is much more robust.

6. **Chris Austin**
   June 9, 2011

   I should have added that Iceweasel is simply Debian's name for Firefox.

7. **UnderlyingEvent**
   June 9, 2011

   Great, the same content as before except now I have to wait a finite time for it to load.

8. **Peter Woit**
   June 9, 2011

   I've reverted the javascript behavior change, since that didn't help Chris, perhaps this will improve performance.

   As far as I can tell, the new theme/widgetization shouldn't affect the time to load signifcantly, since you're getting pretty much the same data, processed the same way. I'm guessing the problem is wp-dtree that handles the archives, and comes in a rewritten version. If anyone has a suggestion for a replacement for that, I'd be interested to hear about it.

   And if people complain too much, I'll contact Lubos and get the info from him about how to install all the widgets he's got running on his blog…

9. **Lukasz Grabowski**
   June 10, 2011

   For me the top picture is now annoyingly huge.

10. **jharvey**
    June 11, 2011

    I do read the comments. Would it be possible for you to number them? That would make it easier for me to keep track of where the previous last one was. Thanks.

11. **Aaron Davies**
    June 11, 2011

    @chris: i think the pipe on the line after "Archives" and before 2011 and its plus/minus box is the "annoying character" in question.ah, i see what's going on–that pipe is supposed to separate two buttons which aren't being rendered properly:

 |

note the two empty <a> tags.(what you should do about this, i have no idea, but hopefully this will set you on the right track.)

12. **Peter Woit**
June 11, 2011

Thanks Aaron, that explains it, by default the there are "Open All" and "Close All" button, but with blank text. Added text, at least now it makes sense.

jharvey,

I'll look into that, but one problem is that comments get added/deleted a lot for various reasons, making any numbering system not necessarily stable.

13. **Visitor**
June 12, 2011

The text column of the comments is now wider than previously; so wide, in fact, that it is far less comfortable to read.

Math and Physics, Summer 2011

June 9, 2011
Categories: Langlands

This week in Philadelphia the String-Math 2011 conference is going on, planned as the first of a series, with String-Math 2012 next summer in Bonn. Slides of the talks are appearing here. There's also supposed to be video, but the saved video seems to require some sort of UPenn login, and I've not been able to get the streaming video to work. The public talk by Cumrun Vafa puts out the classic message that strings have come to the rescue of physics, unifying QM and gravity, and that:

> Smooth geometry of strings seems to explain all known interactions (at least in principle)

The techinical talks cover a lot of ground, much of it having little to do with string theory. Michael Douglas's talk surveys problems related to finding non-perturbative formulations of quantum field theory that one might hope to say something precise about, but it contains a lot more questions than answers. I'm most curious about David Ben-Zvi's talk tomorrow, so hope that slides or video of that will be available.

The circle of ideas relating gauge theories, geometric Langlands, TQFTs and representation theory will be getting even more attention than the mathematics of string theory this summer. In a couple weeks will begin a two-part program at Luminy and then Cargese on Double Affine Hecke Algebras, the Langlands Program, Affine Flag Varieties, Conformal Field Theory, Super Yang-Mills Theory. I don't know who the author is, but some person or group has written up for the occasion a wonderful summary of the current activity in these and related fields of mathematics, see here. Next month, the KITP will be hosting a program on Nonperturbative Effects and Dualities in QFT and Integrable Systems that will cover some of the same topics.

In some other unrelated news, if you understand French, you can listen to an interesting set of interviews with Pierre Cartier here. Finally, it was announced recently that my colleague Richard Hamilton is sharing this years $1 million Shaw Prize for Mathematics with Demetrios Christodoulou. Congratulations Richard!

Comments

1. **Igor Khavkine**
   June 10, 2011

   Hmm, Michael Douglas's talk is interesting. However, from his remarks about cluster expansions, I wonder if he is overlooking potential interaction with the work on position-space renormalization that has been continuously improved since the contributions of Epstein and Glaser in the '70s.

2. **Daniel L. Burnstein**
   June 10, 2011

   Just a note to let you know that the video works fine from my computer.

   DLB

3. **Peter Woit**
   June 10, 2011

   Thanks DLB,

   I'm also now able to access the archived video as well as the stream (using VLC for the latter).

4. **Fabien Besnard**
   June 10, 2011

   Thanks for the link to Cartier's interview. The first part is missing on the link you provided, but it can be found here.

5. **Fabien Besnard**
   June 11, 2011

   Sorry about the preceding link : it says it is the first part of Cartier's interview but it has nothing to do with it ! I'll see what I can do with the people at France Culture.

6. **Thingumbobesquire**
   June 11, 2011

   Bye the bye more hype from the stringers today: http://www.ia.ucsb.edu/pa/display.aspx?pkey=2509

7. **Peter Woit**
   June 11, 2011

   Thingumbobesquire,

   Well, at least that's the first string theory hype press release I've seen in a while that doesn't claim discovery of a way to test string theory…

8. **Tim van Beek**
   June 12, 2011

   A nice talk by Michael Douglas. I think it is understandable that it is biased somewhat towards the work that he himself is involved in. I'd liked to hear a little bit more about axiomatic quantum field theory, and also about the work on making Feynman integrals rigorous. BTW, people in AQFT usually work with the Haag-Kastler axioms, not the Osterwalder-Schrader axioms as Douglas implied. Also, the axioms have been fully generalized to Lorentzian manifolds quite some time ago, see for example this paper on the arXiv.

$6.5 Million for Entropic Gravity

June 12, 2011
Categories: Uncategorized

One of this year's Spinoza Prizes goes to Erik Verlinde. It comes with 2.5 million euros to fund the prize-winner's research. Last fall Verlinde received a 2 million euro ERC Advanced Grant to fund his research program, so that's a total this past year of 4.5 million euros, or about $6.5 million.

Verlinde's current research focuses on ideas about "emergent gravity" (see here and here). According to Wikipedia his work explains the observed value of the cosmological constant.

I've no idea how Verlinde will spend the money, but it looks like emergent gravity research will be extremely well financed. $6.5 million I'd estimate corresponds to about 100 postdoc-years. In a couple weeks Verlinde will unveil his latest work at Strings 2011. Since that's among the most expensive conferences around (see here), perhaps he could chip in to fund it. I'd estimate he should be able to single-handedly fund Strings 20XX through at least 2050.

Comments

1. **anon**
   June 12, 2011

   A scientist that already has a very good, well payed, tenured job, has no need for that type of money. Doesn't Holland want to improve the world and its own country and science? This certainly is not a very efficient way of doing it. If this prize is supposed to increase the prestige of Holland, it has the opposite effect. Now I think the Dutch have their head up their ass.

2. **Anon**
   June 13, 2011

   Verlinde solved the CC problem!? News to me!

   He does very interesting work in more speculative directions – the Dutch seem to be good at original thinking in Physics – but really, I have to agree with anon. I doubt this kind of investment in one well-established secure person is justified.

3. **Octoploid**
   June 13, 2011

   Really, all you guys just sound jealous.
   For me it's a sign of civilization to be able to spend this amount
   of money on a guy whose work is purely theoretical.
   I may not agree with his results, but I think he deserves congratulations
   and not snippy remarks.

4. **Fritz**
   June 13, 2011

   Read the announcement two days ago at the hammock physicist (a Dutch tax payer I presume). He is critical about the way the Spinoza prize committee motivates their choice, but enthusiastic about the choice itself: http://www.science20.com/hammock_physicist/blog/entropic_gravity_snatches_spinoza_prize-79902

5. **Tim van Beek**
   June 13, 2011

   > $6.5 million I'd estimate corresponds to about 100 postdoc-years.

   Verlinde will hardly be able to mentor that many postdocs, but if it turns out that the money is spent on postdocs, that will result in roughly 300 papers, I'd guess? The problem is, that postdocs will have to publish wether they have something to say or not, adding a lot of noise to a topic that already shows severe stress due to overpopulation.

   If Verlinde would like to spent the money on a software project instead, 4.5 million Euros are worth roughly 23 man years (good software developers seem to be more expensive than physics postdocs). That would be enough to start a second Twitter or Facebook. But the problem is the same, of course: One needs a good, a very good idea for people to work on 🙂

6. **Yatima**
   June 13, 2011

   >One needs a good, a very good idea for people to work on 🙂

   But it doesn't work that way.

   In research, as in real life, you at first work on something, and then it may turn out to be "good" along a few of several dimensions. As usual, luck is 80% of it. Facebook or Twitter might never have made it for thousands of reasons; they still might flounder in fact once the hype about advertisement-driven revenue lets up.

7. **Bugsy**
   June 13, 2011

   I agree with Yatima.
   Though it is good to see money go to research in any form, the money would be well spent for instance by the recipient not on research postdocs focussed on one possibly valid idea, but rather on more general support for struggling, honest, independent-minded, creative, and not well known researchers, at times overwhelmed by the stress of trying to job-search, teach, and have some sort of family life in the midst of an often commercial, superficial and ruthlessly competitive world. That is, to fund real science…. and real, stable positions which provide some level of security and some time just to happily think.

8. **chris**
June 14, 2011

oh, come on. 4.5ME is not that much. it's equivalent to about 3 permanent positions. if the work is computer intensive though it will just pay you a few years decent computer time and a few postdocs.

9. **Anonymous Coward**
June 14, 2011

Let me clarify this one bit: the Spinoza prize is both an accomplishment and an encouraging award. Its purpose is to provide academic freedom and financial means to the best, not necessarily Dutch, scientists in the Netherlands. Recipients are next to completely free to spend it as they see fit. For instance, Verlinde's Amsterdam colleague Robbert Dijkgraaf set up an educational project for school children (http://proefjes.nl/).

10. **Peter Woit**
June 14, 2011

chris,

From what I can tell, the main funding for the most computationally intensive area of particle theory (lattice gauge theory) for the entire US comes to about $2.2 million/year

http://www.scidac.gov/physics/quarks.html

so Verlinde should definitely be able to afford some decent computer time. Maybe his new work changes things, but it seemed to me that his previous work on this didn't allow any possibility of computing anything, so costs of computer time are pretty irrelevant to him.

11. **Anon**
June 14, 2011

I am sorry, but I cannot agree with irresponsible throwing money around. Theoretical Physics is so criminally underfunded that to give the money away to some project that has little if any chance of ever advancing fundamental Physics at all (Dijkgraaf's schoolchildren project) just because your own position is nice and cushy, compounds the crime. It is certainly a subversion of the intent with which the money was given.

12. **Pachu**
June 14, 2011

Im available as software architect/developer for Verlinde 🙂

13. **anon**
June 14, 2011

Only problem is that Verlinde's work involves no software. Also, string theorists and computer programmers (e.g., ipad application developers) aren't exactly dying to collaborate with each other

14. **Michael McGuigan**
June 14, 2011

There is a small intersection between string theory and computing, for example to test the AdS/CFT correspondence numerically at intermediate coupling.
An upcoming workshop:
Novel Numerical Methods for Strongly Coupled Quantum Field Theory and Quantum Gravity
http://www.kitp.ucsb.edu/activities/dbdetails?acro=novelnum12
has a description that says:
"Conformal or nearly-conformal large N quantum field theories, supersymmetric lattice gauge theories, out-of-equilibrium QFT, formation and evaporation of black holes, spacetime foam, and ideas for emergent gravity, all illustrate the importance of the development of new or improved methods for studying strong coupled theories. As computers steadily become more powerful, the efforts of many people using numerical techniques to study these problems are becoming increasingly fruitful."

15. **Patrick**
June 15, 2011

Not being a a "theoretical" physicist, I disagree with Anon's remark. There is nothing "criminal" about funding levels in general and certainly nothing "criminal" about the percentage spent on "theoretical" areas. The quotes above are because it is not clear (a) what is "criminal" nor (b) what speculative ideas (to be polite) ideas can be considered to be "theoretical". Is the argument to be that we should fund every crackpot idea especially if it cannot be falsified? If an individual with sufficient funds wishes to do so…well it is his money. As a taxpayer, I expect public funds to be held
hostage by conscensus.

16. **Anon**
June 15, 2011

Well, if you can come up with a better adjective than "criminal" when comparing the amount of money spent on research (of all kinds, but including theoretical) with the amounts spent on the military, for example, I am all ears. And I am using Theoretical Physics in the old sense, not as a "String speculations". Maybe if we hadn't lost the majority of young Ph.D.'s over the past 20 years due to lack of funds, someone might have come up with better ideas by now. I personally know a number of these lost Physics Ph.D.s, some of them of great caliber, whose loss to the field is a crime, I can promise you that.

Also, I agree that private foundations can spend money on advancing whatever speculative ideas they want. What I called "criminal" was Dijkgraaf's subverting this intent by giving the money away.

17. **Anonymous Coward**
June 16, 2011

I think this thread has exceeded its usefulness, but assigning the adjective "criminal" to Robbert Dijkgraaf is absolutely silly. A long-time popularizer of science in general in the Netherlands, he is currently doing a great job as president of the Royal Dutch Academy of Sciences, constituting a pillar of reason and enthusiasm in times of major budget cuts. He's done more good for science than the next young post-doc probably ever will.

Besides, the Spinoza prize doesn't carry a label "money for theoretical physics"; if Dijkgraaf or Verlinde wouldn't have gotten it, they would have given the prize to a historian, medical researcher or whatever.

18. **Peter Lynds**
June 16, 2011

    Just crazy.

19. **maciej**
June 17, 2011

    Wow! Quite a lot of money considering the fact that the argument (that gravity might emerge from some more fundamental statistical system) does not even belong to Verlinde but to T. Jacobson (starting from the 95′ paper http://arxiv.org/abs/gr-qc/9504004).

    Yeah, but Jacobson does not publish papers about string theory unlike Verlinde – this explains the artificial hype.

How the Hippies Saved Physics

June 13, 2011
Categories: Book Reviews

A review that I wrote of David Kaiser's [How the Hippies Saved Physics] is now available at [American Scientist]. A quick summary is that I think it's a marvelous book, telling in well-researched and entertaining fashion a story I've always wanted to know more about. I'm not convinced though by the main argument of the title, that this group of people "saved physics", rescuing it from an oppressive "shut up and calculate" ideology by showing the way towards the importance of Bell's theorem and helping start the field of quantum information theory. Perhaps the author though is just emulating his subjects, known for their playful outlandishness.

There are quite a few interesting things I learned from the book that didn't make it into the review. One example is the story of Werner (of EST fame) Erhard's theoretical physics conferences of the late 70s and early 80s, organized in collaboration with Sydney Coleman and Roman Jackiw. Among the factors that brought these events to an end was the advent of string theory: it was felt that no string theory conference without Witten attending would be taken seriously, and by then Witten wanted nothing to do with EST and its founder (although he had attended, with the likes of Feynman and Weinberg, the earliest conference in the series back in 1977).

If you find this subject at all interesting, I highly recommend the book.

For another take on the same subject, from one of its main participants, Jack Sarfatti's memoir *Star Gate* is available for free these days in a pre-publication version here.

I'm afraid that my own description of where the physicists described in Kaiser's book ended up would not be the field of quantum information theory, but the much larger swamp of dubious claims about quantum physics that is still very influential. For example, this week at the AAAS meeting in San Diego there's a session on Quantum Retrocausation, see this listing from the World of Parapsychology.

Update: I should also mention that Chad Orzel discusses the book here and here.

   June 13, 2011

   Peter,

   EST has metamorphosed into "Landmark Education," which seems to be basically the Rosenberg family business and which has developed a rather unique "business model." ("Werner Erhard" was really Jack Rosenberg – supposedly the "Werner" came from Werner Heisenberg and the "Erhard" from Ludwig Erhard.) I won't go into details about Landmark (I have some friends deeply involved in it) except to say that it is not to my taste nor, I suspect, to the tastes of most of your readers and that Googling Landmark turns up a lot of interesting sociological information: it's a hobby of mine to follow groups like Landmark, the David-Deutsch movement, etc.

   I myself am old enough to remember the transition when people started to recognize that John Bell was right and that von Neumann had made an error in his "proof" of the "impossibility" of hidden-variables theories: I wrote a term paper on the topic during the '74-'75 academic year. I suppose that all this did help open the floodgates to all the "quantum" nonsense (can we do anything about Deepak Chopra, please?), but the underlying physics is interesting and it was good to correct von Neumann's error, even if almost none of us are really convinced that any hidden-variables theory is correct. (I've done some unpublished work in the field, and, no, I do not have any pet theory that I believe is true.)

   Do you know if there is anything to the "retrocausation" stuff that is even remotely physics or is it all just gobbledygook? Bell's theorem does seem to hint at faster-than-light connections of some sort, which of course should violate relativity, except that in all the hidden-variables theories the very dramatic violations of relativity are guaranteed to be completely undetectable experimentally. I've long wondered if some sort of retrocausation could be used to model this – faster-than-light should of course allow signaling into the past according to relativity. However, I've never seen anyone come up with any serious proposals along those lines, nor have I come up with anything myself.

   Yet, I still have this nagging feeling that "Bell's theorem" is trying to tell us all something we do not yet get.

   Of course, a major problem is that the signal-to-noise ratio on this subject is so low that it is hardly worth following even the papers in the arXiv on the subject. But, I'm still not convinced that "shut up and calculate" is the final word.

   Thanks for your post: I guess I need to get the book.

   Dave Miller in Sacramento

2. **Yatima**
   June 13, 2011

   They are not taking prisoners here..

   genuine retrocausal phenomenon

   But these claims are never operational in an engineering sense…

   I would think at the claimed significances, world and dog would know about this and the NSA would be working around the clock to open up the unrivalled frontiers of closed timelike loop computation, faster-than-light signalling and massive entropy reduction going forward in time. The abstract alone raises doubts about the authors being able to keep QM "retrocausation" (certain to be misinterpretation of mathematics) and "foreknowledge of future events" (quite likely to be misinterpretation of statistics and psychology) well apart. Sigh.

3. **Roger**
   June 14, 2011

   You are way to easy on this book. It is crackpot stuff.

4. **Chris Oakley**
   June 14, 2011

The S-matrix approach is a rather mundane attempt to get something for nothing, and arguably the least trippy thing to come out of the theoretical particle physics mainstream in the last 60 years. Had these hippy physicists had Superstrings and 11-dimensional Calabi-Yau manifolds to contemplate with the aid of proscribed substances, their brains would probably have exploded.

5. **martibal**
June 14, 2011

Nice review Peter,

could you – or somebody else – explain why believing in the S-matrix approach aims at claiming something like the standard model could not work (or maybe there is a precedent post about that) ?
That S-matrix and SM are two different views on qft is one thing, but I did not realize they were mutually exclusive.

6. **Tim van Beek**
June 14, 2011

Dave Miller said:

> Bell's theorem does seem to hint at faster-than-light connections of some sort, which of course should violate relativity, except that in all the hidden-variables theories the very dramatic violations of relativity are guaranteed to be completely undetectable experimentally. I've long wondered if some sort of retrocausation could be used to model this – faster-than-light should of course allow signaling into the past according to relativity. However, I've never seen anyone come up with any serious proposals along those lines, nor have I come up with anything myself.

It is possible to show that correlations that are described by Bell's inequalities do not violate relativistic causality, in axiomatic quantum field theory.
See, for example:

* Stephen J. Summers: "Yet More Ado About Nothing: The Remarkable Relativistic Vacuum State" (<a href="http://de.arxiv.org/abs/0802.1854v2";).

An example of a theorem that describes "action at a distance" is the Reeh-Schlieder theorem (see the nLab page). People have written papers about how the Reeh-Schlieder theorem shows that the axiom of locality in AQFT is wrong and needs to be replaced, without noticing that this axiom is not used in the proof of the theorem (ouch!).

Anyway, "action at a distance" aka correlations of states that are spacelike separated, does not necessarily imply that Einstein causalitiy is violated.

7. **Chris Oakley**
June 14, 2011

Martibal,

They are not mutually exclusive. Far from it. S-matrix theory takes the operator that connects initial and final states in a scattering experiment (the S-matrix) and infers a surprising amount about it just from very general considerations (relativity, etc.) Its conclusions are not invalidated by quantum field theory it is just that it does not tell one enough in order to classify as a replacement.

8. **Emanuel Derman**
June 14, 2011

I've read only the first couple of chapters but I agree that so far it's a marvelous book.

I graduated with a PhD in 1973, the year in which the production of physics PhD students maxed out, and the author's description of the sociology of physics and its job market in those days is very accurate. And yes, "Shut up and calculate" was the strict attitude of faculty. I knew grad students who wanted to do research on quantum mechanics rather than on particle physics, and they were strongly discouraged. One prof at Columbia, a nice guy, said cynically "Leave that for when you're old."

I'm always struck, in conversations with biologists and amateur and professional neuroscientists, how naive they are about physics and matter. Spinoza wrote that the body can do many things which the mind doesn't understand at all, and yet many people put their faith in the idea that matter is simple, and that everything follows from that.

9. **Peter Woit**
June 14, 2011

martibal,

I wrote quite a bit about this in my book. The S-matrix philosophy was that symmetry arguments, quantum fields and a specific choice of Lagrangian to determine the dynamics could never explain the strong interactions. The discovery of QCD and asymptotic freedom conclusively showed this was wrong in 1973. In 1975 Fritjof Capra, one of the members of the group discussed in this book, published "The Tao of Physics", promoting exactly this philosophy, just after the point at which it had conclusively failed.

Of course the S-matrix and its properties is a crucial thing to study in particle physics. What Chew and others had hoped though, that general properties of the S-matrix would be enough to determine the theory, turns out to just not be true.

10. **ObsessiveMathsFreak**
June 14, 2011

So, String Theory came out of LSD trips?

More seriously, is the book claiming that modern physics as we know it is a product of the social revolutions of the 1960s? Is it the case that physics underwent a radical break from its past in the 1970s, as profound as that seen in other social and cultural spheres? If so this is a very substantial claim, which may have had profound influences on the way physics is researched and understood in the present day.

11. **Peter Woit**
June 14, 2011

OMF,

The book isn't making claims about most of modern physics, including the Standard Model, string theory, etc. That's just not its topic.

The book is mainly about the story of a group of "countercultural" physicists active in the mid-seventies at Berkeley, and their unorthodox claims about quantum mechanics (that it might have something to do with para-psychology, for instance). They were quite interested in issues like entanglement and Bell's Theorem, topics ignored by the conventional physics establishment at the time, but which now have become quite hot topics in the field of quantum information theory (NOT in string theory or particle physics). One could argue about what effect their interest and activities had on the later movement of these topics into the mainstream.

12. **Eu**
June 14, 2011

Offtopic:

Emanuel Derman, thanks for writing "My life as a quant".

13. **David Bailey**
June 14, 2011

Perhaps the best retrocausation experiment, is that devised by Dean Radin himself, known as 'presentiment'.

Subjects are shown a succession of calm images on a computer (landscapes, etc), with the occasional violent or erotic image randomly inserted. The subjects are monitored using skin conductance to measure their state of arousal. The claim is that the subjects begin to show a response to the disturbing images for about 1 second before they have been displayed, and indeed before they have been selected by the computer! The effect achieves statistical significance over a relatively short test period.

This experiment has been around for many years, with a number of independent confirmations.

I'd say it is time someone determined exactly where this anomalous result arises – it just seems wrong to me that such a bizarre result is just left hanging in the air.

14. **Peter Woit**
June 14, 2011

David,

I just remembered that I've been exposed to Dean Radin before, see here

http://www.math.columbia.edu/~woit/wordpress/?p=342

He's behind the "Institute for Noetic Sciences", and makes an appearance in "Down the Rabbit Hole", the extended Director's Cut version of the appalling "What the Bleep".

I'm afraid he is a good example of what was wrong with the "counter-cultural physicists" and their interest in parapsychology and pseudo-science. The same nonsense about parapsychology and quantum physics that they were pursuing 35 years ago continues to be pursued by a huge group of people, with not the slightest sign of anything you could call scientific progress. I'm sure they'll be at this long after I'm dead. In the meantime, paying attention to them is just a waste of time, so please don't encourage it here. Those who want to discuss this kind of thing can find dozens of other places devoted to it.

15. **Bugsy**
June 14, 2011

There's nothing wrong with mysticism per se, in fact I think that mixing science and mysticism can do a disservice to both.

That said, at their best, what both can have in common is to help awaken our sense of wonder.

Then again, for some people what does the trick is fresh pesto on pasta…

16. **Anon**
June 14, 2011

David, if this were a real phenomenon, surely someone would have used it already to make a fortune on the stock market by converting, e.g., upticks into erotic and downticks into neutral images. A second of foreknowledge is a long time in today's markets. I would like to see someone put their actual money where their mouth is.

There is no such thing as retrocausation in known Physics (despite some speculation on future boundary conditions in gravity). There is certainly no such thing in Quantum Mechanics, and a Physicist pretending that there is some such thing is either ignorant or dishonest.

17. **Roger**
June 14, 2011

Advocating retrocausation is either ignorant or dishonest? I am inclined to agree, but surely the same is true about the hippie physics of this book.

18. **Thomas Barton, JD**
June 14, 2011

Perhaps you could write a blog entry on the irony of the Berkeley hippies giving rise through their idiosyncratic views to the now burgeoning orthodoxy you now find resident in the redwoods of Stanford.

19. **Peter Woit**
June 14, 2011

Thomas,

I don't think multiverse mania can be blamed on the Berkeley hippies. They were guilty of all sorts of nonsense, but not that one. The string theory establishment came up with it on their own, with little to no help from hippies, hot tubs and psychedelic drugs..

20. **Jack Sarfatti**
June 15, 2011

I am reporting from the AAARP USD Retrocausality Conference.
Intellectually honest theoretical physicists will first read Bem's paper before casting stones – especially if they are string theorists.

Here are a few scattered notes from the meeting.

From: Dean Radin
Date: June 14, 2011 8:42:39 PM PDT
To: JACK SARFATTI
Subject: Re: AAAS Retrocausality Meeting at University of San Diego

So Art dreamt that he fired a revolver, you dreamt that a revolver was aimed at you, and I spontaneously decided to tell that story and show the photo of the gun to illustrate presentiment in real life? A genuine three-way entanglement through time. That's a first even for me!

Best wishes,

Dean Radin
Senior Scientist
Institute of Noetic Sciences

On Jun 14, 2011, at 8:33 PM, JACK SARFATTI wrote:

I was with Henry Stapp today and he and I see eye to eye on the same page.
Henry said he changed his mind in past few months because of Daryl Bem's data.
Henry never even heard of Antony Valentini BTW – he independently now says that Bem's data (and Radin's, Bierman's …) show violation of "orthodox quantum theory" i.e. what I call "signal nonlocality" and that messages can be decoded nonlocally in the past as I have been arguing.
Do! ug Hofstader wrote that Bem's results turn physics upside down. Bem today said he was not the Copernicus of the new paradigm alluding to Bierman, Radin, Libet … but I say he is the Michael Faraday of the new paradigm.
Also Russell Targ & Fred Alan Wolf as well as A. Elitzur.
Elitzur agrees with me that Hawking was right the first time and should not have caved in to Gerardus 'Hooft and Lenny Susskind. Like me, Elitzur does not believe in unitarity as absolute. Indeed, I told Stapp and Elitzur at lunch today at USD that "unitarity prohibits novelty" i.e. "novelty" as in Henri Bergson as used by Henry Stapp. Elitzur concurred saying "I'll buy that."
Ibison and I had good discussion on the de Sitter boundary issue – we are converging more.
Before I forget – the Bologna cold fusion and Moddell-Haisch zero point battery patent do not look good – this from a reliable source.
Bem should collect the $1,000,0000 from James Randi who I am told keeps changing the rules and is not honest about his "prize."

Now here is the kicker. I woke up this AM with a dream that I had been shot in the face with a revolver. I almost missed Dean Radin's talk. I came in on the end. Dean told the following story shortly after I came in. "My friend collected guns. He was loading a double action revolver. Something told him not to load the sixth bullet – leaving one empty chamber. Several weeks later one of his drunk friends went berserk and picked up that revolver on the table – pointed it at Dean's friend's face at close range pulled the trigger and of course the gun did not fire since the barrel turned to the empty chamber – that's Novikov loop in time inside a Novikov loop in time. Also, Art Altschuler a retired physics teacher told me and Fred Alan Wolf that he dreamed last night that he fired a revolver at close range into someone's face – i.e. a loop within a loop within a loop.

Andrew Jordan (AJ) University of Rochester
mentions negative pressure from Phys Rev editors re: retro-casual interpretation
Tollaksen is here BTW but Nauenberg did not make it – too bad.
Menas Kafatos also here
ABL 1964 both past and future boundary condition of pre & post-selection – time symmetric
weak value have both pre and post selection constraints.
See my Journal of Cosmology Vol 14 April 2011 paper for the math – free online (edited by Penrose and Hameroff)
weak value WV can exceed eigenvalue range (i.e. negative probabilities weighting the eigenvalues) and need not not be real number, can be a complex number
Stern-Gerlach test of WV actually carried out at University of Rochester with DARPA & NSF funding.
pre-selection
weak splitting in z
strong splitting in x
post-selection in x
record the z-delection

/ = weak

If —> 0 you exceed eigenvalue range but with small probability

weak measurement experiments in solid state quantum hall effect relevant to quantum computers

Jesus Christ! This is like reading random dispatches from free association experiments.

On the same page with Stapp: http://www.mth.kcl.ac.uk/~streater/stapp.html

22. **David Bailey**
June 15, 2011

"I'm afraid he is a good example of what was wrong with the "counter-cultural physicists" and their interest in parapsychology and pseudo-science."

Finding out exactly how those experiments produce the result they do, would be a far more effective repost than calling them pseudo-science.

At the very least such research would expose a problem in an experimental technique that is widely used in conventional psychological experiments.

At the very most…………

23. **Giotis**
June 15, 2011

"The string theory establishment came up with it on their own"

Peter, if you accept inflation (which by now is incorporated in the standard model of Cosmology) then you must admit that eternal inflation and thus the multiverse is at least very plausible regardless if String theory is valid or not. So no String theory 'establishment' came up with this idea. In fact it is quite old. But it happens these two major developments of modern Physics from different starting points to combine and point in the same direction. This deserves people's attention to say the least.

24. **Shantanu**
June 15, 2011

Peter, first result from T2K
See

25. **Peter Woit**
June 15, 2011

Shantanu,

This result can be accommodated with a non-zero mixing angle theta_{13}, somewhat below the previous experimental bounds, right? If so, very interesting and impressive measurement, but the Standard model still remains unchallenged.

26. **Mark**
June 16, 2011

Jack Sarfatti,

With respect to Bem's study, every single attempt to replicate his results has failed. The analysis of his data has been heavily criticized by Wagenmakers et al. and there is clear, unequivocal evidence that Bem performed more trials than he reported, which brings his entire credibility into question.

27. **Mark Hillery**
June 18, 2011

For a nice, short history of the no-cloning theorem, see the beginning of the review article by V. Scarani, S. Iblisdir, and N. Gisin quant-ph/0511088 or Rev. Mod. Phys. 77, 1225 (2005). It includes a nice discussion of some missed-opportunities that could have resulted in the theorem being discovered earlier.

28. **Sebastian Thaler**
June 18, 2011

George Johnson just reviewed the Kaiser book in The New York Times: http://www.nytimes.com/2011/06/19/books/review/book-review-how-the-hippies-saved-physics-by-david-kaiser.html?_r=1&ref=books

29. **Emanuel Derman**
June 18, 2011

One totally unexpected thing I learned from this book was how closely straight-and-narrow physicists like Jackiw and Coleman were involved with the Erhard meetings. I never knew about it at the time. Was it opportunism, open-mindness, or both?

30. **Henry**
June 20, 2011

Leonard Susskind came up with the no-cloning theorem independently while thinking about black hole complementarity. However, he also attended the EST seminars and had a similar background…

31. **David Gladstone**
June 22, 2011

Peter Woit-"The same nonsense about parapsychology and quantum physics that they were pursuing 35 years ago continues to be pursued by a huge group of people, with not the slightest sign of anything you could call scientific progress."
Your comments reveal your negative bias as well as your ignorance of what is scientific progress, which is so easily available to any reader in the content of your missive is laughable at this point, given Bell, Clauser, Aspect, etal.
The S-Matrix theory was an idea worth exploring then, the fact that we know it's not a theory now, just as the Standard Model is not a theory now, just a model, means at worst they are equally fallacious. The Standard Model of physics has no explanation for its own success and no clue about consciousness either. It seems clear that Johnson in his review in the Times, wants to hold retroactive thought crimes trials for these people, and saves his final barb for the sexual enthusiasms of some, which is mere prudishness, but that doesn't hold water when discussing the search for truth. As for retro causality, the anecdotal evidence is astounding at least, compared with the same kind of evidence for UFOs or God and that should eliminate at least the public hectoring of researchers who try to find the there there.

32. **Peter Woit**
June 22, 2011

David Gladstone,

The Standard Model doesn't need to have "an explanation for its success", it just needs to be a success and it is (unlike the S-matrix program).

Like a large number of people, I'm on Jack Sarfatti's mailing list, so can see for myself that, bless his soul, he's still trying to do the same kind of things this group was trying to do in the 70s. Claims for experimental evidence about things like retrocausality remain, 35 years later, at the same "anecdotal" level of that time.

As for Johnson's "physics porn" comment, I've some sympathy for Nick Herbert's point of view that that's not necessarily a bad thing. But Johnson is making a more serious point that this stuff is in the category of "exciting" but not real, solid science, and that's an accurate point to make.

33. **David Gladstone**
June 22, 2011

Two things, Peter, need clarifying.
First given the problems with the Standard model already well-known and articulated, should Johnson have made it it such a key point of his attack in his review? It seems he was just looking for a club to use as a weapon. Understandable, perhaps, but not logical or compelling.
The physics porn comment was nothing but a cheap shot, larded with nastiness. Admittedly the title of the book is tendentious, purposely so, it seems clear from Kaiser's video talks. I can see why Johnson trots out all the old buzz words people use when the word hippie is uncloaked. It's just so easy to respond that way if you don't challenge yourself, as Johnson clearly didn't, and it certainly doesn't shed any light. Yes, we can all see the derision literally dripping off the pages of the Times, but that's about all that's there and readers should and do expect more from the old 'Gray Lady'!

34. **Peter Woit**
June 22, 2011

David,

Actually I thought it was a good review, and Johnson an excellent choice of reviewer. He's someone with a deep knowledge of the history of this subject, as well as a real sympathy for non-hard-nosed, more mystical take on it. I just took the use of "porn" as in "cheap thrill". Nothing wrong with cheap thrills, but there is something more satisfying out there…

35. **David Gladstone**
June 22, 2011

Clearly you thought it was a good review, he agrees with you and vice versa! Quel Surprise!:] He is clearly holding a disapproving mirror up to these guys (and more importantly to us, the public masses), as if saying 'you cannot be serious enough to think you have anything new to say! ' We professionals all have things perfectly well in hand, thank you very much , now move along…! It seems like many people, have a love-hate relationship with this new physics stuff and all the spooky action at a distance effects Einstein himself was afraid of decades ago. The eminent scientist Heinz Pagels, was someone was so enraged by the temerity of people like Jack (actually it's more honest to say it was just Jack who could drive him to distraction), he'd literally chew the carpet and yet he felt compelled to listen to what he had to say (through me) and contest every thought he'd ever have with incredible personal emotional heat. You'd think we were talking about global warming. Wheeler would just throw Jack's mimeos and letters in the circular file, he (JAW) told me that himself, btw.
But I see some of what's wrong with physics right here on this blog in the attitudes of a number of people, a pretty fair number btw, who will never accept this stuff and what it really means till the Angel Gabriel blows his horn on American Idol.
The Palestinians and Israelis will kiss and make up before that ever happens, imo.

36. **David Gladstone**
June 22, 2011

Peter, allow me to say one more thing about this:
But I do believe there are greater concerns at work here, I do not believe it's a theoretical discussion that has no temporal or mundane urgency, it has. The very existence of of just one of the spooky effects, say telepathy, poses grave questions concerning our national security, and our near term futures, that few have addressed, with the exception of people like Martin Reese and Stephen Hawking. The fact is if just one of those things is real, they're all real, because related and what they mean for humanity has hardly ever been addressed and the withholding of recognition, just like in the middle east, will continue to keep us from delving farther into what we're facing, which is a grave mistake, imo. We are a species in denial.

.

37. **Dave Miller**
June 24, 2011

Tim van Beek wrote to me:
>It is possible to show that correlations that are described by Bell's inequalities do not violate relativistic causality, in axiomatic quantum field theory.

Yes, I think we all know this: it is a very, very old result. In fact, I first saw it proved by Lenny Susskind (!) in a class back in the mid-70s.

But that is not what is bothering a lot of us: *of course* the predicted and observed violations of Bell's inequalities do not result in observed violations of relativity. Nevertheless, Bell's inequalities (which do not assume determinism) do seem to follow necessarily from "locality" in the common-sense meaning of the term. Their (expected) violation by quantum mechanics does seem to me to be telling us there is something here we do not understand.

In fact, a similar point can be made more easily in QFT: the VEV of a product of fields with space-like separation often does not vanish. I find that puzzling, even though I of course know that, as long as the appropriate (anti) commutators vanish for space-like separations, then no violation of relativity will be observed experimentally.

I have no axe to grind here: I am not an advocate of any particular alternative to orthodox QM, not even such now-popular alternatives as decoherence or many-worlds.

I am merely puzzled. It seems to me that sometimes a willingness to be puzzled is a good thing.

Dave Miller

This Week’s Hype

June 15, 2011
Categories: This Week's Hype

Last month’s Quark Matter 2011 conference was a venue for discussion of new results from the first heavy-ion run at LHC energies last fall. I’ve looked a bit at the slides of the talks, but this is an area far from my expertise. One thing I’ve been wondering about is whether the heavily-promoted application of AdS/CFT to studying heavy-ion physics could possibly be tested at the LHC. Does AdS/CFT make any distinctive predictions about how things will change as one goes from RHIC energies to LHC energies, and have these been checked? Looking at the slides, there seem to be all sorts of interesting things being learned about heavy-ion physics, but little mention of AdS/CFT modeling of such phenomena. Perhaps an expert can help by pointing to pre-LHC predictions, and explaining whether they’ve been tested already, or may be in the future.

Symmetry Breaking magazine today does cover Quark Matter 11, with String theory may hold answers about quark gluon plasma, which appears to mostly contain the same hype about string theory and heavy ion physics that has been current for the last half-dozen years now:

> Now, scientists have begun to see striking similarities between the properties of the early universe and a theory that aims to unite gravity with quantum mechanics, a long-standing goal for physicists.

Unfortunately there’s nothing in the article about any LHC test of these ideas. The closest we get to that is this from Krishna Rajogopal (his talk is here):

> “String theory is like a gift to us,” Rajagopal said. “We’re challenged with understanding the quark-gluon plasma as a liquid, and while string theory doesn’t give us precision, it can help us get a feel for the shape of the subject.”

So, I gather that AdS/CFT makes no precise, testable predictions, with the best case to be made for it that “it can help us get a feel for the shape of the subject”, whatever that means. A question for experts: if “String theory may hold answers about quark-gluon plasma”, what are the questions for which string theory is giving answers, and what does the LHC data have to say about these questions?

Update: David Mateos has posted a write-up of his Quark Matter 2011 talk here. In it, he explains what the problems are with using AdS/CFT to say anything about QCD. In terms of the question of LHC predictions, he gives an example: the dispersion relation of heavy quarkonium mesons moving through the quark-gluon plasma. Unfortunately, this doesn’t look like much of a prediction:

> I emphasize that whether one obtains a visible peak, simply a statistical enhancement or an unobservable effect depends sensitively on many parameters related to the in-medium J/Psi physics. The latter is not sufficiently well understood to make a precise prediction, so all one should take away from figure 3(right) is that there could be an observable effect for some values of the parameters within the acceptable range.

Comments

1. **Derek Teaney**
   June 16, 2011

   Peter,

   Testable predictions seems to be asking for too much — as the correspondence
   (at its best) is for maximally supersymmetric theories.

   But, it would be certainly unfair to claim that the AdS/CFT has not to heavy ion physics (and vice versa) . For instance, the most striking observations at the Quark Matter conference were the remarkable wealth of new data on hydrodynamic flow (higher harmonics) . In simulating RHIC and LHC events we use a second order hydro formalism which was fully worked out (through work in AdS) by Baier, Romatschke, Son, Stephanov, Starinets. Steve Gubser, recently found an analytic solution to the hydro equations using methods inspired by AdS which will be useful to even the most phenomenological heavy ion smashers, especially those concerned with higher harmonics (myself included). It is also interesting that traditional heavy ion people spoke about work in AdS/CFT. For example, in my case, instead of speaking about flow, I spoke about a new approach to hawking radiation in non-equlibrium geometries which drew heavily upon experience with non-equilbrium field theory (based upon the 2PI formalism).
   I view the AdS/CFT as an extreme limit which can be useful when confused by
   the new data. For example, while it the shear viscosity to entropy ratio may not
   be 1/(4*pi), the new data are placing new constraints which suggest a range (1-3)/4\pi . Berndt Mueller (who could have spoken on any number of current heavy
   ion topics) also gave an interesting talk on thermalization in AdS/CFT
   here.

   In summary, while the correspondence may not provide precise quantitative predictions, it can hopefully provide guidance and insight to complex physics.

2. **Conformal**
   June 16, 2011

   Whatever the status of AdS/CFT as physics, it has inspired some deep mathematics, e.g. in differential geometry. That means that it has not been a waste intellectually.

3. **Yatima**
   June 16, 2011

   Could anyone point me to a succint explanation of where the “liquid” or “hydro-” methapor comes from in this case and what idea it is supposed to encapsulate?

4. **Bernhard**
   June 16, 2011

   Derek Teaney,

   What is very clear from what you are saying is that traditional criteria to handle a certain theory and test it, somehow does not apply to AdS/CFT since it does not provide precise quantitative predictions. “Provide guidance and insight to complex physics” is not enough since one cannot be sure if the theory is correct in the first place, so this guidance could be wrong. Asking for testable predictions is NOT asking too much, is asking for what makes science to actually work. What I would like to see if whether anything being done in heavy ion physics can say if AdS/CFT or ST is correct. Clearly this is not the case, if and when results don’t match with AdS/CFT it does not mean its wrong and even when it does “give guidance” , one is at best confirming a test of equivalence between two theories so no real experimental test was done.

5. **Derek Teaney**
June 16, 2011

Dear Bernhard,

Regarding "What is very clear from what you are saying is that traditional criteria to handle a certain theory and test it, somehow does not apply to AdS/CFT since it does not provide precise quantitative predictions. "

This statement more less discounts models for providing qualitative insight to complex physics. Think back to QCD for how wrong this is — for confinement and asymptotic freedom the Gross-Neveu model; for chiral symmetry breaking we have the linear sigma model and the nambu jona lasinio model; for small x physics (important to heavy ions) the McLerran Venugopalan Model; in energy loss in QCD (important to heavy ions) the Gyulassy-Wang model… None of these models provide "precise quantitative predictions", but all have been extremely useful at capturing one or more aspects of complicated physics

Of course AdS/CFT does make precise quantitative predictions for N=4 SYM theory with a large number of colors and strong coupling. So if "only" the N=4 theory could be simulated on the lattice then the predictions of the correspondence could be tested.

6. **A.**
June 16, 2011

At LC2011 last month there were several talks about AdS/CFT and AdS/QCD. The bulk of questions from the audience were from disgruntled older physicists asking, slightly more aggresively than I would have guessed, "But what does this have to do with real physics?" to which there were some refreshingly honest answers, such as "AdS/CFT has probably taught us nothing about real QCD."

I hadn't seen this kind of attack/surrender pattern before.

7. **Bernhard**
June 16, 2011

Dear Derek Teaney,

Thanks for the answer, that was very interesting. You have a good point that qualitative insight is indeed useful and the examples you gave are very good. But for asymptotic freedom even if the prediction is not all mathematically precise it is certainly not ambiguous and highly testable.

What I find most interesting is your statement:

"So if "only" the N=4 theory could be simulated on the lattice then the predictions of the correspondence could be tested."

If you care to enlighten my ignorance a bit more, are you saying that if this simulation were possible one could test AdS/CFT in the sense that it could also proved to be wrong? I know this would not test ST in any sense, but it would indeed be an exceptional achievement.

8. **Peter Woit**
June 16, 2011

Derek,

Thanks for the detailed and informative content. This still leaves me with the same general impression I got from the slides I was looking at: AdS/CFT provides an interesting toy model to play with, but it's far from being the sort of thing that is in any sense experimentally testable. The descriptions of the situation provided by some physicists to the press are pretty outrageously over-hyped.

It would be useful if people kept separate the different sorts of issues involved here about confronting QCD with experiment which your last comment to some extent mixes up. By my count, there's

1. purely toy models, like Gross-Neveu (which is a 1+1d model), which can't in any sense be confronted with experiment.

2. sigma models, which provide a good approximation to the low energy behavior of the theory in certain sectors. These can be confronted with experiment in some regimes.

3. the McLerran Venugopalan and Gyulassy-Wang models you mention, which I know nothing about.

4. the comparison of AdS/CFT-based calculational methods with other non-perturbative calculational methods in N=4 QCD (e.g. the lattice), which provide checks on the validity of the methods, but have nothing to do with confrontation with experiment.

9. **J**
June 16, 2011

Derek: I am very happy to see you here making nice explanations about quark-gluon plasma physics.

And guys, let's be fair and honest.

Does string theory or more narrowly the AdS/CFT provide precise, quantitative, and testable predictions for QGP physics? I think the answer is NO. Further I think most people in the field of QGP physics hold the same awareness, despite whether they would like to speak this atitude out or not.

Does this tool AdS/CFT useful for the QGP physics? YES, actually very much. Again I believe a lot of people (maybe not the majority, but certainly a fair fraction) of QGP field share this opinion. Look, physics is different from mathematics in many aspects: one distinction of course is the experimental test; yet another distinction is that physics often gets boost from conceptually useful ideas and models even some of those are not the complete story or even wrong. I think playing wild cards a bit is healthy and good for the development of physics, and it is fair to say the application of AdS/CFT for QGP physics has produced many intellectually useful developments.

Of course, over-selling (on purpose or not) is not good. But over-killing is probably another extreme. The only thing that matters, I guess, is that the people who are doing QGP physics know very well the boundary of the usefullness and bullshit-ness for applying AdS/CFT to QGP.

10. **Peter Woit**
June 16, 2011

J,

Thanks for the comment. I assume most experts in the field do know what's useful and what's bullshit in this story. Unfortunately, the press coverage has been uniformly misleading about this.

11. **srp**
June 16, 2011

As a complete outsider, it's kind of interesting how "wild" the theory of the strong force still is, even after it's been incorporated into standard physics. It sounds like it's still very hard to figure out exactly what the theory predicts in any specific case, but I'm a bit confused about just where we are. For example, would it be correct to assume that the proton is the model system where everything can be calculated pretty well from first principles? How about something like a helium nucleus? Is there a quark-gluon derivation of hydrogen to helium fusion?

Naively, if people are trying to study heavy-ion collisions with zillions of pieces flying around you'd think that the simpler cases had long been solved, but I'm not sure because I'm aware that sometimes messy things have to go first experimentally. In any case, it sounds like there's lots of important work to do.

12. **Derek Teaney**
June 16, 2011

This is my last (long) post on this

Dear Peter,

There are models which are somewhere in between toy models such as Gross Neveu and more rigorous approaches such as Chiral Perturabtion theory. For instance, the Nambu-Jona Lasino model does provide a picture of chiral symmetry breaking and does have a phase transition at finite temperature to a chirally symmetric phase. This qualitative feature of NJL models was of course confirmed by lattice (i.e. real QCD) only (much) later.

Lets talk about the Gyulassy Wang model: in this case the medium is replaced by random static scattering centers — this is certainly not the real quark gluon plasma. Nevertheless, the Gyulassy Wang model can be used to study the radiative energy loss of high energy partons propagating through random static scattering centers (as opposed to QCD). (Much) later when people worked out real QCD (at weak coupling) it turned out that the Gyulassy Wang model captured almost all the essential physics, e.g. the probe energy and path length dependence.

One of the qualitative lessons from the strongly coupled N=4 theory is the absence of quasi particles. This leads to qualitative predictions for spectral densities (i.e. photon production rates) which are markedly different from weakly coupled expectations. I (and others) wrote about this here . (See figure 5.)
While no one would reasonably compare the N=4 theory to real QCD spectral densities it is interesting wether this qualitative result survives.
At the quark matter conference, there was, what I would describe as the first serious effort to extract the current-curent spectral density here. The lattice spectral functions (which are not without systematic effects) are disasterously inbetween the quasi-particle theory and the strong coupling theory

Another lesson from the N=4 theory is the appearance at strong coupling distinct inversion of scale, Temperature=T << \sqrt{\lambda} T. lambda = g^2Nc is the 't Hootft coupling. In weak coupling non-abelian plasmas the scales are exactly reversed \sqrt{\lambda} T << T. The not particularly smalln Debye mass (which is proportional to \sqrt(\lambda)) for real numbers forces perturbation theory to go to very high orders and to treat m_D as variational parameter. This was discussed at quark matter here , by Nan Su.
In fact naive first order application of perturbation theory in QCD the Debye mass is several times the temperature. All of this makes the N=4 theory and interesting theoretical foil to the weak coupling calculations.
In particular, the scale inversion implies that the dynamics of high energy probes are distinctly different depending on how the energy compares to these scales, ie. T << E << \sqrt{lambda} T. Or T<< \sqrt{\lambda} T << E . It is interesting to look for such inversion of scales in the heavy ion data.

Peter and Bernhard,

Regarding hypothetical simulations of N=4 theory at finite temperature (which are basically impossible, but who knows…). It would provide numerical evidence for an amazing web of conjectures starting with the Black Hole entropy and arriving that the pressure of N=4 SYM at Large N is 3/4 of the steffan Boltzman pressure. It also would strongly suggest (What do you think Peter) that a non-perturbative formulation of the string theory exsists.

13. **Peter Woit**
June 16, 2011

srp,

Yes, calculations in QCD are amazingly difficult, and for many aspects of it we still have no good calculational methods. The proton itself is still imperfectly understood, and calculating nuclear physics quantities (or heavy-ion physics ones) from first principles is currently pretty hopeless. The amazing thing though is that when something can be reliably calculated (perturbatively, lattice calculations, symmetry arguments) there is agreement with experiment.

14. **Peter Woit**
June 16, 2011

Derek,

Thanks for putting the effort into explaining more about some of these issues.

In principle, calculations at arbitrary couplings and number of colors of N=4 SYM could show that AdS/CFT works, and that you can approximate the theory in some regimes with strings or with supergravity. Even if you did this though, the only well-defined theory you have is a quantized Yang-Mills theory, a QFT. You still can't start from the other end of the duality and write down a well-defined theory whose fundamental variables are strings. What one would really like is a version of the duality that allowed you to start from either end, writing down a complete theory in terms of either strings or gauge fields. Right now you've only got the QFT half of this.

One aspect of this is that you can (in principle!) define precisely any QFT, in any background. AdS/CFT is only going to give you a precise theory you may want to call a "string theory" in one specific background. You can generalize this with more general gauge/gravity dualities, but I still don't see anyone making progress on the question of what string theory in general backgrounds really is non-perturbatively, i.e., what is M-theory?

15. **Peter Orland**
June 17, 2011

In the last few years, I made a few comments on this blog about AdS/QCD. I said something along the lines of:

The real strong-coupling theory is found by a renormalization group. Take QCD with a cut-off up at the Planck mass. Integrate out all the degrees of freedom with wavelength bigger than 0.5 Fermi. There is no universality (the strong-coupling action depends on the cut-off method) and tons of irrelevant operators in the action. THAT'S the right strong-coupling theory. I was metaphorically excoriated as ignorant or worse, as a result.

Anyway, strong coupling is an old story. In the 1970's, Hamiltonian lattice theorists (some of whom later turned to string theory) got a rough caricature of the hadron spectrum, by working at very strong coupling (total confinement without any real gluon dynamics). Their predictions were not that different from the quark model (and they did not get good results for mesons, like the quark model w/o current algebra). Something better came along, namely Monte-Carlo simulations (though it took a long while for them to be much better).

This just means AdS/QCD is a model and not the actual strong-coupling limit. I gather most comments above are saying precisely this.

16. **chris**
June 17, 2011

As a relative outsider to QGP physics i hope not to offend people in the field, but my general impression is that heavy ion physics and quark matter is basically still a mess. and it's no wonder why this is so: strongly coupled multi-particle systems are notoriously difficult from the theoretical side. and (non-equilibrium) thermodynamics of a short-lived collision product of hundreds of strongly coupled particles is a really tough experimental job. experimentalists frankly admit that they can't determine the (pseudo-)critical temperature even. and theorists are fighting about the correct value for years now (on top of which the hydro is really difficult).

in this general setting, things like AdS/QCD are extremely welcome. i have repeatedly witnessed senior heavy ion people trying to understand the lifetime or equilibration time of the QGP in terms of dual black holes. these people know that the model has its limitations but it seems to me at least that the competition is not doing so much better in terms of rigor. the advantage of string duality methods is of course the relative ease. the competition is lattice gauge theory and hydrodynamic simulations – both really tough and computationally intensive. once the field matures – and that may take a very long time – models will hopefully be obsoleted and replaced by ab-initio understanding. but as it stands, AdS/QCD seems to be one model among many and probably not the worst at the moment.

17. **Wolfgang**
June 18, 2011

"… the only well-defined theory you have is a quantized Yang-Mills theory, a QFT. You still can't start from the other end of the duality and write down a well-defined theory whose fundamental variables are strings."

I don't think that's the right way to think about this.

N=4 super Yang-Mills should be seen as the nonperturbative definition of Type IIB string theory on AdS5xS5. That definition implies a prediction: that the large-N, large 't Hooft coupling limit of N=4 SYM is described by classical supergravity in AdS5xS5.

That is a surprising and unexpected prediction. (Not totally-unexpected: it was long-conjectured that large-N Yang-Mills is a classical theory; it's just that no one suspected that the "master field" was a higher-dimensional supergravity.) But it really is a prediction, and it has lots of consequences that have been checked by explicit calculations.

Furthermore, if you supplement the above with an additional hypothesis: "Strongly-coupled gauge theory plasmas have certain universal features of their behavior." then this prediction about N=4 SYM has experimental consequences for the QGP.

Of course, "certain universal features" is a bit vague. That's why AdS/CFT is, at best, a model for the QGP. Still, it seems to capture a lot of the important features of the QGP, which is why the nuclear theorists are excited.

18. **Peter Orland**
June 19, 2011

"Furthermore, if you supplement the above with an additional hypothesis: "Strongly-coupled gauge theory plasmas have certain universal features of their behavior." then this prediction about N=4 SYM has experimental consequences for the QGP."

Right, this is what people say, and I am certain it is plain wrong. There is nothing universal about BARE strong-coupling theories, where the cut-off is large. So, knowing someone will call me an ignoramus or just plain evil, I will elaborate a bit on my comment above.

In field theory and critical phenomena there is nothing universal in a random point of the phase diagram (including the coupling as well as the other parameters) of a cut-off theory. Thus, the strongly-coupled theory with a cut-off has NO universal properties. Universality is something that applies to theories near a critical point (where the cut-off is gone!), which in the case of gauge theories means small bare coupling. The renormalized coupling can be large.

I am convinced this bit of conventional wisdom some AdS people say about the QGP is false. These AdS/QCD theory are models. You can do phenomenology, perhaps even good phenomenology with them. That doesn't make them universal.

It is a technical point, but it is important.

19. **Wolfgang**
June 19, 2011

"There is nothing universal about BARE strong-coupling theories, where the cut-off is large."

You are right that there is nothing "universal" about the UV behavior of QFTs. QCD is weakly-coupled in the UV.

But QCD is strongly-coupled in the IR, and it is that IR behavior (at finite temperature) that we are discussing.

20. **Peter Orland**
    June 19, 2011

    No, I did not mean UV behavior. I meant IR behavior.

    In asymptotically-free theories, the real bare coupling (not the renormalized coupling) goes to zero as the cut-off is removed. It is the properties of the theory with no cut-off that are universal. If you have a large gauge coupling in a cut-off (but otherwise local) field theory, nothing is universal. Not viscosity divided by entropy, not parameters of elliptic flow, not anything!

    If the bare coupling is small, so that the theory is near the continuum limit, you have universality in a quantum field theory. That is not the case here.

21. **Peter Orland**
    June 19, 2011

    I should add that often it seems there is much confusion concerning the phrase "strong coupling". There is a difference between a cut-off theory with a large bare coupling and the strong-coupling (IR) limit of a gauge theory. The strong-bare-coupling theory is just a model. It it the strong-renormalized-coupling theory which is unique, i.e. universal. In this theory, the bare coupling is infinitesimal, not big.

    The bare coupling is not physical. It must be taken to zero with physical quantities fixed (this defines the r.g. equation). This is true for any observable, large Wilson loops or other probes of IR included.

22. **Wolfgang**
    June 19, 2011

    "If the bare coupling is small, so that the theory is near the continuum limit, you have universality in a quantum field theory. That is not the case here."

    I assume by "here," you mean N=4 SYM at large 't Hooft coupling (since, for QCD, the bare coupling obviously is small). N=4 SYM is conformally-invariant. So you are always near the continuum, at any value of the bare coupling.

    "The bare coupling is not physical."

    True in QCD, but not true in N=4 SYM.

23. **Peter Orland**
    June 19, 2011

    But heavy ion physics is not N=4 YM!

24. **Wolfgang**
    June 19, 2011

    In QCD, the bare coupling is unphysical, and is tuned to zero to obtain the continuum limit. In N=4 SYM, the theory is conformal, the bare coupling is physical, and you are near the continuum, for any value of the bare coupling.

    In neither case do your comments, above, seem to be relevant. When you said

    "If the bare coupling is small, so that the theory is near the continuum limit, you have universality in a quantum field theory. That is not the case here."

    what did you mean by "here"?

25. **Peter Orland**
    June 19, 2011

    "Here" is heavy-ion physics, described by (renormalized) QCD. Again, I am not criticizing using AdS methods as models. I just think this talk about universality has no basis.

    If you claim universality, you need a reason. I don't see why AdS models should give universal answers. There is nothing universal about a strong-bare coupling AdS/QCD model. Certainly nothing universal about an entirely different theory like N=4 Yang-Mills. People say it's so, but they don't provide a reason.

26. **K. Kajantie**
    June 20, 2011

    I think one could draw some parallels to QCD around 1970. Then there was an extremely successful constituent quark model, counting rules, parton model, etc, but really no idea why they worked so well. Now we have some very suggestive observational facts (p=3/4 p_ideal, shear viscosity, pattern of quark energy loss) but again no quantitative theory, only rough idea. Then around 1972-3 came QCD Lagrangian, asymptotic freedom and quantitative predictions for logarithmic scale violations in deep inelastic scattering. It took a few years to verify these and convince everybody of the fact that QCD is the correct theory. This is the stage we are missing today and until a QCD-string theory dual permitting quantitative predictions is there, there is no way to convince everybody. This is, of course, a completely trivial statement. Unfortunately this dual seems extremely remote and also there is much less help from experiment to guide us there.

27. **Wolfgang**
    June 20, 2011

    ""Here" is heavy-ion physics, described by (renormalized) QCD."

    Then the bare coupling has been taken to zero, and I don't see what you are going on about.

    "There is nothing universal about a strong-bare coupling AdS/QCD model."

    Perhaps I don't know what you mean by "AdS/QCD", but in N=4 SYM, the theory is conformal, the bare coupling is physical, and the strong bare coupling behavior IS universal (in the commonly-used sense of the term "universal").

You seem to want to apply either the intuition from QCD (where the bare coupling is unphysical) to N=4 SYM (where the bare coupling is physical, and your intuition is incorrect), or you seem to want to work in QCD and take the bare coupling to be strong (which is NOT a sensible thing to do).

I can't figure out which of them you have in mind, but neither of them seems correct.

28. **Peter Orland**
June 20, 2011

Wolfgang,

I made no comments on the validity of calculations for N=4 theories, just for QCD.

I said only one thing: I see no justification in claims of universal predictions for heavy-ion physics. It is a pretty clear statement, even if you don't agree.

29. **Wolfgang**
June 20, 2011

"I said only one thing: I see no justification in claims of universal predictions"

Your statement was about the strongly-coupled lattice gauge theory of QCD. But there is no justification for using the strongly-coupled lattice QCD. To the contrary, one wants to tune the bare lattice gauge coupling to zero.

Whether or not there is some sort of "universality" in the behavior of strongly-coupled gauge theory plasmas, your statement seems to have no bearing on the question.

But perhaps I have misunderstood your argument. Why is the strongly-coupled lattice QCD relevant to heavy ion physics?

30. **Peter Woit**
June 20, 2011

Wolfgang,

Your discussion with Peter Orland I fear is going nowhere. My understanding is that he's simply objecting to your claim about "universal behavior" in N=4 SYM and asking for justification. What exactly does this mean and what is the argument? Presumably it can't be the same kind of universality argument one can make for asymptotically free theories by putting them on a lattice, and defining the continuum limit by going to the critical point at zero coupling.

His reference to strong-coupling lattice theory I take as an analogy: there's a strong-coupling limit in lattice gauge theory, but there's nothing universal about it.

As for your response to my posting: of course AdS/CFT makes a prediction, a very interesting one, but it's a prediction about a specific QFT (N=4 SYM in a certain limit). Again, what's well-defined here at all couplings is a QFT and statements can be made about that. You don't have a method for defining string theory at any coupling. All you can do is, in a very specific background, define away the problem of "what is non-perturbative string theory" by saying that whatever it is, it's the same thing as a well-defined QFT.

31. **Peter Orland**
June 20, 2011

Wolfgang,

OK, I'll try one more time. Here is what I said:

No arbitrary theory with a cut-off and large bare coupling (which includes both lattice and modified AdS approaches. The latter go by the name of AdS/QCD – not standard N=4 susy YM) can give universal results. These are strongly-coupled theories, but they are the wrong strongly-coupled theories.

I wasn't commenting on theories with vanishing beta functions, though it is hard to see why these should produce results in the same universality class either. They have no QCD-type scale, and completely different matter content. There is no reason to think their infrared behavior resembles QCD.

Summary – I don't believe AdS methods give solid predictions for heavy-ion physics, though I don't doubt some good phenomenology can be done.

I tried to give some justification for this statement in terms of the renormalization group.

I don't know what I can add to make the above points clearer.

32. **Peter Orland**
June 20, 2011

Wolfgang: When I posted the last comment, I did not see Peter W.'s clarification. He summarized it very well.

33. **Wolfgang**
June 20, 2011

"… he's simply objecting to your claim about "universal behavior" in N=4 SYM and asking for justification"

The only justification is a semi-empirical one: there are a number of 4d theories (not just N=4 SYM), for which one can form an AdS/CFT correspondence. They have different amounts of supersymmetry, different matter content, etc. Those properties (and only those properties) of the corresponding gauge theory plasmas, which agree between these different theories, have some claim to being "universal."

"They have no QCD-type scale, and completely different matter content. There is no reason to think their infrared behavior resembles QCD."

Their zero-temperature behavior is completely different from QCD. The claim is about (certain features of) their finite-temperature behavior.

"All you can do is, in a very specific background, define away the problem of "what is non-perturbative string theory" by saying that whatever it is, it's the same thing as a well-defined QFT."

To the extent that you can do computations in that QFT (by whatever techniques you, as a field theorist have available), you are computing the behavior of the corresponding string theory in an AdS background.

You surely didn't expect that determining the behavior of the string theory required no computation whatsoever! So the fact that the computation has been reduced to a field theory computation (in lower dimension) is about as simple a result as one could possibly hope for.

And that computation carries with it lots of predictions about the field theory, too: in certain limits, certain "known" features of the string theory ought to emerge from the field theory calculation (the supergravity limit was one such limit, the BMN limit is another). So one learns not just about string theory in AdS, but about (suprising!) features of field theory.

34. **Peter Woit**
June 20, 2011

Wolfgang,

My objection here is one of language, not about the science. When you write "quantum field theory" this is a well-defined term: at least conjecturally, for the relevant class of theories, we know what this means (i.e. how to non-perturbatively define the theory). When you write "string theory", you don't: what is really meant is "something (M-theory?) we don't even have a good conjectural definition of that has a specific limiting behavior that can be written down as a quantization of strings". I don't believe that the fact that certain qft's appear to have strong-coupling limits that can be identified with weakly coupled strings changes this and makes "string theory" a well-defined term.

35. **Peter Orland**
June 21, 2011

Universality is a very strong statement. It means that there are universal numbers.

36. **Wolfgang**
June 21, 2011

"My objection here is one of language, not about the science."

You do have a point.

People speak of AdS/CFT as a duality between the string theory in the bulk and a field theory on the boundary. Usually, when we speak about a "duality", we have two independently-defined theories, which we claim are equivalent. Here, as you say, the field theory, on the boundary, has an independent definition, but the bulk theory does not.

At best, it has a set of properties it should satisfy. In the IIB case:

* It should reduce, at low energies, to type IIB supergravity.
* It should have an S-duality symmetry, which acts on the axio-dilaton by fractional linear transformations
* It should have a certain set of BPS extended objects (branes), permuted by the S-duality symmetry.
* etc.

The "right" way to think about AdS/CFT is to take it to be the DEFINITION of the bulk theory. Then these properties become predictions about the field theory on the boundary.

It's certainly true that it would be nicer if there were independent definitions for both sides of the duality. Then one would get testable predictions in both directions (not just in one direction).

But, in the absence of such an independent definition, it is still true that AdS/CFT provides a nonperturbative definition of string theory in AdS. And it is nontrivial that this definition is consistent with all of the properties that we expect string theory to possess

June 21, 2011

Dear Yatima,
The "hydro" refers to the hydrodynamics of strongly coupled quark gluon plasma that one is interested in studying. AdS/CFT allows one to calculate certain properties of this plasma such as viscosity to entropy density ratio of QGP in the IR region of QCD, where it is now known to be strongly coupled. The asymptotic freedom in QCD means that gauge coupling would decrease exponentially at lambdaQCD limit. This is what makes LHC such an interesting machine. In a few years, when gets up to full power, it would be able to push beyond the lambdaQCD limit and (hopefully) one would then observe the hydrodynamics of weakly coupled plasma! Since Ads/CFT only applies for the strong coupling case, it would not be suitable (in its current form) to study this new plasma. There is some conjecture though, that AdS/CFT applies for weak coupling as well. This is what's known as the 'weak' statement for AdS/CFT.

June 29, 2011

Rumor has it that Atlas has a "Higgs"-like excess at slightly more than 160 GeV. It has not hit the rumormill, but will do so soon. Also an excess of leptonic events at 950 GeV…..something like a Z'.

39. **Peter Woit**
June 29, 2011

Thanks Charles!

It would be pretty funny if ATLAS finds the Higgs right where the Tevatron experiments claim they have excluded it…

Anyone from ATLAS who feels like posting the abstract of any internal documents about this is encouraged to go right ahead.

40. **Shantanu**
June 30, 2011

Peter,
the 2011 TASI videos are online. See

Quick Links

June 17, 2011
Categories: Uncategorized

- The House committee responsible for the DOE budget has passed a FY2012 appropriations bill, details here. Total funding for DOE Science is down .9% from FY2011 at $4.8 billion. HEP gets a .2 percent increase, Biological and Environmental Research is whacked %10.6, with the committee opposed to climate and atmospheric research being funded by DOE. The language about DUSEL argues against it becoming a DOE lab, but money is made available to keep options open. There is support for Fermilab's Project X (the "intensity frontier"), but a warning that it may not be possible to continue funding both the "intensity frontier" and the LHC (the "energy frontier").

Fermilab this week announced a program to offer a "voluntary separation program" under which they hope 100 employees will voluntarily leave. They're clearly trying to better position the lab for tight budgetary conditions ahead.

- Over in the Czech Republic, Lubos Motl is hanging out with President Vaclav Klaus and is one of the contributors to his 70th birthday Festschrift. Lubos may have a career ahead in Czech politics, too bad he left the US just before the Tea Party movement got going. He would have fit in quite well with them, but I guess at least in the Czech Republic, he can legally become President some day.
- From Physics World, it seems that Lawrence Krauss will be joining with 13 other very prominent academics to teach at New College for the Humanities, a new private university in London. The new university has caused quite a stir in Britain, since it's unlike anything else there. Tuition will be set at US private college levels, $29,000/year, twice what other British universities charge. The business plan is not public, but Wikipedia says 10 million pounds in funding for the first two years is coming from private investors, with the 14 senior academics getting a 1/3 equity stake in the venture. It's unclear how much teaching they'll each be doing, since most will retain their current positions elsewhere and just give anything from one to 20 lectures per year.
- The LHC is doing quite well, with over an inverse femtobarn delivered to the experiments already. For the latest, take a look at the slides of the talks here. At the KITP, there was a very interesting talk by Tim Nelson. He addresses the question of whether the LHC detectors, once their searches aimed at standard speculative ideas such as supersymmetry and extra dimensions turn up empty, can be reconfigured to look for other sorts of exotic possibilities, ones that the current triggers are not sensitive to.
- There's an article here about filmmaker Errol Morris, whose new film "Tabloid" is coming out later this year. I saw it a few months ago at a showing in New York, and highly recommend it. It's one of the most surprising and amazing documentaries I've ever seen. Real life is much stranger than fiction. In the article, Morris describes his early career, which included having Thomas Kuhn throw an ashtray at him and have him kicked out of the graduate program in philosophy at Princeton. He moved on to Berkeley, where he hung out with Dan Friedan:

> "I felt that he had destroyed my life," said Morris. It left him reeling for years to come: He still remembers sitting in a coffee shop at Berkeley with Daniel Friedan, a fellow Princeton exile and the son of feminist icon Betty, and commiserating over the frustrating time they'd had out East.
>
> "I'm talking about all these problems that I had with Kuhn, which was a constant refrain, and he's telling me about all the problems he'd had in the physics department," Morris recalls. "He said, you know, 'They just could not appreciate me. I had discovered a new kind of physics!' And I thought, 'Oh, no. This looks bad. This looks very, very, very bad. This is not going to turn out well. We're both going to the nuthouse.' "
>
> Of course, they didn't. Friedan would go on to win a Macarthur Fellowship, and be recognized for his pioneering work on string theory. Morris, meanwhile, left academia behind once and for all to make a movie about a pet cemetery, called "Gates of Heaven," which became a cult classic, and which Roger Ebert described as one of the 10 greatest films ever made.

- There's a conference going on this week and next at the ETH in Zurich on quantum gravity, with slides appearing here. My long held belief about quantum gravity is that it's a problematic subject unless some way can be found to connect it to unification with the rest of physics, and thus some sort of testability or good reason to believe one is on the right track. Matthias Blau promotes string theory by arguing that it should be judged:

> not by, say, its failure to (so far?) provide specific predictions for BSM physics, or disgust with some of the hype and overblown claims regarding string theory (I may share your feelings . . .)

Among other things, he explains some of the problems with M-theory, then notes that Tom Banks has a highly mystifying recent proposal about this:

> For very recent proposal for how to deal with (some of) these issues, see T. Banks, Fuzzy Geometry via the Spinor Bundle, with Applications to Holographic Space-time and Matrix Theory, arXiv:1106.1179 (and then please explain it to me . . .)

His talk, together with the recent preprint Is string theory a theory of quantum gravity?, provides a good understanding of what the problems are facing attempts to use string theory to quantize gravity, from the point of view of a string-enthusiast.

For the latest from the LQG camp, see Carlo Rovelli's talk here.

Comments

1. **anonymous**
   June 18, 2011

   The LHC has been doing extremely well, not "quite well".

2. **anonymous**
   June 18, 2011

   Would it be better to go to higher energy (1.e. 14 TeV) or try to improve luminosity or work on a detector upgrade? From Nelson's slides it looks like the improved luminosity outweighs any detector upgrades and if there is confidence in new splices then an energy upgrade does not present a risk? I can see this going on for many years..

3. **Yatima**
   June 18, 2011

   Lewandowski: Canonical LQG: soluble models and other advances

   "The canonical LQG provides more and more soluble models of quantum gravity with all the local degrees of freedom. The first model was LQG coupled to dust (Giesel-Thiemann). The current second model describes gravity coupled to massless scalar field. It is an exact generalization of the cosmological models of Loop Quantum Cosmology to the full theory with the local gravitational degrees of freedom."

   http://www.conferences.itp.phys.ethz.ch/lib/exe/fetch.php?media=qg11:lqgrecentadvanceszurich.pdf

4. **abbyyorker**
June 18, 2011

On the new college for …

It's just a new education scam. I did not know Mr Krauss was so cynical. Unless he really thinks he's going to help with his "1-20 lectures a year".

5. **Jon Lennox**
June 19, 2011

anonymous #1: I'm guessing your dialect of English is a UK one? In American usage, "quite" means "very", not "somewhat", so Peter agrees with you.

6. **OhDear**
June 19, 2011

As a Brit living in the states, I would say that "quite" and "very" mean the same on both sides of the Atlantic. We used to have a thing for understatement, but not these days.

7. **Aleksandar Mikovic**
June 19, 2011

There is a growing number of physicist, including the string theorists, who realize that the problem of quantum gravity is not just the problem of finiteness, but it also involves the problem of the fundamental degrees of freedom and the problem of applying the standard quantum mechanics to the whole universe. Obtaining a finite or renormalizible quantum gravity theory with the right classical limit, after all, is not that difficult: for example, take the Horava gravity. However, many people believe that the structure of the spacetime changes at the Planck length, so that string theory and loop quantum gravity (LQG) have many more adherents. When comparing string theory to LQG, both have a non-trivial quantum geometry (strings vs. spin foams) and both are finite and have the right classical limit. String theory offers a natural unification of interactions, while LQG can address more naturally the quantum cosmology. String theory allows a multiuniverse, and LQG as well, through the group-field theory approach, which is a type of the third quantization. Still, neither theory has nothing to say about the problem of applying quantum mechanics to the universe, and even less to the case of the multiuniverse. It is clear that one needs to modify the quantum mechanics, and this is the hard part of the quantum gravity problem.

8. **Peter Woit**
June 19, 2011

Yes, I meant "quite" as in "very".

If you look at the projections made earlier this year, typically they were for around 3 inverse femtobarns for 2011. It seems to me that they're on track for this, which is great.

If they do 5 inverse femtobarns, that might merit "extremely", we'll see what happens, maybe that's possible, maybe not. As a general rule though, this subject is hype-ridden enough, I don't see the point in adding to the problem.

9. **noname**
June 20, 2011

OK, would you agree on the following? If by the end of 2011 each experiment collects 3/fb you'll write "the LHC is doing great". If they collect between 3 and 5/fb you'll write "the LHC is doing extremely well". Anything beyond 5/fb (which I believe is what will happen) will merit your "the LHC is doing outrageously well". Deal?

10. **Peter Woit**
June 20, 2011

noname,

Doing just above 3 inverse femtobarn would still be more or less according to plan, not exactly an extreme situation. I certainly hope you're right, and they get above 5 inverse femtobarns, which would get into a more extreme situation. For "outrageous" I think they need to go to 10…

11. **anon**
June 20, 2011

this one goes to eleven.

12. **Caramel**
June 20, 2011

Am I correct in reading Giddings' paper as saying that no-one no how to predict particle-particle scattering at the Planck regime using string theory? How does that square with all the claims I've heard along the lines of "if we only had a Galaxy-sized particle accelerator, we'd *definitely* observe a tower of excited string states"?

13. **Caramel**
June 20, 2011

"…that no-one knows how…" rather.

14. **Peter Woit**
June 20, 2011

Caramel,

I've often pointed out that the argument for those claims isn't very solid. It assumes that the string dynamics at that scale is weakly coupled and that perturbation theory is valid. There never was a good argument that this had to be true. Giddings explains in detail how non-perturbative effects are important even in scattering processes at energies far above the Planck scale.

15. **Casey Leedom**
June 21, 2011

Wow. I know that this is a "physics blog" but no one else is concerned about the 10.6% decrease in Biological and Environmental Research? High Energy Particle Physics is either “hopeless” or “doing great” depending on which side of the String Theory Divide you fall on but Biological Research is doing amazing things these days and promises both fundamental new knowledge and relevant medical breakthroughs. Very sad if that’s taking a hit.

Casey

16. **Peter Woit**
June 21, 2011

Casey,

This is just the DOE budget. Most biological research is funded elsewhere (NIH?). Also, the budget process is a long ways from completion. I don’t think this necessarily reflects how such research will do overall in the budget.

17. **Casey Leedom**
June 22, 2011

Ah, good point. But still, when I worked at Lawrence Livermore National Laboratory there was a big biology effort (breast cancer, human genome, etc.) and my friends at Lawrence Berkeley Laboratory do a ton of basic biology research.

18. **Mark Decker**
June 22, 2011

Well good for Krauss. Maybe some of the lectures will wind up on youtube so some of the Brits (and us) who can’t afford can still watch. In any event, it will be sad to see him go. He is one of the few Physicists left in this country who still has his sanity.

19. **John Baez**
June 24, 2011

I’m at that Zurich conference. You can see some very fragmentary notes on it starting here.

Bad Boys of Physics

June 22, 2011
Categories: Multiverse Mania

Scientific American is running a Bad Boy of Physics story (also see here) in the July issue, about Lenny Susskind. Here's the "nut graph":

> Physicists seeking to understand the deepest levels of reality now work within a framework largely of Susskind's making. But a funny thing has happened along the way. Susskind now wonders whether physicists can understand reality.

In the interview, Susskind explains that he was a bad boy as a youth, but "just so much better than anybody else, including the professor." In recent years he has been the most prominent promoter of the string theory multiverse, and now claims that this pseudo-science convincingly dominates the field (SciAm seems to agree…), with the situation just like in the early days of QCD:

> A large fraction of the physics community has abandoned trying to explain our world as unique, as mathematically the only possible world. Right now the multiverse is the only game in town. Not everybody is working on it, but there is no coherent, sharp argument against it.
>
> In 1974 I had an interesting experience about how scientific consensus forms. People were working on the as yet untested theory of hadrons , which is called quantum chromodynamics, or QCD. At a physics conference I asked, "You people, I want to know your belief about the probability that QCD is the right theory of hadrons." I took a poll. Nobody gave it more than 5 percent. Then I asked, "What are you working on?" QCD, QCD, QCD. They were all working on QCD. The consensus was formed, but for some odd reason, people wanted to show their skeptical side. They wanted to be hard-nosed. There's an element of the same thing around the multiverse idea. A lot of physicists don't want to simply fess up and say, "Look, we don't know any other alternative."

Susskind had a distinguished career as a theorist for many years, and has managed to do quite well with his multiverse campaign for quite a while now. There has been a lot of coverage of this story on this blog, for some high points, see here, here, here and here.

In other news, the media has been full of stories about another physicist who has been a bad boy, David Flory. He started his career as an HEP theorist back in the late 1960s, as a student at Yeshiva University, and collaborator there with Susskind. Like a huge number of other people, he got his permanent academic job in 1969, and has been at Fairleigh Dickinson University ever since.

Comments

1. **anon**
   June 22, 2011

   maybe Flory was working on G-string theory.
   oh, that joke is bad.

2. **Lee Brown Jr.**
   June 22, 2011

   Susskind now wonders whether physicists can understand reality.

   So, Susskind thinks that if he can't understand it, then nobody can.?

   BTW: SciAm also celebrates the main sequence of stars in this issue. Great article. In fact, if you look closely enough at the depiction of the "periodic table of the cosmos" you can see Susskind's ego grouped in with the supergiants.

3. **In Hell's Kitchen (NYC)**
   June 22, 2011

   obviously, working at FDU for 30+ years isn't good for you !

4. **Bernhard**
   June 22, 2011

   The way Susskind sees the history of QCD can be put into context using David Gross´s Nobel lecture introduction:

   "The progress of science is much more muddled than is depicted in most
   history books. This is especially true of theoretical physics, partly because
   history is written by the victorious. Consequently, historians of science often
   ignore the many alternate paths that people wandered down, the many false
   clues they followed, the many misconceptions they had. These alternate
   points of view are less clearly developed than the final theories, harder to
   understand and easier to forget, especially as these are viewed years later,
   when it all really does make sense."

   Of course QCD does make sense and we now do know it is correct. But we know it because (after asymptotic freedom rescued it) we could be guided by experimental data. This is the only reason there is any consensus among physicists, same can be said about the Big Bang or even more basically quantum mechanics. I´m appalled to see Susskind trying to push the argument that consensus is just a sociological phenomenon among scientists: "The consensus was formed, but for some odd reason, people wanted to show their skeptical side" Really? Meaning what? We don´t want to swallow the untestable multiverse "theory" just to play hard ball? Give me a break.

5. **Chris Oakley**
   June 22, 2011

   David Flory seems to have run a web site similar to http://www.ratemyprofessors.com, except rating whores instead of professors (incidentally there *is* a http://www.ratemywhore.com – I just checked – but this is not obviously connected with David Flory). Curiously, Professor Flory is not well reviewed is http://www.ratemyprofessors.com – maybe he had more important things to think about than teaching physics.

6. **Peter Woit**

June 22, 2011

Bernhard,

I think Susskind's comparison to QCD is absurd, and evidence that the man really has lost his marbles. From the beginning QCD made all sorts of precise predictions, and some were tested decisively early on. Unlike the string theory multiverse, it was a well-defined theory from the beginning, very closely related to the rest of the standard model. In 1974 it was very new and people were just starting to understand how to deal with such an unusual theory, weakly coupled in the UV, strongly coupled in the IR (and, to this day there's a lot we don't understand). The fact that, months after its discovery, people were not sure that a new unusual theory was the final answer is neither surprising, nor has anything at all to do with the string theory multiverse (which now has been around a decade or so, with no sign of prospects for predicting anything at all).

7. **Eric habegger**
   June 22, 2011

   "Flory told police he did not make money off of the (prostitution) website and instead saw it as a hobby"

   He obviously was aware that he was one of the more fortunate professors in being tenured and seemingly financially secure. All men need a good hobby.

8. **Sean the Mystic**
   June 22, 2011

   So I guess H.P. Lovecraft was right then? The multiverse is incomprehensibly alien and vast, far beyond our puny attempts to rationally understand it. Is this is where the Enlightenment ends, and the new dark age of Cthulhu cults and hyper-dimensional string theories begins? Why do I have this strange image of physicists like Susskind wearing black robes and supplicating beneath the stars in some black rite of submission before the vast, inscrutable Cosmos? Oh never mind, I'm probably just crazy. Hahahahhahaahahhahahahahahahahah….

9. **abbyyorker**
   June 22, 2011

   L. Susskind. Guilty by association (40 years ago)? Please say that's not what you mean….

10. **Peter Woit**
    June 22, 2011

    abbyyorker,

    No, obviously the fact that Susskind collaborated with and/or supervised as a student Flory 40 years ago has zero to do with Flory's recent activities.

    After 40 years the two of them ended up in very different places. I suppose you could argue about what is more morally noxious, promoting pseudo-science or promoting prostitution…

11. **Mystic**
    June 23, 2011

    Physics is dead! Long live the new physics! Physics has died, and reincarnated as religion! This is the dawn of a New Age!

    Welcome to Reality!

12. **anon**
    June 23, 2011

    Do you think Flory asked a post doc to write the software, or he programmed it himself? It sounds very similar to math-stack to me.

13. **anon**
    June 23, 2011

    Maybe it should be titled "Senile Boy of Physics"

14. **anonymous**
    June 23, 2011

    LHC will blow them out of sight and into oblivion.

15. **Emanuel Derman**
    June 23, 2011

    Off topic and in bad taste:
    The Susskind – Flory first paper was on Hadronic Currents. Kind of says it all. Second word close to what he was offering to rent, first word close to what it took to rent it. Published in 1969. There is a tide to the affairs of men which taken at the flood …

16. **ateixeira**
    June 23, 2011

    "I suppose you could argue about what is more morally noxious, promoting pseudo-science or promoting prostitution…"

    Really?! WOW!

    Susskind has really lost his marbles… Too bad, I guess.

17. **Fred Tucker**
    June 23, 2011

    Peter, Flory hasn't been convicted of a thing. He could well be innocent of all charges. Doesn't seem right to provide a forum for people to spread nasty rumors about a respected physicist.

18. **tristan stefan**
June 23, 2011

After seeing this blog entry I looked at some stories relating to the investigation, it seems pretty unlikely he's innocent in the sense of caught by mistake. On the other hand, is he guilty of an actual crime, ethically? It looks like he was rating prostitutes online and sharing info about them. In my opinion promoting pseudo-science is just as bad.

19. **Joe Ruski**
June 23, 2011

The new look is acceptable. I want credit for having suggested the archive widget. You owe me, forever.

I've been following the lulzsec hackings. You might want to get rid of your meta "login" link and change the name of the php login file. In general, I've been thinking about passwords, answers to security questions, etc., thinking about security in general.

I've thought of a use for twitter for someone who mainly only wants to blog. To promote a blog post on twitter, you would tweet something like this for every blog post:

"Bad Boys of Physics" [link provided of course] is up on the blog. Comments by twitter are welcome.

You might also link to the tweet in your blog post so a person could go to twitter.com and reply to your tweet from there.

There would be several reasons to do this: 1) to allow people to use twitter to get notified of new posts, 2) to allow comments on twitter that you might not want on your blog, and 3) to give people another way to give you feedback; some people might tweet you, but not email you or comment on your blog.

Twitter comments have some advantages. A person's comment can only get so stupid when limited to 140 characters, plus your twitter account won't display comments from people you're not following. It's a happy medium. It lets people comment, but you don't have to host their comments. To find replies to someone's tweets, people have to do a search like this: http://twitter.com/#!/search/%40lulzsec

Here's a guy who uses twitter to promote his blog posts:
http://gerard.cc/
http://twitter.com/gerardvroomen

On his blog, he has a "Tweet" icon below each post, but those links do retweets and searches based on the blog post URL rather than on @gerardvroomen; thus my suggestion above about linking to the tweet in the blog post, so that the twitter replies are synced to the appropriate tweet.

I've had no use for twitter, but people are using it more all the time. It's taken me a while to see the purpose in people tweeting cryptic messages, but I've started to see that some people use it for more than useless and trivial details about their life.

20. **Joe Ruski**
June 23, 2011

I don't tweet yet, so I don't know all the ways twitter forces a tweeter to promote those who reply to a tweet. One way is that if you click on the arrow next to a tweet, it'll show you the replies to that tweet, although I think a person might be able to suppress certain replies on his or her twitter page.

In case you care.

It's not all upside. You wouldn't want me riding on your coattails, would you?

21. **Peter Orland**
June 24, 2011

I am kind of disturbed by some of the negative comments about Susskind here. I don't
care for multiverse ideas, but Susskind made very important contributions to field theory and particle physics (strong-interaction strings, parton models, U(1) problem, Hamiltonian lattice QCD, technicolor). You can have a strong difference of opinion without getting nasty…

22. **Peter Woit**
June 24, 2011

Joe,

It does seem there's a lot happening now on twitter or other social media, moving away from blogs. For now though, since I'm already spending too much time on the internet, I think I'll continue not getting involved in that. It seems quite likely that twitter will either evolve into something interesting or die off within a couple years. I'll try and wait that out and see what happens…

Peter O.,

When people like Susskind, who have a history of real accomplishments, start saying completely idiotic things (like his comparison of QCD and the multiverse), it does create a problem. Do you accurately describe what they are saying as idiotic, or do you politely avoid doing so in recognition of their past history? Susskind unfortunately has gotten and is getting a lot of positive attention for his nonsense, one reason being that most people in the community think it best to politely ignore what he is up to.

In general my own policy is to stick to serious arguments and avoid personal characterizations of anyone I disagree with, and to encourage the same from commenters. In Susskind's case, given his history of launching nasty personal attacks on me and on others who disagree with him, I'm a bit less motivated to worry about whether he is getting the proper respect he is due.

In his case as in quite a few others in recent years as string theory has collapsed, I'm continually suprised not only by the kind of behavior and argument engaged in, but also by the rest of the community's tolerance of it.

23. **Chris Austin**
June 24, 2011

I thought Lenny Susskind's story about the informal poll he conducted in 1974 was an interesting historical anecdote.

But David Gross seems to have given QCD more than a 5 percent chance in 1974: see page 20 of hep-th/9809060, “Like an atheist who has just received a message from a burning bush, I became an immediate true believer.”

24. **Anon**
June 24, 2011

The quality of Scientific American is unfortunately not nearly what it used to be in, say, the 70s or 80s. The caliber of journalism in this publication has become, overall, very poor. Even just the first paragraph is illustrative of this depressing downwards trend:

“And he helped to develop the modern conception of parallel universes, based on what he dubbed the “landscape” of string theory. It spoiled physicists’ dream to explain the universe as the unique outcome of basic principles.”

Both sentences are strictly speaking false, yet marketed as accepted truth. It exhibits the kind of intellectual laziness you would expect to find in a mediocre high school essay.

The writers of this magazine should be forced to read the New Yorker for examples of beautifully constructed and intellectually coherent writing.

25. **Peter Woit**
June 24, 2011

Anon,

I don’t think it’s fair to blame the journalists. They’re just reporting the claims made by some of the most prominent and respected figures in the field of theoretical physics. The two sentences you quote are ones that I’m sure Susskind would describe to journalists as accurate. And he’s far from the only one who would do so.

People seem to expect that science journalists will do the job that other physicists should be doing but aren’t: pointing out the reasons why this is pseudo-science. You can’t expect journalists to have better critical scientific skills than the people they are covering.

26. **Anon**
June 24, 2011

Other physicists are pointing out that this is pseudoscience.

If the New Yorker, which is not a science magazine, can have articles of this quality (written by non-science journalists):

http://www.newyorker.com/archive/2006/10/02/061002crat_atlarge
http://www.newyorker.com/reporting/2008/07/21/080721fa_fact_wallacewells

why shouldn’t we expect better from SciAm?

27. **Leonard Lerner**
June 24, 2011

I have just read “Not even wrong”, a lot of what it says I suspected but did not know for sure. I also belong to the generation of 1980’s PhDs in particle physics, and recall the great the triumph with which we were told at the 1986 summer school in Durham that string theory has proved that the world is ten-dimensional, because only in that case do its infinities cancel.

I wanted to comment concretely on what I think is a more general problem, from which much of what the book discusses flows.

The sharp drop of honesty in physics. And much of this has to do funnily enough with money. On the one hand theres too little, so that only 10% of PhD in particle physics can get a job in what they were trained (as mentioned in the book) on the other hand, there are 20 or so conferences a year in “nice places” for string theorists to choose from. SO money is there, but it is being misspent by those at the top, because of their desire for a certain ‘lifestyle’. They then have to justify the lifestyle by a huge output of papers from their subordinates. This generates a certain lack of honesty, but I will come back to the concrete case I wanted to mention.

Physics Review Letters has been a premium journal in physics, everyone is proud if their article is accepted there. It has a comments and reply section, by now absent in most other journals, where readers are invited to comment on regular articles published in that journal. If you look at the comments you will find that if they do raise some controversial issues about the original article, there is always a ‘collegial’ responce in the reply, which gives further food for thought to both parties. There is never a comment pointing out a major error in a published article to which the authors have no response. Yet there are rules in PRL stating that if the response can not pass the refereeing process, the comment will be published without a response. Yet no comments pointing out major shortcoming in articles in PRL with no response have ever been published.

A few years ago I noticed an article in PRL on some work I did a few years previous, and which I put aside considering it of no promise. The PRL article however manipulating the same formulas got a different result, gave it a ‘big’ interpretation, and this constituted ground for PRL publishing it. I re-analysed the formulas, saw the mistake they made (it was to do with treatment of singularities), and then wrote a comment explaining how these singularities should be dealt with, explicitly drawing terms from a sum the aticles authors claimed was irrelevant to their caclualtions, and showing how it spoiled the overall conclusion. I submitted this to PRL and wondered how it would go. The authors submitted a response which was close to nonsense, and went close to calling me names. The first referee of both comment and reply took 3 months to produce 4 pages restating my comment and the authors reply, and then said he had not the qualifications to decide in the matter as it involved complicated mathematics. The editor asked me to review my comment if I wanted it considered further as refereeing the matter was clearly problematic. I did as the editor asked (which enlareged the comment) and asked the editor to go for a second review. This time he disappeared. I waited 4 months, then wrote several times and got no response. I rang several times, his secretary would answer and then would tell me he is ‘not in’. After several such replies she admitted he was ‘in the building’, but not here, he will return my call, or write to me. After 6 months I did get a message from him stating he is very busy, he is not sure about the matter of my Comment, it is not suitable for publication as is, but Im ‘free to submit it elsewhere’. I raised the matter on appeal, which PRL expressly sets out the rules for. After 4 months I got a response. There were two reviews. The first from 6 months ago stating the comment demonstrates serious problems with the published article, but the reply is unacceptable and should not be published. This was followed by a second review which was generated after my appeal. The reviewer stated that what I raised was all very well, but he would really like to see another problem addressed in the same comment. The editor added his verdict, as my comment was already on the borderline in terms of space it has now run out of both space and time, and the matter is closed. After waisting 18 months of my time and effort, I had the article published in a European (also prestigeous) journal. But what this really demonstrates is what I had commented on at the start of my email.

Thanks for the book

Leonard

28. **Shantanu**
June 25, 2011

Interesting post, Leonard. Can you point to a copy of the article you are referring to?

