Something I ran across that seems worth thinking about, coming at the issue from the supposed opposite side of the political spectrum, an article in the Washington Post advising us what to do about Trump, based on the author’s experiences with Chavismo in Venezuela.

https://www.washingtonpost.com/posteverything/wp/2017/01/27/in-venezuela-we-couldnt-stop-chavez-dont-make-the-same-mistakes-we-did/

January 29, 2017

One positive way forward is suggested by “Justice Democrats”, supported by Cenk Uygur of TYT along with former Bernie staffers. TYT also supports the long-term solution of
overturning Citizens’ United through state-by-state referendum: WoflPac.com. Bernie’s movement Our Revolution is also a great way forward.

Mathematicians should keep in mind part of how we got in this mess: that a brilliant computer scientist Robert Mercer, CEO of Renaissance Technology (after Jim Simons stepped down) and his daughter Rebekka are responsible for bringing us Bannon, Kellyanne Conway and Trump. Unfortunately, Jim Simons’ many wonderful contributions to math, science and the environment will probably
be overshadowed 10,000 times by Mercer’s negative counterweight.

Koch, Adelson, Mercer and other extremist billionaires have been following a clever long-term game, and the same game is playing out in other countries- sometimes with the same monies- what is going on now in Brazil, England, France, and Germany is scarily similar.

So we may soon have no islands of hope or sanity left, which will make resistance even more difficult. The opposition is revitalized with all the looming disasters, but largely depends on the internet- email, social media, You Tube- for organizing and exchange of real information. So Bannon surely has a plan to attack not just the MSM (with threats as well as insults) but more importantly to kill the internet as we know it. Trump’s pick for FCC head wants to kill net neutrality, a huge step in that direction. Divide and conquer will always be the weapon of choice:
a lot of powerful people will stand to make a killing off of that.

Trump is not only repellent and odious in many of his policies but ignorant, incurious, unstable and incompetent, as we are now seeing on a daily basis. He has just doubled the yearly membership at Mar-A Lago to $200,000, so he is selling access to himself, a clear violation of the Constitution. Similarly he’s profiting from his Wash DC hotel and violating the lease. These are just a few of the rapidly accumulating clear grounds for impeachment, but the numbers and popular will is not there.

It is imperative in any case (whether or not impeachment can happen) to get the truth out to the broad base of citizens. Also, it is critical for the opposition to preserve/regain its integrity. When Clintonite Dems attack Trump on the basis of Russian hacking or worse, attacking him for stopping the TPP, they are guaranteeing continued suicide. When they roll over and compromise, ditto. That is why efforts like TYT and Bernie’s are so important. We need to have our own Tea Party, we need

local organizing and local candidates; we need to play the long game like the radical right has been doing for 40 years. We need to get personally involved. We need to meet our neighbors, and discuss politics through local issues that touch them on a daily basis.
TYT has done a great job of reporting on the Disappearing Middle Class- that's an example of the outreach that is necessary.

Also, nonviolence is absolutely fundamental. The indigenous people at NO DAPL have been giving us all profound lessons in the effectiveness and the necessity of these tactics and of the deep spiritual orientation behind it. The presence of 4000 veterans there was deeply moving and must be just the beginning.

The fascists will do their best to provoke violence, even terrorist attacks. That will give them the excuse for rounding people up with 35 year sentences, $850,000 fines like with Barrett Brown or Josh Fox's producer Deia Schlosberg. We must not play into their hands. This will take a lot of patience, commitment and wisdom.

These are dark times, but we have no choice.

Oh, and we will have to start encrypting our hard drives and emails…The Intercept
has some info on this.

32. **Mike Harney**
January 29, 2017

The only thing left that would give the executive branch more power is for good people to stand by and do nothing. I think civil protests are the best action in the short term, we still (at least for today) have freedom of speech and we need to use it. That's the only way I can see the Republicans in Congress reacting to turn the situation around.

33. **Frank Wilhoit**
January 29, 2017

The only positive idea is to leave an absolutely clear, explicit, forthright, comprehensive, and unsparing account for history, because history is the only audience. If that last clause violates the terms of the comment moderation, so be it; pretending is not one of ours, it is one of theirs.

34. **MW**
January 29, 2017

There are minor efforts underway protest the ban outside the US.

For example, in the UK a petition to prevent's Trump's trip to the UK being a State visit has over 700,000 signatures. That is way more than the 100,000 needed to get it discussed in Parliament. It's not much, but at least it is a mechanism to make our voices heard.

https://petition.parliament.uk/petitions/171928

35. **Jeff M**
January 29, 2017

FYI faculty at my school are pushing hard for administration response to this, and working on setting up safe places for students affected by the order. From what I can tell from the faculty email list, it's happening at many universities.

36. **Abby yorker**
January 29, 2017

Not to be too picky but the following sentence seems to imply that a military coup is constitutional. I hope that that is not the case.