29. **David Bailey**
June 25, 2011

"I don't think it's fair to blame the journalists. They're just reporting the claims made by some of the most prominent and respected figures in the field of theoretical physics."

Blame is possibly not the right word, because journalists are only responding to their editors, who are in turn trying to market a magazine.

I see the problem – which I am sure goes much wider than physics – is that magazines like New Scientist and Scientific American have tried to sell themselves to a larger and larger audience. One way to do that (and it may not be an explicit conscious decision), is to pick incredibly grandiose theories, and present them in a shallow way. Explaining that other physicists don't agree, and quibbling over the details, would just spoil the story!

30. **Roger**
June 25, 2011

Anon, you might like the writing style of the New Yorker, but those science and math articles are pretty horrible for their content.

31. **Jack Lothian**
June 25, 2011

I agree with Anon. I subscribe to SciAmer & have for 30 years. The quality of the writing & editing started to declined in the late 80s & the quality of the articles has dramatically plunged in the last 10 years. I pay a lot for the subscription & each year I debate about dropping it because of the lack of interesting articles. I read a lot of math journals as well & in the last few years I have seen a decline in quality. Scientific & math publishing is becoming exclusively a profit business & appealing to the masses brings in more profits. I do not see this trend reversing. I disagree with Peter on this one, it is the owners of journals who are steering the editors towards mass appeal articles. There are still lots of good physists & mathematician's out there but they lack mass appeal.

32. **peterg**
June 26, 2011

I do think it's fair to blame 'the journalists'.

Even before Peter published his book, a decent journalist could and should have known that String Theory as a description of measurable reality runs into huge problems. Around 2000-2001 I met a friend who worked in High Energy Physics in the 70s and 80s and who turned to ST somewhere in the 90s. "So, how do you like String Theory?" I asked him. He replied: "It's great! But it's not physics and I have no idea how we could turn it into physics."

Not to mention that little fact is bad journalism. Susskind apparently says that "there is no coherent, sharp argument against (ST)". "It's not physics" seems to be a pretty sharp and coherent argument to me.

However, having been a journalist myself, I think I understand what's happening.

1) ST is the only game in town, and you're flooded with news about it. You can't keep quiet about it, because everybody else will be writing about it.
2) Many Great Names have put their weight behind it. You need some courage as a journalist to criticize people like Susskind. You know that your editor is going to ask: "Who the f!ck are you?" or "So, how many Nobel prizes did your friend win?"(*)
3) Claims about ST are very sexy and impressive for a lay audience.

Added to this are a few other factors.

4) There's a tendency to limit journalism to 'reporting', without providing much context. The idea is that readers are mature enough to sort it out by themselves.
5) Commercial pressure and lack of time.

If you can't live with this situation – and no good journalist can, in my opinion – you're weeded out. Only the mediocre and the bad ones are left at the end. So yes, I think it's fair to criticize the journalists. You probably won't be criticizing the good ones.

(*) It actually happened to me when I was discussing Prigogine with someone. I mentioned a curious phenomenon: the better scientists knew what his ideas were about, the more critical they were. Reply: "So, how many Nobel prizes do these scientists have?" I was lucky and could mention Anderson.

33. **Cosmonut**
June 27, 2011

Regarding SciAmer – Does anybody else get the feeling that all their physics-related articles nowadays seem to be rehashes of things published in the 80's and 90's ?

Apart from a 1998 article on the accelerating expansion of the universe, there seems to be very little which is new and authentic (as opposed to vague speculation).

I also notice that SciAmer is switching towards more biology/enviornment related articles. This is just an impression – I don't have any stats.

34. **chris**
June 27, 2011

Leonard,

i think your story precisely hits the point. these days, there definitely is a lack of Paulis or Feynmans who declare crap to be crap. wrong or misleading work of a large collaboration can survive long enough to support a few nice careers and generate millions in funding money. respected people are forced into situations where it is socially unacceptable to say they were wrong – too many real life things depend on them being correct. so they act accordingly and crap does not get weeded out at the pace it should.

this is very frustrating, especially for the younger ones. they are held in precarious situations long enough to make them align to the main stream and shut up. it takes some serious nerves today to declare some wrong ideas wrong.

35. **Math Student**
June 27, 2011

Peter Woit wrote

"It seems quite likely that twitter will either evolve into something interesting or die off within a couple years. I'll try and wait that out and see what happens…"

Wasn't that your reaction to the first string theory revolution? Looking forward to your anti-twitter book in 20 years 🙂

36. **Peter Woit**
June 27, 2011

Math Student,

Good point. One major difference though is that, about the fate of twitter, I couldn't care less….

37. **Chris Austin**
June 27, 2011

chris,

"wrong or misleading work of a large collaboration can survive long enough … "

That is a very startling assertion, and a little bit alarming. Are you thinking of lattice gauge theory or HEP experiment? It really doesn't seem likely that something like that could happen when you have two competing experiments like CDF and D0, or ATLAS and CMS. Do you know something to the contrary?

38. **G.E. Hahne**
June 27, 2011

Hi Peter,
Susskind's beliefs on humans' inability to solve some current physics quandaries have at least one historical precedent: I can't recall a citation, but remember reading that at the Berlin Colloquium in the early 1920's, both Einstein and von Laue manifested scepticism that physicists were smart enough to develop a successful theory of atomic structure.

39. **Peter Woit**
June 27, 2011

G.E. Hahne,

Interesting. Whether human beings will get stuck at some point in their ability to understand fundamental physics is an interesting question. One sure way to get stuck is to react to an idea not working out not by abandoning it and trying something different, but by starting to work on an elaborate pseudo-scientific apparatus to explain why your idea was right even though it couldn't ever predict anything. I don't think Einstein or on Laue ever went in that direction…

40. **Leonard Lerner**
June 29, 2011

Here's the reference to the article. B. Elattari, S.A. Gurvitz, Phys. Rev. Lett. 84 (2000) 2047;. The editor of PRL Comments if anyone is interested was and is George Basbas, who played this funny game with me. I did have my article published, in Physics Letters, but that is not how it should be. Firstly without thoroughly reading my article you would not understand the EG article is flawed. Secondly as it was not now a comment it had to be a positive article – I had to write about quantum dots and the Zeno effect, which is a misconception I would never have liked to write about in the first place. So why did I bother? Well with Basbas help I wasted 18 months and I wanted to recoup my time somehow. But this is not at all how it should be.

On the same point, there was a flourish of articles (including PRL) a few years ago about hadronization in the light cone gauge. Now as anyone would know QCD is gauge invariant, so you dont expect to find hadrons in the LCG but free particles in another gauge. But with no progress, people are desparet these days, so this continued for a while. I certainly learnt not to pick up pen and paper and write a comment, and I think so have most people.

I dont think the string theorists whom Peter is rightly attacking, are hearing anything they don't already know. They would be out of a job if what they regard as a cool activity suddenly had to be judged by real world standards. Then articles could be rejected like Peter Higgs article once (unfairly) was, on the grounds that this has no relevance to physics. They would then have to publish in mathematics journals and abide by much higher standards. The truth is that physics has a tradition of accepting lower standards of rigour than mathematics not because physicists care less if something is wrong, but on the tacit assumption that physics is harder than maths beacuse unlike the former you are working with nature where you do not see the whole system. So people publishing in physics on the pretence that this has something to do with the real world, when they make no attempt to make sure it does are cheating this.

41. **coolstar**
July 8, 2011

I agree with anon above along with several others about the decline of SciAm. I don't remember when their last big editorial change was, probably pre 1998, but that seems to be when the slope became pretty extreme. I stopped buying and reading it soon after. They have one editor I find particularly noxious for his arrogant, right-wing views. I find Discover to have much better science and to be much better written. In the U.K., I've found the BBC magazine Focus to be much better than SciAM and I recently discovered Eureka, and it also seems to be better than SciAm, though I think the writing in Discover is still better than in those two.

42. **Anon**
July 8, 2011

I agree with coolstar. I almost always feel that I wasted my time with SciAm, which has become mostly empty fluff targeted at 12 year old ADHD sufferers (what with all those intrusive little summary boxes, lest anyone be expected to concentrate for more than 20 seconds at a time), but I do still read Discover, which most of the time (though not always) tends to have better quality content.

43. **Eric Baird**
July 9, 2011

Back when we were waiting for the LHC to be completed, I saw a number of physicists online complaining bitterly about the low standards of reporting, and criticising articles that frequently used inane headline-grabbing terms like "Big Bang Day" and the "Big Bang Machine".

In fact, "BBD" and "BBM" didn't seem to be media inventions, they were promoted at the media by Brian Cox, who worked at the ATLAS project at LHC (and then got himself a TV presenting gig for the BBC). Cox seemed to be on a one-man mission to turn "Switch-On Day" into a full-blown media event, and if anything, the news reports were a fairly muted version of some of his statements. But the journalists got the blame.

IMO, a number of scientists have worked out how to “game” the media by building “headline” phrases into their press briefings, and it’s then difficult for a reporter to decide //not// to use the obvious headline that they’ve been fed, on the grounds that they reckon that the scientist was exaggerating. A news editor would say that it’s not the job of a reporter to “correct” a scientist’s statements to make them more scientifically accurate, or less cheesy.

“Gaming the system” works over the short term, and generates the headlines and media column inches, but unfortunately the readership eventually gets tired of being constantly hit with exaggerated news stories and stops listening. I’ve heard a number of non-scientists complaining about wide-eyed articles on modern cosmology, because, as one of them put it “These guys just make this ____ up”.

Same thing happened with string theory – to a lot of the general public, string theory is now regarded as a bit of a joke. They may not understand the first thing about what string theory //is//, but they understand how to spot probable B.S., and some of the statements about ST that drifted into the popular press sometimes strayed too far into unintentional self-parody. If a group of scientists make those sorts of grandiose statements, the public tends to give them a few years to come up with something concrete to back those statements up, and if they don’t manage to turn them into something more concrete, tends to regard the whole field as a sham from that point on.

I think that the public used to give scientists the benefit of the doubt a lot more, but too many groups abused the trust that was given them to get more funding. After decades of too-cheap-to-meter fusion power being always “just around the corner”, and biotech companies promising that that they’d be able to solve world hunger any year now if we just gave them special legal concessions, people increasingly stopped listening.

Increasingly, I think the general public are beginning to see scientists as just another self-serving lobbist group after public money, who’ll say anything to get funded. I think that sometimes these researchers think that what they’re doing is playing a harmless and neccesary game to get funds, and they don’t always appreciate the damage that they’re doing.

Strings 2011

June 27, 2011
Categories: Strings 2XXX

Strings 2011 started today in Uppsala, with attendance quite a bit lower than in the past (259 registered participants, versus 500 or so at some of the past such conferences). One reason for this may be the high conference cost ([discussed here]), another may be that excellent [video of the talks] is available, so why bother traveling to Uppsala?

The opening talk was by David Gross, who tried to address the question "Where do we stand?" for string theory. He claimed the field is "extremely healthy", "vibrant and exciting", "making enormous progress in a variety of areas'", with "stupendous progress" in N=4 planar SYM. At the same time, he acknowledged that it was "very sobering" that string theory was 43 years old.

In the past, Strings XXXX conferences often featured a call for progress towards making predictions that could be tested at the LHC. With LHC data now coming in, Gross acknowledged that this had been a failure: there are no string theory LHC predictions. He put a positive spin on this by noting that the lack of any BSM signal at the LHC so far is not a worry for string theory, since string theory can't be tested at the LHC. As for the lack of any supersymmetry signal so far, he says that "I personally am not yet worried", while acknowledging that some people are becoming pessimistic. While no SUSY is not a worry for string theory, he feels that "it would be awfully nice for string theory if SUSY appeared". Supposedly he has made bets on SUSY at the LHC, but he gave no indication of when he would start to worry (or pay off the bets) if SUSY continues to not be there.

The main area of progress he sees is the usual gauge-gravity duality that has dominated the field for years, together with progress on N=4 SYM amplitudes. He sees Verlinde's "Entropic Gravity" as an "exciting development I find enormously interesting". Evidently later this week Verlinde will discuss his latest ideas about this which supposedly include an explanation of dark energy and dark matter.

Gross went over quickly the questions about string theory he first raised in a similar talk 26 years ago, which mostly remain unanswered, including the basic one of "What is String Theory?". The additional questions raised by attempts to understand the emergence of spacetime in a deSitter background were one factor that inspired him to end with the quote that:

> The most important product of knowledge is ignorance.

To which he added "After 43 years of string theory , it would be nice to have some answers."

Surprisingly, not a word from Gross about anthropics or the multiverse. I assume he's still an opponent, but perhaps feels that there's no point in beating a dying horse. Susskind isn't there and oddly, the only multiverse-related talks are from the two speakers brought in to do public lectures (Brian Greene and Andrei Linde, Hawking's health has kept him from a planned appearance). So the multiverse is a huge part of the public profile of the conference, but pretty well suppressed at the scientific sections. Also pretty well suppressed is "string phenomenology", or any attempt to use string theory to do unification. Out of 35 or so talks I see only a couple related to this, which is still the main advertised goal of string theory.

I'm looking forward to the talks of Witten, Gaiotto and Gukov, which I hope will provide a gentle introduction to their intriguing recent long papers on the arXiv. To the extent I find time to watch talks this week and have any comments about them, I'll try and add updates to this posting.

Update: After looking at most of the talks online, the most remarkable thing about Strings 2011 is how little there is about string theory. One of the speakers, Chris Hull, started off his talk with the comment:

> At lunch today one of the organizers was observing that my talk was unusual in being one of the few talks actually about string theory. It would be interesting to speculate on what that might mean about the state of the field, but it would be invidious to do so here.

One of the main themes of the conference so far has been study of mathematically interesting supersymmetric QFTs in 3,4,5 and 6 dimensions, often obtained from a specific class of 6d theories, which themselves remain poorly understood (what is known about them was reviewed by Greg Moore). Witten gave an overview of his work relating Khovanov homology and QFT, which involves a chain of various 6d, 5d, 4d, 3d and 2d QFTs. Nati Seiberg reviewed the technology used for constructing these theories on various special backgrounds, noting that this was all about "rigid" SUSY theories, with supergravity and string theory making no appearance.

Update: The videos of the talks are now all up. I took a look at the Verlinde talk, and the ideas he is putting forward still strike me as pretty much empty of any significant content. In Jeff Harvey's summary of the conference, he notes that many people have remarked that there hasn't been much string theory at the conference. About the landscape, his comment is that "personally I think it's unlikely to be possible to do science this way." He describes the situation of string theory unification as like the Monty Python parrot "No, he's not dead, he's resting." while expressing some hope that a miracle will occur at the LHC or in the study of string vacua, reviving the parrot.

That the summary speaker at the main conference for a field would compare the state of the main public motivation for the field as similar to that of the parrot in the Monty Python sketch is pretty remarkable. In the sketch, the whole joke is the parrot's seller's unwillingness, no matter what, to admit that what he was selling was a dead parrot. It's a good analogy, but surprising that Harvey would use it.

Comments

1. **Marcus**
   June 27, 2011

   The talk that Verlinde is scheduled to give later this week at Uppsala has the same title as one he gave last week (22 June) at Perimeter. Anyone interested can watch the Perimeter video of the talk, which got some lively reactions from the audience.

   http://pirsa.org/11060065/
   The Hidden Phase Space of our Universe
   Erik Verlinde
   By combining insights from black holes and string theory we argue for the existence of a hidden phase space associated with an underlying fast dynamical system, which is largely invisible from a macroscopic point of view. The dynamical system is influenced by slow macroscopic observables, such as positions of objects. This leads to a collection of reaction forces, whose leading order Born Oppenheimer force is determined by the general principle that the phase space volume of the underlying system is preserved. We propose that this adiabatic force is responsible for inertia and gravity. This fact allows us to calculate the hidden phase space volume from the known laws of inertia and gravity. We find that in a cosmological setting the appearance of dark energy is naturally explained by the finite temperature of the underlying system. The adiabatic approximation that leads to the usual laws of inertia and gravity breaks down in the neighborhood of horizons. In this regime the reaction force degenerates into an entropic force, and the laws of inertia and gravity receive corrections due to thermal effects. A simple estimate of these effects leads to the conclusion that they coincide with observed phenomena attributed to dark matter.

2. **Bernhard**
June 28, 2011

"While no SUSY is not a worry for string theory, he feels that "it would be awfully nice for string theory if SUSY appeared"."

I confess I keep being puzzled about this situation. As I understand the situation with string theory without SUSY is pretty ugly, isn't it? I mean, what is left is the bosonic ST, so why people like Gross keep on insisting no SUSY is not necessarily bad for ST? It seems to me that more than half of their business is gone without SUSY.

3. **anon**
June 28, 2011

If the Higgs but no Susy is found by the LHC , I would say it would be a fatal blow to String Theory's reputation. It's kind of exciting that after 43 years, "the day of judgment" for all my friends that are String Theorists is less than 2 years away.

4. **chris**
June 28, 2011

Bernhard,

strings without SUSY are pretty ugly. but the point is that at string scales SUSY can be restored in a lot of models.

what makes SUSY "appealing" for the rest of us is the potential to explain or soften the hierarchy and naturalness problems and to provide a DM candidate. for this you need a relatively low SUSY breaking scale in the region and somehow connected to EW symmetry breaking. but for string theory this is irrelevant. the SUSY breaking scale might be anywhere and it might not explain a single thing at TeV scales or below and yet it is good enough for strings.

5. **Ian Agol**
June 28, 2011

We have some slides from Witten's talk in Berkeley at the Michael Freedman 60th birthday conference available here (as well as from a few other talks):
http://web.math.berkeley.edu/~matthias/conference/abstracts.html

6. **King Ray**
June 28, 2011

Peter, what do you think of this?

http://arxiv.org/abs/arXiv:1009.5414

(Gravity is not an entropic force, Archil Kobakhidze: We argue that experiments with ultra-cold neutrons in the gravitational field of Earth disprove recent speculations on the entropic origin of gravitation.)

7. **Peter Woit**
June 28, 2011

Ian,

Thanks. I watched Witten's talk today, it's a very general overview of what he's doing. The slides you link to give a more detail about one piece of this.

King Ray,

My quick attempt to understand Verlinde's derivation of Newton's law left me suspicious that there was nothing to it but dimensional analysis, in which case, you can't prove it wrong. I don't know if the paper you link to refutes Verlinde in any sense. If Verlinde now claims to explain dark energy and dark matter, that's more substantive. I presume that it will soon get a lot of attention, personally I'll wait for experts to sort out what is going on with these ideas.

8. **Marc**
June 30, 2011

A few years ago, Gell-Mann said in an interview that the biggest failure of string theorists was the failure to clearly specify its principles. After several decades of research into the field still nobody came up to the challenge. I recently did a literature search (both papers and books) and there is indeed nothing on the principles of string theory. If we recall that most string theorists are part-time mathematicians, and mathematics is built on axiomatic systems of some sort, the lack of writing down axioms and principles is an important sign.

Together with the remark that almost nobody is giving talks about string theory anymore, this is a strong hint that people are finding, maybe only unconsciously so far, that the emperor is naked after all.

9. **Proudmemberofthecult**
June 30, 2011

@marc

In the same vein you can ask "What are the principles of Yang-Mills theory?". There's many results about perturbative Yang-Mills in four dimensions, but we lack a complete understanding beyond that. For string theory the situation is about as good or bad depending on your point of view. Definition-wise that is. For pure mathematicians string theory is a black box which generates conjectures.

10. **Peter Woit**
June 30, 2011

Proudmemberofthecult,
That's just ridiculous. We have a rigorous definition of non-perturbative quantum YM in 4d, even if it is an open problem to prove that it has all the properties that it appears to have (for which there is lots of evidence, numerical and otherwise). At every major conference he speaks at, Gross makes the point repeatedly that the big question is "what is string theory?". No one has ever stood up at a major conference and said that the problem with quantum YM is that we don't know what it is.

General conjectures about the properties hoped for in string theory have in the past led to interesting mathematical conjectures. The interesting thing about Strings 2011 is that most of the speakers have stopped trying to do this, instead sticking to QFT itself.

11. **manyoso**
June 30, 2011

> 'As for the lack of any supersymmetry signal so far, he says that "I personally am not yet worried", while acknowledging that some people are becoming pessimistic. While no SUSY is not a worry for string theory, he feels that "it would be awfully nice for string theory if SUSY appeared". '

Forgive me, but how is this possible? It has always been my understanding that String Theory _depends_ upon SUSY. That without SUSY String Theory fails completely as a theory of gravity or unification. If the LHC does not see SUSY or rules out a large parameter space how is this not staggeringly bad for the proponents of String Theory?

I'm just a layman so I'd really appreciate any answers as this has me baffled.

12. **anony**
June 30, 2011

Since string theory is dual to YM theory, there is no reason to discuss the ill-defined string theory anymore, we can stick to things we understand, and this is what most people are doing.

13. **Peter Woit**
June 30, 2011

manyoso,

String theory never has been able to say anything about what causes supersymmetry breaking, in particular, it doesn't even say anything about what the scale of such breaking should be. So, it could be an energies high above where the LHC could reach. It's a generic phenomenon: string theory predicts absolutely nothing, and in particular it predicts nothing at all about what the LHC will or won't see.

anony,

Great. So, Strings 2012 is being renamed "QFT 2012"?

14. **peaceful termination**
June 30, 2011

So, if they really rename it and do just QFT from now on, Peter could peacfully terminate this blog because it`s aim would finally be achieved 🙂

Cheers

15. **anony**
June 30, 2011

The kind of QFT discussed this year is really bizarre (i.e. maximally far from things relevant to nature, except maybe for 1 or 2 talks). So the most suitable name is probably "bizarre QFT 2012."

16. **somebody**
July 1, 2011

If we magically knew that there was no supersymmetry at any energies, I think it is a pretty strong argument against string theory. Unfortunately LHC will check the existence (or not) of SUSY only upto a very low energies ("TeV") compared to Planck scale. This is the sense in which it is "encouraging" for string theorists if LHC finds SUSY, but admittedly nothing more.

As to the reason why some supersymmetric QFTs are being studied at Strings 2012 is because many of them are interesting because of their nuemrous connections to 2D CFTs, string theories, etc. Many string theorists including myself, love to berate our field (who wouldn't like to make a testable prediction?), but that should always be taken with a grain of salt. Sorry to speak truth to the power here, but anyone who claims in this day and age that N=2 (in 4D and analogous things in other dimensions) supersymmetric quantum field theories have nothing to do with string/M-theory is agenda-driven. Seiberg-Witten solution which looks magical from 4D is AUTOMATIC from a brane-engineering point of view. Gaiotto's construction of his N=2 theories which started the recent interest came DIRECTLY from M2-branes wrapping Riemann surfaces. The AGT conjecture whch is another focal point of the current interest immediately relates these theories to 2D CFTs. Not to mention the are numerous connections these things have with topological strings, matrix models, etc.

This message only serves a public service point, Peter of course has been well known on this blog to describe anything interesting to come out of string theory, as NOT string theory. 🙂

17. **peaceful termination**
July 1, 2011

Interesting somebody,

thanks for these explanations 😉

18. **Thomas Larsson**
July 1, 2011

Hm. The claim I saw is that N=2 SUSY has nothing to do with nature ("bizarre QFT"). Does not N=2 have a number of peculiar properties (e.g. non-renormalization theorems) that are manifestly false for the SM.

19. **Peter Woit**
July 1, 2011

peaceful termination,

The disappearance of string theory would certainly mean that this blog would get a lot less attention, not necessarily that it would disappear…

Somebody,

One can make as much hype as one wants claiming that all good ideas in the hot topics of today (amplitudes, N=2 SUSY, various applications of gauge-gravity dualities, etc.) historically come from string theory, but the undeniable fact of the matter is that if you watch the talks at Strings 2011, virtually no one is talking about string theory itself or using string theory anymore to do anything. A student who wants to work on any of the hot topics has no reason to bother to learn string theory anymore.

What's remarkable is that this seems to be true even in those areas where string theory has had some success, far away from the heavily promoted ones. Besides virtually no talks about string theory and unification, there's also almost nothing about string theory as a theory of quantum gravity. The hot topic of recent years, the idea that string theory would explain heavy ion physics, seems to have completely disappeared.

Thomas,

Personally I find some of the work being discussed about these SUSY gauge theories quite fascinating. There's some beautiful mathematics, and techniques being used (e.g. "SUSY localization") that may some day have important applications to physical theories. These theories are not physical, but they are tantalizingly close to physical theories. That said, much of what is being done is "topological quantum field theory", which inherently uses techniques special to topological, not physical, observables.

20. **somebody**
July 1, 2011

Of course I disagree with Peter's claims despite his vehemence. But we already knew that. 🙂

The real reason for this comment is that I wrote "M2-branes" wrapping Riemann surfaces, when I meant "M5-branes".

21. **manyoso**
July 1, 2011

I don't see any vehemence in Peter's post. I think too often we read too much into conversations on the internet. Imagining emphasis and body language that is not inherently conveyed by the printed words on the page. That emphasis and body language we imagine is all too often just a manifestation of our own minds and not actual communication.

Close your eyes and see if you can see the posts above coming in a jovial manner from two respected colleagues frankly disagreeing, but not in a disagreeable way.

22. **Wolfgang**
July 1, 2011

"… virtually no one is talking about string theory itself or using string theory anymore to do anything. "

That's like saying that people doing AdS/CFT are "just doing field theory" (since the string theory side of the duality "isn't defined").

To pick one example, consider Witten's talk on Khovanov Homology. He starts with the D3-NS5 system in Type IIB, S-dualizes to the D3-D5 system, T-dualizes on a transverse circle, to get the D4-D6 system in Type IIA and then, finally, lifts the whole construction to M-theory (where he, finally, obtains a description in terms of the 6D (2,0) theory).

I suppose one could characterize this work as "just field theory" (a "followup on his work on Chern-Simons theory"). But his paper (and most of the talks, however "field theory"-oriented, at Strings 2011) would be completely incomprehensible if you don't know a good deal about string theory.

In fact, what you need to know is "modern" string theory. In his concluding remarks, Jeff Harvey noted that most of the talks would be utterly incomprehensible to even a well-trained string theorist who, Rip Van Winkle-like, had slept through the past 15 years.

23. **Peter Woit**
July 1, 2011

Wolfgang,

The terminology Witten uses in his talk is based on string theory, but what he actually does doesn't use string theory. Those names for dualities and boundary conditions correspond to constructions that are quite independent of string theory. If you look at the more detailed description of some of the same material that Witten gives when talking to mathematicians (see the slides Ian Agol links to), you'll see no reference to string theory at all, with string theory/M-theory terminology replaced by explicit boundary conditions. It's true that the way Witten and others found those boundary conditions was from studying string theory, but that quite possibly is just an historical accident, you could imagine coming upon them from other starting points.

Better yet, look at the main paper of Witten's that his talk is an overview of. All the calculations are in field theory, not string theory. Here's how Witten himself describes the situation (see pg. 12 of the "Five-branes and knots" paper):

"One goal is to give a gauge theory definition of Khovanov homology (as opposed to a definition that requires a full knowledge of string/M-theory). String theory and branes will be used as clues, but the results can be expressed as a gauge theory construction."

My understanding is that he thinks the fundamental object here is the 6-dimensional (0.2) field theory and he would argue that, since that isn't well-defined, much of what we know about it comes from string/M-theory. It seems to me that we'll have to see what the future holds as this theory is better understood. It's quite possible that it will have some good definition and way of studying it that has nothing to do with string/M-theory.

What Witten is finding here (and I think it's true in a lot of the other "physical mathematics" work described at the conference) is that the huge amount of knowledge developed over the last 20 years relating string theory and gauge theory is quite useful in providing hints as to what to look for, but at the end of the day, the interesting results don't require string theory calculations to get to, or string theory ideas to understand.

Jeff Harvey noted that many people at the conference were asking "where did the strings go?", and Chris Hull made much the same point. I don't think the people they were talking to who were asking this question were people who have been asleep for the past 15 years. Quite the opposite: I think they're people who are very aware of what the state of the field is, and are seeing a quick swing away from string/M-theory to return to more conventional field theory ideas and methods.

24. **Cosmonut**
July 1, 2011

The relative absence of "real" string theory in the recent conference has been noticed elsewhere.
Lubos Motl is ascribing it to string theorists trying not to arouse the envy of their non-stringy colleagues. Always entertaining, this Lubos. 🙂

25. **Marcus**

July 1, 2011

"The relative absence of "real" string theory in the recent conference has been noticed elsewhere. Lubos Motl is ascribing it to string theorists trying not to arouse the envy of their non-stringy colleagues."

That could be funny. Do you have a link? I think the relative absence of string (and the relative presence of what Weinberg in a talk at CERN called "good old QFT") needs to be seen in the context of declining string jobs compared with first-time faculty hires in particle theory/cosmology as a whole. Peter reported on that earlier.

26. **Marcus**
July 1, 2011

"Quite the opposite: I think they're people who are very aware of what the state of the field is, and are seeing a quick swing away from string/M-theory to return to more conventional field theory ideas and methods."

You reported on Weinberg's CERN talk almost exactly 2 years ago:
http://www.math.columbia.edu/~woit/wordpress/?p=2199
He plotted the "stock price" of conventional QFT over the past 80 or so years and extended the curve with a dotted line where he expected it to go. Basically he predicted this "quick swing" or QFT resurgence—and described a general pattern or mechanism using several historical examples. The talk video is online and could be worth watching a second time.

27. **Wolfgang**
July 1, 2011

"If you look at the more detailed description of some of the same material that Witten gives when talking to mathematicians (see the slides Ian Agol links to), you'll see no reference to string theory at all …"

Nor to quantum field theory. In the end, the problem comes down to solving certain PDEs. And you can explain those PDEs to mathematicians, without any reference to string/field theory.

It would, however, be impossible to deduce those equation without using string theory (and field theory) as a guide. And, if you read Witten's paper (and the previous papers with Gaiotto), the same can clearly be said of the relations between the various field theories (in 3, 4, 5 and 6 dimensions) that he uses.

It is all very well to fantasize about an alternative universe where a purely field-theoretic explanation of those dualities between field theories was discovered. Perhaps, somewhere in the multiverse, that universe exists. But it's not our universe …

28. **Marcus**
July 2, 2011

The video of Frank Wilczek's talk is no longer online.

I especially liked that talk and would like to watch it again. Does anybody know of an alternative link? I don't see that any of the other talks have been taken offline.
What to expect?
It used to be number 24.
Now you get some kind of message in Swedish.

29. **Yatima**
July 3, 2011

Frank Wilczek's talk is up. The sound is not well synchronized with the image though:

http://media.medfarm.uu.se/flvplayer/strings2011/video24

What did he mean with the Portals though? I suspect a Wheatley joke was planned.

30. **Mark**
July 3, 2011

Wilczek's "I certainly don't recognize it" response to Witten's very insightful comment was, to say the least, puzzling. How can he NOT be aware that low scale SUSY + a QCD axion implies a Polonyi-type problem? Wow!

Local Blogs

July 1, 2011
Categories: Uncategorized

There are now several excellent blogs somehow related to mathematics being run by local people, including a couple new ones, so I thought it would be a good idea to mention these here:

- Andrew Gelman of the Columbia Statistics department runs the very active Statistical Modeling, Causal Inference and Social Science blog, which features a wealth of all sorts of different topics, from technical ones about statistics, to social science applications.
- Emanuel Derman, who started his career as an HEP theorist, was one of the early migrants to the financial industry, and now is teaching here at Columbia in the Financial Engineering program, has a new blog at Reuters. His last book was the very interesting My Life as a Quant, this fall he has a new one coming out entitled Models Behaving Badly.
- Cathy O'Neil, a mathematician who taught here for a while before changing career path, starting with a job at the hedge fund D.E. Shaw, has recently started the wonderful Mathbabe blog.
- I think I mentioned this already, but one of my colleagues, Johan de Jong (Cathy's husband) also has a blog, the Stacks Project Blog. If your metric to evaluate blogs is something like "quality of information" x "degree of abstraction and technicality", his has to be the best blog in the world.

If you have comments on these blogs, I encourage you to post them there rather than here. I would be interested in hearing about any other local math/physics related blogs that I'm unaware of.

Update: Another local math/physics-related blog has made its debut today, Davide Castelvecchi's Degrees of Freedom. It's part of a network of new blogs being launched today by Scientific American, which is based here in New York.

   It seems that Lubos just discovered supersymmetry in Obama's birthcertificate.
   Quite amazing!

Higher Speculations

July 8, 2011
Categories: Book Reviews

Some commenters here a while ago made the excellent suggestion that I should take a look at a book published this spring, Helge Kragh's [Higher Speculations: Grand Theories and Failed Revolutions in Physics and Cosmology](). I've always wondered what historians of science would make of the increasing dominance of research in fundamental physics by unsuccessful highly speculative research programs, and have also often wondered if there are any relevant historical parallels to this situation. This book does a great job of addressing those questions, and it's pretty much unique in doing so.

Kragh spends the first half of the book on history, the second half on currently popular (of varying degrees of popularity…) topics including varying constants of nature, cyclic cosmological models, anthropics, the multiverse and string theory. He doesn't explicitly make any attempt to evaluate how successful these current efforts are, but they are discussed in the context of previous failures and parallels are drawn. I didn't know much about the history of "vortex theory" in nineteenth century physics, and this turns out to be possibly the best historical parallel to the story of string theory. Here's an extract from the extensive and enlightening discussion of that bit of scientific history:

> From its beginnings in 1867 to its end at about 1900, the theory was frequently justified on methodological and aesthetic grounds rather than its ability to explain and predict physical phenomena. In an 1883 review of ether physics, Lodge described the vortex atom theory as 'beautiful' and 'the simplest conception of the material universe which has yet occurred to man'. He added, just as Michelson would do twenty years later, that it was a 'theory about which one many almost dare to say that it deserves to be true'.
>
> The audience listening to William Hicks' address at the 1895 meeting of the British Association for the Advancement of Science would not suspect that the vortex theory of atoms was dying. Without paying much attention to the theory's disappointing record with regard to empirical physics, Hicks reviewed in an optimistic tone the theory of various vortex objects such as rings, spheres and sponges. He realized that relatively little progress had been made over the years in the mathematical development of the theory, and that progress was even more lacking in the theory's contact with experiments. However, these problems he deftly turned into a defence of the theory, for the undeveloped mathematical framework meant that the theory could not be rigorously tested. Hicks was convinced that the road towards progress would be to develop still more advanced mathematical models. The vortex theory, he said 'is at present a subject in which the mathematicians must lead the attack'.

Surely many physicists of the day would have described vortex theory as "our best hope for a unified theory", and one wonders if any of them thought of it as a "part of 20th century physics that fell by chance into the 19th century."

Kragh's book does something really remarkable and valuable: it starts to put some aspects of the last 30 years of fundamental physical theory into a plausible historical context. The future of the subject remains a mystery though, but one can hope that on the vortex theory timeline we're about to hit the analog of 1900, with successful rather than failed revolutions ahead of us.

Comments

1. **wolfgang**
   July 8, 2011

   Vortex theory was a major motivation to study knot theory – a topic advanced much later by Ed Witten.

2. **Chris Oakley**
   July 8, 2011

   From the Wikipedia article "History of knot theory":

   > In 1867 after observing Scottish physicist Peter Tait's experiments involving smoke rings, Thomson came to the idea that atoms were knots of swirling vortices in the æther. Chemical elements would thus correspond to knots and links. Tait's experiments were inspired by a paper of Helmholtz's on vortex-rings in incompressible fluids. Thomson and Tait believed that an understanding and classification of all possible knots would explain why atoms absorb and emit light at only the discrete wavelengths that they do. For example, Thomson thought that sodium could be the Hopf link due to its two lines of spectra. (Sossinsky 2002, p. 3–10)

   …

   > When the luminiferous æther was not detected in the Michelson–Morley experiment, vortex theory became completely obsolete, and knot theory ceased to be of great scientific interest.

   It is just me, or does the first sentence sound a bit like "all matter is comprised of tiny vibrating strings".

3. **Daniel**
   July 8, 2011

   History repeating itself? But doesn't the book discuss the human aspects of the debacle of the vortex theory? I'm curious to know how the vortex theorists reacted and/or adapted.

4. **Peter Woit**
   July 8, 2011

   Daniel,

   The book doesn't have much on the topic of vortex theorists admitting the idea didn't work and moving on. Perhaps this was something that Max Planck had in mind in his famous quote: "science advances one funeral at a time".

5. **Roger**
   July 8, 2011

   The vortex theory was not so stupid. It was before the discovery of electrons, and when so little was known about atoms that some people could still doubt them. The vortex theory was not any worse than other theories. The [1902 Encyclopedia Britannica explained]():

> These properties of vortex rings suggested to Sir William Thomson[5] the possibility of founding on them a new form of the atomic theory. The conditions which must be satisfied by an atom are permanence in magnitude, capability of internal motion or vibration, and a sufficient amount of possible characteristics to account for the difference between atoms of different kinds.
>
> The small hard body imagined by Lucretius, and adopted by Newton, was invented for the express purpose of ac counting for the permanence of the properties of bodies. But it fails to account for the vibrations of a molecule as revealed by the spectroscope. We may indeed suppose the atom elastic, but this is to endow it with the very property for the explanation of which, as exhibited in aggregate bodies, the atomic constitution was originally assumed. …
>
> On the other hand, the vortex ring of Helmholtz, imagined as the true form of the atom by Thomson, satisfies more of the conditions than any atom hitherto imagined. In the first place, it is quantitatively permanent, as regards its volume and its strength, two independent quantities. It is also qualitatively permanent as regards its degree of implication, whether "knottedness" on itself or "linkedness" with other vortex rings. At the same time, it is capable of infinite changes of form, and may execute vibrations of different periods, as we know that molecules do. And the number of essentially different implications of vortex rings may be very great without supposing the degree of implication of any of them very high.

But then it goes on to give an argument that sounds a lot like the string theorists of today:

> But the greatest recommendation of this theory, from a philosophical point of view, is that its success in explaining phenomena does not depend on the ingenuity with which its contrivers "save appearances," by introducing first one hypothetical force and then another. When the vortex atom is once set in motion, all its properties are absolutely fixed and determined by the laws of motion of the primitive fluid, which are fully expressed in the fundamental equations. The disciple of Lucretius may cut and carve his solid atoms in the hope of getting them to combine into worlds; the follower of Boscovich may imagine new laws of force to meet the requirements of each new phenomenon; but he who dares to plant his feet in the path opened up by Helmholtz and Thomson has no such resources. His primitive fluid has no other properties than inertia, invariable density, and perfect mobility, and the method by which the motion of this fluid is to be traced is pure mathematical analysis. The difficulties of this method are enormous, but the glory of surmounting them would be unique.

In other words, it aimed to derive all of atomic theory from a few numbers and mathematical principles, without need for experiment.

6. **Wolfgang**
   July 8, 2011

   Aside from Lord Kelvin, James Clerk Maxwell, J.J. Thompson and Peter Tait, all of whom seem to have survived with their reputations intact, who else worked on "vortex theory"?

7. **Peter Woit**
   July 8, 2011

   Wolfgang,

   Kragh discusses many others who made the case for "vortex theory", including

   Gerald Francis Fitzgerald (Irish physicist)
   George Johnstone Stoney (Irish physicist)
   William M. Hicks (British physicist)
   Donald MacAlister (British physicist)
   Balfour Stewart (British physicist)
   Francis Venable (American chemist)
   Joseph Larmor (British physicist)
   Silas Holman (American physicist)

   So, proponents of the theory include the long-forgotten, as well as physicists who did important work on other subjects.

   There were also skeptics (including mathematician William Clifford), and non-scientist fans (Madame Blavatsky and the Theosophists)

8. **Matti Pitkanen**
   July 8, 2011

   Vortex theory inspired the theory of knots and braid theory is applied in quantum context to topological quantum computation. For the physical space-time dimension D=4 the orbits of space-like 1-knots are 2-knots-knotted string world sheets. If one accepts holography and the space-time correlate for finite measurement resolution as a discretization replacing 3-D space-time hologram with braids, one ends up with 2-knotted string world sheets as basic objects and we have string theory like structure in D=4. Maybe the intersection of string theory and vortex theory- actually developed by Witten- could give us the long waited physics.

9. **Bee**
   July 9, 2011

   Interesting. Can you say a few words on whether the book is well written and worth spending the time on?

10. **Peter Woit**
    July 9, 2011

    Bee,

    The book is well written, and definitely worth the time for anyone interested in these issues. It's more of an intellectually serious, scholarly work, with a lot of research behind it, rather than something aimed purely at a popular audience (the publisher is Oxford University Press, not a trade publisher). From my point of view that's a plus. It's not full of pictures, gee-whiz language, or heavily over-simplified attempts to explain physics by analogy.

11. **Martin Ouwehand**
    July 9, 2011

    > one can hope that on the vortex theory timeline we're about to hit the analog of 1900

    I'm not sure that this is what you want, because that's when the next *unsuccessful highly speculative research program* started, viz. the "electromagnetic view of Nature"…

12. **model and sim**

July 9, 2011

I would agree with Peter that there are some items shared by theories that make the differences between the theories more a matter of semantics. Whether we label solutions as vortexes or strings I think is purely semanitics. The question is more about the governing equations, and the nature of the thing that characterized by those equations. From that point of view, equations in string theory are much more nuanced, for better or for worse. Modern understandings of algebras are much more advanced than at any other time in history, and those algebras are fairly immune from the objects representing them. It is just disheartening that the last decade was more focused on semantics than substance. I just hope that we see something this summer that will finally move us forward.

13. **Wolfgang**
July 10, 2011

Maybe I'm too literal-minded, but this seems apropos of any discussion of "vortex theory."

14. **FrankH**
July 10, 2011

My response is so what? Vortex theory was a reasonable approach to try. It was very difficult to do the calculations and it turned out not to work, or rather a better more calculable theory was developed, but I hold nothing against the physicists who advocated vortex theory. Similarly, string theory is a reasonable approach to try. It is very difficult to do the calculations, but they have been able to calculate a lot more than vortex theory ever did. String theory may or may not be the appropriate theory to explain the elementary particle zoo that we have discovered, but until a better theory comes along, there is nothing wrong with getting as much as we can out of string theory, in my humble opinion…

15. **Peter Woit**
July 10, 2011

Wolfgang,

One can point to lots of ideas that a small number of people have tried to pursue that haven't been any more successful than vortex theory. String theory is different though: it's an example of an idea that dominated the whole field, including getting the attention of the major figures in the subject, for several decades, while not going anywhere.

Actually, back in 1984/85, string theory was a much more specific proposal than vortex theory, with a much more highly developed and detailed structure. As things haven't worked out, it has migrated towards vaguer and vaguer proposals. The latest hot topics, the multiverse and Verlinde's entropic gravity, are even more content-free than vortex theory ever was.

16. **Wolfgang**
July 10, 2011

"The latest hot topics, the multiverse and Verlinde's entropic gravity …"

From the complete absence of multiverse-related talks at Strings 2011, and from the frosty reception that Erik Verlinde's talk received there, one might question how "hot" those topics are.

17. **N. Nakanishi**
July 11, 2011

The vortex model of atom was discussed in comparison with superstring by the famous science writer, Martin Gardner in "The New Ambidextrous Universe" , 3rd ed. (1990).

18. **plum**
July 11, 2011

The vortex theory failed to explain atoms, but let's not jump to conclusions that the "electromagnetic theory" of atoms got it right from the beginning. J J Thomson discovered the electron in 1897, but he was of the opinion that the positive charge in an atom was smeared out — the so-called `plum pudding' model of the atom — the electrons were like raisins, points of negative charge, in a background mush of positive charge. In 1909 Ernest Rutherford discovered the atomic nucleus and proposed the `solar system' model of the atom. But Rutherford's model had immediate problems, which the plum pudding model did NOT have. It was known by 1909 that a point charge moving in a circle will radiate, which meant that Rutherford's proposed solar-system model of the atom was unstable. In 1913 Neils Bohr proposed a solution (the Bohr model of the atom), but it was hardly a rigorously formulated theory. The Bohr theory was really a suspension of belief, with ad hoc postulates to fit the observed data. The Bohr-Sommerfeld quantization just slapped on ad hoc `quantization rules' on top of classical physics, the "old quantum theory". It was hardly a rigorous theory. So who is to say that the vortex theory of atoms was a ridiculous idea to pursue, circa 1900?

19. **Arun**
July 11, 2011

If I remember correctly, there is a lot about vortex theory in Sir Edmund Whittaker's A History of the theories of aether and electricity, specifically the first volume. It would be interesting to collide Helge Kragh's work against it.

20. **D R Lunsford**
July 11, 2011

Focusing of vortex theory in particular is barking down the wrong whirlpool. The point was that the idea of matter in the vacuum, in the light (haha) of Ampere, Faraday, and Maxwell, had become extremely complicated when compared to the sane world of Newtonian continuum mechanics. Vorticity in continuum mechanics itself obeys a sort of conservation law and so naturally, people who were attempting to construct fundamental mechanical models of matter in the vacuum fell back on this fact. The main issue was a wrong-headed and premature attempt to model the vacuum when too little was known about the actual state of matter.

-drl

21. **Nige Cook**
July 13, 2011

The analogy to string theory is deep. The toroidal vortex or smoke ring in an ideal fluid doesn't disperse, so it seemed like a good model for the Greek concept of the atom. It represented atoms of matter as just a disturbance in the Maxwell model of space, a vortex in a fluid in which "displacement current" can flow (his addition to Ampere's current, to make his equations postdict light). When Michelson and Morley failed to detect Maxwell's postulated light-carrying vacuum medium, and when radioactivity was discovered, Lord Kelvin simply dismissed the MM experiment and radioactivity as experimentally bogus because they conflicted with his beautiful model of stable vortex atoms. You can expect the same denialist reaction to the failure of experimentalists to find supersymmetric particles, etc. Einstein is famous for saying (when light deflection was observed in 1919) that general relativity didn't need testing because it is a beautiful theory, so it must be right. (It then turned out he was confused about the role of the cosmological constant in his "beautiful" theory.)

22. **aelight**
July 13, 2011

Einstein – is that so? Einstein wrote to Edwin Hubble to ask his opinion if the deflection of light could be measured by observations of stellar positions **in daylight** (emphasis by Einstein ~ I read this maybe in Physics Today ~ maybe in 2005 celebrations of Einstein annus mirabilis). Hubble replied that there was no hope of doing so, but that measurements during a total solar eclipse might be possible. A suitable solar eclipse took place in 1919, Eddington made the observations, and the rest is history. So possibly Einstein said different things before and after the test of GR proved successful. Dear Uncle Albert was only human?

23. **John Duffield**
July 16, 2011

Pay careful attention to "vortex theory". There are hands-on experimentalists doing work in this area, see for example http://www.physorg.com/news182957628.html, as Roger said the people involved in vortex theory during the 19th Century didn't know about the electron, and it was Thomson and Tait who gave us "spherical harmonics".

24. **CPV**
July 16, 2011

It's obviously not clear which ideas will be successful ahead of time, so Monday morning quarterbacking of failed ideas is not a particularly noble or useful enterprise. I suspect the main point of this blog is the percentage of resources devoted to any one idea, not the concept that there shouldn't or won't be failed ideas, or that people shouldn't be encouraged to work on wildly speculative ideas. Usually experimental evidence will break logjams and sort things out. We just don't have any interesting evidence right now.

25. **Peter Woit**
July 16, 2011

CPV,

In the case of string theory unification, the difference with "Monday morning quarterbacking" is that in the football case, the team that lost on Sunday had to acknowledge it. The problem with string theory unification research has in recent years evolved from a problem about relative allocation of resources into a more disturbing one of pseudo-science being promoted in order to allow failure to not be acknowledged.

In this circumstance, a comparison of the current situation to previous ones where the failure is now clear to everyone may very well be enlightening.

26. **cormac**
July 18, 2011

Peter and Bee: of course it's well-written!
Helge Kragh is the author of Cosmology and Controversy, a highly regarded book on 20th century cosmology that focuses on the debate between the steady-state and BB models. It is a most unusual book in that it is considered historically accurate, scientifically accurate and highly readable. It is cited in almost every major cosmology book I have, whether textbook, popular book or historical analysis!

This Week's Leak

July 12, 2011
Categories: Experimental HEP News

Everyone in the HEP community is breathlessly awaiting the release of results from the 2011 LHC run, expected to come at the EPS-HEP 2011 conference in Grenoble starting July 21. A public press conference has been announced for July 25. Presumably the new results will further tighten limits on supersymmetric particles, extra-dimensional models and other exotica, but the real excitement surrounds the question of what the news about the Higgs will be. The latest LHC data should finally allow competition on this front with the Tevatron.

Philip Gibbs at viXra log has posted here what looks like the bottom line for CMS. They are not yet able to exclude a Higgs at lower masses, including the range where the Tevatron has an exclusion region, but are able to exclude (at 95% confidence level) a SM Higgs in a higher mass region (about 275-425 GeV). This sort of result is not quite what it looks like, since precision electroweak measurements already rule out such a SM Higgs, and recall that the Higgs self-coupling increases with Higgs mass, meaning that one is entering into a region where one is not sure that perturbation theory applies. If the Higgs is not a weakly coupled field, life becomes much more complicated.

The source of the plot is variously described as "shown at a seminar which as far as I know was public", from "a public part of the CERN repository", and "not yet public but was made accessible on a Fermilab site".

ATLAS, the competition for CMS, presumably has a similar plot up its sleeve just about ready for release at EPS-HEP 2011. Once the two experiments have made public their independent results at this conference, they intend to immediately get to work producing a combined plot, with goal of releasing it at Lepton-Photon 2011, which will take place in Mumbai August 22-27.

Comments

1. **DB**
   July 12, 2011

   Minor typo Peter, the EPS-HEP conference begins on July 21st.

   I think it's too early to expect anything really interesting out of the LHC this time around. I suspect that the inexorable closing off of the SUSY parameter space is a bit of a sideshow for most. It's like dutifully visiting a terminally ill relative you never really got along with.

   This is the year to celebrate the machine's performance after the initial disastrous startup. ICHEP 2012 in Melbourne, or especially EPS-HEP 2013 in Stockholm should be another story altogether.

2. **Peter Woit**
   July 12, 2011

   Thanks DB,

   Absent surprises, the most interesting thing should be whether a Higgs is seen in the expected region of 114-158 GeV. Do you really think it will take that long for ATLAS/CMS to be able to exclude or start to see something in this region?

3. **DB**
   July 12, 2011

   I'm a Higgs agnostic myself, Peter, and I won't be hugely surprised if they don't see it, which is why I think it will take until 2013 before we know one way or another.

4. **GS**
   July 12, 2011

   I really enjoy the high quality of the discussions in this blog. Even though my comment may not be living up to the level of the rest, I just wanted to mention–as a (very speculative) side remark–the CERN announcement for the press conference http://www.interactions.org/cms/?pid=1030888
   Notice topic three: "The LHC and other projects: what strategy should Europe adopt for particle physics? by Michel Spiro, President of the CERN Council and CNRS Scientific Director for the Alpes region." This may be exaggerated, but it sounds suspiciously like they are preparing to present no revolutionary results there.

   Best,
   GS

5. **P.**
   July 12, 2011

   CDF has seen B_s -> mu+mu-

   Talk on friday:
   http://theory.fnal.gov/jetp/

6. **Peter Woit**
   July 12, 2011

   P.

   Thanks, very interesting! I'm assuming for them to see this, the signal must be too large to be compatible with the SM, right?

   At the KITP, they were guessing that this seminar would be "possible…D0 ttbar asymmetry measurement", see

   http://lhc11.wikispaces.com/Talks+%26+Discussions

7. **Peter Woit**
   July 12, 2011

P.

The CDF paper is out tonight:

http://arxiv.org/abs/1107.2304

They do claim to see an excess of B_s -> mu+mu- above expected background + SM value, with 1.9% probability of such an excess if the Standard Model is correct. They conclude

“Although of moderate statistical significance, this is the first indication of a B_s -> mu+mu- signal”

Not yet a convincing violation of the SM, but intriguing. Can D0 also see this?

8. **PA**
July 13, 2011

A seriously garbled html version of the CMS presentation remains in the Google cache. It’s very preliminary, so who knows what will really be the result presented. The bottom line is that although “strong statements” about the Higgs are now possible, the upward fluctuations seen in Phil G.’s plot are fully consistent with statistical expectations. So as of now, it looks like CMS will firmly exclude some models (SM Higgs + 4th generation), but a little more patience will be needed for the vanilla Higgs.

9. **anonymous**
July 17, 2011

“This sort of result is not quite what it looks like, since precision electroweak measurements already rule out such a SM Higgs, and recall that the Higgs self-coupling increases with Higgs mass, meaning that one is entering into a region where one is not sure that perturbation theory applies.”

Does this suggest that we may not be able to confidently detect a more massive Higgs if it exists? Does the vanilla Higgs show a better signature over all mass regions?

10. **chris**
July 19, 2011

no, it just means that this was primarily ruling out technicolor Higgses, which are not so popular anyways.

11. **Peter Woit**
July 19, 2011

chris,

It’s not clear to me that ruling out a high-mass Higgs described by SM Feynman rules actually tells you anything about a Higgs in a technicolor theory, which will have a different behavior.

Questions About the Multiverse

July 19, 2011
Categories: Multiverse Mania

The August issue of Scientific American has the multiverse on the cover, with a skeptical feature article on the topic by George F. R. Ellis, Does the Multiverse Really Exist?, which argues that heavily promoted multiverse research isn't really testable and can't explain much of anything. Vilenkin and Tegmark respond with The Case for Parallel Universes.

I just took a look at some of the earliest postings on this blog about the multiverse from as far back as seven years ago (e.g. here and here). Things haven't changed at all. One might be tempted to criticize Scientific American for keeping this alive, but they just reflect the fact that this pseudo-science continues to have significant influence at the highest levels of the physics establishment. The Perimeter Institute recently ran a conference on Challenges for Early Universe Cosmology, which was dominated by multiverse mania. Unlike the case at SciAm, multiverse skepticism didn't get prominent play at Perimeter.

Update: For those of you who just can't get enough multiverse, the Sci-Fi film Another Earth opens Friday. Click on "Parallel Worlds" for an explanation of "the theoretical physics behind the film."

Comments

1. **Sean the Mystic**
   July 19, 2011

   Brilliant article by Max Tegmark. I'm not a physicist, but I find his arguments compelling and perfectly rational. What about Tegmark's arguments do people here object to?

   My only disagreement with Tegmark is his last statement: "The price we have to pay is becoming more humble—which will probably do us good—but in return we may find ourselves inhabiting a reality grander than our ancestors dreamed of in their wildest dreams." Actually, if science continues to humble us in this manner, I fear we may do what Lovecraft warned about in the face of our mind-boggling cosmic insignificance, and "flee from the light into the peace and safety of a new dark age."

2. **Peter Woit**
   July 19, 2011

   Sean the Mystic,

   Unlike mysticism, where there may be other ways to convince people you have interesting insight into something, in science there's traditionally just one way to do this: use your insight to make a convincing testable prediction and then check it. This is what neither Vilenkin nor Tegmark can do, and they've made no progress towards doing this in the years and years that they have now spent promoting multiverse studies.

   There may very well be a multiverse, of levels I, II, III, IV or whatever. But at this point all the years of work on this have led to nothing but:

   1. claims that if everything worked out just right, there'd be a signal visible in the CMB, of exactly the right size to now be just beyond the level detectable. This appears to be just wishful thinking, and even Tegmark says he doesn't believe it:
   "I totally share his skepticism to these claims."

   2. claims that string theory will allow statistical predictions by analyzing the landscape of string theory solutions. This has been a complete failure and there are strong arguments that it is guaranteed to fail.

   As for the argument that skepticism about multiverse studies is some sort of hubris, I think the opposite is true: the hubris of multiverse maniacs with their conviction that we don't need conventional standards of science any more and can happily go on about level IV multiverses is just staggering.

3. **Sean the Mystic**
   July 19, 2011

   Thank you for this reply. Maybe there should be a new field of study then, call it "multiverse studies" or something, so these multiversalists can pursue their ideas separately from the more traditional empirical scientists? Maybe these theories are more pure math or even art than science, but that doesn't mean they aren't worth exploring.

4. **Peter Woit**
   July 19, 2011

   Sean,

   The burgeoning field of "Multiverse Studies" definitely isn't pure math. The papers in this subject typically just use high school algebra. Categorizing the subject as an art form and not a science would be a step forward.

5. **Hakeem Shabazz**
   July 19, 2011

   Let them do all the multiverse studies they want, on their own nickel.
   Just cut off uncle sam's gravy, although that may thin out the crowd milking a nice conference.

   BTW, is this not a corollary, in headline form, of the theory of the infinite mutiverse, where anything consistent with physical laws will happen:
   President Obama and Palin Have Love Child in Alternative Universe.
   'He cheated with that racist dingbat', sobs Michelle.

6. **Peter Woit**
   July 19, 2011

   Hakeem,

There’s very little of Uncle Sam’s money in multiverse studies, since NSF and DOE panels tend to not support this. Private money (Templeton Foundation for Tegmark’s FQXI, Blackberry for Perimeter) is funding most multiverse mania.

And, by the way, multiverse jokes have also gotten really old by now…

7. **Sean the Mystic**
   July 19, 2011

   So is that what this is about? A power struggle for government funds? I suppose you could argue that if the public finds multiverse studies more interesting than experimental particle physics, and wants to spend their tax money on it, then that’s their perogative. My impression is that we’re fully in the postmodern era now, so the pursuit of objective truth for its own sake no longer carries much weight. Multiverse studies fits perfectly with postmodern thinking, whereas traditional physics just seems like intellectual tyranny. These are just the random thoughts of a mystic who used to study physics, feel free to ignore them 😉

8. **Eric habegger**
   July 20, 2011

   Sean,

   “My impression is that we’re fully in the postmodern era now, so the pursuit of objective truth for its own sake no longer carries much weight. Multiverse studies fits perfectly with postmodern thinking, whereas traditional physics just seems like intellectual tyranny.”

   I think you are being too kind by half by describing the current mood as post-modern. If this new era continues as it has been in physics for the last thirty years and isn’t just a temporary blip I think it would be better called the second dark age. Or better yet, in the spirit of the times we should now call the dark ages the first post modern era. That would then make everyone feel better about the second post modern era we may be entering. Anyone interested in eye of newt to put into your latest physics experiment? I have them at rock bottom prices.

9. **Markus Schwarz**
   July 20, 2011

   Dear Sean,

   this “traditional intellectual tyranny” has brought to you such things as electricity, cell phones, GPS systems… In chemistry it led to things like plastics, and in medicine to antibiotics… The list is still growing. If your multiverse/postmodern thinking could produce things like warpdrives or teleporters, or even improve known technologies, I am sure it would have a justified place in natural science. However, they have not contributed anything so far, and my impression is that they don’t even try. Instead, they invent new rules and still want to be part of the natural sciences. To me, they sound like soccer players who pick up the ball by punching other players and, when the referee shows them the red penalty card, argue that this is allowed in rugby. If someone wants to pursue these ideas, he should indeed do so in the humanities department. But why should I abandon the successful traditional way of thinking?

10. **Bobito the Payaso**
    July 20, 2011

    “more traditional empirical scientists”

    This made me laugh. And cry.

11. **Ignatz Thugg**
    July 20, 2011

    Perhaps Alan Sokal can revise his first book (Fashionable Nonsense)
    by replacing the literary post modernists by the mystics and new-agers
    within the Physics community. Not much would have to be changed –
    appropriate quotations of course, but Sokal’s commentary could
    (almost) be left intact.

12. **Aleksandar Mikovic**
    July 20, 2011

    “If someone wants to pursue these ideas, he should indeed do so in the humanities department. But why should I abandon the successful traditional way of thinking?”

    The reason why many physicist are working on the multiverse ideas is that any attempt to extend the current fundamental physical theory, i.e. the Standard Model of particle physics and cosmology, without an experimental input, boils down to the problem of formulating a mathematical theory with certain properties. The main property is to recover the Standard Model in a certain limit, and the other requirements are based on the authors philosophical inclinations. Hence this type of research cannot be done in the humanities departments, since the people there do not know enough physics and math to do it or to evaluate it. Although this type of research is not a traditional science, I think that it is useful, if it is done in an adequate proportion to the usual science research, since it opens new vistas and provides new ideas. There are several episodes in the history of science when such an approach was fruitful, for example: General Relativity and Dirac’s equation.

13. **Alexander Kruel**
    July 20, 2011

    Have you ever heard about Eliezer Yudkowsky and his take on the multiverse? I am curious about your opinion:
    http://lesswrong.com/lw/r8/and_the_winner_is_manyworlds/

14. **Igor Khavkine**
    July 20, 2011

    Alexander, this is a case of one word with multiple distinct meanings. The ‘multiverse’ discussed on Yudkowsky’s blog is logically distinct from the notion of ‘multiverse’ discussed in the recent SciAm issue. The former consists of a certain way of looking at a mathematically precise, empirically well tested theory of quantum mechanics, while the latter consists of a loosely grouped collection of speculative ideas about how to explain some features of our universe, though without any empirical way of separating good ideas from bad ones.

15. **Sean the Mystic**
    July 20, 2011

Markus, who wants you to abandon a successful way of thinking? I just suggested a new field of study, so the different camps don't have to fight each other. I think it would be great if multiversalists joined artists, writers, mystics and other creative people who like to speculate about possible worlds. Maybe it would all be nonsense, but it would be a lot of fun and they might even discover something "important". I just find it fascinating that creatives had ideas about parallel universes a long time ago that sound very similar to what physicists are saying now. (See http://en.wikipedia.org/wiki/Parallel_universe_%28fiction%29 for some examples).

I think you're on a slippery slope if your justification for science is its practical applications; we might as well abolish many areas of higher math, stop building space telescopes and forget about astronomy and cosmology with that attitude. For that matter, what is the practical value of the LHC? I like to think that anything the human mind can imagine is real in a larger multiverse of ideas, and that exploring that realm is a form of empirical science — but then, I am a bit of a crackpot. 🙂

16. **Bob Levine**
July 20, 2011

Sean, I think you've missed the point of Markus's post. If I read him right, he was pointing out a substantial number of technological developments that count as existence proofs of a particular connection between science and something normally labeled 'reality' that corresponds to how the world works, and was suggesting that the multiverse has no such evidence to favor it. The old question, 'If it were wrong, how would we know?' is relevant here. If the multiverse, on your or anyone else's conception were wrong, how would we know. Markus' and Peter's point, and that of a lot of the other contributors to this site, is that hype notwithstanding, there isn't any way we would know. So whether you enjoy 'exploring' the multiverse or not, it's unconnected to science, period.

17. **Christian Takacs**
July 21, 2011

Dear Sean,
Perhaps you need to reassess your definitions of science… Like I did. When I was growing up I read a great deal of Science Fiction and watched Star Trek, Babylon 5, and other Sci-Fi oriented programming. I read The Time Machine, Permutation City, The Broken God, and many other fine books. When I started in great excitement to look into how such things as Warp Drive, Time Travel, Alternate Universe Travel, Teleportation might work, what I discovered was that there was not so much "science" as "plot devices" at work. I began to realize that my love of good fictional stories with technological plot devices was clouding my understanding of what science actually was. While there is truth to be found in fiction, it is usually in the form/message of good and bad human choices and consequences, and not how scientifically accurate or valid the plot devices are. When you read an Aesop Fable like The Fox and the Crow, or The Tortoise and the Hare, you aren't supposed to take away that animals talk, have foot races, or are genetically predesposed to have philosophical discussions, Or that they actually exist in an alternate universe; You ARE supposed to consider the concepts and implications behind the character's actions, masks, and words.

When you study Science/ and or Physics, you are going after "what is it and how does it work?" and to do this you follow very strict rules of definition, methodology, heirarchy, logic and confirmational experimentation. These "rules" are not to be mistaken for "plot devices" and vice versa. These "rules of science" are also designed to be resistant (not fool proof) to sophistry and deceitful manipulation.
As a good general rule, when anyone claiming to be doing science/physics avoids or denies "confirmational experimentation" they should be met with a healthy dose of skepticism, then slapped with a ruler on both palms before being made to write "I shall not evade confirmational experimentation while in THIS particular universe" on a white board for as many times as there are theoretical unproven multiverses, or until they repent, or just renounce all their government funding and start quacking like a duck.

18. **Paul D.**
July 21, 2011

And, by the way, multiverse jokes have also gotten really old by now…

I'm sure there are universes where the jokes are still funny.

Just … not this one.

19. **lun**
July 21, 2011

As a general point, this discussion has been going in circular form in many places, physical and virtual. I think the question is very simple:
Can the multiverse make experimentally verifiable predictions?
Since there have been at least two proposals in the affirmative ((a) cosmological signals of neighbouring universes and (b) correlations among physical constants), dismissing the multiverse idea as unscientific a priori is wrong.

ON THE OTHER HAND, claiming that the multiverse must exist because string theory "must be right" but no other solutions exist for problems like the cosmological constant and vacuum selection is also wrong. I believe I can not explain why.

What gets me about modern string theory is not so much that they do research on the multiverse, as I said to me its a potentially legitimate and productive area of investigation. Its that SOME string theorists make claims of results ("we know string theory is the theory of everything!" "We know the multiverse is predictive") well before results are on the horizon (indeed, well before the results will be on the horizon).

The fault here is not with string theorists, ALL fields of science, today, make wildly overhyped claims because so much of their funding depends on their PR ability.
In the long-term, this corrupts the science. Feynman explained this in
http://www.lhup.edu/~DSIMANEK/cargocul.htm much better than I can here.
String theory, because of the fuzziness of its fundamental picture and the
lack of experimental verification, is more susceptible to this corruption than other fields, thats all.

It is not just with the multiverse: I saw a seminar where an eminent AdS/Condensed matter person and his collegues had a near-shouting match with AdS/condensed matter skeptics on whether AdS/CFT has anything to say about condensed matter.
And the crucial question, "is there a way to tell that a certain system can be described by a classical supergravity dual", was not even addressed!
It is a question which we could answer for some systems. For QCD, for example, it probably is no because of asymptotic freedom and the fact that the number of colors is about the same as the number of flavors.

Which brings me to the second problem of modern science to which string theory is susceptible: the fact that young people have to publish on very short time-scales. Both the multiverse and AdS/whatever provide a good way to publish many papers in a short-time, so they are "popular", even if everyone knows these ideas are probably profounds flawed. Again, this is not because string theory is particularly evil, its just the economics of modern research.

20. **lun**
July 21, 2011

ps: Igor, there have been attempts to unify the two pictures by string theorists:

http://arxiv.org/abs/1105.3796

21. **Condensed Matter Theorist**
July 22, 2011

To all the non-physicist readers out there I would like to point out one thing regarding the potential demise of physics or the burgeoning second dark-age being discussed in the comments. The largest swath of physicists in the American Physical Society are categorized as condensed matter physicists. Virtually EVERY cmt physicist I know thinks the multiverse business is completely without merit and ridiculous. Further, almost all cmt physicists I know also think that string theory is complete pseudo-science and likely to be looked at as the greatest hoax ever played on physics.

Just wanted to assure people that MOST physicists are stuck solidly to the scientific method where theorists are only taken seriously if they make testable predictions and nothing is considered to be close to reality until it is experimentally demonstrated beyond a reasonable doubt.

22. **Giotis**
July 22, 2011

Condensed Matter Theorist you are not qualified to reject HEP/QG theories using such dismissive language. Have you ever studied String theory in depth?

In my mind your opinion about String theory or the Multiverse has the same weight as the opinion of a TAXI driver.

Be modest and don't make pompous statements for things you have no idea about.

23. **Condensed Matter Theorist**
July 22, 2011

Giotis, you're joking, right? Taxi driver? Really? Even most taxi drivers are able to dismiss string theory due to it's lack of adherence to the scientific method. Experimentally verifiable. It's very simple. Taxi drivers….come on, who's pompous?

…I should have guessed I would get a "condensed matter theorists are intellectually inferior to string theorists" type response in the comments of this blog. Most theorists I know actually are quite knowledgeable about "HEP/QC" theories–as you call them–and astonishingly to you–still think they are ridiculous and choose to work on something else. I know it's probably hard to believe but the complement of the set of all string theorists does not equal the set of all theorists too stupid to be string theorists. That may hurt your ego (and I understand that the ego is one of the only thing most string theorists have left) but it's true.

24. **Condensed Matter Theorist**
July 23, 2011

Giotis, one more thing. You've set up such a standard that ONLY a world-renowned and string-theory-establishment-certified expert's rejection of string theory would have any meaning for you. Any other rejection would necessarily come from someone who is "unqualified". That's very convenient for you. I suppose until Witten turns his back on string theory, how dare any other mere mortal to have a judgement. Although, I imagine that if Witten jumped ship, you all would convince yourselves that you threw him overboard due to his loosing his marbles and being no longer credible.

25. **Peter Woit**
July 23, 2011

Giotis,

CMT makes the obvious points about this, but in addition it's worth pointing out that most multiverse papers use very little mathematics (and not that much physics). A bright (or even not so bright) high school student could read and follow some of them (as well as figure out why it wasn't science…)

26. **gregor berkens**
July 24, 2011

Michael Faraday also used very little mathematics, and yet Einstein had a picture of the great Faraday hanging in his office.

This blog also uses very little mathematics, so perhaps this blog isn't really about physics. 🙂

27. **Thomas Curran**
August 3, 2011

The article " Does the Multiverse Really Exiist" states astronomers are able to see to a distance of 42 billion light years……
My question is what do they see past 13.7 billion light years?

First International Spring School on Particle Physics and Philosophy

July 19, 2011
Categories: Uncategorized

From an article in the CERN Courier I recently learned about a program that brought together physicists and philosophers of science earlier this year around the topic of philosophy and particle physics. This was the First International Spring School on Particle Physics and Philosophy held last March in Germany, and I gather that there are plans for a second one in two years.

Unlike many "physics and philosophy" efforts, which often revolve around rather sterile debates, the central topics of this school were very real issues currently at the heart of fundamental physics. In particular, the questions of gauge symmetry and the Higgs mechanism played an appropriately large role, with the experimental situation an important part of the discussion. In a few days (at EPS-HEP2011) we're likely to hear the first significant results about the Higgs coming from the LHC. This will mark the beginning of a new era likely lasting for a while which will be dominated by news coming from the LHC on this topic, and a major re-orientation of theoretical research in response. New ideas will hopefully emerge, and models that have held theorists attention for decades will likely fall by the way-side (in his talk on supersymmetry, Michael Kraemer expresses the opinion that if it doesn't show up in the 2011/12 run, it's all over for weak scale supersymmetry).

The speaker's slides for the conference unfortunately aren't now publicly available since the organizers haven't gotten permission from their authors, but perhaps they'll be made available at some point, somewhere in some form.

Comments

1. **lun**
   July 20, 2011

   Maybe I am too cynical, but 99% of activity at such "interdisciplinary" meetings ends up consisting in people talking past each other.
   The timetable and titles of the talk tends to reinforce my cynicism.
   Perhaps someone present at the conference could report on it…

   As for philosophy of physics… I sat in a graduate class on philosophy of quantum mechanics at a major research university and was stunned that the professor did not know of things like the Schrodinger and Heisenberg pictures. That you can derive the whole of QM just from Heisenberg's uncertainity relations. That the Kochen-Specker theorem precludes ANY consistent hidden-variable description fully agreeing with QM.

   An eminent philosopher once said that the job of philosophers is to define questions in a sufficiently rigorous way that they can be investigated by other disciplines.
   Its a good definition, and by this mark, physicists seem to be doing this job already.

   Again, I would very much like a direct report from the conference, but I would be willing to bet money that the speaker on gauge theory has no idea that in string theory one can easily transform gauge into global symmetries.
   (Not saying that string theory is necessarily the correct description of nature. Just that, before linking gauge symmetry to "structural realism", perhaps one should see if a more concrete understanding of them is available. And fort that one needs to be a physicist at this point).

Results from EPS-HEP 2011

July 21, 2011
Categories: Experimental HEP News

Results from the EPS-HEP 2011 conference that began today are starting to appear. These include the first results making use of most of the 2011 LHC run data. This is a factor of 30 or so more data than that from the 2010 run, which was the source of almost all previous results released by the LHC experiments. Some of the news so far:

- ATLAS pretty much says here that there are no squarks or gluinos below 1 TeV (see page 9). Comparing to analyses of the regions considered mostly likely (see for example here, figure 7) pre-LHC, significantly more than half of the region in which supersymmetry was supposed to appear is now ruled out. Another factor of 10 or so in data should come in during the rest of the 2011/2012 run, which should allow limits to be pushed a bit higher. At this point, it looks like SUSY is on its way out. It will be interesting to see if die-hards insist that the factor of 2 in energy at the next (starting in 2014-5) run will make a difference.
- For results relevant to strings, black holes, extra dimensions, split supersymmetry, and other exotica, CMS has them appearing here, for ATLAS they're here. No such objects are being seen, with limits being pushed up dramatically from those coming from the 2010 data. Again, it's going to be very hard to argue that there's a significant probability that such things will be seen in the rest of this run, or even later ones at full energy.
- CDF results available here say no Higgs between 156 and 175 GeV, D0 exclusion (here) looks like it covers about 160-170 GeV. Fermilab has issued a press release about this, advertising the release of the combined numbers at a July 27 talk. This should also include low mass searches which might provide exclusion above the 114 GeV LEP limit. The press release mentions a "most likely" range of 114-137 GeV for the Higgs mass, and links to earlier Tevatron exclusion limits, but I suspect the 137 number comes from a different source, not a Tevatron direct search result.
- CMS and ATLAS results on the Higgs are to be announced tomorrow afternoon (an early version of the CMS results leaked here). A combination of results from the two camps will be done after the conference, planned to be announced at Lepton Photon 2011 in late August, although a rough guess as to what that will look like should be available just from seeing the two independent results.
- Philip Gibbs is keeping a close eye on this at viXra log.

Update: Tommaso Dorigo has some more news here: CMS is not seeing the SM violating forward-backward top pair production asymmetry seen at the Tevatron (more about it here).

Update: ATLAS results on the Higgs are 95% exclusion 155-190 GeV and 295-450 GeV. They see a 2.8 sigma excess of events in the 120-140 GeV range.

Update: I just noticed that Matt Strassler now has a blog and is blogging from Grenoble.

Update: Matt Strassler reports from the CMS Higgs combination talk that they exclude 145-480 GeV at the 90% confidence level. Some excess 120-145 GeV, smaller than ATLAS.

So, in summary, it looks like the LHC + Tevatron have pretty much excluded a high mass Higgs, narrowed the possible mass range down to 114-150 GeV or so. No evidence at all of anything but the SM. The big story of the next few months will be to watch and see if a Higgs signal emerges in the last non-excluded region. Or not….

Comments

1. **SA**
   July 21, 2011

   Actually, the new ATLAS data does not exclude much of the parameter space not already ruled out by other experiments (in the case of mSUGRA/CMSSM).

2. **Peter Woit**
   July 21, 2011

   Well, the new results rule out a significantly larger region of possible squark and gluino masses than the 2010 data, one that includes the points that various groups were advertising as "most likely". It's very easy to find papers arguing that the LHC was likely to see supersymmetry in this region, here's a couple more:

   http://arxiv.org/abs/0907.2589

   http://arxiv.org/abs/1011.1246

   I'd be curious to see a review of the pre-LHC literature on this, for comparison with arguments likely to be made now about why these masses have to be much higher.

3. **asdf**
   July 21, 2011

   So Susy turns out to be crap after all. Makes sense. It cut too deeply against Ocam. I suspect "diehards" will never give up. Not even after 10 years of operation at full power. I think Planck said that progress in physics is made one funeral at the time.

   I suspect the Higgs will be excluded. Chiral symmetry breaking and supeconductivity were both explained as scalars initially. Scalars are probably just something we resort to when we can't understand the microphysics.

   You'll be sure to update tomorow's Higgs limits Peter?

4. **KD**
   July 22, 2011

   I can't help thinking supersymmetry is so popular because of the name. I mean, who wants to work on ordinary symmetry if we have supersymmetry? If it had been named more modestly, like Fermi-Bose symmetry, perhaps it would have been placed more appropriately.

   Same with string theory. "String theory": boring. "Superstring theory"? Wow! Must be super interesting.

   KD

5. **dir**
   July 22, 2011

just wander how fermilab disfavors 137 – 156 gev higgs

6. **piscator**
July 22, 2011

Seriously. The problem is not that there is no sign of susy, the problem is that so far there is no sign of *any* physics beyond the Standard Model. If a light Higgs is found, then the hierarchy problem remains as a real problem, and something needs to address it. The underlying argument for susy would remain unaffected – and a 1 part in 10^x fine tuning is a lot better than the 1 in 10^32 fine tuning of the Standard Model. This is why the crappest possible outcome would be a light mass Higgs with no signs of new physics – the best way to kill low-energy susy would be a positive signal for technicolour.

7. **younghun park**
July 22, 2011

piscator
I agree with you. Not finding higgs and SUSY paritcles will threaten the quatum field theory and Gauge theory. Now quantum field theory needs higgs or something like higgs. If we find nothing and no new physics, many physicists will doubt QCD and Electro-Weak theroy. Finding nothing will not only threaten SUSY and superstring theory, but also gauge theory.

8. **piscator**
July 22, 2011

QCD and electroweak theory seem in pretty good shape, one would hope so given the number of Nobel prizes already awarded for them….and the correctness or otherwise of strings as a theory of quantum gravity will not be determined by results from a TeV scale collider. But for the question of microscopic structure beyond the Standard Model, the LHC is the best hope there is, and we should hope something new does show up.

9. **Thomas Larsson**
July 22, 2011

My understanding is that the absense of something Higgsish at LHC would disprove QFT – Sean Carroll talks about a no-lose theorem. But the replacement (call it QG) must of course reduce to QFT and the SM in the low-energy limit. This is itself hardly shocking, since neither string theory nor LQG is equivalent to QFT. However, QG must reduce to QFT in such a way that the no-lose theorem is evaded, and this I think is not a property of string theory (and I doubt that LQG has a QFT limit at all).

10. **Alex**
July 22, 2011

Why would not finding a Higgsy thing disprove gauge theory, or even QFT? My take on that always was that it would simply mean that we lose perturbative control around the TeV scale, and it would be hard to explain all the nice electroweak precision observables. But the claim that QFT itself would have to be wrong because of that sounds way too strong to me.
Nonlinear realizations, fine with me.

asdf,

"So Susy turns out to be crap after all. Makes sense. It cut too deeply against Ocam."

It may not be realized in nature, but why does it violate Occams Razor so much? The susy breaking one needs to introduce in order to get a good light spectrum (if one insists) is sometimes, but not always, a little messy, but the concept of SUSY itself is very simple…

KD,

"I can't help thinking supersymmetry is so popular because of the name."

I can help you with that: no, that's nonsense.

Supersymmetry is popular because it's a simple concept, can be integrated in renormalizable theories, solves the hierarchy problem, can solve the dark matter problem. Or do you also think gauge theory is so popular because people like pressurized air so much? 🙂

11. **Peter Woit**
July 22, 2011

Thomas,

No Higgs doesn't mean QFT is disproved (and LQG or string theory are irrelevant), it just means that the simplest (and in many ways unsatisfactory) way that we know to describe electro-weak symmetry breaking is wrong. Every HEP physicist should be fervently hoping this is the case. If the LHC results showing the standard model works perfectly up into the multiple TeV range are joined with results showing the Higgs mechanism also works perfectly, the future of the subject is in big trouble (i.e. a victim of its own success).

Alex,

Supersymmetry actually is not that simple a concept, the MSSM is a lot more complicated than the SM. Many people have always found it an unattractively complicated idea that doesn't explain very much, and the LHC is in the process of justifying this point of view….

12. **Thomas Larsson**
July 22, 2011

Perhaps gauge theories are popular because some of them make predictions which are confirmed by experiments? Nah, that's so 1970ish.

Actually, we already know that QFT is wrong, since it most likely is incompatible with gravity. 🙂 But what I really would like to know if you can explain away the no-lose theorem by just hand-waving a bit about non-perturbative effects. A generation or more of theorists has said that the LHC is guaranteed to find something, or else WW scattering is non-unitary. Were they all mistaken?

Not that I would bet against a Higgs boson at LHC, at least not at even odds. Perhaps at 20:1.

For some reason my link to Sean's post did not work. Here it is in plain text: http://blogs.discovermagazine.com/cosmicvariance/2011/06/14/why-we-need-the-higgs-or-

something-like-it/

13. **Alex**
July 22, 2011

Peter,

No-one sane would disagree that the MSSM is much more complicated than the SM (I think…), but that's because of the modesty of the MSSM, right? – it remains willfully ignorant of the source and mechanism of spontaneous supersymmetry breaking. You can't deny that SUSY as a concept is simple, right? It's about as complicated as BRST, {Q,Q*} ~ 2P. Now you can gripe about how ugly SUSY breaking for "realistic" TeV scale SUSY is, fine, but I think the distinction should always be made for the sake of clarity.

14. **Thomas Larsson**
July 22, 2011

Peter, our posts crossed. Above response was directed to Alex.

15. **Alex**
July 22, 2011

Thomas Larsson,

I wasn't explaining it away, isn't that basically the no-lose theorem? We either observe something "higgsy", *or* we observe (though a lot less clearly) the loss of perturbarive unitarity, however that may look. I wasn't claiming that one wouldn't see anything, just that it wouldn't deserve the label "higgsy", but rather "messy" :).

16. **Paolo Valtancoli**
July 22, 2011

In my opinion, the searches for Higgs and supersymmetry are hopeless. The truth is probably in an orthogonal direction that no one has been able to see.

17. **M**
July 22, 2011

News from EPS: a higgs at 144 GeV and a anti-Higgs at 350 GeV

18. **Peter Woit**
July 22, 2011

Alex,

The very general mathematical idea of "supersymmetry" does lead to some amazing things and probably has something to do with reality (in a way we don't at all understand). But the supersymmetric extension of the SM, even without SUSY breaking, is not at all compelling, it just makes the SM more complicated, with minimal gain. And SUSY breaking is just a disaster. Claiming that "I have this wonderful beautiful symmetry, only problem is it is badly broken and I don't know how" is really not at all convincing.

19. **Alex**
July 22, 2011

Peter,

Of course we can argue all day, in the end nature doesn't care :), and I'm not here to fight the fight for SUSY, really. Just about your last comment, I do not understand your claim that that the supersymmetric version of the SM before SUSY breaking is so complicated. Beyond the unique supersymmetrization of everything, one only needs a second Higgs doublet for three independent reasons (but no second Higgs mass parameter!) and in return we even get rid of the quartic coupling, and the potential quadratic divergence, and that's it. Do I miss something?

20. **Peter Woit**
July 22, 2011

Alex,

You've doubled the number of degrees of freedom and, at a formal level, supersymmetric field theories are just more complicated beasts to write down precisely and do calculations in. I don't buy the argument that the MSSM Higgs sector improves the Higgs situation.

If this actually led anywhere, sure, it would be worth it. But all it leads to is the necessity of totally making a worthless mess because you need SUSY breaking.

21. **David Pennell**
July 22, 2011

http://www.nature.com/news/2011/110722/full/news.2011.435.html "Collider sees tantalizing hint of Higgs" did you already discuss this?

22. **Henry**
July 22, 2011

Peter,

I am sorry to disappoint you but SUSY is not dead at all. I should remind you that SUSY is not just mSUGRA or some simplified model that's been used by ATLAS/CMS to extract gluino/squark exclusion limits. You can have for example a compressed spectrum resulting in soft jets / leptons which will easily lower those exclusion curves. Besides 1 TeV is not too high…

23. **SA**
July 22, 2011

(In reply to comment #2)

The question about being “most likely” comes from naturalness. The papers you have linked are candidates for detection in the first round of combined LHC-7, XENON-100 data. Specifically, they found models where both the gluino (which the LHC is sensitive to) and the neutralino (which XENON is sensitive) are light. This means that in the case of a null result, they would be the first to be ruled out.

However, the naturalness/fine-tuning parameter relating the (high energy) higgs-mixing mass to the Z pole, can remain small for very large sparticle masses. This means that you should not look to squark-gluino or m_0–m_{1/2} exclusion curves, but instead exclusions in the Higgs sector to rule out SUSY. It is extremely unlikely to have SUSY with Higgs > 140 GeV, whereas gluino and squark masses can be very heavy.

24. **Benni**
July 22, 2011

I think I remember some private talking to some reowned person working at LHC. He/she laimed that LHC will have good exclusion data for the higgs in the range of 145-120Gev at the end of 2012… but this is just what their group expects…

25. **Alexandre Fauré**
July 22, 2011

Hi Peter,

Thanks for this very useful post.

It seems that this 2.8 sigma excess could be just background … Let’s see if there is an other end with more stat.
For the SUSY parts, perhaps we should remind ourselves about a low-mass Higgs predicted by SUSY too.

Feel free to answer to me If I have some parts I misunderstand.

Thanks again.
AF

26. **Sebastian Thaler**

Hype from the Guardian:
http://www.guardian.co.uk/science/2011/jul/22/cern-higgs-boson-god-particle

27. **Jobs**
July 22, 2011

“at a formal level, supersymmetric field theories are just more complicated beasts to write down precisely and do calculations in.”

While I agree with most of what you write here, Peter, the above statement is wrong. Something that has become apparent in the last few years is that, contrary to expectations, supersymmetric theories are significantly *easier* to perform calculations in. In fact the more SUSY a theory has, the “neater” it is, and the easier it is to calculate. Take a look at arXiv:0808.1446, a very instructive and interesting paper.

This doesn’t affect your argument about broken SUSY and the MSSM, which I think is just as messy as it appears. But perhaps we have no right to expect simplicity at low energies.

28. **Peter Woit**
July 23, 2011

Jobs,

Another way of saying what I was trying to say is that, to calculate things in the SM, you need to read volumes I and II of Weinberg. For any supersymmetric extension of the SM, you need this, and volume III. When there are lots of supersymmetries (N=2 and N=4 theories) you get interesting new ways to do calculations. That’s much less true of N=1, which is the experimentally viable case.

Is calculating g-2 of the electron easier in N=1 super Yang Mills than in the standard model?

Sebastian,

That article is fairly accurate and hype-free from what I can see.

Benni,

I think we’re not going to have to wait till late 2012, maybe more like late 2011…

Henry and SA,

Sure, you can push up the gluino and squark masses as much as you want to evade non-detection at the LHC. But, if you want SUSY to solve various problems it was supposed to solve, you get the sort of predictions that have now been shown to be wrong. For a more general argument, watch Arkani-Hamed’s talk at Strings 2005. He states quite clearly and vigorously that within a year or so of LHC turn-on, we’ll know whether SUSY is relevant to the electroweak scale (exactly because squarks and gluinos should be easy to see in the early data). His prediction has come true and the answer is now in.

One thing I’m curious about is whether Gross and others who were taking bets on SUSY are still willing to take such bets. I suspect they’re not yet willing to pay off, but they’re not about to take any new bets…

29. **Mitchell Porter**
July 23, 2011

A reminder of why supersymmetry is so popular in physics might be in order. Supersymmetric grand unification produces gauge coupling unification; supersymmetry can protect a light Higgs mass without finetuning; supersymmetry provides dark matter candidates; supersymmetry shows up in unified theories that include gravity. It’s a fairly impressive résumé, so it’s natural that so much effort has been expended in exploring the space of supersymmetric theories, looking for models which realize all the features above.

30. **Tobias**
July 23, 2011

Isn't it also true, that sometimes SUSY is introduced to make calculations easier if the result doesn't actually depend on the SUSY?

31. **piscator**
July 23, 2011

Jobs:

`apparent in the last few years'? Apparent in the last thirty years would be more apt. It has been known for a long time that the more supersymmetry present the more special the theory is, and I don't think the paper you refer to adds to this.

Just to be explict for Peter: there are *lots* of computations that are extremely easy to do in theories with N=1 supersymmetry that are *impossible* to do in theories with N=0 supersymmetry. For example, the question 'does a vacuum of the theory with exactly vanishing vacuum energy exist?' can be answered in N=1 theories to arbitrary order in perturbation theory with very little work. But I'm sure you know this, so I am puzzled why you are trying to argue to the contrary.

32. **Peter Woit**
July 23, 2011

piscator,

My argument is really motivated by an allergy to SUSY hype. Sure, there are calculations you can do in SUSY theories you can't do in non-SUSY theories. But, the technical baggage that comes with SUSY is substantial, and for experimentally relevant calculations in the SM, it's typically either not useful or less than useful. I'm legitimately curious about whether one can point to uses of SUSY to help with loop calculations in the SM like the electron g-2.

One simple example: one main source of reliable non-perturbative calculations in the SM is lattice gauge theory. There SUSY is worth than useless, adding SUSY to the SM generally changes things from difficult to impossible.

33. **Eric**
July 23, 2011

Peter,

Yes, supersymmetry helps with loop calculations, the primary example being the loop corrections to the Higgs mass. The effect that supersymmetry has on loop corrections is, in fact, one of the main reasons for theoretical interest in it.

34. **Eric**
July 23, 2011

Also, supersymmetry can have a strong effect on g-2 of the muon. Corrections to g-2 of the muon have long been looked at as possible evidence for supersymmetry.

35. **anon.**
July 23, 2011

It's just not accurate to say that the LHC is excluding gluinos and squarks below 1 TeV. What they are excluding are SUSY spectra in which gluinos and squarks always decay directly to a light neutralino plus jets. Whatever your prejudices are about SUSY models and mechanisms of SUSY breaking, you should appreciate that this is a very specific assumption. If you assume, for instance, that every decay chain always has one extra step — gluino decays to jets plus a neutralino, which in turn decays to another particle or particles and a lighter neutralino, for instance — you will find that the typical limits on gluino masses are lower by at least a couple hundred GeV, and often more, depending on details.

The limits are very strong; the LHC detectors are working remarkably well and the collaborations are making good use of the data. But it is not yet the case that the results exclude new strongly-interacting particles below 1 TeV. The easiest results are getting out first, and these results are not representative of the bulk of SUSY parameter space.

36. **Low Math, Meekly Interacting**
July 23, 2011

Hi, all,

Without wishing to create a tangent to the argument about the pros or cons of SUSY, SUGRA, or what-have-you, I just have a simple question: Are we now much closer to or at the point that the MSSM has been ruled out?

Thanks!

37. **Peter Woit**
July 23, 2011

anon.,
But where is the "bulk of SUSY parameter space"? By some measures, it's off beyond the LHC reach. I've been pointing to some of the pre-LHC work I'm aware of by groups trying to give an answer to that question in terms of assumptions that SUSY does various things it is supposed to do, as well as general statements such as Arkani-Hamed's one at Strings 2005, and these seem to me starting to be in serious conflict with the data. This is not just my opinion, see the last slide of the talk by Rogerson on SUSY fits: "Air is starting to become very thin for these constrained models of SUSY". If you start relaxing these constraints generically, do you evade the LHC results? Or do you need to start picking specific directions to go in to do this? As an example, is adding steps to the decay chain generic or not?

LMMI,

The problem is that the MSSM has 120 or so extra parameters. You can't ever rule it out, all you can rule out are parameter ranges, specifically the parameter ranges corresponding to various motivations for the MSSM. If your only motivation is that you like the idea of SUSY, that you like the expected CC to be off by 60 instead of 120 orders of magnitude, or some such, there's no way to rule this out.

38. **anon.**
July 23, 2011

see the last slide of the talk by Rogerson on SUSY fits: "Air is starting to become very thin for these constrained models of SUSY".

The key there being "these constrained models." In fact mSUGRA and the other similar constrained models being fitted are not even *models* in any real sense, they're ansätze chosen to evade flavor problems but not really consistent with any reasonable UV-completion I know of. (Of course, I don't know any real SUSY model that's *completely* free of problems; but at least I know some that are honest models.)

If you start relaxing these constraints generically, do you evade the LHC results? Or do you need to start picking specific directions to go in to do this? As an example, is adding steps to the decay chain generic or not?

If the gravitino is light enough (e.g., in low-scale gauge or gaugino mediation), there is always at least one extra step in the decay chain, and generically this weakens limits quite a bit (although more specific targeted searches recover part of the difference). Another fairly common scenario that can arise in high-scale SUSY breaking models is that instead of getting light quark jets in decay chains, you can get a substantial fraction of tops. Because the top mass is bigger and it has more decay products, these events tend to fail the jets+Met cuts (less missing E_T, lower energy jets). Again, though, targeted top-related searches might still exclude part of this parameter space. More generally, it's pretty generic to have extra steps, but the decay considered in the ATLAS search, for instance, still happens with some branching fraction. So the limit is weakened by a model-dependent amount.

It's very hard to make completely general claims. The constraints are very strong and getting stronger; I don't mean to suggest otherwise. I think there's cause for at least a little concern (not just about SUSY, but about finding new physics beyond the Higgs at the LHC at all!). Certainly I was hoping there would be some kind of unambiguous new physics showing up by the time we had 1 fb^-1. But, there *are* still sensible models where the gluino can be in the neighborhood of 500 to 600 GeV without being ruled out, and somewhat more contrived models where it can be quite a bit lighter even than that.

39. **Benni**
July 23, 2011

yes peter, it was a typo. My source ment late 2011. The sentence should be

He/she laimed that LHC will have good exclusion data for the higgs in the range of 145-120Gev at the end of 2011… but this is just what their group expects…

40. **Jobs**
July 23, 2011

"My argument is really motivated by an allergy to SUSY hype. "

This is admirable, but anti-SUSY hype is just as bad as SUSY hype. We should try and be objective.

Regarding supersymmetry being used in SM computations, I can testify that it provides an extremely useful organisation of loop calculations. Indeed, you can separate one-loop amplitudes in QCD into "SUSY parts" and "non-SUSY" parts, and this division is a significant aid to calculation. This says nothing about whether low energy susy exists, but it does point to QFT and SUSY being natural bedfellows.

41. **Low Math, Meekly Interacting**
July 23, 2011

Hi, Peter,

That's kind of what I thought, but thanks for clarifying.

42. **anonomous**
July 23, 2011

What are the chances of finding an attractive alternative to Higgs/SUSY through phenomonology by the end of the year? Is anybody suggesting new settings for the detectors? I am just thinking that if the Higgs is excluded by the end of 2011 there won't be much data in other areas as the LHC shuts down for the next year.

43. **Peter Woit**
July 23, 2011

anonomous,

The LHC will run not just through the end of this year, but through the end of next year. The Higgs should keep them busy, either conclusively ruling it out, or studying a real signal.

If the Higgs is ruled out at all masses, there will be a lot of attention on the implications of this, and the question of where the LHC can look that might provide a clue as to what is going on. Maybe different kinds of triggers and searches will get attention, but I'd guess that this would wait until after the machine turns on again at higher energy in late 2014/early 2015.

44. **Garrett**
July 23, 2011

"One thing I'm curious about is whether Gross and others who were taking bets on SUSY are still willing to take such bets. I suspect they're not yet willing to pay off, but they're not about to take any new bets…"

At the last FQXi conference, Frank Wilczek expressed a lot of confidence in SUSY. During the questions after his talk I suggested we place a bet, and he took me up on it. (He's a good guy, and I respect him a great deal, but we differ in our SUSY confidence.) I figured it would be a typical $1 physicist bet, but he suggested $1K and a six year deadline. I agreed. So now we have a public bet that superparticles will or won't be seen before July 8, 2015. Max Tegmark is our referee.

There has to be a better way to make money than betting against nobel laureates, and I may lose, but it's certainly fun.

45. **piscator**
July 24, 2011

LMMI:

IMO we are a lot closer to the point where the MSSM is ruled out, but not any closer – in fact perhaps further – from the point where low-energy susy is ruled out.

For the MSSM, the required fine-tuning in the Higgs mass looked contrived before the LHC turn on and looks even more contrived now. If the hints of broad excesses in

120-150 GeV in the Higgs search turn out to be true, then things will be even trickier, as to further raise the Higgs mass in the MSSM requires either very heavy sparticles or large trilinear terms, and this all looks terribly ugly and fine-tuned.

However, for supersymmetry in general, this does not hold. From a top down perspective there is diddly squat reason to think that the only new particles nature can have is one Higgs doublet. In models beyond the MSSM it is not hard to raise the Higgs mass and so a Higgs of (say) 135 GeV is not a good reason to reject low energy supersymmetry per se.

The way I see it, the hierarchy problem is real and there is something that solves it. The only two good candidates for this are susy and technicolour (or its modern Randall-Sundrum avatar). If a light Higgs exists – and the EPS results give preliminary hints that it does – then I regard weakly coupled solutions to the hierarchy problem (like susy) as preferred, if not definitively, to strongly coupled solutions like technicolour.

IMO anti-susy partisans need an intelligible opinion on the hierarchy problem – the Higgs mass *is* quadratically divergent in the Standard Model. You either think this isn't a problem (and if so why not?) or if you do think this is a problem, then you must describe how you will solve it. If you think susy is bad, study the alternatives….

46. **Unknown**
July 24, 2011

Dear Peter,

You complain about the doubling of degrees of freedom in SUSY but you fail to realize that multiplying by 2 is not the same as adding 50 new particles. After all, doesn't antiparticles double the number of degrees of freedom? Does that bother you?

Then you say that SUSY QFTs are more complicated. How could this be? They are
as good QFTs as any other but with more symmetry (which means less independent couplings, more predictive power, unexpected cancellations an so on). How could this be more complicated?
If you "don't buy the argument that the MSSM Higgs sector improves the Higgs situation", then I'm afraid is hopeless to argue with you at all.

47. **Peter Woit**
July 24, 2011

Unknown,

This is just ridiculous. Adding SUSY to the SM give you the MSSM (or worse), which has 120+ more parameters than the SM and is vastly more complicated. After 30 years of failure, believing the problem of SUSY breaking can be solved in some simple way that gives a simple, predictive theory is just wishful thinking. With no symmetry breaking, all you have is a theory in violent disagreement with reality, with lots of new symmetries, all of which do nothing but relate degrees of freedom we know about to ones that can't possibly exist.

Piscator,

The Higgs mechanism seems to me to have more serious problems than the hierarchy problem. Problems with the Planck scale are QG problems we really don't understand. Before worrying about whether another scale (e.g. the GUT scale) can be stabilized with respect to the weak scale, one should first have evidence for its existence.

Besides the problem of whether a non-asymptotically free theory like the Higgs really makes sense at high energies, the really serious problem is that the Higgs makes it impossible to ever calculate most of the SM parameters. This is really ugly, unlike the rest of the SM, which is a fantastically powerful and beautiful mathematical structure. SUSY doesn't solve this problem, instead makes it worse.

In any case, first of all the question is whether the Higgs really is there, and it's very exciting that the next few months might see an answer to this question after so many years.

48. **Unknown**
July 24, 2011

I guess I'm losing my time arguing with you, but maybe some readers of this blog will benefit after being exposed to your misconceptions.

"…new symmetries, all of which do nothing but relate degrees of freedom we know about to ones that can't possibly exist." I beg your pardon, maybe you published some proof of the inconsistency of SUSY?

"Adding SUSY to the SM give you the MSSM (or worse), which has 120+ more parameters than the SM and is vastly more complicated."
The trees don't let you see the forest. What you get out of SUSY is the ability of explore experimentally, through the SUSY spectrum, physics at extremely high energies, and it's difficult to imagine how the hell could you get a similar ability in any other theoretical framework.

"After 30 years of failure," 30 years of failure are fine as soon as the first superpartner turns up. Let's talk about failures then.

"The Higgs mechanism seems to me to have more serious problems than the hierarchy problem. Problems with the Planck scale are QG problems we really don't understand." Do you find the see-saw mechanism attractive? If you do, you have the Higgs hierarchy problem exploding in your face.

"Besides the problem of whether a non-asymptotically free theory like the Higgs really makes sense at high energies,…" Next time I hear this often repeated B.S. I'm gonna throw up. You're really concerned about QED then?

"the really serious problem is that the Higgs makes it impossible to ever calculate most of the SM parameters." Excuse me?

"This is really ugly, unlike the rest of the SM, which is a fantastically powerful and beautiful mathematical structure." Yeah, like the flavour sector.

Sometimes one wonders if you're really a particle theorist.

49. **MF**
July 24, 2011

Btw, QED is beautiful.
The SM and gauge theories are not, there is a lot of ugliness that people tend to forget about. Like ghosts, BRST and so on…

And who cares about the Planck scale? The Higgs sector has problems even without looking at such an high scale. EWPT? Little hierarchy problem? On the other hand if we forget about the Higgs boson there is loss of unitarity in W scattering. I don't think i have to go on with such famous old stories (even if it seems people forget them too).

50. **Alex**
July 24, 2011

PW: "…new symmetries, all of which do nothing but relate degrees of freedom we know about to ones that can't possibly exist."

Is spontaneous breaking against the law now?

Unknown: "You're really concerned about QED then?"

Or, more to the point, the U(1) of hypercharge…

Unknown: "Yeah, like the flavour sector."

I think Peter meant exactly that in the comment before when talking about the Higgs taking away our inability to calculate most parameters. That phrasing is maybe a bit obscure. I suppose he hopes for an alternative which tells us all about flavor at the TeV scale where we can observe the mechanisms, as do I. Wouldn't that be nice indeed. Unfortunately, we do not have any hard reason to think that nature is this nice to us , not theoretical nor phenomenological, apart maybe from the hierarchy problem itself, which he however discusses away.

Repeating the slogan "susy has 120 parameters" over and over again is not good style. I'm also not in favor of hyping anything, but throwing wrong statements around is not the way to respond to a hype. A little more nuance is all I would be asking for. There are more adequate ways to criticize the idea of TeV scale supersymmetry than repeating simplistic half-truths like that, there really are. Talk about how gruesome difficult many models of SUSY breaking are, and how msugra is nonsense and why.

51. **Alex**
July 24, 2011

"taking away our inability"

erm, I meant "taking away our ability" of course.

52. **Peter Woit**
July 24, 2011

MF,

Personally I think the ghosts/BRST issue does involve beautiful mathematics. The problem is that we don't completely understand it (which makes it more interesting, and it's why I work on it..). Mathematically, this is about using Lie algebra cohomology to understand fundamental issues in representation theory. The question of exactly how "beautiful" this is does await a fuller understanding.

Going from QED to the SM – Higgs is just going from U(1) to slightly larger Lie groups, so the "beauty" issue doesn't change much. The fact that this requires a more sophisticated way to deal with imposing gauge symmetry may be a feature, not a bug.

53. **Peter Woit**
July 24, 2011

Alex,

The problem of the 120 extra parameters and the problems of models of spontaneous SUSY breaking are functionally the same. I don't see anything wrong with avoiding a long description of the various ugly and complex ways people have found to spontaneously break SUSY without contradicting experiment, and just referring to the bottom line: lots of undetermined parameters. In general, I think it's misleading for anyone to go on about the beautiful physics of their favorite symmetry, when they have to introduce a lot of ugliness to avoid contradicting experiment.

54. **Peter Woit**
July 24, 2011

Unknown,

"…new symmetries, all of which do nothing but relate degrees of freedom we know about to ones that can't possibly exist." I beg your pardon, maybe you published some proof of the inconsistency of SUSY?

You deleted the first part of this sentence "with no symmetry breaking", which is the point. Without SUSY breaking, your symmetry relates each particle to one with the same quantum numbers and the same mass, something that is known not to exist.

"What you get out of SUSY is the ability of explore experimentally, through the SUSY spectrum, physics at extremely high energies" This is just unadulterated hype. So far SUSY has told you zero about physics at the GeV/TeV scale. Conviction that it's going to not only appear, but in a form that tells you about "extremely high energies", is nothing but wishful thinking.

No, I'm not a huge fan of the see-saw mechanism. Introducing yet another higher energy scale as an explanation isn't very convincing. Maybe it's right, who knows, but the bottom line is that we now really don't know anything about where fermion mass matrices come from.

The problem of the SM U(1) being non-asymptotically free can be evaded with GUT unification. The cost of course is adding yet more scalars, so the problem with scalars like the Higgs has to be dealt with somehow.

"Excuse me?" Maybe you've heard that Higgs Yukawa couplings give fermions masses? These are unconstrained in the SM. I suppose the standard ideology about this these days though is that we're supposed to give up, and just bow down to the glory of the multiverse, which picks such couplings out at random.

The flavour sector is a beautiful structure (the Dirac equation coupled to gauge fields) IF you throw out the Higgs couplings.

"Sometimes one wonders if you're really a particle theorist."
Besides being a mathematician, I am a trained particle theorist, although my training (late 70s-early 80s) was in a period when supersymmetry was around, but it had not hardened into a hype-filled ideology. My concern is that the standard training of many theorists over the past 25 years has been within an ideological framework based on some wrong assumptions. The LHC is in the process of blowing up some of the underpinnings of this ideology. The interesting question is whether many people will admit this is what has happened or hold fast to their ideology in the face of contradiction by experiment. I'm afraid that even post 2015-6, when LHC results at the highest

energies are in, SUSY die-hards will be repeating the same mantras, unwilling to give up on the idea, no matter what. You can already see that happening with string theory….

55. **Peter Woit**
July 24, 2011

Garrett,

Thanks for that piece of information. I'm curious whether Wilczek is still willing to take bets on the same odds post this summer's LHC results. If you hear that he is, let me know…

56. **Low Math, Meekly Interacting**
July 24, 2011

Thanks for your perspective, piscator.

57. **Alex**
July 24, 2011

"With no symmetry breaking"

D'oh, one should always go to the primary literature!

I see your point that merely talking about the beauty of supersymmetry misrepresents the difficulty of constructing a realistic low energy susy model. That being said, there may be one that is simple

58. **piscator**
July 24, 2011

Peter,

>>In any case, first of all the question is whether the Higgs really is there, and it's >>very exciting that the next few months might see an answer to this question after >>so many years.

Amen to that.

LMMI,

Cheers, no problem.

59. **Yatima**
July 24, 2011

To misquote a movie villain:

"This bickering is pointless. LHC will provide us with the location of the Higgs mass by the time this year is over. We will then crush the doubters with one swift stroke!"

(Or not)

60. **Low Math, Meekly Interacting**
July 24, 2011

I have to say, it's truly, truly wonderful to start seeing the first hints of theoretical people arguing about…lots of data! Nothing at all against theorists of any kind, but I've felt the field of HEP has suffered long enough without some fresh meat to chew on. As a huge fan of physics, especially that golden era of the 20th century when the SM was born and matured, the idea that we might be on the verge of seeing something utterly new is exciting.

61. **chris**
July 25, 2011

Higgs at ~120GeV and nothing else. looks like i'll win by bet about what LHC is going to find 🙂

62. **DGP**
July 28, 2011

SUSY isn't dead yet but it's certainly sick. I suspect that the experimentalists are going to lose interest in it completely if the LSSP is not found under ~1.2TeV, for one simple reason: the best pointer to new physics we have is the high mass of the top quark. If something isn't found that can explain that then there will be plenty of work for theorists – but not on supersymmetry and string theory (superstrings were originally attractive because they could save supersymmetry from its internal contradictions: that won't be necessary if SUSY is no go).
Searches for supersymmetry will probably continue even if a blank is drawn but really they will be searches for new physics (and a reason for the top quark mass).

I personally wasn't expecting evidence for supersymmetric particles below ~0.9 TeV since I think that there would be some evidence in the form of effects on lower-energy physics which would have already been puzzling us so the current results haven't changed my opinion (that SUSY is unlikely) either way.

The measurements I am looking forward to are the ones of the various coupling "constants" (alphas) at increasing energies. The most reasonable interpretation of the current data is that Unification does not happen. If there isn't some evidence of a tendency for the coupling "constants" to head for a common asymptope by 14 TeV, Grand Unification hypotheses will look far less tenable. As it is, I am amazed by how many people seem to be taking the Unification Energy as a data point.

63. **echo**
July 30, 2011

But even if only a single, SM-like Higgs is found, its dynamics should be pretty interesting. Without SUSY (if it's actually not there) the naturalness problem remains unsolved. And it is quite doubtful that a simple quartic potential put by hand into the lagrangian just for the purpose of breaking the symmetry is the end of the story. More statistics, and eventually more energy, are going to reveal a lot of interesting stuff.

String Theorists Throw SUSY Under the Bus

July 25, 2011
Categories: Favorite Old Posts, Uncategorized

Over the past few days the results of the 2011 LHC run have been revealed at the EPS-HEP 2011 conference in Grenoble, where a press conference today marked the beginning of the next part of the conference, featuring summary talks. For some discussion of these results see for example here, here, here, here and here. The bottom line is much stronger results ruling out supersymmetry, extra dimensions, black holes and other exotica, restriction of the possible mass range of the Higgs to about 114-150 GeV, and a tantalizingly small and not yet statistically significant excess of possible Higgs events in the mass range 120-145 GeV.

The big surprise here is that the experiments have done a fantastic job of getting these analyses of the data done at record speed. Before the LHC turn-on, estimates based on experience at the Tevatron tended to be that it would be 2012 before we saw completed analyses of a significant amount of the 2011 data. A lot of people have been working long hours and going without a summer vacation… The bottom line though is not a surprise, but rather pretty much what many people (including myself) expected. The unconvincing popular theoretical models of the last few decades have finally been confronted with experiment, which is falsifying them, to the extent that they can be falsified. It's an inspiring example of the scientific method working as it should. The remaining mass range for the Higgs is the expected one, and, as expected, this is the hardest place to separate the Higgs from the background. If it's really there, the data collected during the rest of this year should be enough to give a statistically significant signal. So, within a few months we should finally have an answer to the question that has been plaguing the subject for decades: "Higgs or something else?". This is very exciting.

For more than a quarter-century, supersymmetry has been advertised as the most significant prediction of string theory. Back in 1996 Gross and Witten responded to John Horgan's skeptical take on string theory in *The End of Science* with an article in the Wall Street Journal where they claimed:

> There is a high probability that supersymmetry, if it plays the role physicists suspect, will be confirmed in the next decade. The existing accelerators that have a chance of doing so are the proton collider at the Department of Energy's Fermi Lab in Batavia, Ill., and the electron collider at the European Center for Nuclear Research (CERN) in Geneva. Last year's final run at Fermi Lab, during which the top quark was discovered, gave tantalizing hints of supersymmetry. The situation should be clarified when this machine is upgraded in 1999. (A further upgrade, which would cost the Department of Energy about $300 million, should be seriously considered.) As for the CERN electron collider, its energy is being increased by 35% in the next few months. The results could be dramatic, since electron colliders, though their energy is generally much lower than that of proton colliders, are rather thorough and swift in exploring certain phenomena.
>
> If supersymmetry is out of reach of these existing colliders then it is very likely to be discovered at the Large Hadron Collider, which will begin operation at CERN in about a decade…
>
> Wherever it occurs, the confirmation of supersymmetry would open up one of the golden ages of experimental physics. It could provide us with essential insights about the unification of the four major forces; that is, a theory that would describe gravity, the strong nuclear force, the weak atomic force and the electromagnetic force as varying expressions of a single phenomenon. And it would give a big boost to the development of a remarkably rich new theoretical framework known as string theory. For supersymmetry is one of the basic predications of string theory.

The next year Physics Today published Gordon Kane's String Theory is Testable, Even Supertestable, which included a plot showing gluinos and squarks as having expected masses in the range of 200-300 GeV (the latest results rule them out in typical SUSY models up to about 1000 GeV).

Today, the most prominent active string theory bloggers have blog entries reacting to the weekend's news. Clifford Johnson has Living in Interesting Times, where he writes:

> One of those hoped for stories is called Supersymmetry, which would imply the existence of several more particles besides just the Higgs. Now, the cool thing is that the simplest models of supersymmetry could be in danger as well if we do not see something in the coming several months. Wouldn't it be interesting if both the Standard Model Higgs and the simplest models of Supersymmetry were ruled out? (I'm not saying that they are – it's all to soon to tell – but it is a possible outcome.)

When the LHC turned on, Lubos Motl was blogging about Why supersymmetry should be seen at the Large Hadron Collider, giving the probability of the LHC seeing SUSY as "90% or higher". After the results of the last few days, he's done a 180 degree turn, with a new blog entry attacking phenomenologists and arguing that the LHC results just show that HEP theorists should be doing string theory, not phenomenology:

> No hep-th theorist has ever claimed or boasted that the bulk of his work had too much in common with the data produced by the next-generation collider so of course, the hep-th work isn't really affected by the "null" results from the LHC. Many theorists and many string theorists – but not all – would feel more excited if the LHC were generating totally new phenomena and their phenomenological friends would be really thrilled. However, it's still true that the theorists don't care as much as the phenomenologists do.
>
> What I really want to say is that most of the phenomenological work has been a waste of human resources and time. Instead of producing 1,000 models that could be relevant for the sub-TeV observations, those people could have just waited for a few years and let Nature speak. And it seems that Nature has spoken – and it may still speak in an ever clearer language – and so far, the answer is that the right model of these phenomena is called the Standard Model…
>
> So I hope that instead of shifting the energy scales from 200 GeV to 1,400 GeV and continuing in random guessing, many phenomenologists will buy some string theory textbooks and begin to think about the Universe at a slightly deeper and less sensationalist level.

Update: Lubos clarifies here: he's only throwing some SUSY models under the bus, not all of them. It's no longer above 90%, but he still thinks there's a 50% chance that the LHC will see supersymmetry. And all the bogus claims for "tests of string theory" are my fault, since I created a hostile environment for string theorists where they felt they had to do this kind of thing.

Update: The MasterCode Project has moved up to higher masses its "best-fit" points for SUSY now that 2011 LHC results have ruled out previous "best-fit" points, see here. Now the "best-fit" for SUSY is not even a very good fit… Tommaso Dorigo explains and comments here.

Update: In his talk concluding the conference, David Gross throws just the CMSSM under the bus, saying it is now "on life support". He argues though that this is just one possible SUSY model, and one can't conclude much from the death of the CMSSM. Much of his talk was an advertisement for N=4 SSYM and AdS/CFT. He's sticking to his prediction of last year that SUSY particles will appear within 10 years, no word on when he'll give up if the LHC continues to see nothing. Near the bottom of his list of predictions was "string theory will start to be a THEORY, with predictions", which drew laughter from the crowd. He acknowledged that it was next to last on a list ordered by plausibility, but insisted "Some day…"

Update: Pauline Gagnon reports on what theorists are up to in response to all this:

> This summer, I had the opportunity to spend a week at a theory workshop. Being the only experimentalist there, I spent plenty of time discussing what was going on in their camp. Clearly, they are not sitting idle while we are frantically searching our recently collected data for signs of new physics or the Higgs boson. On the contrary, many of them were already hard at work trying to find excuses for supersymmetry and reasons why it has not shown up yet as anticipated.

At Cosmic Variance John Conway summarizes the situation, and draws flak from Matt Strassler, who explains more here, and has a new paper out about how to evade the LHC results:

> This is a key job of particle theorists; make sure **all** the ground gets covered by the experimentalists before they give up and move on!

Given the huge number of possibilities and parameters for how to implement SUSY, insisting that all of it gets tested by experiment will ensure that SUSY phenomenology will be with us for a very long time. Ideas like SUSY can never be completely ruled out, they can just be made so unlikely that they're not worth people's time anymore, and the argument over how much more unlikely the LHC results make SUSY will continue…

Comments

1. **chris bolger**
   July 25, 2011

   If supersymmetry is not found, what is the best explanation of the running of the coupling constants meeting precisely at the GUT level, as found in the early 90's, in its absense?

2. **Peter Woit**
   July 25, 2011

   Chris,

   They don't actually meet "precisely", although the agreement is better than in the non-SUSY SM. The relative strengths of the SM couplings is just something we fundamentally don't understand. GUT explanations haven't worked out well, with their generic observable prediction (proton decay) not being observed. Note that to believe the SUSY GUT calculation of meeting of couplings, you have to believe that there is no physics affecting their running, from 1 TeV scale up to the GUT scale (the "desert hypothesis"). Most physicists have always found this difficult to accept.

3. **John Baez**
   July 25, 2011

   I've never believed supersymmetry was true in our universe. Earlier this spring I won a case of scotch from the particle physicist Dave Ring, on an old bet about whether the LHC would see "strong evidence for supersymmetry" after one year of operation.

   A true gentleman, he sent me an email saying "I believe I owe you a case of scotch. I knew they'd go over schedule at the LHC, but not by this much!" And he even got me 18-year-old Laphroaig.

   I would feel guilty if I won on a technicality. So, I'm glad they're not seeing evidence of supersymmetry.

4. **Eric**
   July 25, 2011

   Might it be pointed out that the remaining low-energy range (115-135 GeV) allowed is precisely where the Higgs should be if TeV-scale SUSY exists?

   Furthermore, the energy range above 450 GeV is still allowed, which is where the Higgs should be if there turns out to be a heavy fourth generation.

5. **neo**
   July 25, 2011

   I am confused. I read elsewhere that at Higgs found between 115-140 GeV could be a SM Higgs or a SUSY Higgs. Why do you think the current range is ruling out SUSY?

6. **Alex**
   July 25, 2011

   Dang! I should have placed bets with Laphroaig. But wait! there is still time!
   Who is willing to bet a bottle of Laphroaig against the idea that there are particles that look like color-charged superpartners between 1200 and 1500 GeV? 🙂

   neo,

   Such a light Higgs is not only compatible with the SUSY, it is almost a necessity to have a Higgs in this region unless you add further stuff like a fourth generation, or make the superpartners very very heavy, to pull up the higgs using large loop corrections. Many models of SUSY being ruled out is simply for the lack of a signal in the usual SUSY discovery channels, like jets or leptons with missing energy (For R-Parity conserving SUSY), or corresponding observables for R-Parity violating SUSY.

   Eric,
   "which is where the Higgs should be if there turns out to be a heavy fourth generation."
   Not too long ago, a standard fourth generation could maybe barely hide there, the trouble is that this would not only generically predict a heavy higgs, but also a production cross section that is a factor 5-9 higher than the SM one, because all of those new particles contribute to the coupling of gluons to the higgs. The ways to circumvent that is 1) to have a fourth generation and a fourth antigeneration, which would not have to talk to the higgs to be massive. But that's not really a proper fourth generation, or 2) Have the higgs decay invisibly, which is of course not very compelling if only done for that reason.

   chris bolger,

   Making the couplings kind of meet without SUSY is possible by adding further fields, like for example a handful of scalar doublets. But then if you really postulate some kind of GUT at the resulting unification scale, you have to engineer away proton decay, and the hierarchy problem really shows up explicitely in your theory then because you have introduced explicitely a very high scale which turns up in the radiative corrections to the Higgs potential.

7. **Peter Woit**
   July 25, 2011

   neo,

   The Higgs results don't rule out SUSY. What is causing trouble for SUSY is separate searches for strongly interacting superpartners which have turned up nothing.

8. **DB**
July 25, 2011

“a tantalizingly small and not yet statistically significant excess of possible Higgs events in the mass range 120-145 GeV.”

In the hands of idiot journalists, this becomes
“Scientists in the US announced they may have detected the elusive and potentially universe-changing Higgs boson particle yesterday, just two days after rivals in Switzerland signalled that they, too, have caught their first sight of it. “

The Independent is considered to be a quality UK newspaper.

9. **Peter Woit**
July 25, 2011

DB,

As usual, in this case it’s not only journalists who are to blame, see

http://blogs.nature.com/news/2011/07/hep2011_a_whiff_of_higgs_at_th.html

10. **Peter Woit**
July 25, 2011

For a more problematic journalistic take on the situation, see

http://www.newscientist.com/article/dn20729-should-we-worry-about-what-the-lhc-is-not-finding.html

where we learn that:

“there is no sign yet of gravitons – particles that transmit gravity and are essential for a quantum theory of the force – below an energy of 2 TeV”

11. **Alex**
July 25, 2011

“For a more problematic journalistic take on the situation, see”

Apart from giving Supersymmetry, which you dislike, a prominent position and attributing it a tiny bit more than it can actually do for us, I thought it’s not that terrible an article. The 2 TeV Graviton, that obviously came out of a mingled statement about Randall Sundrum I suppose. I’ve seen much worse in official LHC public relations, like the whole recreating the big bang business…

12. **lun**
July 25, 2011

I think one needs to be careful about confusing “string theorists” with famous bloggers who write on string theory and more or less accepted spokespeople of the string theory community.

Some string theorists have “trown supersymmetry under the bus” well before the LHC gave them a reason to do so:
http://arxiv.org/abs/0804.4718
http://arxiv.org/abs/hep-ph/0104274
while these papers were ignored by bloggers and the scientific press, this does not necessarily make them invalid. This, in fact, illustrates one of the main problems of the way string research is done: The extreme faddishness of the field.

13. **David Bailey**
July 25, 2011

Given the colossal pressure on CERN to come up with some results, can we be 100% certain that they would not fudge the evidence for the Higgs?

14. **Peter Woit**
July 25, 2011

David,

It’s not even clear which way you would want to fudge this. If they find the Higgs, they have an important discovery to crow about. If they rule out the Higgs, that’s an equally important (and much more interesting…) discovery.

Remember that there are two major independent experiments looking for the Higgs. Each one of them is under a lot of pressure to not only make a discovery, but get it right. If they don’t get it right, their competition is sure to take advantage of this. Also remember that there are 3000+ physicists on each experiment. If some subset of them tried to fake the most important result they were looking for, their colleagues would not stand for it. Getting 3000+ physicists to agree to anything is nearly impossible, much less getting them to agree to a faked result.

15. **Alex**
July 25, 2011

@David Bailey,
It’s not CERN’s job to analyze any data. They just provide the bang for the buck so to speak. Two collaborations of thousands of people who run the two main Higgs search experiments independently, do that. That does not mean that the people doing the analysis for the collaborations didn’t put some prejudice in these early results about our indirect expectations of a light Higgs, but that will quickly fade away with more statistics. You can be certain that, barring a sheer criminial conspiracy, an eventual Higgs discovery claim will be held under great scrutiny by a large number of people.

16. **Yatima**
July 25, 2011

I sure am glad that Lubos is an outlier. This mindset is appalling, tending towards occultism. A lifetime study of Kabbalistic texts can’t be far away.

17. **anonymous**
July 25, 2011

People have realized that string theorists are out of touch with reality, as evidenced by the near-absence of string theorists in this year's Particle Rumor Mill.
The LHC might soon prove that "phenomenologists" are out of touch with reality as well, as their models get decimated.
How about we simply disband the whole hep enterprise? 30 years ago smart people already knew that particle physics was a dying field.

18. **Bee**
July 26, 2011

I'd agree that "Instead of producing 1,000 models that could be relevant for the sub-TeV observations, those people" SHOULD "have just waited for a few years and let Nature speak." (Funny enough, I've said almost exactly the same in my talks during the last years to explain why I stopped working on models with large extra dimensions 6 years back…) But whether they COULD have waited is a different question. I believe I've commented here several times saying that this trend towards phenomenology seems unreasonable to me because many of the models are very poorly motivated (if motivated at all). And I say that as a phenomenologist myself. So why the paper flood? I guess the reason is simply too many people, too few jobs, pressure to publish and then in the late 90s everybody started yelling 'falsifiability' which did the rest. It doesn't really matter which way you shove scientists, it always has a backlash. However, since that is unlikely to change anytime soon the question is now where will the next bubble be? I actually think we already see it coming, and it will be in cosmology.

19. **Neil Harris**
July 26, 2011

I don't understand why Lubos Motl has to be so rude about Peter Woit, but then I'm southern English.
This quote from Motl is worrying: "No hep-th theorist has ever claimed or boasted that the bulk of his work had too much in common with the data produced by the next-generation collider so of course, the hep-th work isn't really affected by the "null" results from the LHC." It begs the question: what experimental evidence does affect hep-th work?
It cannot have escaped the notice of all physicists that the world seems to be running out of money (next week, in the case of the US federal government). It may be that the CERN LHC is the last particle collider, or that any successor will be a long way into the future. This has implications for experimental and theoretical physicists. There again, if experimental evidence is irrelevant to theorists like Motl, he'll be able to carry on.
As a mere science documentary film-maker I cannot contribute at a technical level, though I was honoured to film an interview with Peter Higgs back in 1995. He's a charming, modest man and strove mightily to explain a difficult subject to a general audience. I am crossing my fingers for his sake that the LHC will resolve some of the theoretical predictions made by him and others getting on for nearly 50 years ago. I know he at least respects experimental evidence.

20. **rhofmann**
July 26, 2011

Like Neil Harris I also would like to thank Peter Woit for his constant efforts in exposing the desolate state of a failed research program in high-energy particle theory in spite of humiliation and aggressive action by some of its followers. It takes a presently rare-to-find strength of character, intelligence, conviction, wit, and integrity to stand as solid as Peter did over the last seven or so years.

21. **chris**
July 26, 2011

i don't quite get it why Motls opinion is still discussed. he is out of the business for several years now and it shows in all his comments.

22. **Arun**
July 26, 2011

…resulting in the Superbus!
http://www.superbusproject.com/

23. **CM Theorist**
July 26, 2011

Firstly, Motls' opinion….I agree…who gives a crap. He's just a typical internet blowhard trying to maintain some reputation of expertise by constantly giving his un-asked-for opinion.

Regarding the coupling constants meeting at the GUT level? My problem with this has always been that one has to be confident in a linear extrapolation of many many many orders of magnitude. This sort of extrapolation almost never works. It is tantalizing…don't get me wrong…but it's completely absurd to take as some sort of evidence for supersymmetry.

25. **Peter Woit**
July 26, 2011

rhofmann,

Thanks, but being witty and staying amused by it all is made very easy by Lubos.

Actually I agree a bit with the point made by him and Bee that the emphasis on "phenomenology" in recent years is not necessarily healthy. The subject needs a good balance between phenomenology and formal theory. The dominance of formal theory by a failed research program, whose proponents refuse to admit this failure, is what has caused the rest of the community to lose patience. The multiverse nonsense and the spectacle of string-theory fanaticism that Lubos is the poster-boy for haven't helped. If you're going to work on ideas that aren't ready for experimental test, you have to be honest with yourself when they aren't working out.

26. **Phenner**
July 26, 2011

It should be pointed out that "phenomenology" is much wider than the caricature being portrayed here. The field involves a lot of SM (especially QCD) predictions, vital for separating new physics from backgrounds at the LHC. All the simulation programs – Pythia, Herwig, Sherpa etc – are written by phenomenologists. Deciding which observables can give the best chance to discover physics (i.e. where to look, what to plot, how to interpret it) is also part of this field. It's true there are a lot of papers, especially recently, which make spurious attempts to explain ~2sigma deviations in terms of fanciful models, but I don't see this as representative.

27. **Yousuf**
July 26, 2011

If SUSY, and by implication Superstring Theory are going down the toilet, then what's the next best theory down the line that needs to be falsified? Technicolor? Loop Quantum Gravity? Etc.?

28. **Peter Woit**
July 26, 2011

Yousuf,

Superstring theory can't really be falsified since it doesn't predict anything. In particular, it doesn't predict SUSY at LHC energies.

The LHC will have nothing to say about LQG. It should have something to say about technicolor, which won't survive if a Standard Model Higgs is found.

So far, the LHC is finding nothing that disagrees with the Standard Model, already falsifying various models of extra dimensions, low energy strings, and much much more. If this continues, ALL models that make predictions about LHC scale physics different than the SM will be falsified.

29. **abbyyorker**
July 26, 2011

Maybe a little too celebratory here. SUSY is an appealing theory for many reasons and I am personally sad that there's no evidence for it. It looks like LHC is decisively showing that the popular versions of SUSY are not correct in their details. But I secretly suspect that those versions were tilted towards those with low energy predictions, to take advantage of the presence of the LHC. So, as many have said, SUSY will never go away because it cannot be disproved, and un-disproved versions will likely be promoted and will sound good to many.
My guess is that people will soon become unable to do high energy physics, because of the expense, unless there is some astonishing breakthrough in the method.

30. **Yousuf**
July 26, 2011

Peter, if even a Standard Model Higgs isn't found amongst all of the noise of the range of energies that they are now looking for at LHC, then is the Higgs dead, or do they continue looking for it at ever higher energy ranges? Also if SM Higgs isn't found, then does Technicolor then automatically get promoted into the Standard Model in its place? I.e. if there's no Higgs then it's Technicolor, or if there is Higgs then there's no Technicolor.

31. **Justin Hilburn**
July 26, 2011

I found this post by Urs Schreiber at the n-category cafe on the difference between local and global supersymmetry to be very enlightening.

32. **KD**
July 26, 2011

Chris:

Is there empirical evidence that "the running coupling constants meet precisely at the GUT level"?

33. **chris**
July 27, 2011

if they meet they meet at the GUT scale, because that's how the GUT scale is defined.

34. **rhofmann**
July 27, 2011

Peter,

I completely agree with you in seeing the phenomenological industry as a necessary consequence of the hyping spear head of "deep" theory. Trying to make a connection to nature of "deep" theoretical concepts certainly was pleasing some of the formalists until it was universally realized how obviously embarrassing this industry became. (The story about black holes at LHC in connection with extra dimensions that developed its own life after being received by broader society, …)

Keep on pushing, Peter. And thank you again.

35. **Peter Woit**
July 27, 2011

Justin,

I think that counts Urs as another string theorist now throwing SUSY under the bus. He does make clear that what is at issue here is space-time SUSY, which is what the LHC can test. There's also world-sheet SUSY , SUSY in the 1+1 d world-sheet of the string, which goes back to the earliest days of SUSY. That's a different issue. He also makes the good point that there's SUSY QM, the 0+1 d case, where a form of SUSY show up in the simple theory of a spinning particle. That's a very important and deep idea, but it's not 4d space-time SUSY, which is what the LHC is looking for.

36. **Peter Woit**
July 27, 2011

abbyyorker,

There are always people willing to swallow hype about untestable ideas. I think they are a minority though among professional scientists, even if some of them get a lot of exposure in the media. If they deal with the LHC ruling out their favorite ideas by changing them to make them untestable, they're not going to have much credibility with their colleagues. Whether the popular media continues to give them prominent attention will be interesting to see.

37. **somebody**
July 27, 2011

Among the physics bloggers, Lubos is probably in the top one or two when it comes to his grasp of the subject matter. No two ways about it. That doesn't mean that his OPINIONS, even about physics, aren't crazy sometimes. What I always find amusing is when people -including him- say there is a 90% (or 50% or 0.001% or whatever) chance of finding SUSY. Either we find it or we don't. Percentage a-priori probablities are emotional nonsense.

I also don't understand what it means when people say the LHC is "ruling out" parameter space for SUSY. Do they mean the soft-breaking parameters of the MSSM? If that is the case, I think it is important to keep in mind that weak-scale SUSY is a much more general thing than our sociologicakl obsession with the minimal supersymmetric extension of the standard model. Weak scale SUSY is a nice idea – MSSM is just the simplest realization of it. Even weak scale SUSY could be wrong, but it is not going to be so easy to rule in/out SUSY without some serious time and hard work, it seems to me.

And finally, as Peter correctly points out, string theory does not make the prediction of weak-scale SUSY. It will be good to find susy somewhere because string theory is ultimately supersymmetric, but there is no reason why it should already be there at minscule energies like the weak scale.

38. **Technicolor**
July 27, 2011

I am also wondering about the technicolor question posted by Yousuf. If the Higgs and SUSY is not found is the only other theory technicolor (which I have heard is a very ugly theory)? What theories get promoted if we find nothing?

39. **manyoso**
July 27, 2011

Technicolor is not the only alternative to Higgs for explaining electroweak symmetry breaking: http://en.wikipedia.org/wiki/Higgsless_model

40. **Dan**
July 27, 2011

Peter, I disagree on technicolor. Recently a lot of composite Higgs models showed how difficult it is to distinguish some of these composite states from a Standard Model elementary Higgs.

41. **Shantanu**
July 27, 2011

so if no supersymmetry is found at LHC accessible energies are all proton decay
models ruled out or can one have proton decay but no supersymmetry?
shantanu

42. **multigoal**
July 27, 2011

Peter
Two questions: 1) What do we mean by SUSY being ruled out?… it's actually CMSSM that is getting ruled out, right?
2) What beyond standard model we can learn from LHC if they find 114-150 GeV Higgs and nothing else?

Multigoal

43. **Neg**
July 28, 2011

PW,
Would the data the LHC is collecting from now to the year's end be enough to either find or r/o higgs in the interesting region of 114-140? And SUSY?

I understand the LHC will power down to save on money. Then restart, again, but it will be another 3-5 years before it reaches design beam collision energy of 14 TEV?

What additional physics is the higher 7/beam 14 TEV is supposed to find over the original 3.5/7Tev?

Any word on when SuperCDMS and the Xenon100 dark matter detection ?

44. **Peter Woit**
July 28, 2011

Shantanu,

Sure, you get proton decay in non-SUSY GUTs. Actually, this is one of the arguments for SUSY: non-SUSY GUTs have lower unification scales, so higher proton decay rates, mostly already ruled out by experiment.

multigoal,

You can't completely rule SUSY out by experiment, since one can always find regions in its huge parameter space that are inaccessible to experiment. You can make it a lot less plausible by showing that the sorts of regions of parameter space intensively studied by theorists as the most likely place for it to be are ruled out. The CMSSM involves a particularly simple choice of parameters, but I don't know that moving away from that simple choice to a random generic one changes the conclusion (the LHC results would still rule it out). Expect to see lots of frantic back-pedaling by SUSY theorists over the coming days and months, saying that the analyses they published pre-LHC are now to be ignored, instead you should pay attention to their latest effort to find some SUSY models that aren't ruled out by the LHC.

The Higgs is the most dubious part of the SM, best bet for falsifying the SM is to either rule it out, or observe it and see that it behaves differently than expected. If the SM Higgs works perfectly, it may be possible there is no observable violation of the SM at LHC energies.

Neg.

I suspect this year's data may be enough to see the Higgs if it is there. If not, the 2012 data should do it. The exclusion of more and more SUSY models should continue as more analyses are done, but I don't think you'll see another big jump in energy scale of SUSY exclusions until the machine energy is raised. They're shutting down the machine in 2013/4 not to save money, but to fix the magnet interconnections. This is a huge job, they're a lot of them. It is supposed to come back on early 2015, presumably mid-late 2015 will see first higher energy results.

45. **Leonard Lerner**
July 28, 2011

I do not understand whar all this Higgs excitement is about. Most of the excess at 120-130 is driven by the WW channel, while the othetr channels show nothing extraordinaty in this range. Its a differential signal in all channels that would indicate a Higgs, an integral over the channels, where most of the excess comes from one of them is more likely a background error

46. **DGP**
July 28, 2011

While I might agree with "Somebody" that Lubos Motl is still reasonably on the ball as far as physics is concerned (without giving support to his fanaticism about strings and supersymmetry or endorsing his view that worries about the validity of renormalisation schemes are evidence of a weak mind), I observe that the physics postings in his blog now get very few comments compared to the global warming denial and general right-wing politics ones. It wasn't surprising that he has been accused of being a holocaust denier since he seems to have adopted most of the other baggage of the unsavoury wing of European right-wing politics. It looks like most physicists have given him up.

Does anyone know how he is funded now? I assumed he had taken an academic appointment in his native Czech Republic but that doesn't seem to be the case.

His view of phenomenologists is on a par with his other prejudices. One would hardly gather from his diatribe that HEP experiments could not proceed without good hands-dirty theoreticians to help design the experiments and compute the backgrounds. I have said before that I am awed by the difficulty of the background subtractions in modern experiments.

47. **DB**
July 28, 2011

@Leonard.
It's pretty straightforward. It's just competitive human nature. The Tevatron, about to be shut down, is engaged in the same sort of "I think I see a hint of something there" that LEP2 was up to just before they were shut down (to make way for the LHC). In response, the LHC has uncovered "hints" of their own.
The competition between American and European accelerator communities has been the very lifeblood of particle physics since the field's inception and is a very healthy thing. It's a great pity that the US will have effectively exited experimental particle physics once the Tevatron shuts down. Who's going to keep those pampered fois gras munching Europeans on their toes now? (I jest, I jest)
Unfortunately, naive, gullible journalists with little understanding of the field's history can't see this for what it is. A harmless outbreak of I-wanna-be-first-itis.

48. **Henry**
July 28, 2011

CMMSM or CMSSM?

49. **Peter Woit**
July 28, 2011

Henry,

Thanks, fixed. It's Constrained Minimal Supersymmetric Standard Model.

50. **Neg**
July 28, 2011

"I suspect this year's data may be enough to see the Higgs if it is there. "

About when should the results for the end of 2011 Higgs/SUSY LHC results be available? Dec 2011 or Jan 2012?
I'll mark it in my calendar.

51. **Peter Woit**
July 28, 2011

Neg,

The normal schedule would be to release results at one of the so-called "Winter Conferences" in early 2012. In this case though, if one or both of the experiments has a statistically significant Higgs signal, I find it hard to believe they'll keep it under wraps waiting for an appropriate conference date. Maybe someone will post the news to a blog…

52. **mtarifi**
July 28, 2011

Hello Peter. Just to make sure I understand: if "somehow" we can prove that super-symmetry is false, does this rule out String Theory?

53. **Peter Woit**
July 28, 2011

mtarifi,

You can't prove that SUSY is false, all you can do is show that certain versions of it that have been advertised as solving certain problems disagree with experiment. Similarly, you can't rule out string theory, it's compatible with just about anything. You can however, like SUSY, show that certain heavily advertised versions of string theory are falsified by experiment, and that's what's happening. Versions of string theory which have SUSY discoverable at LHC energies have always been the been string theorist's best bet for a version that has some observable consequences.

54. **Matt Strassler**
July 28, 2011

Dear Peter,

It isn't really appropriate to suggest that collider theorists are now backpedaling, and looking around for supersymmetric models that would evade current searches at the LHC, in some desperate effort to save supersymmetry. Many of us have been saying for a long time that the LHC experiments' reliance on a missing-energy-based search strategy for supersymmetry (and supersymmetry-like models) would lead to large classes of very reasonable models being initially undetectable. (There are papers going back at least to the 1990s and probably earlier.) Many of us are also on record since the 1990s saying that it would take many years for LHC data to convincingly disfavor supersymmetry.

The current news from the LHC is neither a disaster for supersymmetry, nor a shock to those who like supersymmetry, nor forcing theorists to backpedal. In fact, rather than backpedaling, what many theorists are actually doing is pulling out old work they did years ago, knowing this situation was likely, and making their old results more precise.

Just as an example, look at a 1999 paper by collider theorists Konstantin Matchev and Scott Thomas, on gauge mediated supersymmetry with decays of the next-to-lightest superpartner to a Z or a Higgs plus a gravitino. This OLD class of models, which has a large parameter space, would not easily be observed with the strategies shown at the EPS conference last week — the missing energy signature is simply too small. And this is just one of many examples.

best regards,

Matt Strassler

55. **Peter Woit**
July 28, 2011

Hi Matt,

Thanks for the comments and interesting added details about this. To an outsider, it certainly seemed that pre-LHC, the kind of signals that are now ruled out were ones that were being promoted as typical expectations. The idea that it was going to take many years to see if SUSY was there as expected wasn't something I remember seeing advertised. Instead, the typical kind of thing I remember hearing was Arkani-Hamed's remarks at Strings 2005:

"If weak scale supersymmetry is right, then we will know by spring 2008 [e.g. a few months after expected start of LHC physics]. I think this is really a very sharp statement."

From context, he was talking about roughly the sort of integrated luminosity now available. It's true he was expecting an extra factor of two in energy, and 1-2 TeV mass particles, so he could be right if the gluino is 1.5 TeV. He definitely wasn't saying anything though about it taking years to find a hard-to-see signal.

56. **Neg**
July 28, 2011

"The normal schedule would be to release results at one of the so-called "Winter Conferences" in early 2012. In this case though, if one or both of the experiments has a statistically significant Higgs signal, I find it hard to believe they'll keep it under wraps waiting for an appropriate conference date. Maybe someone will post the news to a blog…"

Based on LHC current luminosity, would the data in the Jan 2012 LHC would be able to either provide evidence (i.e 2-sigma) or rule out in the more interesting "Higgs events in the mass range 120-145 GeV"?

57. **Peter Woit**
July 28, 2011

Matt,

One more comment: pre-LHC I remember often hearing that the Higgs would be hard, SUSY much easier. Now we're almost at the point of seeing a Higgs or ruling it out…

Neg,

No one is sure how well the LHC will do the rest of the year, but typical estimates are that it will produce a factor of 3-5 more data than analyzed at this latest conference (and there should be further refinements and improvements in the analysis). By some measures, the hint of a Higgs signal already seen is already getting to be around 2 sigma, it doesn't seem unreasonable to expect a 3 sigma or more signal (depends on mass, much harder at lower masses).

58. **Peter Woit**
July 28, 2011

The Higgs Hunting 2011 conference is now going on, see this presentation

http://indico2.lal.in2p3.fr/indico/getFile.py/access?contribId=25&sessionId=10&resId=0&materialId=slides&confId=1507

for details on prospects for the near future and 2012. By my reading, if there's a 140 GeV Higgs, both CMS and ATLAS expect to see a 5 sigma signal (if they get 5 inverse femtobarns) by the end of the year.

59. **Thomas Larsson**
July 28, 2011

It might be sobering to recall some statements from Frank Wilczek's Future Summary from a decade ago, http://arxiv.org/abs/hep-ph/0101187 :

5.1. Small Effects Among Known Particles
[…] The modern experimental limits on deviations from the Standard Model in each of these processes puts very significant pressure on the supersymmetric parameter space already [i.e. 10 years ago].

5.2. Proton Decay
[…] but it will not be easy to reconcile limits tau_proton > 10^34 years with straightforward models.

5.5. Produce the New Particles!
Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, **there must be several accessible to the LHC.**

60. **Neg**

July 28, 2011

http://indico2.lal.in2p3.fr/indico/getFile.py/access?contribId=25&sessionId=10&resId=0&materialId=slides&confId=1507
page 9

I see that if the Higgs does NOT exist, then the 5 inverse femtobarns is enough data to exclude it even in the low-mass range. So apparently by Q1 2012, if the LHC collects 5 inverse femtobarns as expected, if the Higgs does NOT exist, the LHC 5 inverse femtobarns would be enough to exclude it over the 115-150 Gev range.

Is that a correct reading of page 9?

Do you think that the LHC with 5+ inverse femtobarns excluding the Higgs, (if it doesn't exist) even in the low mass range, would be like the Michelson–Morley experiment null result on the luminous aether?

61. **Peter Woit**
July 28, 2011

Neg,

That's also my reading of that document. If there is a 5 sigma exclusion of the SM Higgs late this year, that will have a huge impact on the field, maybe the Michelson-Morley null result would be a good analogy. I don't know if this was the case with Michelson-Morley, but here I think most theorists are rooting for the null result, which would be a lot more interesting than an observation of a Higgs with SM behavior.

62. **Neg**
July 28, 2011

There's no mention of technicolor in those slides. How does say 5 or 10 inverse femtobarns (at the end of 2012) data collection have to say about technicolor models?

63. **Peter Woit**
July 28, 2011

Neg,

I haven't seen any results from the LHC yet specifically about technicolor.

64. **Neg**
July 28, 2011

"Given the huge number of possibilities and parameters for how to implement SUSY, insisting that all of it gets tested by experiment will ensure that SUSY phenomenology will be with us for a very long time. Ideas like SUSY can never be completely ruled out, they can just be made so unlikely that they're not worth people's time anymore, and the argument over how much more unlikely the LHC results make SUSY will continue…"

If LHC does NOT find evidence of higgs or technicolor, and no evidence of SUSY, would SUSY still be viable? If the LHC rules out the Higgs, would that also rule out SUSY?

65. **Peter Woit**
July 28, 2011

Neg,

The question of SUSY and the question of electroweak symmetry breaking (Higg or no Higgs? Technicolor?) are pretty much independent questions.

As far as electroweak symmetry breaking goes, SUSY and the SM aren't very different. They both have electroweak breaking via a Higgs, only difference is that in the SUSY case you need at least two Higgs fields, unlike the SM, where you can get away with just one. If a Higgs is found, one big question will be whether it behaves like the SM Higgs, or like one of the two minimal supersymmetry Higgses.

66. **mtarifi**
July 28, 2011

Thank you, Peter, for taking the time to respond to my comment.

67. **Neg**
July 28, 2011

"As far as electroweak symmetry breaking goes, SUSY and the SM aren't very different. They both have electroweak breaking via a Higgs, only difference is that in the SUSY case you need at least two Higgs fields, unlike the SM, where you can get away with just one. If a Higgs is found, one big question will be whether it behaves like the SM Higgs, or like one of the two minimal supersymmetry Higgses."

But if come Jan 2012, the LHC rules out the higgs, it would also rule out two minimal supersymmetry Higgses. If it doesn't even find a single Higgs, much less 2. Or to put it another way, if the LHC rules out electroweak breaking via a Higgs, wouldn't it also falsify both the SM single higgs field, and the SUSY 2 Higgs fields at the same time?

thanks

68. **Leonard Lerner**
July 28, 2011

Thanks DB, its good to see someone agrees with me. I absolutely discount these claims of a 3sig signal already been observed. This is very misleading because it suggest theres a 95% chance we have seen the Higgs. In reality there data more conclusively excludes the Higgs than vice versa. Why? Because these combined channle statistics make no sense in light of what the LHC has been seeing.

Take a look at the way the WW background behaves over the energy spectrum. Our SM expectation (this is loose becuase a whole pile of assumtpions are needed to related the SM predictions to what ATLAS actually SHOULD see) has about a 2sig deviation from what ATLAS actually is seeing over the entire 100-170GeV energy range. Thats not suprising, because of the W mass the branching ratio is very low there. Yet almost the entire of the present 3sig from the Higgs comes from these handful of events.

In this light we really have to look at the three main channels separately. Lets list the events as: expected background, expected background + SM Higgs, observed. I will sum events over the expected Higgs width in each channel (you can see the width in the ATLAS histograms). We have

In the WW channel a strong signal for a 150GeV Higgs: 43back/64 back+H/64 observed. So the data is spot on with a SM Higgs, at a 3sig CL. BUT caution, over the rest of the WW spectrum 20 events are expected versus 29 observed, a 2sig devitation, and also positive.

In the gamma_gamma channel for a 150GeV Higgs: 31oback/320back+H/380 expected. So we would have expected almost a 4sig Higgs signal, but got almost nothing. The Higgs is fairly narrow in this channel (only about 5 GeV, see ATLAS plot). So it makes sense to separate the spectrum. If we repeat the analysis at 130GeV, we have 310/340/370, that is 2sig expected vs 1 sig observed.

In the H-bb channel at 130 GeV: 700/700/820. So a 0sig deviation vs 4sig expected. (I neglect the bb via ZH since its muich smaller than via WH)

I think the data speak more clearly for no Higgs than anything else, I would be glad if someone can show where the above is wrong.

From the ATLAS presentation, almost all luminosity came in the last month. So in 3 months we will have 4 times the integrated luminosity, and so all the sigmas above will be multiplied by 2, and if the above trnd continues, this will exclude the Higgs at something like 5sig.

69. **Leonard Lerner**
July 29, 2011

Im sorry for the spelling mistakes above. I should have checked it, I had too little time.

70. **andhor thjorjend**
July 29, 2011

When you refer to “black holes” as “exotica”, are you suggesting that black holes in general don’t exist? I had thought black holes’ existence was accepted as deriving from general relativity. Is this incorrect?

71. **Einstein's Bastard Son**
July 29, 2011

andhor thjorjend,
He’s referring to hypothetical micro black holes that are supposedly produced in high energy particle collisions, not to the astrophysical black holes of general relativity.

72. **Martin**
July 30, 2011

> And all the bogus claims for “tests of string theory” are my fault, since I created a hostile environment for string theorists where they felt they had to do this kind of thing.

So now it is official. Peter, you’re to blame for all these “string theory is testable” claims. You’ve been really mean to these guys! I hope your feeling sorry for poor Lubos and his pals.

73. **William Nelson**
August 3, 2011

One of the arguments string theorists have made over the decades is that string theory is the “only game in town” when it comes to unification. Certainly it would seem to have been the most *interesting* game, given that other approaches have less mathematical interest and have also not had support from experimental data. Do you think these new findings (or lack thereof) change this situation at all? In other words, do the new findings provide a compelling reason for a would-be high energy theorist to work on anything *besides* string theory?

News From Simons Center

July 28, 2011
Categories: Uncategorized

The Simons Center for Geometry and Physics at Stony Brook has a new web-site, and this week their annual summer workshop got underway, talks available in very high quality video here. Luca Mazzucato, a postdoc there, has started putting together an Outreach section of the web-site, which now includes some wonderful interviews with various theorists, often covering topics well-known on this blog. The last of the interviews looks the most intriguing, it promises "the formula of love". Unfortunately, when you try and get access to this intriguing formula, for now you find that it is password-protected…

I'll be spending much of the next two weeks on vacation in Scotland. Blogging may be light to non-existent.

Comments

1. **Fred Tucker**
   July 30, 2011

   There's a new bloggingheads.tv episode on String Theory. Perhaps you should watch it while unwinding after an aggressive day hiking in the rain-swept Scottish highlands?

2. **Peter Woit**
   July 30, 2011

   Thanks Fred,

   The weather in Edinburgh is unusually sunny, warm and pleasant. Noticed the Bloggingheads thing a little while ago. Both John Horgan and George Musser are well-informed on the string theory controversy, with John a skeptic and George much more pro-string theory. Worth watching if you want an introduction to the controversy, probably nothing much new if you've been reading this blog….

   August 13, 2011

   Shantanu,

   I don't have anything really new to say about that. Lee Smolin's article back in 2003

   http://arxiv.org/abs/hep-th/0303185

   seems to me to have done much the same thing, quite a bit more thoroughly, and I don't see that much has changed since then.

This Week’s Hype

August 5, 2011
Categories: Multiverse Mania, This Week's Hype

I noticed today that BBC News has a story headlined ‘Multiverse’ theory suggested by microwave background that assures us that:

> The idea that other universes – as well as our own – lie within “bubbles” of space and time has received a boost.

After taking a look at the PRL and PRD papers that are behind this, it’s clear that a more accurate title for the story would have been “‘Multiverse’ theory suggested by microwave background – NOT”. As usual, the source of the problem here is a misleading university press release, one from University College London entitled First observational test of the ‘multiverse’. Somehow the press release neglected to mention something one might think was an important detail, the fact that this “First observational test” had a null result.

It’s well-known that one can find Stephen Hawking’s initials, and just about any other pattern one can think of somewhere in the CMB data. The authors of the PRL and PRD papers first put out preprints last December (see here and here). In these preprints they essentially claimed to have found four specific features in the CMB where the hypothesis that they were due to bubble collisions was statistically preferred. A guest post by Matthew Johnson at Cosmic Variance explained more about the preprints. I didn’t understand their statistical measure, so asked about it in the comment section, where Matthew explained that, by more conventional measure, the statistical significance was “near 3 sigma“.

It turns out that the PRL and PRD papers differ significantly from the preprint versions. In the acknowledgements section of the PRD paper we read that:

> A preprint version of this paper presented only evidence ratios confined to patches. We thank an anonymous referee who encouraged us to develop this algorithm into a full-sky formalism.

and the result of the new analysis asked for by the referee is summarized in the conclusion of the paper:

> The posterior evaluated using the WMAP 7-year data is maximized at $N_s = 0$, and constrains $N_s < 1.6$ at 68% confidence. We therefore conclude that this data set does not favor the bubble collision hypothesis for any value of N_s. In light of this null detection, comparing with the simulated bubble collisions...

So, the bottom line is that they see nothing, but a press release has been issued about how wonderful it is that they have looked for evidence of a Multiverse, without mentioning that they found nothing. As one would expect, this kind of behavior leads to BBC stories about how the Multiverse has “received a boost”, exactly the opposite of what the scientific evidence shows.

Update: The FQXI web-site has an article about this. In it, the authors seem far more interested in promoting their PRL paper as “first test of the multiverse” than in acknowledging that a referee made them do a better test of the idea and they got a null result. There’s no mention of the null result in the article.

Update: News stories based on this keep on coming. The latest: Proof of a multiverse discovered?

   August 5, 2011

   After following your blog for the last several months, I think it will soon be time for a new book, Peter (I read the first one). 2012, when the Higgs and other “predictions” have been ruled out would be a good timing for an update on the state of theoretical physics. I’d buy that book. You working on it?

2. **neo**
   August 5, 2011

   University press releases are always suspect If my institution is any example, such offices are paid to make the big splash, putting them one step below the tabloids.

3. **neo**
   August 5, 2011

   That would be above the tabloids. I think.

4. **Bee**
   August 6, 2011

   I also wrote about the Feeney et al paper here.

5. **Peter Woit**
   August 6, 2011

   Daniel,

   No plans for a new book. So far, the situation described in the old one hasn’t much changed (except that string theory has become a lot less popular). I hope new physics worth writing a book about comes out of the LHC, but if so there likely will be many people doing a better job than me of writing such a book.

6. **Giotis**
   August 6, 2011

   “…exactly the opposite of what the scientific evidence shows.”

   Scientific evidence?? Peter until now your mantra was that the multiverse hypothesis is pseudo science because it can’t be tested; now you are saying that it can? Then surely is not pseudo science…

7. **Davide Castelvecchi**
   August 6, 2011

   Peter:

I agree that over-hyped press releases are a big problem, compounded by the fact that certain web sites aggregate press releases making them look like they are journalistic reports, as you have pointed out in the past. Do you agree, though, that some universities have more reliable press offices than others? And ultimately, when a supposedly reliable publication covers something, it's that publication's responsibility to see the science (if there is any) through the hype.

8. **kyrilluk**
August 7, 2011

@Giotis: The fact that they tested the idea of the existence of Multiverse is not a proof that this idea is a valid scientific theory. It would have been a valid scientific theory and I'm sure that Peter would have been happy to recognized that he was wrong, if after testing their theory and finding nothing, the scientist would have conceded that their theory had been refuted.
The issue with the Multiverse ideas is that they can't be refuted. We cannot create a test that can disprove such theories. There's always going to be way of saving this theory.

9. **martibal**
August 7, 2011

Peter:
a blog technical question about the pingback
According to wikipedia, a pingback is added to your blog because this other blog on Intelligent Design has quoted your post. But does it require your approval ? (i.e. do you think that ID is an interesting answer to multiverse ?).

10. **John Baez**
August 7, 2011

Someone should start a blog or wiki or weekly column all about university press releases: the good, the bad and the ugly. It might eventually exert some discipline on the people who write those releases, if word got back to them.

11. **Peter Woit**
August 7, 2011

Davide and John,

I suppose the quality of university press offices varies, but the amount of hype they put out depends largely on what researchers are willing to feed them. A lot of these over-hyped press releases are the fault of PRL, which evidently has a policy of encouraging press releases when they publish papers. I find it hard to believe that many university press offices are issuing press releases over the objections of the researchers involved, or without letting them see the text of the release and vet it before it goes out. Few faculty that I know would tolerate their institution issuing without their approval a press release that they felt misrepresented their research.

If you look at the collected "This Week's Hype" postings about university press releases I think there's a pattern. They're mostly about how someone at the university has made progress towards solving the problem of some well-known speculative theory being untestable. There's every reason to believe that the researchers themselves think they have done this, and are on-board with the idea of a press release promoting their work. These press releases are often carefully worded with crucial caveats placed so as to be technically accurate, but highly misleading in that they don't mention problems with the claims being made. When various news sources pick them up, it's not surprising they often take them at face value, are successfully misled, and miss the significance of the caveats. Good news organizations aren't fooled, do their own checking, and then decide to ignore the misleading press release, weaker ones are fooled.

You can blame the news organizations for getting fooled, or the press offices for spreading hype about topics they don't really understand, but I think the most significant blame should go to the researchers themselves, who are either misrepresenting their own research or standing by and letting their employers do so.

12. **Peter Woit**
August 7, 2011

martibal,

pingbacks appear here automatically, without needing to be approved by me. If they're spam, or from someone trying to introduce links to off-topic material here, I delete them when I get a chance. If they are legitimate postings of some kind that happen to refer to something here, I leave them, no matter what I think of the posting.

I happen to think that ID is worthless pseudo-science, and also that arguing with people over anything related to religion is a waste of my time and energy. One of the worst aspects of multiverse pseudo-science is that it delegitimizes real science, the best tool available for fighting irrationality. I'm glad that some people are willing to spend time making the argument against ID, mystified that some of them think it's a good idea to sign on to multiverse pseudo-science as part of this argument. This seems to me ultimately self-destructive behavior. You can go ahead and say that the string theory anthropic multiverse deals with the argument from design for the existence of a deity, but you're then stuck without a legitimate answer when IDers point out to you that their "science" is as good or better than yours.

13. **Peter Woit**
August 7, 2011

Giotis,

Kyrilluk does a good job of explaining the point: there may very well be a multiverse, but current heavily advertised multiverse theories are often inherently unfalsifiable. If you have a theory compatible with almost everything, you can't ever show it is wrong.

The authors here did a careful job of measuring something and achieved a real scientific result: they looked for evidence in the CMB of effects of certain kinds of bubble collisions and showed that no statistically significant such effects are visible in the WMAP data. Then, for unclear reasons, they allowed a press release to be issued implying that they had figured out how to "test" multiverse theories, but not mentioning that the "test" had failed. Perhaps mentioning that the "test" had led to a null result would have made it necessary to explain that this wasn't the sort of "test" of multiverse theory that one might think it was, since failing the "test" wasn't a problem for the theory.

To be clear: I don't think studying models of the early universe involving bubble collisions is pseudo-science. You can make predictive, scientific such models, although I don't personally think you're ever going to find evidence for them. You're going to get null results like in this work. What is pseudo-science is the use of the multiverse as an excuse for the failure of string theory unification. It is the heavily overhyped and oversold string theory landscape multiverse framework that is inherently unpredictive, untestable and unscientific. If you want to choose specific cosmological models with a multiverse and examine their observational implications, that's not inherently unpredictive, untestable or unscientific. So far though, there's no evidence for such models, so such work is highly speculative and likely to lead to nothing but null results, a good reason not to issue press releases about it.

14. **martibal**

August 8, 2011

Peter: thanks for the explanation.

15. **Emile**
August 8, 2011

A propos of delegitimizing real science: here's a comment that Kenneth Miller, a biologist from Brown U. who makes the case in his book that science and religion are compatible:

"Believers … are right to remind skeptics and agnostics that one of their favored explanations for the nature of our existence involves an element of the imagination as wild as any tale in a sacred book: namely, the existence of countless parallel simultaneous universes with which we can never communicate and whose existence we cannot even test. Such belief also requires an extraordinary level of "faith" and the nonreligious would do well to admit as much."

Hard to argue with the logic. The premise though is that theories "…whose existence we cannot even test." is science…

16. **Kenneth Cohen**
August 8, 2011

When these papers refer to a collision between universes, in what space are the universes thought to be moving and colliding? And with what laws of motion?

17. **Bernhard**
August 9, 2011

Here comments from "Physics":

http://physics.aps.org/synopsis-for/10.1103/PhysRevLett.107.071301

18. **Anon**
August 9, 2011

A bit off topic, for sure, but I am surely not the only one who bemoans the effect the multiverse ideas have on science fiction. True, they were writing multiverse stories long before the current popular mania, but now it is out of control. If I have to read yet another friggin' intellectually lazy multiverse story, I might just go mad.

19. **chris**
August 10, 2011

so much about the obsolescence and inadequacy of the refereeing process…

20. **Anon**
August 12, 2011

Here is another popular article on this same issue:

"Weird! Our Universe May Be a 'Multiverse,' Scientists Say"

http://old.news.yahoo.com/s/livescience/20110812/sc_livescience/weirdouruniversemaybeamultiversescientistssay

The way these people misrepresent their own work is outrageous.

Talks at the KITP

August 12, 2011
Categories: Langlands, Uncategorized

Back now from vacation, and found that there have been quite a few interesting talks at the KITP in Santa Barbara this week which are now available on-line:

- Since the EPS-HEP conference last month, the "First Year of the LHC" program has some interesting results to discuss. Yesterday Matt Reece gave a talk on Assessing SUSY after 1 fb $^{-1}$, on the hot topic of how worried SUSY proponents should be that no sign of SUSY has been found at the LHC so far. He takes the point of view that the failure of direct collider searches to see anything is much less of a problem than the pre-LHC failure of SUSY to show up indirectly in flavor physics or in cosmology. While it's true that SUSY was in trouble pre-LHC, there's psychologically a big difference between indirect effects not showing up, and directly looking for something and finding it's just not there. The discussion with the audience is quite interesting, with some audience members a lot more worried about SUSY. One of them reminded people that SUSY is supposed to solve naturality problems, so relatively light squarks were expected, but now "those models are being screwed." Someone else (Lisa Randall, I think) reacted to Reece's mentioning R-parity violating models as one way to evade the LHC limits with "Is there any good reason to think about R-parity violation?" All in all, the discussion gives a good indication of what prominent theorists are thinking now that the initial results from the LHC are in.

About a year ago on this blog, I had the following exchange with a well-informed phenomenologist on this blog:

> *If there's no sign of supersymmetry in this year's LHC data, how discouraging will this be for those who expect to see supersymmetry at this energy scale?*
>
> In 2010 data? Not discouraging at all. In 2011 data? Fairly discouraging. In 2014 data? Enormously depressing.

The LHC has now gathered as much data as expected for all of 2011, so I think that with the negative results, "fairly discouraged" is where SUSY proponents would have expected to be and are now. "Enormously depressed" is on the agenda for late 2014, early 2015, after the LHC reaches design energy.

- Adam Falkowski, the Jester of Resonaances fame, also gave an interesting talk this week, on Higgsless theories.
- On the mathematical end of things, Ed Frenkel gave a very nice expository "Blackboard Lunch" talk on What do Fermat's Last Theorem and Electro-magnetic Duality Have in Common?, explaining to physicists a bit about the Langlands program and the connection between geometric Langlands and QFT pioneered by Witten and developed by him and others over the past few years. For something more technical with newer ideas about the relationships between TQFT, gauge theory and representation, see David Ben-Zvi's talk on Geometric Character Theory.

Comments

1. **Eric**
   August 12, 2011

   Regarding R-parity violation, I think the important thing that must be kept in mind that this is only introduced to solve the problem of rapid proton decay through dimension-4 operators in the MSSM. However, if the MSSM is extended such that baryon and lepton number conservation result from local gauge symmetries, then R-parity really isn't necessary. So, in such a scenario, there is no problem with R-parity violation, which makes detecting superpartners much more difficult.

2. **Shantanu**
   August 13, 2011

   Peter, are people worried about finding no evidence for extra dimensions (thinks like Randall-Sundrum models etc)?

3. **Peter Woit**
   August 13, 2011

   Shantanu,

   I don't think anyone seriously thought the LHC would find evidence for extra dimensions. This was always just a talking point for the media, and a class of models that some people found interesting to study for various reasons, but not because there was any serious reason to believe they would actually show up at the LHC.

   Supersymmetry is different. In that case, quite a few people did expect it to be seen at the LHC.

4. **Bernhard**
   August 13, 2011

   Peter,
   what do you think will happen to string theory if supersymmetry does not show up at the LHC at all? I know what string theorists are going to say, i.e., string theory never predicted it would, etc, but I wonder what will happen in terms of their funding, in terms of presence in the media, respect from the rest of the community. I cannot believe (or I don´t want to) that the strange situation we have now, that a theory with no predictions will go on receiving so much attention. Do you agree?

5. **Peter Woit**
   August 13, 2011

   Bernhard,

   I think string theory in the last few years has already been seriously affected along the lines you ask about, partly because of its failure to make any real LHC predictions. It has been clear for a while to most people in HEP that string theory is a failure at saying anything at all about TeV scale physics, and that has had an impact. Finding supersymmetry was kind of the last hope along those lines, and no supersymmetry will just continue current trends.

   One thing I've learned is that it's just about impossible to get people to give up on an idea once they have a certain amount invested in it. Many string theorists will go to their graves insisting string unification is a great idea, not a failure, and they'll be prominent in the media, as well as having influence on funding. Their colleagues will just take them less and less seriously. Instead of being "cutting edge" they will be seen as has-beens.

   The situation of supersymmetry itself may be a more dramatic story. There's a large community of people who have invested 20-30 year careers in TeV-scale supersymmetry phenomenology, and by 2015 or so, that may be a really dead subject. How they will deal with this will be interesting, it's already kind of fascinating to see how this is starting to play out.

6. **Clara**

August 16, 2011

Peter,

is there any recent news on what Ed Witten is thinking, now that Susy looks so bad?

7. **gradstudent**
   August 16, 2011

   I have a general (factual) question, coming from a math student who doesn't know modern physics, but is trying to follow. When you and others say string theory makes no predictions, does this mean more precisely that, "it does predict things like supersymmetry, but leaves open a wide (perhaps infinite?) range of energies at which the first SUSY phenomenon would be detectable, which in particular means it can never be absolutely invalidated by a (finite) number of experiments?"
   ,
   Thanks! I've always been confused about this point. And another similarly fundamental and ignorant question: what do people mean by the "landscape"? Is it related to the above point about an infinite range of predictions?

8. **Peter Woit**
   August 16, 2011

   Clara,

   I don't know what Witten thinks about the latest discouraging news for SUSY. In the past he has given talks about SUSY that acknowledged that SUSY effects should have already showed up, at least indirectly, so it was not at all guaranteed to show up at the LHC (this is somewhat the same at what Matt Reece starts off by pointing out).

   gradstudent,

   The problem with supersymmetry has always been that it has to be a broken symmetry, and the scale of the breaking is undetermined. There have been arguments (the "hierarchy problem") made that the scale should be around the electroweak breaking scale (100 GeV), and that is what is now being ruled out by experiment. In string theory, normally you need supersymmetry, but it predicts nothing about its breaking (or about much of anything else..). By the way, I wrote a book about this, where things are explained carefully, in a way that should be accessible to math students…

9. **Dave**
   August 17, 2011

   So with string theory being thrown under the bus, what is the new theory of everything? I've heard LQG has even more problems and is also not a leading contender.

10. **Peter Woit**
    August 17, 2011

    Dave,

    It's SUSY that string theorists are throwing under the bus. It may be a while before string theorists throw themselves (i.e. string theory) under the bus, although that might happen. LQG is not something that has ever had a way of giving a unified theory.

    As far as unification goes, I think the situation is that it's pretty clear right now that no one has a good idea. Not an unusual circumstance in face of a hard problem.

11. **HoldYourHorses**
    August 17, 2011

    It's worth pointing out that TeV-scale SUSY has not *yet* been ruled out. It has not appeared in the most obvious places, and for sure my degree of belief is rather less now than it was 6 months ago, but let's not react prematurely.

    Peter, if it is discovered, which I consider possible but not probable, you're going to have some back-tracking to do…

The Fabric of the Cosmos on PBS

August 15, 2011
Categories: Uncategorized

A four-part NOVA series based upon Brian Greene's The Fabric of the Cosmos is coming to PBS this fall, starting November 2. In some sense this is a follow-on to his wildly successful The Elegant Universe NOVA series from 2003, which was largely devoted to promoting string theory. From the program description and preview it appears that the new shows don't emphasize string theory, although the fourth of the series promotes the Multiverse (Clifford Johnson joins the effort here), along the lines of Brian's latest book The Hidden Reality.

Comments

1. **Roger**
   August 15, 2011

   The episodes are: (1) microscopic forces can generate whole universes, our universe is just a hologram, (2) wormholes, time travel, (3) goofy speculations about the meaning of quantum mechanics, (4) multiverse fantasies. I think that I'd rather watch Michio Kaku on the Discovery Channel.

2. **Mel B.**
   August 15, 2011

   Dear Prof Woit,

   What portion of Brian Greene's work is actually based on testable and falsifiable science? Are his books based on religion-like, unprovable fantasy concepts?

   Thank you

   Mel

3. **Peter Woit**
   August 15, 2011

   Mel B.,

   Much of theoretical physics research has always been not testable/falsifiable. The point is that when you start investigating a new idea, you typically don't understand it well enough to know exactly what its implications are. You can't just say "since this is not testable, it's not science", when people are still struggling to see if they can come up with a test. That struggle is a legitimate part of science. The real question is whether they are getting anywhere: are they making any progress towards coming up with a test, or is it looking increasingly unlikely that this is possible?

   I haven't seen the new programs, but I'd guess that they're very much a mix of solid, tested science, together with a range of speculative ideas, including some that are extremely unlikely to lead anywhere. As long as one makes clear what is solid and what is speculative, with some clear indication when one has entered the realm of the "wouldn't this be cool, even if it's very unlikely", I don't see a problem.

   Personally I thought "The Elegant Universe" programs didn't do enough to make clear how speculative some of the ideas there were, because many theorists were very optimistic about them at the time. In retrospect a decade later I suspect that some things in that program might be much more carefully hedged if redone today. There's a similar over-enthusiasm these days among some people for the idea of a string-theory based multiverse. I hope the new program does better in making clear that there are good reasons for skepticism about this.

4. **Roger**
   August 15, 2011

   No part of Greene's work is testable. His last TV show started with him saying, "One thing that is certain is that string theory is already showing us that the universe may be a lot stranger than any of us ever imagined." No, string theory has not shown anything about the universe. Greene occasionally says that experimental confirmation would be a good thing, but he makes reckless and untestable statements anyway.

5. **Peter Woit**
   August 15, 2011

   Roger,

   "string theory is already showing us that the universe MAY be a lot stranger…"

   Note the carefully placed caveat. Unfortunately I think these often don't get noticed by the viewer since they're not much emphasized, but they are there.

6. **Bernhard**
   August 15, 2011

   Peter,

   I see simply no reason to make such documentaries, they´re a disservice to making the general public about science. The caveats you mention, are noticed by nobody and the public impression is not that their talking about established accepted science. A documentary to talk about speculations in HEP could be even made, but the point of it should to inform the public of some of the really many scenarios thought by theorists. String theory could of course be there with the multiverse hand by hand, provided it was explained this is something less and less taken seriously by the scientific community.

7. **Bernhard**
   August 15, 2011

   sorry, *they´re a disservice to making the general public aware about science.*

8. **Jason**
   August 15, 2011

Brian Green – he is a good writer.
He can deliver those ideas of particle physics to a large audience.
Much like Martin Gardner, also a good writer, and the author of this blog.
I believe good writers can bring much enthusiasm to a field of interest, whether
or not some of the ideas in that field are still questionable.
To bring the story up front, to generalize the technical details.
Not even wrong
Would you agree?

9. **Peter Woit**
August 15, 2011

Bernhard and Jason,

It's by now an old argument about whether these kinds of enthusiastic and potentially misleading promotions of highly speculative theoretical ideas are a good thing because they get people interested in physics, or a bad thing because they misinform people about physics. I don't know of any data quantifying the effect one way or another.

One can say though that this kind of TV program has been popular for quite a while now, and I don't see any evidence that they have inspired a huge cohort of brilliant young theorists into getting physics Ph.D.s and revolutionizing the field.

10. **Casey Leedom**
August 16, 2011

Hhmmm, I don't know. I think that it would be hard to find people who would argue against the value of Carl Sagen's "Cosmos" series in 1980. It was absolutely a popularization of physics (general, not HEP) and it absolutely had to cut corners (in terms of details) for the general audience. But it did a great job explaining science. And I'll bet there are a bunch of people who ended up in science because of that series.

The point is: it *is* possible to generalize science for popular consumption and not have to tell fairy tales.

11. **John Baez**
August 16, 2011

If people wanted to popularize physics that actually matters, they could talk about climate physics, starting with the laws of thermodynamics, the laws of radiation, atmospheric physics, the theory of ice ages and other climate cycles, and other basics. There are lots of people who know nothing of this, and are easily fooled by any second-rate "climate skeptic" who comes along. Meanwhile physicists are trying to teach them about wormholes, time travel and the multiverse. You can't say we don't deserve what's coming.

12. **Peter Woit**
August 16, 2011

John Baez makes a good point about the nature of science programs on TV, but as I feared, his comment immediately led to a host of comments from people who want to engage in ideological debate about global warming here. Don't even think of it, not on this blog. The internet is full of plenty of other places for that (including John's blog if you want to argue with him…).

13. **chris**
August 16, 2011

The physics behind electric energy generation would be another thing that a lot of people would hugely profit from i guess. The whole nuclear vs. renewable vs. fossil energy debate could use some good physics input.

14. **Trulo**
August 16, 2011

I think a good program about the LHC, and its first year of physics results would be terribly interesting to me. And it would certainly be popularizing real-world physics.

But I guess it'd be way too much to ask for. These days, even particle physics blogs barely mention it.

15. **Giotis**
August 16, 2011

I don't agree with some of the comments here regarding Brian Greene. Brian Greene desperately wants to connect String theory to the "real world". His research shows that; from Calabi Yau compactifications during the early Heterotic era to topological transitions, String cosmology and now transitions between flux vacua.

Initially he hoped that our world could be derived from String theory in a unique way and my understanding is that he is not very happy with the multiverse but since the theory points to that direction he feels (due to his strong belief that the theory deep down is correct) obliged to examine this possibility seriously.

16. **M**
August 16, 2011

actually, there is some TV here at CERN.

17. **Bernhard**
August 16, 2011

Giotis,

Greene and others tried to connect string theory to the "real world", but he and everybody who tried failed miserably. Furthermore, it is clear that they are still not going anywhere and the multiverse, landscape and other things are not really much a direction, but simply they giving up. Connection with the "real world" would be to make a prediction for the LHC. No, I take it back, it would be to make any falsifiable prediction at all.

18. **Jason**
August 16, 2011

All I'm suggesting is it takes a lot of editing power to successfully encompass a large subject, such as the study and history of physics, into a smooth few hundred pages while keeping it original in perspective. I'm not talking about marketing a theory, I'm talking about telling a story from begining to end. Asimov was the master.

19. **Anon**
 August 16, 2011

 Carl Sagan was indeed a great popularizer who wasn't afraid of addressing controversial topics such as the nuclear arms race in his series. We need more people like him.

 As for Green, I bought his new book and if that is what this program is going to be talking about, I don't have high hopes. His book is poorly written, and full of rather ridiculous claims such as the statement that, if the universe is infinite in extent, there must be exact copies of us far away. This is as absurd as saying, for example, that any infinite sequence of integers /must/ contain the number 42 more than once.

20. **Mitchell Porter**
 August 16, 2011

 Anon said

 "His book is poorly written, and full of rather ridiculous claims such as the statement that, if the universe is infinite in extent, there must be exact copies of us far away. This is as absurd as saying, for example, that any infinite sequence of integers /must/ contain the number 42 more than once."

 No it's not, because Greene would be assuming standard ideas about how physics works. It would require some unusual hypotheses about initial conditions and/or dynamics for such copies to *not* exist in an infinite universe.

21. **MP**
 August 17, 2011

 I think these programs are great. As a layman myself who doesn't grasp the complex mathematics required to truly understand these theories I love to read books, blogs, etc and watch shows that bring the complexity down a notch. I have my own opinions on what theories I think are a waste of time; what is insulting to me is that there are (educated) people who believe that the people who pay for this would not be interested in the results or capable of separating speculative from hard science.

 Bernhard, saying that the unwashed masses should remain unwashed has historically never worked. I am astonished to read comments like you made.

22. **Peter Woit**
 August 17, 2011

 MP,

 I don't think Bernhard is calling for keeping the public unenlightened about science, but rather for providing them with information about science that will be enlightening rather than just dazzling. You may be able to separate speculative from hard science, but there's a real danger that these programs give people completely misleading ideas about science, while doing little to explain what the real thing is.

23. **D R Lunsford**
 August 17, 2011

 John Baez made the essential point above, that there is a great deal of hard science involved in the climate change scenario and that would be a lot more interesting to people than endless, pointless speculations about ephemera.

 There is hard data that this sort of "fuzzics" is turning people off. Many media portals, newspaper sites etc. don't even bother to have a dedicated science section -it gets lumped under some amorphous "tech" section. Why? There is just no interest in the same old crowing about how many dimensions are curled up into cosmic dust bunnies.

 -drl

24. **Anon**
 August 17, 2011

 Mitchell Porter, I don't think any of us know what the hell we are talking about when we discuss the initial conditions of the universe. In fact, "standard ideas about physics" are at still pretty much at a loss in this regard, given our current ignorance regarding quantum gravity. Even in the absence of gravity, the existence of copies is not a solid mathematical prediction of any quantum field theory in infinite space as far as I know, unless you posit some /very/ special initial conditions. If you have references to the contrary , I'd be all ears. So to claim the existence of infinite numbers of copies, as he does, is science fiction dressed up as fact.

 I am so tired of my doctor, my brother in law, my freshman students, and others, wanting to talk to me about some nonsense from his books because I am a physicist, and having to be the bad guy who shatters their illusions. I am just tired of it.

25. **Mitchell Porter**
 August 18, 2011

 Anon:

 "the existence of copies is not a solid mathematical prediction of any quantum field theory in infinite space as far as I know, unless you posit some /very/ special initial conditions. "

 Let's consider, for the purposes of argument, that we are talking about our solar system within the orbit of Pluto. Now consider the whole past light-cone of that region, back to the initial conditions, however you choose to think of them. The important point is that the cosmological initial conditions will be defined across an infinite spatial volume, for a universe that is spatially infinite later on. But the portion of the initial conditions relevant for our existence are only going to take up a finite part of these infinitely extended cosmological initial conditions.

 So we know that our own existence is an outcome of finite probability, given the existence of a finite initial region in a particular initial state. But the full cosmological initial conditions are spatially infinite, therefore contain infinitely many finite regions. If the local initial conditions that led to us are repeated infinitely many times across the overall initial conditions, then copies of us should be realized infinitely many times, because our existence is a finite-probability outcome for any one of those duplicates of the local initial conditions. So to avoid this outcome, you have to postulate that the local initial conditions which gave rise to us occur only finitely many times throughout the whole infinity of the cosmological initial conditions.

 As I said, it requires an unusual hypothesis about initial conditions or about dynamics to avoid Greene's conclusion.

26. **Luke**
August 18, 2011

I have to agree with a point John Baez made and a point I've heard Feynman make in a video of his. I'd much rather, being a mathematical physicist, watch a scientific documentary on thermodynamics (say global warming) or perhaps some interesting optical phenomena. Heck, even a documentary on some fascinating results from fluid mechanics would be interesting because you have all sorts of cool demonstrations and whatnot to show. Heck, I'd say that those branches of physics are more popular then quantum gravity in terms of thought and effort put into them. But people don't want to see or hear that. They want to learn about quantum gravity and hear about cool things like time travel or wormholes. It's very unfortunate.

27. **DB**
August 18, 2011

Peter, you might be interested in the following as an illustration of the seige mentality which often accompanies the cult-like behaviour of those caught up in the multiverse idea:

http://www.science20.com/alpha_meme/internet_study_guide_nonlocal_quantum_physics_and_solution_einstein_podolsky_rosen_paradox-81760

After announcing that "The proof against local realism is humankind's the (sic) most relevant finding in the realm of science and philosophy" the author assures us "I will ensure the comment thread here is going to be helpful for readers, so pseudo-scientists and religious anti-multiversers please stay away or get deleted."

So no criticism allowed while he tries to explain his non peer-reviewed paper for the benefit of gullible undergraduates.

I wouldn't mind but this guy holds down a postdoc in a large university.

28. **Peter Woit**
August 18, 2011

DB,

I think that author is overly optimistic about the level of anyone's interest in that kind of philosophical discussion of of "realism" and the many-worlds interpretation of QM. To get "religious anti-multiversers" to overwhelm his blog comment section I think he's going to have to expand his interests from QM to cosmology and TOEs.

29. **Anon**
August 20, 2011

"**If the local initial conditions that led to us are repeated infinitely many times** across the overall initial conditions, then copies of us should be realized infinitely many times, …

As I said, it requires an unusual hypothesis about initial conditions or about dynamics to avoid Greene's conclusion."

Aren't you *assuming* an unusual hypothesis about initial conditions in your argument (namely, the part I bolded)?

30. **srp**
August 21, 2011

I read The Fabric of the Cosmos, and it is primarily about non-speculative ideas in physics, such as special and general relativity and quantum mechanics, along with mainstream cosmological theory. Greene is pretty careful to say when something is speculative or that others disagree with his opinions (often giving a citation so the reader can check it out). The one thing in there that was new to me was a thermodynamic argument for the Big Bang–that without the whole universe starting out in a lower-entropy state, reversible micro-physical laws force us into paradoxical conclusions about the world-lines of melting ice cubes. I'd be curious to see if that rather subtle argument makes it into the show.

31. **Mitchell Porter**
August 22, 2011

Anon: "Aren't you assuming an unusual hypothesis about initial conditions in your argument"

No; other possibilities would be of measure zero in the set of initial conditions.

That is not a *refutation* of the idea of unusual cosmological initial conditions, but it means that you need some new physical principle or other argument that specifies the unusual starting point you have in mind.

Does String Theory Predict Low Energy Supersymmetry?

August 16, 2011
Categories: Uncategorized

It used to be that string theorists would respond to arguments that string theory predicted nothing with the claim that it predicted supersymmetry. For example, in an interview with Witten done for the PBS *Elegant Universe* series, one sees:

> **NOVA:** It seems like the standard criticism of string theory is that it isn't testable. How do you respond to that criticism?
>
> **Witten:** One very important aspect of string theory is definitely testable. That was the prediction of supersymmetry, which emerged from string theory in the early '70s. Experimentalists are still trying to test it. It hasn't been proved that supersymmetry is right. But there is a very precise relationship among the interaction rates of different kinds of particles which follows from supersymmetry and which has been tested successfully. Because of that and a variety of other clues, many physicists do suspect that our present decade is the decade when supersymmetry will be discovered. Supersymmetry is a very big prediction; it would be interesting to delve into history and try to see any theory that ever made as big a prediction as that.

Of course the problem with this was always that supersymmetry had to be broken somehow, and string theory said nothing about how to break it, not even the scale of the breaking. Back in 2004 when the anthropic landscape business began, Susskind was enthusiastic about the idea that it could be used to predict the scale of supersymmetry breaking, and Michael Douglas started working on computations counting string vacua that were supposed to say something about this (I've followed this story in several blog postings, an early one was here). The bottom line quickly became clear: a host of problems make this impossible, string theory remains incapable of predicting anything about this.

Today at the Simons Center, Douglas gave a talk entitled *Does String Theory Predict Low Energy Supersymmetry?* (video available here), and not surprisingly the conclusion is still that string theory predicts nothing about this. Amusingly, someone in the audience took exception to Douglas saying that string theory doesn't now make predictions, and one gets to hear Douglas try and explain to his fellow string theorist what a real prediction is. The video quality is great, but the sound doesn't work so well when two people are loudly trying to talk over each other.

This particular talk was held indoors, for a report on what the outdoor ones have been like, see here.

Comments

1. **Anon**
   August 16, 2011

   I am surprised that someone of Witten's calibre would commit this elementary logical error so publicly. To claim, as Witten did, that the hunt for experimental supersymmetry is a "test of string theory" is an example of the fallacy known as "affirming the consequent", given the existence of supersymmetric quantum field theories.

2. **Peter Woit**
   August 16, 2011

   Anon,

   I suspect that, given the opportunity to elaborate, Witten would have explained that what he meant was just that discovering supersymmetry would have provided support for the ideas behind string theory (but not proved string theory, since you can have supersymmetry without string theory). To pin him down, the interviewer should have asked about the falsifiability question: would a failure to find supersymmetry provide evidence against string theory?

3. **Mitchell Porter**
   August 16, 2011

   Anon, your diagnosis of Witten's error is wrong. If theories A and B both predict unobserved phenomenon X, the search for X is still a test of A, even though B also predicts it.

4. **Peter Shor**
   August 17, 2011

   Does anybody know what Witten mean when he said *"But there is a very precise relationship among the interaction rates of different kinds of particles which follows from supersymmetry and which has been tested successfully?"*

5. **AV**
   August 17, 2011

   Isn't supersymmetry an assumption of string theory as opposed to a prediction? If this is the case it seems like no physicists care to make this distinction any more even though there is a clear logical difference between the two, basically what Anon is saying I think.

6. **piscator**
   August 17, 2011

   I guess it must mean gauge coupling unification, and what that says about the relative size of the three gauge couplings at the weak scale.

7. **piscator**
   August 17, 2011

   @AV: since consistent string theories appear to require supersymmetry for their internal validity, I think it is fair to say that supersymmetry *at some energy scale* is a prediction of string theory. Supersymmetry at the TeV scale is clearly not a prediction of string theory – its absence does not falsify the subject – although its presence would suggest that string theory is on the right track.

8. **Peter Woit**
   August 17, 2011

   Peter Shor,

As piscator comments, what Witten is referring to is a supersymmetric GUT calculation, where coupling constant unification works better than in non-supersymmetric GUTS. This assumes, among other things, a "desert hypothesis" of no new relevant physics between the weak and GUT scales. While supersymmetric GUTs push up the GUT scale and thus make the proton lifetime longer, some classes of these models are ruled out by proton lifetime limits. Of course, as usual, there are lots and lots of models and choices to be made, so one can evade experimental limits.

9. **Giotis**
   August 17, 2011

   Douglas correctly says that the importance of Low SUSY for String theory has been diminished after the latest theoretical developments, mainly because the theory has now other mechanisms to solve the hierarchy problem like warped compactifications, large extra dimensions or even anthropic reasoning via the string landscape. Low SUSY was very important in the early days of String theory when only the Heterotic model could produce the standard model and Low SUSY was the only available mechanism to solve the hierarchy problem. Now on the other hand there is no such restriction you can get the standard model from D-branes in IIB or IIA where the aforementioned mechanisms could be used to deal with the hierarchy problem and thus do not need Low SUSY (they do not preclude it though). In this case SUSY could break at larger scales since it doesn't have to solve the hierarchy problem anymore.

10. **Giotis**
    August 17, 2011

    Just to add something to my previous comment.

    Of course large hierarchies (large enouph to solve the hierarchy problem) produced by large extra dimensions or strong warping, means new physics at TeV scale that should be detected by LHC. So far though this doesn't seem to be the case.

    So if they found just a light Higgs at LHC and nothing else at TeV scales (no new physics) the stringy landscape may be the only explanation for the stability of the EW breaking (unless of course someone comes up with a better idea).

11. **Roger**
    August 17, 2011

    The LHC is discovering that there is no supersymmetry — at least none of the sort that had been widely predicted. The string theorists are like a doomsday cult that desperately needs an alternate story to cover up their failed predictions.