'Other than something like a military coup, the only constitutional way out of this is impeachment or the 25th amendment route.'

37. **Frankel**
January 29, 2017

The solution is for this blog to finally give up its silly war against string theorists and multiverse advocates. With a full acceptance of the MWI we can all exist in a universe where Trump is impeached.

38. **Peter Woit**
January 29, 2017

Abby yorker,

Thanks, that was badly worded and now fixed.

Hard to imagine how a military coup would work here, but I have to say, seeing what has happened to the political system in this country recently, you start to understand why in many places a military coup may seem like one of the better options.

39. **Robert Gauthier**
January 29, 2017

I think we need to consider the possibility that the outrages perpetrated by the Trump administration in the last two days are an overt attempt to incite the sort of response that will allow them to declare martial law and dismantle what is left of legal challenges to their full takeover.

40. **Florin Moldoveanu**
January 29, 2017

I agree with Anonyrat

Right now:
Call your representative's office in Washington DC and talk to the staff who take the call.

Later:
Vote against the politicians who supported Trump.

41. **Blake Gentry**
January 30, 2017

Martial law is resisted by mass movements, not visits to congressional offices.

The emoting here appears to suggest several lines of analysis: One is a liberal line that seeks to contain an authoritarian presidency through constitutional legal channels on executive orders (vis a vis "donate more to ACLU") another seeks to impeach by his violation of the ban on accepting "foreign gifts" (can be neutralized if Supreme Court Majority is installed in his favor), others consider political pressure against moderate members of his party (they failed to coalesce against him before the general election, and will not now either since there is too much money to be made by lobbyists), and others suggest general rejection and some types of street actions to oppose specific orders or acts.

The former Bernie Sanders staff and Bernie himself have not articulated movement through mass organizing, but through donations. Really? That's it?

What Europe and Latin America can offer is how to organize mass movements to stop military control, if it gets to that. Such movements cannot wait until the last moment to realize electoral politics is dead, they must create a movement on the ground to resist. Parallel politic movements can attempt to upend the corrupted political system politically engineered by Citizens United, but most of us need to have local mobilizations to show force in the streets. If you are really afraid of fascism, then own the streets before they own you. Ukraine is a case in point. Prague is as well. Santiago de Chile waited too late.

If Trump tries to impose sanctions on major cities who resist compliance with ICE against immigrants, then those cities can call for major progressive strikes. Start with the airlines, move to public transport, and interrupt businesses as usual, and yes that means your sacred universities as well. Block production of pipelines and well heads. Close down ports. The capital interests in this country will then move to remove him if that is the cost of stopping such "free speech".

If thousands of people had waited to call their representatives offices instead of arriving at airports last night, if the Women's March did not occur, if there was no march on Selma, or the Sit down strikes in Chicago and Flint, we'd be facing small militias with guns terrorizing the citizenry. The Vietnam war war was not ended with visits to congressional offices. It took a nation of people protesting and fighting back.

Stop thinking as if the middle class is going to arrest this situation. The middle class was sold down the river in the crash of 2008 and that is why millions voted for Trump. The Occupy Movement refused to target infrastructure, and insisted on consensus. Consensus in a mass movement is an oxymoron, those are tactics of the state.

That is also what democracy can look like. Many may cringe at these suggestions, but you will cringe more when the beat the shit out of people on the street and you realize then -too late – that your friends are next. Start your own Local Movement of Resistance, in this you are constitutionally bound to act as a citizen of the United States. Hope that's positive enough.

All my relations.

PS
It takes a child to raze a village, but only if the village watches itself burn to the ground.

42. **martibal**
January 30, 2017

Could be of interest: a detailed analysis on what is going on, and what may happen next
https://medium.com/@yonatanzunger/trial-balloon-for-a-coup-e024990891d5#.g8k084pfz
Interesting also the idea that the muslim ban could be a diversion for public not to pay attention to the raise of Bannon to the national security council.
One question from a non US citizen: to what extend do single state have possibility to resist (e.g. in the scenario of terrorist attack = emergency state = more power for Trump, is there some piece of the army that depends on states and not on the federal government ?)

43. **Maurice**
January 30, 2017

Positive ideas, drawing lessons from what happened in Germany 1933.
Firstly I agree with Peter that the parallels are close:
1. I compared Trump's with Hitler's "inauguration speech" (there was no such thing in the Weimar constitution, it was his first public speech as chancellor on February, 10 1933). They are strikingly similar, as if Bannon had used Hitler's manuscript to draft Trump's address: same subject, same slogans, same omissions.
2. The "violent event" that Peter rightly fears, was the fire in the German parliament, about one month after Hitler came to power. This event marked the beginning of pure Nazi terror.