12. **Anon**
    August 17, 2011

    Mitchell Porter, I guess it depends on the semantics of "test of string theory" that Witten could have reasonably taken his audience to understand. In the context of the interview question, it is clear to me that the average educated listener would have taken this to mean "something that can distinguish string theory from other serious proposals such a field theories". In this sense, even if you may be right in your statement that Witten did not commit an error of logic in a strict technical sense, in my opinion he certainly did so given the context. I am pretty sure that he was bloody well aware of the loophole at the time and made a conscious decision to take advantage of it for political reasons, which I find somewhat immoral.

    In any case, you will no get many physicists today still seriously claiming that the LHC is testing string theory. Why do you think that is?

13. **DB**
    August 18, 2011

    "In this case SUSY could break at larger scales since it doesn't have to solve the hierarchy problem anymore." – Giottis

    Now that the hierarchy problem has been magically airbrushed from the scene don't forget about Split Supersymmetry. Or my own personal favourite, Supersplit Supersymmetry.

$100 Million From Simons and Simonyi for the IAS

August 18, 2011
Categories: Uncategorized

The Institute for Advanced Study in Princeton announced today that Jim Simons and Charles Simonyi will donate \$100 million to the Institute, in the form of matching funds for a \$200 million campaign mainly aimed at increasing the endowment. For some idea of previous fund-raising by the IAS, see here.

Simons and Simonyi have donated significant sums to the IAS in the past, including \$6 million from Simonyi to endow a professorship for Witten. The IAS has about 25 permanent professors, with salaries reaching above \$300K/year. To get some idea of the scale of the new endowment funds, if they all went to new permanent professorships (unlikely), the number could be doubled or more. This kind of sizable increase of resources for prestigious pure research positions in math and physics, funded by huge fortunes made in the technology and financial industries, is part of a trend, with Perimeter and the Simons Center at Stony Brook two other noteworthy examples.

Comments

1. **donations**
   August 18, 2011

   That is good. One hopes the money will be put to good use. Note that endowing a chair for Witten in years past also meant (to some extent) endowing a chair for (the pursuit of research into) string theory. See previous post about Witten interview and "string theory predicts supersymmetry". So don't complain. It's a mixed bag.

2. **Peter Woit**
   August 18, 2011

   donations,

   Who is complaining? Not me. Witten's as good a choice (if not better) than anyone for an endowed chair. That a sizable chunk of $200 million in new money will be available in the future to support theoretical physics and math research is a good thing. For the physics part of it, it will be interesting to see which direction the IAS takes.

   The continuing trend away from public funding for math/physics research in favor of funding from the great fortunes of the wealthy is interesting and in some sense a reversion to the pattern of many centuries ago. At least in the form of an endowment, such funding may be more stable than public funding, which is at the mercy of the politics of science and university state and federal budgets. One might worry that the wealthy sources of the funding will have too much influence, and take research in dubious directions. Besides the Templeton multiverse funding, that doesn't seem to me to have been a problem, with people like Simons, Simonyi and Lazaridis arguably making as good or better choices than DOE/NSF peer-review panels.

3. **Mitchell Porter**
   August 18, 2011

   If they haven't explained the particle masses within five years, Simons and Simonyi should insist on a refund.

4. **Amitabha**
   August 19, 2011

   Is it better (for the future of research) to put a lot of money in a top theory place that is already reasonably well-funded, or to spread the money over several mid-ranked places so that each can attract one or two very good theorists?

5. **Guillaume**
   August 19, 2011

   Peter: Isn't the endowment revenue highly dependent on the state of the stock market, and therefore subject to large fluctuations? I'm not sure that's better than even the currently poor state of public funding.

6. **Peter Woit**
   August 19, 2011

   Guillaume,

   In the long term, endowment revenue does depend on how well the endowment is invested. In the shorter term, endowment pay-outs typically depend on the average value of the endowment over several years, not what happens in any one year. If revenue is down, you can always take more out of the endowment to keep funding whatever you want (and hope that either investments will turn in your favor, or your patrons will come up with more money. Note that $50 million is less than 1% of the Simons net worth…).

7. **Douglas Natelson**
   August 20, 2011

   That's quite an investment, particularly for a theory-focused institution. I'd love to see that kind of growth in support for experimental work….

8. **abacus salam**
   August 23, 2011

   that sounds pretty good; i hope more hedge fund managers will follow suit.

String Theorists Suggest Space Wormholes Possible

August 18, 2011
Categories: This Week's Hype

I was just out for a bike ride, during which an idle thought came to me about a rule of thumb that might deserve publicity. This rule of thumb is that the mention of wormholes in a popular science book, TV program, etc., indicates that real science is not what's being discussed. When I got back to my office, I found that USA Today has a new story: [String theorists suggest space wormholes possible](). The source of the story is [this preprint]().

Via Twitter, the story's author did get the obvious response to this claim: this isn't news since everything is possible in string theory.

Comments

1. **Shantanu**
   August 18, 2011

   Peter there is no mention about string theory in the paper. (wormholes
   is an old concept in relativity and there are papers on it from 30's onwards)
   shantanu

2. **Cliff**
   August 18, 2011

   I dont suppose there is any way to map this 'rule of thumb' into a meaningful statement about whether string theory is relevant to understanding the world or not?

   After all, according to the rule general relativity isn't "real science" either.

   Interestingly, you seem to advocate the opposite demand than those of e.g. Smolin. Instead of insisting that string theory be formulated with manifest background independence, it is now apparently required to be unable to deal with certain backgrounds. Is this basically what you're saying?

3. **Jeff**
   August 18, 2011

   Well, I work with a physicist (who ended up in the math department for various reasons) who's a GR guy, and has written several papers on this stuff. In particular he has done work on limitations on negative energy, which is what you need to keep a wormhole stable. Together with collaborators they found limits on the duration of any localized negative energy, these are based on the uncertainty principle. The upshot is that you can't get stable wormholes in standard GR. From what I can deduce from the paper here, they are trying to get around this, and it does use string theory – they get the extra curvature they need from the compactification from 10 dimensions down to 4 (I thought M theory was 11 dimensional 🙂

4. **Peter Woit**
   August 18, 2011

   Cliff,

   This rule of thumb is not about string theory, it's about TV programs…

   There may very well have once been a TV program that discussed wormholes and GR in a scientifically solid way. I missed that one though.

5. **GR student**
   August 18, 2011

   It would be sad if the public internalized your rule of thumb and then denied themselves the pleasure of reading "Black Holes and Time Warps: Einstein's Outrageous Legacy" by Kip Thorne because they thought "real science" was not being discussed.

6. **Natron**
   August 18, 2011

   @Shantanu,
   Yes, the paper mentions string theory 4 times. Also, Peter was just reporting on what the article is claiming based off this paper.

7. **Peter Woit**
   August 18, 2011

   GR Student,

   Well, it's just a rule of thumb, doubtless there are exceptions. I think it works better for TV shows, and has become more and more accurate as time goes on. Less accurate for books from more than 15 years ago.

8. **Casey Leedom**
   August 19, 2011

   Peter, I think you're "re-coining" a rule of thumb that's already been covered in "Jumping the shark." Isn't that what the entire multiverse thing is? Once you run out of other ideas …

   Casey

9. **Shantanu**
   August 19, 2011

   Natron, the paper says that Gauss-bonnet gravity is motivated from heterotic string theory. but again G-B gravity has a much longer history than string theory.

btw, see this paper on wormholes
http://arxiv.org/pdf/0902.1994v3

10. **DB**
August 19, 2011

Enjoyable paper all the same, especially if read from the perspective: "what corrections to the GR Lagrangian would permit stable traversable wormholes?" Although it uses a particular string theory lagrangian to derive those corrections as its starting point, I would be more interested in a research program that tried to explore what the most general class of such corrections were and then seek constraints on them.
Also interesting that the most recent paper to be referenced was 1988.
Aside from all the string theory hype, the fact remains that without some means of faster than light travel and communication we are stuck in this solar system for eternity, so I consider research efforts in this utterly neglected area worthwhile and deserving of the title "fundamental", provided always that they take GR as their starting point.

11. **DB**
August 19, 2011

That should of course have read "string theory action" and not "string theory Lagrangian"

Sunday Night Higgs?

August 18, 2011
Categories: Experimental HEP News

Lepton-Photon 2011 begins Monday morning, the schedule is here. It should start off with a bang, with the latest Higgs search results from ATLAS and CMS presented starting at 11:20am local time, the middle of Sunday night here. There will be a press conference on Wednesday.

If the hints of a Higgs signal seen in the data presented last month at EPS-HEP 2011 are real, they should be more pronounced in the new data (the experiments have now collected about twice as much data as that used in the analyses presented at EPS-HEP 2011). The Higgs Combination Group should by now have produced a combined analysis using last month's data from the ATLAS + CMS and presumably that will also be released on Monday or soon thereafter. They have just today released a new document giving the details of how the combination is done: Procedure for the LHC Higgs boson search combination in summer 2011. Still holding out on us though in terms of the real data, that document just shows toy data…

Update: The latest rumor I'm hearing is that the only analyses updated with new data (nearly twice as much) since EPS-HEP that will be available Monday will be from individual channels. Analyses combining the different channels won't be ready for another 2 to 3 weeks. I still think though that we should see the CMS+ATLAS combination of the old data shown at EPS-HEP. So, if the Higgs is there, a definitive signal may still not quite yet be available. These people do need to take a vacation sometime in the summer…

Update: The news is that CMS and ATLAS have produced new combinations (although the combination of older ATLAS + CMS data has not been released, and I'd love to know why…). The bottom line is that the hints of a Higgs around 140 GeV have weakened with the addition of more data. A simplified summary of the current situation would be:

- No Higgs above 145 GeV
- In the region 135-145 GeV, both experiments are seeing somewhat more events than expected from background, but less than expected if there really was a Higgs there.
- Not enough data to say anything about 115-135 GeV, the Higgs could still be hiding there. If so, a malicious deity has carefully chosen the Higgs mass to make it as hard as possible for physicists to study it.

More details available on the conference slides that should be available here. Tommaso Dorigo and Matt Strassler have commentary.

Update: Still no word on why no CMS+ATLAS combination has appeared. Philip Gibbs has hacked together an unofficial version (see here and here). Comparing the EPS data to the latest, one sees clearly that a marginally significant signal consistent with a Higgs has weakened quite a bit with the new data (and thus, there was little to no evidence for such a Higgs in the new data). Also worth reading, commentary from Jester here.

Comments

1. **M**
   August 19, 2011

   The rumor is different

2. **Charles**
   August 19, 2011

   What is the rumor this round?

3. **Peter Woit**
   August 19, 2011

   Charles,

   If I had heard any believable rumors, I'd post them here. Maybe M can share more details with us. Or, anonymous posting by the well-informed is encouraged…

4. **null**
   August 19, 2011

   Would there be any reason for "Lepton-Photon 2011" and "Higgs Combination Group" to announce a null result (if there is one)? So if they do plan an announcement, presumably they found some evidence for a higgs?

   How many fb-1 have been collected to date?

5. **SA**
   August 19, 2011

   Over 2/fb

6. **bonk**
   August 19, 2011

   There's no point in keeping announcing null results. BUT, since many people have nothing better to do other than wait for Higgs results, suddenly there is a point.

7. **Peter Woit**
   August 19, 2011

   null, bonk,

   With this amount of data, the result (even a null result) is guaranteed to be interesting. If you really don't see anything, you can rule out the possible existence of a Higgs on more and more of the allowable mass range. If this can be done all the way to the LEP limit (this is still a ways away), you've shown there is no SM Higgs and shown there is something dramatically wrong with our understanding of the SM. If you do see a signal, that's of course big news and the beginning of a research program to understand exactly how the Higgs behaves.

The least interesting thing is a signal of marginal statistical significance, but as data accumulates this starts to become impossible. Either you see the thing or you show that it isn't there.

8. **Emile**
   August 19, 2011

   Bonk: since there is no point in announcing null results, the two experiments will not tell the rest of the world in what mass range the Higgs has been excluded. And, they won't bother to tell the world if/when the whole mass range has been excluded either.
   CDF and DO would also like to apologize for releasing null results.

9. **Michael Schmitt**
   August 20, 2011

   Hi,

   I think "bonk" must be joking. 😉 CMS and ALTAS are testing a wide range of possible Higgs masses and any statement that there is no evidence for a standard model Higgs boson within that range is an important scientific result. There is an hypothesis, and then there is the experimental test. This is not really grounds for cynicism, right? 😉

   About 2 fb-1 has been collected by each experiment, but you can expect some fraction, say 20%, not to ready yet for analysis. Since the increase in the data samples is rapid, the need to combine ATLAS and CMS results is not so strong. I'm sure each experiment will show updated combined results, but I would not necessarily expect to see an ATLAS+CMS combination.

   bye

10. **Peter Woit**
    August 20, 2011

    Hi Michael,

    I'm hearing from other sources the opposite: that individual ATLAS and CMS combinations of new data aren't yet ready (although some individual channels are). Also, the LHC Higgs Combination Group was supposed to have an ATLAS+CMS combination based on analyses released at EPS-HEP ready a week or two ago for release at Lepton-Photon. Is there any reason that won't happen?

11. **M**
    August 21, 2011

    The rumor is that the combinations of different channels within single experiments will be shown at 1.5 fb-1 (but no ATLAS + CMS combinations) and that unfortunately the hint at 140 GeV XXXXXXXXXXXX, partly because the background XXXXXXXXXX.

12. **Anonymous**
    August 21, 2011

    Do you personally believe that they're going to find the SM Higgs boson, Peter?

13. **Peter Woit**
    August 21, 2011

    Anonymous,

    I have no idea whether there's an SM Higgs, or something more interesting is causing electroweak symmetry breaking. I've been wanting to know this for more than 30 years, so very much looking forward to finding out….

14. **bonk**
    August 21, 2011

    In the Tuesday talk "BSM results from LHC", we will also get an update on SUSY with over 1.5 fb^-1. Is that right?

15. **bonk**
    August 22, 2011

    Just watched ATLAS and CMS talks. Moderate enlargement of last month's exclusion regions. They expressed disinterest in combining data, because data are being produced faster than can be combined. Also, last month's excess has decreased in significance.

16. **Thomas Larsson**
    August 22, 2011

    Does decreased significance mean probably no Higgs? If the signal were real, we would expect significance to increase with more statistics, right?

17. **Fred**
    August 22, 2011

    There is no Higgs and probably no new physics. Wow.
    Sorry Higgs, Guralnik, Hagen, Kibble, Brout, Englert, Anderson, Weinberg, and Salam, but you were wrong all along. Good effort though.

18. **DB**
    August 22, 2011

    The UK's guardian newspaper is reporting from the Lepton-Photon conference in Mumbai that there's nothing to see here, the signals have all but vanished.

    http://www.guardian.co.uk/science/2011/aug/22/higgs-boson-signals-fade

19. **Bernhard**

August 22, 2011

CERN press-release on this:

http://press.web.cern.ch/press/PressReleases/Releases2011/PR14.11E.html

20. **jon-student**
August 22, 2011

Suppose there's no Higgs. From wikipedia, there appears to be several proposed Higgless models: are some of them testable with LHC data accumulated so far? If not, how much more data would be needed: end of 2012? or the 7 Tev run after 2013? or even more? Thanks, exciting times!

21. **Thomas Larsson**
August 22, 2011

Don't Higgsless models also require something like a Higgs at the LHC, even if it is composite. E.g. a bound state of technifermions?

22. **m**
August 22, 2011

Wow, some people are fast at concluding there's no Higgs! The limits do not cover the whole mass range; the Higgs could still be light and compatible with SM predictions if it exists!

23. **Peter Woit**
August 22, 2011

jon-student,

The search for the SM Higgs is very straightforward in the sense that you have a very precise model to test, with everything completely determined except the value of one parameter. In terms of testability/predictivity, it almost never gets any better than that.

If there is no Higgs, and something else is responsible for electroweak symmetry breaking, there are lots of possibilities that have been suggested, but none that are really compelling. These have lots of undetermined parameters. In many cases evidence should be visible at the LHC if you do the right analysis, but you can also come up with models that would not have effects visible at the LHC. For now I suspect the experiments will remain focused on looking for the Higgs, but if that gets ruled out, attention will move to other possibilities, and in some sense the subject will get a lot more interesting…

24. **Alex**
August 22, 2011

Slow down, what are you people talking about? Looking at the ATLAS/CMS exclusion plots, they are still pretty much what one would expect to see right now if there was a Higgs at above 140 GeV for example. Any data points that go beyond the sigma/sigma_SM =1 line are bound to become smaller if it is a SM like Higgs. Large peaks beyond that line are not expected to prevail if the SM Higgs is realized in nature.

@Thomas Larsson,

The family of so-called Warped Higgsless Models which became famous around 2003, do not have to have any fundamental scalar resonances, in their range of perturbative validity, which extends up to about 5 TeV. (apart maybe from the radion which represents fluctuations of the size of the extra dimension).
This is in contrast with so-called composite-Higgs models. It is conceivable that if the radion is light, it might get some effective nonrenormalizable somewhat higgs-like couplings, but not necessarily comparable to what a Higgs would do.

25. **Alex**
August 22, 2011

In my last comment it was supposed to read

"The family of so-called Warped Higgsless Models which became famous around 2003, do not have to have any —————- scalar resonances, in their range of perturbative validity, which extends up to about 5 TeV."

26. **felix**
August 22, 2011

95% CL exclusion:
ATLAS
146~232, 256~282, 296~466
CMS
145~216, 226~288, 310~400
Tevatron
100~109, 156~177
I don't understand why people take this as a sign that the Higgs might not exist. Since precision electroweak constraints favor a light Higgs, ruling out larger Higgs masses only makes us more confident in the SM.

27. **Charles**
August 22, 2011

The "Higgs" also could be composite – consistent with the general proof of some of the theorists back in 1964.

28. **Harry Johnston**
August 22, 2011

Out of curiosity, do there happen to be any theoretical models which predict that the Higgs should be exactly where it is most difficult to find?

29. **chris**
August 23, 2011

Harry Johnston,

yes, in fact one extremely compelling one. if there is the SM Higgs in the region of 130~160 GeV then unitarity of the SM is guaranteed up to beyond the Planck scale. so if you think the SM is all there is up to gravity and if you disregard all naturalness-based arguments, the Higgs is 'expected' to lie in that region.

if it will turn out to be a 130GeV SM Higgs – well then very probably goodbye to all accelerator-based signals of BSM physics for probably the rest of our and our grandchildrens lifes (although one has to be careful with this sort of statements).

30. **chris**
August 23, 2011

the SUSY summary was just given: no signal again.

31. **Eric**
August 23, 2011

"Not enough data to say anything about 115-135 GeV, the Higgs could still be hiding there. If so, a malicious deity has carefully chosen the Higgs mass to make it as hard as possible for physicists to study it."

Isn't this precisely the Higgs mass range expected in the MSSM (< 130 GeV)? Apparently, the malicious deity goes by the name, Susy.

32. **Peter Woit**
August 23, 2011

Eric,

Minimal susy (as well as precision electroweak fits) most naturally leads to lower values of the Higgs mass. It's the LEP bound that gives you the 115 GeV. Already a malicious deity seems to have been at work, pushing the Higgs mass just above where LEP could see it.

Maybe the LHC will find no superpartners, just the Higgs of the MSSM. Hard to see how that would work, but I'm sure susy modelers can find a way…

33. **Eric**
August 23, 2011

Peter,

You need to be careful about what you mean by "natural". Natural is whatever nature does, not what you think it should be based on your personal judgment. In the case of minimal supersymmetry, the Higgs mass can be as great as 130 GeV. In fact, taking into account all current constraints, the "most likely" Higgs mass is around 118 GeV. If this is the case, then no Higgs signal should have shown up yet, but it should show up by the end of 2012.

In the case of the observation superpartners, you are essentially looking at the situation with a very naive and uninformed point of view. As has been pointed out to you by other commenters, the current contraints are based on simplified models which make certain assumptions. The main assumption of these models is that squarks and gluinos decay directly to the lightest neutralino, and thus produce large missing energy signatures. This definitely does not have to be the case, which would cause the signals of the superpartners to be much more difficult to see. Similar considerations apply if R-parity is violated. Besides these considerations, the squarks and gauginos easily be as heavy as 2 TeV, meaning that it would not be possible to see them until the second higher energy LHC run after the year-long shutdown/upgrade.

34. **Tom**
August 24, 2011

The CMS speaker himself said it would be worthless to present a combination plot at this point as it would be outdated by the time it appears since the data has been coming in so quickly. Since pp data taking ceases at the end of Oct. it is reasonable to expect a combination to appear before the end of the year holidays.

35. **Peter Woit**
August 24, 2011

Tom,

From what I hear, while there was some concern about the value of a combined CMS+ATLAS result when the individual experiments already had more data and better results, a deciding fact was that at the last minute a mistake was found in one of the input channels to the combined result. So, an excellent reason not to release it publicly at the conference…

36. **D R Lunsford**
August 26, 2011

Blast from the NEW past

http://www.math.columbia.edu/~woit/wordpress/?p=163

-drl

37. **Peter Woit**
August 26, 2011

Thanks drl,

Looks like Tommaso's prediction was pretty good. By the time all Tevatron data is analyzed next year, their limits may be about what he was expecting. The LHC schedule however, didn't work out as expected….

38. **Funes the Memorious**
August 27, 2011

Another quote from that same thread, showing not-so-accurate predictions:

> My personal preferred guess (30%) is that the Higgs is at the 115 GeV level, and it's one of the light Higgs scenarios that are natural in SUSY.

> But the discovery of Higgs will be a few-day celebration only. It's a trivial thing. We know that something like the Higgs must be there to make the WW WW scattering unitary, and the fundamental scalar is simply preferred by precision measurements.
>
> The real question to answer is SUSY below TeV, and other potential new physics.

Ah! Those were the days when "SUSY below TeV" seemed to be just within reach…

39. **steve newman**
August 27, 2011

"Not enough data to say anything about 115-135 GeV, the Higgs could still be hiding there. If so, a malicious deity has carefully chosen the Higgs mass to make it as hard as possible for physicists to study it."

.
Could someone explain what makes one energy range easier or harder than another for Higgs detection.
thanks.

40. **Bill K**
August 27, 2011

What makes the Higgs boson easier or harder to detect is which decay channels are available, what their branching ratios are, and how easily they can be distinguished from the QCD background. See for example http://www.hep.lu.se/atlas/thesis/egede/thesis-node14.html. At low mass the leading decay is H -> b-bbar, very hard to identify. But the H -> WW is easy, and note how rapidly its branching ratio rises with increasing Higgs mass.

41. **Allan Rosenberg**
August 27, 2011

I used to think Lederman called the Higgs the God particle just to sell books. I didn't give him enough credit. Now I realize that he called it the God particle as a sly prediction that it doesn't exist.

42. **Chris Oakley**
August 27, 2011

Lederman has covered the possibility of the Higgs being composite, too, since God, assuming he exists, is also composite, comprising the Father, Son and Holy Spirit.

This Week’s Hype, Part II

August 21, 2011
Categories: This Week's Hype

String theory hype is still coming fast and furious, so much so that the latest edition of *This Week’s Hype* needs to be a double issue. Today we learn that Black holes and pulsars could reveal extra dimensions, solving that thorny problem of testing string theory:

> String theory, which attempts to unify all the known forces, calls for extra spatial dimensions beyond the three we experience. Testing the theory has proved difficult, however.
>
> Now John Simonetti of Virginia Tech in Blacksburg and colleagues say black holes orbited by neutron stars called pulsars could do just that – if cosmic surveys can locate such pairings. “The universe contains ‘experimental’ setups we cannot produce on Earth,” he says.

The source of the hype isn’t really new though, they were featured a few years ago in an earlier edition of *This Week’s Hype*.

Comments

1. **Bernhard**
   August 21, 2011

   I have to say this sort of hype worries me a bit. Since string theory is a theory of anything at all, it won´t take long until any random astronomical signal to be consider evidence of string theory. Is the black-hole radiation loss going to be precisely predicted by the theory so that in the who-knows chance some experimental group see this it could be confronted? No, of course not. So, if we see nothing, situation stays as it is, string-theory is the marvelous theory of zero predictions. If on the other hand we see anything (at all) we can´t really precisely fit to general relativity, sure enough that´s string theory being “confirmed”.

2. **abbyyorker**
   August 21, 2011

   Peter,

   It seems like a simple idea that could provide a test although there is some “work” to be done in discovering a system with the appropriate properties. As a layman, I cannot see the difficulties. Where does the idea break down?

3. **KanzasTabasco**
   August 21, 2011

   This would be a fascinating development if true (about the black holes and pulsars), but it won’t do much for string theory. We can have extra spatial dimensions without any string theory.

4. **Peter Woit**
   August 21, 2011

   abbyyorker,

   It’s the same problem as every other “test” of string theory. String theory predicts nothing about these supposed extra dimensions, they could be any size whatsover and have all sorts of different properties. So, even if there are extra dimensions, and you manage to get yourself a pulsar and a black hole with just the right properties to see evidence for them, this in no sense “tests” string theory.

5. **Brandon Greggs**
   August 22, 2011

   Dear Peter,

   I just started following your blog.

   In two recent posts you showed how a) Ed Witten stated that String Theory is testable, and that b) Ed Witten deserves an endowed chair.

   So why is it that you are surprised when other physicists hype string theory as testable?

   Is only Ed Witten allowed to state that string theory is testable, and if so, why? What rules/laws are you following?

6. **Peter Woit**
   August 22, 2011

   Brandon,

   There’s no contradiction between someone being a great physicist, deserving of an endowed chair, and at the same time being over-enthusiastic about some idea, to the point of making claims for it that are not really supportable. If believing or saying something not quite true disqualified one from an endowed chair, we would have extremely few professors occupying such chairs.

   In this particular case, I’d suspect that Witten, given a chance to revise and extend his remarks, might have something a bit different to say today about this (and even back then probably would have liked to add appropriate caveats). But, no matter what, nothing can change the fact of the matter that he has a fantastic list of achievements to his name, and is a scientist of the highest accomplishment.

7. **Shantanu**
   August 23, 2011

   Note also that we don’t have a single known example of pulsar-black hole binary.

This Week's Hype, Part III

August 25, 2011
Categories: This Week's Hype

Today's [Wisconsin State Journal] covers the [String Phenomenology 2011] conference going on in Madison this week, where, according to the organizers, about 100 scientists are discussing how to "test string theory":

> The Madison conference is something of a milestone in the study of string theory, Shiu said, because it represents 10 years of thought and advances. "It means the field is moving forward, that interesting things are going on," he said.
>
> Kane agreed and said much of the conference focuses on the predictive powers of string theory. If the theory can predict the existence of certain particles or behaviors, Kane said, and those are then borne out by successful experiments at projects such as the Large Hadron Collider in Europe, string theory would become an accepted explanation for the workings of the universe.

Kane has a long history of making "predictions" based on string theory, including a 1997 Physics Today article String Theory is Testable, Even Supertestable, which gave a plot showing the masses of all superpartners, in the range of 50-300 GeV. His latest "generic predictions" from the conference are here(see page 22). These days most of the superpartners have for some reason moved up to 50 TeV, well beyond any hope of observation at the LHC. There's a gluino though at a bit above current bounds of around 500 GeV, and claims that, with the right sort of analysis, this will be visible. Once this analysis gets done, one suspects the gluino will go join its friends at much higher masses. There's also a "prediction" of the range of the Higgs mass, which happens to be within the range not yet ruled out.

Another conference going on at the moment is at Les Houches. There Luis Alvarez-Gaumé gave a survey talk about string theory, and in his conclusion he makes quite clear what he thinks of efforts like Kane's:

> One cannot make LHC-accessible predictions.

Update: After posting this, I remembered that I'd once read a much more interesting story about theoretical physics in the Wisconsin State Journal. This was from when Dirac, not string phenomenologists, came to town, and gave the paper an interview.

Comments

1. **Frank Sharkany**
   August 25, 2011

   Dirac interview was pretty funny! Keep up the good work.

2. **kane1997**
   August 26, 2011

   Technically, the 1997 Kane article in Physics Today displayed a "possible spectrum of superpartners". Kane didn't say that his graph was a firm prediction of sparticles. Nevertheless, it is a valid ponit that the spectrum of possible superparticles has always been just beyond the reach of then-currently accessible energies. So supersymmetry has always been just around the corner. The Wisconsin State Journal article is well known, but retains its humor after all these years.

3. **Thomas R Love**
   August 26, 2011

   Dirac was capable of longer sentences. After he gave a talk, I asked him if he would sign my copy of his book. He replied "I don't do that."

4. **Dathan**
   August 26, 2011

   Please take care this weekend when the hurricane hits NYC!

5. **fgh**
   August 27, 2011

   Peter, you may want to have a look at this http://www.bbc.co.uk/news/science-environment-14680570

6. **Peter Woit**
   August 27, 2011

   Dathan and fgh,

   Thanks. New York should be fine, but I don't think the field of supersymmetry is going to ever recover from the devastating effect of the recent LHC results…

7. **Shantanu**
   August 27, 2011

   Peter, just a warm-up to another possible rumor. At the taup meeting next week,
   there is apparently a press release from CRESST which claims to have found dark matter. See
   http://taup2011.mpp.mpg.de/?pg=Press

8. **anonymous**
   August 28, 2011

   Supersymmetry is a very interesting possibility to test, regardless of the fact that some researchers have oversold it. The LHC will test weak scale SUSY, assuming the machine continues to work well enough to do so, and the results will be very useful to know, whichever way it goes. This mode of argumentation — picking out extreme statements by some individuals and then making snide comments about the field based on them — is not useful. The posts on news of recent developments of various sorts are useful.

9. **Peter Woit**

August 28, 2011

Irene also turned out to be seriously overhyped. Went out this morning at what was supposed to be the height of the hurricane: found modest amounts of rain, wind gusts going all the way up to 20-25 mph. It was high tide, and the Hudson was about a foot higher than usual. Traffic was moving fine on the West Side Highway in both directions around 100th St, whereas it normally floods up here at the drop of a hat. Bought a newspaper and some ice cream, then came home. At home, turned on the TV news, which was full of frantic warnings not to go outside, 4-8 foot storm surges, 65 mph winds, etc. Also learned from the TV news that the West Side Highway was closed from 96th St. to 125th St.…

10. **Peter Woit**
    August 28, 2011

    anonymous,

    A more accurate statement than "the LHC will test weak-scale SUSY" would be that weak-scale SUSY already was tested by LEP and Tevatron null searches for superpartners, as well as null results for various indirect effects. The last hope was the LHC, and the null results it has found pretty conclusively finish this off. So, the LHC HAS tested weak-scale SUSY, and this is (or should be) over, no matter how strenuous the efforts of SUSY partisans to deny reality. Pointing out the huge differences between SUSY partisans's past and present arguments isn't just being snide.

LHC results put supersymmetry theory 'on the spot'

August 28, 2011
Categories: Uncategorized

The HEP theory community is atwitter over a BBC News story LHC results put supersymmetry theory 'on the spot' that reports from the Lepton-Photon 2011 conference in Mumbai, where more null results relevant to supersymmetry were reported. According to the story:

> Results from the Large Hadron Collider (LHC) have all but killed the simplest version of an enticing theory of sub-atomic physics.
>
> Researchers failed to find evidence of so-called "supersymmetric" particles, which many physicists had hoped would plug holes in the current theory.
>
> Theorists working in the field have told BBC News that they may have to come up with a completely new idea.

Joe Lykken, an organizer of the SUSY11 conference about to start at Fermilab, is getting worried:

> "There's a certain amount of worry that's creeping into our discussions," he told BBC News.
>
> The worry is that the basic idea of supersymmetry might be wrong.
>
> "It's a beautiful idea. It explains dark matter, it explains the Higgs boson, it explains some aspects of cosmology; but that doesn't mean it's right.
>
> "It could be that this whole framework has some fundamental flaws and we have to start over again and figure out a new direction," he said.

On Twitter, there's Carlo Rovelli gloating here, Matt Strassler (here and here) and Lisa Randall (here) claiming all is not lost. In an exchange here, Strassler notes that he's fighting to prevent the risk of "no money for your research". It's unclear if he's referring to funding for the LHC experiments or for SUSY theory. There is a real long-term danger to HEP experimental funding once the public realizes that they're not getting the extra dimensions some have promised them, but the time to fight that risk was the many years during which hype about the LHC was rampant.

Both Strassler and Kane now seem to attach great importance to the point that, in some SUSY variants, gluino mass bounds are lower than the 1 TeV of the most popular models, more like 500 GeV. Kane goes so far as to claim that the gluino will be found, at masses below 1 TeV:

> The current limit on gluino masses is not above 500 GeV. Whether the squarks are indeed so heavy is not the issue, the point is that if they are the limits on gluino masses are smaller than is often stated. I and others expect this decay to tops and bottoms is the signature by which gluinos will be found, with masses well below a TeV.

Presumably LHC searches are underway for signatures of gluinos in this mass range in these versions of SUSY. I'd be very curious to hear what the status of those searches is. If they come up negative, will SUSY proponents finally give up? New results relevant to SUSY are appearing rapidly, see the latest from CMS here and here.

For some historical perspective, something I ran across recently was a 1993 New York Times report 315 Physicists Report Failure In Search for Supersymmetry, which described null results from early days of the Tevatron. One very funny thing about the article is that much of its emphasis was on the unwieldy nature of the CDF detector, with its $65 million budget and huge number of 315 physicists.

Update: SUSY11 opens tomorrow with a talk by Murayama that incorporates the BBC News story and describes evidence against superpartners as "impressive, worrisome, but not quite there yet". No indication of when it will get there. The title of the talk: Why do SUSY in 2011?

Update: Quite interesting reading is Michael Peskin's summary talk at Lepton Photon. On the topic of this posting, he writes:

> Before the start of LHC, I expected early discovery of supersymmetry in the jets+MET signature. Many other theorists also had this belief. But, it was not correct.

and he explains why this was (large amount of fine-tuning required if superpartner masses are even as large as 1 TeV). He also explains possible ways to construct SUSY models that evade current experimental bounds while keeping superpartner masses relevant to the fine-tuning problem from getting much too large.

This week at CERN there's a workshop on Implications of LHC results for TeV-scale physics, which should have many interesting talks.

Update: Yet another technical talk about the state of SUSY searches that begins by reproducing the BBC story is today's talk at CERN by John Ellis. Ellis gives an overview of SUSY fits. The regions identified by these (pre-LHC) as the most likely place for SUSY to show up have in many cases now been ruled out. With the latest LHC data, the "most likely" region moves out to higher and higher masses, with less and less of a good fit. Ellis concludes:

> LHC data putting pressure on popular models.

Update: Another review of the SUSY situation is here (from the Physics in Collision conference). A quote from Altarelli:

> It is not time to desperate yet… but maybe it is time for depression already."

Comments

1. **Giotis**
   August 28, 2011

   Why on earth Rovelli is gloating and why these results are good news for LQG? Did LQG make a prediction about SUSY at LHC that I'm not aware of? LQG has nothing to say about SUSY, for or against (especially about SUSY at LHC).

   It's really a pity; I thought Rovelli was a modest guy and a serious scientist but he jumped at the opportunity to mislead the public and his pet theory for no good reason.

2. **Giotis**
   August 28, 2011

   "and his pet theory for no good reason."

   It should be:

“and to hype his pet theory for no good reason.”

3. **Maury Markowitz**
August 28, 2011

““It’s a beautiful idea. It explains dark matter, it explains the Higgs boson, it explains some aspects of cosmology; but that doesn’t mean it’s right.”

Forgive this comment from the laity, but as I understood it, nothing in this quote is, at first glance, correct. That being the case, I’m wondering if someone can help point me in the right direction for further reading, as I assume the problem is mine.

1) “It explains dark matter”: I was under the impression that it was *possible* that one of the super partners might have the right mass and properties to serve as a WIMP suitable for DM. I have not heard of anything more direct that that, however, along the lines of “with supersymmetry, DM is not an issue in the first place”, or, less difficult, “in order to work, susy must have a [insert super partner here] with mass of xx TeV that would exactly explain DM”.

2) “it explains the Higgs boson”: I assume he is referring to the problems with the hierarchy problem of Higgs mass. If that is what he’s talking about, I was under the impression that susy simply moved the goalposts on this problem, as it does not explain the μ problem. But is this what he is saying?

3) “it explains some aspects of cosmology”: well so does practically everything – notably the DM that was already mentioned. This is definitely something I am weak on, what does susy talk about in cosmology that isn’t part of DM?

4. **Bernhard**
August 28, 2011

That BBC article was not so good, but the journalist was probably only passing on what he was being told, there´s no way for him to judge how the LHCb results affect SUSY. Besides, people can´t complain about a little bit of hype against SUSY since in the pre-LHC era some people abused from it in the other direction.

I agree with those who say that SUSY is not ruled out and that is rather premature to make those claims. However, there is no way the LHC or even the super LHC could rule out the complete SUSY parameter space, which means that arguments such as “the strategy to find SUSY at the LHC rest upon assumptions” can go on forever.

What we should be checking is how the LHC results are messing up with SUSY motivations. I´m sure right now it´s easy to evade experimental limits in terms of affecting the SUSY “solution” to the hierarchy problem, but would it be after 2012? After, 5 10 years of LHC running?

5. **anonymous**
August 28, 2011

“There is a real long-term danger to HEP experimental funding once the public realizes that they’re not getting the extra dimensions some have promised them, but the time to fight that risk was the many years during which hype about the LHC was rampant”

Some of us have been saying this for a long time – it’s a bad coincidence (or maybe fate) that the current government funding crisis is happening at the same time that many of our theories (which have been made popular through broadcast science channels) are being proven only to be fantasies. Biology is starting to look pretty interesting …

6. **Peter Woit**
August 28, 2011

Maury,

I also thought this was fairly outrageous hype. Your explanations of 1 and 2 I think are correct, and I also have no idea what he was referring to about SUSY explaining cosmology.

Bernhard,

The LHCb results are relevant, although they’re just one more example of this problem for SUSY of it not showing up in precision electroweak measurements. Matt Reece, in his recent KITP talk, claims that these are actually a more serious problem for SUSY than not finding superpartners at the LHC. If you had seen 1 TeV squarks or gluinos at the LHC, it would be very hard to understand why they didn’t contribute measurably to cause deviations from SM predictions in the electroweak sector.

It has become increasingly difficult to come up with a plausible explanation for why experiments that should be sensitive to SUSY see nothing. With the missing superpartners at the LHC, and the new LHCb result, this may have reached the tipping point, where even long-time SUSY proponents like Joe Lykken are getting ready to throw in the towel.

7. **Emile**
August 28, 2011

Anonymous: before you enroll in biology courses, you should wait to see if a Higgs is found and if anything else shows up. Will there be a Higgs and nothing else? Too soon to bail out… (besides, have you ever seen Joe Lykken top ten list of why physicists are better than biologists?)

8. **Shantanu**
August 28, 2011

Maury, I agree you should take all such claims with a grain of salt.
in 1998, P. Ramond claimed that the Super-K results for non-0 neutrino mass point evidence for low-energy supersymmetry.

9. **anonomous**
August 28, 2011

Emile: Just saw the list and liked #3:

Particle Physics promises:
– superstrings, supersymmetry, supercolliders.
Biology promises:
– supermice, supertomatoes.

I guess we will have to settle for the big tomatoes!! What will string theorists do with their free time?

10. **Roger**
August 28, 2011

A 2006 NY Times article said, “Physicists are a bit frustrated that their results keep agreeing with the Standard Model and so far show no hint of supersymmetry.”

11. **Maynard Handley**
August 28, 2011

“impressive, worrisome, but not quite there yet”
“There’s a certain amount of worry that’s creeping into our discussions,”

Am I the only one extremely irritated by this language? “What do you mean, WE, white man”.

The discomfort these people are feeling seems fully justified by the fact that they have no qualms about speaking for the whole of physics.
Perhaps they’d be mocked a little less by other physicists if they used phrases like “this is worrying for OUR theory” in their statements? Until they learn that level of humility, personally I say to Carlo Rovelli et al “good work and keep at it”.

12. **Matt Reece**
August 28, 2011

I’m going to violate my personal rule against writing blog comments that can be easily found by Googling my name, because I want to take issue with this:

> Matt Reece, in his recent KITP talk, claims that these are actually a more serious problem for SUSY than not finding superpartners at the LHC. If you had seen 1 TeV squarks or gluinos at the LHC, it would be very hard to understand why they didn’t contribute measurably to cause deviations from SM predictions in the electroweak sector.

Rather, what I said in my KITP talk is that *flavor* is still the strongest constraint that we worry about when we think about SUSY models. I don’t agree that precision electroweak physics is a strong constraint on supersymmetry. Flavor is a strong constraint on *any* physics beyond the Standard Model: check out Table 1 of this paper by Isidori, Nir, and Perez to see just how bad. Because the bloggy audience might not know about this aspect of high-energy physics, I’ll briefly summarize. If we add generic higher-dimension operators to the Standard Model, we find that some of them associated with flavor-changing neutral currents are suppressed by a scale of 10,000 TeV (or even more if we allow them to violate CP). This means that if we had new particles that couple strongly and in a completely generic way to the Standard Model, they have to be heavier than 10,000 TeV, *way* beyond the reach of the LHC. The constraints in sensible models are *not* this bad, because the new physics isn’t completely generic: it couples weakly and often at least approximately respects the Standard Model’s flavor structure, both of which make the constraint more mild. But compared to precision electroweak, it’s a much bigger worry, and absolutely any model of new physics near the TeV scale has, as a zero-order task, to explain how it avoids causing problems with these constraints.

So how bad is this for SUSY? It’s not necessarily bad at all. One well-motivated way of breaking SUSY in the Standard Model, gauge mediation, has a special structure that’s automatically free of flavor problems. (However, it has some cosmological problems, especially if you try to embed it in a more UV-complete framework, which were second on my list of things to worry about but far beyond the scope of this comment box.) Other approaches to SUSY breaking are somewhat more susceptible to flavor problems, but are also less well-understood, depending more on high-scale physics. I gave a brief, but I think reasonably complete, list of such scenarios in the KITP talk (and Yael Shadmi pointed out that other models with somewhat more interesting possible flavor signals are still allowed). So if we see squarks, I agree that we will need “to understand why they didn’t contribute measurably to cause deviations from SM predictions,” but in the flavor sector, not in the electroweak sector — and the answer might turn out to be a mechanism we already understand, like gauge mediation.

Precision electroweak really doesn’t bother me at all for SUSY. It’s a somewhat more serious problem for technicolor (or Randall-Sundrum), which as far as we know *always* has dangerous contributions to electroweak observables, but a mild tuning can get around it, so we could just be unlucky that nature didn’t give us that hint. Flavor is the biggest constraint on technicolor/RS, just as much as on SUSY, if not more so (indeed, the most serious attempt I know to really confront flavor in technicolor is probably Markus Luty’s work on using SUSY to solve the problems!).

Anyway, let’s be patient and wait for more data and more thorough analysis of existing data. The LHC is doing amazing things, but so far we’re only seeing the first-pass results coming out. A lot more is on the way, and I for one hope for surprises….

13. **Jeff**
August 29, 2011

Matt Strassler describes in more detail his position on funding concerns, as written on the comments section of his webpage (http://profmattstrassler.com/2011/08/19/current-lhc-data-and-supersymmetry-is-supersymmetry-in-trouble).

He says:
“… a 9 billion dollar experimental facility’s long-term future [is] on the line. There are consequences to making incorrect or overoptimistic statements to the press. In my view, we need to be quite precise about what we say; the public, and the politicians that provide the money, want to know what is going on, and we will pay a price if we say one thing and then have to backtrack. And if we disagree with each other, that’s fine; it is best that the public and politicians know that there is no scientific consensus yet.”

14. **DB**
August 29, 2011

@Jeff
Human nature being what it is, I expect experimentalists and SUSY advocates to come closer together and not engage in the dogfights that Strassler fears. Why?, well, there is only one positive outcome on the cards and it plays to the interests of both camps: a discovery of a “low” energy Higgs in the 115-128Gev range. No Higgs and a simple confirmation of the standard model would be a disaster for both camps: the premature shutdown of the LHC and all that that would entail.
A low energy Higgs discovery – the only one still just about on the cards – keeps SUSY alive as the search strategies are changed to hunt for every conceivable variation in the 100+ parameter SUSY universe, and so stretch out the life of the LHC.
Bad news for those who would hate to see experimental physics go down the road of hype and false promise, but hey, folks gotta eat. And the alternative looks like no machine at all.
But lurking always in the background is the data from precision electroweak data which points to a Higgs of c.72 Gev, already ruled out by LEP2. One could argue with some justification that the LHC was built on the basis of a solid dose of hype all of its own. Tick tock, tick tock.

15. **Peter Woit**
August 29, 2011

Matt,

Many thanks for the helpful explanations about this.

16. **Maury Markowitz**
August 29, 2011

DB:

"And the alternative looks like no machine at all."

That's true, but the "no machine" case was either going to happen at LHC or the one after it. SSC's cancellation wasn't entirely surprising in that respect, and that LHC is alive is a testimonial to the very interesting funding system CERN's arranged (took notes from NASA it seems 🙂

Looking to the future, I suspect that this is the last new high-end accelerator I'm likely to live to see. There's nothing particularly interesting beyond LHC except "bad" higgs, and I suspect that funding for such a machine is unlikely to be forthcoming.

But on that note, I don't think I'll live to see man on Mars either, so maybe I'm just a spoilsport. And who knows, someone might get a surfatron working!

Peter:

Darn, I was hoping I simply didn't understand the issues well enough. I'm always looking for an excuse to pick up a new read.

17. **Bobito the Payaso**
August 29, 2011

Perhaps soon deans will count twitters when deciding on promotion.

18. **AlBme**
August 29, 2011

I can see how some researchers might be concerned over future funding over an idea that may very well fail to produce empirical evidence. On the other hand, it's an opportunity for new ideas to be considered and seriously examined. These scientists shouldn't need to be reminded that even a negative experimental result advances our knowledge of nature. The LHC is producing more data probably than any other experiment preceding it. If they bother to look, I'll bet they'll find plenty that isn't explained completely by even the Standard Model. From that, new ideas can be proposed and examined.

19. **Bernhard**
August 29, 2011

I can´t access Peskin´s talk. I´m trying it for days already but just loads forever and nothing.

20. **Peter Woit**
August 29, 2011

Bernhard,

The talk is there, it's about 6.5 MB, although downloading and opening in my firefox browser was slow and sometimes flaky. One might want to try a different browser…

21. **Jack Levitt**
August 29, 2011

Let's wait to hear what Witten has to say before we panic, okay?

22. **anon**
August 29, 2011

I can't help but feel that SUSY is in a deeply oversold condition at the moment. I'd be tempted to buy shares in anticipation of a short-term snapback rally in the fall.

23. **null**
August 29, 2011

Would not finding a Higgs rule out SUSY?

24. **Peter Woit**
August 29, 2011

null,

No. SUSY also has a Higgs, actually at least two of them. One question everyone will be asking once a Higgs is found is whether it is a SM Higgs or a SUSY Higgs.

25. **Marcus**
August 29, 2011

Giotis' first comment (with the snide omitted):
"why these results are good news for LQG? Did LQG make a prediction about SUSY at LHC that I'm not aware of? "

Yes and you are evidently not aware of it. Finding signs of SUSY would be a considerable setback for the Loop researchers. It would make it incumbent on them to incorporate SUGRA which would mean back to the drawing board for some.

The current LQG does not do supergravity. This was pointed out by Thomas Thiemann at the recent loops conference in May, where he presented a seminal paper on how to formulate LQSG. He discussed the problems to be overcome. (Also with extra dimensions.) The motivation he gave was basically to have "insurance". Suppose the LHC detects signs of supergravity and or extra dimensions, just in case let's see how the theory could adapt.

One would presumably have to abandon the results of the past few years–I'm guessing it might amount to going back to how things were around 2005 or 2006.

Thiemann and two of his PhD students have come out with several papers on this subject in the past 3 or 4 months.

So from a practical standpoint it is certainly good not to see SUSY and this is a simple observation, not "gloating", which any one familiar with the situation can make.

Here are 3 papers if you want to read up:
1. arXiv:1106.1103 [pdf, ps, other]
Towards Loop Quantum Supergravity (LQSG)

26. **Chris Austin**
August 29, 2011

Matt Reece, thanks for the clarifications. Could you comment on Lunghi and Soni's claim that "the CKM-paradigm now appears to be in serious conflict with the data"?

27. **Shantanu**
August 30, 2011

So Marcus, how then does LQG address the dark matter problem? or is the dark matter have nothing to do with electroweak scale according to LQG?

28. **Giotis**
August 30, 2011

Marcus,

It is widely accepted that LQG is not incompatible with SUSY/SUGRA and the papers you mentioned just prove this point. This is the reason why no one in this field ever said that finding SUSY at LHC would mean that LQG is wrong.

No, Rovelli is not gloating due to these technical implications you mentioned. He is gloating because he believes that not finding SUSY at LHC will be a blow for String theory at least at psychological level and LQG (as a rival) will benefit from that.

LQG has nothing to say about physics at LHC; it can't even derive GR at the classical limit.

29. **Peter Woit**
August 30, 2011

All,

Please, enough LQG/string warfare, this really isn't very relevant to the topic of SUSY.

30. **Marcus**
August 30, 2011

Shantanu and Giotis,
My reply to your recent comments addressed to me is here:
http://physicsforums.com/showthread.php?p=3476917#post3476917
I responded in some detail. You are cordially invited to continue discussion there, if you wish.

31. **null**
August 30, 2011

null,

No. SUSY also has a Higgs, actually at least two of them. One question everyone will be asking once a Higgs is found is whether it is a SM Higgs or a SUSY Higgs.

PW, to clarify, my question was what would be the ramifications to SUSY and SUSY extensions of the SM like MSSM if future LHC results rule out Higgs in the 115-145 range? So instead of finding 1 as predicted in SM or 2 as predicted in MSSM, LHC rules out the Higgs.

32. **Peter Woit**
August 30, 2011

null,

The main thing the LHC is looking for is a SM Higgs, with only one unknown parameter. If that is ruled out, it will mean only that that specific theory is ruled out. SUSY extensions of the SM contain something like a SM Higgs, as well as other Higgs fields. There are more parameters, so completely ruling out SUSY Higgs fields is trickier, but they need to have something that plays the role of the SM Higgs, so you should be able to see that.

This still wouldn't rule out the general idea of SUSY though, just SUSY extensions of the SM (ruling out Higgs, you've ruled out the SM). Whatever replaces the Higgs field and causes electroweak symmetry breaking, you can imagine a SUSY extension of that new theory existing. So, no, ruling out the Higgs does not rule out SUSY in general.

33. **null**
August 30, 2011

You answered my question thanks.

34. **Shantanu**
August 31, 2011

Peter, another article in New scientist

35. **Shantanu**
August 31, 2011

Sorry the url is
http://www.newscientist.com/article/dn20838-dont-panic-about-the-missing-higgs–for-now.html?DCMP=OTC-rss&nsref=online-news

36. **Bernhard**
August 31, 2011

Here is an article on a perhaps not most reliable magazine for scientific matters, but anyway, it´s interesting to see the SUSY hype is now going "counter stringwise":

http://www.pcmag.com/article2/0,2817,2392094,00.asp

37. **Peter Woit**
August 31, 2011

Thanks Bernhard. The comment section of that article is priceless…

38. **SpearMarktheSecond**
August 31, 2011

Perhaps the most impressive thing is we aren't replaying the mid-1980's, when UA1 (mostly) and UA2 (a little) had false SUSY signals for a while, which were really background. CMS and ATLAS are way better run with better background estimates.

The flavor sector constraints on SUSY have long been quite strong… Haim Harari among others long emphasized this point. But contemporary SUSY models all were engineered to evade the constraints from the lighter flavors, although the Bs results keep squeezing the parameter space more.

In the early 1990s all the greats testified to Congress that LHC at 14 TeV couldn't make a discovery if the Higgs got heavy… therefore the SSC with 40 TeV in the center of mass was mandatory. Although we've had an interregnum where the Higgs has been light, with good justification, maybe the multiple blurry pictures from loops of the Higgs were over-interpreted. And so the SSC scenario might be coming true.

For sure the SUSY and extra dimensions stuff was oversold. But when Columbus argued for his ships, he portrayed the riches of Asia, which he never actually obtained. So the real point is the machine builders at CERN and in the old days at the SSC CDG knew they were shooting for the highest energies possible for pure exploration. Mel Schwartz was so clear in his testimonies on this point. The outer circles of HEP experimentalists and theorists pitch SUSY and extra dimensions.

Perhaps the deeper point is… if nothing knew is seen at the LHC, even no Higgs, what next? Give up? Or build the next hadron collider in…. China? In Texas under President Perry? But a linear collider doesn't seem wise.

39. **Peter Woit**
August 31, 2011

SpearMarktheSecond,

I'm also surprised that we haven't had some mistaken "discoveries" of supersymmetry so far.

Sometime soon I should write about the question of the "next collider". I don't think extra dimensions and supersymmetry can be used to sell it if they don't show up at the LHC. Unless the LHC comes up with something that falsifies the SM, the case for a new machine is going to be difficult. Best bet I think is no Higgs, but some alternative origin of electroweak symmetry breaking. The argument has always been that the LHC is a "no-lose proposition", either it finds the Higgs or has to find something else. We're going to find out if that argument was right…

In practical terms, the most viable higher energy "next collider" seems to be a revamped LHC with higher field magnets, more than doubling the energy. But even for that, the case won't be easy to make unless the LHC gives some reason to believe that there's something to be seen at 33 TeV that can't be seen at 14 TeV. Maybe that old testimony needs to be dusted off…

40. **SpearMarktheSecond**
August 31, 2011

I think the old argument was that W's and Z's become strongly interacting under a very heavy Higgs… so you start getting W-W- hard scattering, and jets of W's and Z's like we now have jets of quarks and gluons. The weak become strong.

Good enough to justify $30 billion or something like that in today's dollars? Don't know.

Maybe an LHC upgrade is the only way to go. We've seen how hard even getting to 7 TeV in the center of mass is. But last time I checked, Europe had some money problems too. Maybe China and India can become full member states at CERN…

41. **Lee Brown Jr.**
August 31, 2011

The argument has always been that the LHC is a "no-lose proposition", either it finds the Higgs or has to find something else.

Maybe it's a bit premature, but you addressed precisely what I was wondering, "Is it possible for the LHC to find nothing?" How would physics move forward?

42. **Bernhard**
August 31, 2011

Lee Brown Jr.,

Of course this is possible, although many of us hope it won´t happen, me included.

Other fields of physics will move forward for sure, just not sure how particle physics would without new experimental evidence. Would be near to impossible to justify building another billion dollar accelerator, so in my opinion the only hope in this scenario would be to wait for technological advance to a point that to create TeV collisions you don´t need a 27 km accelerator and expensive magnets. And this possibility is in a really distant future.

43. **SpearMarktheSecond**
August 31, 2011

I think the advocates of the SSC circa 1990 most definitely argued that the LHC could find nothing. That's how the justified 40 TeV in the center of mass for the SSC… by saying that energy was necessary to confidently project observation of the new physics deemed necessary if no Higgs (or SUSY) were detected.

As far as I remember, that physics is, at high momentum transfer, W's and Z's behaving as though they had effectively strong interactions, due to new effective terms in the lagrangian necessary to forestall infinities.

Back in 1990 there was a fair amount of skepticism about achieving the luminosities now actually achieved at the LHC. Center of mass energy seemed like the bet more reliable than luminosity. So unless the Higgs pops out between 115 GeV and 145 GeV, a lot of scrutiny of the LHC's ability to see high Q^2 W/Z scattering will happen… likely interesting info is already buried in all the studies.

Maybe the achieved high luminosities prove the early 1990's arguments wrong.

If no Higgs, too hard to tell if LHC will be the high water mark of HEP, like the Apollo program was for NASA. Could be, but there are huge differences…

44. **HoldYourHorses**
August 31, 2011

Guys, the LHC was designed to run for *decades*, and after one year with no superpartners everyone is losing their minds. I get the impression people are thinking "so the LHC had its shot, found nothing, so what's next". This is nonsense.

People used to think in the 80s the top quark would be found at 30 GeV, then it was "always around the corner" until it was discovered at 175 GeV in the nineties. The moral is that we (and I speak as a theorist) are actually quite bad at predicting what nature will do.

45. **Model and Sim**
August 31, 2011

I think the what happened to SSC will go down as one of the great tragedies of our era. Its still too early to tell with LHC, but I agree with Peter that if we don't see something it will be very difficult to go to the next level. The margins simply are not there to justify such a large expenditure. High energy searches in space might be the only option in the near future.

46. **younghun park**
August 31, 2011

It is possible to think the next collider without finding something valuable at LHC
in the case of no money problem in Europe and USA. Now, Europe and USA have big money problem. Other people won't agree to bulid the expensive collider.
So, our friends in CERN have to find higgs or something else.

47. **Peter Woit**
August 31, 2011

HYH, Model and Sim,

There are two distinct issues here. The first is supersymmetric extensions of the standard model, which never had much to recommend them. Here the on-going piling up of negative evidence is finally causing believers to rethink, and that process will just continue for the next few years. To the extent that these were used as a big selling point for the LHC, that was a decision bound to incur some future cost, we'll see how large. Even more so for extra dimensional models, which virtually no one takes seriously. Using these as part of the LHC sales pitch was guaranteed to cost something in credibility later.

The real issue is the Higgs, and there the time-frame for something interesting happening is months not years, with evidence for or against a SM Higgs likely to start showing up soon, although the current situation is highly ambiguous. If there is a Higgs, the sales job for a new machine is going to be about the importance of being able to study the thing, with a serious problem the argument that "the SM Higgs theory seems to work, why spend lots of money checking it?" If there is no SM Higgs, there's going to need to be a serious effort to explain to the public why this is a major discovery, opening up whole new areas of research. There will undoubtedly be a lot of analysis of issues like the W/Z scattering one explained by SpearMarktheSecond. Unfortunately, absent the kind of breakthrough mentioned by Bernhard, viable options for making progress are limited (in particular, going into space doesn't help). Increasing the LHC energy with new magnets looks like something that could address the physics issues, at tolerable cost.

Anyway, I'm guessing that by next year it will be clear which way this is going to go with respect to the Higgs.

48. **null**
August 31, 2011

PW,
"The real issue is the Higgs, and there the time-frame for something interesting happening is months not years, with evidence for or against a SM Higgs likely to start showing up soon, although the current situation is highly ambiguous. "

do you have any idea how soon the Higgs issue will be decided at current rate of data accumulation?
It's my understanding the recently published exclusion of 145 gev and above was based on an accumulated 2 fb-1 data set? 95% confidence

Is 95% exclusion really a strong exclusion? I am aware that "discovery" is 5-sigma, so exclusion is a lower 2-sigma?

1-how many fb-1 per month is being collected and analyzed by LHC
2- how many fb-1 to find evidence or rule out Higgs in the 115-145 range? 95%

Is a 95% exclusion of Higgs in 115-145GEV acceptable to researchers to give up on the Higgs or is it more stringent? If excess events are reported at 3-sigma at 115GEV, this would be reported as a possible Higgs discovery?

49. **Peter Woit**
August 31, 2011

null,

The LHC will run with protons until the end of October. Estimates are that they'll accumulate 5 inverse femtobarns in each experiment. Latest public release of data was based on 1-2 inverse femtobarns (and no combination of data from the two experiments). There are old projections made last year about how much data it would take to exclude at 95% level all the way down to the LEP limit, I believe it was about 5 inverse femtobarns or so.

Yes, typical standards for exclusion are different than for a discovery claim. If the Higgs isn't there, there seems to be a good chance of having a 95% exclusion result, possibly using both experiment's data. If it is there, the 5 sigma standard may not get met, but a 3-4 sigma signal would start making people think something was there.

Anyway, we'll see what the data says, sooner or later….

50. **null**
August 31, 2011

PW
you answered my question. What happens after October? Do they shut down or switch to heavy nuclei, or retool for 4TEV (8 TEV total)?

Does combining the data from both channel change results?

How soon after they collect 5 fb-1 will they report their finding?

51. **Peter Woit**
August 31, 2011

null,

They switch to heavy ions in early November. After a shutdown, early next year it's back to protons, with an energy increase possible depending on the results of measurements made during the shutdown.

In principle the data gathered by the two experiments is independent, so it should make sense to combine it and improve the statistical significance of any signal. As far as I know, they have a mechanism in place to do this kind of combination, and I don't see why they wouldn't do it, after each experiment has independently reported its own combined result. I have no idea what the timing of this all will be. End of year? Earlier if one of the experiments feels they have a convincing signal and wants to announce it?

52. **Paolo Valtancoli**
September 1, 2011

I remember that Hawking doesn't believe to the Higgs boson, but believes in supersymmetry and M-Theory. I think that the idea of supersymmetry will survive for many years to come even though LHC finds absolutely null results.

53. **Peter Woit**
September 1, 2011

The latest projections about the Higgs are consistent with my comments above, and given in detail here:

http://indico.cern.ch/getFile.py/access?contribId=54&sessionId=13&resId=1&materialId=slides&confId=141983

54. **chris bolger**
September 1, 2011

Can the W+, W- and Z be considered as supersymmetric to the e+, e- and neutrino. If not, why not?

55. **Eric**
September 1, 2011

Chris,

The W's and Z are in the adjoint representation of SU(2), while the electrons and neutrinos are in the fundamental representation. Supersymmetry does not act on the group representations, and so there is no way for the W's and Z's to be transformed into e's and neutrinos by supersymmetric transformations.

56. **null**
September 1, 2011

"On the topic of this posting, he writes:

Before the start of LHC, I expected early discovery of supersymmetry in the jets+MET signature. Many other theorists also had this belief. But, it was not correct.

and he explains why this was (large amount of fine-tuning required if superpartner masses are even as large as 1 TeV). He also explains possible ways to construct SUSY models that evade current experimental bounds while keeping superpartner masses relevant to the fine-tuning problem from getting much too large."

What is the upper bound for SUSY masses while keeping superpartner masses relevant to the fine-tuning problem , and is it within LHC full design energy 14TEV, or does it evade it?

57. **Peter Woit**
September 1, 2011

null,

The problem is that there is no well-defined point at which the necessary fine-tuning is "too much". 1%? .1%, .01%???

Many people did argue before the LHC was turned on that the LEP and Tevatron bounds on superpartners (and bounds on the Higgs mass) already forced a degree of fine-tuning that made supersymmetry unlikely. In simplified terms, the scale of electroweak symmetry breaking is of order 100 GeV, and if supersymmetry breaking is responsible for this, it should be of the same order, whereas this is ruled out by Tevatron/LEP bounds.

The problem for SUSY enthusiasts is that bounds are now moving up to 1 TeV and above. They have to either give up on the fine-tuning argument, or say that 1 TeV is not a problem. Once you say 1 TeV is not a problem, there's no reason 2, 3, 5 TeV should be a problem, so it really doesn't matter how much the LHC bounds get pushed up.

The argument Strassler and some others are trying to make is a bit different. They argue that until you rule out all the different kinds of signatures (not just the simplest ones) you can get from different patterns of masses, you really haven't ruled out SUSY below 1 TeV.

58. **Bernhard**
September 1, 2011

Yes, some people are definitely giving up on the fine-tuning problem as SUSY motivation:

http://www.math.columbia.edu/~woit/wordpress/?p=3479&cpage=1#comment-81529

59. **Eric**
September 1, 2011

Peter,

Low-energy supersymmetry was formulated to stabilize the Higgs mass against radiative corrections, rather to provide an explanation of EWSB as you state above. Thus, there is absolutely no reason to expect that the superparner masses should be the same as the electroweak scale ~100 GeV. In order to make the Higgs radiatively stable, the superpartners only need to be of the order of a few TeV, not 100 GeV. When you quote this number, it gives people the wrong impression about the current degree of fine-tuning necessary for supersymmetry to solve the hierarchy problem.

60. **Model and Sim**
September 1, 2011

Thanks for the clarification. I must defer to your better opinion on the matter. I suppose null results for luminiferous aether in 1887 did lead to a revolution in physics, although it all seems a little discouraging at the moment.

61. **Marcus**
September 2, 2011

I'm not a physicist; I'm a professor of philosophy, and all I know about this stuff is the (considerable) amount of pop physics I've read, blogs like this one, and a tiny bit of online self-education. So, having drawn attention to my ignorance, I have a simple conceptual question that has been bugging me. The question is this: how is it even coherent to say (1) that the SM Higgs is supposed to give other particles their mass, and then say that (2) the SM gives no account of gravity (which is true), when we also know that (3) an object's mass is what generates its gravitational field. This looks plainly incoherent. If the SM cannot account for gravity, how COULD there be a SM Higgs (given that gravity is a matter of something's mass)? I'm sure I'm making a mistake somewhere, but where?

62. **SpearMarktheSecond**
September 2, 2011

Marcus… the Higgs gives certain fundamental particles their mass. But there are other sources of mass… most of the mass of our kind of matter is caused by energy in the gluon field between the quarks in neutrons and protons, which is not the Higgs at all. However, the masses of neutrons and protons are not quite as fundamental as the masses of neutrinos, or electrons, or quarks (the fermions), and it has been the fundamental questions that have attracted people.

Classical gravity doesn't care what the origin of the mass is… given some mass of any origin classical gravity can take it from there.

Of course everyone would like a complete unified quantum theory of it all, but we don't have that yet…. or perhaps we have too many and don't know which to pick . In any case it is unsettled.

On the no lose theorem… here is an old paper in favor of the SSC and against a center of mass energy lower than 20 TeV…

http://www.osti.gov/bridge/servlets/purl/6397394-oQaPRo/6397394.pdf

63. **Florian**
September 3, 2011

I don't particularly like SpearMarktheSecond's explanation to Marcus's question, so I offer another one.

Mass is not only associated to gravitation. Mass also measures how inert a body is. The masses one talks about in the context of the Standard Model refer to this understanding of mass.

Well, actually the masses in the SM are just parameters in the theory. We call them masses, because in some experiments particles appear to be inert (e.g. electrons in a synchrotron). Now if you want to formulate the SM in a certain way (gauge invariant), it seem to be necessary to introduce one more particle – the Higgs boson. (Otherwise putting masses for some particles in by hand would destroy gauge invariance.)

64. **Igor Khavkine**
September 3, 2011

@Marcus: There is a hidden equivocation in your logic on the term "mass". Physicists can easily spot the change in the meaning of that word from context, as partially explained by SpearMarktheSecond.

In general, *mass*, *energy* and *momentum* are distinct but related concepts and quantities. When used colloquially, the term "mass" may stand for any one or combination of them. Here are some different context where it can appear.

Inertial mass is an empirical notion which can be determined from experiments comparing the force acting on on object and its acceleration. Inertial mass is combined in a specific with an objects energy and momentum into an *energy momentum tensor* (which just reduces to gravitational mass in Newtonian gravity), which is entirely responsible for the object's interaction with gravity in General Relativity. For a *composite* object, its inertial mass is determined in a specific way from the energies, momenta and inertial masses of its *constituents*. For *elementary* (non-composite) particles, the inertial masses are determined in a specific way by parameters that enter into the mathematical formulation of the Standard Model. These parameters can be roughly split into two classes: the *particle masses* and the *interaction strengths* (aka coupling constants). Oddly enough, the Standard Model sets all particle masses (except for the Higgs boson) to zero. This means that the inertial masses of the elementary particles that we observe are entirely due to the strength of their interaction with the Higgs boson. In particular if a certain property of the Higgs boson known as its *vacuum expectation value* increases by a factor of 10, the inertial masses of all other elementary particles universally increase by 10 as well.

It is in the following sense that the Higgs boson gives other particles their masses: the strength of the interaction of an elementary particle with the Higgs boson determines its inertial mass. Since inertial mass does not necessarily involve gravity in its definition or measurement, the points (1) and (3) in your reasoning are actually logically disconnected.

65. **Anon**
September 3, 2011

Could someone explain to this naive reader what is keeping us from doing these kinds of searches with high energy cosmic rays, which commonly have much higher energies than those achievable at the LHC? Not enough supply?

66. **Peter Woit**
September 3, 2011

Everyone,

Enough about mass, this isn't a forum for general physics discussion, I can't moderate such a thing. As general advice to anyone trying to learn more about basic topics in physics, internet comment sections are not a good place for this. You're much better off getting hold of a real book, with equations, where someone competent has put a lot of effort into writing something long, careful, with equations. This is what you need to understand a basic concept like mass.

Anon,

For short questions like yours, you can get the answer from a comment section, although I really wish people would stick to the topic of the posting. Again, a general discussion area is too hard to moderate. In this case though, the simple answer is luminosity. At the LHC you have many high energy collisions every nanosecond and you may need a year's data to get what you want. If you instrument some area of the earth or space and wait for LHC energy collisions, they will be very rare events.

67. **Bernhard**
September 4, 2011

Seems the focus for the Higgs mass searches are now between 114-145 GeV by all accounts, but Bill Murray´s slide 6 points to the possibility that in fact its mas could be say 600 GeV. I thought this was almost excluded by electroweak measurements. How much not excluded is this > 460 GeV region? And of course, what does it mean for SUSY? Are there any SUSY models floating around with such a heavy Higgs?

68. **Eric**
September 4, 2011

Bernhard,

A superheavy Higgs (m> 600 GeV) would be natural in a four-generation SUSY model, since in such a case the Higgs receives large radiative corrections.

Knocking on Heaven’s Door

September 4, 2011
Categories: Book Reviews

Lisa Randall’s new book is about to come out, it’s entitled Knocking on Heaven’s Door: How Physics and Scientific Thinking Illuminate the Universe and the Modern World. It turns out that it’s really two books in one, both of which are much better and more clearly written than her previous effort, Warped Passages. One reason might be help from well-known novelist Cormac McCarthy who is thanked (together with Lubos Motl) for extensive feedback during the book’s writing.

One of the books here is not surprising, it’s somewhat of an update of the earlier book, emphasizing the story of the LHC. This includes a very detailed explanation of the history of the LHC and how it works, together with a wonderful and clear examination of the design of the ATLAS and CMS detectors, as well as the physics they are looking for. All in all, this is about the best popular-level explanation of what is going on at the LHC that I’ve seen, up-to-date as of a few months ago.

The second book inside the book is of much wider scope. Randall’s prominence as a scientist has brought her into contact with a wide range of people (Bill Clinton’s endorsement is on the book’s cover), including artists, government officials, financiers, technologists, and a wide range of thinkers of different sorts. She has taken on the role of a public face of physics, and has written a book which is in part a very general defense of science and the materialist, rationalist world-view that modern science is based on. Her experiences with non-scientists are reflected in how she writes about a range of topics, including the notion of beauty in science, the question of how to analyze risk, the relation of religion and science and much more. Her discussions of these topics are uniformly sensible, although rather conventional and unsurprising.

In the end though, the book left me somewhat uncomfortable. Understandably, Randall is overly enthusiastic about the prospects of Randall-Sundrum models, describing them as “an idea that probably stands as good a chance as any of being right” (most theorists would assign a much higher probability to SUSY). She writes that, if correct, the LHC is expected to see KK gravitons at a mass of around 1 TeV. Recently limits on masses of such particles have been pushed up to nearly 2 TeV. These extra-dimensional models were considered interesting but not especially plausible by most theorists pre-LHC. Like SUSY, they’re starting to be ruled out by the LHC, a process which may take a while until their defenders finally admit that the expected signals just aren’t there.

The time period of Randall’s career roughly corresponds to my own (she’s a few years younger), and, as she acknowledges, her field of model-building throughout this career has been dominated by string theory-inspired SUSY and extra dimensional models. These were never very convincing, and they are now biting the dust. From the experimental side, this is an inspirational story of the triumph of the scientific method and the huge achievements of the LHC machine and detectors, but from the theoretical side, the story of this period is darker and much less inspirational. It’s not something that makes the best topic for a defense of how science is conducted.

One odd thing about the book is the title, which for Randall carries a positive meaning that she acknowledges doesn’t correspond to the very dark one of the Bob Dylan song from the soundtrack of the Sam Peckinpah film. It’s a beautiful song, but one not about finding truth, but about getting shot in the gut and facing death, hopefully not relevant to particle physics in the LHC era:

> Mama, put my guns in the ground
> I can’t shoot them anymore.
> That long black cloud is comin’ down
> I feel like I’m knockin’ on heaven’s door.

Comments

1. **Proudmemberofthecult**
   September 5, 2011

   > Like SUSY, they’re starting to be ruled out by the LHC, a process which may take a while until their defenders finally admit that the expected signals just aren’t there.

   “Science advances one death at a time”: Models only ever really go away once their proponents have died.

2. **Bernhard**
   September 5, 2011

   “but about getting shot and facing death, hopefully not relevant to particle physics in the LHC era”

   Well, getting shot and facing death is basically what will happen with all this extra dimension models…

3. **Henry Bolden**
   September 5, 2011

   Peter, you’re wrong about string theory not being good for anything: it’s good for making money by selling popular books to the public. Fiction writing is still a profitable business for a select group of authors. Brian Greene and Lisa Randall are essentially part of the entertainment industry. Look for more cameos on “The Big Bang Theory”.

4. **Hamid Gupta**
   September 5, 2011

   This is a reply to Henry Bolden’s comment.

   Why you should not expect a Lisa Randall cameo on “The Big Bang Theory”.

   It has been alleged that Dr. Elizabeth Plimpton character in the “The Big Bang Theory” episode “The Plimpton Stimulation” (Season 3, number 21) is modeled on Lisa Randall. If there is any truth to this rumor then expect lawsuits rather than cameos. The fictional character is a Princeton lady cosmologist, not from Harvard, so perhaps that’s how the producers of the show might defend themselves against possible legal action. One person connected to the show allegedly said that the original script mentioned “Plimpton-Humdrum models” but this was deleted on advice by lawyers. Of course all this is probably just more internet disinformation only slightly more likely to verified than the physics of a Randall-Sundrum model.

5. **Mitchell Porter**
   September 5, 2011

   Lisa Randall already appeared on The Big Bang Theory.

6. **abbyyorker**
   September 6, 2011

   Do y'all watch TBBT? I watched one episode and it was terrible.

7. **Peter Woit**
   September 6, 2011

   abbyyorker,

   I'm a fan. Any TV show with a main character pretty much based on Lubos is bound to be a hoot.

   Sorry though, discussing the pros and cons of TV shows is really off-topic here, the discussion is fluffy enough as it is…

8. **Anne Marie Thomas**
   September 7, 2011

   Given that string theory and multiverse theories have slid from speculative physics into a form of entertainment, perhaps the discussion of TBBT is justified. By the way, which episode of TBBT features a guest appearance by Lisa Randall? I couldn't find her in Wikipedia's list of cameo appearances for the show:

   http://en.wikipedia.org/wiki/List_of_The_Big_Bang_Theory_characters

   Now, if we could only get a Peter Woit cameo on the show, that would be way cool. Readers of this blog lobby the producers for it!

9. **martibal**
   September 9, 2011

   Anne Marie: great idea ! Peter on TBBT!!
   How can we lobby the producers for it ?

10. **Sebastian Thaler**
    September 12, 2011

    Peter,

    Speaking of interesting new books, you might like the upcoming title PHYSICS ON THE FRINGE by Margaret Wertheim. Most of her book is devoted to the motivations of crank physicists and their bizarre theories, but chapter 11 includes a bit on string cosmology and multiverses. I'm pretty sure the string community will not be happy to see itself mentioned in a book like this…

11. **Peter Woit**
    September 12, 2011

    Thanks Sebastian,

    I look forward to seeing that book. Over the years I've received large numbers of documents from cranks. It has struck me that it's unclear how to distinguish a lot of multiverse papers by respectable scientists from the crank literature.

12. **Ulrich Mohrhoff**
    September 21, 2011

    "These were never very convincing, and they are now biting the dust." So why do people keep doing string theory? I found a possible answer in the April 2011 issue of *Discover* Magazine, in an interview with Lynn Margulis :

    > Population geneticist Richard Lewontin gave a talk here at UMass Amherst about six years ago, and he mathematized all of it — changes in the population, random mutation, sexual selection, cost and benefit. At the end of his talk he said, "You know, we've tried to test these ideas in the field and the lab, and there are really no measurements that match the quantities I've told you about." This just appalled me. So I said, "Richard Lewontin, you are a great lecturer to have the courage to say it's gotten you nowhere. But then why do you continue to do this work?" And he looked around and said, "It's the only thing I know how to do, and if don't do it I won't get my grant money." So he's an honest man, and that's an honest answer.

Imagine There's No God Particle

September 5, 2011
Categories: Favorite Old Posts, Uncategorized

It's easy if you try (as John Lennon would say).

The LHC is back in business after a technical stop, getting ready to collide protons for the next couple months, perhaps reaching an integrated luminosity of about 5 inverse femtobarns. This is a factor of four higher than the luminosity used in most analyses that have been made public so far, and the latest projections are that this should allow an exclusion of a Higgs over the entire expected mass range at 95% confidence level, if such a particle really doesn't exist.

My pre-LHC predictions (see here) of five years ago have held up well, and nothing yet has changed my view that a Higgs particle scenario and a no-Higgs scenario are equally likely. The best argument for a Higgs in the mass range of 114-145 GeV is that it's the simplest way anyone has found of making the Standard Model work, and explains a range of precision electroweak measurements.

The best argument against the Higgs is that elementary linear scalar fields are problematic (since not asymptotically free) and esthetically displeasing (not geometrical and constrained by symmetries, so lead to lots of undetermined parameters, mainly for the Yukawas that determine the masses of all fermions). By analogy with the theory of superconductivity though, one can imagine that the Higgs makes a good low-energy effective theory (a la Landau-Ginzburg), even if there's a more interesting fundamental theory, which may require going to a smaller distance scale (a la BCS theory). As the allowed Higgs mass range has narrowed though, I'm starting to think that there may be something to the argument that it's implausible that the mass would end up being in the hardest mass range for colliders to examine. More likely it's just not there, and the hardest range is the last one to fall to experiment.

By the way, I was interviewed about this on a Wired podcast (see here), not sure how it turned out. I don't think I said anything surprising or controversial.

The imminent arrival of an experimental result deciding the issue of the SM Higgs has focused attention on what the implications will be, and here's what I've been thinking:

If the SM Higgs is found, there will be rejoicing at first at CERN and within the physics community, and an appropriately proud announcement to the public. Debate will begin on who gets the Nobel: experimentalists? which of the 6000+ people at LHC/CMS/ATLAS? or theorists? Anderson/Higgs/Englert/Brout/Guralnik/Hagen/Kibble, or ? I gather Brout is no longer with us, maybe this will have to wait until the list gets down to three by attrition. Probably the best case would be for Weinberg/Salam, but they already were rewarded for the SM. Maybe the Swedes could make Weinberg's a double. The LHC experimentalists would have an active research program for many years trying to measure the Higgs properties. Theorists though would face the gloomy prospect that these would just agree with the SM. We'd be stuck pretty much where we have been for thirty years: no clues as to how to do better than the SM.

What though if the SM Higgs gets ruled out? CERN may consider this an embarassment, but it's actually a far more exciting result, one even more worthy of the Nobel than finding the long-sought particle. SUSY enthusiasts will claim this means it's a SUSY Higgs, and model builders will get to work on constructing more complicated models designed to explain the result by making the Higgs even harder to see (Matt Strassler is starting to write about such models here). My guess would be though that no Higgs means the argument from esthetics was right, so adding in more scalar fields in some complex pattern isn't a very plausible explanation of the null result.

A commenter here pointed out that this possibility was discussed during the debate over the SSC, when it was argued that, in the case of no Higgs, you would need a 40 TeV machine to look at W/Z scattering, to get information about what was really going on. The LHC should be capable of quite high luminosity, which may compensate for its lower energy in such searches, see a recent discussion here.

My own very vague favorite idea has always been that, non-perturbatively, there's something important we're missing in our understanding of gauge symmetry in chiral gauge theories and that this may hold the secret to the mystery of electroweak symmetry breaking. While this idea has been a motivation for research I've been pursuing in recent years, I can't claim to have made any progress on it. My second real blog posting here was about this, back in 2004, leading to a torrent of abuse. Maybe if there's no Higgs, SUSY and extra dimensions are gone, this could become a legitimate question in the eyes of mainstream theorists.

> You-hoo-oo-oo-oo, you may say I'm a dreamer
> But I'm not the only one…

Update: It seems that I'm definitely not the only one inspired by John Lennon recently, with CIP beating me to this a while ago.

Update: On the topic of this posting, see Slava Rychkov's talk that just appeared on the arXiv. From the summary:

> We have seen many impressive new physics limits set at this conference. But, have we ever truly believed in the models that are being pushed away? Z-prime, CMSSM, split SUSY, to name a few? I myself certainly never believed in these. Take Z-prime. In spite of what you may have heard, this is a completely unmotivated extension of the SM. It solves nothing of its problems and has nothing to do with Naturalness. Same for split SUSY, anathema to Naturalness. CMSSM is the only victim on the list for which I feel sorry, but we can't give up on SUSY just because this straightjacketed version of it failed.
>
> Another early casualty has been the Large Extra Dimensions scenario. But again, this was hardly a bona fide solution to the hierarchy problem. The mechanism which cuts off the Higgs mass quadratic divergence has not been concretely specified. It's only because the idea was so original that we ever gave it the benefit of the doubt. Now with LHC limits on the (4+n)-dimensional Planck scale already a factor two above the Tevatron limits, it's basically gone. The truth is, apart from SUSY, there are only two other motivated scenarios for TeV-scale physics: strong EWSB and Composite Higgs. I mentioned some of the signals expected in these models. Unlike CMSSM, they typically require much higher luminosity to be seen.

Comments

1. **Paolo Valtancoli**
   September 5, 2011

   I studied in my thesis the quantization of chiral symmetry in gauge theory in presence of anomalies. For what I remember the main problem is that the anomalies ruin unitarity. Now that I have more experience with noncommutative geometry, it is pretty natural that anomalies, being nonlocal, enter in conflict with unitarity. Maybe one should try to extend the notion of quantization, by allowing that pure states go into mixed states, i.e. introducing a microscopic arrow of time in quantum field theory.

2. **Amitabha**
   September 5, 2011

   While it is not polite to plug one's own work here, I would simply like to mention that it **is** possible to get massive vector bosons even in the absence of a Higgs particle.

3. **chris**

September 5, 2011

Paolo,

t'Hooft has been working on this for over a decade now.

4. **ru**
September 5, 2011

So I read Matt Strassler's Higgs FAQ, and he says that whether or not there are Higgs particles, there is definitely a Higgs *field*, "essentially by definition".

Do you (plural) agree with this assertion?

5. **Thomas Larsson**
September 5, 2011

No Higgs: spontanous breaking of EW symmetry is wrong.
Dynamic symmetry breaking: no expert, but know that technicolor models are already in trouble, and a Cooper pair of technifermions should effectively look like a Higgs, so probably wrong.
Explicit symmetry breaking: ouch, too ugly!!!
So if all other modes of EW symmetry breaking is wrong, how could the electro-weak symmetry be broken. Easy, by symmetry breaking 🙂

6. **Marton Trencseni**
September 5, 2011

Can someone point to a good paper that discusses/re-examines the state of EW symmetry breaking assuming no Higgs is found? Thank you.

7. **DB**
September 5, 2011

"The best argument for a Higgs in the mass range of 114-145 GeV is that it's the simplest way anyone has found of making the Standard Model work, and explains a range of precision electroweak measurements. "

Let's put on our sceptic's hat for a moment.

The second argument is iffy at best. The Review of Particle Physics (Higgs Bosons: theory and Searches, May 2010, p.12) quotes the best global fit to precision electroweak data giving the mass of the SM Higgs at 87(+35/-26)GeV. So the heaviest an SM Higgs could be, and remain consistent with precision EW is 122GeV.

This tension has been around since LEPII ruled out Higgs below 114GeV leading to the waving of many hands in the interim, not least the "reworking" of the EW fits to "incorporate" the direct search result of LEPII.

The other problem posed by Higgs is the implication of the scalar Higgs field for cosmology. Under reasonable assumptions, the vacuum energy contribution of the Higgs field results in a cosmological constant fifty times larger than the one actually measured, contributing to some of the anthropic fine-tuning nonsense, notably that peddled by a certain Steven Weinberg as far back as 1987.

Another Nobel Laureate, Martinus Veltman, has been openly derided for expressing long-held scepticism towards the Higg mechanism. It will be some irony if he is vindicated, and a catastrophe for the HEP establishement which pitched the LHC to funding politicians on the basis that the Higgs was a slam dunk.

Back 2000, Nobel Laurate Martinus Veltman was on record expressing scepticism on the existence of the Higgs Boson.

8. **Yatima**
September 5, 2011

> a catastrophe for the HEP establishement which pitched the LHC to funding politicians on the basis that the Higgs was a slam dunk

Really, why? It's not as if people holding the purse strings were promised lucite blocks with an embedded Higgs that they could show off at home. Or antigravity devices to revive the (flagging, money-printing, laden-by-social-promises-that-can't-and-won't-be-kept, arbitrarily warfaring) national economies.

There was a decision by the respective national funding agencies to go ahead and contribute to a project for which the outcome was open-ended, maybe get some redistribution effects for industry, parking space for PhDs, work for university departments as well as the occasion to do international collaboration and speeches in front of worthy audiences.

LHC did a lot more than the international space station, and no-one is embarrassed about the 150 billion USD or so that went into it.

9. **Bernhard**
September 5, 2011

"Debate will begin on who gets the Nobel: experimentalists? which of the 6000+ people at LHC/CMS/ATLAS? or theorists? Anderson/Higgs/Englert/Brout/Guralnik/Hagen/Kibble, or ?"

From the experimental side, LHC collaborations as a whole should start getting Nobel prizes with CERN director going to Stockholm to get it, representing them, not simply give to the spokesperson of an experiment. The prize should go to the whole collaboration and although I agree 10M SEK is not really much and can't pay the collaboration electricity bill, it's the correc thing to do.

From theorists, tough call…

10. **Bernhard**
September 5, 2011

But to be clear, I believe it should be a shared prize between theory and experiment, I'm just not sure which theorist should get.

11. **Chris Oakley**
September 5, 2011

At first I detested the term “God particle”, feeling that it was merely an invention of those too ignorant to understand that a particle with zero rest mass could still exist. However, given the possibilities for humour and/or relating to popular culture I am slowly coming round to it.

12. **Igor Khavkine**
September 5, 2011

    @Amitabha, about your [arXiv:1107.1501]. It’s likely that your construction is equivalent to the Stückelberg mechanism, where gauge bosons are derivatively coupled to auxiliary scalar fields instead of 2-forms (2-forms in 4d are in fact equivalent to scalar fields [Weinberg, v.I, 8.8]). However, an analysis by Dütsch & Scharf [arXiv:hep-th/9612091] shows that a Higgs field is then still required if both *renormalizability* and *freedom from gauge anomalies* are required. They are probably not the first to get this result, but their analysis is quite careful. This makes me skeptical about the viability of your construction. 🙁

13. **DB**
September 5, 2011

    @Yatima
Perhaps catastrophe is putting it too strongly, but the HEP establishment will lose a great deal of credibility with funding politicians if the Higgs doesn’t turn up, or, at least, a discovery of comparable importance is not forthcoming within a reasonable timeframe. It was seen as a pretty safe bet and sold as one. CERN, don’t forget, has been outmanoevered by the US on more than one occasion, and the prestige to Europe that would accrue from discovering the Higgs is what these politicians are really paying out for, and the other benefits that you mention are viewed by them as mere cream on the strawberries.

14. **Igor Khavkine**
September 5, 2011

    A follow up on my last comment. It seems to me that the case for a Higgs-like mechanism is solidly backed up by the requirement of simultaneous *renormalizability* and *freedom from gauge anomalies*. According to Dütsch & Scharf, allowing the theory to be gauge anomalous eliminates the need for a Higgs field and results in a model that’s apparently due to Curci & Ferrari.

    Naturally, I wonder: is known whether a Higgs field is still needed if one drops the renormalizability requirement instead? After all, to quote Weinberg: “Non-renormalizable theories are just as renormalizable(*) as renormalizable ones.” Of course, he uses the term “renormalizable” in two somewhat different technical senses. I believe that the (*) sense is the more important one.

15. **Thomas Larsson**
September 5, 2011

    Btw, Brout will not receive a Nobel for Higgs. It is not awarded posthumously.

16. **bonk**
September 5, 2011

    DB: “The Review of Particle Physics (Higgs Bosons: theory and Searches, May 2010, p.12) quotes the best global fit to precision electroweak data giving the mass of the SM Higgs at 87(+35/-26)GeV. So the heaviest an SM Higgs could be, and remain consistent with precision EW is 122GeV.”

    That’s exactly why I think that ruling out heavier higgs mass at the LHC is *evidence* for the standard model, rather than a warning that something might be wrong. But somehow many people including Peter don’t share this opinion.

17. **anonomous**
September 5, 2011

    “The LHC is back in business after a technical stop, getting ready to collide protons for the next couple months”

    This is what I fear the most – not proving or disproving the existence of the Higgs but not getting enough data by the end of the year because of a major technical outage like the one in 2008. My experience is that Murphy’s law is much like the uncertainty principle – the less you pay attention to it the larger it’s momentum gets!

18. **frank**
September 6, 2011

    Peter,

    did you reread that 2006 comment of Lubos in your blog where he answers “B” saying that the LHC “must” find something, and that it was “againt logic” that it found nothing? He wrote that the LHC “had to” find something at 1 TeV (we are already beyond that). Lets wait till Christmas, and then he should get depressed while eating his own words.

    By the way, Lubos is now claiming in his blog that the possibility that nothing happens at 1 TeV scale “is in the literature since the 1980s” – a statement which is completely false. I claim to have read every review on the standard model since that date and have not found a single mention of this option. In contrast, the general, unanimous opinion is that standard model has to break down at 1 or 2 TeV. Now that the LHC is telling us otherwise, everybody who has ever written a review with a title such as “beyond the standard model” should get a red face.

    What would be even more interesting is to have a discussion on the arguments that led people claiming that the standard model is “incomplete” or even “wrong” at 1 or 2 TeV. There are a number of such arguments, and obviously they are all wrong. The whole issue shows that nobody from the quantum field theory “experts” who abused you so much in 2006, from Distler to Lubos to Srednicki, said anything correct about the limitations of the standard model from the time they are in charge of teaching about it. (Remember how they questioned your qualifications, as if truth in physics depended on the qualification of the messenger?) I wonder how these people are doing now.

19. **Amitabha**
September 6, 2011

    Igor, this discussion is not strictly on-topic, so Peter is unlikely to encourage its continuation, but I would like to mention that the recent paper is only a part of the story — you may want to look at Phys. Rev. D63 (2001) 105002 regarding renormalizability, and bring the discussion to email if you wish.

    And this is not the Stuckelberg mechanism — the two-form is not dual to a scalar. Weinberg’s statement about equivalence is not very useful when the fields have cubic or higher couplings — even though there is only one degree of freedom (per gauge index), which you can think of as a scalar, it is not possible to write the theory as a local field theory in terms of that single degree of freedom. But you probably knew that already.

If a theorem claims that a Higgs field or similar is `required', it usually assumes that all degrees of freedom appear as local fields in the action. Even though the two-form action is local, the actual degree of freedom does not appear in the action in a local combination. IIRC that is why these theorems are not applicable to this case.

20. **OhDear**
September 6, 2011

frank, your comment is way premature. The LHC has not shown there is nothing going on at the TeV scale. We are not "beyond" 1 TeV (only cMSSM and other constrained variants are ruled out). The time may well come for red faces among BSM physicists, but that time is not now.

21. **mark**
September 6, 2011

+1 to OhDear

All thats been ruled out are the simplest SUSY models surely? We are hardly at the point where you have to concoct absurdly contrived models to explain its absence (yet).

22. **Paolo Valtancoli**
September 6, 2011

I think that physicist should learn from the failure of LHC a simple pratical principle, i.e. that Nature is essential, nothing that you see is superfluous. That's why I am convinced that all the models proposing a river of extra particles to be detected have
a lot of chances to be wrong.

23. **Bernhard**
September 6, 2011

Peter,

I wonder if the Higgs is not discovered (and this seems more and more plausible) if people will shift the holy grail of physics research to electroweak symmetry breaking, as you have been discussing for years now. Personally I think it's also a fascinating but more tangible question, perhaps one we really need to answer properly before worrying too much with gravity. In any case, would be ironic to see the very same people who fought against you some years ago to engage in the activity you pointed out as the most important one… 😀

24. **Charles**
September 6, 2011

I think the big question is what if it is determined there is no "boson" (it could be a composite particle) but there is a mechanism? I am not sure that is being clearly stated or addressed here. Or I am not getting it (quite possible).

What does LHC do?
What does the Nobel Academy do? (PH gets a lot of credit for this "sentence" on the boson)
What happens to the SM?

Thanks.

25. **DB**
September 6, 2011

A curious PR release from the Tevatron to Reuters claims that it will be in a position "to rule out the existence of a Higgs boson with a mass within the most likely range" before is shuts down for good on September 30th. Is this a last attempt at an end-run around the LHC:? "we discovered the non-existence of the Higgs before you did"!

http://www.reuters.com/article/2011/09/05/us-science-higgs-idUSTRE78445C20110905

Of course, the phrase "with a mass within the most likely range" can be interpreted many ways.

26. **AcademicLurker**
September 6, 2011

CERN, don't forget, has been outmanoevered by the US on more than one occasion, and the prestige to Europe that would accrue from discovering the Higgs is what these politicians are really paying out for

Hasn't Europe in a sense already won on the prestige issue? With the U.S. powering down its colliders, CERN is now the only game in town*, in terms of experimental HEP.

*to use a phrase that's much disliked around here…

27. **Peter Woit**
September 6, 2011

DB,

I think the caveat here is that, while a fully complete, combined D0+
CDF analysis with all the Tevatron data (up to shutdown at end of Sept) might be able to rule out a Higgs in the interesting region above 114 GeV, my understanding is that the schedule for availability of this is the summer 2012 conferences. The LHC experiments have huge numbers of people to throw into these analyses, not so at all at the Tevatron these days. So, even if this works, it may come out after the LHC has already put out results about this. A good thing to have such very independent results though…

28. **Igor Khavkine**
September 6, 2011

Amitabha, I see now that you are right about the 2-form field not being equivalent to a scalar via a local field redefinition. I'm still skeptical about both renormalizability and non-anomalous gaug invariance being satisfied, but I'll look into it. In any case, not being an expert in this area, I'm now happy to know another method (other than Stückelberg's) of representing a system with second class constraints (Proca's massive vector bosons) as one with only first class constraints. At the very least, your paper points to some interesting literature.

29. **Bernhard**
September 6, 2011

AcademicLurker,

true, but only if the experimental activity "here" in Europe lead to a discovery, otherwise we are all going down.

30. **Peter Woit**
September 6, 2011

frank,

Despite what one might think from the various hype fed the public, my impression of the situation has always been that virtually no one ever believed extra dimensions would show up at the LHC. As for SUSY, while it's the most popular of "BSM" ideas, I still suspect that the median particle theorist would always have assigned it a probability of showing up at the LHC of somewhat less than 50%. So, the median theorist is probably not too surprised at no extra dims and no SUSY, but may have expected something unexpected to show up by 1 TeV, if not SUSY.

Most theorists are aware of the argument that, if no Higgs, something else must show up to make WW scattering unitary, and that's part of what people typically are thinking of when they say: if no Higgs, must be something around 1 TeV. This argument is going to get vastly more attention if the SM Higgs gets ruled out, which will be a very good thing. The basic problem for years is that theorists like to work on relatively easy problems in well-understood frameworks (like SUSY), not spend time banging their heads on a problem for which no one has a promising idea.

31. **Peter Woit**
September 6, 2011

OhDear,

Besides SUSY, as I mentioned, limits on RS KK gravitons are already getting towards 2 TeV, and there's lots of other exotic physics searches also ruling things out to that energy scale. From trying to follow the arguments about the state of SUSY searches, my impression of the situation is that they are already filling in holes in parameter space pointed out by model builders, and describing the situation as "no strongly interacting superpartners below 1 TeV" is a reasonable description of the generic situation, although of course special classes of models can always be found for which the bound is lower. Something else I don't understand though is why anyone would believe there's a large probability that the gluino will show up precisely above 500 GeV but below 1 TeV, making it worth their time to argue much about this.

32. **Mark**
September 6, 2011

"Something else I don't understand though is why anyone would believe there's a large probability that the gluino will show up precisely above 500 GeV but below 1 TeV, making it worth their time to argue much about this."

My best guess as to why Kane would make such a claim comes from this paper:
http://arxiv.org/abs/1105.3765

In particular, in eq. 2, where the first two terms on the right hand side almost cancel out, the next term denoted by R(t) contains a product A0*M3 (see the expression above eq. 3) where A0~O(10-50) TeV and M3 is directly related to the gluino mass. So, I suspect that for such models with very heavy scalars and trilinears Radiative Electroweak Symmetry Breaking , where the Higgs vev is of O(100) GeV, becomes much harder to achieve when M3 goes above 1 TeV because of the A0*M3 contribution. Again, this is just my guess.

33. **VP**
September 6, 2011

Looks like CERN might be preparing for the possibility of "No God Particle". In the agenda of last June's Scientific Policy Committee meeting there is a talk with the title:
"Interim report on: The scientific significance of the possible exclusion of the SM Higgs boson in the mass range 114-600 GeV and how it should be best communicated."

34. **Peter Woit**
September 6, 2011

Mark,

I see that that's a carefully constructed example of a model with this feature, I still don't understand why anyone would believe it….

35. **Charles**
September 6, 2011

"CERN, don't forget, has been outmanoevered by the US on more than one occasion, and the prestige to Europe that would accrue from discovering the Higgs is what these politicians are really paying out for"

This outcome is one of the sub-plots of the story. It is not just CERN vs. FermiLab but making the "Higgs" a true European story from theory to discovery. Folks are working together to make this happen at CERN and ultimately in Stockholm. Guralnik made this point in a historical survey from a theorist perspective (*quoted on this blog months back*). I'm also told t'Hooft also feels **strongly** the "Higgs" is an opportunity to make good on previous Stockholm snubs for European Nobels in favor for US scientists. The Veltman/t'Hooft Nobel paper listed all the 1964 theorists and referred to it as the "Higgs-Kibble mechanism". Since being buttressed by the Nobel, it is the BEH Mechanism whenever he speaks or writes on the topic.

Time will show if this broader European strategy is successful. Recent results from LHC certainly make it more interesting.

36. **Peter Woit**
September 6, 2011

Charles,

Thanks. I haven't followed the twists and turns of the names used over the years, but I did do my own historical research last year on the early literature, results were in this posting:

http://www.math.columbia.edu/~woit/wordpress/?p=3282

37. **Rick Ryals**
September 6, 2011

Nobody has an answer for "ru"… ?

38. **Peter Woit**
September 6, 2011

Rick Ryals,

I left that comment there in case it attracted an interesting response, but I'm not surprised it hasn't. It's not really well-defined (what exactly do you mean by "Higgs field" and what exactly do you mean by "by definition). Even choosing ways to make the question well-defined, it's a complicated issue. And, all in all, I think trying to start discussions here of material on someone else's blog is a bad idea. Better to discuss it over there, where the text explaining what the author means is in place, and he can clarify it as needed.

39. **Mark**
September 6, 2011

"I see that that's a carefully constructed example of a model with this feature, I still don't understand why anyone would believe it.…"

To be fair, Kane has been heavily advertising such a model during the past 4 or 5 years, while most SUSY folks, especially gauge mediators, were expecting light squarks and sleptons to show up, and I'm not surprised that as the CMSSM gets ruled out these ideas will draw more attention. Models with a split spectrum have been around for a while but the amount of splitting and the scale of SUSY breaking in bottom up approaches was always kind of arbitrary. On the other hand, Kane's example is actually rooted in a top-down approach (see his work with Acharya et al), where the gaugino-scalar splitting is highly constrained. I personally don't know how general such a spectrum really is but I do know that gaugino mass suppression relative to the gravitino mass is rather generic in many string compactifications, while scalar mass suppression is much "less generic".

40. **Rick Ryals**
September 6, 2011

"I left that comment there in case it attracted an interesting response…"

Okay, Peter, that's what I was hoping for too, since I've already been to that blog and had some conversation with the author. Anyway, thanks for the reply.

41. **SpearMarktheSecond**
September 6, 2011

Thanks for finding the Govoni talk, Peter. Looks to me like page 23 indicates the LHC is not very promising for like-sign W's. But maybe page 17 indicates W/Z scattering is hopeful in distinction from background… the raw number of events is awfully low, however.

If the Higgs really is discovered between 115 GeV and 145 GeV, that will be amazing and should make heroes out of everyone involved. It is too easy to let the hype detract.

Sure, there is always hype. Without hype there would have been no machine. The only guaranteed route to a totally predictable outcome is to do nothing… then for sure nothing gets discovered. If scientific funding had been easier for the last 20 years, the hype could have been dialed down. So I'm definitely in favor of copious forgiveness for the hype, particularly if the Higgs is 115-145 GeV.

If no light Higgs, and the SSC was the right machine, darn, darn, darn.

42. **Thomas Larsson**
September 7, 2011

Looking back at my previous comment, I realize that it makes little sense. Fear of Peter's censorship made me mutilate my comment into incomprensibility. So let me write a comment which is both on topic and does not explicitly mention my own work. A reference for the statements below is chapter 4 of Pressley-Segal: Loop groups.

If the LHC does not see a Higgs, spontanous symmetry breaking is wrong (modulo more epicycles), and EW must be broken in some other way. The mechanism which has not been beaten to death by generations of physicists is anomalous symmetry breaking.

To be precise, by a gauge anomaly I mean an extension of the group of gauge transformations, as in "the conformal anomaly is the central charge in the Virasoro algebra". The group of gauge transformations in Yang-Mills theory has two types of extensions: the Mickelsson-Faddeev group, which is responsible for the anomalies found in QFT, and the central extension. The former has no unitary reps of quantum type (Pickrell 1989) and can hence not be used in physics. Anomalies of MF type must cancel, as they do in the SM.

In contrast, the central extension does have unitary reps – in fact, the unitary irreps are classified in PS – and hence it may provide a mechanism for anomalous symmetry breaking. However, this extension does not arise in QFT, so if it is responsible for EW symmetry breaking, one must go beyond QFT. Unfortunately, I did not manage to turn this observation into useful physics, but my shortcomings do not change the mathematical facts above.

43. **Giotis**
September 7, 2011

Peter,

Do you doubt that there is a field with a non zero VEV that breaks EW ?(*regardless* of its nature, properties and particle manifestation)

44. **Bernhard**
September 7, 2011

"Take Z-prime. In spite of what you may have heard, this is a completely unmotivated extension of the SM. It solves nothing of its problems and has nothing to do with Naturalness."

I strongly disagree with such a claim. Z´are neutral bosons that appear in many extensions of the SM, also in the most conservative, strongly motivated and only relying in model building rules for renormalizable gauge theories, such as the 331 models. It´s not correct to say these models don´t solve SM problems. I quote the generation problem, the solution of the strong CP problem and the explanation of the heavy top quark mass as a few. Not to say I am because of that a strongly believer, but the statement is incorrect.

45. **Bernhard**
September 7, 2011

sorry, *strong believer*

46. **DB**
September 7, 2011

@Peter
"while a fully complete, combined D0+ CDF analysis with all the Tevatron data (up to shutdown at end of Sept) might be able to rule out a Higgs in the interesting region above 114 GeV, my understanding is that the schedule for availability of this is the summer 2012 conferences."

Dmitri Denisov of DZERO is on record in July as saying "We should be able to exclude the Higgs particle or see first hints of its existence in early 2012".

A key factor is that the Tevatron can detect the dominant mode of Higgs decay into quark anti-quark pairs, whereas due to its high QCD background the LHC is forced to look for the much rarer Higgs decay to pairs of W bosons decaying to two photons and therefore is at a disadvantage in the lower end of the remaining 114-145GeV range.

The LHC has more bodies yet the Tevatron has more experience. Reminds me of the tortoise and the hare.

That the Tevatron intends to race the LHC to the finish line is definitely the sense I get from reading the Fermilab PR release. Time will tell if it's just bravado but I hope they make a real race out of it.

47. **Peter Woit**
September 7, 2011

Giotis,

If there is no Higgs field, I think we really just don't understand what is going on. One possibility is that there's some other field (elementary or composite), with some other dynamics, that does what the Higgs field does. But there may be something else going on. How gauge degrees of freedom get handled in chiral non-abelian gauge theory is very tricky, maybe there's some subtlety there we're missing.

48. **null**
September 7, 2011

DB "A key factor is that the Tevatron can detect the dominant mode of Higgs decay into quark anti-quark pairs, whereas due to its high QCD background the LHC is forced to look for the much rarer Higgs decay to pairs of W bosons decaying to two photons and therefore is at a disadvantage in the lower end of the remaining 114-145GeV range.

The LHC has more bodies yet the Tevatron has more experience. Reminds me of the tortoise and the hare."

Since Tevatron intends to shut down at the end of Sept, 2011, will it be able to present results in the interesting region of 115-145Gev? How long after Sept 2011 will Tevatron announce its results?

49. **SpearMarktheSecond**
September 7, 2011

Or maybe it is simply that the Higgs field is there, but the width of the Higgs is a whole lot larger than we expected, due to couplings to (as yet) unknown particles. I'm not aware of limits on the width of the Higgs from the precision electroweak, although maybe someone has looked into that. If only SM couplings, then we'd know the width up to QCD. But perhaps the width should be viewed as a parameter to be measured, in which case, maybe the Higgs can be so broad as to be everywhere, smeared out.

50. **Chris Austin**
September 7, 2011

DB:

"the vacuum energy contribution of the Higgs field results in a cosmological constant fifty times larger than the one actually measured,"

I think you mean about 10^{55} times larger than measured. The observed cc corresponds to a vacuum energy density $ \Lambda / (8 \pi G_N) $ of about (2.3 x 10^{-3} eV)^4, while the Higgs vev gives in order of magnitude about (100 GeV)^4.

51. **Joe S**
September 7, 2011

If the Higgs is 'found', I predict people will begin naming their firtborn male child by the particles name.

52. **Anonymous**
September 7, 2011

I once read in an article (of which I don't seem to remember the name or author(s)) that a pseudo-Riemannian metric or frame field may act as a Higgs field. The article dealt with the mechanics and its consistency with the electroweak Higgs mechanism. This, albeit just like a scalar Higgs field, would shed light to the problematicity and inelegance of elementary scalar fields unlike the scalar Higgs, and would explain the origin of the Higgs and why it occupies every point in space, since the metric/frame field is simply a property of space-time, and every point in space has a metric. Also when it is switched from Einstein frame to Jordan frame, the scalar Higgs mechanism is recovered. Thus this would be a more than decent argument to resort to whether the Higgs is found or not.

53. **Peter Woit**
September 7, 2011

Anonymous,

I've always had some fondness for the idea that the Higgs field has something to do with the choice of a time direction. But the problem with any of the many ideas around that interpret the Higgs field as some element of space-time geometry is that you need to come up with a real consistent and complete theory, i.e. at least a

Lagrangian or something. You'll need to explain where the Yukawa couplings come from, and thus you'll explain all particle masses. Since you're unifying a crucial element of the electroweak theory and the space-time geometry, set by gravity, you probably also need to figure out how to quantize gravity and unify it with the Standard Model….

54. **DB**
September 8, 2011

@Chris Austin
Thanks Chris, I meant, of course, fifty orders of magnitude.

@SpearMarktheSecond

Actually the decay width of the SM Higgs is only 10MeV for a Higgs mass < 135GeV and is much too narrow to be measured by the LHC. The very narrow width is governed by the dominant decay to quark anti-quark pairs in this energy range and is not related to precision electroweak fits, it's a theoretical calculation. The RPP reference I gave above has a nice plot of SM Higgs width vs mass on page 9 (figure 4). For a Higgs mass above 145GeV the width expands dramatically but ironically the LHC has ruled those masses out. If the Higgs exists in the range still open to it, the LHC is not well-placed to elucidate its properties; you really need a muon anti-muon collider to achieve the precision necessary to measure such narrow widths. Fermilab is planning to build one but will they get the money?

@null
Who knows? If the Tevatron shut down six months from now it would make little difference to the huge dataset they already have, since they have virtually maximized the data taking capability already, whereas the LHC needs to and is aggressively accumulating data and is at a disadvantage anyway in the lower end of the 115-145 GeV range. It's also not clear to me whether DZero and CDF are now pooling their resources compared to Atlas and CMS which, AFAIK, are still operating as independent competing teams. Morale might also be an issue at the Tevatron. And there is the complicating factor that quite a few researchers have a foot in both the Tevatron and LHC camps.

55. **Peter Woit**
September 8, 2011

DB,

Do you really need a muon-anti-muon collider to measure the SM Higgs width? Why couldn't it be done with the ILC or CLIC? Besides money issues, my understanding is that it's still not at all clear if the technology for a muon-anti-muon collider (and detectors…) is even feasible. One surprising problem that comes up is a radiation hazard from so many neutrinos…

56. **Bernhard**
September 8, 2011

And are we also going to be sure about the "Higgs" spin at the LHC if it has a low mass?

57. **Rhys**
September 8, 2011

@DB
I think the point about the Higgs width was that hidden sector fields can have renormalisable couplings to the operator |H|^2, where H is the Higgs. This won't affect its production rate at a collider, but will certainly increase its width if it is kinematically allowed to decay to such hidden sector states.

58. **Bernhard**
September 8, 2011

This article http://arxiv.org/abs/hep-ph/0212396 for example seems to implicitly indicate this is going to be at least inconclusive.

59. **SpearMarktheSecond**
September 8, 2011

Sure, DB, if the Higgs couples exclusively to the SM particles. But maybe, as Rhys points out, there are other as yet undiscovered fields that the Higgs couples to that broaden it. Maybe the Higgs is so broad that it is under the LHC backgrounds.

A limit plot that treated the Higgs width as an unknown parameter would be an interesting CMS/ATLAS output.

I think one of the well-known members of the I-missed-the-J/Psi club had a nice plot in their thesis that included resonance width… at that time no-one expected the *narrowness* of the J/Psi, and so scan points skipped over the resonance. But a proper limit was still made, where the limit admitted the possibility that a narrow resonance would have been passed over.

Maybe a *wide* Higgs would be passed over with current searches.

60. **DB**
September 8, 2011

@Peter
Given a Higgs width in the 10 MeV range a muon antimuon collider is your only option. This is because the production of Higgs at high rates in the s-channel is a unique feature of muon colliders – whence the moniker "Higgs Factory". (s-channel is the scattering mode that describes the gluon-gluon fusion leading to Higgs as an intermediate particle which then decays to a bottom antibottom quark pair – this largely dominates if Higgs is around 120GeV and unlike the LHC, it's what the Tevatron is tuned to observe). Next, you have very small radiative losses (vs electron colliders) which allow you to achieve extremely narrow beam energy spreads. Plus, you can determine the beam energy very precisely using the time-dependent asymmetry from the polarized muons in the beam itself. Also, because the Higgs couples to particles based on their mass, an electron-positron collider will generate too few Higgs vs its much heavier cousin, the muon. In turn, this enhanced coupling of the Higgs boson to the muon makes for an ideal opportunity to perform ultra-high precision measurements of the Higgs mass. Finally, because of the greatly reduced radiative losses (bremsstrahlung) you can design circular muon colliders in lieu of the traditional linear ep colliders. It's this unique combination of features that gives a muon collider its preferred status as a high-precision probe of *low* mass Higgs properties.
That the LHC would need help in measuring Higgs properties is no surprise. Electron-positron colliders have long been been the backbone of the high-precision measurements of Standard Model parameters, the LEP2 studies of the Z boson being a prime example. Lepton colliders are just better suited to high precision measurement than their hadron equivalents.
As to the high levels of neutrinos from decaying muons, this is a considerable bonus, because of the high luminosity of the resulting beam and the fact that its flavour content is precisely known makes it an excellent source for neutrino spectroscopy. In addition, it's expected that muon decay within a storage ring can be greatly reduced

using ionization cooling so that decay can be tuned as and when secondary neutrino experiments require. This is currently the object of study of the International Muon Ionization Cooling Experiment (MICE), which recently became operational and is due to complete its work in 2015 or so.
Ultimately, a great deal depends on precisely where the Higgs boson is found. If it's below 120 GeV then you simply need a muon collider if you want precision measurements. As we move above 120GeV, and especially above 130GeV, the charged vector boson decay process rapidly takes over from the s-channel as the decay width expands dramatically. Then traditional linear collider alternatives such as CLIC become competitive. After all, they have two orders of magnitude higher luminosity than a muon collider and there is less technological uncertainty associated with them, and since the Higgs width is now much wider, and the s-channel no longer dominant, the unique precision of the muon collider is less relevant.
But in any event, the recent exclusion of Higgs above 145GeV has already done serious damage to the rationale and justification for CLIC and will do the muon collider case no harm at all, assuming, that is, that we find the Higgs.

(For more detail see Berger's article in Lee (ed.) Search for the Higgs Boson, p.85-99, Nova Science 2006)

@Rhys, Spearmark the Second
I simply don't buy into such open-ended speculative scenarios and was just responding to the query re Higgs width.

61. **jpsi**
September 8, 2011

There are many people who missed the J/psi. Leon Lederman was prominent amongst them. Lederman ran an expt at the AGS at BNL, and found something which came to be called "Lederman's schoulder".

http://www.science20.com/quantum_diaries_survivor/blog/say_week_ledermans_shoulder

With the benefit of hindsight this is now known to be due to production of the J/psi. The BNL management wanted someone to propose an experiment to investigate the Lederman shoulder, but years went by. In the meantime Lederman went to CERN and ran an experiment at the ISR, but so much `background noise' was coming from the mass range of 3.1 GeV/c^2 that they cut it out. Also at the ADONE ring at Frascati, Italy, they found background noise from the mass range of 3.1 GeV/c^2 and they cut it out. At the same time the CEA (Cambridge Electron Accelerator ~ MIT/Harvard) reported an increase in R (ratio of e+e- –> hadrons/e+e- –> mu+mu-) consistent with the creation of a new quark. But nobody believed CEA because it had lost credibility because of prior publication of false claims. Finally Sam Ting proposed an experiment (at the AGS at BNL) which did the job. (Although Ting did not specifically propose his experiment to investigate the Lederman shoulder.) Ting's experiment was sufficiently detailed that it proved the existence of a new particle of width less than 10 MeV/c^2 (the J). Then it becomes the well-known story of how Ting delayed publication, and Richter's team at SPEAR (using the Mark II detector) discovered the psi, and there was no doubt of the existence of a narrow resonance, with width less than 1 MeV/c^2 (the psi). It was only after that, that the various puzzling results were recognized as the J/psi.

So one hopes that there is not a similar glossing over of backgrounds (or false assumptions about what constitutes `noise') or whatever, especially given that this time around people are specifically searching for the Higgs.

62. **jon**
September 8, 2011

To expand on what VP mentionned, what I've noticed is that:
1) last june there has been such an interim report (see this page) presented as "Given the level of public investment and interest in the LHC and implications of the LHC's discovery potential for the natural and human science fields, the Council *underlined* the importance of a policy on communicating discoveries at the LHC that was geared to providing information accessible to politicians, the general public and other scientific disciplines and not just to the particle physics community"
2) the final report will apparently be delivered on september 15 by the Chairman of the Scientific Policy Committee (see http://indico.cern.ch/conferenceDisplay.py?confId=152955).

But not sure what to make of that: that's his job after all to plan for every possible outcome, just in case, not necessarily anything to do with as yet undisclosed data.

63. **DB**
September 8, 2011

"gluon-gluon fusion" should of course read "muon antimuon interaction"

64. **Chris Austin**
September 8, 2011

DB, thanks for the fascinating info on muon colliders. Am I correct in thinking that "gluon-gluon fusion" here is a typo for "muon-antimuon fusion" via the Yukawa coupling? The idea being that you would tune the beam energy to the Higgs peak, as they did with the Z peak at LEP2?

65. **SpearMarktheSecond**
September 9, 2011

@DB, perhaps the muon collider, and also all the SUSY scenarios involve speculation too… in the old days one had to measure a particle's mass, spin, width/lifetime, parity, and C (when pertinent) to declare it a particle. It seems a bit less than open ended to work out Higgs limit plots with a variable width, but that is just my opinion.

@jpsi, great stuff, great stories. There are so, so many with the J/Psi. Let's pray for a rerun with something new!

66. **DB**
September 9, 2011

@Chris
For a suite of Feynman diagrams that show the various ways muon-antimuon interactions can generate Higgs see the Higgs/Scalar Physics section of http://home.fnal.gov/~rruiz/FeynLib/

You're correct, in a Higgs Factory, muon collider centre-of-mass energy is set equal to the Higgs mass. Then this centre-of-mass energy is varied over a narrow range so as to scan over the Higgs resonance. One of the benefits of LEP2 having excluded the Higgsbottom anti-bottom pairs which would have compromised a muon collider's sensitivity to Higgs. So if there is a Higgs around 120 GeV, then a muon collider is really in the sweet spot as far as not only precisely determining Higgs parameters, but also in distinguishing between SM and SUSY versions of Higgs.

One further point about Peter's neutrino shielding issues: Using a conventional accelerator as a beam source of neutrinos, as originally proposed in the late fifties by Pontecorvo and Schwarz and implemented at CERN in the early sixties, does require massive shielding, because here you smash protons into a target, generating a large number of pions which have to then decay over a distance into muons and neutrinos. Similarly if you are using a nuclear reactor as a neutrino source where you are restricted to antineutrinos and cannot generate collimated beams. But muons just decay into electrons/positrons which are easy to shield.

67. **DB**
September 9, 2011

That should have read: One of the benefits of LEP2 having excluded the Higgs below115GeV is that there is very significant background at the Z-pole via Z–>bottom anti-bottom pairs which would have compromised a muon collider's sensitivity to Higgs.

68. **Peter Woit**
September 9, 2011

DB,

What I was referring to is a different potential problem, the intensity of the neutrino beam from the muon decays being high enough to create an unshieldable radiation hazard off-site, see for instance here:

http://www.hep.princeton.edu/~mcdonald/mumu/johnson/neutrino.pdf

69. **Ric - ½ g tr(Ric) = 8πT**
September 9, 2011

Now if the Higgs is discovered it would be horrible. The tabloids will be screaming the variants of "Physicists have found God" for the next few weeks or even months.
–
Also, for Anonymous's comment, here are some articles that might be of interest:
– I. Kirsch, A Higgs mechanism for gravity, Phys. Rev. D72 (2005) 024001; arXiv: hep-th/0503024
– M. Leclerk, The Higgs sector of gravitational gauge theories, Annals of Physics 321 (2006) 708
– D.Ivanenko, G.Sardanashvily, The gauge treatment of gravity, Physics Reports 94 (1983) 1
– L. Nikolova, V. Rizov, Geometrical approach to the reduction of gauge theories with spontaneous broken symmetries, Reports on Mathematical Physics 20 (1984) 287
– G. Sardanashvily, O.Zakharov, Gauge Gravitation Theory (World Scientific, Singapore, 1992)
Interesting indeed.

70. **Peter Woit**
September 9, 2011

Ric,

It should be made clear that those articles are about the idea of using gauge symmetry and spontaneous symmetry breakdown in GR, and this, until somebody has a really good idea about unifying quantum gravity and the SM, has nothing to do with gauge symmetry and spontaneous symmetry breakdown in the the electroweak theory, which is what the LHC results are relevant to.

71. **DB**
September 9, 2011

@Peter

To be able to examine a 120GeV Higgs with a muon collider, the Fermilab studies concluded one would only need a centre of mass energy sqrt(s) in the range 100-500GeV, commonly known as the FMC or First Muon Collider. The paper you cite only considers high energy muon colliders in the 1-4TeV range where the neutrino radiation begins to become a serious concern. However, even the authors conclude "For CoM energies *exceeding 4 TeV* (my emphasis) some countermeasure must be adopted to limit the radiation dose". Furthermore it takes no account of muon ionization cooling which would be expected to contribute significantly to reduced muon decay and lowered neutrino radiation levels. Incidentally a 4TeV version is considered the ideal machine to fully explore strong vector boson scattering – a far cry from the 40TeV estimate required for the SSC.

In any case, it's difficult to imagine building a 4TeV collider without having prototyped the various novel technologies with an FMC in the first place.

72. **null**
September 10, 2011

Db,

What do you think the likelihood of finding or not finding a Higgs by Dec 2011, given that Tevatron is shutting down Sept 2011 and LHC will complete its run by Oct, 2011?

If there is no Higgs, then does the 10^55 cosmological constant/energy density no longer a problem (i.e QFT calculation for particle physics for cc can be close to the astronomical cc)

73. **Sakura-chan**
September 11, 2011

Happy B-day Peter!

74. **Shantanu**
September 12, 2011

Peter slightly OT, but given that the nobel prize will soon be announced, what do you think of http://arxiv.org/pdf/1109.1972v1

75. **DB**
September 12, 2011

@null
For a good analysis of this issue, see Richard Ruiz's Sep. 1st updated posting on Quantum Diaries, especially Figure C:
http://www.quantumdiaries.org/2011/08/29/presusy-2011-natures-little-secrets/

I'll just recast that table:
Exclusion of SM Higgs: Excluding an SM Higgs Boson at 95% confidence level down to 114 GeV requires *significantly less data than discovering same to 5 sigma over the same range*. As I'm unsure as to whether Ruiz's numbers are correct for the 95% confidence exclusion I won't quote them here but in any event both LHC and Tevatron should have enough data already to do this.

Discovery of SM Higgs: For a 5 sigma detection of a SM Higgs based on a joint analysis of Atlas and CMS data *their simulations* project that they need the following:
Down to 140GeV: 1 fb-1 for each experiment separately and subsequently combined
Down to 128GeV: 2.5 fb-1 ditto
Down to 117Gev: 5 fb-1 ditto
Down to 114GeV: 7.5 fb-1 ditto

On June 17th the LHC had collected 1 fb-1 for each experiment.On August 5th, 2 fb-1. They expect to achieve 5 fb-1 by end October which, when combined (joint analysis), tells us that by then they should have accumulated enough data to do the discovery job down to 117GeV. End 2011 for a preliminary result one way or the other is quite realistic.

The reason we are hearing from the Tevatron now is that, although they may not be in a position to discover a SM Higgs boson to 5 sigma levels, they have enough data to exclude one at 95% confidence level.

It will be quite a bitter pill for CERN to swallow if Fermilab gets to the exclusion finish line first.

76. **null**
September 12, 2011

Db,

thanks. also thanks for the link. So when should we hear an announcement from Fermilab? How long after collecting the data does it take for the analysis and number crunching to occur?

77. **Peter Woit**
September 12, 2011

null,

From here:
http://www.sciencenews.org/view/feature/id/334164/title/Last_Words
"We expect to complete our Higgs analysis by March," says Fermilab's Rob Roser.

Thanks Shantanu,

I had never really looked into the story of Salam's role in Weinberg-Salam. That's quite interesting.

78. **Amos**
September 12, 2011

So, how negative is the mood in the HEP community at this point? I don't mean with the proponents of any one theory or another, but the community as a whole?

If the LHC finds *nothing* …

79. **Anon**
September 12, 2011

@null: "If there is no Higgs, then does the 10^55 cosmological constant/energy density no longer a problem (i.e QFT calculation for particle physics for cc can be close to the astronomical cc)"

I don't think so. You still have to somehow resolve the problem of the vacuum energy of all the other fields in the Standard Model. Formally, the contribution of each field to the vacuum energy is infinite, although these can typically be renormalized to pretty much any value you like by what amounts to a simple redefinition of the measure of the path integral. The signs of the vacuum contributions may be different for different fields, but it is difficult to make an argument that they would all cancel (never mind "almost" cancel, which is probably even more difficult) without some symmetry principle, lacking in the Standard Model.

80. **Peter Woit**
September 12, 2011

Amos,

I think the mood in the HEP community as a whole is very positive, with a lot of excitement that the answer to the question "is there a SM Higgs?" may finally be close.

The mood among SUSY enthusiasts may not be so good (they're still in the first stage of grief, denial). As for the mood among those who seriously thought the LHC would see extra dimensions, that also would not be good, but I'm not sure there's more than a vanishingly small number of such people.

81. **Anon**
September 13, 2011

Dombey's paper is disgraceful. What an evil, vindictive little gossip.

82. **Anon**
September 13, 2011

Sorry, wrong thread. Don't know how that happened.

83. **VP**
September 14, 2011

DB,

"One further point about Peter's neutrino shielding issues: Using a conventional accelerator as a beam source of neutrinos, as originally proposed in the late fifties by Pontecorvo and Schwarz and implemented at CERN in the early sixties,…."

Actually the first accelerator source of neutrinos for an experiment was used by Mel Schawartz himself (along with Leon Lederman, Jack Steinberger, et al) in the early sixties at the AGS at Brookhaven and not CERN. It led to the discovery of the muon neutrino and a Nobel prize for the three mentioned above a quarter century later. As

Jack once advised: “Do your good work early and live long enough”.

84. **DB**
September 16, 2011

@null
Professor Guido Tonelli, the spokesman for CMS, told the BBC on Sep.1st: “We could discover the Standard Model version of the Higgs Boson or exclude it earlier than expected. Could we discover it by Christmas? In principle, yes,”

In fact, both Fermilab and the LHC should be in a position to exclude the Higgs by Christmas, if it doesn’t exist. If it exists, discovery to 5 sigma will take longer and only the LHC has a realistic chance of achieving this. The closer the Higgs is to 114 GeV, the harder it is for the LHC to see it and the longer it will take.

@VP
I was wondering if anyone was awake. 🙂 Actually CERN was ready to go before Brookhaven, but an outsider, Guy von Dardel was brought in to verify the neutrino flux calculations and he argued that the team (wrongly it turns out) had made important errors, as a result CERN postponed startup until June 1963, too late to do anything but verify the Brookhaven results.

85. **null**
September 19, 2011

thanks DB. Is the fact they’ve not found any signal above background 115-145GEV mass range with the data thus far collected and analyzed telling?

86. **Peter Woit**
September 19, 2011

null,

There is signal above background at various places in this mass range, just not enough give a statistically significant signal. And, with the amount of data available, you shouldn’t see a statistically significant signal (at least not in the lower part of this range). So, for the moment, all is consistent with either Higgs or no Higgs in this region. It will take more data to resolve this, everyone’s waiting…

87. **null**
September 19, 2011

So by the end of Oct 2011, there should be enough inverse femtobarns to decide the issue one way or the other 95% confidence from both LHC and Fermilab?

How to Win the Nobel Prize

September 12, 2011
Categories: Uncategorized

I'm too busy to write much on the blog just this moment, and besides, there's nothing of great interest I can think of that need's writing about. So, I'll take up commenter Shantanu's suggestion and try and stir up a little trouble with two quick topics related to the Nobel Prize.

- Norman Dombey recently posted on the arXiv [Abdus Salam: A Reappraisal. PART I. How to Win the Nobel Prize]() which more or less seems to argue that Salam didn't deserve his 1979 Nobel. He describes a lot of history I didn't know, but I'm not completely convinced. Part of the argument seems to be that he stole the idea from Weinberg, and didn't even know the importance of what he had stolen, but my impression was that no one, not even Weinberg, thought very much of the unified electroweak theory at the time. A quick look at the paper in his collected papers that I take to be the 1968 one that justified the Nobel to him appears to discuss the crucial points: a gauge theory with Higgs mechanism.

Unfortunately I don't have more time now to look into this history carefully. If someone expert on this history has comments on the Dombey claims, that would be interesting.

- One way to win the prize is to do revolutionary work. This year's prize will be announced October 4, and for the past few years I haven't had much in the way of thoughts about obvious candidates. After reading Richard Panek's *The 4% Universe* early this year and learning more of the story of the discovery of the acceleration of the universe, I'm pretty sure that sooner or later there will be a Nobel Prize for that, maybe this year. Those better informed than me can speculate about what the exact names will be that will go on the prize.

Comments

1. **noprize**
   September 12, 2011

   There are many who deserve a Nobel Prize and didn't get one. Conversely I suppose some people feel that there are those who did win but didn't deserve it. A pointless debate, unless one can prove fraud or something like that. Consider:

   – Weinberg's 1967 is titled "A Model of Leptons" Leptons only! No hadrons! And yet it is one the classic papers of HEP theory. Weinberg explicitly admitted that he did not know if his model was renormalizable. Is that a valid unification?

   – Glashow 1961. Weinberg 1967 stated that his model was an extension of Glashow's 1961 "partial" model of the weak interactions (see title of Glashow's paper). Dombey states that by 1979 Glashow's model had been almost forgotten, but Gell-Mann stepped in at the last moment to speak up for Glashow. Glashow's model was not renormalizable. The Higgs mechanism had not been proposed yet, in 1961. Is that a valid unification?

   – Salam 1968. Salam explicitly emphasized that gauge invariance was absolutely necessary to obtain a renormalizable theory, and to this end the bare masses of the gauge bosons (called"mesons") must be zero, in a nonabelian theory. Salam stated that a possible way to generate mass and preserve gauge invariance was to have a coupling to a scalar boson, which would exhibit spontaneous symmetry breaking, and the Higgs mechanism would transform away the Goldstone bosons. All well and good, but known by others. Salam did NOT relate the strengths of the weak charged and neutral currents (which Weinberg 1967 did). Salam claimed that the original unbroken theory was renormalizable because it was gauge invariant. Salam could not prove that the symmetry breaking did not destroy renormalizability. Salam talked nonsense at the end about extending the model to hadrons, because he knew only of the Cabibbo angle and three quarks. Is that a valid unification?

   Glashow (not in 1961 but later ~ GIM) proposed the existence of a fourth quark to explain in a natural way the absence of flavor changing neutral currents (the quark was so named because it solved so many problems that it worked like a charm). So did Glashow not deserve his Nobel? Do GIM deserve a separate Nobel? Cabibbo did NOT share the Nobel Proze with Kobayashi and Maskawa, even though the matrix is universally called CKM and Cabibbo was still alive at the time of the award to KM. Is that unfair?

2. **physicsphile**
   September 13, 2011

   For the accelerating Universe prize, Perlmutter would certainly be one of the names.

3. **chris**
   September 13, 2011

   I do not konw the story of Salam and I have heard other people doubt his contribution (notably Veltman), but Dombeys paper is a disgrace. one just needs to read the first paragraph do draw some conclusion regarding his character.

4. **John**
   September 13, 2011

   Only one question: Why did Dombey not raise these issues when the prize was being given out?

5. **Will**
   September 13, 2011

   "Only one question: Why did Dombey not raise these issues when the prize was being given out?"

   Or object to writing his own reference…

6. **hrk**
   September 13, 2011

   "I do not konw the story of Salam and I have heard other people doubt his contribution (notably Veltman), but Dombeys paper is a disgrace. one just needs to read the first paragraph do draw some conclusion regarding his character."

   Agreed.

   Its also funny because at least according to some people, the Nobel for 't Hooft and Veltman, should really have only gone to 't Hooft. Salam and 't Hooft and Weinberg and Glashow all have many other contributions named after them other than what they are cited for in the Nobel prize. What does Veltman have? It is not impossible that his biggest discovery was a spectacular graduate student named ‘t Hooft.

7. **MathPhys**
September 13, 2011

Dombey’s paper doesn’t contain any scientific information that isn’t already known, and I found it in bad taste. Salam wished to help him, trusted him, and told him in confidence “Write the letter and I will sign it”. It’s disgraceful to reveal that in public after the man’s died.

Why he didn’t he write this paper while Salam was alive? Salam had many friends, particularly in the UK.

8. **MathPhys**
September 13, 2011

Veltman stayed with quantum field theory when no else did. He stayed with gauge theory and the very well defined question of renormalizability. He gave ‘t Hooft a concrete problem to solve. A precise definition of what the problem to solve is, is half the way towards a solution. He fully deserves his half of the Nobel prize.

9. **Per**
September 13, 2011

I find it a bit tasteless. In the first paragraph of the paper its mentioned that Salam was the first muslin to receive the noble prize, which is a rather strange comment to make. But then, looking at the publishing date 9th September 2011, the reference to 9/11 seem almost to obvious to be just a mere coincidence.

In any case, just my two cents. Besides, who is this Dombey and why is his opinion of interest?

10. **MathPhys**
September 13, 2011

Per,

Yes, I wondered why this paper? and why now? Could it be the anniversary of 9.11? Well, that would be worse than in bad taste.

Dombey wrote a book with Bailin on weak interactions. That was about 30 years ago.

11. **Arun**
September 13, 2011

Norman Dombey’s article on Abdus Salam seems to be a wee bit prejudiced, from terming him a “Moslem” (really oldfashioned) , to referring to a series of lucky coincidences that enabled Salam to study physics as a miracle (somehow violating the laws of physics?).

Dombey starts off with how the New York Times described Salam’s contribution:

> So did Salam do what the New York Times (presumably based on a briefing by the Nobel Committee) had claimed that he had done; namely propose a theory in 1967 which predicted the size of the parity-violation in electron scattering off hydrogen nuclei as observed in 1979. If he didn’t why was he awarded the Nobel prize? I knew all three prize winners and NATURE had asked me to write about the award of the prize in November 19797. So I would like to explain how Salam won the prize even though he was unable to predict the result of the 1979 experiment.”

There’s a problem in this framing of the question:

As an example of the Nobel citation,
http://www.nobelprize.org/nobel_prizes/physics/laureates/1979/presentation-speech.html
or
http://www.nobelprize.org/nobel_prizes/physics/laureates/1979/#

Once you understand that

The Nobel Prize in Physics 1979 was awarded jointly to Sheldon Lee Glashow, Abdus Salam and Steven Weinberg “for their contributions to the theory of the unified weak and electromagnetic interaction between elementary particles, including, inter alia, the prediction of the weak neutral current”.

then one can look at the totality of Salam’s contributions to the theory.

12. **dopey_john**
September 13, 2011

The comments from some people here objecting over Abdus Salam being described as a muslim are rather silly. He was the *first muslim* to win a Noble prize in physics which is an important point. The funny thing is that whereas Abdus may be paraded as the first muslim to win this prize by some in the muslim community, the majority brand him as a heretic because he was a member of the Ahmadiyya Muslim Community and therefore not an “orthodox” muslim.

13. **Trulo**
September 13, 2011

> So the prize was awarded on the basis of a non-peer-reviewed
> publication which quotes an unpublished lecture. Yet the name
> Weinberg-Salam model stuck because almost everyone used it. Weinberg
> was happy with that arrangement: he knew that he could only benefit
> from association with Salam.

I’m rather puzzled by this statement. What kind of benefit could Weinberg obtain from being (fairly or not) associated with Salam? Trips to Trieste?

14. **Jack Levitt**
September 13, 2011

Given the tone of Dombey’s article, I have no choice but to wonder to what extent racism and anti-muslim feelings are behind the attack on Salam. Sad, but not without precedent in the field of theoretical physics.

15. **Math Student**
September 13, 2011

Trulo,

That part that made no sense to me as well. I don't see any reason why Weinberg and Glashow would just go along with Salam getting credit if it was obvious he didn't deserve it.

16. **Hugh Osborn**
September 13, 2011

It is too easy to ascribe racism or other prejudices to views one does not like. Norman Dombey wrote an article saying similar things many years ago, I don't have the reference. The reason for the current article appears to be that he has had access to papers not previously available. It is a fact of life that people do campaign behind the scenes for Nobel prizes. It is also true that, perhaps rarely, they are given in small part at least for political rather than purely scientific considerations.

17. **M. Wang**
September 13, 2011

Dombey's writing may exude the appearance of prejudice, but that does not necessarily imply that he is lying. Whether or not he tells the truth is the real issue and should be evaluated based on independent facts. Sadly I don't seem to find any discussions along that direction here. Does anyone have something solid to contribute?

18. **Arun**
September 13, 2011

M. Wang,

Dombey's paper is titled "Part I". I'd wait for Part II to see what else he says.

The events of 1960-1968 might be beyond most people here's personal memory, but one could examine, e.g, if Antonio Zichichi has written anything – as per Salam, he attended the 1967 lectures where Salam expounded on the model. One can examine the literature to see how the model got named. One can examine why P.A.M Dirac nominated Salam for the Nobel – would Dirac do so as a political favor?

If none of the readers here happen to know it off the top, and no other write-ups appear, then I'll do some of this work to examine the factual basis of Norman Dombey's claims; but there is no point in starting just now.

-Arun

19. **Arun**
September 13, 2011

From M.J. Duff's tribute to Salam:
http://155.198.210.128/~mduff/talks/salam.html

"One of my greatest regrets is that as a student in the Theory Group at Imperial from 1969 to 1972, a group that included not only Abdus Salam but also Tom Kibble, no-one suggested that weak interaction physics would be an interesting topic of research. In fact I did not learn about spontaneous symmetry breaking until after I got my PhD! The reason, of course, is that neither Weinberg nor Salam (nor anybody else) fully realized the importance of their model until t'Hooft proved its renormalizability in 1972 and until the discovery of neutral currents at CERN."

20. **J**
September 14, 2011

Regarding the 1979 Nobel Prize: my personal feeling is that Weinberg deserves more credits than the other two. The most striking of the 1967 paper, I guess, is the concrete prediction of a neutral current in weak interaction (W+- exchanges were known for long time by then) and a specific angle of mixing (Weinberg angle).
Nobel committee often favors an original theoretical proposal solving old problems and predicting new things that are verified.

21. **Chris Oakley**
September 14, 2011

> One can examine why P.A.M Dirac nominated Salam for the Nobel – would Dirac do so as a political favor?

One has to assume so, as Dirac did not buy into the actual theory.

22. **MathPhys**
September 14, 2011

Salam lobbied for his Nobel prize. So what?

Salam wrote to Dombey explaining to him why it should be the Weinberg-Salam model. Weinberg called up those who didn't cite his paper, explaining to them why they should. What's the difference?

23. **d nom**
September 14, 2011

Dirac may have nominated Salam out of personal friendship and admiration, even if Dirac did not agree with the idea of renormalisation. The electroweak unification was still an elegant model, and other ideas Salam was working on. What political favours would Dirac possibly have received or cared about (in view of his attitudes throughout his life), by 1971 and later?

24. **SpearMarktheSecond**
September 14, 2011

There are always shoving matches and lobbying over Nobel Prizes. Ho hum.

I'd have given one to Prescott for the polarized electron scattering at SLAC in the late 1970's that turned the tide on people believing in the Z^0. Up until that time the atomic parity violation experiments were confusing, as were the neutral current experiments.

But surely politics prevents *4* Nobels for work at SLAC in part (J/Psi, tau, DIS are first 3).

25. **np**
September 14, 2011

Prescott deserves a Nobel Prize. Three Nobel prizes (in physics) were also awarded for experiments at the AGS at BNL (J/psi, CP violation, multiple neutrino families). But no Nobel prize was awarded for the discovery of the Omega- particle (an experiment also done at the AGS). Note that Ray Davis won a Nobel (2002), for the solar neutrino problem. Davis was on the staff at BNL, although his experiment was done off-site.

So who knows how the politics works out. At Columbia in the 1950s, a Nobel was being won almost every year. Some of the students (I think Lederman amongst them) minted buttons "I have not a Nobel Prize". PW should be able to confirm this.

26. **mo**

So citation count doesn't accurately measure impact.

29. **july**
September 15, 2011

Peter, don't you think Michel Mayor is an obvious candidate?

30. **Shantanu**
September 16, 2011

Someguy that paper was from 2007. I think its fairly robust now with new evidence
from BAO, LSS .
Anyhow probably it will given to Reiss, Perlmutter and Schmidt.

31. **Some Guy**
September 16, 2011

Shantanu, all that "evidence" was known already, and discussed in the paper.

32. **Peter Woit**
September 16, 2011

Some Guy,

Arguments over what the supernova observations mean for theoretical cosmology are irrelevant here. The Nobel prize would be awarded for the observational achievement, which found something unexpected.

33. **Some Guy**
September 16, 2011

Fair enough, a Nobel prize for finding that high-z SNe Ia are not as bright as expected (as opposed to accelerated expansion) might be justified. But it would be unusual to award a Nobel prize for an unexplained observation. Offhand, I can't recall a precedent. Then again, the committee has done strange things before…

34. **piscator**
September 16, 2011

While on the theme of Nobel prizes that should have been awarded, surely the observation of weak nuclear currents at Gargamelle is right up there?

35. **weak neutral currents**
September 16, 2011

The case of weak neutral currents is a sad story, and an embarrassment to CERN. The discovery richly merited a Nobel Prize. But the Fermilab experiment (HPW ~ Harvard-Penn-Wisconsin ~ Carlo Rubbia, David Cline, Alfred Mann) successfully muddied the waters with their claims of what are now called (tongue in cheek) `alternating neutral currents'. The CERN management failed to stand by the excellent work of their own people. Later, when the existence of weak neutral currents was generally accepted, CERN realized too late that it had let a Nobel Prize slip through. Sadly, Paul Musset, Andre Lagarrigue and Andre Rousset are all dead, so there is no hope of a Nobel Prize for the discovery of weak neutral currents.

36. **Charlie**
September 16, 2011

My perpetual nominee: Mitchell Feigenbaum. It's not every day that someone discovers a few new constants of nature.

37. **Shantanu**
September 16, 2011

weak neutral currents, HW stood for Harvard-Purdue-Wisconsin (not Penn)

38. **weak neutral currrents**
September 16, 2011

Shantanu – HPW in the 1970's was the Harvard-Penn-Wisconsin experiment at Fermilab. It was a fixed-target experiment. Carlo Rubbia was from Harvard, Alfred Mann from U Pennsylvania and David Cline from Wisconsin.

However, you prompted me to look up HPW on Google and I discovered that HPW also refers to a later proton decay experiment (big underground tank of water), and that is indeed Harvard-Purdue-Wisconsin.

So you are correct and I am not even wrong.

39. **CWJ**
September 16, 2011

I agree with Charlie–Feigenbaum is a good candidate for a Nobel and it's a shame Ed Lorenz didn't get it before he died.

40. **Shantanu**
September 17, 2011

Yes and Carlo Rubbia was also the PI of Harvard-Purdue Wisconsin water Cherenkov experiment.

41. **zafhore**
September 17, 2011

Salam did no less than Glashow and Weinberg to merit this award, and probably more. His first attempts at unifying forces were in 1955 (with Polkinghorne), and continued to 1973 (with Pati). None of the others hung in there for so long, and meanwhile created an international centre on the side. After publishing his disgraceful piece, Dombey has the audacity to thank ICTP management after they let him sift through Salam's archived papers.

42. **Euler**
September 17, 2011

This is not a research article on history of physics, it only expresses doubtable opinions of the author, made without a serious and in-depth scientific discussion of ideas, theories, experiments and literature of the time. Its place should not be the historical section of arXiv.

43. **MathPhys**
September 17, 2011

No one takes Salam's work with Pati seriously.

44. **weak neutral currrents**
September 17, 2011

Shantanu (and anyone else) – read these interesting and informative articles from the CERN Courier about the discovery of weak neutral currents, and more generally the genesis of the Gargamelle collaboration. (And if you don't know that Gargamelle was the mother of Gargantua … well now you do.) BTW it was HPWF at Fermilab (Harvard-Penn-Wisconsin-Fermilab).

http://cerncourier.com/cws/article/cern/29168

http://cerncourier.com/cws/article/cern/28875

The second article is by Donald Perkins and gives more detail about the mistakes by HPWF, and the care with which the CERN analysis was performed. The articles also tell you how the CERN results were greeted with skepticism. They allude to how timid the CERN management was. They indirectly say how the HPWF collaboration boldly announced all of its bogus claims. By the time weak neutral currents were widely accepted, the damage had been done. CERN realized too late that it had let a Nobel Prize slip through its fingers.

Andre Lagarrigue died in 1975. Paul Musset was killed in a mountaineering accident in 1985. Andre Rousset died in 2001. No Nobel Prize for weak neutral currents.

The HPWF experiment was a bad experiment. It was responsible for many false results. I recall the acronym as just HPW. I am reading between the lines here, but I suspect that the acronym HPW = Harvard-Purdue-Wisconsin was deliberately chosen so that people would forget about Harvard-Penn-Wisconsin. Certainly Shantanu thought so (and clearly did not know about HPWF), and saw fit to correct me. I am guessing Shatanu is young.

45. **weak neutral currents**
September 17, 2011

Towards the end of Don Perkins' article he mentions Willi Jentschke. Willibald Jentschke was the DG of CERN at the time (1971-75).
http://cerncourier.com/cws/article/cern/28878

Previously Willibald Jentschke was the DG of DESY.
http://cerncourier.com/cws/article/cern/28880

Being DG of DESY was a stepping stone to becoming DG of CERN. This tribute to Jentschke was written by Herwig Schopper, who was himself DG of DESY and later DG of CERN.
http://cerncourier.com/cws/article/cern/28873

Actually Jentschke founded DESY, much as Robert Wilson founded Fermilab. Jentschke was the first employee of DESY, and had to build a lab and his staff. His first employee was Klaus Steffen, who later built DORIS. I never met Jentschke (or maybe I saw him from a distance once), but I knew Klaus Steffen, who was very nice to me (and who was already old when I met him as a freshman graduate student). I also recall another senior DESY person (maybe employee #3) who told me he named his daughters Deli and Desi, because it had not yet been decided if the new lab would build a linear accelerator or a synchrotron, so he covered both bets.

And if anyone objects that this is all off-topic, let me just say that they all assured me that they were all fiercely anti-string theory. Back in the 1950s. Before I was born.

46. **anonomous**
September 18, 2011

@Charlie:

I agree – Feigenbaum deserves the prize for discovering a very important constant in nature and his paper was dismissed for years as irrelevant. For as many people working in the field of dynamical systems today, you would think he would have been awarded already, but maybe the trend is towards experimentalists.The sad thing is that Feigenbaum's constant has been experimentally verified, but the topic doesn't qualify under the glamorous physics that the award committees are looking for.

47. **IM**
September 20, 2011

If there is a Nobel for HEP, part of it can be given to Faddeev. When the Prize was given to 't Hooft and Veltman, Faddeev also deserved it. Perhaps Polyakov can also be awarded for his work on topological objects and on CFT (2-D CFT being now important in condensed matter).

48. **MathPhys**
September 20, 2011

Topological objects first appeared in the paper of Nielsen and Olesen on vortex lines as models for strings. Based on that, there were the papers of 't Hooft and Polyakov on monopoles, followed by Belavin et al. on instantons. Faddeev's work on gauge theory was joint with Popov and with Slavnov.

49. **Thomas Larsson**
September 20, 2011

IM, a Nobel prize for CFT for its application in 2D statphys would be appropriate, and something I have argued for over the last 20 years. It would go to BPZ, not just to Polyakov himself (it was the other Zamolodchikov twin that died, right?). I have long suspected that the reason why Dotsenko and Fateev were not included in the seminal BPZ paper was that only three people can share a Nobel.

But from a condensed matter perspective, the restriction to 2D is serious. Yes, 2D materials can be manufactured in the lab, but most real materials are 3D.

50. **Trulo**
September 20, 2011

> Topological objects first appeared in the paper of Nielsen and Olesen on vortex lines

As a topological theory, the Skyrme model is much older and more relevant to our world, me thinks.

51. **MathPhys**
September 21, 2011

Trulo, You are perfectly correct. But as far as I know, teh gentlemen that I mentioned were not aware of Skyrme's work. Who re discovered Skyrme's work? Was it Witten?

Thomas L,

Dotsenko and Fateev's work is based on an earlier paper by Dotsenko alone. The latter is based on the BPZ paper and distinct from it, in content as well as in time.

52. **Trulo**
September 21, 2011

> Who re discovered Skyrme's work? Was it Witten?

I know Balachandran worked on it, and I believe it was him who suggested Witten to look into it. But the truth is I only know that story at the level of unsubstantiated rumors.

By the way, isn't Dirac's monopole theory a topological theory as well? Probably the first one in the context of QFT.

53. **MathPhys**
September 21, 2011

Trulo,

Yes, I believe that you are right again. Witten's work is based on Balachandran, Nair, Rajeev and Stern.

54. **abbyyorker**

September 21, 2011

Does anyone know at what energy unitarity kicks in to demand a Higgs boson? Or perturbative effects on other processes?

55. **IM**
September 22, 2011

1. Polyakov has another contribution to CFT : He was the first to say that critical phenomena have not only scale invariance, but also conformal invariance.
2. I think that the Dotsenko paper MathPhys refers to is
Critical behaviour and associated conformal algebra of the Z3 Potts model:
Nuclear Physics B, Volume 235, 1984, Pages 54-74.
(This is the earliest paper by
Dotsenko or Fateev in the collection edited by Itzykson, Saleur and Zuber).
Yes, the Introduction of this paper clearly acknowledges that the new development in 2D CFT was initiated by BPZ.

56. **Andrew**
September 22, 2011

Dear Peter,
Love your blog and hope to get around to reading your book in full one of these years.
I was wondering,since you're infinitely better qualified to judge this then I am-have you heard of this and if so, what do you think?

http://www.npr.org/blogs/thetwo-way/2011/09/22/140713791/scientists-report-breaking-the-speed-of-light-but-can-it-be-true?sc=tw

Personally,I think it's Bell's incompleteness theorem all over again-a lot of wild speculation that ultimately goes nowhere in terms of a real challenge to general relativity's ontology.

Andrew L .

57. **Charles**
September 30, 2011

When I first read this I had to double check that it was not written by Frank Close at Oxford. He is in the process of writing a book which will dive deeper into this topic and has been probing many theorists who were around Imperial College London and the "Higgs" phenomenon in the 1960's. On a further review I noticed Dombey has connected with Dr. Close as indicated by the paper's notes.

I am grateful to Frank Close for early sight [38] of some material from his book [39] which presents an independent summary of Salam's role in the 1979 Nobel prize: in particular the memos from Salam to Matthews [33] in which Salam writes his own nomination letter.

I (*and many others, such as a bloggers here*) put Close, Dombey, and John Ellis in similar light…on the peripheral from the front line of theoretical physics with clearly some sort of axe to grind or motive behind their positions or fronts.

No News

September 15, 2011
Categories: Experimental HEP News

I've been hearing no interesting news from the LHC recently, about all I've learned is that CMS/ATLAS haven't even decided whether it's worth combining their latest public data (probably not, what is much more interesting is the large amount of data they are now analyzing separately). So my plan for next week is to travel to Antwerp, where I'll try and get Tommaso Dorigo drunk and see what I can find out. We'll both be at TEDx, he's got more of the story here.

Adrian Cho has a wonderful long piece in Science (and podcast here) about the sociology of the two big experiments at the LHC. It gives some insight into the process by which a Higgs result is likely to emerge, including the steps being taken to make sure that some group doesn't "parachute in" at the last moment to try and capture glory. I'm still trying to figure out who gets a Nobel prize if the Higgs is found.

For some other reading material, there's John Ellis's 65th birthday colloquium, an interview with Bianca Dittrich, and yet more evidence that MathOverflow rules.

Comments

1. **bruno**
   September 16, 2011

   I'm still trying to figure out who gets a Nobel prize if the Higgs is found.

   Higgs?

2. **Bobito**
   September 16, 2011

   I love math overflow, but why has Lurie's answer gotten 68 votes? Many much more informative answers get only 5 or 10 votes. The answer to my question is that the answer was by Lurie.

3. **Octoploid**
   September 16, 2011

   > I'm still trying to figure out who gets a Nobel prize if the Higgs is found.

   Lyn Evans would deserve it…

   BTW there will be an interview with Lisa Randall on Charlie Rose tonight.

4. **DB**
   September 16, 2011

   Cho makes the interesting point that with groups the size of CMS and Atlas with around 3,000 physicists in each, the issue of competition *within* groups is a phenomenon which may need to be reckoned with, as compared with the straightforward traditional competition *between* groups, illustrating it via the story of how, earlier this year, the University of Winsconsin was accused of trying to steal a march on "discovering" the Higgs boson diphoton decay, a decay mode memorably described by Tommaso Dorigo as: "two angry gamma rays, each roughly carrying the energy of a 2 milligram mosquito launched at the whooping speed of four inches per second toward your buttocks."

5. **Jack Levitt**
   September 16, 2011

   Peter, the obvious answer re the Nobel question, while the discovery of the Higgs is certainly worthy of the prize, no person or group of persons have done enough (in comparison to their colleagues) to warrant the award. Hence, no Nobel for the Higgs should be awarded. Simple, huh?

   By the way, please take care in Antwerp. I hear the city has gotten more violent in recent years.

6. **Yatima**
   September 16, 2011

   That should be "angry gamma quanta", I guess.

   Slow news day? Slow news day. But we have this:

   http://arxiv.org/pdf/1109.0702v1

   "Results from 730 kg days of the CRESST-II Dark Matter Search"

   64 events maybe.

7. **Peter Woit**
   September 16, 2011

   Yatima,

   Somehow, ambiguous claims to see dark matter that conflict with other experiments no longer seem newsworthy…

8. **weichi**
   September 16, 2011

   bobito – but isn't Lurie's answer the only answer?

9. **Garrett**
September 16, 2011

Hey, cool — have fun at TEDx.

The nobel committee will no doubt struggle to outdo their previous curious decisions.

10. **Dan L**
September 16, 2011

Actually, your link is one more example of why MathOverflow appears to be more interesting than it really is. The stated purpose of the site is for researchers to answer research questions posed by other researchers. The link is to a question that a (presumptive) graduate student asked that could have been answered simply by looking at the Preface of the book. This is one of many examples of what I would call "lazy grad student" questions on MO.

Frankly, I have no idea how successful MO is with its stated goal. That is because its greatest successes are too technical to be understood by a broad audience. If an answer to a question gets 50+ votes, then maybe it's a great little exposition of some piece of mathematics, but I seriously doubt that it was an answer to true research question, because real research questions are typically only understandable by a few dozen people in the country (if that). The main exceptions occur only when you need something from outside your field of expertise.

11. **Dopey john**
September 16, 2011

Maths Overflow is an amazing success, probably because f**kwits like me can gawp at the brain exploding questions being asked there, and check out the profiles of today's rising stars and Fields medal winners. There's now a high-brow theoretical physics version currently private, but going public in 6 days time: http://theoreticalphysics.stackexchange.com/ Who knows, even Witten may post there someday if it's as successful as Maths Overflow. On the other hand, maths seems to be far more popular than physics so it may not flourish.

12. **Bernhard**
September 16, 2011

If the Nobel committee follow what they did in the past, the answer is easy. They will pick up the spokesperson(s) of the experiment(s) . This used to make sense I guess, in the time of Rubia and Van der Meer. Now these would be a much less logical decision. First they have decide in ATLAS for example between F. Gianotti, current spokesperson, or P. Jenni, who was the spokesperson of ATLAS for years and in this sense who put things to work. In an experiment involving the LHC I´m afraid that´s not good enough, why not give some credit to the accelerator guys? So, best solution, give it to CERN, and let Rolf Heuer go to Stockholm to get it, in the same way that UN got a piece prize. Otherwise my suggestion is to give the prize to Tommaso Dorigo, because even people working in experimental collaborations learn more reading his blog than actually working, so this should have an influence in the discovery itself 🙂

13. **null**
September 16, 2011

Would a Nobel be awarded for establishing the Higgs does NOT exist?

14. **Anon**
September 16, 2011

I think one would do well not to start counting Nobels (or Higgses) before they are hatched.

15. **Alex**
September 16, 2011

LHC and collider physics are clearly dead…check out the new OPERA results next week: it seems that neutrinos are tachyons !!!!

16. **Artie**
September 16, 2011

Dan L: I agree that the link is a pretty terrible example of what MO is good for, but I disagree with your overall premise. There's a lot of material on MO that isn't research-level but is fascinating nevertheless (irrespective of the site's stated goal). And there are plenty of fascinating things that are research-level, but are not "too technical to be understood by a broad audience", for example this question by Bjorn Poonen (which, I admit, is an outlier). I don't expect anyone to come along and solve Poonen's problem, but that doesn't make the question any less interesting.

17. **Truly Anomalous**
September 16, 2011

I say give the Nobel to Tommaso D…

18. **Jeff M**
September 16, 2011

As a mathematician I'd have to agree with Artie about MO. Actually, one of the great things about MO is that as a researcher you can ask questions about areas outside your field, and get expert input. I'm a geometric analyst, but I've recently been using graph theory to get results about Riemann surfaces. I just posted a question to try and get unstuck on something that has been driving me crazy for a while now, it's much easier than asking all my analysis friends if they happen to know a nice graph theorist I can bother 🙂

19. **johnR**
September 16, 2011

Octoploid I agree
Lyn Evans would highly deserve it.
Instead, I would hardly figure out which is the point to have some high level burocrat going to Stockholm to get the prize.
Is Lyn still involved with the machine operation?

20. **anonymous**
September 16, 2011

I think we have a long ways to go before somebody gets a Nobel for HEP – this year's Nobel will probably go for dark energy (Riess or Perlmutter is my guess), but I am thinking the Higgs is on it's last leg (wouldn't we hear some leaks by now)?

21. **lun**
September 17, 2011

Actually, the news that CRESST has found dark matter is accompanied by the news dark matter is incompatible with galaxy formation
http://www.bbc.co.uk/news/science-environment-14948730

22. **Thomas Larsson**
September 17, 2011

"Would a Nobel be awarded for establishing the Higgs does NOT exist?"
Michelson won a Nobel prize, Morley not, so who knows.

23. **null**
September 18, 2011

"Would a Nobel be awarded for establishing the Higgs does NOT exist?"
Michelson won a Nobel prize, Morley not, so who knows.

It's funny you say this b/c I've wondered whether the Higgs (and SUSY, GUT, string theory) is the"luminiferous aether". of 21 century.

24. **visitor@CERN**
September 18, 2011

Here at CERN, My colleagues tell me that in a recent Scientific Policy Council meeting DG Rolf-Dieter Heuer was asking advice how to best tell European political leaders that there is no Higgs.

25. **not@CERN**
September 18, 2011

That is simply gossip and hearsay. The DG will necessarily have to prepare speeches for multiple eventualities. How can anyone positively conclude that there is "no Higgs" so early in the game? One can say that the task is very difficult, and there is no conclusive signal as yet, but a lot more – and painstaking – work remains to be done. The LHC has not even reached its top design energy of sqrt{s} = 7 TeV yet. Too much idle gossip.

Blood, toil, tears and sweat?

26. **not@CERN**
September 18, 2011

E_max = 7 TeV/beam, sqrt{s} = 14 TeV

27. **topper**
September 18, 2011

The Tevatron came online in 1985, with adequate energy to produce top quarks, but the top quark itself was discovered only in 1995 (approx). It required a lot of integrated luminosity and also enormous data analysis to discern the top in all of the accumulated data. (The Tevatron devoted part of its time to fixed-target experiments. The LHC devotes part of its time to heavy ions. Then there is downtime for maintenance. This all takes time.) So no reason to panic about `no Higgs' just yet.

28. **Peter Woit**
September 18, 2011

topper + people@CERN,

The Standard Model makes very precise predictions about the Higgs, and, if all goes well, the LHC experiments should have the necessary luminosity to test the prediction, letting us finally know whether there is a SM Higgs or not. Waiting for higher energy or much higher luminosities should not be necessary to decide the question of whether the SM is right. It's true that, for Higgs masses near the lower bound, the statistics will be near the edge of what is necessary for 95% exclusion, and one may end up with an ambiguous result. But, even in that case, the luminosity available in the first part of next year should decide the issue.

Coming up with a CERN statement for the case of no Higgs has been an agenda item for quite a while at their Scientific Policy Council, so that's not necessarily indicative of anything. It's an interesting question whether the DG is being fed inside rumors from the experiments about what the data is saying. Quite possibly not, in which case he knows no more than the rest of us about the Higgs existence question.

29. **Yatima**
September 18, 2011

"DG Rolf-Dieter Heuer was asking advice how to best tell European political leaders that there is no Higgs."

That's pretty simple, innit "THERE IS NO STANDARD MODEL HIGGS and here is where we go from here: … ".

Why do I get the feeling that some think the situation is that of Admiral Piett having to tell Darth Vader that Han Solo hast just slipped through the fingers of the combined might of the imperial expeditionary force.

Please stop it!

I find it actually refreshing that some things in this universe do not bent to incessant spin, political hemming and hawing or Jedi mind tricks.

30. **OhDear**
September 19, 2011

"I find it actually refreshing that some things in this universe do not bent to incessant spin, political hemming and hawing or Jedi mind tricks."

Me too, but unfortunately government funding of scientific research is not one of them.

31. **Shantanu**
September 19, 2011

Peter, maybe you could blog about Avi Loeb's talk which is a must watch for particle physicists (than astrophysicists) esp. now that there is no evidence for supersymmetry, extra dimensions etc

32. **Marcus**
September 19, 2011

Shantanu, which Avi Loeb talk is that? Is there an abstract, or slides pdf, or online video? I searched and could not find any recent talk by Loeb.

33. **Shantanu**
September 19, 2011

Marcus see
http://online.kitp.ucsb.edu/online/colloq/loeb1/
He also gave a similar talk at CFA, but I can't find a link right now.

34. **Peter Woit**
September 19, 2011

Shantanu,

By Loeb's investment analogy, I'd say most particle theorists right now have moved to cash (most risk-free investment), waiting for ongoing market crashes to get sorted out. SUSY and extra dimensions are in free-fall, with people trying to get everything they've invested in them out before the market value is zero. Depending on the Higgs/no Higgs question, the field could look very different in a few months, but I have no idea which way this is going to go, so no idea what happens next.

35. **Peter Lee**
September 19, 2011

Is there any comment to be had concerning the current and ongoing (??) debates within the Gran Sasso neutrino experiment (including the views of the Lyon data analysis team) about the potential (but possibly/probably false?) signal of supra-luminal neutrinos in that experiment?

36. **Peter Woit**
September 19, 2011

Peter Lee,

Someone wrote a comment about this here 3 days ago.

The rumor seems to be a "6 sigma" observation of timings indicating faster than light propagation of neutrinos. This seems almost certain to be a mistake; to believe it, you would need overwhelming evidence. Supposedly details to be released later this week, we'll see. If it is real, presumably it should also be observable by other experiments in other conditions. My rule of thumb is don't believe something like this until it's confirmed by a second experiment: people on the first experiment want to believe they've found something revolutionary, people on the second experiment want to shoot down the result of the first experiment…

37. **none**
September 19, 2011

Shantanu,
Thanks for the Loeb link. In addition to the paper linked there
(Taking "The Road Not Taken": On the Benefits of Diversifying Your Academic Portfolio
http://arxiv.org/abs/1008.1586), there is also a recent paper
(Rating Growth of Scientific Knowledge and Risk from Theory Bubbles
http://arxiv.org/abs/1108.5282) with abstract:
In physics the value of a theory is measured by its agreement with experimental data. But how should the physics community gauge the value of an emerging theory that has not been tested experimentally as of yet? With no reality check, a hypothesis like string theory may linger for a while before physicists will know its actual value in describing nature. In this short article, I advocate the need for a website operated by graduate students that will use various measures of publicly available data (such as the growth rate of newly funded experiments, research grants, publications, and faculty jobs) to gauge the future dividends of various research frontiers. The analysis can benefit from past experience (e.g. in research areas that suffered from limited experimental data over long periods of time) and aim to alert the community of the risk from future theory bubbles.

38. **Zathras**
September 20, 2011

Regarding superluminal neutrinos, this is not the first time the possibility has come up. In the early 90s, there was a nuclear experiment (sorry, can't remember the name) which produced a Curie plot for neutrinos indicating that the square of the neutrino mass was negative. Such a result is consistent with superluminal neutrinos.

39. **Reply to Zathras**
September 20, 2011

http://arxiv.org/abs/hep-ph/0009291
lists some of the experiments with negative neutrino mass-squared.

40. **SpearMarktheSecond**
September 21, 2011

I doubt their will be any Nobel for a Higgs or no Higgs. Too many cooks. Unless there is a twist that some clever group figures out and sees the Higgs in an unexpected manner.

Peter Woit is right… dark matter has lots of claims and counterclaims, and is just a mess right now.

No Higgs? The DG should just say, `Waxahachie'.

As for superluminal neutrinos, I thought Telegdi ruled that out years ago for electron antineutrinos, and then someone else did it for muon neutrinos. But, who bothers to read the literature anymore? Perhaps I'm misremembering though.

41. **Charles**
September 21, 2011

Pretty safe bet that there will not be a Higgs Nobel on October 4, 2011 for Theory or Experimental. Awarding would bring too many questions and undermine final steps in confirmation of the theory.

42. **Bernhard**
September 22, 2011

The shut-down of the Tevatron in nine days or so is perhaps a new subject to be discussed (on the absence of something more exciting).

43. **kristo**
September 22, 2011

(@Jack Levitt)
I will be volunteering at TEDx Antwerp. There is nothing unsafe about walking around in Antwerp – at any hour. True in certain quarters there has been more 'uproar' in recent years, but this is restricted to some streets in certain area's a normal visitor of Antwerp will not stroll into.

European (Belgian) cities are nothing like what I hear from US main cities, where walking around in the evening or at night is indeed dangerous. Quite the contrary here. US visitors are amased when you say during or after a night out that you're walking to another place or homewards. BTW I live in Ghent, you should visit.

44. **M. Wang**
September 22, 2011

Dr. Woit, the superluminal neutrino story has hit the Economist. Will you do a more detailed blog entry when more info is released in the next few days?

45. **Bernhard**
September 22, 2011

Not only the Economist, the buzz is growing exponentially and will hit the official peak tomorrow when CERN will make the announcement.

48. **Peter Woit**
September 22, 2011

kristo,

I've spent a day in Antwerp and enjoyed it a lot, maybe I'll run into you. No sign of anything dangerous. It's also true that in Manhattan these days, you would have to go to a fair amount of trouble to find a place that wasn't safe to walk around anytime of day or night. Both New York and major European cities are much safer now than what I remember several decades ago. Several people have told me I must see Ghent, and maybe a plan to visit Bruges will be modified to add a short trip to Ghent.

49. **Peter Woit**
September 22, 2011

About the superluminal neutrinos. My initial reaction is that this has to be a problem with the experiment, and making a big public announcement of this is a really bad idea, even if you do this together with explaining that it's almost surely an experimental problem. If I get time and there's something more interesting to the story, I'll try and write a posting on the topic.

50. **Andrew Foland**
September 22, 2011

If ever there were an experimental result that deserved the tagline "not even wrong", surely it would be superluminal neutrinos.

51. **Low Math, Meekly Interacting**
September 22, 2011

Well, it's already in the NY Times now, so if this is spurious (and pretty much everyone thinks it is, apparently), it does seem to have the potential to be a rather ignominious claim.

52. **abubakar**
September 22, 2011

hey … some new cern data is saying (but not totally confirmed) that speed of light maybe exceeded by neutrinos http://www.bbc.co.uk/news/science-environment-15017484 .. plz comment. Thnkx

53. **chris**
September 23, 2011

what has the world come to? a rumor hits the NYT before any result has been announced.

54. **Bernhard**

September 23, 2011

As usual, if it were true, it would be confirmation of string theory:

"Zichichi speculates that the "superluminal" neutrinos detected by OPERA could be slipping through extra dimensions in space, as predicted by theories such as string theory."

http://www.scientificamerican.com/article.cfm?id=particles-found-to-travel

55. **Paolo Valtancoli**
September 23, 2011

I think that Zichichi should be fired immediately from all universities.

56. **martibal**
September 23, 2011

Well… I cannot believe nobody has posted comments yet, on the CERN presentation of Opera experiment. So Michael, these people obviously have done a really serious job, they seem to have taken into account many of the effects one can think of (e.g. gravitational effect). Still, there is a discrepancy in the speed of the neutrino of order 10^-5 of the speed of light. They do not how to explain this as a statistical bias. Many people will try to find other explanations than faster-than-light neutrinos. Before theoretician start to propose hundreds of models with tachyonic neutrinos, maybe it would be worth letting the experimentalist confirm – or not – these result.

57. **Bitboy**
September 23, 2011

The cynic in me thinks "hmmm, no Higgs yet. No SUSY. What a great way to hold over CERN's political and financial handlers."

I understand that such extraordinary claims as superluminal neutrinos require peer review and independent verification but I wonder whether under other circumstances these wouldn't be conducted without such fanfare.

58. **martibal**
September 23, 2011

@bitboy: I did not find the CERN presentation was done with fanfare. And in their preprint, the Opera collaboration is very prudent, insisting that they do not drive any phenomenological or theoretical conclusions from their result.
Now, it is true that there has been a lot of fanfare in the media. I am not sure this was a desire from CERN or opera.

59. **Vince**
September 23, 2011

Neutrinos from the 1987 supernova were clocked in at precisely the speed of light. How? The supernova was around 150,000 light years away, so even if neutrinos travel faster than light by even a tiny amount, they would have arrived months before the light from the supernova was detected. Instead, due to the dynamics of supernovas, the neutrinos were detected up to 3 hours before the light was first observed. (Neutrinos are generated from the collapse of the core, with the emission of light happening a little afterwards, when the star is blown apart.) Also, more robust experiments show that neutrinos have a very tiny mass, which means they should travel a teeny weeny bit slower than light.

For more, look at Matt Strassler's posting on this:

http://profmattstrassler.com/2011/09/20/supernovas-and-neutrinos/

60. **Fabien Besnard**
September 23, 2011

How ironical that the title of this entry is "No news" 😉

It almost makes me believe that there is something real there.

Vince : thanks for that link. Maybe
this one could be helpful too.

Now my two cents (sorry I can't resist) : the definition of time of flight for a quantum particle is quite tricky. Claims of FTL transmission of information through tunnel effect have been made in the past. Apart from a general relativity effect not taken properly into account, this would be my second best bet for where the error comes from… if there is one !

61. **Peter Woit**
September 23, 2011

All,

I'm afraid I think the "No News" heading is quite appropriate for the neutrino story. Even if I weren't traveling I'd probably not write a posting about it here. It seems nearly certain that there is some subtle problem with the experiment, so the only story here is what that problem might be, and virtually no one submitting comments here appears to have the kind of expertise necessary to make a good guess about that (I certainly don't). So, please, if you want to discuss this, find a blog where the owner is interested in the topic and willing to moderate a discussion. Matt Strassler and Tommaso Dorigo are good bets along those lines, and surely there are others.

62. **martibal**
September 23, 2011

Just a last word (if Peter allows): maybe the topic could move to "this week hype" instead. Just heard from the news on France Culture (a well informed radio, with good scientific programs in addition) a brief interview of a well established particle physicist, claiming that the explanation could be that neutrino have shorter distance to travel, because they travel in extra-dimension.

63. **Kent Traverson**
September 23, 2011

Peter, it might be wise for you to make some kind of answer about the FTL neutrinos, otherwise the media and the masses will keep pestering you about it. This is human nature.

64. **Peter Woit**
September 23, 2011

martibal,

One thing this story does show is that string theory, since it predicts nothing, can be invoked as an explanation of anything.

Kent,
To make this absolutely clear: I'm convinced this has to be due to some sort of error in the experimental analysis, and I'm pretty sure this is the majority opinion of knowledgeable people in this subject. To find the error though requires a real expert, and I'm certainly not that.

65. **Stephen**
September 23, 2011

No News = Headlines on all major media outlets announcing "Einstein was wrong" , how ironic.

66. **Chris W.**
September 23, 2011

The Washington Post's coverage of this story (FTL [?] neutrinos) is pretty good, making clear that a definitive evaluation of the experiment and its results will take quite a while to complete.

67. **MathPhys**
September 24, 2011

This is not the first time that I hear that the speed of light was violated at CERN.

Peter W, When was the first time that you heard that the speed of light was violated at CERN?

68. **M. Wang**
September 24, 2011

I find it ironic that string theorists are trying to jump on this FTL neutrino bandwagon, because isn't string the only quantum gravity theory that insists on preserving Lorentz invariance down to Planck scale? In other theories (including LQG?) Lorentz symmetry is emergent, and small violations can manifest themselves at low energy scale as tiny corrections to various particles' propagators. Effectively, each elementary particle sees a slightly different c. (I am simply quoting Coleman & Glashow 1999.)

I am not saying that the latest result is likely true, just possibly so. After all, 10^-5 is quite large. Not to mention the 1987a supernova experiment, which seems to have already set an upper bound of 10^-8…

69. **Mike**
September 26, 2011

Just heard a great joke:

Neutrino. Who's there? Knock knock.

😉

70. **Mike**
September 26, 2011

Someone just pointed out to me that we already knew that neutrinos pass through air faster than sound, so I guess even if true, FTL neutrinos won't add anything to our humor knowledge base. Ah well . . . . 🙁

71. **Marc**
September 29, 2011

@Charles (from Sept 6)

You are correct in your comment…"*Folks are working together to make this happen at CERN and ultimately in Stockholm*."

At best, John Ellis is the main front-man for CERN and the effort to make this case for a Euro-centric Nobel. At worst, he thinks he should get part of a Higgs Nobel.

His most recent comments in Telegraph in UK make me think more and more it is the later. Pretty remarkable as he has no role in this other than being a prop.

TEDxFlanders

September 25, 2011
Categories: Uncategorized

Tommaso Dorigo and I put on a bit of a show yesterday here in Antwerp at TEDxFlanders, and the results are already available on YouTube (and Tommaso has blog postings here and here). Doing this sort of thing for 1000 people in a venue like the Antwerp Opera House is not at all the sort of thing I'm used to, so I'm glad that it seemed to come out reasonably well.

Much of this was due to the incredible all-volunteer staff, which put on an ambitious day-long program on a shoe-string (+ crucial help from some sponsors) and pulled it off with only the most minor hitches. Christophe Cop was the "curator" and founding father of TEDxFlanders, and Thomas Goorden led the production team to victory. It was a great pleasure to meet them, many of the other volunteers, and some of the other speakers, as well as to get a chance to enjoy some time in the beautiful city of Antwerp.

Back to New York (and maybe somewhat more regular blogging) on Tuesday. Hoping to make Dick Gross's second Eilenberg lecture on Local Langlands at the Columbia math department in the afternoon…

Comments

1. **Bernhard**
   September 26, 2011

   Very enjoyable. I kind off lost a bit what you were saying at 13:31 as the camera decided to show a really beautiful woman instead of you, but the rest I´ve got it :-).

2. **P**
   September 27, 2011

   is it true you don't own a car?

3. **keinkar**
   September 27, 2011

   George Washington didn't own a car either.

4. **Peter Woit**
   September 27, 2011

   P,

   Yes, no car. This isn't exactly unusual though for people living in Manhattan, where it makes a lot more sense to rent a car when one needs to go out of town and rely on public transportation, taxis (and a bike..) in the city.

5. **Lau**
   September 27, 2011

   Great talk, both you and Tommaso!

   I'm shocked to see Lubos' comment on Tommaso's blog about it. I hope Tommaso doesn't delete it, so everyone can see how impolite (I don't want to use a stronger word) Lubos is…

6. **Peter Woit**
   September 27, 2011

   Lau,

   It's not really anything new for Lubos, he's been at this for years. That string theory skepticism has been getting a lot more attention than string theory advocacy in recent years really drives him nuts, with the results that you see….

7. **Quantumburrito**
   September 28, 2011

   Great talk, and not much to add about Lubos Motl whose comment was disgusting. For all his apparent erudition in swearing, Motl is nothing but a failed physicist (who was denied tenure at Harvard) who has crashed and burned and is simply jealous that others are getting more attention than his lunatic, hateful ravings. He hates the fact that he will never make an important contribution to physics and he hates the fact that criticism of string theory is now mainstream; all he can do is foam about it. Face it Lubos, you will probably end up a jealous, cussing old geezer who will never make it even to the footnotes of the physics books. Enjoy your wretched life.

8. **Peter Woit**
   September 28, 2011

   Quantumburrito,

   I do wonder what Lubos will end up as, maybe a major political figure in the Czech Republic?

   For the sake of accuracy, it's my impression that he wasn't denied tenure at Harvard, but (like many if not most of their junior faculty) left before a tenure decision came up. In some places like Harvard, it's assumed that typical junior faculty will do this, with most going on to very respectable positions elsewhere. I don't know exactly why Lubos left academia totally, but string theory crashing and burning was probably part of it (not that he would admit this). Maybe a larger part was realizing that if he wanted a tenured position somewhere he'd have to stop ranting public attacks on people he disagreed with.

9. **King Ray**
   September 29, 2011

   This comment is a little off topic, but might be illuminating. I read Understanding Other People by Stuart Palmer, since it was recommended in a book about writing fiction, to help you understand your characters and develop their motivations. Palmer's thesis is that everyone is motivated by the need to gain approval and/or the need to avoid disapproval. If someone is frustrated in these needs, and they are not properly socialized, then they turn to aggression against others. Someone who is too socialized to aggress against others may end up aggressing against themselves, e.g., suicide. An example given in the book is that of a hermit. A hermit doesn't have a strong need for approval, but has a very strong need to avoid disapproval, so they avoid other people.

10. **Rane Bowen**
    October 3, 2011

    I seem to have taken too long to get about watching this – the youtube video is now private, and I can't see it!

This and That

September 27, 2011
Categories: Uncategorized

- Since everyone wants to hear about the faster-than-light neutrinos, here's some additional information about why I don't believe it. Jon Butterworth explains here the problem with timing the neutrinos at the CERN end. In a postscript, a senior member of OPERA points out that he and four other senior members of the collaboration kept their names off the paper. Their reasoning seems to have been that this is a very preliminary, likely wrong, result, being sold as more robust than it is. Tommaso Dorigo had a similar analysis to Butterworth's up on his blog early on, but was induced to take it down because the release to the press and the associated hullabaloo had not yet taken place.
- I had been wondering what had happened to the million dollars from the Millenium Prize that Perelman turned down. The Clay Mathematics Institute has recently announced that the money will go to fund, for the next five years, a postdoctoral position at the Institut Henri Poincaré, to be called the Poincaré Chair.
- A sign of the times: today's HEP seminar at the IAS was titled "Is SUSY still alive?". I wasn't there, so don't know what the answer was, but clearly the question is now being asked.
- The Tevatron will shut down on Friday for good, ending an era. There's an article about this in Science magazine here. Gordon Kane was expecting SUSY to be discovered by this machine, but that didn't work out, and he's no fan of Fermilab management:

> But Kane argues that the Tevatron underperformed all along because of weak management at the lab and the Department of Energy, which funds Fermilab. "It could have performed much better and done much more," he says.

Reaction to this from Nicholas Samios was:

> "I would not trust a theorist to talk about management," Samios says.

Comments

   September 27, 2011

   http://arxiv.org/abs/1109.5687

2. **Tom**
   September 27, 2011

   A million bucks only pays for five years of a postdoc? Mathematics must pay a heck of a lot better than experimental HEP does.

3. **chris**
   September 28, 2011

   it should have been named Perelman Chair at the very least.

4. **mo**
   September 28, 2011

   > A million bucks only pays for five years of a postdoc? Mathematics must pay a heck of a lot better than experimental HEP does.

   I guess they meant an endowed chair funded by interest income. A million dollar endowment yields these days about $40k in income which is barely enough provided the administrative overhead at IHP is very low.

5. **Piérick**
   September 28, 2011

   chris says: *"it should have been named Perelman Chair at the very least."*

   I do not want to offend the work of Perelman but, IMHO, he has not yet accomplished a sufficient work so that we can claim to substitute its name with that of Henri Poincaré…

6. **Peter Woit**
   September 28, 2011

   mo,

   It doesn't appear to be an endowment, since it is not permanent, but only for five years. This does seem to be a lot of money to pay for a postdoc for five years.

7. **Bobito**
   September 28, 2011

   Why working in a Mediterannean, crisis-affected country is a bad idea: a million dollars would pay my salary for the rest of my life, and retirement too (remember, no need to adjust for inflation, since austerity measures cut my pay yearly).

8. **martin**
   September 28, 2011

   They probably mean many postdoc positions.

9. **EscherBach**
   September 28, 2011

   aha! the long awaited experimental proof of string theory.

   Of course, ST is also compatible with this result being hokum (phew!) 😉

10. **EscherBach**
September 28, 2011

referring to MathPhys' link above

11. **Steven Colyer**
September 28, 2011

Peter,

The cost of an employee is huge, sometimes more than twice sometimes of what the salary is, thanks to government regulations and internal bureaucracy. For example: benefits, insurance, travel, etc. Payroll is often 60% of expenses, so a $100,000 salary at Poincare seems reasonable.

12. **francois**
September 28, 2011

Regarding the seminar at IAS, there is a popular saying that states that:

When the title of a talk is a question, then the answer is most likely NO…

13. **Peter Woit**
September 28, 2011

Steven,

It's still unclear though how this can add up to 200K/year to fund one postdoc, unless the postdoc is extremely well paid. Maybe there is more than one position, or maybe not just the postdoc is getting funded.

14. **mgr**
September 28, 2011

A theorist can be a good manager, for example Neils Bohr and his institute of theoretical physics (now named after him). Oppenheimer was a theorist and manager of the Manhattan Project. Isaac Newton was Master of the Mint and by all accounts he ran the place well. (But was Newton a theorist or a mathematician?) Experimentalists can also be good managers. Both theorists and experimentalists can also be outrageously bad managers. Being a good manager is a skill unto itself. What could the Fermilab management have done better, with the Tevatron? They could have operated it to higher energy. The Tevatron magnets run at 7.7 Tesla (approx) to reach a beam energy of 1 TeV. Operation at higher energy would have required a higher magnetic field, also higher operating costs. There was also a scheduling problem for collider vs. fixed-target operations. Remember that the Tevatron also operated as a fixed-target proton synchrotron, not exclusively as a p-pbar collider. The Fermilab management eventually built the Main Injector, which could deliver beam for neutrino physics in parallel with Tevatron collider operations. The integrated luminosity could perhaps have been higher, but it is not clear how that could have been done any better than it was. It is not so simple to figure out what more the Tevatron could have done.

15. **Coin**
September 28, 2011

"it should have been named Perelman Chair at the very least."

I would question whether Perelman himself would want that.

16. **EscherBach**
September 28, 2011

No doubt Perelman is fine with "Poincare" name for the Chair, for obvious reasons.

$200,000 per year might include expenses and travel for organising annual seminars. Also $1million dollars don't get you as many euros as it used to, and the trend could be downward (depending on which currency has the biggest crisis over the next few years)

17. **BJM**
September 28, 2011

Maybe million dollars is not to be all spent and the plan is to revisit what to do with the remaining sum after five years.

18. **Bernhard**
September 28, 2011

I find a bit curious the claims that the top quark "had to be there". Had to be there like what? The Higgs? SUSY? I think Kane put in SUSY the same kinf of faith, perhaps even more faith. I remember when I was in a school for which David Gross was the director. The question raised for the audience was "what was the last big discovery in HEP?". Someone shouted "the top quark!". Dave Gross turned around and said loudly with a grumpy voice "iiit was a confirmation!". Perhaps. What is the difference compared to the Higgs tough? Easy to say something had to be right after you know the answer…

19. **Reply to Bernhard**
September 28, 2011

Wasn't the top required to be there for triangle anomaly cancellation?

20. **Bernhard**
September 29, 2011

Reply to Bernhard,

Sure. There were indeed strong reasons to believe the top quark would be discovered. These reasons were proved to be correct, but I don't think they are stronger than the reasons we have to believe the SM Higgs should also be there. My point is that you can't be sure until you really detect it. This attitude of "of course it will be there because my model said so" is what put us in this situation of over confidence with SUSY. Guys like Kane were not really worried about discovering SUSY, but simply confirm it, since of course the s-partners would be there to "solve" the hierarchy problem, explain dark-matter etc etc. The success of the top-quark prediction is undeniable but could have been proved wrong too, for some reason. We were right and that's nice but we won't be always right.

21. **besnard**
September 29, 2011

I've counted 12 papers already (with 2 replacements) about OPERA in the arXiv, just for today !

22. **J**
September 30, 2011

"francois says:
September 28, 2011 at 11:45 am
Regarding the seminar at IAS, there is a popular saying that states that:

When the title of a talk is a question, then the answer is most likely NO…"

FYI: there was actually a talk a bit earlier at BNL with the title "Is SUSY dead?" I think although this title is a question the intended answer was most likely YES 🙂

Peter: I like the amusing comment from Nick.

23. **Craig Dukes**
September 30, 2011

mgr:
The Tevatron magnets run at 4.2 T, not 7.7 T, half the LHC magnet design field of 8.4 T. At the present the LHC magnets are at about the same field as the Tevatron magnets.

24. **James Matterson**
October 1, 2011

Every time I keep hearing about this FTL neutrino nonsense, I think of [this recent xkcd comic]!

25. **Reply to Bernhard**
October 2, 2011

The reasons to expect the top quark were much stronger than the reasons to expect the standard model Higgs. A triangle anomaly renders the theory fundamentally inconsistent. No Higgs or other-than-standard-model Higgs doesn't violate consistency, it only violates the Standard Model.

26. **Bernhard**
October 2, 2011

Reply to Bernhard,

Triangle anomalies are solved within models (e.g. in the SM is solved family by family separately while other models solve them between families) . It is perfectly possible to build a QFT without a top quark making an arrangement to cancel it out. Sure you can´t find many of such models since model building in HEP starts with the SM, but a top quark does not make QFT inconsistent it makes the SM and other models inconsistent. I´m not saying the top quark solution was not a expected one, quite the contrary, but I´m not convinced it makes the "theory" (which by the way?) inconsistent. Within a certain framework, like the SM, but not necessarily, is unavoidable, but this is not to say is unavoidable as a general rule. It´s like you are saying "model building rules for renormalizable QFT depends on the existence of a top quark". That ´s not true.

27. **Reply to Bernhard**
October 2, 2011

All I can say is that an alternative-to-the-top anomaly canceling solution would be revolutionary.

28. **Bernhard**
October 2, 2011

I still think you´re talking about the SM.

29. **Reply to Bernhard**
October 2, 2011

Use the particles known prior to the top consistent with the then known facts, and tell us how anomaly cancellation does not require the top or why we don't care to have an anomaly-free gauge theory.

Over and out.

30. **Bernhard**
October 3, 2011

Sigh… Anomaly cancelation where my friend? In the SM, I have no idea how to do that. But if I'm allowed to throw in the theroy whaetver mirror particles (with high mass) that I want mass that's not difficult.

31. **Reply to Bernhard**
October 3, 2011

Sigh, you're mixing up "known experimental facts" and "standard model". If prior to top discovery, you were able to throw something together with no top **and** no anomalies that was compatible with the then-state of experimental knowledge, that would have been a valid competitor(then) to the standard model. Either such a model was proposed but is hidden behind the veil of time, or physicists were singularly unimaginative back then. Or the existence of the top was postulated on a very sound basis. Contrast with the Higgs. Right now, there are plenty of alternatives to the standard model Higgs, none of them yet ruled out by experiment.

32. **Eric**
October 3, 2011

Dear Bernhard,

It is well-known that the anomalies from the the quarks are canceled by the anomalies from the leptons in the SM, separately within each generation. Once the bottom quark and the tau lepton were discovered in the 70's, it was clear that the top quark should exist in order to satisfy the anomaly cancellation. Since the anomaly cancellation is within each generation, one could add any number of generations of quarks and leptons to the SM and still cancel anomalies.

33. **Peter Woit**
October 3, 2011

Eric, Bernhard, Reply to Bernhard,

Discussion of this not-very-interesting off-topic question has gone deep into pointlessness. Enough of this.

This Week's Hype

September 28, 2011
Categories: This Week's Hype

It had to happen. New Scientist managed to find a physicist willing to describe the OPERA result as "evidence for string theory":

> So if OPERA's results hold up, they could provide support for the existence of sterile neutrinos, extra dimensions and perhaps string theory. Such theories could also explain why gravity is so weak compared with the other fundamental forces. The theoretical particles that mediate gravity, known as gravitons, may also be closed loops of string that leak off into the bulk. "If, in the end, nobody sees anything wrong and other people reproduce OPERA's results, then I think it's evidence for string theory, in that string theory is what makes extra dimensions credible in the first place," Weiler says.

Update: hep-ph is chock-a-block with papers purporting to explain the OPERA results, using theoretical models of varying degrees of absurdity. There is however one much more sensible paper this evening, from Cohen and Glashow, which points out that superluminal neutrinos would produce electron-positron pairs via bremsstrahlung, and lose energy, which is not observed. This is also incompatible with Super-Kamionkande and IceCube data. No matter what sort of extra dimensions you introduce for the neutrinos to travel in, the OPERA claim seems to be in violent disagreement with other observations.

Comments

1. **Ben Martin**
   September 28, 2011

   I remember when New Scientist was a decent, reputable publication. This make me feel very, very old.

2. **Peter Woit**
   September 28, 2011

   Ben Martin,

   And I can remember when the only people the press could find to make absurd claims like this were obvious crackpots, not respectable physicists…

3. **Bernhard**
   September 28, 2011

   Was easy to see this one coming. String theory is the explanation for anything new, right or wrong.

4. **Proudmemberofthecult**
   September 28, 2011

   Compared to the current flood of papers on hep-th,hep-ph, gr-qc with the word superluminal this is but a small trickle. Sometimes it seems physicists are like locusts in search of food.

5. **MathPhys**
   September 29, 2011

   When I posted that link to Gubser's paper, I thought it was the only one on the subject. How silly of me.

6. **Phil**
   September 29, 2011

   I'm more sorrowful for the decline of Scientific American… as I remember it New Scientist was always sensationalist, albeit often in an entertaining sort of way. Anyhow I wouldn't beat them up too bad for this – *if* the OPERA results hold up it *will* point to *something* very unexpected and bizarre. Can't argue with that. Given how unlikely it is they'll hold up, it's admittedly a surreal discussion…

7. **Misha**
   September 29, 2011

   Who is this Weiler, after all? Is he a reputable physicist? I have not heard of him. The superluminal hype will inevitably continue for some time, since many theorists are indeed hungry and in search of ideas, but then it will fizzle out …

8. **I wonder ...**
   September 29, 2011

   If string theory explains the OPERA result, why didn't any string theorist cite their work before it came out?

9. **chris**
   September 29, 2011

   so… does that mean that when the opera result doesn't hold string theory is falsified?

10. **MathPhys**
    September 29, 2011

    Misha, I expect that Tom Weiler hasn't heard of you either.

11. **Yatima**
    September 29, 2011

    Neutrinos Faster Than Light, or Artifacts of the FPGA?: Comments About the FPGA Platform Used in the Data Acquisition System of the OPERA Experiment"

    > After devouring everything I could read about the experiment, I speculate ("gut feeling") that the explanation of these unexplainable numbers are variable

timing delays introduced by the FPGA-based data acquisition system (DAQ), for the reasons stated below.

I guess that's a possible explanation.

12. **Shantanu**
September 29, 2011

Tom Weiler is a very respected physicist at Vanderbilt who has worked on neutrinos
including astrophysical aspects.

13. **Noah Smith**
September 29, 2011

Hi Peter, this may only be on-topic regarding hype occurring this week. I'm curious how you interpret this press release. It seems to almost ignore the possibility there is no Higgs.

http://www.spacedaily.com/reports/Could_the_Higgs_boson_explain_the_size_of_the_Universe_999.html

14. **Peter Woit**
September 29, 2011

Noah,

I took a very quick look at their paper. It looks like they're trying to put together the Higgs field with another scalar field (the "dilaton"), and get an underlying scale-invariant theory with known mass scales picked out by dynamical symmetry breaking. This certainly does require a conventional Higgs field, so if no Higgs shows up at the LHC, it rules this idea out. Like most ideas, it's quite speculative, and not particularly convincing. They are trying to use it to make predictions about inflation, maybe this goes somewhere, but to evaluate that you need a cosmologist, not me. It doesn't say anything new about LHC-scale physics.

The story involves just the usual amount of hype always there whenever theorists try and promote ideas they're working on. I suppose it's worth noting sociologically that maybe now it's considered much more promising to relate one's ideas about a dilaton field in cosmology to the Higgs than to string theory…

15. **Noah Smith**
September 29, 2011

Thanks Peter, the sociology seems interesting. When I see this type of press release I wonder about the types of people involved. Last weeks neutrino news felt like a similar case. I wonder if I'm just noticing these things more often, or the frequency is actually increasing…:)

16. **Peter Woit**
September 29, 2011

Noah,

The Higgs/dilaton thing is something very common, an isolated story about some speculative theoretical idea, one that isn't getting a lot of attention from anyone except the authors.

The neutrino thing is quite different, there a major experimental collaboration is releasing an experimental result claiming to overturn fundamental principles of physics. If this were solid, it would be huge, and deserve the attention it got in the press. The problem here though is that it's a very implausible result, and not that solid. Many experiments at one time or another appear to be giving exciting data that violates fundamental principles, but this is essentially always a mistake in the experiment. So experimentalists typically are more wary than the OPERA people seem to have been about going public, since the likely end is that this will be shown to be mistaken, in which case the fewer people who see your mistake, the better…

Once the experimental result is out there, I guess it's not surprising that lots of theorists try and jump on the bandwagon and get attention for speculative ideas of their own. That anyone these days puts out a story about "evidence for string theory" with a straight face is perhaps a bit surprising.

17. **Chris Austin**
September 29, 2011

This is the list of Weiler's articles on arXiv.

18. **Daniel**
September 29, 2011

There seems to be a number of scientists who will be coming up with a posteriori explanations of the OPERA results, but that's a little too easy imho. Too many theories can be retrofitted.

My question is, are there any theories that predicted superluminal speeds, and in particular, superluminal neutrinos?

19. **Bernhard**
September 29, 2011

Daniel,

Perhaps this might be of interest to you:

http://www.sciencedirect.com/science/article/pii/0370269385904605

20. **Coin**
September 29, 2011

Yatima: … hm. Having worked with FPGAs in the commerical engineering space, I would be * really * surprised if this turned out to be the problem, just because this is the sort of thing you'd normally expect any competent FPGA engineer to get right. FPGA engineers are usually– basically have to be– highly sensitive to timing issues, and it would seem that the kinds of (highly plausible) error the blogger proposes would be very easy to test and calibrate for without requiring actual neutrinos in the system. I'm sensitive to the argument an experiment run by physicists might not think to worry about some of these issues even where it would be the first thing engineers would think of, but I'd assume if an experiment like this is hiring someone to design this sort of thing for them then that person is basically being paid to think of these sorts of things…

I mean, I do think the blog article author raises some excellent questions that deserve answers but I'm not going to expect this to be the source of error.

21. **Daniel L. Burnstein**
September 29, 2011

Thanks Bernhard. Very interesting indeed.

22. **M**
September 30, 2011

Notice that already http://arxiv.org/abs/1109.5682 had an inconsistency argument against the OPERA anomaly:
"We point out that, quite generically, electroweak quantum corrections transfer the information of superluminal neutrino properties into Lorentz violations in the electron and muon sector, in apparent conflict with experimental data."

The argument from Cohen and Glashow is probably more clean.

23. **Shantanu**
September 30, 2011

Peter, this maybe offtopic , but what happened to the unparticle by Georgi a few years ago? Is it completely ruled out?
Thanks

24. **Sascha Vongehr**
September 30, 2011

Actually, one can in hind sight say that the results were expected:
http://www.science20.com/alpha_meme/expect_tachyonic_neutrinos_have_their_higgs_and_smoke_it-83157
Anyway, why so negative?

25. **Anon**
September 30, 2011

One thing that bothers me, is that if neutrinos are tachyons, why should all extant measurements of their speed give a result so close to the speed of light, instead of being distributed over all possible velocities on their purported tachyonic mass hyperboloid? In an experiment like this one, maybe there is a kinematic reason, but what about the supernova observations? Would there also be a kinematic reason?

26. **somebody**
September 30, 2011

Me and none of my string theory colleagues have ever heard of this Weiler character. There are plenty of fossils with tenure in various universities. Not suggesting that Weiler is one such, but it also doesn't mean that his opinions are the opinions of the string "community".

Gubser paper says in fact that it is not easy to explain superluminal neutrinos even with extra dimensions, if you only have ordinary matter. Anybody who wants some attention from the media just has to make some statement (positive or negative) about string theory. Shrug.

27. **J**
September 30, 2011

There is actually a paper focusing on the experimental issues

http://arxiv.org/abs/1109.6160

which seems to suggest "the effect of the synchronisation convention is not properly taken into account in the OPERA analysis and may well invalidate their interpretation of superluminal neutrino velocity".

28. **M. Wang**
September 30, 2011

Thanks for the link to Cohen & Glashow. It is most pertinent. Now theorists can conclusively say that the OPERA result has to be wrong.

Too bad that Sidney is no longer with us, but I am glad to see that Sheldon is there to cut through the clutter in 3 simple pages. They don't seem to make physicists like them any more.

29. **DPB**
September 30, 2011

@M. Wang

While I agree that superluminal neutrinos are incredibly unlikely I have to disagree on one major point. It isn't the job of theorists to conclusively say that experimentalists are wrong. Experiments must always have the final say, eventually.

30. **abbyyorker**
September 30, 2011

DPB

According to Glashow and Cohen, the experimental evidence IS there, but the experimentalists could not parse it. Not dumping on them but theorists have a bigger role than you imply.

31. **high school physics teacher**
September 30, 2011

Sir,
Having Glashow's tour de force "refutation" existing under the main heading of This Week's Hype seems a bit amiss. I'm just saying…

32. **MathPhys**
October 1, 2011

"Me and none of my string theory colleagues have ever heard of this Weiler character. "

If your string theory is as good as your grammar, I don't think my colleagues and I will ever hear of you.

33. **D R Lunsford**
October 1, 2011

Glashow seems to keep a pretty low profile, probably because he's just a nice man and doesn't want to get involved in controversies. In this case, I get the strong feeling that "enough was enough", and the world's great expert on neutrinos had to say something correct 🙂

-drl

34. **Shantanu**
October 1, 2011

Its also nice to see 3 of my papers cited in Cohen and Glashow reference (ref 8 to 10) 🙂

35. **Aaron Sheldon**
October 1, 2011

As a statistician, after reviewing the OPERA paper, the analysis conducted is seriously flawed. They fitted only a single MLE for a time offset against the empirical proton distribution; that is they fitted assuming all the neutrinos have a uniform time of flight. They should have fit additional MLEs for the dispersal in neutrino velocities. This oversight should have sunk the paper out of the gate, as it makes the numerical analysis is fatally flawed. It is very likely that including MLEs for velocity dispersal would have reduced the time offset MLE to within the range of the systematic uncertainties and biases.

Overall it is a bad sign for the quality of the editorial statistical review in the literature.

36. **Aaron Sheldon**
October 1, 2011

Just to be clear how the dispersal MLE would work. One would fit for the parameters of a normal distribution that is convoluted with the empirical proton distribution, where the mean is the time offset and the standard deviation is the velocity dispersal along the flight path.

37. **doctor physics**
October 1, 2011

would i be far off, in saying, that this seems to be not-even-wrong theories seeking out faulty experimental results as life-blood?

38. **David Nataf**
October 1, 2011

Aaron,

Would you care to elaborate on why that would matter?

Are the mean and variance of a Gaussian not supposed to be uncorrelated?

39. **Aaron Sheldon**
October 2, 2011

Basically the opposite of over fitting the data, you are under fitting the data. In the OPERA article they assumed they knew more about the velocity distribution then they actually did. If you assume you know less about how the velocity is distributed, then your uncertainty in the time offset is going to be much greater. Really they assumed there is much less variance (and co-variance) in the data then their actually is.

The dirty little secret of statistics is that p-value, and sigma counts are really just indicators of likelihood of convergence of the MLE to a particular value, not the validity of the model. If you choose the wrong distributions to fit to the data, the MLE will in most cases still converge (as long as the Kullback-Leibler divergence of the fitted distribution against the actual, unknown, distribution is finite), but the answer will not be meaning full.

The best test would be to use the likelihood ratio test to compare the convolution with the normal hypothesis to the linear shift hypothesis, because the linear shift is a sub-space of the convolution hypothesis (normal with zero variance, i.e. the Dirac linear shift functional).

It will take a solid week to work out the differences formally, but basically it comes down to work on a couple theorems like this:

1. Given a family of probability density functions f(x – \theta) parameterized by \theta, if we find the MLE of the family of probability density functions parameterized by a convolution with the normal distribution n({x – \mu} over \sigma) \star f(x) then the distribution of the MLE of \mu and \sigma are…

2. (dual) Given a family of probability density functions parameterized by a convolution with the normal distribution n({x – \mu} \over \sigma) \star f(x), if we find the MLE of the family of probability density functions f(x – \theta) then the distribution of the MLE of \theta is…

the physics community should take some solace that this is an incredible common mistake in the life sciences, my particular haunt, and hence I've become particularly attuned to this error.

40. **Aaron Sheldon**
October 2, 2011

PS,

A literature search on my name will not turn up much of anything meaningful.

Because I am a senior analyst for a large health care provider much of the work I do is either privileged within the organization and its oversight body, or is restricted by the prohibition against the secondary use patient information laid out in health information laws in the jurisdiction in which I work.

41. **Reply to Zathras**
October 2, 2011

OPERA assumed that all neutrinos travel at the same speed. Theoretically there was no a priori reason to believe that neutrinos with an average of 17 GeV energy travel with any significant speed dispersion.

42. **Reply to Zathras**
October 2, 2011

One more point – it is difficult to be sure from the OPERA paper, but it does appear that the time interval from the earliest to last detected neutrino events matches the duration of the proton pulse – i.e., there is no spreading. It bothers me – physical processes tend to spread pulses. A 60 ns spread in a 10,000 ns pulse is only 6 parts per 1000, and yet might swallow up the 60 ns that they found. On the other hand it is difficult to think of a known physical process that would cause so much spread. So as far as we know there is no spreading of the pulse; and so, at least to me, it seems there can be no speed dispersion of significance.

43. **Aaron Sheldon**
October 2, 2011

Unfortunately the Law of Large Numbers is not as kind to such assumptions as one would assume, and in the case of the OPERA results, all the 6-sigma level tells me was that the N was more than large enough to get good convergence of the MLE, but little else.

As I stated before a statistical hypothesis that understates the sources of variability will over state the statistical confidence of the MLE. Without writing a single equation down I can tell you with certainty that if you do not include dispersion in your statistical fit of the MLE you will underestimate the variance in the fitted MLE.

In information theoretic terms, adding the dispersion “uses up” part of the information in the data set, and so the variance in the time offset will be larger because you have less information to constrain its value.

44. **David Nataf**
October 2, 2011

Zathras,

1) You have a fantastic screen name for someone on a time travel discussion thread.
2) If the neutrino has a mass, real or imaginary, does that not mean that an energy dispersion implies an velocity dispersion?

In light of the very small effect they “measure”, even an energy dispersion of say… 1%, could give the velocity dispersion sufficient to yield the systematic effects mentioned by Aaron.

45. **Reply to Zathras**
October 2, 2011

David,
Wiki says the muon neutrino has a mass less than 170 KeV. In conventional Einstein theory, at 1700 KeV, already the neutrino is within 0.005% of the speed of light, and we are talking here of neutrinos with an average energy of 17 GeV = 17,000,000 KeV. There is no room for a 1% speed dispersion here, if the speed of light is the upper limit of speed. Note also that the superluminal speed that OPERA finds is about 0.0025% faster than light.

The second point, on which I would like clarity, if anyone has it, is what I pointed out already – there seems to be no spreading of the pulse, and that would suggest no speed dispersion, even if the neutrinos were superluminal.

Unless there is something new to say, I’ll be silent now; Peter does not like repetitions.

46. **Aaron Sheldon**
October 2, 2011

Actually, according to the paper they have sufficient N to detect a dispersion of about 1 part in a thousand, but the cost would be that the 6-sigma intervals would be much larger (roughly your MLE distribution is over area instead of length).

Interestingly, this is also why political polls are so unreliable, because they underestimate the variance, which is calculated for simple binary choices, when in fact political polls typically have four or more choices depending on the number of candidates. It comes down to the problem of volume, if you want 90% of a centimetre you only need 9 millimetres, but an area of 9 X 9 millimetres is only 89% of the square centimetre, you need ~9.48 X 9.48 millimeters to get 90% of a square centimetre…the logic continues inductively, remembering that probability is just a fancy way of saying volume.

47. **Aaron Sheldon**
October 2, 2011

About the restrictions due to being close to the speed of light, that actually adds one more hypothesis with one more unknown parameter that needs to be fit. To enumerate:

1. A simple uniform time shift with a single parameter, the time shift.

2. Convolution with the normal distribution with two parameters, the time shift and the dispersion

3. Convolution with the normal distribution where the underlying variable is first Lorentz transformed by some unknown speed (which destroys the symmetry of the dispersion), this has three parameters, the time shift, the dispersion, and the speed of the Lorentz transformation.

Hypothesis 2 is a sub-space of hypothesis 1 in the limit that the Lorentz speed parameter goes to 0.

Hypothesis 1 is a sub-space of hypothesis 2 in the limit that the dispersion goes to 0.

This makes all of these hypotheses ripe for the likelihood ratio test.

And that is pretty much how a statistician thinks.

48. **Aaron Sheldon**
October 2, 2011

Opps hypothesis 2 is a sub-space of hypothesis 3…

I think you can see where I was going

49. **Bob McElrath**
October 2, 2011

Aaron Sheldon,

First, the assumption of velocity dispersion is, not reasonable from a physics perspective. To have a delta-v large enough to affect the pdf, the energy of the neutrino would be so low that it would not be detected. One can easily calculate the expected dispersion from several sources and it is vanishingly small. Second, from a statistics perspective, the assumption of velocity dispersion would broaden the observed distribution of arrival times, as well as possibly bias it toward later arrival times. A careful look at Figs. 11 and 12 in the paper shows that this is not supported by the data.

Second I think you are misinterpreting the "six sigma" quoted as a statistical p-value, and as that p-value is very tiny, you're attributing disbelief in that small value to an error in fitting. It is not a p-value. The experiment clearly does not have enough statistics to report such a p-value (they only have ~16000 events). In physics the distribution of errors on a counting experiment such as this is generally unknowable, and is generally not Gaussian. One can only know the actual arrival time error function as well as the 16000 events will allow you. So what happens instead is that a fit is done, and a central value for that fit, with 1-sigma error bars is reported. When the 1-sigma error bar is separated from the expected value by a factor of six, we report "six sigma". That is six times the 68% confidence interval, *not* a statistical p-value of 2e-9. e.g. the unobserved tails of the arrival time pdf are assumed to be gaussian. They never are. They are always much flatter than gaussian far away from the central value. The 5-sigma used in physics to report a "discovery" is a rule of thumb, forced upon us by the fact that we cannot reasonably determine the pdf of the measurement to the precision required. In most cases we can simulate the pdf using a model of the detector and backgrounds, but simulating the tails to the required precision to report the p-values of a discovery is out of the question computationally. Furthermore, the tails tend to be dominated by extremely rare physics that is not accounted for in the simulation. There are a very large number of possible sources of 0.1% errors, most of which are not known, and to chase them all down in order to improve the simulation is impractical from a manpower perspective, and usually impossible physically. In our field, we see three and four "sigma" results disappear on a regular basis, while any reasonable statistician would agree that the p-value corresponding to three sigma is sufficient to claim a discovery. Often the cause of an erroneous measurement is never actually discovered, but subsequent experiments fail to confirm it, and the older experiment is dismissed.

50. **Bernhard**
October 2, 2011

Off-topic: Witten will be Ireland talking about "The Quantum Theory of Knots.":

http://www.irishtimes.com/newspaper/sciencetoday/2011/0929/1224304927736.html

http://muon.wordpress.com/2011/10/01/theories-about-superluminal-neutrinos/

A list of theories about OPERA results.

52. **Reply to Bernhard**
October 2, 2011

J mentioned: http://arxiv.org/abs/1109.6160
The story seems to be that a portable atomic clock was synchronized with the OPERA clock, and then transported to CERN, and used to measure the offset with the clock there. There are obviously all kinds of problems – special and general relativistic effects would make that measurement useless.

Fortunately, the "Portable Time Transfer Device" that was used does not such thing. OPERA used highly accurate GPS based clock synchronization. The common view time transfer mode is explained here:
http://tf.nist.gov/time/commonviewgps.htm

The one problem is to measure accurately the offset between the GPS signal and the local clock, and the "Portable Time Transfer Device" enables the use of exactly the same device at both CERN and OPERA, so that uncertainties introduced by the use of different devices is eliminated.

53. **ZZZ**
October 2, 2011

The Cohen and Glashow paper does not prove the OPERA result wrong, but instead suggest a way to reconcile OPERA with the 1987 supernova observations.

OPERA showed that the average velocity of the neutrinos over their first 730km of travel was higher than c. C&G suggests that neutrinos can slow down to c via pair production. Therefore their average velocity from the supernova to Earth can remain very close to c even if their initial velocity was higher.

This deceleration might also explain why OPERA observes neutrinos with different energies to have average velocities that differ only slightly.

54. **Reply to Bernhard**
October 2, 2011

ZZZ, OPERA reports seeing neutrinos of 42.9 GeV or higher. Cohen and Glashow say that if neutrinos are superluminal, even travelling over just 730 kilometers, they shed energy so rapidly that whatever their initial energy, few if any should have reached OPERA with energies greater than 12.5 GeV. "The observation of neutrinos with energies in excess of 12.5 GeV cannot be reconciled with the claimed superluminal neutrino velocity measurement." If C&G are correct, OPERA is wrong.

55. **Aaron Sheldon**
October 2, 2011

Bob,

First I'm not any reasonable statistician, I'm in fact a quite unreasonable one, who is more of an extremely diligent probability theorist disguised as a statistician.

What it comes down to is very simple, they fit a flawed statistical model. The attractively simple model of a linear time shift, assumes a prior that any and every time shift is possible. All the 6-sigma indicates is that there is good convergence in the MLE, not that the finding is correct. Bluntly MLEs do not test hypotheses.

Another possible attack they could have used is to propose a model with a parameter controlling the lower bound of time shifts allowed, and that limits toward the simple linear shift model. Then fit the MLEs of each model and use the likelihood ratio test to compare the two models.

56. **Mitchell Porter**
October 3, 2011

I bet that in the coming weeks, the assumptions behind the derivation of superluminal bremsstrahlung will be a point of contention. There will be a need to return to first principles. For those who want to play, http://arxiv.org/abs/hep-th/0611263 revisits Wigner's classification of representations of the Poincare group and includes the tachyonic cases…

57. **Mitchell Porter**
October 3, 2011

There's also a large literature on tachyon physics, like Feinberg's original paper, and the work of Dawe and Hines, which so far isn't playing any role in the discussion about OPERA. (Dawe and Hines raise the issue of tachyonic bremsstrahlung in their second paper.) So far the model builders are all trying to "save causality", e.g. with extra dimension models in which the true relativistic speed limit is only realized off our braneworld. But the next step has to be an examination of models in which there are closed timelike curves and retrocausal influences. There have been various attempts to explain quantum mechanics itself as arising from such effects (e.g. http://arxiv.org/abs/gr-qc/0703150) or to employ quantum mechanics in order to neutralize their paradoxical threat (e.g. http://arxiv.org/abs/1005.2219). Hopefully one side effect of OPERA's announcement will be a closer examination of these issues.

58. **Chris Oakley**
October 3, 2011

Mitchell,

The Bekaert/Boulanger paper points out (near the end) that tachyonic unitary irreps cannot have finite-dimensional spin, whereas the neutrino has spin 1/2, which is finite (NB: I look at tachyonic ISO(3,1) myself on page 12 here: http://www.cgoakley.demon.co.uk/qft/RQM.pdf) so in the unlikely event that there is anything superluminal here, Unitary Irreps of the Poincare group are probably going to be an early casualty.

59. **Igor Khavkine**
October 3, 2011

For those entertaining thoughts of using tachyonic representations of the Poincaré group to explain superluminal neutrino propagation, isn't anyone bother by the fact that the wave equation whose solutions furnish such representations is essentially the Klein-Gordon equation with the sign of the mass term flipped? The reason someone should be bothered by this is that a general theory of hyperbolic PDEs shows that the speed of signal propagation (say as characterized by the support of the retarded Green function) entirely depends on the highest derivative terms, which are unaffected by the sign flip. In other words, the speed of signal propagation by Poincaré invariant "tachyonic" wave equations remains squarely ≤ c.

60. **Chris Oakley**
October 3, 2011

Igor,

Not following you here. Tachyonic Poincare irreps have E = √((pc)^2-(μc^2)^2), so the dispersion relation of the de Broglie waves is ω=√((kc)^2-(μc^2/hbar)^2) and hence group velocity ∂ω/∂k = kc/√(k^2-(μc/hbar)^2) which is greater than c.

61. **Marcus**
October 3, 2011

Remarkable paper by Dmitri Nanopoulos and co-author where he gets string to explain stuff going all different speeds in agreement with various observations:
http://arxiv.org/abs/1110.0451
Background Dependent Lorentz Violation from String Theory

I know there are scads of "string theory predicts FTL neutrino" papers, but this could just be a cut above the rest. It explains how they can go FTL thru rock here on earth and yet slower than light out in space between galaxies. It takes the cake.

62. **Igor Khavkine**
October 4, 2011

Chris,

However fast either group or phase velocities are, the information contained in a pulse (be it encoded in a peak or some kind of modulation) cannot outrun the discontinuous edge of the same pulse.

If you model signal propagation with a **retarded** solution of the "tachyonic" wave equation *box φ+(m^2) φ = f* , where *f* is a source with support in a bounded region *S*. Then, interpreting *&phi* as carrying the news about what happened in *S*, the retarded boundary conditions ensure that *φ* is exactly zero everywhere outside the domain of influence of *S* (the region reached by **null** or **timelike** rays emanating from *S*). Hence, the news of what happened in *S* does not reach anywhere faster than light (null rays). This conclusion holds independently of the sign of the *(m^2)φ* term.

If one disallows generation of signals through discontinuous (just non-analytic is enough, actually) processes, then it becomes very difficult to draw the distinction between communication and a priori conspiracy. Then the notion of the speed of a signal becomes significantly muddier.

63. **Anon**
October 7, 2011

Ehrlich dismisses Cohen and Glashow's objection (and some other objections) here: http://arxiv.org/abs/1110.0736v2

64. **Reply to Zathras**
October 7, 2011

Ehrlich argues that the high energy neutrino events logged at OPERA were caused by subluminal neutrinos, and the overall velocity determination is by a mix of super- and sub-luminal neutrinos. Interesting idea, but this would justify Aaron Sheldon's point on the previous page that speed dispersion needs to be part of the statistical analysis.

65. **Henry Bolden**
October 7, 2011

A good, old-fashioned clock synchronization problem may the source of the apparent FTL neutrinos according to:

“The OPERA neutrino velocity result and the synchronisation of clocks” by Carlo R. Contaldi

http://arxiv.org/abs/1109.6160

66. **Reply to Bernhard**
October 8, 2011

Contaldi wrote: “In an effort to go beyond this accuracy thresh- old, the OPERA experiment employed a travelling Time- Transfer Device (TTD) to calibrate the difference in time signals at each receiver. We assume this device to be a transportable atomic clock of sufficient accuracy.”

Unfortunately his assumption is wrong. The Travelling Time Transfer Device was not a transportable atomic clock. It was yet another portable clock synchronized by GPS and carrying a time difference counter. The TTD was used at CERN and at Gran Sasso to measure an offset between the GPS signal and the local clock. To the extent the TTD remained physically identical at CERN and Gran Sasso, its antenna, antenna cable, electronics delays remained identical, and hence the difference of offsets it measured gives the difference in the two local clocks with high accuracy.

67. **Jeff Moreland**
October 11, 2011

Did anyone predict superluminal particles based on string theory? That would be much more impressive than an after-the-fact rationalisation.

New Pursuit of Schrodinger's Cat

October 3, 2011
Categories: Uncategorized

Prospect magazine has an excellent new article by Philip Ball on recent developments in the fundamental problem of the interpretation of quantum mechanics: why don't we see superpositions? Most popular discussions of this seem to me to be stuck back in debates from the 1930s, and ignore the main question. QM is a simple, beautiful mathematical structure that works perfectly experimentally, the confusing question is that of how classical behavior emerges during a measurement process (typically involving huge numbers of degrees of freedom, making analysis difficult).

At the end of the article, Ball mentions one particularly intriguing set of ideas, due to Wojciech Zurek, about "quantum Darwinism". For more about this, see Zurek's survey here.

There's a new preprint out by Steven Weinberg on Collapse of the State Vector. Weinberg claims that "There is now no entirely satisfactory interpretation of quantum mechanics", and refers for more detail about this claim to Section 3.7 of his *Lectures on Quantum Mechanics*, a manuscript that is "to be published". I'm definitely looking forward to this book when it comes out. The sort of thing that Weinberg examines in the preprint though, modifying QM to take into account wave-function collapse, is the kind of idea I've never found promising. Why modify QM, it works perfectly and is mathematically extremely aesthetically compelling? Better to keep QM as is, and closely examine one's understanding of what the problem really is.

Comments

1. **Mike**
   October 3, 2011

   Peter,

   I agree that modifying QM does not look promising. As Zurek notes in the paper to which you link, his mathematical approach looks a lot like Everett — which just takes the equations as they come — without making any ontological judgements, which Zurek calls a "virtue". Not sure I agree on that point, but I do agree with you that we probably shouldn't go around changing a very successful theory just to find an "acceptable" foundational interpretation — if that's the point you were making.

2. **Joel Rice**
   October 3, 2011

   The Ball article did not mention Feynman's approach in 'QED: the strange theory…', which seems quite a bit less spooky than the Schrodinger wave approach – though the two are supposed to be equivalent. The possible paths go thru both slits, but nothing like a photon somehow going through both in some spooky fashion.

3. **Peter Woit**
   October 3, 2011

   Joel Rice,

   The Feynman path integral formalism is supposed to be completely equivalent to the Schrodinger equation formalism for QM, and has nothing to say about the measurement problem that Ball was writing about. You can't invoke it to solve the problem.

4. **Anon**
   October 3, 2011

   A "measurement" (at least in human terms) always involves, even if implicitly, space position and time. So it's not unfathomable if the final answer would be given by unified quantum theory of space-time as suggested by R.Penrose. It just may be that classical notions of space-time are logically incompatible with the quantum world that is supposed to live in it. That's why asking these questions isn't useless and may lead, in the eventuality, to a valuable insights.

5. **Peter Woit**
   October 3, 2011

   Anon,

   Quantizing space and time variables brings in a much more difficult set of problems. They're important and interesting, but I've never seen much evidence for the idea that they have something to do with the measurement problem. It seems to me that what Zurek is doing is much more promising, concentrating on trying to understand the (difficult enough) problem at hand (QM in a fixed space-time geometry). One should be wary of trying to solve a hard problem by embedding it in an insanely hard one, especially if one hasn't first completely understood what the hard problem itself actually is.

6. **Derek**
   October 3, 2011

   Could someone comment on whether the Couder experiment (Single-particle interference observed for macroscopic objects) is, in any way, relevant to quantum theory?

   Somewhat embarrassingly, I learned of both this experiment and the de Broglie–Bohm theory / Pilot wave theory via an episode of Through the Wormhole (section begins at 16:30).

7. **Peter Woit**
   October 3, 2011

   A request to all: please limit comments to the topics of this post (articles by Ball, Zurek, Weinberg). I've no more time for moderating a general discussion of quantum mechanics.

   Derek,

   I hadn't heard of the Couder experiment before. From a quick look, it seems like it doesn't actually have much to do with QM, but rather is an experimental set-up that is supposed to behave deterministically according to the pilot-wave equations. It's typical that this and de Broglie-Bohm are the sort of thing you "learn" about from "Through the Wormhole", which completely mixes up real physics issues with hogwash. "Pilot wave theory" may or may not succeed as an awkward way to rewrite single-particle QM, but mathematically it is much more shallow than QM. Furthermore it doesn't generalize well to a true fundamental theory, which needs to be a relativistic quantum theory of fields and incorporate the symmetries and structures of the Standard Model.

8. **Mitchell Porter**
   October 3, 2011

   I agree with Mike that what Zurek writes sounds a lot like the many-worlds interpretation. Except that for some reason he doesn't want to go there, and so he writes gibberish like the paragraph at the end of section III.

   For example, he says there that "Quantum states acquire objective existence when reproduced in many copies." What on earth does that mean? Would he apply this criterion of existence to the Andromeda galaxy as well? You know, there only seems to be one Andromeda galaxy, and yet we don't consider it any less real for that reason.

9. **Peter Woit**
   October 3, 2011

   Mitchell,

   The difference is that Zurek is trying to actually understand how classical behavior emerges from QM, this is not part of the standard Many Worlds Interpretation as far as I know.

10. **neo**
    October 3, 2011

    I question Ball's assertion that decoherence can be suppressed with an "isolated" Schrodinger cat experiment. If he means an actual cat, there is no way it can be isolated. If he means a laboratory buckyball as a metaphoric cat, then the essence of the paradox (quantum uncertainty applying to a familiar macroscopic entity) is lost.

11. **Bernhard**
    October 4, 2011

    Peter,

    Zurek article is interesting, but I think it goes into the category "philosophically interesting". I´m not sure how can one go forward from Zurek´s ideas. Can one suggest new experiments, new tests that will shed new light on what we already know about QM? Otherwise I´m afraid the debate will end up going to where you don ´t want it to go, .i.e., a general debate about QM interpretation, that will be appealing to some but not others with no way of deciding who is right.

    For example concerning how classical behavior emerges during a measurement process, how do decide if quantum darwinism is any better then what we learn at undergraduate school if not by philosophical taste?

12. **CWJ**
    October 4, 2011

    Off topic, I know, but congratulations for successfully predicting the Nobel this year. (Comments appear to have been turned off in the relevant post.)

13. **Allan Rosenberg**
    October 4, 2011

    I find it refreshing to see a science journalist suggesting that we address interpretational questions experimentally. Can anyone point me to any reviews of the real experiments that explore the classical-quantum boundary (or whatever it is)? I thought Haroche and Raimond did a pretty good job of this in Exploring the Quantum (2006).

14. **new fan**
    October 4, 2011

    Hi Peter,

    I enjoyed your book and I'm a fan of your blog. Regarding the Ball article, many discussions of the "measurement problem" neglect the fact that classical and quantum-mechanical measurement theories have much in common. See, for example, A.E. Glassgold and D. Holliday, Phys. Rev. 155, 1431-1437 (1967). In particular, note the discussion of the limit hbar –> 0.

    Keep up the good work!

15. **Anon**
    October 7, 2011

    With due respect, as best I can tell, Weinberg's paper is contentless.

16. **George Purdy**
    October 20, 2011

    I agree with Peter. Modifying a theory that has never been wrong seems like a bad idea. There are some things worth changing. Throw out those things in the Copenhagen Interpretation that aren't actually part of QM–for example the idea that a measurement must disturb A, or must disturb it by a certain amount, which is disproved by Aharonov's weak measurement.

Two for Two

October 4, 2011
Categories: Uncategorized

Back in 2004 I made my first venture into Nobel Prize predictions, then decided to retire from that business. This year I came out of retirement with another prediction. After the posting, I consulted with experts who assured me that the right names were Perlmutter, Riess and Schmidt, something I thought I mentioned in a comment, but it appears that I didn't, instead leaving this to Shantanu.

Congratulations to Perlmutter, Riess and Schmidt. The theoretical significance of their tour de force observational work remains still controversial, but it richly deserves the Nobel prize.

Comments

1. **Some Guy**
   October 4, 2011

   Yes, Shantanu nailed it. Riess' presence at http://agenda.albanova.se/conferenceDisplay.py?confId=1125 this spring was a strong hint. What I find surprising is the unequivocal motivation, "for the discovery of the accelerating expansion of the Universe through observations of distant supernovae". No room left at all for all the ongoing work on dark flows, anisotropies etc. The "scientific background" document, http://www.nobelprize.org/nobel_prizes/physics/laureates/2011/sciback_fy_en_11.pdf , is also quite unequivocal, starting from the title. I may have to write something about the politics of it all… somewhere else, under my own name.

2. **SpearMarktheSecond**
   October 4, 2011

   Bravo, although perhaps the winners might have preferred a satellite devoted to dark energy measurements. Doubtful that the US political class will reverse the current course and give it to them based upon Scandinavian laurels.

   Now perhaps dark matter can get a price. Vera Rubin?

3. **Christopher Nubbles**
   October 4, 2011

   I really thought Guth was going to win it this year.

4. **Math Student**
   October 4, 2011

   No share for Weinberg for the prediction? 🙂

5. **Shantanu**
   October 5, 2011

   Christopher,
   We still don't have any smoking gun evidence that inflation happened or if it did, what caused inflation. Inflation also has a whole set of conceptual problems (cd Steinhardt article from Sci. Am in 2011).

6. **John**
   October 5, 2011

   In the scientific justification of Nobel Prize there is the sentence "None of the alternative models … extra dimensions or modifications of general relativity, seem to convincingly account for all observations." At the announcement video I can see Lars Brink one of the godfathers of string theory, he also seems to be a member of the Nobel Prize Committee. Does this mean he is getting doubts?

P-adic Numbers and Cosmology

October 4, 2011
Categories: Multiverse Mania

The next math department colloquium at Stanford will feature Lenny Susskind lecturing on p-adic numbers and cosmology, here's the abstract:

> The biggest conceptual problem of cosmology is called the measure problem. It has to do with the assignment of probabilities in an exponentially inflating universe, which falls apart into separate causally-disconnected regions. Neither I nor my friends had ever intended to learn about p-adic numbers until we realized how similar such a universe is to an endlessly growing tree-graph. The result has been some new insights from p-adic number theory into the measure problem and other puzzles of eternal inflation. Within the constraints of a one-hour lecture, I will explain as much of this as I can.

I've no idea what this is about, but I'm guessing that Susskind is somehow drawing inspiration from two facts:

- p-adic integers can be represented using a "tree" diagram vaguely remniscent of the logo for the Stanford theoretical physics group on their web-site.
- The p-adic integers, unlike the usual integers, are compact, so you can put a finite measure on them.

It's hard to believe that any of the special features of these mathematical structures will make the problems of eternal inflation go away, but who knows…

Coincidentally, I've spent a lot of time recently learning about the p-adics, with a very different motivation. The way these things come up in mathematics is that you can think of number theory as being about a space, the space of prime numbers. The p-adics appear naturally when you decide to ask what happens locally near one point (i.e. at one prime). P-adic integers correspond to power series expansions, p-adic numbers to Laurent series. Various people have thought about analogies between conformal field theories on a Riemann surface, where one also wants to focus on what happens at a point and use representation theory methods, and the Langlands program which does something similar in number theory. This is part of the geometric Langlands story, and has roots in a remarkable paper of Witten's from 1988 entitled Quantum field theory, Grassmannians, and algebraic curves.

As I've mentioned before, this semester here at Columbia we have Harvard's Dick Gross as Eilenberg lecturer, and he's giving a wonderful series of lectures starting with local Langlands. I'm hoping at some point to put together what I've been learning about this and possible connections to QFT in some readable form, but at the moment things are still too speculative and hazy. In any case, no sign that these ideas are going to solve the problems of cosmology…

Update: The Susskind et al. paper on this topic is now out at the arXiv. A p-adic model is studied, but no reason is given to believe that it has anything to do with eternal inflation and cosmology.

Comments

   October 4, 2011

   The link to the Witten paper is wrong (missing w in www):
   http://ww.springerlink.com/content/k30v44524276r854/

   Why not link to the free version instead?
   http://projecteuclid.org/DPubS?service=UI&version=1.0&verb=Display&handle=euclid.cmp/1104160350

2. **Peter Woit**
   October 4, 2011

   Octoploid,

   Thanks, will fix and point to the Euclid version.

3. **Shantanu**
   October 4, 2011

   Peter when is the last time you met (or corresponded with) Lenny?
   Or let us know the talk and your meeting with him goes

4. **Chris Austin**
   October 4, 2011

   I would guess Lenny might be trying to deal with the problem that if eternal inflation is past eternal as well as future eternal, and the 3 extended spatial dimensions are infinite flat space, and the bubble nucleation rate \Gamma_{tot} is always less than R_{de Sitter}^{-4}, so that bubbles don't collide, then every bubble is contained in an infinite tower of bubbles extending into the past, and every bubble has an infinite nest of descendant bubbles, which does indeed look like an infinitely branching tree.

   Using spatially flat FRW coordinates, the worldsheet of each bubble stops expanding relative to the spatial coordinates after about the de Sitter time and tends to become a tube of fixed coordinate radius, inside which the worldsheets of its descendant bubbles develop into tubes of ever smaller coordinate radius.

   The vacuum energy density of each child bubble has to be less than the vacuum energy density of its parent by a non-zero amount, so if you want eternal inflation to be some sort of "steady state" model for which you can define time-independent probabilities for finding yourself inside a bubble with given characteristics, you face the problem that since the branching tree containing our bubble is not a steady state because the vacuum energies are decreasing, your "steady state" model also has to contain an infinite number of *other* infinite branching trees of bubbles, shifted backwards and forwards in time relative to "our" infinite branching tree, by all possible amounts.

   But since the infinite tower of bubbles in the past of "our" infinite branching tree contains bubbles whose coordinate radii presumably get ever larger without limit as we go to earlier times, there is no "room" in the usual infinite flat extended spatial dimensions to put those other infinite branching trees of bubbles. So perhaps Lenny is trying to use the compactness property of p-adic numbers to get around this. I would guess that the resulting "enlarged" spatial dimensions might look something like infinite numbers from Non-standard analysis.

   In my opinion, a simpler resolution of the problem would be to give up the idea of having a "steady state" picture of eternal inflation, with time-independent probabilities, and the corresponding requirement that eternal inflation be past infinite.

5. **Bernhard**
October 4, 2011

I just hope Susskind will stay with cosmology problems and not try to use p-adic numbers to make nonsensical claims about multiverses.

6. **Peter Woit**
October 4, 2011

Shantanu,

My only interaction directly with Susskind was asking him a question when questions were called for after a colloquium talk he gave here many years ago promoting the anthropic multiverse. He basically politely refused to answer. While we've never met, he does seem to have various opinions about me, positive and negative, which he made clear publicly during the "string wars" period, see for instance

http://www.math.columbia.edu/~woit/wordpress/?p=454

and

http://www.math.columbia.edu/~woit/wordpress/?p=437

I have no idea what he's trying to do with p-adics nowadays, but don't see how they could help him deal with the measure problem. The general problem of most of the multiverse people seems to me that they are trying to sum over "all universes" without any non-trivial input as to what the set of "all universes" looks like. Unless you start with non-trivial structure, I don't see how you get anything non-trivial out. But, who knows… I'll be curious to hear what this is about from anyone who attends the talk at Stanford.

7. **plm**
October 5, 2011

Perhaps you can explain a little more what you thought when writing:

"The p-adic integers, unlike the usual integers, are compact, so you can put a finite measure on them."

You can put finite measures on any measurable space. Any absolutely convergent series gives one on Z, any absolutely convergent integral on R, etc.

Thanks.

8. **Peter Woit**
October 5, 2011

plm,

To be more accurate I should have specified something like "translation invariant". The point is that on the p-adic integers the Haar measure you get from thinking of them as an additive group can be normalized to get a finite result, something you can't do for the usual integers.

9. **jpd**
October 5, 2011

so its bubbles all the way down?

10. **Chris Austin**
October 5, 2011

Correction to my comment above: the infinite number of branching trees of bubbles, shifted backwards and forwards in time by all possible amounts, that you need for a true "steady state" model of eternal inflation, actually *can* live side by side in the spatially flat FRW coordinates of what Harlow, Shenker, Stanford, and Susskind (HSSS) call the noncompact case, (page 4). The point being that the physical 4-volume of a region bounded by a fixed spatial coordinate sphere and extending from a fixed FRW time into the infinite past is finite, due to the exponential time dependence of the FRW R(t). So in the noncompact case, just like in the compact case, there can reasonably be a first, or outermost, bubble in the history of any bubble.

It seems to me that the numbering of the descendant bubbles of a given outermost bubble by the p-adic integers, (Fig 6 on page 16), is simply the natural base p decimal numbering of the reals >= 0 and less than 1, reflected in the decimal point. And the p-adic numbers used for distinguishing descendant bubbles of different outermost bubbles, (eqn (3.7) on page 17), are the reals written in base p and reflected in the decimal point.

The HSSS scheme usefully answers the following question: in the noncompact case, how should we label the outermost bubbles that are present at a fixed FRW time t? The answer: number the outermost bubbles such that their number roughly increases with their distance from the origin of the spatial coordinates, but such that *the larger the coordinate radius of an outer bubble, the more powers of p its number is divisible by*.

The scheme then reproduces itself: one de Sitter time later, the outermost bubbles that were present at the earlier time all have almost the same coordinate radii as before, and for each of them, approximately p – 1 new outermost bubbles have appeared between them, all with approximately the same coordinate radius, 1/e times smaller than the previous minimum coordinate radius. Multiply the numbers assigned to the outermost bubbles present at the earlier time by p; these are then those outermost bubbles' new numbers. And label each new outermost bubble by the new number of its nearest neighbour old bubble, plus a unique number from 1 to p – 1.

So I think the HSSS scheme certainly helps with clarification and visualization. I am not able to judge, from a quick look through the article, whether the use of p-adic numbers gives you anything beyond what you would get by working with the real numbers obtained by reflecting the p-adic numbers in the decimal point.

11. **plm**
October 5, 2011

"the Haar measure you get from thinking of them as an additive group can be normalized to get a finite result"

First, I do not see the importance of having a (multi)universe with finite measure. Or at least I do not really understand you mean.

Second, the integers are amenable, they have a finitely additive translation-invariant probability measure (though not countably additive, and not the Haar measure).

Third, Haar measure is unique up to multiplication by a nonzero real number. We "get a finite result" from all Haar measures on p-adic integers. Also, if you had an nonfinite Haar measure on your space (say Z) normalization would not help.

12. **Peter Woit**
October 5, 2011

plm,

The basic problem is that the multiverse people want to make statistical predictions, but have no real theory of what the space of universes should be or how they should be statistically weighted. So, they decide to weight everything equally. Even for a toy model where the integers parametrize your universes, this doesn't work (since you can't normalize such a weighting). If you take as your toy model the p-adic integers, then you can make this work. Again, I haven't carefully looked at the paper, but I'm guessing this is what is going on.

13. **plm**
October 6, 2011

Thanks, I looked at the paper.

Actually the p-adic integers do not seem to play any particular role. The p-adic numbers (rationals) are used in places in the paper, and infinite branches of the p-adic tree, i.e. p-adic integers which are not standard integers, are not really necessary for much of the discussion.

What matters seems to be the p-adic distance itself, between vertices of the causal tree/multiverse cells/universes in the multiverse, arising from the assumption that all edges of the causal tree with p branches at each vertex have the same length (p^{-u}/2 at time u),.

So compactness of the p-adic integers does not seem to be basic, neither translation invariance, rather the "homogeneous distance"/ultrametric assumption (which can be restricted to Z).

In any case thanks for the blog post and replies to my comments. It was all interesting to think about.

14. **plm**
October 6, 2011

Correction to my comment: the assumption is that all vertices causally separated at time u are at distance p^{-u}.

15. **Shantanu**
October 15, 2011

Peter,
how was the colloquium and did you get a chance to interact?

16. **Peter Woit**
October 16, 2011

Shantanu,

The talk was at Stanford on the West Coast, I'm in New York….

17. **Shantanu**
October 16, 2011

oops, I thought its at columbia

18. **Jonathan Langdale**
October 17, 2011

Was this recorded and put up online?

What's That at the Top of This Page?

October 5, 2011
Categories: Uncategorized

The graphic chosen years ago as the header for this blog is an event display from the UA1 detector in 1982, of historical importance since it was the first event found with a W candidate. To be honest, the reason it's there is that I was looking for something quick to use at the interactions.org Imagebank, figuring these were graphics I could steal without getting sued. What I ended up with is a cropped, lower-resolution version of the much better image available here.

Even stripped of identifying info, UA1 experimentalist Jim Rohlf of course recognized it, and recently wrote me to tell me some more about it. He also tells me that he will soon be blogging at Quantum Diaries, and I look forward to seeing that. So, here's the story behind that image:

> The collision is Run 2958, Event 1279 and was the very first W candidate that was found. It was recorded in the Fall of 1982 with UA1. As a newly minted junior faculty member and CERN scientific associate, I was resident at CERN and the first round of the W event selection and analysis was completed during the CERN holiday shutdown. On 23 January 1983 we submitted the W discovery paper for publication (Phys. Lett. 122 B, 103 (1983)). The details of the events were given in this paper. Within a few days, I got a letter from Lev Okun who had become a good friend of mine due to his frequent visits to CERN and his great interest in the working details of our experiment. In this letter which was several pages long he referred to this event as a "monster" because it decayed in the "wrong direction" and asked if we could have made a measurement error. Then the obvious hit me instantly- nobody had thought of this before- we don't measure the longitudinal momentum of the neutrino due to the singularity in the direction of beam pipe but we can solve it to a quadratic ambiguity knowing the W mass. Furthermore, I saw that the kinematics of a 80 GeV object being produced with a relatively low cm energy of 540 GeV gave a remarkable result: often one of the 2 solutions was kinematically forbidden and when it wasn't, the two solutions were often close together. Therefore, we could solve for the longitudinal momentum of the neutrino and be able to transform to the rest frame of the W. Since the W was polarized because it was produced in proton-antiproton collisions, we could measure the angle of the decay wrt the spin direction. Very simple idea, but be the first to do it and it becomes interesting and fun. I immediately wrote this up as a UA1 internal note in which I acknowledged the contribution of Okun. This technique subsequently became a standard at the Tevatron and now at the LHC.
> In the following months, we collected more data and the next international conference to come along was at Fermilab and I was told by Rubbia to give the talk which was published (J. Rohlf, "Physics at the Proton-Antiproton Collider," Proceedings of the 12th International Conference on High Energy Accelerators, Fermilab, 619 (1983). I reported the first measurement direct observation of parity violation in (real) W decay and measurement of the spin. I attach a slide from a talk I gave at Fermilab 20 years later in 2003 where I pulled up some of my 1983 slides. (Notice I fit the W mass to 2% and got the right answer.) You can see the "monster" event in the bin at cos(theta) =-1. This W decayed in the wrong direction. We went on to collect about 300 W events in UA1. We never saw another one go in the wrong direction. We also could not find anything wrong with that original event 1279. So you see the event was "not even wrong".

Update: A copy of the talk slide that Jim Rohlf refers to is here.

Update: Jim Rohlf's blog at Quantum Diaries is now up here. His first blog entry is great, it's about, independent of the Higgs issue, the fundamental problem the LHC hopes to investigate: what is causing electroweak symmetry breaking? He emphasizes that one way to study this is to try and see the self-interactions of Ws and Zs, which become strong at the TeV scale.

Comments

1. **Chris Austin**
   October 5, 2011

   With reference to solving for the longitudinal momentum of the neutrino up to a quadratic ambiguity, I raised this recently here after Tommaso said that we only know the transverse component of the neutrino momentum. But from Jim Rohlf's message, apparently the longitudinal momentum of the neutrino *is* sometimes measured this way. Is it possible to clarify when this can be done?

2. **B Experiment At Small Theta**
   October 5, 2011

   Very interesting! I recognized the image as one of the UA1 W events too, although I did so from having previously dug around on CDS for images from the infamous megatek
   (I wasn't born when that event was read out!). You can see the beautifully rendered event displays these things produced here: http://cdsweb.cern.ch/record/1049887

   would it be possible for you to host the slide Jim sent you (pending his permission?) I'd love to see more.

3. **Peter Woit**
   October 5, 2011

   B experiment,

   He didn't send me the image, it's always been hosted at Imagebank, and you can access it there. There may be some other source of UA1 event display images, but I don't know anything about this.

4. **Jim Rohlf**
   October 5, 2011

   Chris:
   Directly we measure only the transverse component of missing energy because hundreds of GeV can escape down the uninstrumented beam pipe. However, for the case of W –> e nu, mass of the parent particle is known and we have m**2 = E**2 – p**2 (where E is electron plus neutrino energy and p is electron plus neutrino vector momentum). This is a quadratic equation for p_z , the unknown longitudinal momentum of the neutrino which has TWO solutions. Now visualize where the neutrino can go to see the two solutions conceptually. If the electron has energy nearly half the W mass and is produced nearly at right angles to the colliding beams, then the neutrino must recoil opposite the electron and have very little p_z. If on the other hand the electron is going forward (like the monster event), then to make the W mass the neutrino could be also going forward and have large energy so that p_z plus the electron p_z exceed the proton energy (kinematically forbidden) or it can go at large angles and have smaller energy.

   Peter:
   I think B Experiment was asking about the W angular distribution I sent you which you may post if you want.

   B Experiment:
   I have tons of events displays because I never throw anything out. I am at Fermilab now but when I return to Boston I may find some time to dig up some more pictures of

this famous event.

5. **Chris Austin**
October 6, 2011

Jim, thanks very much for the explanations. To summarize when the two solutions coincide, (I think you described a special case for simplicity), if M is the W mass, p and q are the neutrino and electron transverse momenta, and c is the cosine of the angle between the neutrino and electron transverse momentum 2-vectors, the solutions coincide when M^2 = 2 p q (1 – c). I guess with enough statistics, "lucky" events, where this is approximately satisfied, could be selected to improve the mass resolution of some of the Higgs searches.

6. **Peter Orland**
October 6, 2011

Hi Peter,

You should substitute "what's" for "what".

Regards,
Peter

7. **Peter Woit**
October 6, 2011

Thanks Peter! Fixed.

8. **Bernhard**
October 7, 2011

This story is really interesting, is nice to know more about how it happened and the REAL persons involved with it. I had enormous trouble reading "The God particle" from Leo Lederman, because he gives the impossible impression he almost did everything by himself, had all the ideas, and therefore got the Nobel. I immediately thought "but who was the postdoc (or "newly minted junior faculty member ") who really did the work anyway?". Same thing with the W discovery. Only now, I know who did it. Not to say John did it alone too, but reminds us how giving Nobel prizes to individuals for experimental collaboration work is totatally bogus.

9. **Bernhard**
October 7, 2011

Sorry, I meant Jim, not John.

10. **SpearMarktheSecond**
October 7, 2011

Great to hear from Jim Rohlf, he is a gem.

`Nobel Dreams' by Taubes describes the subsequent discovery of Supersymmetry by UA1 and UA2.

http://www.nytimes.com/1987/01/29/books/books-of-the-times-556387.html

11. **Jim Rohlf**
October 7, 2011

Chris:
What Higgs? Only joking (well, sort of). At the LHC, Higgs searches in fact do select "lucky" decays by asking for the charged lepton + neutrino transverse mass to be an appreciable fraction of the W mass. These lucky decays BTW are not so improbable because a 2-body decay makes the so-called Jacobian peak which is just a solid-angle effect. This is the reason the W mass can be determined so well from only measuring the charged lepton. I was truly thrilled when I first understood this!

12. **Jim Rohlf**
October 7, 2011

Spear:
The problem with the Taubes book is he arrived way too late to document the W and Z… at least I got to be the Prince. For the record, UA2 was not part of the SUSY false alarm which was largely propagated by theorists. I stand behind the two major talks I gave on the subject at ICHEP Leipzig 1984 and APS Eugene 1985.

News From Europe

October 7, 2011
Categories: Experimental HEP News, Uncategorized

A few items with a European flavor:

- The news from Dublin is that Witten will be in town soon to give the Hamilton Lecture, with the Irish Times reporting that

> Witten's Hamilton Lecture will abandon string theory, however, in favour of knots, with a talk entitled: The Quantum Theory of Knots.

He may be there the previous day, when they hold the annual Hamilton Walk, commemorating Hamilton's discovery of quaternions and inscription of the quaternion relations on a bridge.

In other mathematical physics coverage by the Irish Times, one of their columnists describes the interaction of the Irish revolutionary leader de Valera with Schrodinger and Dirac, speculating (humorously) that the three of them might have come up with an Irish "unified field theory."

- From a meeting today in Madrid, here's an overview of theoretical particle physics in Spain. There's the same pattern reported as has been going on in the US for a while: "moving from more formal and mathematical developments to phenomenology and also astroparticle/cosmology", as well as trying to get theorists more involved in LHC physics. Another similar pattern to the US, the threat of "decreasing funding support for basic science in difficult economic times."
- The question of what future facilities for particle physics should be is not just a European one, but I fear that in practice a higher energy machine is not likely to be built anywhere except at CERN. This week at CERN there was an ICFA Seminar on Future Perspectives in HEP, which gives a good overview of the state of the field and prospects for the future. The question of what to build next to get information at the energy frontier is very unsettled, pretty much completely up in the air waiting to find out if there's a Higgs particle or not. The SUSY and extra dimensional models used as partial selling points for the LHC are dying and won't be convincing arguments for what the next generation should do.

Comments

1. **Paul Collins**
   October 7, 2011

   For a fictional treatment of Schrödinger's time in Ireland, see Neil Belton's "A Game With Sharpened Knives".

2. **martibal**
   October 8, 2011

   A bit off topic, but still it is news from Europe. For those who understand italian, you should have a look at:
   http://www.youtube.com/watch?v=FcUDjxXu0pc&sns=fb

   For those who don't here is the context: a few hours after the announcement of the FTL neutrino, the ministry of italian research (Mrs Gelmini) has published an official comment, where she explained this was an historical discovery, to which Italy had greatly contributed by spending, at least, 40 something millions in the construction of a tunnel between Italy and CERN ! She has not dismissed, but her spokesman yes.
   And in this very funny audio-piece, some people (I do not know who, but there are very talented), report an accident that happened in the Gelmini-tunnel, between Gran Sasso and CERN, when a neutrino tried to overcome a photon. The neutrino warn the photon with "light-signal" (sorry, I do not know the exact english term), but since he was going faster, of course, he bumped into the photon before its signal, and this made a lot of mess in the tunnel, with protons abandoned on the side of the road etc etc

3. **Bernhard**
   October 8, 2011

   martibal,

   great story :-).

   Peter,

   I wonder if the reason for the choice of Witten´s talk has more to do with the occasion or if it could be that not even Witten is willing to talk directly about string theory these days.

4. **Peter Woit**
   October 8, 2011

   Bernhard,

   During the past year or so Witten's papers have mostly been about his research on QFT and knot theory (especially Khovanov homology), so it's a natural topic for him to talk about. I don't think he has given up on string theory as a unified theory, but I suspect that even he would acknowledge that there has been little progress in recent years, making it a less viable topic for the talk.

   Witten's recent research extensively uses various dualities among QFTs. He might point out that even though these can be understood as QFT phenomena, string theory research has been responsible for insight into these in the past, so in that sense his current research still has a connection to string theory.

5. **DB**
   October 8, 2011

   If you are ever in Dublin, you can visit Kilmainham Jail, where DeValera – who founded the Dublin Institute of Advanced Studies – was imprisoned after the 1916 Easter Rising, narrowly escaping execution, and where his graffiti of Hamilton's quaterion equation can still be seen on the wall of the cell he occupied. A video of his visit to his old cell is available here.
   http://www.youtube.com/watch?v=-I-SSTN5Nko

   As to what accelerator should be built next, if there is a Higgs in the energy range not yet excluded it is unlikely to be CLIC but more probably a muon collider, once the technical problems are resolved. This we should know within months.
   If no Higgs, it will depend on what clues the LHC turns up regarding dynamical symmetry breaking among other things. It might motivate CLIC or something else

entirely. But nothing is likely to happen until the LHC is much further down the road and discovers something really important, because in the absence of Higgs and SUSY, funding politicians may feel they were sold a pig in a poke. Once bitten…

6. **Sheldon Pherris**
October 8, 2011

Does this mean that Peter will soon start a new blog titled: Knot Even Wrong?

7. **cormac**
October 9, 2011

It's a good Irish Times column, but it doesn't explain *why* Dirac was so surprised to see de Valera at the conference. At a lecture in Dublin a few years ago, Professor Goddard of IAS Princeton explained that Dirac said he ' was amazed that the Irish Prime Minister could take a few days out to attend a mathematics conference!'

8. **DB**
October 9, 2011

Unless the story is apocryphal, such a lengthy response from Dirac to a question must surely be something of a record.

9. **Chris Oakley**
October 9, 2011

DB,

No necessarily. It could have gone something like this:

Reporter: Are you amazed that the Irish Prime Minister can take a few days out to attend a mathematics conference?

Dirac: Yes.

De Valera's passions, BTW, were (i) hatred of the British and (ii) mathematics, in that order. The odd combination of schools (i.e. Celtic studies and theoretical physics) at the Dublin IAS, which he founded, more or less reflect this.

10. **Stephen**
October 9, 2011

Peter I just read the USA Today article concerning the OPERA claims. Glad a non-stringy expert is called upon when expert advise is needed. Your comments were great.

11. **Peter Woit**
October 10, 2011

Stephen is referring to this:

http://content.usatoday.com/communities/sciencefair/post/2011/10/pundits-puzzled-by-physics/1

12. **SpearMarktheSecond**
October 10, 2011

If no Higgs in the remaining allowed interval (115-145 GeV or so), I think we'll know the SSC was indeed the correct machine and not the LHC. The Republicans supported the SSC (aka, the Ronald Reagan Lab); it was the Clinton administration and democratic congress that killed it.

Newt Gingrich was a big SSC supporter.

All uncomfortable truths, those. But maybe a light Higgs will emerge and they won't be truths at all.

13. **RRL**
October 10, 2011

The SSC was born as a panic-stricken reaction to the failure of ISABELLE at BNL (=USA) and the discovery of the W (and Z) by the SppS at CERN (=Europe, aka "not USA"). An important part of the SSC mandate was to rub it into people's faces that "America has the biggest accelerator in the world". Yes indeed the SSC was supported (enthusiastically, I might add) by Ronald Reagan. The (papa) Bush administration continued the SSC. Yes indeed the SSC was cancelled by the Clinton administration. But it is also true that DOE micromanaged the SSC from the start, and it is also true, in these modern times, that every new administration cancels the projects of its predecessor (if from the opposing party). The SSC was part of US-HEP, so it gets mentioned on a blog like this. But other non-HEP special interest groups will point to their own pet programs, which got cut by some incoming administration, Democrat or Republican.

14. **Eric**
October 10, 2011

Actually, it is not true that the Clinton administration canceled the SSC. The Clinton administration actually supported the SSC, though not as enthusiastically as Bush/Reagan. It was really opposition in Congress that killed it, due largely over political jealousy from other states over Texas having two big ticket items, the SSC and the space station. If the SSC had been designated for some other state, say Nevada or Illinois, then it would have been built. Also, there was a lot of opposition from physicists in other research areas who were upset that high-energy physics was receiving so much funding.

15. **ssc**
October 10, 2011

Most of that is true. But if the SSC had been designated for some other state, such as Nevada or Illinois, the SSC proposal might not have been approved at all. There was a lot of jealousy from non-HEP physicists. They thought that if the SSC was cancelled, the funding would go into their pockets, e.g. solid-state. This proved to be both greedy and wrong. The cancellation of the SSC led to a general reduction in physics funding overall. However it is also true that the SSC was mismanaged. The estimated cost kept going up and up, and it was clear that the proponents were just telling lies, and it eventually became too much for Congress.

16. **RayGun**
October 10, 2011

As I recall, Reagan was also enthusiastic about the atomic-bomb driven space-based X-ray laser as part of his Star Wars anti-missile fantasies; I wonder if he somehow saw the SSC as linked to this?

17. **Ilya**
October 10, 2011

"Comments that just add noise and/or hostility are not." Does the post by RayGun above belong to the aforementioned category?

18. **Peter Woit**
October 10, 2011

Ilya,

I'm not sure that Raygun's contribution was any more objectionable than others but I'll agree that the "who to blame for the SSC clusterf–k" discussion is off-topic anyway, and political arguments about it generally contain more noise than signal. There was plenty of blame to go around on that one. Enough about it here.

19. **cormac**
October 10, 2011

DB and Chris:
Dirac's comment on Dev was not verbal, but contained in a letter (to his wife, I think) describing the DIAS conference and Dublin in general

20. **piscator**
October 10, 2011

In regards to the DIAS and the presence of both Celtic studies and theoretical physics, I think it is appropriate to repeat the waggish Irish Catholic comment that the purpose of the Institute was to prove that there was no God and two Saint Patricks.

21. **D R Lunsford**
October 11, 2011

When I was visiting Dublin in the mid-80s, of course one of my prime destinations was the Broom Bridge. I was surprised to find in surrounded by a typical US-style suburb. The Royal Canal had some sad-looking water in it, not at all reminiscent of a pastoral scene involving W.R. and Lady Hamilton. The bridge itself is very narrow and small cars were zipping by as I examined the stone railing. "This is dangerous!" I thought. Just about then a guy slowed down as he passed me and stuck his head and shoulders out the window…

He smiled and shouted at me – "Ya wooon't find it! Ya wooon't!!"

I gave up 🙂

-drl

22. **Artie**
October 11, 2011

DR Lunsford: "typical US-style suburb"? My wife, who moved from the US to Cabra (the suburb in question) about ten years ago, would be amused by that one…

I agree, though, that the surroundings are less than idyllic. As you mention, the bridge doesn't even have a footpath! I've risked being run over a couple of times to bring visitors there, only to see their faces fall at the sad, worn-down little plaque under the bridge. (Not to mention the shopping trolleys and traffic cones floating down the canal.)

Weinberg on Symmetry

October 10, 2011
Categories: Uncategorized

The latest New York Review of Books has an article by Steven Weinberg entitled [Symmetry: A 'Key to Nature's Secrets'](). It's a bit unusual for the NYRB, since it is both scientifically more technical than usual for them (coming from a write-up of Weinberg's talk at [this conference]()), and doesn't review any books. The printed version tells readers to go to the web version for footnotes, but some of these just note that things are being over-simplified. One of the footnotes is worse than useless: the editors have replaced x^3=x as an example of an equation with solutions that break a symmetry (x goes to -x) by "x 3 equals x", an equation with the same symmetry but only a symmetric solution (x=0). The idea seems to have been to remove or replace any symbols in the equation that might upset people.

Weinberg tells the conventional story of how the Standard Model emerged during the 60s and early 70s out of the realization that non-abelian gauge symmetries were important and an understanding of what happens when symmetries are spontaneously broken. He tries to do some much more ambitious things, explaining the idea of "accidental symmetries" that are due to the limited number of possible renormalizable terms you can build out of a specified list of fields, but I'm not sure the typical reader of the NYRB is going to get much out of this.

The question of how to explain the notion of "symmetry" is an interesting one, and I thought a lot about it when writing *Not Even Wrong*, the book. To my mind, most such explanations mix up two conceptually distinct things: the group of symmetries (a group), and the action of the group on some other mathematical object (the representation: mathematically a homomorphism from the group to the group of automorphisms of something). It's both the group and the representation that are important in the use of symmetries in physics, although often what is important is the trivial representation. From a mathematician's point of view, the simplest representations to look at are unitary representations on a complex vector space, so the mathematical structure of quantum mechanics is very natural. To each symmetry generator you get a conserved quantity, and it appears in quantum mechanics as the thing you exponentiate (a self-adjoint operator) to get a unitary representation. In Weinberg's piece, which aims at sophisticated issues in particle theory, the question of the basic relation of symmetries and conservation laws is relegated to a footnote which says only "For reasons that are difficult to explain without mathematics…".

Weinberg ends with a landscape sort of picture, involving symmetries emerging only when a specific ground state emerges out of an initial chaotic inflation state. Philosophically this is a popular view of the future of the subject these days, but one that has so far led nowhere, and one that I think even in principle can never lead anywhere. Much more interesting would be to try and draw lessons from what has worked well in the past: exactly the gauge symmetries and spontaneous symmetry breaking phenomena that led to the standard model. We may very well soon find out there is no Higgs particle, turning this whole subject into a wide-open one. Future progress may come from exactly the same place as in the past: new ideas about how to exploit the mathematical structures inherent in quantum mechanical symmetries.

Update: The missing exponentiation in the on-line footnote has been fixed.

Comments

1. **peterg**
   October 10, 2011

   "To my mind, most such explanations mix up two conceptually distinct things: the group of symmetries (a group), and the action of the group on some other mathematical object (…)"

   Very true, but it's incredibly difficult to explain the difference to a layman.

2. **Peter Woit**
   October 10, 2011

   peterg,

   I agree. I'll also admit that I was confused about this myself for an embarrassingly long time as a student, studying the topic from a physicist's view-point. Part of the problem is that if you think of groups as groups of matrices, your very definition of what a group is comes packaged with a representation.

3. **neo**
   October 10, 2011

   It is not at all unusual that this NYRB article does not review books. Many of their articles do not review books. Kind of strange for a book review periodical.

4. **udi**
   October 11, 2011

   Can someone explain why Weinberg makes a statement, which seems to me to be wrong:

   "these symmetries, known as lepton and baryon conservation, would dictate that neutrinos (particles that feel only the weak and gravitational forces) have no mass"

   Neutrinos can have a Dirac mass term, which is renormalizable and invariant under all local symmetries.

5. **Emanuel Derman**
   October 11, 2011

   Not being in physics anymore, I find it a little depressing to see this evolutionary psychology approach to physics being espoused by Weinberg himself. What fraction of physicists ascribe to this?

6. **Peter Woit**
   October 11, 2011

   Emanuel,

   I think Weinberg has more sympathy towards this kind of thing than you might expect, since he's credited with the earliest argument that the anthropic "explanation" for the size of the cosmological constant gives a bound at least the right order of magnitude to correspond to the observed value.

   I'm curious to hear what other's impressions are of how this kind of empty pre-big bang scenario is thought of among physicists in general. From what I've seen, I'd describe physicists who are not theorists as mostly quite hostile to the idea as not being science. Within the theory community there's a vocal group actively pushing it, but perhaps a silent majority that sees it as kind of an embarassment, best ignored, hoping it will go away.

7. **Giotis**
   October 11, 2011

   Strictly speaking Weinberg, for the prediction of the (bound of the) value of the CC, would deserve to share this year's Nobel prize.

   Why not? He is a physicist and he made a prediction based on physics.

8. **Jon**
   October 11, 2011

   For Higgs stuff, it looks like the last 2011 update will happen in Paris on wedenesday november 16 http://hcp2011.lpnhe.in2p3.fr/hcp-2011_program.pdf (at least I couldn't find a december conference).

   What puzzles me is that the sections on the Higgs that day consist only on reports on experimental results, except the last one (on "combinations and beyond") which is planed to end with a talk entitled "Electroweak Symmetry Breaking without SM (or SUSY) Higgs" by C.Grojean: might it be a hint that still nothing has been found? Is that what you are alluding to, Peter?

9. **Peter Woit**
   October 11, 2011

   Giotis,

   If the Nobel Prize committee had done anything that idiotic, I suspect that Weinberg himself would have turned down the prize, and a bunch of other physics medalists would have mailed theirs back…

   Jon,

   As far as I know, the Paris conference will be the next time CMS and ATLAS announce new results about the Higgs (and a combined CMS/ATLAS analysis using this summer's results also appears). I don't now how much data they will have analyzed by then, at the moment they've collected something like 3 times the amount used in the summer results. This should be very interesting…

   The fact that a theory talk about models without a Higgs is scheduled isn't surprising, and doesn't reflect any inside knowledge about the new data. There's no point to a theory talk about the Higgs, everyone has known for decades exactly what the theory says there. The failure to find the Higgs so far is leading to more and more interest in Higgsless scenarios.

10. **Eric**
    October 11, 2011

    Lubos Motl is hinting on his blog that he has inside information that a Higgs signal has emerged and he knows its mass….

11. **Chris Austin**
    October 11, 2011

    An observational test of Weinberg's anthropic explanation of the small value of the cosmological constant has been proposed by [Abraham Loeb](). The idea is to search for exo-planets in nearby dwarf galaxies that formed at redshifts up to 10. Discovery of such planets would provide evidence that planets could form even if the cosmological constant was larger than the observed value by a factor of up to 1000. Loeb said that the search could be carried out with 2006 technology, but no results appear to have been reported so far.

12. **Peter Woit**
    October 11, 2011

    Eric,

    One would expect some news to start leaking out of CMS/ATLAS soon, on the other hand, the idea that Lubos would keep something he knows quiet isn't all that plausible. Anyway, we'll see soon….

13. **mo**
    October 12, 2011

    > udi says:
    > October 11, 2011 at 12:19 am
    > Can someone explain why Weinberg makes a statement, which seems to me to be wrong:
    >
    > "these symmetries, known as lepton and baryon conservation, would dictate that neutrinos (particles that feel only the weak and gravitational forces) have no mass"

    Weinberg explains it himself in footnote 9.

14. **DB**
    October 12, 2011

    @Peter "we'll see soon…"

    In the valuable link you provided to the ICFA seminar in CERN, Terry Wyatt from Manchester appeals for a 5-sigma standard for *exclusion* on the Higgs (slide 30), effectively excluding the Tevatron from the exclusion process. He states "The gold standard for SM Higgs discovery or exclusion is the same 5σ" That's a first for me and was understandably challenged by a questioner after the presentation. He doesn't indicate how he proposes to rejig the LEP2 results which only reach the 95% confidence level, especially given that LEP2 originally eliminated most of the range originally predicted by precision electroweak data.
    He continues: "Excluding the SM should be regarded (*and presented to the outside world* – my emphasis) as a discovery of equal or greater significance."
    Yeah right….

15. **x3**

October 13, 2011

There may be more typos. Cna't b too quick to judge.

16. **ZZZ**
October 13, 2011

Re: old planets in dwarf galaxies. There was some report last year regarding finding some very old planet around a star that most likely came from a dwarf galactic neighbor. Another point is that many of them would have been swallowed by their stars by now, so there is a built-in selection bias for lower mass long burning stars.

17. **S. Molnar**
October 13, 2011

I'm a bit late on this, but the missing exponentiation in the footnote was clearly an HTML-type error and not an intentional change to the text. I'm unhappy with the continuing decline of editorial rigor in the New York Review of Books (an article recently referred to a film actor who played Dracula as "Bella Lugosi", apparently confused by the fact that Béla Lugosi appeared in "Glen or Glenda"), but let's apply Hanlon's razor when appropriate.

18. **Chris W.**
October 16, 2011

Footnote 3 of Weinberg's NYRB piece might catch the eye of a few people. Consider how it would be phrased if one replaces Galilean invariance by Lorentz invariance, and adopts the perspective of general relativity; the Earth's orbit is locally inertial. There is no need to talk about gravity balancing the effects of the centrifugal force caused by the earth's curved motion. 🙂

19. **anonymous**
October 17, 2011

Eric,

some atlas and cms people seem to believe that there is a higgs signal at 120GeV. others don't. this is the reason why there is no new update for so long. let's be patient a bit longer and let the experimenters do their job, then we'll know.

20. **Lau**
October 21, 2011

I've recently come across this discussion between Weinberg and Dawkins and thought of sharing it, in case anyone would like to watch. It is 3 years old, so you may have seen it before.

Starting approximately at the end of part 2, they discuss the multiverse.

http://richarddawkins.net/rdf_productions/steven_weinberg

21. **Georges MELKI**
October 27, 2011

I don't really get the difference between x^3=x and x3 equals x, and how the latter upsets people less than the former! Usually, when the number is at the right of the letter, it's supposed to be an exponent, not a coefficient…unless the reader is completely illiterate, and he/she wouldn't be reading an article by S.Weinberg!

Welcome to the Multiverse

October 19, 2011
Categories: Multiverse Mania

The October issue of Discover magazine has a new feature, a column by Sean Carroll, whose inaugural effort is now on-line as Welcome to the Multiverse. Sean makes the argument that opposition to multiverse mania is due to people having too naive an idea about what science is. They don't realize that testing those parts of a theory you can directly observe allows you to draw conclusions about those parts you can't directly observe:

> A lot of people, both inside and outside the scientific community, are viscerally opposed to the idea of other universes, for the simple reason that we can't observe them—at least as far as we know. It's possible that another universe bumped into ours early on and left a detectable signature in the cosmic background radiation; cosmologists are actively looking. But the multiverse might be impossible to test directly. Even if such a theory were true, the worry goes, how would we ever know? Is it scientific to even talk about it?
>
> These concerns stem from an overly simple demarcation between science and nonscience. Science depends on being able to observe something, but not necessarily everything, predicted by a theory. It's a mistake to think of the multiverse as a theory, invented by desperate physicists at the end of their imaginative ropes. The multiverse is a prediction of certain theories—most notably, of inflation plus string theory. The question is not whether we will ever be able to see other universes; it's whether we will ever be able to test the theories that predict they exist.

Sean makes quite clear that multiverse mania is driven by string theory. Inflation is part of the story, but it's not a fundamental theory by itself. All it can tell you is that your fundamental theory should have an inflaton field of some kind, with a potential satisfying certain properties. The big idea that justifies the multiverse is that:

> In short, string theory predicts that the laws of physics can take on an enormous variety of forms, and inflation can create an infinite number of pocket universes. So the different laws of physics predicted by string theory might not be just hypothetical. They might really be out there somewhere among the countless parts of the multiverse. This is not a situation that cosmologists dreamed up in a flight of fancy; it is something we were led to by trying to solve problems right here in the universe we observe.

The problem that Sean doesn't mention is one of circularity. Since you can't observe anything about it directly, the multiverse must be justified in terms of another theory that can be tested and this is string theory. But if you talk to string theorists these days about how they're going to test the unified theory that string theory is supposed to provide, their answer is that, alas, there is no way to do this, because of the multiverse. You see, the multiverse implies that all the things you would think that string theory might be able to predict turn out to be unpredictable local environmental accidents.

So, the multiverse can't be tested, but we should believe in it since it's an implication of string theory, but string theory can't be tested because of the multiverse.

Until recently, string theorists would sometimes hold out hope that the LHC would see low-energy strings, extra dimensions, or supersymmetry, and that these discoveries would somehow pick out a predictive version of string theory from the landscape of the multiverse. This year's data from the LHC has pretty much destroyed such hopes.

Sean ends with the inspirational admonition:

> The proper scientific approach is to take every reasonable possibility seriously, no matter how heretical it may seem, and to work as hard as we can to match our theoretical speculations to the cold data of our experiments.

What's going on in this story though is not a concerted effort to match theoretical speculation to experimental data, but something very different, a concerted effort to build a theoretical framework perfectly insulated from testability, and sell it to the rest of the physics community and the public, hoping no one notices the circularity.

Update: Besides the usual spam, this topic seems to attract mostly empty comments supposedly agreeing with me, and comment moderation is unusually annoying. I think I'll turn off comments on this posting, and encourage people who want to discuss the topic to do so over at Cosmic Variance, where Sean has a posting devoted to this.

Comments

1. **Roberto**
   October 19, 2011

   agree with you: what Sean C. does with the multiverse happens, somehow interestingly, elsewhere: e.g.; evolutionary biology, where some unverifiable ideas (and not good either) are deemed dogma, for example: the "selfish gene', the "meme' and so forth.

String Theory Finds a Bench Mate

October 19, 2011
Categories: Uncategorized

There's a nice article this week in Nature about AdS/CMT, entitled [String Theory Finds a Bench Mate](). According to the article, the whole thing is (partly) my fault:

> But in 2006, string theory took a public battering in two popular books: *Not Even Wrong* by Peter Woit, a mathematician at Columbia, and *The Trouble With Physics* by Lee Smolin, a physicist at the Perimeter Institute for Theoretical Physics in Waterloo, Canada. Both books excoriated the theory's isolation from experiment.
>
> "It's hard to say whether the interest in condensed-matter applications is a direct response to those books because that's really a psychological question," says Joseph Polchinski, a string theorist at the Kavli Institute for Theoretical Physics in Santa Barbara. "But certainly string theorists started to long for some connection to reality."

The main point of the story is to tell about what is probably the hottest topic in hep-th these days, attempts to use AdS/CFT to say something about some models in condensed matter physics. For some idea of what this is all about, see the review article What can gauge-gravity duality teach us about condensed matter physics? by Subir Sachdev, and take a look at the online talks from the KITP workshop Holographic Duality and Condensed Matter Physics.

The article does go into the history of this in some detail, including its roots in efforts to use AdS/CFT to say something about heavy-ion physics phenomena observed at RHIC (for the string theory promotional campaign surrounding this, see e.g. here). I had expected to see a lot about this topic when higher energy results from heavy-ion collisions at the LHC were released earlier this year, but it seems to have gone quiet, perhaps because of the kind of comparison of data with AdS/CFT predictions that Sabine Hossenfelder points out here:

> As the saying goes, a picture speaks a thousand words, but since links and image sources have a tendency to deteriorate over time, let me spell it out for you: The AdS/CFT scaling does not agree with the data at all.

My knowledge of condensed matter theory is minimal, and the hype level surrounding string theory makes it hard to know whether to take at face value many of the claims being made. On general principles, this looks a bit more promising than the heavy-ion case, since there are many different kinds of systems one might look at, and the connections are more to QFT than to string theory. Experts quoted in the Nature article give opinions ranging from:

> Polchinski admits that the condensed-matter sceptics have a point. "I don't think that string theorists have yet come up with anything that condensed-matter theorists don't already know," he says. The quantitative results tend to be re-derivations of answers that condensed-matter theorists had already calculated using more mundane methods.

to condensed matter theorist Andrew Green's:

> "Maybe string theory is not a unique theory of reality, but something deeper — a set of mathematical principles that can be used to relate all physical theories," says Green. "Maybe string theory is the new calculus."

Time will tell whether this suffers the same fate as in the case of heavy ions.

Comments

1. **Nige Cook**
   October 19, 2011

   Here in England, tonight BBC2 TV just screened a "Faster than Light" program with Michael Duff giving some string theory hype to explain the alleged 60 ns "faster than light" neutrinos. Duff stated that the results could be explained by neutrinos leaving our 4-d brane, taking a super-fast short-cut through the 11-d bulk, and then appearing again on the 4-d brane nearer the detector. Eventually, after claims about the experiment being "proof" of string, they showed Duff making a more sensible comment that he *wasn't* actually hyping the experiment as proof of superstring or even confirmation of a falsifiable prediction from string theory. But it left the viewer in no doubt that superstring offers the only "real" good explanation. Duff illustrated the 4-d brane with a slice of bread, using a loaf for the 11-d superstring bulk.

2. **SteveB**
   October 19, 2011

   Gerard 't Hooft has updated his web site. Similar to your quote from Andrew Green, in the quantum gravity section 't Hooft now says:

   > …many of my colleagues are convinced that "string theory solves the problem". But why does this happen? How does string theory resolve the paradox? Curiously, string theorists themselves do not quite understand this. But I think I might understand this now. String theory is just an instrument to do calculations in regions of a theory that are otherwise inaccessible.

3. **Peter Woit**
   October 19, 2011

   Nige,
   Duff can really be relied upon when string theory hype is needed. There's a page about this program here:

   http://www.bbc.co.uk/programmes/b016bys2

   It seems to have been produced in record time.

   SteveB,

   't Hooft is referring to AdS/CFT's supposed role in resolving the information paradox about black holes, which is a somewhat different topic. Whether it does this is independent of whether it provides a useful approximation method for certain condensed matter systems.

4. **Spinons**
   October 20, 2011

   As a condensed-matter theorist, I don't really appreciate the AdS/CFT papers. Although they might be useful in the vague sense of being a phenomenological model, they don't really solve anything fundamental. For example, this Gauge/Gravity paper on Science: Faulkner et al., 329 (5995): 1043-1047 talks about their findings of a class of non-Fermi liquids through the AdS/CFT correspondence, with a tantalizing application for the normal state of high-Tc superconductors. However, such approach couldn't give any clue at all about the mechanism of the high-Tc superconductor, or even what makes the electrons non-Fermi liquid. It is beyond their capability.

With the arXiv flooded with this kind of take-the-easy-route papers, I was wondering whether this correspondence between AdS and CFT is really well established as rigorous mathematical theorems ? Probably not…

5. **lun**
October 20, 2011

Spinons, while I am skeptical of AdS/phenomenology in general, I do not think your argument works: With the same reasoning, you would have also had to ditch the Ginzburg-Landau theory of superconductivity, since it also offered no clue as to the origin of the scalar field responsible for spontaneusly breaking U(1).
Your namesake origin, spin-charge separation became famous well-before any microscopic explanation was even proposed, if I remember correctly.

The 10^n dollar question is what are the necessary requirements for a physical system to be described by a holographic theory. How do we know if a generic field theory is dual to SOME string theory?
For QCD, the "obvious" answer is that classical gravity is only good for SU(N), and hence one either needs to quantize gravity or concentrate on things that dont change between N=3 and N=infinity. I would be interested to know if something similar exists in condensed matter.

6. **Spinons**
October 20, 2011

lun, but Ginzburg-Landau theory is indeed a phenomenological theory, and is indeed very useful. So as I said, the AdS/CFT might be useful in this sense if this gravity/gauge equivalence is really well established.

The GL theory finds even more applications than superconductivity. But as far as the (old) superconductivity problem is concerned, only BCS theory provides the true explanation and advances our understanding of superconductivity (electron-phonon coupling, cooper instability, etc).

As you must have known, the GL theory can be derived from BCS theory. Without this connection, I believe the GL approach is not much different from what engineers are doing.

I guess what GL approach also symbolizes is the "universality" aspect of physical systems. Different microscopic models share the same field theory at the critical point. The AdS/CFT is also similar in this spirit. But again, it makes more sense to talk about universality when you have a bunch of explicit model systems which show similar behavior.

I'm not so sure about what you said "spin-charge separation became famous well-before …" But in 1D this is well known theoretically with explicit lattice models long ago. Although there are a lot of talks about fractionalized excitations in high dimensions, but without at least some lattice models or (better) experiments, it is indeed not much different from stringy speculations in my opinion (fortunately, we have several such models already)

7. **lun**
October 20, 2011

Agree with spinon. Having said all that, for Peter, see my comment
[at your link]()

While I am convinced QCD is fundamentally different from any theory with a classical gravity dual, I think ruling out AdS/CFT as phenomenology for heavy ions is premature,

8. **Derek Teaney**
October 22, 2011

Dear Peter,

I posted this remark at Bee's web site.

I think this post of Bee is off the mark, when it comes to
heavy ion collisions.
In particular the remarkable aspect of the
new data is the success of hydrodynamics
in describing the new data on the higher
harmonics flow when the shear
viscosity is of order 1-3/4\pi . This was the truly
new (and remarkable) aspect of the new data from
the LHC. It is certainly very difficult
to reconcile this with weak coupling . I spoke
about the higher harmonic flow at the
AGS Users meeting:

http://www.bnl.gov/aum/content/plenary/ps1.asp

(see Current Theory Perspective, D. Teaney)

Certainly when the momentum becomes
large p_T >> Lambda QCD \sim T it
becomes increasingly dubious to use strong
coupling methods. So, although there
are many reasons to be skeptical of the
AdS/CFT this example (which Bee used) does not change
my opinion one way or the other.

9. **David Brown**

My translation of "Confutatis maledictis, flammis acribus, voca me cum benedictus" is "When the cursed sinners are condemned to the hot flames, may the Lord call me among the blessed."

This Week’s Hype

October 19, 2011
Categories: This Week's Hype

A couple people have written to tell me about the new BBC Faster Than the Speed of Light? documentary on superluminal neutrinos which evidently featured trademark hype from string theorist Mike Duff about how string theory could explain this. For better or worse, I don’t think I have access to the show from the US, although I’m sure that sooner or later it will arrive on our shores.

Update: Philip Gibbs has more here.

Update: The BBC program is now on Youtube, see here.

Comments

1. **Matt Leifer**
   October 19, 2011

   I watched this tonight and can confirm that it did include stringy hype. The entire last segment was given over to a speculation that neutrinos might travel in the bulk in a braneworld scenario and thus appear to be travelling faster than light to those of us who are stuck on a brane. I’ve never heard anyone propose that anything other than gravity might operate in the bulk, so this seems like an extreme example of opportunism to me. Of course, I am not an expert on braneworld scenarios, so I could be wrong about this. Nevertheless, to claim that the OPERA result might be evidence for string theory seems quite a stretch to me.

   To be fair, the documentary did include a reasonable amount of discussion of the possible errors in analysis of the OPERA result, but, apart from some vague talk about tachyons, this stringy explanation was the only serious alternative mentioned. There was not even any discussion of the possibility that Lorentz invariance might be violated.

2. **may c j**
   October 19, 2011

   The presenter claims that the mass changes if the speed of the body is increased – moreover he claims that this follows from Special Relativity. He is a mathematician so perhaps this is why he does not realise how false that statement is. A mass is a Lorentz invariant – it cannot be changed by Lorentz transformations (like a boost) – what changes is the 4-momentum.

3. **Roger**
   October 20, 2011

   Not everyone equates “mass” with “rest mass”. It is okay to say that speed changes mass.

4. **Philip Gibbs**
   October 20, 2011

   Don’t criticize this program if you have not seen it. It gives a very balanced view of the theory and experiment. Mike Duff explains in hypothetical terms the idea of how extra dimensions could explain the effect and then makes a very clear statement that he does not believe that this is the right explanation. There is no hype.

5. **may c j**
   October 20, 2011

   Roger:

   no, it is not ok to say “the speed changes mass”. The numerical equivalence between the gravitational mass and the inertial mass is the reason why “M times \gamma” has no physical meaning i.e. cannot be called a mass. You will not increase the gravitational field of a body by increasing its velocity.

6. **Roger**
   October 20, 2011

   Do you similarly object to people saying that speed changes length, or speed changes time?

   I do not wish to argue it here, except to point out that both views are common and tenable, as explained by John Baez and Wikipedia. It is silly to complain about the BBC, when many physicists and textbooks say the same thing.

7. **Eric**
   October 20, 2011

   Back in the day, people did tend to refer to the “relativistic mass” rather than the relativistic momentum. This is because the momentum for a particle with non-zero mass is given by

   p = gamma*m_0*v

   so sometimes people would consider the combination gamma*m_0 to be the relativistic mass as opposed to the invariant mass m_0. From a practical point of view, it’s just semantics. From the theoretical point of view, it is more technically correct to speak of the relativistic momentum rather than the relativistic mass.

8. **may c j**
   October 21, 2011

   No Roger, I am not objecting to length contraction and time delays.

   Gravitational mass m_g is equal to m_0(rest mass, inertial) and not to m_0*gamma therefore the statement “the speed changes mass” is not true (as it would imply that m_g is speed dependent which is clearly not the case). Note that the equality m_g=m_0 is empirical therefore the statement “the speed changes mass” would contradict the (Eötvös) experiment.

9. **Roger**
   October 21, 2011

   may c j, what you have is an argument for a definition that some textbooks use, and some don't. The concept of relativistic mass is just as legitimate as the FitzGerald contraction. You could likewise argue that the lengths do not really contract, but it appears that way when measured in another frame. There are some advantages to saying that the mass changes, but you ignore those.

10. **Henry Bolden**
    October 21, 2011

    Better hype: Hints of supersymmetry seen at the LHC, according to Matt Strassler:

    http://profmattstrassler.com/2011/10/19/something-curious-at-the-large-hadron-collider/

11. **Peter Woit**
    October 21, 2011

    Please, enough about relativistic mass.

12. **Bob Levine**
    October 22, 2011

    @ Henry Bolden

    What Strassler actually *says* is,

    "There's absolutely no evidence at this point that this has anything to do with supersymmetry. ZERO. So keep that in mind."

    So it seems a little unfair to attribute SUSY hype to him, on this score at least.

13. **Celestial Toymaker**
    October 22, 2011

    In fact, Mike Duff said that, having worked on the concept of extra Dimensions for 30 years, he'd be very pleased if the Opera result provided experimental confirmation for them.
    But he also said that he didn't think this was the case.

    So there wasn't really any hype involved; no more so than any other theoretical conjectures that would arise were it confirmed that neutrinos were indeed superluminal particles. Which would be pretty paradigm shifting, if true.

    Marcus du Sautoy pointed out that none of the attempts to find measurement errors in the results had produced a quantitiative explanation for the excess speed calculated. But I think it was made before Ronald van Elburg's paper on the subject, which does seem to provide such an explanation – ironically one that confirms Einstein's theory rather than refuting it.
    http://www.technologyreview.com/blog/arxiv/27260/?ref=rss

Solvay Centenary

October 19, 2011
Categories: Uncategorized

The first Solvay conference was in 1911 (at the Hotel Metropole in Brussels, where I stayed one night of my recent trip to Belgium, without knowing the history), attended by the great men of the early days of quantum theory, and one woman (Marie Curie). For more about the 1911 conference, see this [recent paper by Norbert Straumann](). Today the [25th Solvay conference]() got underway in Brussels City Hall, celebrating the 100th anniversary of the first conference.

Like the first one, this conference is by invitation only, and it upholds a policy of confidentiality that goes back to 1911, with not even a schedule or list of attendees for the scientific session publicly available that I can see (just the statement that they are "most of the prominent physicists working on the subject). We do however have Lisa Randall reporting on [Twitter]() about the proceedings. Evidently she's the only woman there :

> Seems ratio of x to y chromosomes hasn't changed in 100 years since first Solvay conference in 1911…

The only other source of info on the internet seems to be [this Cal Tech news item](), which lists the Solvay chair as David Gross and rapporteurs as:
John Preskill (Quantum Computation)
Anthony Leggett (Quantum Foundations)
Ignacio Cirac and Steven Girvin (Control of Quantum Systems)
Frank Wilczek (Particles and Fields)
Edward Witten (String Theory)
Alan Guth (Cosmology)

The gender distribution may have stayed the same, but it looks like the age distribution is somehat different. Today the average age of the chair and Rapporteurs is about 61, back then it was about 46.

Comments

1. **Kea**
   October 19, 2011

   How embarrassing. But then, they aren't embarrassed, are they.

2. **Peter Morgan**
   October 19, 2011

   Even in that social class, people died younger a century ago.

3. **M**
   October 20, 2011

   100 years ago Einstein and Curie did not discuss about feminism and string theory.

4. **Johntheman**
   October 20, 2011

   I found this concluding passage in the Strauumann article interesting:

   "I conclude with personal remarks, that look totally disconnected with what was said in this historical account, and may just reflect my advanced age. One often hears that the present day situation in fundamental physics (string theory, loop gravity) has some similarity with the early years of quantum theory, before the great breakthrough – mostly by a young generation – in 1925-26. I find this analogy totally wrong. Without the precision experiments by the Berlin group (Kurlbaum, Rubens, etc.) and the difficult measurements of the specific heat of molecular hydrogen and other diatomic gases at low temperatures, that demonstrated the freezing out of the rotational degrees of freedom, as well as the low temperature measurements of the specific heat of solids by Nernst, Lindemann and others, it is hard to imagine that quantum theory could have been developed. This is, of course, not new, but it may not be inappropriate to be recalled in an article for this journal."

5. **anonymous**
   October 20, 2011

   any conference on the foundations of physics that does not invite Weinberg can't be taken seriously.

6. **Bernhard**
   October 20, 2011

   The gender distribution of this conference roughly reflects the actual gender distribution in physics, as far as I know. Then why is the distribution like this is not an easy question but I would not say that is for the lack of initiatives. At least in Sweden they are everywhere, to the blowing point of being unfair with men. Besides Randall which other woman comes to mind that is in the same caliber as Witten? Right now I can' t think of any. Not to say that would not be nice to have more women in the field, would be very nice and healthy, but the situation as it is, seems to a result of a mixture of things. The most decisive point is a lack of interest of women to go to graduate school, even tough the rate women/men seems to raise drastically from undergratuate to graduate school (because of the many initiatives that are taken, this is a key point in all European Union applications, for example). The rate is still not in a satisfying proportion. It' s beyond me tough what else could be done to change this situation.

7. **Bernhard**
   October 20, 2011

One action that could be taken of course is to try to get more women in the filed at undergraduate level not leave the problem to graduate school, because then one already has too few choices. But this is a complicated task. How to force someone to choose to do physics?

8. **justanotheranon**
October 20, 2011

I agree with the anonymus above- how could they not invite Steven Weinberg (not to say Wilczek is undeserving- but still Weinberg is a living legend- the greatest physicist alive and probably in history – how could you not invite him to such a prestigious conference (well maybe they did but he declined?)
Any news/dates(!) on his "Lectures on Quantum Mechanics"- really looking forward to this one…

9. **Lisa Randall**
October 20, 2011

I'm not the only woman here. Eva is participating too. But there are more than twice as many participants which is why I mentioned the ratio.

10. **Peter Woit**
October 20, 2011

Thanks Lisa, correction added.

11. **Łukasz Grabowski**
October 20, 2011

nitpick: Marie Skłodowska-Curie.

12. **Bernhard**
October 20, 2011

Łukasz,

Living people, please.

13. **fem**
October 20, 2011

Weinberg might have been invited and could not attend. In later years, Einstein was invited but was not always able to attend the Solvay conferences.

"100 years ago Einstein and Curie did not discuss about feminism and string theory."

By 1911 Einstein was married to his first wife and embarking (or would soon embark) on an affair with his (eventual) second wife, while Marie Curie was a widow (Pierre died in 1906 in a street accident in Paris) and embarking on an affair with Paul Langevin. Feminism, anyone?

14. **Charles**
October 20, 2011

Two things are likely given the focus and sponsors…the conference invited Weinberg…and they are paying many tributes to Brout (who unfortunately passed early May) and Englert (in attendance) as the primary folks behind the Higgs Field and Boson (excluding PH and GHK).

15. **Peter Woit**
October 20, 2011

Bernhard,
I suspect that Lukasz was nitpicking about my not giving Marie Curie's full name, not your comments about the small number of female physicists. The question of why there are so few women physicists at the top ranks of the profession is a complicated one, and discussion of it a whole other topic.

In this case, the standard shouldn't be Witten though, since in many ways there aren't even any other male theorists in his league.

16. **Bernhard**
October 20, 2011

Hi Peter,

I agree, and sorry if I went a bit off-topic, surely I know you don' t want a general debate about women in physics. But going back to the Solvay conference I agree Witten is putting the bar too high, but a fair bar is to ask for a woman in the same level of all the other guests, including Lisa Randall. Perhaps people can can up with one other name, I could not come with one tough.

17. **Paulus**
October 20, 2011

Eva who?

18. **Rapunzel**
October 20, 2011

Kea, why should "they" be embarrassed?

19. **Kea**
October 20, 2011

Rapunzel, unlike the dudes here, who feel entitled to wax lyrical about women in physics, I actually know about the research that proves without any doubt whatsoever that the reason for few women is Discrimination Discrimination Discrimination. Bernhard's inability to read even one paragraph of this research is a good demonstration of his misogyny. Fact: women leave physics AFTER getting PhDs, and sometimes very good ones, for a number of reasons, but mostly because of Discrimination Discrimination Discrimination.

20. **Peter Woit**
October 20, 2011

Paulus,

Eva Silverstein

21. **anon.**
October 20, 2011

Weinberg's absence could just be due to limited funds — he never goes anywhere unless whoever invites him pays for a first-class airline ticket. (I can't say I blame him, as I think he's earned that sort of thing; but it is very expensive.)

22. **SpearMarktheSecond**
October 20, 2011

I hope they all have a nice time but the chances are slim that anything innovative will result. Laying the groundwork, both theoretical and experimental, for a post-no-Higgs situation might be nice. But hasn't the trend, like graphene and quasicrystals, been away from the mainstream? Even Dark Energy, although the greats leapt in front of that parade and hypnotized us into neglecting that they totally missed predicting Dark Energy.

23. **Jeff**
October 20, 2011

@spear – hey, didn't Einstein get "dark enegy?" Of course, he didn't come up with a clever name for it 🙂 Still remember working out the field equations for GR as an undergrad at Hampshire and getting into the CC discussion with Herb Bernstein.

24. **Edgar Loesel**
October 21, 2011

There are no female physicists giving public lectures or participating on the panel discussion no woman:

25. **Bernhard**
October 21, 2011

Kea,

Nothing I said justifies what you are implying. I asked a simple question, and perhaps there is an answer to it, but so far nobody, including you, actually gave me good examples of women in the level of Randall to attend this meeting. I suppose there could be such persons, I am just not aware of them. If you however are, please share your knowledge. I am with my mind open and I am glad to recognize I was wrong if you or anybody proves me wrong. But please, do not simply rotulate me as misogyny without actually answering the question seriously. And in any case even if the problem were that I am not aware of them it is not because I have something against them. There could be a not famous other Lisa Randall, but if there is, then is not my fault not knowing her, since the hypothesis is that she is not famous enough for me to know her in the first place.

As for why women leave physics and when I don ´t think you are right, but in any case this is not the place to discuss it. I am however open to new information and if there is something ("the research") I missed please send me a link.

This is my last reply to this, otherwise this will become an annoying debate for Peter to moderate.

26. **Peter Woit**
October 21, 2011

Bernhard,

Eva Silverstein immediately came to mind when I started to think of prominent women theorists that could have been invited to Solvay besides Lisa Randall. Turns out she is there though, so not an example of someone passed over or ignored.

What Kea addresses is kind of a different, not why Solvay is passing over prominent women, but why women don't rise to prominence. Again, that issue is a complicated one that is kind of off-topic, and I'm not up to moderating a discussion of it here and now.

27. **Bernhard**
October 21, 2011

Thanks Peter, agreed.

28. **lun**
October 21, 2011

I hope Peter allows me to link this talk from his collegue, as it answers comprehensively why the X chromosome ratio moved so little.

29. **jg**
October 21, 2011

The most famous Solvay Conference of all (1927) is analysed in detail in the book

'Quantum Theory at the Crossroads: Reconsidering the 1927 Solvay Conference'
by Guido Bacciagaluppi, Antony Valentini

which is available in draft version on arxiv (all 553 pages)

http://arxiv.org/abs/quant-ph/0609184

30. **cormac**
October 21, 2011

Looking forward to curling up on the couch and reading that Straumann paper tonight, he's an excellent historian of physics….wish more physicists would do this. Many thanks for the link Peter

31. **Łukasz Grabowski**
October 22, 2011

"I suspect that Lukasz was nitpicking about my not giving Marie Curie's full name"

Yes, or rather as I'd put it, your not giving her correct name 🙂 (my understanding is that if you stick with what she called herself you should use Marie Skłodowska-Curie, if you prefer the legal state of matters after her marriage with Pierre Curie, it's probably Maria (not Marie) Curie, unless she changed her name. But this seems to me very unreasonable, see for example Michel Thomas on wikipedia – no one called him anything other than that, presumably because that's the way he wanted it to be, so why not granting Marie S-C the same luxury?)

32. **Giotis**
October 22, 2011

If Silvertsein was there then why not Kallosh or Becker&Becker for example? If they wanted more females participants they could easily invited them and others.

But I guess who you know makes a huge difference. If you know Witten I think you have better chances.

33. **Giotis**
October 22, 2011

If you know Witten and Gross even better

34. **anonymous**
October 22, 2011

Most people in high energy physics know Witten and Gross, and most people
go to plenty of conferences. No doubt there are many men and women who could have been invited, as with any conference.

35. **Kent Traverson**
October 25, 2011

If Madam Curie's husband was deceased, how could it be said that she was having an affair with anyone?

36. **Eric**
October 25, 2011

Kent,

The man she was involved with, Paul Langevin, was married at the time.

37. **Umesh**
October 31, 2011

Am sorry, but I have to point out that nobody compares to Edward Witten, male (or) female. Besides, he's 'The Martian'!! On a more serious note, it's not for nothing that he's said to posses superhuman intelligence, which puts him beyond anyone currently involved in the field. So please stop throwing around comparisons with this great man so freely.

The Status of SUSY

October 22, 2011
Categories: Experimental HEP News, This Week's Hype

You may have seen by now claims from various sources about evidence for SUSY coming from CMS, for instance Hints of New Physics Crop Up at LHC, A Lifeline for Supersymmetry?, and CMS sees SUSY-like trilepton excesses. This nonsense is all due to Matt Strassler, who for some reason thought it was a good idea to post a blog entry Something Curious at the Large Hadron Collider that starts off:

> Finally, something at the Large Hadron Collider (LHC) that does not seem to agree that well with the predictions of the equations of the Standard Model of particle physics.

followed by various caveats, which include though the advice:

> But this is clearly something to watch closely over the coming months.

As one could easily have predicted, this got picked up by the media and various blogs, mostly dropping the caveats. In a later more detailed posting, Matt carefully three times in italicized red explains that "The excess will probably disappear". He does continue to claim that "particle physicists are paying close attention" to this statistically insignificant discrepancy between data and theory, something I suspect was true before his blog posting for an equally statistically insignificant number of particle physicists.

During this past week or so, there has been a lot of various news about SUSY at the LHC, all of it bad. For some background, one should look at Mike Peskin's write-up of his summary talk at LP2011, which he posted last week to the arXiv. See pages 37-41 for his discussion of the state of SUSY. He explains why one would expect that all SUSY mass terms are of the order of a few hundred GeV, with the Tevatron bounds on gluino and squark masses (around 300 GeV) already making one suspicious. Similar LHC bounds are already around 1000 GeV, getting close to the limit (around 1200 GeV) of what can be produced at current beam energy. When the LHC comes back on-line with higher beam energy in 2014, these bounds should then go up to 2000 GeV or more. Much has been and is being made of the fact that one can find SUSY models that evade these bounds, with LHC results then giving lower limits in the range 500 GeV and above.

Peskin writes:

> As the LHC experiments become sensitive to hypothetical new particles with TeV masses, we are reminded of the phrase from the Latin Requiem Mass:
>
> Confutatis maledictis, flammis acribus addictis, voca me cum benedictus.
>
> A loose translation is: Thousands of theory papers are being tossed into the furnace. Please, Lord, not mine!
>
> …
>
> Before the startup of the LHC, I expected early discovery of events with the jets + missing transverse energy siignature of supersymetry. It did not happen. A particularly striking comparison is shown in Fig. 33. On the left I show the expectation given in 2008 by De Roeck, Ellis, and their collaborators for the preferred region of the parameter space of the constrained Minimal Supersymmetric Standard Model (the cMSSM, also know as MSUGRA). The red region is the 95% confidence expectation. On the right, I show the 95% confidence *excluded region* from one of the many supersymmetry search analyses presented by CMS at LP11. No reasonable person could view these figures together without concluding that we need to change our perspective.

Peskin goes on to argue though that the thing to do is not to abandon SUSY since it hasn't shown up where it was supposed to, but to "acknowledge that, to test SUSY, we must search over the full parameter space of the the model". The obvious problem with this is that the "full parameter space of the model" is huge, containing all sorts of corners that will never be accessible to the LHC, or that can be made arbitrarily difficult to rule out, requiring intensive effort from LHC experimenters for decades to come.

For details on what has been going on, various recent sources to consult include Anyes Taffard's FNAL talk on ATLAS SUSY searches ("SUSY was NOT 'just around the corner' … must be hiding well … Or may be … need to go back to the drawing board") and the many talks at the Berkeley Workshop on Searches for Supersymmetry at the LHC which included a huge array of negative SUSY results, including the one that for some reason got Matt so excited. Besides the kinds of models that Peskin expected to see at the LHC, lots of other more obscure ones are being ruled out by new LHC analyses. These include some that had gotten a lot of popular attention, such as split supersymmetry and F-theory models. These predicted things like long-lived gluinos or staus, which have now been searched for and ruled out in regions where they were supposed to show up. For example see here for more about F-theory and the stable staus, which CMS now says are not there where they were supposed to be (below 300 GeV).

For some other recent news, see the talks at the BNL conference running the past couple days, A First Glimpse of the Tera Scale.

Finally, for the best in recent HEP news, see this from Warren Siegel.

Comments

1. **Phil**
   October 22, 2011

   Dear Peter,

   I would very much appreciate your thoughts in response to my comment (#60) over at Sean's post. My comment was in response to your response (#59) to an earlier comment I had made (#19). Here is the link to Sean's post:
   http://blogs.discovermagazine.com/cosmicvariance/2011/10/18/column-welcome-to-the-multiverse/#comments

   You'll also find a comment (#62) from "somebody" (not me, I assure you) and I am also very interested in your response to him/her. Thank you!

2. **Bernhard**
   October 22, 2011

   I don´t think it is absurd to ask SUSY to be tested over a larger parameter space, since who knows, it could be there and Nature not necessarily care about our experimental difficulties. What I would however like to see is how likely some regions of the SUSY parameter space is with respect to its motivations, most notably the "solution" of the hierarchy problem. Some interesting plots would be to show different regions of the SUSY space with a calculation of the percentage of extra fine tuning one needs to "solve" the hierarchy problem. I guess one could go on searching for SUSY forever but the community would slowly start to understand it is probably not there if the remaining parameter space to be searched for were a theoretically already disfavored one.

3. **Giotis**
October 22, 2011

Phil, of course Peter knows better but I can tell you my opinion about your comment i.e. how QFT is different from String theory in that respect.

QFT is not a theory of everything and thus it doesn't have to explain everything e.g. the values of the various constants it contains. It waits for a more fundamental theory to explain these things i.e. to explain QFT, GR and the Standard model itself.

ST on the other hand claims that it is a TOE and consequently must explain everything. Specifically it must certainly explain why we live in this particular low energy effective world with this particle/force content and with these constants.

Now if the String vacua picture is true then ST obviously can't do that. In this picture there is no reason whatsoever why from these enormous number vacua only our vacuum, with these particular properties, is realized. So far nothing indicates that there are probability distributions highly peaked over our kind of vacuum.

Faced with this problem ST theory must admit her failure or else claim that indeed all these vacua can be realized using eternal inflation as the mechanism to populate them. This is how the multiverse picture emerges.

So Peter objection (as I understand it at least) is that ST instead of admitting its inability to predict anything regarding our world (and thus to admit her failure as a TOE) it justifies this inability by adapting the multiverse paradigm. According to this perception this situation resemebles a drowning man clutching at a straw.

4. **Joel Rice**
October 22, 2011

I had not seen Warren's parodies – still rolling around on the floor trying to catch my breath – he should team up with Weird Al Yankovic and make some videos.

5. **Eric**
October 22, 2011

Dear Giotis,

Your comments in regards to string theory basically reflect the exact same attitude that many physicists had towards QFT in the 1950's and 60's. It is a myopic way of looking at the real situation as it is today. Just because our current understanding of string theory is limited doesn't mean that the theory itself is limited.

Bernhard: Any supersupersymmetry parameter space with superpartners less than around 2 TeV can naturally solve the hierarchy problem. The present experimental limits are not even close to this.

6. **Bernhard**
October 22, 2011

Eric,

I would like to see this for the future. At 14 TeV we will eventually get there and at some point the amount of fine tuning will start to get troubling (do you agree?). I´m not sure when this will start to happen to you, my understanding of this is that what come out is already worrying. So in any case, I would like to see a more detailed prediction on this, for when we get there I know exactly where we are standing in terms of the likelihood of SUSY being correct.

7. **Phil**
October 22, 2011

Giotis,

Isn't it true that theorists haven't been able to use QCD to calculate the proton's mass? From my understanding, this is due to the failure of perturbative QCD and only non-perturbative QCD (which we don't know very well) can allow us to calculate the proton's mass. Isn't this similar to our lack of knowledge of string theory non-perturbatively?

Maybe if we understand string theory non-perturbatively, we will be able to find our low energy universe in the theory and rule out the rest of the landscape? But we don't know if such a thing is possible, hence the continuing research in string theory.

Also, one can argue that string theory is NOT a TOE because it is only a perturbative theory of strings that postulates what the degrees of freedom are beyond the standard model and towards the Planck scale. Perhaps M-theory, or whatever the nonperturbative formulation of string theory is, is the real TOE.

If QCD is the theory of the strong interactions, why haven't we been able to use the theory to calculate the proton mass? Because we don't understand the theory very well non-perturbatively. Perturbative QCD, like perturbative string theory, cannot explain everything (i.e the proton mass), but a more fundamental formulation (i.e. non-perturbative QCD) can. The same may be true with string theory.

8. **Roger**
October 22, 2011

Phil, I thought that lattice QCD could calculate the proton mass from the masses of the up and down quarks, and they have values for those masses.

9. **Eric**
October 22, 2011

Bernhard,

If superpartners are not observed below ~ 2 TeV, then supersymmetry cannot solve the hierarchy problem. Thus, a major motivation for the expectation of observing supersymmetry at the LHC would go away. At the moment, we are not there. It will be a few years into the second LHC run before this scenario might be realized. However, I think it is probable that signals of the superpartners will show up by the end of next year, if they haven't already i.e. the observed trilepton excesses. Also, I think it is likely that in the next few months, the first evidence for the Higgs will be anounced, and it will in fact be in the region favored by the MSSM.

10. **Peter Woit**
October 22, 2011

Phil,

QCD does have a precise non-perturbative definition, there is a lot you can say based on it, and this all agrees precisely with experiment.

Trying to say that the QFT framework which is the most predictive and successful theoretical framework ever developed by human beings is the same as the completely unpredictive string theory framework is really absurd. What you're doing is saying that black is just like white since they're both shades of gray.

11. **Peter Woit**
October 22, 2011

Eric,

If you look at the Peskin paper I linked to, you'll see that his argument is that for SUSY to solve the hierarchy problem it should have superpartners at the mass scale of 100s of GeV, not 2 TeV.

12. **anon**
October 22, 2011

Siegel's frog parody is funny, but it's impossible because the total energy of the protons that ever collided in the tevatron is far less than the rest mass energy of a frog.

13. **Eric**
October 22, 2011

Peter,

If you read Peskin's paper carefully, you will see that what he actually says is that the simplest possibility is for the superpartner masses to be in the few hundred GeV range, not that this is where they have to be in order to solve the hierarchy problem. The superpartners can be heavier than this, and masses from ~100 GeV to 2 TeV can do this.

14. **Phil**
October 23, 2011

Peter,

There are many quantum field theories possible, corresponding to the many possible choices one can make for the underlying gauge groups. Similarly, there are many possible perturbative string theories, corresponding to the many possible ways of compactifying C-Y manifolds, etc. So what is the difference between these two?

The only difference I see is that we are able to perform experiments that show us the way towards the gauge groups of the standard model, but we do not yet have the technology to conduct experiments that show us what physics looks like far beyond the standard model or near the Planck scale. When string theorists get better at building stringy models that match the standard model they will have many models that not only contain the standard model, but also have different possibilities for what lies beyond the standard model and near the Planck scale. When or if our technology improves to the point which allows us to conduct much higher energy experiments, nature will guide us to the correct model, just like how nature guided us to the correct SU(3)XSU(2)XU(1) quantum field theory after we performed lots of particle physics experiments.

Do you agree with the above?

If it is shown that no stringy model contains the standard model (which hasn't been done yet) or the results of beyond standard model experiment, then string theory will be shown to be wrong. If such a thing is not shown, then string theorists will keep on looking.

15. **Bernhard**
October 23, 2011

Eric,

OK then, bets are on :-).

As for the Higgs, I think we would already be hearing rumors by now if it were true and things are really quiet, but who knows…

16. **Martin**
October 23, 2011

I was so fascinated by your latin quote that I used Google's translation tool.

> Confutatis maledictis, flammis acribus addictis, voca me cum benedictus.

translated to

> Confuted curses, devoted to acrid flames, call me with the blessed"

I think you did better. But then I assume Latin is merely like another Italian dialect to you.

Shame about SUSY. I have always been a great fan.

Cheers,
Martin
PS I did find this official translation, although I still prefer yours

> When the accused are confounded,
> and doomed to flames of woe,
> call me among the blessed.

17. **JE**
October 23, 2011

Bernard said, "As for the Higgs, I think we would already be hearing rumors by now if it were true and things are really quiet, but who knows…"

Referring to the Higgs, Tommasso commented on his blog a couple of days ago that "… CMS and ATLAS experiments are now seeing an excess exactly of the right size at the most probable mass".

So let's wait and see if this turns out to be a hint of a true signal…

18. **Bernhard**
October 23, 2011

JE,

Really?? OK, I missed that. But as you said, let´s wait and see.

19. **Peter Woit**
October 23, 2011

Phil,

You're trying to argue that black is just like white by starting with "first assume that black somehow turns into light grey..". This is a waste of time.

Eric,

Why 2 TeV? Why not 4, 10, 100?

Martin,

The translation is not mine, but Peskin's.

20. **Eric**
October 23, 2011

Peter,

You can do find this calculation in any QFT book which discusses supersymmetry. It is a simple calculation of the loop corrections to the Higgs mass. For exact supersymmetry, the correction is zero. As the mass difference between the SM particles and their superpartners gets bigger, then the corrections to the Higgs mass get bigger. At some point (~1-2 TeV), the Higgs mass becomes unstable. I would suggest actually performing the calculation yourself so that actually know what you are talking about for once.

21. **Artyom**
October 23, 2011

Dear Peter

I recently started reading your blog, thanks, it`s very interesting.

What do you think is it possible that theorists do not recognize the failure of SUSY and simply close their eyes on LHC results?

False theories have taken place before but in SUSY too much invested… Academic degrees, thousands of papers, grants etc. Do scientific community able to recognize the crash of SUSY, strings and other "great theories"?

Sorry for my English, I am from Russia.

22. **Phil**
October 23, 2011

"You?re trying to argue that black is just like white by starting with ?first assume that black somehow turns into light grey..?. This is a waste of time."

Peter, I really don't understand your point here. Can you please clarify?

You say QFT is predictive. Does QFT predict the SU(3) X SU(2) X U(1) group structure as the one that describes our world? No. Experiments were needed to elucidate this fact about our low energy world. Likewise, experiments are needed to elucidate the correct compactification for the extra dimensions, assuming extra dimensions and string theory describe our world. Again, experiments are needed to determine whether or not string theory and compactified extra dimensions describe our world, just as experiments were necessary to show us that group theory and the formalism of quantum field theory describe our world.

So, in that sense, QFT is just as unpredictive as perturbative string theory.

Do you agree with this? Why or why not, and please, for the purposes of enlightening and persuading me to adopt your point of view, refrain from using the "black", "white", and "grey" "argument", since I have absolutely no idea what any of that means. Thanks!!

23. **ha!**
October 23, 2011

Phil,

the point is that simple groups like SU(3), SU(2) and U(1) are the very first thing one would think of. They are quite the simplest thing to try. Calabi-Yau compactifications, however, are mind-numbingly complicated, and there appear to be so many of them that if ever one of them is found that reduces to the standard model in the low engery limit, it would hard to claim that that is a "prediction" of string theory. This is why string theorists are reduced to nonsense like the landscape, and spurious statistical arguments based on it.

24. **Bernhard**
October 23, 2011

Phil,

QFT as an effective theory cannot predict a bunch of things, like masses. But once you used it there is a clear predictive power to it, once you use e.g. the rules for renormalizable gauge theories you are very be able to compare the model you built with experiment. The models based on QFT´s are very predictive each one separately, reason way we can start discussing which models will be excluded at the LHC. That is in this sense a big difference between SUSY and string theory (ST), even if SUSY was born inspired by ST we can really discover or rule out SUSY. That´s very exciting and interesting. ST comparatively have nothing even remotely close to that. There are is no way you could use ST to make different models as predictive as QFT and there has been no advances on how to solve this in the last years. Even if you had a gigantic accelerator there would be no way you could say "right, that´s the correct ST model", because there are no precise quantitative predictions to compare to. QFT is a powerful framework, ST on the other hand is… well I´m not sure what it is.

25. **Phil**
October 23, 2011

ha! and Bernard,

Thank you very much for your helpful responses! I'm not a string theory expert by any means (my field is in a different area of physics), and I'm pretty neutral about all this, but I just want the straight dope about all this. Here are my responses.

ha!, True the simplest groups turned out to be the right ones, but isn't it true that Nature doesn't care what is simple or not? Her laws are what they are. If Nature cared about simplicity, then why don't we simply live in a "billiard ball" universe controlled only by Newton's laws of motion?

Bernard,

So are you saying that, as of now, if a string theorist produced a particular compactified calabi-yau manifold, it wouldn't lead to definite predictions for what our low energy universe should look like according to the model (and, therefore, to see if it matches the standard model), or what physics beyond our low energy universe should look like? How come? I always assumed that once you choose the parameters for the calabi-yau, you will get a definite theory of particle interactions by using the rules of string interactions. Are there no definite rules for string interactions? I always thought strings join together and break apart and that there were clear expressions for amplitudes for these processes. Why is building a string theory model, based on a particular calabi-yau manifold, capable of telling us what the particle interactions at different scales should look like, such a hard problem?

26. **Peter Woit**
October 23, 2011

Eric,

In my advanced old age, I have trouble performing loop calculations in the MSSM, especially keeping track of the extra 105 undetermined parameters. And then, I never know whether I should really be using the NMSSM or some other extension of the MSSM, and sometimes I'm not sure if I need to go to higher loops or not. So, maybe you can help me out by pointing to where someone has done this calculation. And, by the way, is it 1 TeV or 2 TeV? If it's 1, the subject is just about done.

27. **Peter Woit**
October 23, 2011

Artyom,

Theorists aren't closing their eyes to LHC results, they're paying close attention. Right now, the question is, what do you do if these results rule out the generic picture of how SUSY appears that you had been advertising for a long time as the one to be expected? One attitude (mine) would be that there is already a long list of reasons not to expect SUSY, so this should finish the subject off as a popular one to work on. Lacking a better idea, experimentalists might want to keep doing searches for SUSY variants, but should be under no illusion that they're likely to see anything.

If you have been spending the last 20-30 years of your professional career investing your time in developing expertise in the ins and outs of the intricate details of SUSY models, or you have loudly advertised SUSY as an implication of another subject you are deeply invested in (e.g. string theory), you might not be willing to give up so easily. In this case you would start going on about all the special cases of SUSY you could think of that might be such as to evade the current LHC limits. There may be some limit though to how long you can keep doing this, and still have people pay any attention to you.

28. **may c j**
October 23, 2011

I am always surprised when people say that Supersymmetry was born inspired by String Theory (as Bernhard says). Miyazawa, in papers from 1966 and 1968, introduced Supersymmetry a few years before the superstring hype. Of course no strings are mentioned in Miyazawa papers. The superstring was introduced in 1971.

29. **Peter Woit**
October 23, 2011

Phil,

I see that part of the problem here is that you don't actually understand what is involved in constructing a realistic string theory model. To start with: you can't just "pick a Calabi-Yau and calculate". Calabi-Yau's come in a very large number (possibly infinite) of families, each family locally parametrized by a space of high dimension. If you pick a point in such a space, that does pick out a Calabi-Yau, but you basically know almost nothing about its metric, and that's the first thing you would need to start doing calculations. Oh, and this actually is only approximately true: you really don't want Ricci-flatness, but a more complicated condition with higher order terms.

Let's say you actually could do this. Then you'd have a theory that was clearly wrong, it would have the "moduli" problem. The parameters defining your Calabi-Yau would behave like massless fields, giving you lots of long-range forces of gravitational strength, violating the equivalence principle. So, you need to add a bunch of non-perturbative structures in by hand to "stabilize moduli". Take a look at the KKLT construction which is supposed to do this, which even its advocates refer to as a "Rube Goldberg construction".

Let's say you've done all this in some specific case. Then you have the problem that vacuum energy is completely wrong. Etc, etc, etc. What's going on here is nothing at all like QFT, where you can just sit down and calculate. Here anything you can calculate comes out wrong, so you are forced into more and more complicated constructions, just to avoid being ruled out by experiment. This is black where doing the calculation and getting an answer that agrees with the real world to 10 decimals is white. String theorists who go on about how they really can calculate things in principle, there are just some minor technical problems are being intentionally misleading.

30. **Bernhard**
October 23, 2011

may c j,

Miyazawa proposed a proto-SUSY (meson-baryon) thing but as far as I know was not exactly the same SUSY (fermion-boson) that we have today. But in any case, I´m fine to give credit to Miyazawa, makes no difference to me.

31. **Eric**

October 23, 2011

Peter,

Once again, you are throwing in spurious arguments that have nothing to do with the actual point. I presume you are doing so with the intent of being deliberately misleading. Whatever extra parameters (SUSY soft terms) there are in the MSSM, they have no relevance in regards to the loop corrections to the Higgs mass. The loop corrections are only sensitive to the scale of the mass splittings between the SM particles and their superpartners, not on the detailed superpartner spectra which are determined by the soft terms.

32. **Mark**
October 23, 2011

Phil,
Just to make what Peter is talking about more explicit, here is a reference http://www.springerlink.com/content/2845m53jmpw5754h/fulltext.pdf , where the authors first considered a general case with an arbitrary Kahler metric to obtain some general expressions but then picked a particular Calabi Yau and looked at stabilizing a subclass of the moduli (so called Kahler moduli) – the scalar fields that describe the deformations of the internal metric that correspond to the volumes of two- and four-cycles and also control the overall volume of the compactification. You don't have to look through all the details but I would like to draw your attention to the expressions in eq. 3.24. Here \tau_i describe the volumes of four-cycles, t_i describe the volumes of two-cycles and V_X is the volume of the Calabi-Yau manifold used in this example. If you examine eq. 3.24 you will notice immediately that all these volumes are controlled by a single parameter, denoted by \tau_D while all the numerical coefficients are completely fixed by the topology of the Calabi-Yau. In Type IIB compactifications, Kahler moduli control the values of gauge couplings, e.g. the value of the unified gauge coupling \alpha_GUT=1/25 is literally equal to the inverse volume of the four-cycle wrapped by the visible sector D7-brane stack, so if you assume the standard gauge coupling unification and disregard the small threshold corrections, the corresponding volume \tau_GUT=25. Now, if you have a realistic compactification, you could use this as input to determine the value of \tau_D and therefore automatically determine the numerical values of all the t_i, \tau_i as well as the overall volume V_X. So, once you pick a Calabi Yau, your model would be extremely predictive because you would be able to immediately constrain all the physical quantities whose values are controlled by Kahler moduli.

33. **Jim Rohlf**
October 23, 2011

People are quick to forget that LEP took a BIG bite out of supersymmetry pushing it to an odd corner of parameter space for survival. The LHC is only mop-up.

34. **Shantanu**
October 24, 2011

Phil/Eric, if you are so sanguine about supersymmetry.string theory can you tell me what it predicts for theta_13? This is anumber we shall measure very accurately in next few years.
shantanu

35. **anonymous**
October 24, 2011

Phil,

http://www.sciencemag.org/content/322/5905/1224.abstract

36. **anon**
October 24, 2011

Phil/Eric, if you are so sanguine about supersymmetry.string theory can you tell me what it predicts for theta_13?

Non-zero. Because SUSY etc. doesn't have any symmetry principle that requires it to be zero.

37. **Kish J**
October 24, 2011

@anon,

A frog genome weighs roughly 5pg. LHC collisions can accumulate this rest mass in less than an hour, I guess.

38. **Phil**
October 24, 2011

Shantanu,

If you read my comment carefully you will have noticed that I am not sanguine about string theory. Like I said, I'm no expert in string theory (my field, though in physics, is something completely different). I am merely after the truth about string theory and its prospects and how the situation with string theory's predictive power (or lack thereof) is different from quantum field theory's predictive power. No bias, just the "straight dope". So, in answer to your question, I have absolutely no idea. I'm not even so sure of what a theta angle is. I think it's something to do with neutrino masses.

39. **Shantanu**
October 25, 2011

anon,
I want a prediction for its value with error bars. we sort of already know its non-0(I think 3 sigma from T2K results). If string theory is a theory of everything it should be able to predict its value.

40. **aa**
October 25, 2011

i think string theory doesn't require it to be 42 either.
thats my prediction, its not 42.

41. **Denis Boers**
October 26, 2011

If SUSY goes, does that imply that inflation has to go too ?

42. **Peter Woit**
October 26, 2011

Denis,

SUSY and inflation have pretty much nothing at all to do with each other.

43. **HoldYourHorses**
November 1, 2011

Peter, what do you think of this: Natural SUSY Endures, arXiv:1110.6926 ? One of the points it makes is that one must distinguish between sparticles which must be low-mass in order for the theory to be `natural', and others who can be as heavy as they like.

44. **Peter Woit**
November 1, 2011

HoldYourHorses,

Was thinking of writing a post about this, not sure if I'll have time. It's interesting to see that people are focusing on this one sort of scenario, kind of a last hope of avoiding fine-tuning. Interesting question it whether this (and next year's) data will be enough to test it, or if one will have to wait until 2014-5. And when it gets shot down, will SUSY advocates give up?

Besides the paper you mention, there's lots about this at

http://indico.cern.ch/conferenceOtherViews.py?view=standard&confId=157244

Especially pithy is Arkani-Hamed's presentation, see

http://indico.cern.ch/getFile.py/access?contribId=7&sessionId=2&resId=0&materialId=slides&confId=157244

Higgs Non-News

October 24, 2011
Categories: Experimental HEP News

The two main LHC experiments have now recorded just about 5 inverse femtobarns each of data this year (CMS here, ATLAS here). This is the last week of the proton run, so that number will be near the total available for analysis until next spring when the next proton run gets started.

For some idea of what this means for the Higgs search, see for example Tommaso Dorigo's discussion here of last year's ATLAS projections about this. 5 inverse femtobarns was at the high end of what was expected, and the ATLAS projection was that this would be just barely enough to expect to be able to rule out a Higgs at 95% confidence level, all the way down to the LEP limit at 114 GeV. Of course, this expectation is statistical. If the Higgs is not there, and one is lucky (downward statistical fluctuation in number of events), then one can exclude at better than 95%. If one is unlucky (upward fluctuation), or the Higgs is really there, the 95% exclusion will not be achievable.

The LHC Higgs Combination Group has now combined the ATLAS + CMS Higgs results released at the summer conferences, and plans to release this in time for the HCP 2011 conference next month. Because of the efforts of Phil Gibbs, about all that needs to be said about the LHC-HCG plot is that it looks an awful lot like his, which is available here. An SM Higgs is excluded at 95% for masses below about 480 GeV, down to a lower limit of around 135 GeV (the data is actually very flat and close to the right value to exclude the SM from 135 GeV to 145 GeV).

The huge question of course is now whether there is a Higgs with mass between 135 GeV and the LEP limit (114 GeV). The current LHC data shows no definite sign of the Higgs, but the statistics is still too low to really say anything, especially for the lower part of the region. The crucial thing to watch now is the Higgs to gamma-gamma channel, which is the only one sensitive enough to hope to rule out or see a Higgs in the 115-125 GeV region, for the current amount of data collected. I don't know when the experiments expect to release new data in this channel, just that their goal has been to each have some sort of result in December. Perhaps they'll release something at HCP 2011, more likely not. The only rumor I've heard is from someone who has seen a recent plot of the ATLAS data for this channel, and he tells me he doesn't see any bump in this region. But work on this data is on-going, and I have no idea what CMS is seeing or not seeing (my efforts to get Tommaso Dorigo drunk in Antwerp last month didn't yield much).

At last month's CERN Council meeting, there was a report submitted to the Council on "The scientific significance of the possible exclusion of the SM Higgs boson in the mass range 114-600 GeV and how it should be best communicated." The report is based on the summer 2011 data, and it emphasizes excluding the Higgs at not just 95% (2 sigma), but at 5 sigma, something that will require (if the Higgs is not there) combining the 10 inverse femtobarns of data from each of the two Tevatron experiments and a similar amount from each of the two LHC experiments, something that won't be possible until sometime after mid 2012.

Update: One more related item. At Berkeley starting today, ATLAS is holding an Analysis Jamboree on Higgs Searches. First two days is the good stuff, open only to ATLAS members, but the last day there will be an open session with theorists allowed.

Comments

   October 24, 2011

   Your link to Tommaso Dorigo's post starts http://http//.

2. **dir**
   October 24, 2011

   to fix the higgs mass, zz*–>4l and h–>2gamma channels are important. it seems to me that philip gibbs's combination of these channels does hint a 140 gev higgs, see http://blog.vixra.org/2011/09/18/higgs-days-at-santander/

3. **Peter Woit**
   October 24, 2011

   Anon,

   Thanks, fixed.

   dir,

   I guess the kind of question raised by Phil Gibbs in that posting explains why CERN is looking for better than 95% exclusion in the combined channels, just to make sure.

4. **chris**
   October 25, 2011

   where are all the spies if one needs them 🙂

5. **Paolo Valtancoli**
   October 25, 2011

   If the Higgs is not found, phenomenologists are ready with their fancy higgless models…

6. **Bernhard**
   October 25, 2011

   Paolo,

   the discussion is about the SM Higgs for the moment. It will take a huge amount of data to discard just any Higgs.

7. **Tony Smith**
   October 25, 2011

   As to the Higgs to gamma-gamma Channel,
   Eilam Gross in Slide 57 of his 29 August 2011 presentation
   "Higgs Searches at the LHC"

described CMS results at around 1.7/fb saying:

"… A local moderate (yet genuine) 2.3 sigma excess
is seen in CMS around 120 … LEE washes out the excess
…
There is 2.8 sigma [around 140] with Higgs to gamma-gamma
which is reduced to 1.7 sigma with the LEE …".

So, whether or not use of LEE (the Look Elsewhere Effect) is
a decision with significant consequences
that needs to be taken carefully in analyzing the 5/fb Halloween data.

Tony Smith

PS – His slide 22 shows the connection between
the 140 peak on the CMS Brazil Band plot
and
the same 140 peak as a bump on the CMS data histogram.

8. **Peter Woit**
October 25, 2011

Tony,

The released gamma-gamma data from this summer is just not enough to have any realistic hope of seeing a SM Higgs signal, at 120 or 140 GeV. To get an idea of the significance of any excess you see anywhere in it, you definitely need to include the look elsewhere effect, since you are looking for an excess anywhere in a large region. Statistically, you're sure to find some excess somewhere.

By now CMS and ATLAS should have much more data analyzed, approaching the amount needed to actually see something. Whether they have enough to say something definitive will be very interesting to see. Maybe we'll find out in December…

9. **null**
October 25, 2011

Has the Tevatron collected enough fb-1 to decide the issue in the interesting region 114-135GEV?

10. **ohwilleke**
October 25, 2011

IIRC, the issue with the 135-145 GeV range was that given the power of LHC to see a signal there, there possible signal was much weaker than one would expect from a SM Higgs even if it had some statistical signficance – we should have see twice as many sigmas of significance as we did at last publication. In contrast, at 115-125 GeV where there was also some hint of a signal, the power of the LHC to see anything in that mass range was weak enough to not be inconsistent with a SM Higgs.

11. **Shantanu**
October 25, 2011

Peter, curious about your comments on the discussion about eternal inflation on cosmicvariance between Tom Banks and Sean Carroll.

12. **younghun park**
October 25, 2011

Peter
As null said, many people including me want to know about the analytic result of Tevatron. Do you know something on Tevatron? If you have heard, I hope to get good information from you.
Cheers

13. **Peter Woit**
October 25, 2011

null, yonghun park,

For the details of the Higgs story at the Tevatron, see here:

http://indico.cern.ch/getFile.py/access?contribId=60&sessionId=0&resId=1&materialId=slides&confId=141983

They have reported results this past summer based on up to 8.6 inverse femtobarns (per experiment), now have about 10 inverse femtobarns. Speculation is that they might report results at Moriond (March), but definitely by next summer's conferences. They should be competitive with this year's LHC results at the low end of the interesting mass range (just above 114 GeV), less so as the mass gets larger. In any case though, they should be able to just barely see or exclude a Higgs in the interesting region. Whatever their result is, if it's consistent with the LHC results (either an exclusion or positive evidence) that would provide confirmation (or the LHC would provide confirmation to them depending on how you look at it…).

So far though, they're not seeing anything in the interesting mass range, but so far with statistics too low to claim exclusion. But they're almost there…

14. **Peter Woit**
October 25, 2011

Shantanu,

I haven't followed the details of their discussion, but from what I did read and what I've heard from Banks in the past, I tend to agree with his argument that effective field theory arguments being used in this area are dubious, so there's no particular reason to believe in eternal inflation. But I'm equally dubious that he has any believable alternative. This is an area where physics has gotten too close to metaphysics for my taste. There's neither experimental observation nor solid theoretical argument available to decide the issues they are discussing, so this kind of discussion can go on eternally without getting anywhere….

11/11/11, Portal to Another Universe?

October 25, 2011
Categories: Uncategorized

According to World News Forecast, 11:11am on 11/11/11 could, if Uri Geller is right, be a portal to another universe. This is from Geller's web-page on the subject:

> **String theory** is said to be the theory of everything. It is a way of describing every force and matter regardless of how large or small or weak or strong it is. There are a few eleven's that have been found in string theory.
>
> I find this to be interesting since this theory is supposed to explain the universe! The first eleven that was noticed is that string theory has to have 11 parallel universes (discussed in the beginning of the "11.11" article) and without including these universes, the theory does not work.
>
> The second is that **Brian Greene** has 11 letters in his name. For those of you who do not know, he is a physicist as well as the author of The Elegant Universe, which is a book explaining string theory. (His book was later made into a mini series that he hosted.) Another interesting find is that Isaac Newton (who's ideas kicked off string theory many years later) has 11 letters in his name as well as **John Schwarz**. Schwarz was one of the two men who worked out the anomalies in the theory. Plus, 1 person + 1 person = 2 people = equality.

Whether or not a portal to another universe does open up, there will be a film opening that day about the topic, see here. In possibly related news, Brian Greene's *Fabric of the Cosmos* series will start appearing on broadcast TV 11/2/11, with the first episode already available here if you are an iperson.

Comments

1. **anonomous**
   October 25, 2011

   Amazing! So if there are 11 characters in a phrase then it's proof of string theory? How about "W+h+a+t + a+n + i+d+i+o+t" = 11 ?!!

2. **Mitchell Porter**
   October 25, 2011

   Also, there are 4 letters in John and 7 letters in Schwarz, and Schwarz's ideas about 3-dimensional superconformal field theories (hep-th/0411077) paved the way for ABJM to figure out the dual theory for AdS_4 x S^7 (arXiv:0806.1218).

   And while we're on the topic, the period between the discovery of the Veneziano amplitude and the Green-Schwarz second superstring revolution was 1968-84; and 196884 is the coefficient in the j-function which led to the discovery of monstrous moonshine.

   Obviously, we're all living in the M(atrix), and string theory is not a theory of physics, it's a set of cheat codes for the corny MMORPG we all happen to be trapped in.

3. **Bee**
   October 26, 2011

   Best post I've read lately! (I'm not a spambot.) In Germany, Nov 11th (at 11:11am) is the begin of the carnival season. If you're not German, I suppose it may appear like a portal to another universe 😉 Widely used paper streamers are clearly a connection to string theory.

4. **apeleytheros**
   October 26, 2011

   Interesting is also, that this guy is reading a sting theory related article and the most he can say about is something about counting the letters. I think kids over 1rst class elementary school can do better.
   Terrifying is that there is still people considering him a kind of a genius or something.

5. **Giotis**
   October 26, 2011

   When a scientific theory becomes part of the popular culture it means that a paradigm shift indeed took place in the public eye.

6. **chris**
   October 26, 2011

   I knew that Ed Witten was a traitor ^_^

7. **Avattoir**
   October 26, 2011

   I think your point is well taken, particularly as a thread enhancer (or, given this one deteriorated pretty quickly, and perhaps predictably so, in this instance more of a savior), but I suspect Gellar doesn't regard himself as part of pop culture (whether his self awareness is important being maybe another sort of thread enhancer); indeed, his periodic encounters with James Randy would suggest he's perfectly aware he's something more like the vulture in the famous cartoon telling his companion that sometimes he just feels like going out there and actually killing something.

8. **Avattoir**
   October 26, 2011

   Ach: I meant to make clear I was addressing my earlier comment to Giotis.

9. **Alejandro Rivero**
   October 26, 2011

   Perhaps we are going to close the time loop reported in http://insti.physics.sunysb.edu/~siegel/parodies/sam/sam.html "The Nobel Prize Singularity": "the time of the work for which they were awarded has long since converged to 1973; It is not yet clear exactly what happened that year: perhaps a time loop or phase transition"

10. **Bernhard**
October 26, 2011

I hope the dimensional portal will be open 11:11 am GMT otherwise it will be a mess of portals opening all over the planet at different times and places. Well if no GMT, people in Australia will be one of the first to enter the portal. I'm afraid the portal in New York will be one the last ones to open, unfortunetly for you Peter.

11. **TR**
October 26, 2011

I don't see anything about string theory on the "iperson" link.

12. **Coin**
October 26, 2011

There's also a new Tarsem Singh (director of "The Fall") movie coming out 11/11. I think I am more excited about that.

Hey, what's the next big prophesied-doomsday date after 2012's past? Do we just start worrying about the Year 2038 Problem?

13. **ja carl**
October 26, 2011

WTF is this pathetic clap trap doing in your blog?

14. **Peter Woit**
October 26, 2011

TR,

The link just advertises the "PBS" app, if you install that you can then download many of their programs, including the first episode of the Nova series.

ja carl,

Either trying to provide entertainment, or warning that you really should watch out for that portal at 11:11 on 11/11/11.

15. **martibal**
October 26, 2011

11:11 am US time ? East coast or west coast ?
I know Newton did a lot of weird stuff, including alchemy, but who could imagine his ideas kicked off string theory many years later ?

16. **may c j**
October 26, 2011

Peter,

considering the fact that your blog is quite popular, I think that by accident you just made an advertisement of Brian Greene's Fabric of the Cosmos series. Perhaps he should thank you 😉

17. **crazy yeti**
October 26, 2011

Did anybody catch this amusing detail:

"HOWEVER, if you count the fingers on your hands in unary arithmetic – no zeros – then 10 fingers, in unary mathematics, = 11111111111 – EXACTLY 11 ONES"

What, does Uri Geller have an extra finger or something?? 😉 Or is he just a bit confused about "unary mathematics"?

18. **derek**
October 26, 2011

Do people like Geller actually believe their own ramblings?
That's not a rhetorical question – I am genuinely curious. I see two possibilities:
1. For reasons unknown (Attention? Psychological games with the naive?) they make absurd statements, but don't actually believe the nonsense.
2. They truly believe in what they say (A much scarier scenario.) One wonders how many numerological calculations were thrown out when they failed to support the hypothesis. Calling such behavior delusional is an understatement.
–
If only I knew how to enter the multiverse's Konami code… I could transport to a universe anthropically tuned for less stupidity.

19. **Thomas R Love**
October 26, 2011

I think 12/12/12 is much more likely to be important. After that, the next triple date is 1/1/1; 89 years later, and I don't plan to be here for that.

20. **Seth Thatcher**
October 26, 2011

This dude is seriously on to something! Barack Obama has eleven letters in his name. Coincidence? i think not!

21. **Philip Gibbs**
October 27, 2011

"Do people like Geller actually believe their own ramblings?"
Do you think there is even the slightest possibility that he believes it? Do you think he might believe that he uses magic to bend spoons too? I think he has amazing powers. Powers of persuasion that is.

22. **Marc**
October 27, 2011

Don't forget that the number of generators of E8 x E8 is 496, which, when multiplied by the number of large spacetime dimensions, gives 1984, the year of the first superstring revolution!

23. **Lau**
October 27, 2011

I actually think it makes sense that to draw attention to himself, he chose the most sci-fi topic.

24. **Coin**
October 27, 2011

Thomas R Love: I think, when the date 13/13/13 comes, THAT is when we need to be really concerned

25. **S. Molnar**
October 27, 2011

Those 11-lettered guys might be pretty good, but Edward Witten goes to 12.

26. **Chris W.**
October 27, 2011

You would think that after all his years in this game Geller could produce something more than fourth-rate numerology.

Check out his appearance (many years ago) on the Tonight Show with Johnny Carson, which can be found on YouTube. Carson (a good amateur magician himself) consulted with James Randi beforehand, and made hash of Geller, and he did it in the nicest, least confrontational way one can imagine.

27. **mandy**
October 28, 2011

its a really interesting perception you have there, but at the end of the day, 11/11/11 is still an ordinary day like any other. It is just my birthday.

28. **jpd**
October 28, 2011

wow, you are going to be born next month?

29. **Andy**
October 28, 2011

The stupid, it burns!

30. **derek**
October 28, 2011

Nigel Tufnel: The numbers all go to eleven. Look, right across the board, eleven, eleven, eleven and…
Marty DiBergi: Oh, I see. And most amps go up to ten?
Nigel Tufnel: Exactly.
Marty DiBergi: Does that mean it's louder? Is it any louder?
Nigel Tufnel: Well, it's one louder, isn't it? It's not ten. You see, most blokes, you know, will be playing at ten. You're on ten here, all the way up, all the way up, all the way up, you're on ten on your guitar. Where can you go from there? Where?
Marty DiBergi: I don't know.
Nigel Tufnel: Nowhere. Exactly. What we do is, if we need that extra push over the cliff, you know what we do?
Marty DiBergi: Put it up to eleven.
Nigel Tufnel: Eleven. Exactly. One louder.

31. **monoceros4**
October 29, 2011

Well, 11 o'clock on 11 Nov *was* the original Armistice Day (and hour) so you can't quite say it's just another day.

32. **Richard**
October 29, 2011

In important scientist sartorial news, [11|11|11 is The Date that Most Closely Resembles Corduroy, Ever].

33. **Henry Bolden**
October 31, 2011

"The second is that Brian Greene has 11 letters in his name. …"

Lisa Randall also has 11 letters in her name. This proves that the universe has 11 dimensions and either that God is androgynous or that God loves show business.

Surely this insight is worth a Templeton Prize!

34. **JAC**
October 31, 2011

crazy yeti: The "unary" he was referring to is probably the one from automaton theory. In the usual formulation, a Turing machine can only store two distinct values on its tape: marks (or 1s) and blanks (or 0s). So the usual method of representing the natural numbers is as a sequence of marks separated by blanks and since having an empty sequence of marks represent a value is inconvenient, zero is usually represented by a single mark and the representation of N+1 is the representation of N followed by another mark.

What this has to do with portals to other universes isn't clear, unless he thinks life is like *The Matrix* only with hardware even more impractical than that shown in the movies.

35. **Uwe**
October 31, 2011

I think Uri Geller is right with his addiction to the 11 at least in one respect: In Germany the carnival season starts at the 11th of November at 11:11h which means you can expect all sorts of foolish behaviour on that date.

http://en.wikipedia.org/wiki/Carnival#Germany.2C_Switzerland_and_Austria
http://en.wikipedia.org/wiki/Cologne_Carnival

36. **Kent Traverson**
November 1, 2011

So what happened on 10/10/10?

37. **Bernhard**
November 11, 2011

Is today Peter, you still have a chance to see it in New York.

No portals opened in Europe unfortunately.

38. **Peter Woit**
November 11, 2011

Here in New York we seem to have survived…

39. **Sakura-chan**
November 11, 2011

Everything is OK in the Pacific Northwest. That's ok, there will be other portals to look forward to.

Templeton Frontiers Program

October 28, 2011
Categories: Uncategorized

The Perimeter Institute announced yesterday a new partnership with the Templeton Foundation, in the form of something to be called the Templeton Frontiers Program. The research areas to be supported are “quantum foundations and information, foundational questions in cosmology, and the emergence of spacetime.” A $2 million grant from Templeton will pay for three postdocs, as well as other programs in this area.

The previous major Templeton effort in this area was the $8.8 million dollars in grants a few years ago that funded FQXI. I’m not aware whether FQXI is still getting money from Templeton, or if it has successfully found other sources of funding.

Update: I hadn’t realized this, but over the last year, the Templeton Foundation has awarded an even larger sum of money in direct individual grants (for details, see here). They’ve made about $2.4 million in grants for research in the area of foundations of quantum theory, and another $1.1 million in grants in mathematics/logic, emphasizing foundational results on the limits of mathematics. These are quite large sums relative to the previously available research funding in these particular areas.

Comments

1. **moneyyyyyy**
   October 28, 2011

   Why exactly should FQXI be either/or wrt Templeton and other sources of funding? Why not get Templeton money AND funding from elsewhere too?

2. **Peter Woit**
   October 28, 2011

   moneyyyyy,

   My understanding was always that FQXI was always trying to get funding from both Templeton and elsewhere, I just don’t know how much success they’ve had.

3. **Bernhard**
   October 28, 2011

   Supporting research for emergence of space-time (EST) is an idea I´m in favor of. Kind of thing Lee Smolin is advertising for years. I´m curious tough how projects for EST are judged. The funding agencies I know here in Europe would never have something so specific. In any case, as usual, money goes to postdoctoral positions, not jobs.

4. **Allen Massey**
   October 28, 2011

   How does this fit with unbiased science? The Templeton foundation seems to insist on linking all science to God and religion.

5. **Richard Séguin**
   October 28, 2011

   In addition to the religious aspect of their foundation, John Templeton has also been contributing money to the extreme right wing politics of the day. A recent example is a contribution to fund the reelection of a Wisconsin supreme court judge who was probably crucial to maintaining a supreme court favorable to program of governor Walker. I believe they also contribute to the Heritage Foundation.

6. **Avattoir**
   October 29, 2011

   So, the first temptation is to think Perimeter has made some deal with the devil in taking money from Templeton, implying this compromises Perimeter in pursuing science in an areligous way, but I actually think most here would see this as something more subtle; after all, not just is Smolin there but the joint is run by Neil Turok, both of whom have written more than enough for us to judge them on this, and each comes out looking fine.

   This, I think, and again I’m sure I’m not alone in this, is John Templeton purchasing tolerance for his activities in support of the right by covering his areligious left flank. He and his apologists will be able to point to this funding of Perimeter in an effort to blunt criticism for the inexcusable bigotry and ignorance they will continue to fund elsewhere. I think it was Martin Rees who earlier this year tried to erect some sort of wall between the prize money Templeton ‘gave’ him and his science chops, and that sort of thing, a general gift to a person, gets way too obvious because then Rees had to talk and talk about that dang wall. This is shrewder: both Templeton and Perimeter can point to the specificity of the grant, and no one is going to be going after Turok or Smolin as having volunteered to wear a scarlet R.

   It also suggests to me John Templeton is very likely anticipating doing some awfully nasty things in the 2012 election.

7. **may c j**
   October 29, 2011

   As far as I remember this 2M is exactly (or close to) the amount Verlinde got for that entropic thing he is doing. Funny coincidence.

8. **Harry Dale Huffman**
   October 29, 2011

   Just another instance of “The World is in the Hands of Children”, as I see it. Money, money, money, money, money, money, MONEY — it’s a gas (as Pink Floyd used to sing). Put that together with “the emergence of spacetime” in the same sentence, and it becomes clear, to me, that this is a circus announcement, meant to thrill the geeks (the paying customers/supporters; the academic establishment first and the public last). It’s Not Even Wrong, and It Is To Laugh, or Cry.

9. **Yatima**
   October 29, 2011

   I don’t know what the problem is here (and no problem was mentioned in Peter Woit’s post, either). Cries of “right-wing” this and that and bemoaning of money changing hands seems to be a hankering for some bizarre Marxist position that should have been abandoned when people promoted from high school.

Or to put it more succintly:

"If all the researchers would work for free, all of this could have been avoided."

10. **Peter Woit**
October 29, 2011

For more about the complicated issue of what the Templeton Foundation funds and how it is run, see a previous posting

http://www.math.columbia.edu/~woit/wordpress/?p=3396

and the links contained there.

11. **Albert Z**
October 29, 2011

Rumor has it that Don Page is going to be appointed the Archbishop of Perimeter.

12. **Allen Massey**
October 29, 2011

Of course research needs funding (and lots of it), but taking money from a group that tries to bend science to support their view of creationism seems like a bad idea.

Would the PI be comfortable accepting money from the flat earth society? Especially if the PI knew the flat earth society would advertise that the PI and the society were working together?

All I am saying is that taking money from people that want to turn back the clock a few thousand years may not be the best idea.

13. **Jim Akerlund**
October 29, 2011

may c j,

According to Peter's post of June 2011, Verlinde got 6.5 M. http://www.math.columbia.edu/~woit/wordpress/?p=3781
Just wanted to let you know.

14. **Peter Woit**
October 29, 2011

Allen Massey,

The Templeton people are not creationists, Flat Earthites, or multiple thousand year clock-turn-backers. They are in favor of both religion and science, which is not exactly an unusual combination among people in the US and Canada today. From what I have seen they generally keep religion out of their physics research funding. Except perhaps in the case of their fondness for multiverse studies, but there the danger to science is coming not from without, but from within…

15. **Avattoir**
October 30, 2011

Peter, I found your take-down of Sean Carroll's inaugural feature in Discover on the multiverse compelling for the latter materially depending on string "theory", but then a few days later I read this:

http://scienceblogs.com/startswithabang/2011/10/why_we_think_theres_a_multiver.php

which purports to rely entirely on concepts both consistent with the Standard Model and not at all on string "theory".

I wonder if you'd consider letting us know your view on whether that purport is accurate, and secondarily your take on the argument as a whole.

16. **Peter Woit**
October 30, 2011

Avattoir,

That blog posting is mostly just about inflation, with eternal inflation mentioned at the end. Not everyone agrees about inflation implying eternal inflation, see the Tom Banks guest post at Sean's blog. There's certainly no relevant experimental evidence, and the theory is highly speculative.

As the blogger notes at the end, the eternal inflation argument gives something different than what Sean and the string theorists are promoting. All the extra disconnected universes you get have the same physics, this isn't a multiverse with different physical laws in different places. You can't use it to try and justify not being able to explain anything. It really tells you nothing about fundamental theory, as I wrote:

"Inflation is part of the story, but it's not a fundamental theory by itself. All it can tell you is that your fundamental theory should have an inflaton field of some kind, with a potential satisfying certain properties. "

17. **Giotis**
October 30, 2011

"the eternal inflation argument gives something different than what Sean and the string theorists are promoting. All the extra disconnected universes you get have the same physics, this isn't a multiverse with different physical laws in different places. You can't use it to try and justify not being able to explain anything. It really tells you nothing about fundamental theory"

Peter, the eternal inflation described in the aforementioned blog is one type of eternal inflation. The string landscape picture fits with the false vacuum driven eternal inflation where part of a universe in a inflating dS false vacuum may tunnel to another lower dS vacuum while the parent false vacuum keeps inflating. As you know the properties of the compact extra dimensions changes in the new vacuum because the moduli fields (which constitute the landscape) change and thus in general you may have different physical laws e.g. a different standard model.

Of course these things are well known but for some reason you avoid to mention them in your reply and thus your statement may be misinterpreted by the uninitiated.

18. **Peter Woit**
October 30, 2011

Giotis,

The eternal inflation argument made in the blog entry that I was being asked about is explicitly one where you have a simple dilaton field. This doesn't affect at all the SM. The author states this quite clearly and notes that the string theory landscape, with its multiple moduli fields, and moduli stabilization problem is something quite different and much more complicated, for which there is not the slightest evidence (unlike inflation itself).

What's misleading is the often-made argument by string theory multiverse proponents that evidence for inflation based on a single scalar with a specific potential chosen to make inflation work is somehow evidence for the string theory landscape picture with its (hundreds…) of moduli fields, determining all low energy physics.

October 30, 2011

I'm a grad student advised by Wojciech Zurek, and our work is partially funded by the Templeton Foundation. Here's my impression, for what it's worth.

I have not gotten the slightest hint from the foundation that we should connect our research with religion in any way whatsoever. Wojciech's grant proposal to the foundation made no mention of it, and the conference we attended back in July with the other grant recipients was similarly completely secular. (The description of [Wojciech's grant] and those of the other grant winners are available on the Templeton website.)

As you can expect, the topic of Templeton bias came up during dinner conversation. Among the presenters I spoke with, none claimed to be theists or expressed any sympathy with religious ideas. I also had a chance to speak with the two representatives of the Templeton foundation who were personally chosen (along with others) by John Templeton to help direct the foundation after his death. They seemed very genuine in their belief, which they said was shared by John Templeton, that truths about science and religion would arise naturally from objective research. I didn't get the sense that they had any interest in trying to influence anyone at all.

Of course, just choosing who to fund unavoidably influences the direction of scientific research. And the Templeton Foundation unabashedly funds scientists sympathetic to religious ideas. But, to my knowledge, they do so with grants which are explicit about this. (Presumably, they think these ideas aren't given adequate consideration from other funding sources.) The idea that they are cleverly trying to steal the reputability of Perimeter Institute or of the physics community at large is pretty laughable.

And yes, even genuine, nice people can do harm if they are convinced of sufficiently destructive ideas. But I really don't think this is true of the Templeton foundation. The impact on physics of the foundation's funding will be grossly positive.

20. **Peter Woit**
October 30, 2011

Thanks Jess,

I agree that from what I've seen, when the Templeton people fund something related to religion, they are explicit about it, when they fund science they leave religion out of it.

I hadn't realized that this year they have funded a variety of physics related grants, including the one you're associated with, with information about them at their web-site at:

http://www.templeton.org/what-we-fund/grant-search/results/taxonomy%3A2?page=1

I'll add a note about this to the posting.

21. **Anon**
November 2, 2011

Avattoir, just wanted to mention that John Templeton has been dead since 2008.

22. **Peter Woit**
November 2, 2011

Anon,

He means the son, John M. Templeton, Jr. (Jack), who is now in charge of the Foundation.

23. **Bobito**
November 3, 2011

Yatima: When one takes money from the Templeton Foundation or the NSA or the DOD one is at least implicitly, and often explicitly, participating in the agenda of the funder. In the case of the NSA or the DOD the legitimacy of the funder, in a purely scientific sense, is not much questioned, whereas in the case of the Templeton Foundation, some regard its agenda as even anti-scientific. It's not a question of right or left wing. It's a question of whether the goals of the agency funding one's research act in favor or to the detriment of science and understanding. In the case of the NSA or the DOD those goals might even be to the detriment of humanity (how one sees this depends on how one views activities such as building atomic bombs or cloaking devices for robotic aircraft rather than on ideology per se – comparing the Obama and Bush administrations, one sees that these goals are not much dependent on political ideology, at least in the US, both being fully supported by all important political actors).

What also happens is that all these organizations fund genuinely basic research that apparently has no direct contact with their explicit agenda. They do this for at least two reasons. The two I have in mind are: 1. they understand that basic research, directed by curiosity, is at least as likely to produce results useful to them as is heavily focused research. 2. they see funding basic research as a way to counteract the sort of criticisms I implicitly made in the previous paragraph. For example, the Templeton Foundation can defend itself by saying that it funds much research that has nothing to do with religion, and those who accept that money can salve their consciences by believing that what they do does nothing to promote its agenda, although their acceptance of its funds gives it credibility.

24. **Anon**
November 3, 2011

Bobito, you have raised a good point. Those among us (almost all in the U.S., I think) who have accepted funding from the NSA or the DOD have no moral standing to condemn receivers of Templeton funds.

25. **patfla**
November 3, 2011

Is PI's funding particularly problematic given the declining fortunes of RIM (as in the Blackberry)?

PI was founded (in the money sense) by one of the founders of RIM, Mike Lazaridis, but I don't know the extent to which PI has remained a beneficiary of either Lazaridis or RIM.

If so, then your iPhones (I'm a programmer but haven't sprung for an iPhone) are contributing to PI's difficulties.

26. **Avattoir**
November 3, 2011

Patfla, I cannot see why that would be. Just going off the disclosure on the Perimeter Institute website, it looks like not just Lazaridis but anyone connected to RIM last provided large funding in 2009, with the bigger donations from that group coming even earlier, and at about the same time that roughly comparable funds were coming in from the governments of Ontario and Canada. A lot of all that would have been construction, and just from having been involved in a few of these sorts of things in the past, it looks like the PI is working on an endowment model for its basic work, with the new projects like the one raised in this post being the ones that need new targeted funds.

27. **Bobito**
November 4, 2011

Anon: I think your "almost all" is too much, as I know physicists who for many decades have had funding, never once from the DOD, DOE, NSA, or anything similar. In the 60s and 70s there was more consciousness about this, I think, than there is now. There is always the NSF. One can argue that it's the same government, but I think that is not entirely fair. On the other hand, I agree with what may be implicit in what you say – I'd perhaps go further – while I object to the Templeton Foundation's mission, I find that its mission is far less problematic than that of the DOD or the NSA, for instance, simply because it never intends to do any concrete harm to anyone, whereas those institutions certainly do.

28. **Anon**
November 4, 2011

Bobito, it is my impression that the majority of important high energy physics departments in the U.S. get a large part of their funding from DOE grants and that it would be almost impossible to avoid benefiting from this. Even if you are not the grantholder, you may be his student and get paid from his grant, your postdoc may be funded by such a grant, you may share lab equipment, computers, or secretaries paid for with DOE money, your expenses or your office as a visiting scholar to a department may be paid from such a grant, or you may attend a conference sponsored by the DOE.

Recollections of Rudolf Haag

November 3, 2011
Categories: Uncategorized

Thomas Love pointed me to a wonderful article from last year by Rudolf Haag. It's more or less a short memoir of his scientific career, entitled Some people and some problems met in half a century of commitment to mathematical physics. There's a lot about the history of mathematical physics related to quantum field theory that I learned from the article, which covers the second half of the twentieth century. Haag started out his career heavily influenced by Wigner and his work on representations of the Poincaré group, investigating what this had to do with quantum field theory. He has been one of the leaders of the operator algebra approach to formulating QFT.

His comments about the Witten and string theory bring back memories of the late eighties, when several people told me of similar experiences. Haag writes:

> I had been asked to give a physics colloquium talk about my views on quantum gravity and hoped to have some discussion with Ed Witten. Next morning he greeted me by saying: "Your talk was very interesting but I would really advise you to work on string theory". When he saw the somewhat incredulous look on my face he added "I really mean it. I shall send you the manuscript of the first chapters of our book". This ended our discussion. Back in Hamburg I received the manuscript but it did not convert me to string theory. I remained a heathen to this day and regret that meanwhile most physics departments believe that they must have a string theory group and have filled their vacant positions with string theorists. To be precise: It is good that people with vision like Ed Witten spend time trying to develop a revolutionary theory. But it is not healthy if a whole generation of young theorists is engaged in speculative work with only superficial grounding in traditional knowledge. In many popularised presentations the starting point of string theory is explained as the replacement of the fundamental notion of "particles" with its classical picture of a point in space or a world line in space-time by a string in space respectively a two-dimensional worldsheet in space-time. This, I think, is a misunderstanding of existing wisdom. First of all, paraphrasing Heisenberg, one may say "Particles are the roof of the theory, not its foundation".

Comments

1. **younghun park**
   November 3, 2011

   Thanks for introducing haag's writing.

   In his writing, I notice these sentences that First of all, paraphrasing Heisenberg, one may say "Particles are the roof of the theory, not its foundation".

   Could anyone say what this means in detail?

2. **Peter Woit**
   November 3, 2011

   younghun,

   See the more detailed comments about Heisenberg and S-matrix theory at the bottom of page 272 and top of page 273.

3. **Thomas R Love**
   November 3, 2011

   IMHO, Haag's most powerful statement comes a few lines later:

   String theory is hailed as the most promising among present endeavours. But it is
   an overstatement to call it a theory. It has not settled down to a well defined formalism
   nor has it explained any existing puzzle nor can I see that it can make contact with
   any observable phenomenon in the foreseeable future.

4. **Peter Woit**
   November 3, 2011

   Thanks Thomas,

   I should have included that quote too…

5. **Peren Woondeen**
   November 4, 2011

   > "This had induced Heisenberg 14 years earlier to search for the truly observable quantities in elementary particle physics. It led him to the concept of the S-matrix and the … " (p. 272)

   I thought the S-matrix was invented by Wheeler in 1937. Did Heisenberg actually anticipate Wheeler?

6. **Thomas R Love**
   November 4, 2011

   Peren, According to Wikipedia:

   "S-matrix theory was proposed as a principle of particle interactions by Werner Heisenberg in 1941, following John Archibald Wheeler's 1937 introduction of the S-matrix." So Haag's memory is faulty.

7. **David Brown**
   November 5, 2011

   Haag won the 1970 Max Planck medal. Has anyone compiled a list of criticisms of string theory from Planck medal winners?

8. **Maynard Handley**
   November 10, 2011

A link to SpringerLink? This (not even a paper, just a reminiscence) is stored behind a paywall, not at arxiv? Not cool, Haag, and not cool for linking to it, Peter.

Columbia and other US institutions may get free access to everything on SpringerLink, but the rest of us are not so lucky. A great advantage of physics over other fields is that we have rather more arxiv and rather less SpringerLink, and this is maintained in part by letting those who use SpringerLink rather than arxiv know just how much scorn and contempt we have for them.

9. **Tim van Beek**
November 11, 2011

younghun park said:

> First of all, paraphrasing Heisenberg, one may say "Particles are the roof of the theory, not its foundation".
> Could anyone say what this means in detail?

A simplified and short explanation: The starting point of AQFT is a net of operator algebras which contain all observables of a given QFT as selfadjoint elements fulfilling a certain set of axioms. This is the only input to the theory, so you could say that AQFT is quantum field theory without fields. Fields may be used as an auxilliary device to construct the net of observables, but they are no necessary ingredient.

The philosophy of AQFT is to derive every other concept from the net of observables, including the particle content. The concept of a particle as a point in space or as a worldline in spacetime does not enter the theory here. Instead, it is a theorem that the algebra of observables of a point of a spacetime is necessarily trivial, which means that AQFT already says that the concept of a pointwise localised particle is oversimplified.

Furthermore, the Reeh-Schlieder theorem says that there cannot be a localized particle number operator, which means that the question "how many particles where in a certain time interval in a certain box" is meaningless in AQFT.

For more information I would like to recommend the nLab as a starting point:

http://ncatlab.org/nlab/show/AQFT

November 15, 2011

Alas it is behind a paywall.

Solvay Update

November 3, 2011
Categories: Uncategorized

With the Solvay Centenary conference now finished for over a week, some information has been posted about it on the Solvay Institute web-site, where you can see a group picture of the attendees on the main page. Lisa Randall's comment comparing the gender balance to that at the first conference is actually rather restrained, given that the fraction of women (2.9%, 2 out of 69, Randall and Silverstein) is smaller now than back in 1911 (4.1%, 1 out of 24, Skłodowska-Curie). Oddly, only women working in extra dimensions seem to have made the cut.

The schedule of talks is here. Perhaps someday we'll see proceedings of the conference and learn what was in the talks and discussions. For now, this page has links to some outlines of the rapporteur talks. There were two separate sessions related to quantum computing (here and here), as well as sessions on condensed matter, particle physics, quantum gravity and string theory.

The string theory talks seem to have just been about possible applications to condensed matter and to quantum gravity, rather than about using string theory to get a unified theory. Witten attended, but appears not to have given a talk of any kind.

Comments

1. **Kea**
   November 3, 2011

   Oddly, only women working in extra dimensions seem to have made the cut.

   Not at all odd. To have one's existence acknowledged, it is often a prerequisite for intelligent women to be working on Safe Topics.

2. **Peter Woit**
   November 3, 2011

   Kea,

   Well, in that case it's odd that speculating about extra dimensions is a "Safe Topic", whereas doing condensed matter physics or quantum computing isn't…

3. **Lee Brown Jr.**
   November 3, 2011

   But she was talking about the number of chromosomes, in which case, this year there were 71 X's and 67 Y's, a ratio of ~ 1.06 . At the original Solvay, 25 X's 23 Y's ~ 1.08.

   So, she was right. Not much change in the ratio, considering it's been 100 years.

4. **Kea**
   November 3, 2011

   I meant Safe from the dangerous possibility of being phenomenologically important. That is, I would not blame Gross here. It is the CMTs and QITs who *don't* believe String Theory who are at fault for neglecting women.

5. **Shantanu**
   November 4, 2011

   Peter or anyone else, any talks on LQG or background independent approaches to quantum gravity at this meeting?

6. **manybodycpa**
   November 4, 2011

   Are the talks really just five minutes long, as suggested by the schedule?

7. **chris**
   November 4, 2011

   come on, this institution is obviously past its prime.

8. **Aleksandar Mikovic**
   November 4, 2011

   The link outlining the talks of the Solvay conference rapporteurs was quite interesting to read. For me the most interesting was the quantum gravity outline by Maldacena, since I do research in quantum gravity. Although not being able to see the
   complete content of the talk, the outline was quite indicative. Maldacena´s view of QG
   is heavilly biased by string theory and AdS/CFT correspondence. The other approaches to QG, like Loop Quantum Gravity, seem to have been completely ignored, and I consider this as a serious flaw in his rapport, since a rapporteur should review the field and not just give a rapport of his own work.

9. **Anonymous**
   November 4, 2011

   > Oddly, only women working in extra dimensions seem to have made the cut.

   Do physicists prefer women with extra dimensions?

   (apologies to everyone, I just couldn't resist it)

10. **Kea**

November 4, 2011

Anon, no, I assure you. Extra dimensions count against you.

11. **anon2**
November 4, 2011

One possible objection to AdS/CMT is that a practically minded physicist cares about whether the investment into a theory is worth the output. In the theory of critical phenomenon, mean field theory and Landau's theory are extremely simple, and provide some qualitative insight into phase transitions despite being a toy model. On the other hand, the exact solutions of the Ising model and other integrable models are (were) mathematically very challenging, but provide more detailed information than mean field theory.
In contrast, AdS/CFT is by all accounts very mathematically involved, yet only gives you a crude *toy* model, and attempts to construct more realistic models soon get more complicated and ugly.
It's good that a small number of single-minded people are pursuing this research direction, but the above cost/reward analysis means that the majority of condensed matter theorists who are result-oriented are justified to ignore this topic.

This Week's Hype

November 3, 2011
Categories: This Week's Hype

Now that the LHC has turned out to be dud, producing no black holes or extra dimensions, the latest news is that physicists are planning a new machine, "to follow in the footsteps of the Large Hadron Collider". This one will be based on "A laser powerful enough to tear apart the fabric of space", able to "rip a hole in spacetime", and it will do this much more cheaply than the LHC ($1.6 billion).

For details, see for instance here, here and here. The new laser will also explain what dark matter is, and provide new treatments for cancer.

It's unclear to me who is responsible for the extra-dimensional hype, which appears to be inspired by ADD models that were popular 10 years ago (and that became much less so once the LHC turned on and saw nothing).

Comments

1. **anonymous**
   November 3, 2011

   So Europe is going to fund this with their bailout money? I can't believe anybody would pay ten cents towards it. I guess this is what happens in the ultimate fantasy – after all dimensions and black holes have been exhausted we will just through billions of $$ of cash into the furnace.

2. **Nat Singleton**
   November 3, 2011

   Seems to me that the military will find this new project of particular interest.

3. **Z**
   November 4, 2011

   I think the NIF lasers at Livermore has higher radiative flux (and energy) per pulse than this proposed laser, although the purpose is different. There were some nice news focus articles last week in Science on the NIF.

4. **Dave**
   November 4, 2011

   The LHC is far from a dud. The experiments are doing exactly what they were designed to do – hunt for the Higgs. Its also doing this in a careful, non-sensationalist way and the results (positive or negative) will be landmark measurements.

   In addition to that, the LHC experiments are steadily falsifying a number of models which purport to describe new physics at the TeV scale and making precision measurements of SM processes in the electroweak and strong sectors which take place at the smallest measurable distance scales .

5. **Armin Nikkhah Shirazi**
   November 4, 2011

   If the laser can be used to measure the gravitational field of a laser beam, then that would seem to me to constitute the first direct experimental test of the assumption that gravity must in fact be described by a quantum theory. As this fundamental assumption underlies basically all current theories of quantum gravity, it seems to me that this would make it a very important experiment. In fact, if it finds something totally unexpected, it could become the MM experiment of the 21st century.

   I really hope that they are considering this type of experiment.

6. **chris**
   November 4, 2011

   Armin,

   this assumption has been tested by neutron interference in a gravitational field almost 2 decades ago.

7. **Armin Nikkhah Shirazi**
   November 4, 2011

   Hi Chris,

   You are probably referring to Staudenmann et. al 1980 (although there are probably others) where Bragg reflected neutrons were observed to accelerate at g. In fact, when you get down to it, the gravitational bending of light, Einstein Rings etc. have already tested the same assumption that you speak of.

   What characterizes these kinds of tests (and all others that are tests of gravity involving quantum objects that I am aware of) is that strictly speaking, they involve testing the passive gravitational charge of quantum objects.

   The test I mentioned would be a test of the active gravitational charge of a quantum object (here, a beam of photons). Now, I agree that it is eminently reasonable to assume that since we have already confirmed that they obey the equivalence principle as applied to passive gravitational charge, then we should also expect that it applies to the EP as applied to gravitational charge. If it didn't, it would appear that conservation of momentum would be violated, as a first of a host of major consequences…

   …but still, should we not at least make an effort to test our assumptions by experiment? If you know of a direct test of the gravity field produced by a quantum object, please do let me know, as I am unaware of any, despite searching for it. So, to the best of my knowledge this is still an empirically unverified assumption, as plausible and reasonable as it is.

   I made the comparison with MM consciously. If anyone had suggested a null result prior to the performance of the actual experiment, they would have been laughed at for making such an obviously ridiculous suggestion.

   However, it was a null result, and as result the physics of the 20 century looks completely different from the physics of the 19th century.

8. **Bernhard**
November 4, 2011

Apart from the confusing hype of probing extra-dimensions, does anyone know what is the real physical potential of this experiment and what is it really trying to measure?

9. **Anon**
November 4, 2011

I am not sure why the negativity. I would have thought proposed expenditure on foundational experimental HEP were a good thing. What am I missing?

10. **mesasola**
November 4, 2011

Hello from Greece
here in Europe we do not have that kind of money just for theories.

11. **Rhys**
November 4, 2011

Never mind the brief mention of extra dimensions; the whole Telegraph article is awful. I don't know whether it is entirely the journalist's fault, or whether somebody has fed him the nonsense line "this laser will tear apart the fabric of space", and misled him into suggesting it will allow scientists to observe the "ghost particles" which usually "pop in and out of existence too fast to be seen". "Ghosts" are a technical feature of certain QFTs, but certainly can't ever be observed, even in principle. And did a physicist really say "even a true vacuum is filled with pairs of molecules…"?

The Daily Mail is, unsurprisingly, even worse:
"Scientists say it will be so powerful they will be able to boil the very fabric of space and create a vacuum."
FFS, to use the vernacular of the age…
In fact, this article also says "tear apart the fabric of space", so that has obviously come from somebody who should know better, rather than the journalists themselves.

Bad reporting of science, whether caused by the journalists or the researchers whom they interview, is at least partly to blame for the stupidity of people like "mesasola" and the first anonymous commenter in this very thread.

12. **anon.**
November 4, 2011

It seems pretty clear that what they're actually proposing is to test the Schwinger effect….

13. **jg**
November 4, 2011

At the offical site there is no obvious hype about extra dimensions etc
http://www.extreme-light-infrastructure.eu/what-is-eli.php

And in fact there may be practical benefits:

> ELI will have a large societal benefit in medicine with new radiography and hadron therapy methods. It will also considerably contribute to material science with the possibility to unravel and slow down the aging process in nuclear reactors and in the environment by offering new ways to treat nuclear wastes.

14. **Julien Sorel**
November 4, 2011

Peter, please don't judge the ELI Ultra High Field Laser until it has had a chance to produce results. This machine has great potential. The physics community should put its whole support behind this project.

15. **AI**
November 4, 2011

So far LHC is a dud, it didn't lead to any new leaps in our understanding of reality. Cutting down empty speculations is far from enough. What we need to justify it's costs is new actionable knowledge to further fuel technological progress of human race. Progress which when it comes to fundamental physics has stalled for decades.

The reality is that you physicists are failing us all. Whether it is due to your personal shortcomings or the fact that remaining problems are "objectively" intractable at current levels of human intelligence and technology is in the end irrelevant. If all you can come up with is speculations and hype don't expect the money to keep coming.

16. **strong field physicist**
November 4, 2011

While generally sympathetic to the aims of your crusade, you can really bend the stick too far – this article being a case in point. The physics behing ELI is really quite simple, to produce an electromagnetic field strong enough to polarise the vacuum and pull virtual particles onto the mass shell. Its nothing more complicated than basic QED.

Yes everyone knows the high energy laser facilities have spin offs that include medical applications. That's one of the selling points of FELs and Synchrotrons around the world.

Are you against selling points for the funding of physics facilities? Whose side are you on?

17. **Peter Woit**
November 4, 2011

Dave,

The "LHC is a dud" comment was tongue in cheek, it only made sense if you believed the hype about the LHC being designed to look for extra dimensions.

Others,

This in no way is intended as a criticism of the ELI project, which seems likely to do interesting science with practical applications, including medical ones. The "tearing apart the fabric of space-time" hype though I think is a big mistake. This kind of intense EM field may do all sorts of interesting things, but it's not going to do anything to space-time degrees of freedom. I can't see exactly where the reporters got this from in this case, but physicists need to put a stop to selling everything with a helping of extra-dimensional BS. This may work for a while, but sooner or later is going to do significant damage to the credibility of the field (this may already have happened).

18. **jpd**
November 4, 2011

"ADD" = attention deficit disorder?

19. **Andy**
November 4, 2011

I think this is just an endemic problem with science communication. Scientists have a duty to talk to the public about these sorts of big iron projects (we are, after all, spending their tax money) but having to go through the media is really hurting the message.

Of course the media is going to muddle the details and sensationalise; they're the media, that's what they do. I wouldn't be surprised (if this was some sort of press conference rather than a press release, they don't seem to reference their sources…) if the scientists were fed the question about extra dimensions, answered it in a typically scientific way with caveats (e.g. "I suppose the possibility exists that extra dimensions could be seen under such and such a condition" etc.) and the media spins it into "Experiment looking for extra dimensions!".

Likewise things like "the vacuum is full of pairs of molecules" is almost certainly a misquote. No physicist would be daft enough to say that on purpose.

That said, I don't know what the solution is, other than training people who come in contact with the media to consider them as the enemy.

20. **SpearMarktheSecond**
November 4, 2011

At first I thought that link might have something to do with old proposals to backscatter lasers off of electrons beams, and do gamma + gamma > Higgs. But looking at the link, it seems to be (as strong field physicist notes) a QED experiment. I liked Uranium + Uranium for strong field QED better.

What I'm hearing is a`absence' of an LHC Higgs might be interpreted as a suppression of the rate of Higgs ->gamma gamma via loops from new physics that destructively interfere with SM or SM+SUSY loops. Anyone got info on that?

21. **Doug**
November 4, 2011

I think the negative consequences of the thoughtless hyping of speculative physics are quite right here in this thread. The commenters anonymous in the first post, mesasola, and AI. People who are not informed enough to know what is actually going on and just get their info from sound bytes and press releases (although one would hope that people coming to a blog like this would know better) and make erroneous comments like "Progress which when it comes to fundamental physics has stalled for decades." AI is right about one thing though: if the public feels like they've been misled by the physics community they will not decide to fund future important projects on the level of the LHC or ELI (and many smaller projects that will be shut out of the smaller monetary pool).

I do think it is perhaps a problem of irresponsible journalism: I would wager that whoever made the "tear a hole in spacetime" comment was being purposely hyperbolic, and that any speculations are couched in realistic views about what can be achieved (unless the interviewee was Kaku or Greene). The journalist probably just decided to only include the "sexy" bits because that's what sells papers.

Which goes to illustrate: unless you know the periodical publishing your interview is scientifically reputable, you should treat them as a tabloid and give them the bare minimum of speculation to work with.

22. **Doug**
November 4, 2011

*quite apparent

23. **MP**
November 4, 2011

Actually AI is right. Scientists *are* failing us. The amount of money sunk in theoretical models that are basically a bunch of BS are hurting the community and it's creditability. The LHC certainly is a dud in that respect. Never mind it is doing fantastic work. It isn't working as advertised. No SUSY, no extra dimensions, no Higgs, no no no. Just confirmation of what we already knew. Woit and Smolin are dead on. The string mafia is keeping valuable money out of alternative research. The amount of money sunk into to that BS in incredible and there are no signs of letting up. Variety is the spice of life; there *needs* to be more research done in something else than string.

24. **Peter Woit**
November 4, 2011

SpearMarktheSecond,

I don't know anything about the particular scenario you mention, but if the Higgs is really not there, part of the way it will play out is with theorists coming up with a sequence of models, more and more complicated, trying to evade the no-Higgs conclusion. Lowest masses around 120 GeV will be the last to be ruled out, mainly by the H->gamma gamma data, so evading that SM prediction will be the first order of business….

25. **Peter Woit**
November 4, 2011

MP,

I don't think there's a lot of money (on the scale on which HEP is financed) being sunk into string theory, extra dimensional models, the multiverse, etc. these days. There is a huge attention given to them in the press though, and that's going to cost a lot to the credibility of theorists. The LHC has cost and is spending a lot of money, which is money well spent: the only way to find out if there is a Higgs or not and to make progress is to look for it with something like the LHC. I think it was a mistake for people to try and justify the LHC with extra dimensional models, but already people are stopping doing that, as the models fail. Hopefully that mistake won't have long-term consequences.

26. **anonomous**
November 4, 2011

AI is dead on – the consequences (from a public perspective) of the LHC are damaging. Many exotic objects were promised – we all know good science comes from ruling out models but not getting positive evidence on any model is bad news from a funding perspective. In other words, we believe in science but the era of big budget science funding is likely go the way of Apollo and Orion missions of NASA. Once this happens it will take quite a while to get some public trust back. Our criticism of ELI is not based on the science (which would be very interesting) but on the hype that is surrounding it to try and get it funded.

27. **Christian Takacs**
November 5, 2011

Peter,
String Theory and a great deal of physics hype and speculation for the last fifty years may quite possibly be ruled out by the LHC quite soon. Before more money is spent on the next shiny new toy, should not the physics community do some house cleaning? I am curious at this point how far back the wayback machine is going to have to be set to put physics on level footing with testible reality again…back to QCD? earlier perhaps? It would be wise in the name of enlightened self interest for the high energy physics folk to reacquaint themselves with the formula HYPE = BULLSHIT = BAD FOR FUNDING.

28. **Eye**
November 5, 2011

AI and MP are happily using the web (which was given for free to the world as a result of developments that ocurred at CERN) to show us their ignorance. Shame on you. Those who say the LHC is failing us don't seem to understand very basic things. One is that doing science is not a Hollywood movie, full of easy discoveries every two months. It is a painful endeavour. What the LHC guys are doing is extremely difficult and they are doing a superb job of it. What comes out of the LHC is whatever nature hides there for us to find and the LHC finds will remain forever in the history of science as a treasure for all humankind, long after nobody remembers who Obama was.

29. **Jeff**
November 5, 2011

Eye

I'm not going to comment on the lhc, as a mathematician I have the luxury of not worrying about heavy duty funding. The notion that the web came frome CERN however is just silly, HTML came from CERN, but HTML is just an Implementation of hypertext, an idea which goes way back (the first Mac came with a program "HyperCard" which had clickable links and allowed you to build your own decks). The nuts and bolts of the web go back well before that. It is certainly true that the web came from public funding though.

30. **MP**
November 5, 2011

EYE,

You are misunderstanding me. The LHC is doing great and fantastic work and will be for the foreseeable future. The folks who work there are advancing science the way science should be advanced.

The failing part is selling machines to the public that don't produce the predicted speculative models. The public quickly starts thinking that the science community are a bunch of clowns that simply make (complicated) stuff up.

If the LHC was sold as a "advance science" machine then it would be exceeding expectations. Speculative science is great and needs to be part of the eco-system but it is called speculative for a reason.

Again, LHC = good, selling lies to the public who pay for it = bad. I have nothing but admiration for the hard working folks at the LHC and I sure hope that speculative science community didn't blow it for these types of experiments.

31. **Eye**
November 5, 2011

Sure, the web didn't come out of the blue and any given breakthrough, in technology, science or otherwise is stepped on the work of others. The crucial step forward for the web was taken at CERN as everybody knows.

Then, describing the output of LHC so far as "Just confirmation of what we already knew" is plain wrong. One example among many: so, you knew already the SM Higgs didn't weight 160 GeV? Hey, you should've told everybody!

You are being mislead by the likes of Woit or Dorigo who can't wait to bury Supersymmetry even if the surface of those theories has been barely scratched. Searching for new physics is a tough business and the attitude of some bloggers that should know better is just shameful.

32. **Peter Woit**
November 5, 2011

Eye,

"the surface of those theories has been barely scratched"

I understand the tactic of doubling-down on the hype when faced with failure, but don't think it's ultimately going to work out for the people trying it…

33. **Eye**
November 5, 2011

Peter, there is no tactic and there is no hype, at least in what I'm writing. I can understand that some people dislike some particular theory, for whatever the reason. But they should at least share with the rest some standards on what it means to check a theory against experiment in a serious way. You are not helping science when you say SUSY is dead, because nobody can help science by propagating falsehoods. I actually sympathize with your criticisms of those claiming string theory will be tested at the LHC (not with your conclusion that string theory is a failure) but you should be more careful when criticizing the hard work of many people (theorists and experimentalists) who are trying to test the best motivated models beyond the Standard Model, simply because you happen to dislike those proposals. That's not very serious and in my opinion is bad service to the popularization of the scientific endeavour.

34. **jpd**

November 5, 2011

and roger ebert must hate movies because he criticizes so many

35. **MP**
November 5, 2011

For now Woit and Dorigo are more right than string, SUSY, multiverse etc speculators. 30 years in and not a single shred of evidence or testability. Serious science can only be advanced when grounded in reality and experiments.

36. **Eye**
November 5, 2011

MP, to be "right for now" is very cheap. What do you guys propose as a meaningful search goal to the LHC experimentalists? Do you have any theoretical insight about what to expect for physics beyond the Standard Model? If not, maybe it would be smarter to shut up and let people do their job.

What does your 30 years time span mean? The greek were right about the atomic structure of matter and experimental confirmation had to wait for centuries. Who told you the pace of scientific discovery is fixed?

Why don't you stop whining and advance some positive idea?

37. **Peter Woit**
November 5, 2011

Eye,

The claim that for SUSY, "the surface of those theories has been barely scratched" is just hype. This has nothing to do with whether I 'like" SUSY models or not. You know very well that the main motivation given for low-energy SUSY, stabilization of the weak-scale, implies a SUSY-breaking scale low enough that it was hard to understand why SUSY effects were not being seen pre-LHC, and even more difficult now. The LEP + Tevatron + flavor physics + LHC results are not "a scratch on the surface" in any honest description of the current situation, they're a huge problem for the whole idea.

Besides the Higgs work, it IS hard to come up with well-motivated suggestions for what LHC searches should be looking for. I trust the experimentalists to have pretty good judgment about what the LHC + their detectors can do, and to work hard at viable analysis targets. Theorists of course have an important role to play, but I don't think they're doing anything helpful if they engage in hype, dramatically over-estimating the chances of extra dimensions, black holes, or superpartners being found.

As far as what the most useful thing physicists can do in terms of presenting the situation to the public, I think stopping the "LHC is looking for really cool stuff like extra dimensions, or super-this and super-that" hype would be a good idea, instead getting to work on explaining that ruling out a SM Higgs would not be a failure, but the most exciting thing to happen in high energy physics in more than 30 years.

38. **Eye**
November 5, 2011

Peter,
what's the LHC limit for neutralinos or for stops? We can discuss about how dead SUSY is after you tell me this.

"Besides the Higgs work, it IS hard to come up with well-motivated suggestions for what LHC searches should be looking for."

They need to know what to trigger on, don't they?

There is a similarity between overselling ideas, which I dislike as much as you and
overselling how bad the situation is, which you are very good at.

39. **Peter Woit**
November 5, 2011

Eye,

"They need to know what to trigger on, don't they"

Exactly. If a load of hype is being used to convince them to trigger on obscure SUSY signatures and dump everything else, that's a problem that deserves pointing out.

Sure, one can reasonably point out that ruling out gluinos and two-thirds of the squarks up to around 1 TeV still allows an stop at a mass worth looking for. However, describing this situation as "barely scratching the surface" is just absurd.

40. **Eric**
November 5, 2011

Peter,

It is not true that gluinos and two-thirds of squarks haven been ruled out up to 1 TeV. This is only true for certain benchmark points in the mSUGRA parameter space which feature large missing transverse energy signals. The reason these points were chosen as benchmarks is that they have well-defined signals that are easy to see. The majority of the SUSY parameter space is not the same as these benchmark points, and for these points in the parameter space it is much more difficult to identify a signal. So, the true statement is that most of the supersymmetry parameter space has not been tested yet. You should really please stop attempting to mislead your readers, although I am aware that you and Dorigo have been making a planned and concerted effort to do so.

41. **Peter Woit**
November 5, 2011

Eric,

The claim that the only thing ruled out is specially chosen benchmark points is just not true. See for example

http://www.slac.stanford.edu/th/lectures/RIZZO/CERN-Scans_8-31-11.pdf which reports that more than 90% of 2 million randomly chosen points in parameter space have now been ruled out.

42. **Bernhard**
November 5, 2011

Eric,

The majority of the SUSY parameter space is a really large thing, so sure, the LHC will have a hard time scanning it. But what Peter is saying is that for the part that was sold in the pre-LHC era as likely to show up and natural, this has been killed. One has to admit this is not a strach in the surface, this is a serious wound. That´s why you hear depressing comments from SUSY enthusiasts like John Ellis. Of course, for the die-hards (like you) the limits will have to be much stronger and that´s fine. But the limits Peter is quoting, however particular are a serious injury the idea of SUSY. It might still be correct but it got unquestionably less popular and less compared to pre-LHC era. If you have been in particle physics congresses (at least here in Europe) in the last months like I did, you for sure heard that from people who worked and were cheering for SUSY their whole carrier lifes.

43. **Eric**
November 5, 2011

Bernhard,

Sure, what was advertised in the pre-LHC era was the most optimistic possibility based on the simplest assumptions, namely universal soft supersymmetry breaking soft terms as in mSUGRA/CMSSM. Now, it may be true the this simplest possibility has been nearly ruled out, the majority of the supersymmetry parameter space has not. Obviously, the simplest version of supersymmetry with the cleanest and most identifiable signals were used to sell the idea of supersymmetry to those making decisions on funding etc.. However, just because this simplest and most highly optimistic possibility may not be correct does not invalidate or lessen the motivation for expecting superpartners to show up at the LHC. It simply means that it will be much more difficult to find them since the signals are not as clean. It may take some time to establish discovery, however in the next year we should expect at least a three-sigma Higgs signal in the region favored by the MSSM, and there should be anomalies such as trilepton events (which have already been seen) which are predicted by generic SUSY models.

@Peter: You should have a look at the comment section of the Resonaances blog.

44. **Eye**
November 6, 2011

Peter,
"If a load of hype is being used to convince them to trigger on obscure SUSY signatures and dump everything else, that's a problem that deserves pointing out."
It doesn't need to be pointed out: everyone involved in the searches knows the importance of this issue. Now, it's very cheap to call the best motivated BSM theory that has been proposed obscure or overhyped. By pointing this out without offering alternative BSM signatures or theories you're just being a pain in the ass.
So, experimentalists are eager to know what other alternatives they could be looking for. Please contribute to this if you have anything worth saying. Otherwise let more competent people do their jobs.

45. **Jim Rohlf**
November 6, 2011

The LHC triggers are dominated by electroweak interactions in order to look beyond the 100 mb strong-interaction garbage pail. These triggers are first-principle simple: single muon, single electron, single tau, MET, single photon, and then combinations of dileptons, diphotons, and then leptons plus jets, etc. The only reason to make combination triggers is to lower the thresholds, but these are still very generic. The LHC is pretty much a lepton and photon game. The exception is inclusive jet which was foreseen to be explored very early, indeed the jet spectra are very well measured out to a few TeV. The inclusive electroweak net catches W, Z, top, onia, rare B decays, etc. So there really is no "SUSY", "higgs", "black hole", "put your favorite theory here" trigger as these things are (very importantly) caught by generic triggers. All it costs us to make limits on SUSY, etc. is analysis manpower.

46. **Jim Rohlf**
November 6, 2011

BTW a nice what I would call "even handed" talk was given by Joe Lykken at the US LHC users organization on Friday, Nov. 4 on the status of SUSY at the LHC. It is available here:
https://twindico.hep.anl.gov/indico/getFile.py/access?contribId=46&resId=0&materialId=slides&confId=641
An interesting political issue is whether limit setting will be outsourced to theorists. It is currently being discussed by the experiments.
I have only ever heard 2 really motivational talks for SUSY: one by Steve Weinberg in the early 1980s and another by Ed Witten 7 years ago. They were enough to make a person believe that there might be something to it.
I personally think LEP took a very big byte out of SUSY. People are quick to forget this.

47. **emile**
November 6, 2011

For the non-specialists reading this blog:

The main motivation for the LHC (and the SSC) and the main selling point was that it was going to find something: either the Higgs, or if there is no Higgs, the new physics that prevents WW scattering from violating unitarity. A second motivation is that we could understand the new physics that solves the naturalness problem: if there is a Higgs, then we would like to know what allows the the Higgs mass to stay at the electroweak scale. If there is no Higgs, then we are back to the first motivation above. Some potential solutions to the naturalness problem have received a lot of publicity and some will have been over-hyped. One possible answer is that our world is fined-tuned (to some unknown amount) or maybe we just don't understand the naturalness problem (theoretical physics has bigger problems with the smallness of the cosmological constant). Bottomline is that the LHC was sold to find the Higgs or the physics that replaces it. It will do that. It was not built or funded to find extra dimensions.

P.S. to Rolf above: you forgot the incl. etmiss trigger

48. **SpearMarktheSecond**
November 6, 2011

Rizzo has posted a pretty good Higgs summary… don't know where he spoke…
http://www.slac.stanford.edu/th/lectures/RIZZO/BSM_Higgs.pdf

Hilarious that Lykken characterizes the need for good SUSY searches as a `fiduciary responsibility to the taxpayer'. Odd language, perhaps all the money spent on theorists salaries is the taxpayer investment, and if there is no Higgs, no SUSY, at the LHC, that would be the financial loss like a Greek bond.

But among experimentalists, merely getting good luminosity at the high energy frontier has always been the point. Mel Schwartz was always the most direct about that, and he was right. Promising great discoveries is and was hype, but getting the machine and experiments built always has great value: without experiments, we would never advance.

Jim, you've heard 2 more inspirational SUSY talks than I ever have. I lost it at the complexities introduced to suppress flavor changing.

Why not outsource limit setting to theorists? If SUSY is present and important, it should not be so subtle to discover. I doubt, however, that theorists and phenomenologists will ever be convinced by mere experimentalists, so let them dig through the data (after the straightforward analyses have been done) and convince themselves.

49. **Peter Woit**
November 6, 2011

Jim Rohlf,

Thanks for the reassuring comments about triggers…

I think the Witten talk Jim was referring to might have been something like this one:

http://conferences.fnal.gov/lp2003/program/papers/witten.pdf

while Witten is quite fond of SUSY, he's careful there to explain the problems.

50. **Jim Rohlf**
November 6, 2011

I don't think Lykken meant that we have a fiduciary responsibility to make a discovery but rather that we have such responsibility to extract as much as we can quantitatively about SUSY and other limits. I hate setting limits. Nobody will ever care that we did not see something and the only worthwhile thing about not seeing something is to help tell us where to look next. I agree there is absolutely no possibility that a theorist could discover SUSY because the signatures are not subtle.

I agree totally with your comment about Mel Schwartz. We used to joke that our friends Jack and Leon may never get the prize because then they would have to give it to Mel too, which was thought to be politically incorrect because he left the field, unlike the other 2 who made sustained, important, high-visibility contributions throughout their careers. They had to wait a long time, from 1962 to 1988, considering the central importance of the result (2 neutrinos). It was a great prize. Whenever I teach particle physics, I always spend a whole class going over the 1960 paper of Schwartz on how to make a neutrino beam with enough intensity to study the weak interaction. The actual beam made in 1962 was very much according to the vision of Schwartz. Of course, Bruno Pontecorvo also had the idea but was not in a position to do the experiment. It is absolutely amazing that from conception to construction to discovery took only 2 years. This was as far as I can tell in a large part due to the drive of Schwartz.

54. **A.**
November 7, 2011

I seem to have come late to this party. I'm working on ELI stuff. I'm shocked by how bad the Telegraph article is and I agree with some comments above that "we" are not doing ourselves any favours by promoting the machine in this way.

ELI will not get closer than two orders of magnitude *below* the Schwinger limit (at least not for the foreseeable future). This doesn't mean that there is no chance of seeing the Schwinger effect, but it is not the first experiment they'll be doing. I think the attosecond science, medical imaging, radiography cases for ELI are perhaps stronger, but that's not my area and it seems the higher-ups want to keep the "fundamental physics" aspects in the public eye, and that seems to require this ridiculous sensationalism. Quite how committed they are to doing QED experiments… well, time will tell.

Also depressing is the list of comments in the Telegraph article which reveals both the woeful levels of scientific education in the UK and the abstract terror which such press releases can engender in the public eye. People are actually _scared_ that ELI will kill us all. Of course you can't stand up and say "oh come on, it's just a big laser pointer" without jeopardising both your funding and your prospects in the field.

55. **Bernhard**
November 7, 2011

Off-topic, but fresh hype:

http://www.newscientist.com/article/mg21228374.500-nuclear-clock-could-steal-atomic-clocks-crown.html

"Such clocks could shed light on string theory. The frequency of the jumps in a nuclear clock will depend on the strong nuclear force, while the jumps by electrons in atomic clocks depend on a different fundamental force. So together they could reveal if the relative strength of the forces changes, as string theory has it."

Interview With Sidney Coleman

November 4, 2011
Categories: Uncategorized

Via [Steve Hsu], at the AIP Center for History of Physics, there's a transcript of an [interview with Sidney Coleman] from 1977. It's provocative and amusing, like the man himself, as well as informative history. Go and read the whole thing, but here are some excerpts:

> **But you do enjoy working with students or do you?**
>
> No. I hate it. You do it as part of the job. Well, that's of course false…or maybe more true than false when I say I hate it. Occasionally there's a student who is a joy to work with. But I certainly would be just as happy if I had no graduate students…
>
> **I guess your remark means then that you would like to avoid teaching undergraduate courses or even required graduate courses…**
>
> Or even special topics courses. Teaching is unpleasant work. No question about it. It has its rewards. One feels happy about having a job well done. Washing the dishes, waxing the floors (things I also do on a regular basis since I'm a bachelor) have their rewards. I am pleased when I have done a good job waxing the floor and I've taken an enormous pile of dirty dishes and reduced them to sparkling clean ones. On the other hand, if I didn't have to, I would never engage in waxing the floors, although I'm good at it. I'm also good at teaching; I'm considered very good at teaching, both by myself and others. And I'm also terrifically good at washing dishes, in fact. On the other hand, I certainly would never make a bunch of dirty dishes just for the joy of washing them and I would not teach a course just for the joy of teaching a course…
>
> **So I guess really you would be happier with the format of an institute of theoretical physics? Rather than a teaching institution like a university?**
>
> Well no. That makes it too abstract. Because that means, would you like to have a position at, say, the Institute for Advanced Studies? And then all sorts of other things would enter the picture. Like you'd have to live in Princeton which is truly an awful experience.
>
> **I was there as a young bride a long time ago.**
>
> Young brides get the worst of it. They're even worse off than the people who are at the University or the Institute because at least the people at the University or the Institute can fill their days by engaging in their professional interests from the moment they wake up until the moment they go to sleep. But if you don't have that, there is really nothing. Nothing. It's a terrible place. Dullest place in the world. No I wouldn't say that, but certainly the dullest place at which decent science or decent scholarship is done in the world today. The only advantage to Princeton is that it's close to Princeton Junction.

Personally I'm quite glad that Harvard was wealthy enough to support Coleman, while forcing him to teach, since I benefited quite a bit from his teaching, right around the time of this interview. I had heard before that he didn't enjoy his time in Princeton. Once at lunch at the IAS, a senior physicist visiting there told me about the advice Coleman had given him when he told him he was going to Princeton for a year. The advice was "Be sure to bring with you everything you need." The senior physicist then told me that: "I recently realized what Sidney was trying to tell me: there are no women here so I should have brought someone with me…"

Comments

1. **erice**
   November 4, 2011

   Taking all of the above at face value, one wonders why Sidney taught at the Erice summer schools (some of the most brilliant lectures they have had). Harvard could force him to lecture at Harvard, but nobody could force him to lecture at Erice. Zichichi must have had fantastic powers of persuasion.

2. **Kea**
   November 4, 2011

   I was in Princeton for a few months in '96 (studying mathematics) and I loved it precisely because it was so quiet. One can sit at lunch at the IAS without being bothered by passing traffic, work in a quiet space, and watch squirrels in peace. I have never seen a better working environment anywhere.

3. **Bob Levine**
   November 4, 2011

   Coleman's dislike of teaching reminds me of something that the great G. H. Hardy said in his A Mathematician's Apology: that he disliked teaching but loved lecturing. I suspect that quite a few of the professoriate, if they were being completely candid, would have something similar to say.

4. **Peren Woondeen**
   November 4, 2011

   I would happily wash dishes and wax floors for a one-week trip to Erice, all expenses paid. Sicily is a beautiful place, you know.

5. **Shantanu**
   November 4, 2011

   Peter, thanks for the link. very nice interview. Btw do (or anyone else) know whether Harvard think of forming a relativity group during the heydays in 70s?
   Do you recollect the attitude of Harvard folks in 70s towards relativity?

6. **Chris Oakley**
   November 4, 2011

   Erice was rumoured to have connections with the Mafia. Maybe they threatened to kneecap Coleman if he refused to give lectures there.

7. **Thomas R Love**
   November 4, 2011

   I sincerely doubt that Princeton is the "Dullest place in the world", outside the Lab, it has to be Los Alamos.

8. **Peter Woit**

November 4, 2011

Shantanu,

When I was there (75-79), the November revolution had just happened and the Standard Model was becoming widely accepted, with new confirming results coming in regularly. The investigation of QCD had really just begun, with people trying to extract as much from perturbation theory as possible (jets, charmonium), and beginning to try to understand its non-perturbative behavior. With all of these dramatic developments, gravity was not something that many people were thinking about. I'm sure there was no discussion of starting a new relativity group then. Elsewhere, supergravity was getting off the ground. Lee Smolin was a graduate student, working on gravity, nominally with Coleman, but I think mostly with Stanley Deser at Brandeis. I vaguely remember that he discusses this period in his book.

9. **Franklin Chen**
November 5, 2011

I took Quantum Field Theory from Sidney Coleman way back. I remember how he had planned his lectures down to the jokes. I also remember how he would sometimes respond to students in the class, "Ask a stupid question, get a stupid answer."

10. **Edward Pickman Derby**
November 5, 2011

I don't get it; if Princeton is such a sh*t hole then why would Witten, who could get a lucrative job at any university in the world at a moment's notice, choose to work there?

11. **Richard**
November 5, 2011

It's always worth reminding people of the the splendid Coleman [QFT lecture notes] from 1985, transcribed from [Brian Hill]'s records.

12. **MathPhys**
November 5, 2011

I knew Coleman a bit and from the little that I knew, Princeton was too quiet for him.

13. **Jim Rohlf**
November 5, 2011

I knew Sidney pretty well when I was at Harvard. Two of the funniest things I ever heard him say were:
1) at a poker game in the middle of the night in Aspen (keep in mind we played poker often in Cambridge) a prominent Cornell physicist exclaimed after as I recall was a very strange situation, "Professor Coleman why did you fold?" and Sidney without a missing beat said "I don't know, I'm a poker player not an analyst."
2) for those that know David Cline (also a friend of mine) who was calculated to travel at an average speed of 43 mph because he flew so much, in a chance encounter of the 3 of us at the CERN cafeteria, I said to Sydney, "You've met Dave Cline, I presume."
Coleman: "No. The flux is large but the cross section is very small."

14. **MathPhys**
November 6, 2011

I was told by no less authority than (okay, let's not get into dropping names) that Sidney C did not know a word of French, but he was an expert on reading the menu in French restaurants.

15. **M. Wang**
November 7, 2011

My favorite story about Sidney is that when he was asked to give a talk at 10am, he replied, "I don't think I can stay up that late."

16. **MathPhys**
November 7, 2011

When lecturing on magnetic monoploes, Sidney would make a circle with the thumb and index finger of one hand to represent closed magnetic flux lines, use the index finger of the other hand to represent charges flowing through it, then look at the audience and say "I shouldn't be making these obscene gestures". He was great fun.

17. **chris**
November 7, 2011

M Wang,

that was Pauli to Heissenberg…

18. **JadedIdealist**
November 7, 2011

A recent newscientist article argued (well enough to give the idea credit in my eyes) that part of the reason for the backlash against science funding in the american right wing was due to poor engagement with a) the public and especially b) the rich – ironically due in part to secure science funding.

This interview fits right in with that 70's zeitgeist of "we don't want to and don't need to talk to ignorant people", I hope we can see now that in the long run that attitude is a mistake.

19. **Steve Christensen**
November 7, 2011

I was at Harvard 1977-79 in Physics and at the Center for Astrophysics. Also there doing relativity related work were Bill Press and Larry Smarr. Most of the other gravity related work was being done by Mike Duff, Stan Deser, Marc Grisaru, Burt Ovrut, and others at Brandeis where I spend most of my time working with Mike. My discussions with Sidney at the time were all about science fiction due to his writings in Fantasy and Science Fiction magazine.

20. **Chris Oakley**
November 7, 2011

> This interview fits right in with that 70′s zeitgeist of "we don't want to and don't need to talk to ignorant people", I hope we can see now that in the long run that attitude is a mistake.

Sure, but if, when journalists telephone, scientists start prattling on about extra dimensions, supersymmetry, wormholes, parallel universes, strings and other stuff that has no experimental support whatever then *they* are the ignorant people.

21. **Patrice Ayme**
November 8, 2011

JadedIdealist and Oakley have it exactly right. The most important function of scientists is not to pose as if they had made great strides in magic, but to explain humbly and thoroughly real science, and how it progressed through more exact thinking, and the general interest this has for society, thus insuring the social support of science and the powers that be, for a long time to come.
Certainly presenting as facts fancy flights of the imagination is long term disastrous for the support of thinking by this civilization. Because when those turn out completely silly, scientists, and, therefore science, lose all credibility. We should be modest, because our theories are modest, and so doing other decision makers can take heed.

And if he weren't, he wouldn't? Interesting assumption about the natural order of things.

Extortion

November 6, 2011
Categories: Uncategorized

An explanation of something that readers of this and other related blogs may have run into recently:

An ex-boyfriend of a close personal friend of mine has been posting here and elsewhere repulsive and delusional material about the two of us. A few weeks ago he wrote to her to demand money, telling her that if she didn't pay up he would go on a campaign to broadcast information discreditable to me and embarrassing to her. She didn't pay him and what you may have seen is the result of him making good on his threat.

I've never met this person, and his accusations are simply untrue. If you're owner of a blog where this is posted, please delete this material, although it might be a good idea to save a copy in case it becomes evidence in a criminal case. Otherwise please just ignore it completely, unless you'd like to help me out by contacting the blog owner to tell them what is going on and ask them to delete it. Thanks.

Note added: I appreciate the intention, but please do not post comments or advice about this here on the blog.

This Week’s Hype

November 7, 2011
Categories: This Week's Hype

A couple people have pointed me to an article at *New Scientist* that requires another edition of This Week’s Hype. According to Nuclear clock could steal atomic clock’s crown:

> Such clocks could shed light on string theory. The frequency of the jumps in a nuclear clock will depend on the strong nuclear force, while the jumps by electrons in atomic clocks depend on a different fundamental force. So together they could reveal if the relative strength of the forces changes, as string theory has it.

The amusing thing about the string theory “prediction” that relative strengths of forces change over time is that many string theorists promote as a “prediction” exactly the opposite: according to this argument, change in these strengths would imply large changes in the vacuum energy, which we don’t see, so a prediction of the landscape is constancy. See for example here.

Comments

1. **Carl**
   November 7, 2011

   “It’s not that this experiment contradicts string theory, it’s just that you’re looking at the wrong universe.” — All string theory defenders, ever.

2. **Bernhard**
   November 7, 2011

   Peter,

   Not sure I follow. Why would the landscape imply that? Perhaps a bit mathematically formulated would be easier to understand.

3. **Peter Woit**
   November 7, 2011

   Bernhard,

   You’d have to ask Michael Douglas for the details of the argument, it’s his. But I gather the idea is just based on the fact that your changing couplings and your vacuum energy are both determined by the details of the potential function for moduli fields. If your universe moves in the moduli parameters, the energy will also change, on a scale that ruins your extremely low, anthropically tuned CC.

4. **SpearMarktheSecond**
   November 8, 2011

   Hmmm… doing the highest possible precision test of the time-stability of the strong interaction strength relative to electromagnetic strength is simply a good idea!

   Don’t need a string theorist or string theory to know which way the wind blows in this case. Sadly, though, experimental groups feel compelled (maybe even justifiably) to tie what are excellent ideas to the latest fashion.

   I guess Columbus had to argue that he’d improve trade to Japan in 1490 or so too.

   It is rather remarkable to have a low-lying nuclear level that is accessible with UV or optical photons. Never knew that before.

   Now out there somewhere in the literature are studies, I’m sure, of the time stability of the mass of nuclei/atoms measured with electromagnetic mass spectrometers. Another test of the time-constancy of strong/em. Mass spectrometry is darned sensitive, but in the end optical methods probably win in sensitivity.

   Good for these guys!

Higgs Rumor Roundup

November 10, 2011
Categories: Experimental HEP News

As far as I've been able to tell, there's still nothing definitive one way or the other about the SM Higgs, as the experiments continue to analyze data from the now-finished 2011 pp run. Starting Monday is the HCP 2011 conference which at one point seemed to be a possible venue for announcement of confirmation of hints from early this summer of a Higgs around 140 GeV or so. Those hints disappeared later in the summer, so conventional wisdom recently has been that not much new will come out next week in Paris. A new blog entry from one of the organizers refers to this disappointment, leading to worries about conference attendance, but adds some dramatic and mysterious news at the end. It seems that some experimental collaboration requested a last-minute slot at the conference to unveil a new result that might be the highlight of the conference. They're on for 15 minutes on Monday, still not announced which collaboration this is, who the speaker is, or what their title is. This may very well have nothing to do with the Higgs: maybe something else travels faster than the speed of light…

At HCP2011, ATLAS will have new results from the H->ZZ->llnunu channel (already released, see here) and from the H->ZZ->llqq channel. Unfortunately neither of these are relevant to the low mass region where the Higgs is believed to be hiding. I don't know what CMS has up its sleeve. One other thing that will be released is the combination of ATLAS and CMS summer conference data, which will exclude the Higgs at 95% confidence level from 141-476 GeV (and come very close to this exclusion down to about 135 GeV).

It looks like release of new data in the channels that are sensitive to a low mass Higgs will wait longer, until the experiments have had a chance to do some analysis on the entire 2011 data set. Mid-December has been rumored as a date, and a logical bet would be that the CERN Council week would be the time for this, in particular at the Scientific Policy Committee meeting on December 12-13. Rumors going around about this are that there's still nothing definitive in the crucial H->gammagamma channel, and that in the H->ZZ->llll "golden channel" (very low background), one experiment is seeing no excess at low mass, the other is seeing an excess. Higher quality, better informed rumors are encouraged…

Nature reports here on the discussion at CERN about what to do in the (wonderfully exciting…) event that the SM Higgs is not seen. The first action they're taking is semantic: if no Higgs is seen at the 95% confidence level, instead of saying that this "excludes" the Higgs, they will announce that it "disfavours" it. So, the first reaction will not be jumping for joy, but a defensive one about how it might still be there.

Whatever comes out in December, I hear the plan is to wait for the Moriond conference at the beginning of March to release a result combining data from all channels (separately for each experiment). The Tevatron may have a result to release then too. Philip Gibbs will then swing into action for the full combination.

Update: Via Philip Gibbs, this talk includes the information that "The CERN DG has requested updates for December council". Not clear to me if the plan is to release these publicly, or to try and keep them confidential (which may not be easy…).

Update: The mystery new result is from LHCb, a 3.5 sigma observation of CP violation in an unexpected place. Details here, Jester has analysis here.

Comments

1. **this conference's hype**
   November 10, 2011

   "A new blog entry from one of the organizers refers to this disappointment, leading to worries about conference attendance, but adds some dramatic and mysterious news at the end."

   There is your answer in a nutshell: "… worries about conference attendance, …" And so it is a self-fulfilling prophesy that conference organizers **must** promise the prospective audience some sensational news. "… but adds some dramatic and mysterious news at the end." Et voila!

   Don't blame string theory for any of this. And don't restrict the responsibility for this state of affairs to HEP.

2. **Coin**
   November 10, 2011

   "Higher quality, better informed rumors are encouraged…"

   In other words you are looking for something like a 5-sigma rumor to distinguish the event from the noise floor? Or if we collect a sufficient number of 3-sigma rumors is that adequate…

3. **emile**
   November 10, 2011

   I think rumors and hype are not so distant cousins… There is a problem with honesty in hyping results or spreading false rumors. If someone if spreading "true rumors", you need to realize that that person has agreed not to discuss unapproved results but is doing it anyway after saying that they would not do that. This is not about whether collaborations should or should not impose a ban on discussions of internal results. Simply put: if you agree to something, abide by it. Don't encourage hype and don't encourage the spreading of rumors. Science does not profit from either.

4. **icebug**
   November 10, 2011

   Apologies for OT comment, but I just received an email about this new particle physics textbook from Princeton, purporting to be "a cutting-edge introduction to the field, preparing first-year graduate students and advanced undergraduates to understand and work in LHC physics at the dawn of what promises to be an era of experimental and theoretical breakthroughs." Do you have any thoughts on the timing? I suppose it is timely in one sense, but I wonder how they decided how much speculation/prognosticating to put in or leave out…

5. **Peter Woit**
   November 10, 2011

   icebug,

   That's a serious book, from the experimental view-point, with only a minimal level of theoretical speculation. The LHC will be operating for many years, and most of what's in the book will continue to be relevant. The author has chosen to go ahead and publish even though some of the material may be out of date soon. Nothing wrong with that, if a field is moving fast, doesn't mean people shouldn't try and write textbooks about it.

6. **Peter Woit**
November 10, 2011

emile,

I won't get into the debate about discussing rumors about unapproved results, other than to note that I try to do so accurately, and only when I have some good reason to believe the rumor (note that information leaks out in many ways…). I don't think this damages the progress of science.

Also note that much of the information in this posting that may be confidential is not unapproved analysis of data. As far as I know, this summer's ATLAS/CMS combination is approved and final. Sometimes people have results that have gone through the proper vetting procedure, and they're just keeping them confidential for non-scientific reasons, e.g. waiting for some conference or press release. Other information in this posting is rumor/speculation about tentative scheduling of future releases of data, and I actually don't see any good reason for that to be confidential.

7. **M**
November 10, 2011

…or maybe something else violates CP at 3.5 sigma level.

8. **Greg**
November 10, 2011

It seems that some experimental collaboration requested a last-minute slot at the conference to unveil a new result that might be the highlight of the conference. They're on for 15 minutes on Monday, still not announced which collaboration this is, who the speaker is, or what their title is.

W mass from CDF?

9. **Jester**
November 11, 2011

According to my sources, it's going to be the LHCb measurement of a large CP asymmetry difference between D -> K K and D -> pi pi decays.

10. **M**
November 11, 2011

Jester, your sources are right. Can we start discussing what is the Standard Model expectation for that?

11. **David Brown**
November 12, 2011

Do the CERN physicists have a Higgs betting pool?

12. **Nige Cook**
November 12, 2011

"The first action they're taking is semantic: if no Higgs is seen at the 95% confidence level, instead of saying that this "excludes" the Higgs, they will announce that it "disfavours" it."

How far will they have to go to "exclude" it? Is it just that they want perpetual funding to go on searching and have job security forever? Not only does the Higgs not predict a certain energy, but the LHC experiments can't definitely exclude it?? If these people were searching for ESP phenomena, would they be similarly cautious?

13. **Peter Woit**
November 12, 2011

Nige,

I think they want to reserve the word "exclusion" for a higher standard than 95% sure it's not there, e.g. 5 sigma. In terms of communicating with the public, this is not unreasonable, since in this business analysis of systematic errors is tricky and "95% sure" has been known to be wrong more often than expected. However, "disfavored" sounds to me misleadingly weak…

In any case, I'm sure they'll keep reporting 95% results, whatever they call them, and if the SM Higgs is excluded at that level, most physicists will start assuming it's quite likely that it's not there.

14. **cc**
November 13, 2011

Indeed non-leptonic D decay seems to be it. Difficult to think of a tougher nut to crack, re. a decently clean SM prediction.

What about the Dec 16 CERN announcement buzz, though?

15. **Neo**
November 13, 2011

I am not a physicist, just an interested observer. What impresses me is that if the SM Higgs is not found, there appears no particular direction to go. Yes, the kluge-assisted standard model is wrong, but so what? Technicolor seems doomed. String theory can retreat to any level of energy to avoid being refuted. What to do?

16. **Peter Woit**
November 13, 2011

neo,

A situation where there's no good theoretical idea, and experimentalists are hard at work producing results that might provide important hints sounds to me like a pretty good situation for a theorist. Far preferable to the LHC data just confirming the SM or some other well-known theoretical model. If the SM Higgs doesn't show up, for the first time you'll have an experimental result in radical disagreement with the SM, and that's what we need in order to start figuring out how to do better than the SM.

17. **Peter Woit**
November 14, 2011

cc,

What is the "Dec. 16 CERN announcement buzz"? Does this have to do with a plan to publicly update the Higgs search results at the CERN Council week?

18. **CPV**
November 14, 2011

Direct link to the HCP talk about CPV in the charm sector at LHCb.

19. **Shantanu**
November 15, 2011

Peter, or anyone else:
Do you know what happened about the muon (g-2) anomaly. what's the latest
theoretical and experimental consensus?

20. **BJM**
November 17, 2011

I remember when it was exciting to think that a final theory was within reach. Now it's exciting to think that perhaps everything we know is wrong and we need to start over again. Sheesh!

Models.Behaving.Badly

November 14, 2011
Categories: Book Reviews

Emanuel Derman has a fascinating new book out, Models.Behaving.Badly, which I've been intending to write about here for a while now. One of the problems that has kept delaying this is that every time I start to write something I notice that a new review of the book is out, and it seems to me quite a bit better than anything I have to say. An example that comes to mind is this review from Cathy O'Neil at mathbabe a while ago, another is a new one out today at Forbes. Any book that attracts so many thoughtful reviews has to be worth reading as well as capturing something important about what is going on in the world.

There is a somewhat frivolous virtue of the book that I haven't noticed other reviews discussing: the wonderful title. I can't help but enjoy the double meaning linking two of the out-of-control groups that are features of downtown life here in New York. One might think that drunken fashion models in downtown clubs and quants at financial firms don't have a lot to do with each other, and yet…

Derman's first book, My Life as a Quant (which I wrote a little bit about here in the early days of this blog) tells the story of his move from high energy theory into financial modeling. He was one of the first to do this, and that book reflects a time when the financial industry was riding high, with the role of quants and their models relatively uncontroversial. With his new book, he's also one of the first, this time in his disillusioned but serious look from the inside at where we are today:

> I am deeply disillusioned by the West's response to the recent financial crisis. Though chance doesn't treat everyone fairly, what makes the intrinsic brutalities of capitalism tolerable is the principle that links risks and return: if you want to have a shot at the up side, you must be willing to suffer the down. In the past few years that principle has been violated.

His focus is on the role that models inspired by physics have played in this debacle, arguing that they have been used in a fundamentally misconceived way, and explaining the evolution of his own understanding:

> … I began to believe it was possible to apply the methods of physics successfully to economics and finance, perhaps even to build a grand unified theory of securities.
>
> After twenty years on Wall Street I'm a disbeliever. The similarity of physics and finance lies more in their syntax than their semantics. In physics you're playing against God, and He doesn't change His laws very often. In finance you're playing against God's creatures, agents who value assets based on their ephemeral opinions. The truth therefore is that there is no grand unified **theory** of everything in finance. There are only **models** of specific things.

Much of the book is devoted to explicating his views about the importance of distinguishing between "theories" that are supposed to accurately capture phenomena, and "models", which are metaphors which which only approximately capture some aspects of phenomena. As examples of theories, he discusses not just QED, the quintessential accurate theory of the physical world, but also Spinoza's theory of the emotions. Besides the financial models that are the focus of the book, he also covers a wide range of other failed models. The book begins with a short memoir of growing up in South Africa, where he was a member of a Zionist youth organization, and its failed models as well as the racial ones of apartheid played a role in his coming of age.

If you're part of the modern world which generally finds actual books too long and time-consuming to read, Derman has an often enjoyable blog, and for the truly ADD-afflicted, he also has one of the very few twitter feeds I've seen worth following.

Comments

1. **Tim van Beek**
   November 14, 2011

   FWIW I faced the career choice ten years ago of wether I should try to get a PhD, become a quant or do something entirely different (choosing the latter). After working on models in classical statistical physics, the necessary mathematical machinery for doing mathematical finance isn't hard to learn.

   But I was and am convinced that while the abstraction of fast varying degrees of freedom of 10^23 particles following static rules of dynamics may be of some value, transferring the modelling techniques to 10^4 or 10^5 interacting humans can lead to catastrophic failure only.

   Several years later, in about 2005, I very much regretted my career choice, while watching the financial markets and the earnings of quants. In 2008 I was very much surprised how much I did not regret my choice then.

   Meanwhile I start to regret the choice again, as I see how virtually all quants continue their work, and get a lot of money for it, after causing a global economic meltdown. I wonder what will happen during the next catastrophy, which almost surely will take place within the next decade (I know this, I have a sophisticated model) 🙂

2. **M. Wang**
   November 14, 2011

   I first met Dr. Derman nearly 20 years. I always considered him lucky in the sense that his job was quite academic by bank standard and he did not have to get his hands dirty as often as traders had to do.

   _
   I am glad that he has also reached the conclusion that I believe every financial professional with a conscience should have suspected by 2000 and be thoroughly convinced by 2008: Modern finance as practiced in the US is a game rigged for the powerful insiders. Contrary to what business schools have trumpeted over the years, no high level personnel in investment banks care a bit about optimal allocation of resources. The biggest rewards inevitably go to those who are the most nasty and shameless in ripping off first their customers and later the taxpayers.

   _
   While this kleptocratic arrangement goes all the way to every branch of government and therefore is a much bigger problem than finance alone, it was made significantly worse by the willing and enthusiastic participation of the financial academia. It is so easy and common to buy off a few big-shot professors and have them pump out fact-warping papers to push for more deregulation or excuse blatant thefts of public goods, all without the slight bit of disclosure, that even when caught red-handed, no one will suffer any damage either legally or in reputation.

   _
   All this was a little hard to stomach for an ex-physicist like myself. I have escaped a field dominated by the nonsense that was string theory only to land among an immense group of shameless thieves. Although the string theorists have wasted 30 years of public resources pursuing an increasing pointless venue, the waste pales completely in comparison to the willful and wide-spread wrong-doings by financial academics and practitioners and their incredible damage to this nation and the world.

   _
   Those of you who had the fortune of not having to bear witness to the avarice and debauchery prevalent in the US banking industry of the past decade, consider yourself

blessed.

3. **Visitor**
November 14, 2011

I wonder if is Derman as sanctimonious as the quotes make him appear to be – because he sounds *very* sanctimonious indeed. (i.e. He is full of mea culpas but will be keeping the money.)

4. **M. Wang**
November 14, 2011

Why do you think Derman should give up his salary? To everyone's best knowledge, he has never participated in ripping off clients or the taxpayers. He was hired to produce research papers on pricing options and he did a decent job of it.

Thousands of string theorists have produced no results relevant to this universe. Don't they owe the public their salary back?

5. **Chris W.**
November 14, 2011

So, Visitor, if you observed the corruption from the inside, you're culpable like everyone else, so you should STFU.

On the other hand, if you observed it from the outside, you're ignorant and naive about how finance works, so you should STFU.

Enough venting on accusations of sanctimoniousness. On the question of linking risks and return, the real problem is that the risk takers can put other people—sometimes millions of other people—at risk besides themselves. When risk-taking is allowed to become systemic in that sense, it becomes very hard to just say "let 'em burn". Of course, the risk takers *wanted* to pull as many suckers into the game as possible, and they convinced our elected representatives to help them do it—not that some of them needed much convincing.

If a gambler wants to indulge his proclivities, let him do so, but require that he not have any dependents. The goal is to protect the dependents—in particular, from being held hostage to ensure a bailout—and not to punish the gambler, who will be punished by his bad bets.

The point is all pretty much moot where the U.S. government is concerned. The 2008 bailouts were a one-shot deal; we can't possibly afford to do them again. If we forget that, I think Japan and China (and much of Europe) will remind us.

6. **Peter Woit**
November 14, 2011

Sorry folks, but I'm not about to try and moderate an open forum for everyone to explain what they think about economics or the financial system. If it's not about Derman's book, it's off-topic here. There are lots of blogs out there devoted to economics and finance in general, try one of them.

7. **Yatima**
November 14, 2011

Young ones finding back the wisdom of those who went before?

As Ludwig von Mises said in The Ultimate Foundation of Economic Science

The study of economics has been again and again led astray by the vain idea that economics must proceed according to the pattern of other sciences. The mischief done by such misconstructions cannot be avoided by admonishing the economist to stop casting longing glances upon other fields of knowledge or even to ignore them entirely. Ignorance, whatever subject it may concern, is in no case a quality that could be useful in the search for truth. What is needed to prevent a scholar from garbling economic studies by resorting to the methods of mathematics, physics, biology, history or jurisprudence is not slighting and neglecting these sciences, but, on the contrary, trying to comprehend and to master them. He who wants to achieve anything in praxeology must be conversant with mathematics, physics, biology, history, and jurisprudence, lest he confuse the tasks and the methods of the theory of human action with the tasks and the methods of any of these other branches of knowledge. What was wrong with the various Historical Schools of economics was first of all that their adepts were merely dilettantes in the field of history. No competent mathematician can fail to see through the fundamental fallacies of all varieties of what is called mathematical economics and especially of econometrics. No biologist was ever fooled by the rather amateurish organicism of such authors as Paul de Lilienfeld.

When I once expressed this opinion in a lecture, a young man in the audience objected. "You are asking too much of an economist," he observed; "nobody can force me to employ my time in studying all these sciences." My answer was: "Nobody asks or forces you to become an economist."

8. **David Brown**
November 15, 2011

According to Derman, "In finance, you can't predict the future to even one decimal place."

9. **Bernhard**
November 15, 2011

"As examples of theories, he discusses not just QED, the quintessential accurate theory of the physical world"

I almost feel bad about making this comment since it is on QED, which is as far as I know the most successful thing ever made IMHO in physics, but isn't fair to say QED is a model based on a theory (QFT) just as the SM, just as SM extensions…?

10. **Christopher Faille**
November 15, 2011

Allow me to advertise my own review of Derman's fascinating book here:

http://allaboutalpha.com/blog/2011/11/10/derman-why-all-models-are-toys/

Thanks.

11. **Peter Woit**

November 15, 2011

Bernhard,

I think Derman is trying to make a useful distinction, and using the terms “theory” and “model” to name it. The same terms do get used in different ways though. For instance, “string theory” refers to all sorts of very different things. The Standard “Model” is the name given to the most extreme case of a “theory” we have, in Derman’s usage. The general question of how mathematical structures like QED and the SM relate to the “real” world is a very interesting and intricate one, but I don’t think that’s what Derman is trying to get at. It seems to me that he’s mainly interested in examining why the models used in finance are of a different nature than things like the Standard Model.

12. **Suraj**
December 3, 2011

@Bernhard.. “As examples of theories, he discusses not just QED, the quintessential accurate theory of the physical world”

Thanks for this.

Dijkgraaf Next Director of the Institute for Advanced Study

November 14, 2011
Categories: Uncategorized

The IAS in Princeton announced today that Robbert Dijkgraaf will take over from Peter Goddard as director starting next summer.

Like Goddard, Dijkgraaf has devoted much of his career to string theory, more specifically the formal side of the subject, including conformal quantum field theories, topological quantum field theories, and their manifold interesting relationships to mathematical issues. Unlike Goddard, he's from a later generation, getting his Ph.D. in 1989 and entering theoretical physics after string theory had begun to play a dominant role. His cohort of theorists who entered the subject as Young Turk revolutionaries riding the wave of string theory is now settling into the role of Grand Old Men.

Dijkgraaf is known as a masterful expositor, with pretty much any survey article by him you can find sure to be lucid and very much worth reading. He also has world-class political skills, recently overseeing the review of the IPCC, a topic putting him at the center of the religious war over climate change. His background makes him an ideal choice to lead an institution like the IAS, one with a great history in theoretical physics and mathematics, and an important ongoing role to play in keeping those subjects healthy.

Comments

1. **Marcus**
   November 15, 2011

   Here is a video
   http://loops05.aei.mpg.de/index_files/abstract_dijkgraaf.html
   of the invited plenary talk that Dijkgraaf gave at the Loops 2005 conference at the Einstein Institute (Potsdam MPI.)
   http://loops05.aei.mpg.de/
   The title of the talk was "Quantum geometry and topological strings".

   I think this video illustrates what Peter said about excellent expository skill and it also gives a sense of the person (who may also be highly able politically, as was suggested.)

2. **Edward Pickman Derby**
   November 15, 2011

   Peter, the importance of the IAS has declined greatly in recent years. Why is the announcement of its next director news? Do you actually believe he can right the ship?

3. **cthulhu**
   November 15, 2011

   Declined in favor to what?

4. **Marcus**
   November 15, 2011

   *Peter, the importance of the IAS has declined greatly in recent years. Why is the announcement of its next director news? *

   I don't know what Peter will say to this EPD, and I'm interested to hear his answer. But your question contains a non sequitur: it is precisely when such a notable institution's importance has declined that the announcement of a new director is news.

   There may be a broader problem, not limited to the IAS. I see several areas of fundamental physics where the importance of US research has declined relative to Europe and Canada (happily not in cosmology though!) and I attribute this to a US leadership that is set in its ways and lacks fresh vision in these areas. Changes in leadership could be part of the solution.

5. **Peter Woit**
   November 15, 2011

   Edward,

   I don't see the importance of the IAS as changing much at all in recent years. In math they've just hired away from Harvard Richard Taylor, who is about the best there is in number theory, and more generally they remain one of the great centers of math research. In physics they recently hired Arkani-Hamed, who arguably is the most influential theorist in his generation. They're pretty heavily loaded down with string theorists these days (even more so bringing in Dijkgraaf, keeping Goddard as a professor), but the string theorists there are the best in the world, with no sympathy for nonsense like the landscape, and increasingly moving from string theory to other topics. Like everyone else in particle theory, I think they're trying to find their way and waiting to see what the LHC says. But, like in math, the IAS has been and remains extremely influential in particle theory.

6. **Zakok Allen**
   November 15, 2011

   Peter, hate to interrupt the discussion (although this is not really off topic) but video of Witten's talk on Knots and Quantum theory is up on the IAS website. Would love to hear your take on it.

7. **lun**
   November 15, 2011

   regarding the no sympathy for landscape nonsense….

8. **Peter Woit**
   November 15, 2011

   lun,

What I wrote was carefully worded:

"the string theorists there are the best in the world, with no sympathy for nonsense like the landscape"

Arkani-Hamed is not a string theorist…

9. **Peter Woit**
   November 15, 2011

   Zakok,

   Thanks for pointing out the Witten talk. I think maybe it deserves its own posting, however short…

10. **Bobito**
    November 16, 2011

    Pickman Derby: to paraphrase Mark Twain: "the reports of my demise are greatly exaggerated".

Knots and Quantum Theory

November 15, 2011
Categories: Langlands

A commenter on the last posting pointed to the new video available at the IAS site of Witten's recent public talk there on Knots and Quantum Theory. The talk is aimed at a general audience, including supporters of the IAS, so it's rather non-technical. For the technical details behind what Witten is talking about (his recent work on Khovanov homology and QFT), see this survey for mathematicians, a survey for physicists at Strings 2011, and this paper.

For me an interesting part of Witten's talk was how he described the evolution of his ideas about this topic, and the relationship to geometric Langlands. He also had interesting comments about number theory and the Langlands program, denying any real knowledge of the subject, but arguing that sooner or later (probably later, after his career is over), there would be some convergence of number theory Langlands and physics. He finds the coincidence of geometric Langlands showing up in QFT so remarkable as to indicate that there are deep connections there still to be explored. I suspect that he sees the likely path of information going more from physics to math, with QFT ideas giving insight into number theory. While I agree with him about the existence of deep connections, I suspect the influence might go the other way, with the powerful ideas behind the Langlands program in number theory someday providing some clues about QFT useful to physicists.

Also on the Langlands program topic, this semester we're having a wonderful series of lectures on the topic by Dick Gross. He's a fantastically gifted lecturer, and this series is pitched at just the right level for me, explicating many of the parts of the subject I've been trying to learn in recent years but have found quite confusing. It's a beautiful, very deep, but rather intricate subject, bringing together a range of remarkable ideas about mathematics. In the end though, the Langlands program is really mostly about new ideas in representation theory, and since I'm convinced that deeper understanding of QFT will require new ideas about how to handle symmetries, which is the same thing as representation theory, perhaps finding connections between the subjects won't have to await Witten's retirement.

Comments

1. **martin**
   November 16, 2011

   Of course there is a big difference between Geometric Langlands Program and Langlands Program in the sense that Langlands uses the term. When you say that Witten expects a connection between number theory and physics does he mean Geometric Langlands or number theory?

2. **Peter Woit**
   November 16, 2011

   martin,

   Witten has already done extensive work on the connection between geometric Langlands and physics (and there was such a connection, to conformal field theory, there from the beginning). What he was speculating about was the possibility of a connection to the number theory case.

3. **martin**
   November 16, 2011

   Peter Woit,

   Thakns, so he did mean number theory. I've just finished watching the talk, and I saw the part where he said that about the Langlands program, but it was only one sentence in passing. Has he explained somewhere why he thinks so? Or is ti really just a speculation, he did say that he was not very familiar with number theory.

4. **Peter Woit**
   November 16, 2011

   martin,

   As far as I know he doesn't have anything specific in mind, this is just speculation. Philip Gibbs at vixra log transcribed the relevant part of his comments:

   "I had in mind something a little bit more ambitious like whether physics could affect number theory at a really serious structural level like shedding light on the Langlands program. I'm only going to give you a physicists answer but personally I think it is unlikely that it is an accident that Geometric Langlands has a natural description in terms of quantum physics, and I am confident that that description is natural even though Ithink it mught take a long time for the math world to properly understand it. So I think there is a very large gap between these fields of maths and physics. I think if anything the gap is larger than most people appreciate and therefore I think that the pieces we actually see are only fragements of a much bigger totality."

5. **Sakura-chan**
   November 16, 2011

   I really enjoyed Gross's lectures on undergraduate abstract algebra. He is a great speaker.

6. **aa**
   November 16, 2011

   Knot even wrong?

7. **Chris Austin**
   November 16, 2011

   On the topic of possible applications of the Langlands program to physics, there is a famous conjecture of Atle Selberg about the lowest nonzero eigenvalue of the Laplace-Beltrami operator on 2-dimensional cusped hyperbolic manifolds obtained by quotienting 2-dimensional hyperbolic space, with sectional curvature -1, by a k principal congruence subgroup of SL(2,Z), k >= 3, which has no torsion. Selberg conjectured that the lowest nonzero eigenvalue is 1/4, and proved it is >= 3/16. Selberg's lower bound was improved to 171/784 = 0.2181… by Luo, Rudnick, and Sarnak, and has been increased to 975/4096 = 0.238… by Kim and Sarnak. The analogous conjecture for the lowest non-zero eigenvalue on cusped principal congruence quotients of n-dimensional hyperbolic space H^n is that it is (n – 1)^2/4, which is where the spectrum starts on H^n. Sarnak has obtained a lower bound of 21/25 = 0.84 for a family of cusped hyperbolic 3-manifolds called Bianchi manifolds.

   I understand from page 5 of this article by Peter Sarnak that Selberg's conjecture, and from pages 14 to 16, possibly also the above generalization to cusped principal congruence quotients of H^n, are now understood to be part of Generalized Ramanujan Conjectures that are part of the (number theory) Langlands program.

If I have got that correct, (and I have to admit that there is a lot in Sarnak's article that I don't understand), does Ngo's proof of the Fundamental Lemma of the Langlands program mean that Selberg's conjecture, and its generalization to higher dimensional cusped hyperbolic manifolds as above, are now proved?

8. **Peter Woit**
November 16, 2011

Chris,

The proof of the Fundamental lemma only proves a small piece of the conjectures that make up the Langlands program, and as far as I know doesn't tell you anything about these Generalized Ramanujan conjectures.

For an interesting connection between physics and number theory that Sarnak has worked on, see his lectures about "Arithmetic Quantum Chaos" here http://publications.ias.edu/sites/default/files/Arithmetic%20Quantum%20Chaos.pdf

There are evidently examples of chaotic dynamical systems such that the problem of quantizing them and finding their spectrum is related to problems like the one you mention. This however I think is very different than what Witten has in mind, which involves not just QM, but quantum field theory.

9. **Chris Austin**
November 16, 2011

Thanks, Peter, I'll take a look.

10. **Jeff M**
November 17, 2011

I guess I should educate you physics types 🙂 The history of the Selberg conjecture and related issues is fascinating, McKean in the early 70s published a "proof" of the fact that the first eigenvalue was > 1/4 for ANY surface, thing was there was a mistake in the proof. Burt Randol (who taught me complex and real analysis) showed this by coming up with examples of surfaces with first eigenvalue going to zero (Randol is both a great mathematician and the best teacher I ever had, he just retired). The reason that 1/4 is so important is that it is the bottom of the L^2 spectrum of the Laplacian for the hyperbolic plane, and is related to the zeros of the zeta function (that is in fact how Selberg got his 3/16 result, he used Weil's theorem on zeta functions over finite fields). This sort of thing is why I ended up in geometric analysis, somehow everything seems to come together in strange and interesting ways…

11. **Chris Austin**
November 17, 2011

Thanks, Jeff. Randol's article appears as ref [26] of this review by Peter Sarnak. The examples with 1st eigenvalue going to 0 on the 2nd page here use a thin neck such that the length of a closed geodesic going round it goes to 0. You can't have examples like that in n > 2 dimensions because you can't put a hyperbolic metric on the "neck" of a connected sum for n > 2, and furthermore a finite volume hyperbolic structure has no shape moduli for n > 2 by Mostow rigidity. Which raises the question of whether the result claimed by McKean, (which I had not previously heard of), might be valid at least for n >= 4, with 1/4 replaced by (n – 1)^2/4. For n = 3 you could perhaps look for examples with large Dehn surgery coefficients in Thurston's construction.

12. **Jeff M**
November 17, 2011

Chris,

Yes, n=2 is a special case. Basically for hyperbolic manifolds, there are 3 different cases, n=2, n=3 and n>3. In dimension two you can have continuous deformation, in dimension 3 you can still shrink a geodesic to length 0 to get a cusp, but the deformation isn't continuous, and in dimension 4 and higher you can't even do that, there is a direct relation between the length of the shortest geodesic and the volume. My thesis was the n=3 case for the Laplacian on differential forms, and I studied the accumulation of eigenvalues near the bottom of the essential spectrum as the length of the cusp goes to infinity. For functions the bottom of the essential spectrum is (n-1)^2/4, but there can be isolated eigenvalues below that. The relevant theorem is due to Buser, Colbois, and Dodziuk, and says that for n>2 with pinched negative curvature, the number of eigenvalues below the bottom of the essential spectrum is a constant times the volume, and the constant depends only on n and the curvature bound. I have a paper with Ruth Gornet which discusses the bounded curvature case for forms, it's in Contemporary Math 237, and if I remember right it lists at least most of the relevant references in case you're interested.

Peter – hope it's OK to mention a paper of mine here, it was the best place I could think of for a reasonably complete list of interesting references for Chris.

13. **Chris Austin**
November 17, 2011

Thanks a lot Jeff, I'm reading your article, "Small eigenvalues of the Hodge Laplacian for three-manifolds with pinched negative curvature," in Contemporary Mathematics 237, now.

To find examples with small eigenvalues for all n >= 2, section 2.8.C in Gromov – Piatetski-Shapiro gives examples for all n >= 2 of finite-volume hyperbolic n-manifolds X, both compact and cusped, that contain a 2-sided non-separating embedded closed hypersurface S. If we take 2N copies of X, cut each along S, and join side b of copy 1 to side a of copy 2, side b of copy 2 to side a of copy 3, … , side b of copy 2N to side a of copy 1, we get a hyperbolic n-manifold that is a 2N-fold cover of X, and if we choose the function f on page 2 of the Sarnak review to be 1 on copies 1 to N and -1 on copies N + 1 to 2N, with smooth transitions across the two copies of S where f changes value, we get an upper bound on the first non-zero eigenvalue that is reduced by a factor 1/N, so can be made arbitrarily small by choosing N large.

Peter, I'm sorry if this has got off-topic.

14. **Jon**
November 18, 2011

Off-topic but highly interesting: a recent paper, with lots of apparently serious people backing it, claims the wavefunction has no statistical interpretation, it is real: see this Nature description…

15. **lun**
November 18, 2011

Honestly, I have watched this presentation and was disappointed.

He failed according to Feynman's criterion, "You do not really understand something unless you can explain it to your grandmother", and a lot of Witten's classic papers are classic precisely because they succeed in this respect, in the sense that they are remarkably clear in their arguments, both in stating the conclusion, supporting it, and elucidating the consequences.
I understand of course that this is a public talk on a specialized subject, but I failed to get even an inkling of what he was trying to accomplish, and why this worthwhile to do, and this is what the talk should have been about.

16. **hello!**
November 18, 2011

Witten's old paper on Free Fermions on an Algebraic Curve has some connection to number field Langlands, as well as geometric Langlands (that it predates).

17. **mbn**
November 19, 2011

hello!,

could you tell us which paper. Thanks.

18. **Peter Woit**
November 19, 2011

mbn,

The paper "Free Fermions on an Algebraic Curve" is in

The mathematical heritage of Hermann Weyl (Durham, NC, 1987), Proc. Sympos. Pure Math. 48, Amer. Math. Soc., Providence, RI, 1988, pp. 329-344. 16. Garland, H. and Zuckerman, G.: R

A more extensive version is

Quantum Field theory, Grassmannians, and algebraic curves,
Comm. Math. Phys. 113 (1988), 529-600.

For a more recent paper along similar lines, see Leon Takhtajan's
http://arxiv.org/abs/0812.0169

19. **David Ben-Zvi**
November 21, 2011

I think it's fair to say that ideas from the geometric Langlands program have recently started having an impact in number theory. The starting point is Ngo's celebrated work on the Fundamental Lemma, which doesn't explicitly use geometric Langlands but uses ideas that are very much part of that world. Since then this interaction has expanded significantly, primarily (in my not completely informed view) thanks to work of Ngo, Zhiwei Yun (MIT) and Xinwen Zhu (Harvard). In a spectacular recent preprint on his website, following up on ideas of Frenkel-Gross and his prior joint work on Kloosterman sheaves with Heinloth and Ngo, Yun used geometric Langlands ideas to construct motives with exceptional groups as Galois groups (in particular solving the inverse Galois problem for a large family of exceptional finite groups of Lie type). Other exciting developments in this direction include Zhu's resolution of a conjecture of Pappas and Rapoport on Shimura varieties and a variety of works deepening our understanding of various fundamental lemmas and their geometric origin. Behind all of this at some basic level is the realization of the motivic or geometric nature of many quantities of arithmetic interest, such as the constituents of the trace formula (see eg Nadler's BAMS article on the Fundamental Lemma), which enables arithmetic questions to be deduced out of more structured questions that can be approached in a function field setting using geometric ideas.

(Let me note that some of this work, eg Yun's work on global Springer theory, EXPLICITLY acknowledges a debt to physics: the influence of Kapustin-Witten on our understanding of the geometric Langlands program shouldn't be underestimated.)

20. **David Ben-Zvi**
November 21, 2011

I should also mention the fascinating work of Frenkel-Langlands-Ngo, proposing a strategy to understand Langlands functoriality based again on ideas of geometric (and physical) origin.

21. **Peter Woit**
November 21, 2011

David,

Thanks for your comments. I should note that, following up on Dick Gross this fall, Edward Frenkel will be the Eilenberg lecturer here this spring. I'm hoping we'll be hearing more about some of the topics you mention from him.

22. **Lee Flight**
November 24, 2011

Gross' Eilenberg lecture series is being made available:

http://www.math.columbia.edu/~staff/EilenbergVideos/Gross/index.html

kudos to Columbia for doing this.

23. **Ignatz Thugg**
November 25, 2011

Kudos to Columbia???? – what is SliverLite?

Generic problem: science for the rest of us should not be dependent
on on the fact that (a) not everyone uses Windows, (b) not everyone
has access to a university library – e.g. it costs ~$30 to read an article
published in Nature or a Springer or IOP journal.

24. **Peter Woit**
November 25, 2011

Lee and Ignatz,

The videos were produced, with no help from the university or department, for free by some of our grad students (especially Alex Waldron and Ioan Filip, maybe others I don't know about). They definitely deserve thanks from the whole math community for doing this on their own. One of our staff members, Nathan Schweer, helped put them up on the web server.

As for the format, it works fine on Macs (I just tried it out). Yes, you do need to install a "Silverlight" browser plugin from Microsoft. If you're allergic to them, in this day of Apple and Google dominating the internet, you should try and get over it and get outraged about something more up-to-date. Under Linux, there seems to be a Silverlight firefox addon, which, as usual in these things, doesn't work with the version of firefox I have, so I gave up. If we were paying somebody for this video, I suppose I'd look into demanding that they use a Linux-friendly format, but, you get what you pay for in the free software and content world….

As for the Nature/Springer/IOP problems, yes, in many cases it's outrageous that content produced by scientists that should be in the public domain isn't. In some cases though, I'm linking to material produced by professional science journalists, and someone has to pay them…

25. **Lee Flight**
November 25, 2011

Well I confess I did not notice the dependency when I watched using Chrome on whatever my netbook was booted as at the time, of course barriers are offensive just as it's offensive that there are millions who have no access to the Internet at all.
As one of the fortunate it astonishes me that material like this is there (thanks to grad students in this case); if I had been told 25 years ago when I was a student that material like this and some of the open courseware, lecture notes and also videos of the quality found on SCGP,KITP and PIRSA and elsewhere would be "available" it would have seemed to me the stuff of science fiction.

Higgs Non-News

November 18, 2011
Categories: Experimental HEP News

The combination of summer ATLAS and CMS Higgs results has finally appeared today (see here and here). This was originally supposed to be ready back in August, and has been circulating in various versions for quite a while. The bottom line (95% exclusion for 141-476 GeV) was mentioned here last week. They also quote limits using a much more stringent standard (99% exclusion for 146-443 GeV, excepting three small regions). Also worth mentioning is the 90% exclusion result, which reaches down to 132 GeV, leaving a SM Higgs possible only within the region 114-132 GeV.

What everyone really wants to know is when the experiments will release results based on the much larger full 2011 data set. Today's HCP 2011 talk just says:

> LHC experiments will analyze the x3 data already collected before 2012 Winter Conferences.
>
> Tevatron will provide the final results on 10 fb^{-1} by the 2012 Summer Conferencences.
>
> On the same time scale, there will be a combination LHC + Tevatron.

On this schedule, a possible 95% Higgs exclusion would not happen before next summer. However… I've seen comments from Fermilab that they should have results ready for Moriond in early March, and they expect to be able to rule out the Higgs at 95% (if it isn't there), over the relevant mass region. More immediately, the LHC experiments have been tasked to provide updates of their Higgs results, including per/experiment combinations, for the CERN Council Week (December 12-16). Rumors from the two experiments indicate that one experiment is seeing no excesses that could be attributed to the Higgs, the other only a very small number of events in one channel (ZZ->4l). It seems not impossible that the results available (publicly or not…) mid-December will come within striking distance of ruling out the Higgs (at 90% or 95% level) over the relevant low mass range.

One interesting aspect of today's data release is that it agrees closely with what Philip Gibbs put together back in September. For more about this, see here, especially this plot. In the past, many have speculated that the first observation of the Higgs would be reported on a blog. Now, it's looking not unlikely that a possible exclusion of the Higgs will be first reported at viXra log…

Update: CMS has released a video including footage of their internal discussions back in August when they decided not to release the ATLAS/CMS combination. There's no real explanation of what changed, but by November people's concerns had been addressed and they decided to release the combination.

Comments

1. **Kid Icarus**
   November 18, 2011

   But Peter, isn't news that the FTL neutrino experiment has been duplicated at CERN worthy of comment? Everybody's talking about it….

2. **Bernhard**
   November 18, 2011

   Kid Icarus,

   The experiment was not duplicated. It is the same OPERA experiment that did the measurement not another independent experiment. What they did was to repeat the measurement with very short beam pulses from CERN, which allowed the extraction time of the protons that lead to the neutrino beam. Since this more precise measurement did not change the conclusion the only thing one can say is that this specific source of systematic error was not responsible for the anomaly. Does not mean that there aren´t others. Until another experiment confirms it (most likely disprove it) the best bet is still a unknown source of systematics.

3. **Peter Woit**
   November 18, 2011

   Kid Icarus,

   As Bernhard points out, this is just the same experiment, with one of many sources of error removed. I still don't believe the result, and think it's getting way, way, way too much attention for something that is almost certainly wrong. Then, there's the added fact that I don't know anything much about the experiment, so it would be silly for me to write much about it here. As in many cases like this, I urge anyone interested in HEP to also follow the Resonaances blog, as well as Tommaso Dorigo's. They actually know something, and in this case I think Tommaso knows some of the people involve and has spent some time trying to understand the result. He has a bunch of postings up about it, I'm not going to compete with that…

   On the other hand, the Higgs story seems to me incredibly exciting, I can't figure out why people would rather talk about superluminal neutrinos at this moment in history…

4. **Bernhard**
   November 18, 2011

   And back to the Higgs, if the SM Higgs is excluded we are probably going to see a huge increase of interest in WW scattering.

5. **Amitabha**
   November 18, 2011

   Bernhard,

   Some of us expected some increase of interest in WW scattering already, but alas, few actually seem to care.

6. **Anonymouse**
   November 19, 2011

   Just remember to catch the bear (SM Higgs exclusion) before selling its skin (strong WW scattering). And please relax: this is science, not football.

7. **Anonyrat**

November 19, 2011

Tommaso Dorigo reads the same charts and thinks the Higgs will show up at 119 GeV.
http://www.science20.com/quantum_diaries_survivor/lhc_combination_higgs_limits_mh141_gev-84800

"In the lower part of the figure you see (black curve with blue "one-sigma" band overlaid) the "best fit" Higgs cross section, again in SM units. Here you see that while the 135-150 GeV fluctuation is only consistent with a Higgs boson that has a cross section much smaller than SM predicts, the 120 GeV one is in the right range: in other words, a 120 GeV Higgs (or rather, 119 GeV Higgs, as I predicted some time ago) would fit the bill quite nicely.

At the 2012 winter conferences ATLAS and CMS will present their search results employing three-times more statistics -all the data collected in 2011. By then we will know more about the possibility that the 120-GeV fluke is the real thing. "

8. **Anonyrat**
November 19, 2011

Meanwhile an antagonist chooses to highlight this: the scent of SUSY wafting from CERN:
http://arxiv.org/abs/1111.4204

9. **Peter Woit**
November 19, 2011

anonyrat,

I agree with those authors that there is a smell coming from SUSY these days, I just wouldn't describe it as a "delicate perfume"…

10. **Anonymouse**
November 19, 2011

Any respectable theorist, whether working on SUSY or not, knows what it means that somebody says SUSY is nearly killed. Being a polite mouse I will spare our host that knowledge.

11. **Low Math, Meekly Interacting**
November 20, 2011

I don't know if this is something anyone should worry about or not, but I figured I could ask here. I also know that consensus isn't a gold standard of anything in science, but there appear to be very few serious physicists who wouldn't agree that something simply must be going on at the TeV to break electroweak symmetry. The odds in favor of nothing showing up in the LHC appear to be pegged at about the same quantity.

So, fine, if the Higgs is about 120 GeV, that's a fiendishly difficult range for a hadron collider to probe, and it will take a lot more data. Still, some folks are apparently starting to get a little worried. Let's say that fluctuation vanishes. Let's say we see nothing else either.

Out of necessity, only a tiny fraction of collision data is captured, and those events are screened according to some entirely justifiable, but undoubtedly biased, criteria. When do we have to start wondering about missing something? Could a real signal be thrown away?

12. **Peter Woit**
November 20, 2011

LMMI,

I'm sure the current triggering choices being made at the LHC are designed to be optimal for looking for a SM Higgs signal. If it turns out there is no SM Higgs signal, then the question of what the LHC should be looking for to understand electroweak symmetry breaking will become a very important one. One answer will be "some SUSY or multiple Higgs model in which the Higgs is harder to see", and if triggers start being designed to look for these, one might worry about that.

In general though, I think the LHC experimentalists can be relied upon to not pay too much attention to theorists, and design triggers most optimal for picking out interesting classes of events. But in principle the possibility does exist that electroweak symmetry breaking comes from some source we haven't thought of, one that the LHC triggers aren't sensitive to

13. **David Brown**
November 20, 2011

… "some SUSY or multiple Higgs model in which the Higgs is harder to see"… Are there leading candidate theories (references?) for such SUSY or multiple Higgs models?

14. **Peter Woit**
November 20, 2011

For a good overview of many possible such models, see Matt Strassler's page

http://profmattstrassler.com/articles-and-posts/the-higgs-particle/implications-of-higgs-searches-as-of-92011

The problem is that none of these models are well-motivated (i.e. no evidence at all indicating them, and they're significantly more complicated than the SM: you're adding lots of new particles for no good reason other than to avoid conflict with experiment).

15. **Anonymouse**
November 20, 2011

I feel obliged to correct our kind host on this very common misunderstanding he repeats time after time: SUSY versions of the SM are not more complicated because you have to add lots of new particles which are not well motivated. The spectrum is doubled due to a fundamental hypothetical new symmetry of the world, which is something altogether different. I guess our kind host in his daily life multiplies 2×13 by summing one by one from 13 to 26.

16. **ZZZ**
November 20, 2011

Anonymouse, are you saying when you double a quantity, you are not adding anything to it?

17. **Chris Oakley**
November 20, 2011

[The Supersymmetric Black Knight](#) "Come back here! I'll bite your legs off!"

18. **Dave**
November 20, 2011

@Anonymouse
Its not a case of adding a fundamental new symmetry, rather a broken fundamental new symmetry. One needs to explain how the breaking occurs and this adds complications.

19. **Peter Woit**
November 20, 2011

Anonymouse,

I was specifically answering a question about the Higgs, so, in the context of supersymmetry, the point is that no one has seen evidence of any of the multiple Higgs particles needed in that theory. So, one has to go to some trouble to hide the things, a problem that will get worse if a SM-like Higgs is ruled out.

More generally, as Dave points out, what makes supersymmetric extensions of the SM complicated is not the doubling of degrees of freedom, but the huge number (>100) or parameters that must be introduced to describe supersymmetry breaking. In the world of SUSY-dreams, some new physics will be found to dynamically break SUSY and determine those parameters, but even in SUSY-dreamland, the new physics that does this will make for a significantly more complicated theory than the SM.

20. **ohwilleke**
November 20, 2011

@ Anonymouse

Most of the SUSY spectrum not already excluded requires a light Higgs just as much as the SM does. A Higgs exclusion greatly squeezes the parameter space of these models as well, arguably more, since its mass spectrum is more tightly constrained theoretically.

21. **N. Nakanishi**
November 21, 2011

I would like to note that four years ago I proposed a modification of SM in which the Higgs becomes unobservable. In this modification, in which a Weyl gauge field is introduced, manifest covariance, renormalizability, and unitarity are maintained. See, N.N., Prog. Theor. Phys. 118 (2007), 913.

22. **Bernhard**
November 21, 2011

N. Nakanishi,

Are you saying your idea is to have the SM with a mechanism to avoid a possible conflict with experimental data? With no disrespect but that sounds not too impressive. Unless this extension actually produces a measurable difference that can be cached, either than one that cannot, this does not seem to improve our understanding of what´s going on.

23. **N. Nakanishi**
November 21, 2011

Bernhard,
Have you read my paper (arXiv: 0704.2645v2 [hep-th])?
If the Higgs is not found experimentally at all, do you have any idea rescuing SM?

24. **Anti Ant**
November 21, 2011

ZZZ:
What the mouse says is that claiming SUSY adds too many new particles misrepresents the idea.

Chris Oakley:
Nice clip. Love those guys. But life may improve over art: keep posted.

Dave:
You're right, that's the ugly side of it, not the doubling of the spectrum. But this will turn out to be an opportunity to learn, once we have experimental access to the details of the spectrum.

Peter:
You're now completing your previous misleading reply, but you cannot help
your dislike of SUSY showing through. People don't try to "hide things". They try to figure out how the theory might be guided by experiment. There is a world of difference between these opposite ways of putting things. You are transmitting the message that scientists are cheating and fooling themselves while I know many honests physicists who are just trying hard to figure out things. You do a disfavour to science.

Concerning the huge number of parameters related to SUSY breaking that's just the low-energy point of view, which would be wrong to use if you want to gauge the complexity of your theory. You can't say much about how complicated SUSY breaking is till you have experimental information about the spectrum. People also forget that SUSY could've been dead long ago, e.g. if it predicted that scalars should be lighter than fermions. Or disfavored if it predicted the wrong running of gauge couplings.

25. **Bernhard**
November 21, 2011

N. Nakanishi ,

Now I did, nice paper. I was indeed expecting that any model that would make the Higgs unobservable clearly predicted something else and your model cleraly does that:

"in addition to the physical absence of the Higgs boson, slight violationof Lorentz invariance and the existence of a new massive gauge boson."

So that is fine, your first comment made me jump to the wrong conclusion but I anyway should have looked with more attention before criticizing it.

26. **Paolo Valtancoli**
    November 22, 2011

    The requirement of unitary and renormalizability always implies something extra to be discovered beyond the SM. If LHC doesn't find anything new, this means that these requirements are too strong. In fact quantum gravity (and Nature) is in conflict with these requirements and works fine without them.

Still Waiting for Supersymmetry

November 21, 2011
Categories: This Week's Hype

The headline story at the APS Physics site is Still Waiting for Supersymmetry, by Sven Heinemeyer, which reports on a PRL article from CMS reporting no evidence for supersymmetry.

According to Heinemeyer:

> It's important to realize that CMS's results do not exclude supersymmetric theories. Rather, they only conclusively say one of two things. One possibility is that the CMSSM (the specialized version of the MSSM) is realized in nature, but the supersymmetric partner particles, the gluinos and squarks, are relatively heavy—too heavy to be produced in large numbers at the LHC so far…
>
> The other interpretation is even simpler: while supersymmetry is realized in nature, it might not take the form described by the CMSSM, but possibly that of any one of the many (GUT scale) models. Different versions of supersymmetry make different predictions for the outcomes of high-energy proton-proton collisions. Many of these outcomes are more complicated than what is shown in Fig. 1, and to see them would require experiments to investigate many more collisions (and to study them for a longer time). Consequently, in these other models, it will only be possible to place much weaker bounds on the new particle masses (so far, however, no such dedicated analysis has been performed).

I would have thought that there's an even simpler third alternative: no supersymmetry in nature at all, but I'm not a SUSY phenomenologist…

Comments

1. **neo**
November 21, 2011

Einstein was once asked what he would conclude had the evidence of the deflection of light by the sun not supported the theory of genral relativity. He answered something along the lines of "that would be too bad for the evidence, because general relativity theory is too beautiful not to be true." Is SUSY too beautiful not to be true?

"It is difficult to get a man to understand something, when his salary depends upon his not understanding it!" — Upton Sinclair

3. **Peter Woit**
November 21, 2011

neo,

No.

4. **N. Nakanishi**
November 22, 2011

Neo

General relativity was quantitatively confirmed by the perihekion shift of Mercury before the observation of the deflection of light. On the other hand, SUSY has absolutely no experimental support.

5. **Henry Bolden**
November 22, 2011

The supersymmetry debacle was predicted by the The Everly Brothers:

Wake up, little SUSY, wake up
Wake up, little SUSY, wake up
We've both been sound asleep, wake up, little SUSY, and weep
The movie's over, it's four o'clock, and we're in trouble deep
Wake up little SUSY
Wake up little SUSY, well

6. **Bernhard**
November 22, 2011

That Sven wants to give SUSY the benefit of doubt is fine of course. Technically speaking he is correct (SUSY is indeed not excluded). But he is being deliberately misleading in not talking about the third possibility that SUSY might simply not be realized in nature and to say this out loud. All in all I think it is not nice APS asks a SUSY fanatic to talk about an article that is clearly not good for the SUSY idea without asking also an anti-SUSY person to make a counter comment in the name of keeping the discussion two-sided. This is not healthy.

7. **Cesar Laia**
November 22, 2011

Comments here are too harsh, I think. I am a layman, but I clearly see "…suggests that if the theory is correct, it may be more complicated to discover these particles than previously thought."

So, he states "if the theory is correct" and then goes on. I don't see the problem with this.

8. **Bernhard**
November 22, 2011

Cesar Laia,

Of course Sven did not forget the usual caveats, but this is in my opinion not putting all possibilities with the same weight. If we add the fact that the particular article he is talking about should lean to the possibility he does not explicitly discuss this is even worse.

9. **William Tell**
November 22, 2011

Time will tell and put everybody in place.

10. **Peter Woit**
November 22, 2011

Cesar Laia,

What you're quoting is from the headline summary of the article, something which is normally not written by the author, but by an editor. The normal complaint is that physicists write something accurate, and the editor then hypes the story in the headline. Here, the physicist is writing inaccurate hype, and the editor is correcting the story in the headline.

To be clear, I don't think Heinemeyer is unaware of the logical possibility of no SUSY, but it's psychologically interesting that he can't bring himself to mention this in print.

11. **CIP**
November 22, 2011

Or perhaps the squark, like the snark*, is a boojum.

*with apologies to Lewis Carroll

12. **Philip Gibbs**
November 22, 2011

Peter, he is not giving a list of all the logical possibilities. He is giving a list of the possible things that can be said "conclusively" from the CMS results. In the first sentence he makes this clear and he says explicitly that excluding supersymmetry is not on that list.

13. **Peter Woit**
November 22, 2011

Philip,

I'm sure one can come up with a strained reading of the text involving unmentioned other "inconclusive" possibilities, and, again, of course Heinemeyer is aware of the non-SUSY case and would not deny it is possible.

Still, I think a straight-forward reading of the text as written is that there are only two interpretations of the data he is willing to refer to explicitly and discuss: one is that SUSY partners are too heavy to see, the other is that they are hiding.

14. **Cesar Laia**
November 22, 2011

I made the remark because that headline looked to me as an abstract written by the author, not a feature added by the editor. And to me it is an useful statement about the point of view discussed further in the article. It looks like a good paper, anyway, although I am not a physicist so I miss details. The editors of that journal should consider to give an opportunity for other to express non-SUSY alternatives, no doubt. But that is not the problem of the author, I think, he expresses only is point of view.

15. **Philip Gibbs**
November 22, 2011

Peter, I am just reading it as it is written. It is your reading that is the strained one because you are always looking for your particular angle which is that the theorists are not willing to accept that supersymmetry has failed (which it has not yet).

That angle is not there in this story. Nowhere does it imply that supersymmetry must be found. The bold line below the heading uses the phrase "if the theory is correct" . I can see nothing unbalanced there at all.

16. **Peter Woit**
November 22, 2011

Philip,

People can read the thing and make up their own minds whose reading is strained. The only place you or anyone else has pointed to in the article that mentions the possibility that SUSY may not be realized in nature is the headline, which usually is written not by the author, but by an editor.

17. **SpearMarktheSecond**
November 22, 2011

Someone used to say… SUSY has no experimental support, but it has withstood the test of time.

There are lots of contrived aspects of the current SUSY models… not one of them is as beautiful as General Relativity. But the non-GR part of the Standard Model is pretty darned ugly too… where does the ratio of the mass of the top quark to the mass of the up quark come from?

The excitement of the LHC is like what Columbus and his crew must have felt when they sailed westward. And that is sufficient!

What is distressing about the hype is that it has setup a sense of disappointment if SUSY is not there. I don't care, the great value is in *knowing*, even if that is knowing that SUSY is absent at LHC mass scales.

18. **emile**

November 22, 2011

"It's important to realize that CMS's results do not exclude supersymmetric theories."
What if he had said: "I think it is important to realize that SUSY theories cannot be excluded." I think that would have been more helpful to the reader…

19. **flog**
November 22, 2011

Flogging a dead horse? SUSY will never be disproved. Epicycles were never explicitly disproved. The luminiferous ether was never explicitly disproved. In both cases they just kept getting more and more contrived as new data came in. Also in both cases, an alternative theory came along which could do a better job of explaining the facts, and which did not require fine-tuning every time more data was found. People just lost interest in the outmoded clumsy way of doing things. SUSY will only go away when a new theory comes along that can explain things better. But there is no compelling alternative which does a better job.

20. **srp**
November 22, 2011

Do ellipses have fewer free parameters than epicycles (and equants and eccentrics?) That sort of inductivist criterion, while fine for assessing rival models within known-to-be-stationary, common data generation processes (such as pattern-recognizing neural nets), flops for comparing theories with non-stationary or overlapping but distinct predictive domains. The theory that the farmer loves the chicken and that his morning visits are for feeding purposes parsimoniously explains the data right up until the chicken is fat enough and gets slaughtered. Then the more complex theory that the farmer has extrinsic reasons for feeding the chicken looks a lot better, even though it has a lot of free parameters about how fat the chicken should be depending on prices for feed and for chicken parts.

I'm sympathetic with our host, but a lot of non-systematizable judgment is needed in order to decide when more theoretical complexity is called for.

21. **N. Nakanishi**
November 22, 2011

Certainly, SUSY may be beautiful mathematically, but as a physics, it is evidently violated very badly. There is no Nambu-Goldstone fermion. If one wishes to use the super-Higgs mechanism, one has to introduce supergravity. However, quantum supergravity is a very ugly theory! There is no SUSY-invariant gauge fixing. The SUSY anticommutation relation for global super-charges no longer holds because of index mismatch (Note that gamma matrix is a local quantity; there is no global quantity having the same set of indices as gamma matrix in the framework of supergravity).

22. **Shantanu**
November 23, 2011

Peter, is there a similar sentiment on extra-dimension models or people have resigned
to the fact these are all ruled out.
(I asked this question to Lisa Randall when she did a guest post on cosmicvariance, but didn't receive any response),

23. **Sven**
November 23, 2011

Hi,
I feel I should also say a few words here…

The journal asked me to write a layman explanation of the CMS paper, which deals
with the search for SUSY. They did not see any excess and set limits. The real question is how these limits are to be interpreted. Interestingly, many people draw wrong conclusions from this kind of limits. I tried to convey what these limits really mean. Nothing more, nothing less.

Any negative search that sets a limit can of course be interpreted as an indication that the 'object' searched for does not exist. However, this was not the question here. On top of that, the consequence would be to consider that nothing beyond what
we know for sure so far exists: no Higgs, no SUSY, no extra dimensions, … because the LHC did not see anything new so far. Not a very helpful approach in my opinion.

On the other hand, I would be interested whether I succeeded to explain the consequences of the SUSY searches published by CMS in a comprehensible way.

24. **Peter Woit**
November 23, 2011

Thanks Sven,

It seemed to me your article avoids mentioning the elephant in the room: not finding SUSY evidence of the sort many people were expecting does throw more doubt on the whole idea of TeV-scale SUSY. There really are three possibilities here worth mentioning, not just two…

25. **Anon**
November 23, 2011

From logic there can be only two definitive resolutions on supersymmetry: 1) it exists (direct or indirect observation of behavior predicted by or indicative of it) or 2) it does not (every single variant and flavour of it has been disproven experimantally. Which would be an immensly daring task indeed). Everything in between would be little more than ideology exchanges between theorists' camps (at least for a long long time before not yet disproven parameter space of supersymmetry would start drying up).
Want something more productive? Sure, just come up with an alternative theory that would achieve at least the same results as SUSY with superior observability and testability in experiment!

26. **Peter Woit**
November 23, 2011

Shantanu,

In the extra dimensions case I think very few people ever seriously thought these would be seen at the LHC. So the LHC results just move the bounds up, and in a few years when the LHC runs at full energy, there will be another jump in the bounds. This is all just what was expected, so no one is talking about it. One can of course keep going working on such ideas, saying the scale is just higher up, but there's likely to be less interest in this.

27. **helvio**

November 24, 2011

Gauge coupling unification, which can be extrapolated from current data to be an exact match at some very high energy (unlike the prediction from the Standard Model as it stands), is experimental evidence albeit indirect. Explain that without SUSY, in a simpler way.

28. **archytas**
November 24, 2011

Here is something that might amuse you all.

I was re-watching the Elegant Universe the other day, and I noticed that Brian Green explicitly states that supersymmetry is a "central prediction of string theory."

If you want to find the quote, it is in the latter part of the program when they talk CERN.

29. **Eric**
November 24, 2011

Supersymmetry is a prediction of string theory since it is inconsistent without it. However, this does not necessarily mean low-energy supersymmetry which is observable at the LHC or other colliders. As far as string theory is concerned, supersymmetry can be broken at any scale below the string scale. So, if SUSY is not observed for LHC, this has absolutely no implications regarding whether or not string theory is correct.

The reason for believing in low-scale supersymmetry is that it may allow several phenomenological issues relevant to the Standard Model to be elegantly resolved. These issues are the stability of the Higgs mass against quantum corrections, the apparent unification of the gauge couplings, and a natural dark matter candidate. The existence of a light Higgs boson which is an elementary scalar and low-energy supersymmetry are really tied together.

30. **Beelzebud**
November 25, 2011

It just strikes me as rather convenient that people declare SUSY as a central prediction of string theory, and then also say that if SUSY isn't found that is has absolutely no implications for string theory.

I don't have to be a genius to see the problems with this. After awhile it just looks like a classic case of moving the goal posts around, every time you don't get the results you hoped for.

31. **Eric**
November 25, 2011

Beelzebud,

You seem to be missing the fact that, although supersymmetry is a necessary component of string theory, the scale at which it is broken is not fixed. Supersymmetry may only be observed at the LHC if it is broken at a relatively low scale. If it broken at higher scales, it will not be seen. As I stated, there are phenomenological reasons for believing in low-scale SUSY which have nothing to do with string theory. If SUSY is observed at the LHC, then this will provide support for string theory, but does not prove that it is correct. One can have supersymmetric point particle theories without any connections to strings. Conversely, the non-observation of supersymmetry at the LHC would only show that SUSY is broken at a higher mass scale, if it exists.

32. **Peter Woit**
November 25, 2011

Eric,

The problem is that, in places like Brian's NOVA series, the public was told something like "string theory does make predictions: it predicts supersymmetry, and this will be tested at the LHC". One can be sure that if SUSY had (or does…) show up at the LHC, string theory enthusiasts would be vigorously claiming it as a confirmation of a string theory prediction. Not telling the public that no SUSY at the LHC was fine for string theory, since string theory really makes no predictions of the usual sort, was kind of misleading. I think the people doing it did believe that SUSY was likely to show up at the LHC and they would be vindicated. Now they're trying to get away with claiming it wasn't a real prediction. There's an obvious attempt here to have it both ways…

33. **Eric**
November 25, 2011

Peter,

The statement, "string theory does make predictions: it predicts supersymmetry, and this will be tested at the LHC" is technically correct. It does predict supersymmetry and this can be tested at the LHC, so I really don't see your problem. You seem to be incorrectly interpreting this statement as saying that string theory predicts that supersymmetry should be observed at the LHC. If string theory is correct, then supersymmetry might be observed at the LHC, which is much different than saying that it predicts that it should be seen.

If supersymmetry is found at the LHC, then this would indeed constitute evidence in favor of string theory, although it does not prove it is correct. However, you cannot claim that the a non-observation of supersymmetry disproves string theory since string theory minimally only requires unbroken supersymmetry at the string scale.

34. **Eric**
November 25, 2011

Also, it should really be pointed out that the expectation of seeing supersymmetry at the LHC comes from particle phenomenology rather than string theory. I do think that you have a tendency to give people the wrong impression about this.

35. **Bob Levine**
November 25, 2011

@Eric

"The statement, "string theory does make predictions: it predicts supersymmetry, and this will be tested at the LHC" is technically correct. It does predict supersymmetry and this can be tested at the LHC, so I really don't see your problem. You seem to be incorrectly interpreting this statement as saying that string theory predicts that supersymmetry should be observed at the LHC. If string theory is correct, then supersymmetry might be observed at the LHC, which is much different than saying that it predicts that it should be seen."

————————————————
I really *don't* think so, Eric. Putting an hypothesis in an experimental situation where in principle its *in*validity cannot be tested—where it can be confirmed if it's true, but not ruled out under any of the experimental protocols in question—is not what most of us understand as a 'test' of that hypothesis. It's precisely this sort of disingenuousness that makes statements like Greene's so suspect. If the lab conditions involved don't make it possible to disconfirm, please *don't* pretend you're "testing" the proposal. And note also that it doesn't help that Greene said, not 'can/might be tested' as per your gloss, but *will* be tested.

36. **Eric**
November 25, 2011

Dear Bob Levine,

As in Peter's case, I believe that you are misinterpreting Brian Greene's statement, which has two points:

1) String theory predicts supersymmetry
2) Supersymmetry will be tested at the LHC.

Each point separately is completely correct. However, you are combining these two points into a single point claiming that string theory will be tested at the LHC. This does not follow logically.

As I clearly stated, the observation or non-observation of SUSY at LHC does not prove or disprove string theory. However, the observation of SUSY would, in fact, provide experimental support for string theory. This is all that Brian Greene is saying, nothing more, nothing less.

37. **Bob Levine**
November 25, 2011

No, Eric, I'm misinterpreting nothing. I was not talking about string theory at all, and I wonder why you thought I was. The defense of SUSY against its no-show at the LHC is, as you yourself have expressed it, that the energy regime of the breaking scale may be higher than what can be tested at the LHC, so that nothing that happens at the LHC can disprove SUSY; all that can happen at the LHC is that observations might confirm SUSY. So in what sense will SUSY actually be *tested*?? And that's the problem with both what Greene says and what you say: string theory or no string theory, Greene is making an unjustifiable claim when he says that 'this ([i.e. supersymmetry] will be tested at the LHC', and you are making the same unjustifiable claim in defending his statement. An experiment which cannot in principle exclude a particular family of hypothesis can in no sense be said to *test* that hypothesis. Why is this conclusion even slightly contentious?

38. **EDR**
November 26, 2011

Dear Bob Levine and Eric,

I agree with Bob's criticism that the most natural reading of Brian Greene's statement is misleading.

This does, however, raise the question of how best to make a brief statement that suggests something more like: "If the LHC were to find evidence supporting supersymmetry, this would give a significant (though utterly inconclusive) measure of support to string theory."

The word 'test' is misleading in Greene's context. What word or phrase would be better?

39. **Eric**
November 26, 2011

Dear Bob,

What is being tested at the LHC is low-energy supersymmetry. More specifically, the theory that low-energy SUSY solves the hierarchy problem, provides the dark matter, and allows the gauge couplings to be unified is what is being tested. Yes, the scale of SUSY can be pushed higher if the superpartners are not observed at the LHC. However, in this case, SUSY cannot solve the above problems.

40. **Bernhard**
November 26, 2011

Eric,

The statement Greene should have made is that SUSY is a testable theory and it will be tested at the LHC. Discovering SUSY would be supportive of string theory but in no way a test of it since of string theory is not a testable theory. Not finding SUSY or not finding anything at the LHC would not contradict string theory. You expect people to consider the two statements of Greene separately but for crying out loud this is the definition of a misleading way of arguing even if it were to agree with you that it is logically correct. Mind you also that even some physicists not very much into SUSY or strings might get the wrong idea, what to say the layman, which is Greene ´s target.

The Infinity Puzzle

November 22, 2011
Categories: Book Reviews

There's a fascinating new book by Frank Close out this week about the history of the Standard Model, called The Infinity Puzzle. Until now I've always recommended The Second Creation, by Crease and Mann, as the best popular book for this history, but Close's new book gives that one a run for its money. While Crease and Mann is a comprehensive overview, covering theory and experiment, as well as a longer time-frame, Close gives an insider's look focused on the decade or so that led up to the Standard Model coming together around 1973.

Knowing the history of a subject has always seemed to me an integral part of really understanding it, so I'd argue that anyone who wants to really understand modern particle physics should spend some time with a book like this. In addition, there's an outside chance we may soon be seeing the collapse of one of the central pillars of the Standard Model, the Higgs field, and if this happens, an understanding of where the Higgs came from may very well be relevant to anyone who wants to think about how to live without it.

About a year ago I spent some time looking into the history of what I think is best called the Anderson-Higgs mechanism, writing a long posting about it here. Particle physicists have long overlooked the fact that it was condensed matter theorist Philip Anderson who not only first understood the basic physics that was going on, but even wrote a paper aimed at explaining it to particle theorists (which they ignored). Anderson's insights grew out of his work on the BCS theory of superconductivity, a subject in which the role of gauge invariance was not so easily understood. If the Higgs field needs to be replaced, the analogy with BCS theory might provide a clue about what could replace it. Another book I've been reading recently is a collection of Anderson's essays, called More and Different: notes from a thoughtful curmudgeon. Many of the people and topics he discusses there are much less familiar to me, but I confess to enjoying the curmudgeonly tone, and wishing I knew more about the history and physics behind the superconductivity research that he describes. Included in his collection is a review of my book I was very pleased by. His prediction about what the LHC will see is one I'm very sympathetic to: no supersymmetry, and "we will probably discover unexpected complexity in the Higgs phenomenon."

Anderson is justifiably scornful that the APS awarded the ~~Dannie Heinemann prize~~ for work on the Higgs to no less than ~~seven~~ people, managing to leave out Anderson. Close gives Anderson his due, but also gives by far the most detailed and well-researched account available of the work of Higgs, Brout, Englert, Guralnik, Hagen and Kibble in this area. He puts the most dramatic revelation from his research in a footnote (page 388):