Positive conclusions for American liberals from the major mistakes of Hitler's opponents:

1. unite against Trump even with Americans whose views you detest. I am convinced
that there are many ultra-conservative anti-liberal Americans who are still firmly against being governed by a fascist regime in Washington. All other political issues have to take a complete backseat in this time of imminent danger to democracy in the US.

In the Germany of 1933 social democrats and communists, extremely hostile against each other before Hitler, while both being firmly anti-Nazi never united their forces against Hitler and in support of the Weimar republic.

2. organize a general strike against Trump.

I know such an action is very unusual for the US. In Germany it never was, and that it was not attempted against Hitler is seen by many historians as a major factor for Hitler's success to become dictator.

While it is true that a strike of students and professors of a university does not really bring public life to a halt, it would still be a very strong sign of resistance.

44. **Anonyrat**
January 30, 2017

Blake Gentry:

The unorganized individual can only work through Constitutional means; anything more needs organization and/or numbers. The individual is too vulnerable in acting alone in using extra-Constitutional methods.

I don't know if our host wants us to discuss this here.

45. **bks**

January 30, 2017

Scientists' March On Washington:
https://www.marchforscience.com/
I recently re-watched *Fail-Safe* (1964). Not good for 3am ruminations!

46. **GlenO**
January 30, 2017

In my opinion the most likely trigger for a martial law situation is a premature or excessive action in opposition. We have survived bad presidents before, and I think going outside the constitutional remedy for bad presidents (impeachment) would be a cure much worse than the disease. The only course forward I can see is to try to channel Trump's egoism into more positive directions, such as his stated desire to create jobs, and save the demonstrations, work stoppages, etc for responding to negative actions on his part. Otherwise it looks like sore-loserism, and will only be counter-productive

47. **Low Math, Meekly Interacting**
January 30, 2017

To all those suggesting more radically subversive approaches to combating the problem of Trump: Let me concur with those proposing you will be giving the current administration EXACTLY what they want and need to justify imposition of more authoritarian measures to suppress even lawful opposition. Don't do it.

48. **Fred P**
January 30, 2017

"How does one get the Republican establishment (legislators and/or Fox News, Wall Street Journal, etc.) to turn on Trump?"
– you have to make it more palatable for them to help out the protesters than to stick with Trump. That said, while I've helped swing congresspeople on individual votes, I've never swung one against a President. Here's a guide that may help:

https://www.indivisibleguide.com/web

49. **Anonyrat**
January 30, 2017

Back in 2007, my then-representative, Rush Holt (NJ-D), who has since retired from Congress and is now CEO of the American Association for the Advancement of Science (AAAS), in a townhall that I attended, addressed the issue of impeachment of the then-incumbent George Bush.

Holt entered Congress in 1998, he believed at least in part because of reaction to the impeachment of Clinton which he condemned as a partisan affair.

Holt said there were two preconditions for impeachment:

1. That impeachment not be seen as a partisan issue.
2. The vast majority of Americans need to sign on to impeachment.

Holt thought that Bush had committed impeachable offenses, but that most Americans did not understand what was at stake. Also, no Republicans had signed on to impeachment, and Holt feared that that if a substantial minority – even 25% – begin to have the attitude that "we lost the last elections, but we have impeachment – the country is in trouble".

Since neither precondition was satisfied he was not signing on to the proposed impeachment bill, HR 333.

Holt thought that (paraphrasing) rather than having this neon sign "Impeachment" at which half the country would turn one way and half the other, it was important to firmly mark out that "Habeas Corpus cannot be suspended", "Wire-tapping without a court warrant will not be allowed", etc.; impeachment in the current political climate would only be a distraction.

IMO, Holt's objections still hold some force, and before calling for impeachment or a 25th Amendment removal of Trump, these objections should be considered. They also square with the advice of the Venezuelan who wrote about opposing Hugo Chavez:

Attempting to force Trump out, rather than digging in to fight his agenda, would just distract the public from whatever failed policies the administration is making. In Venezuela, the opposition focused on trying to reject the dictator by any means possible — when we should have just kept pointing out how badly Chávez's rule was hurting the very people he claimed to be serving.

50. **martibal**
January 30, 2017

About the attack in Quebec, this morning on the Quebec news this was called an "attentat terroriste" ("terrorist attack" is a fair traduction I think), not an incident. See e.g. http://ici.radio-canada.ca/nouvelle/1013929/attentat-terroriste-a-quebec-qui-est-le-suspect

51. **Peter Woit**
January 30, 2017

Anonyrat,
A couple points:

1. It never occurred to me that impeaching Bush was a good or viable idea.

2. The Republicans don't share Holt's view at all (see the Bill Clinton case). Do you really think that, if Hilary Clinton had managed to win the election with a minority of the popular vote, the Republican House would not already have drawn up articles of impeachment?. The Republicans have, since the Clinton era, adopted extreme tactics of personal attack to delegitimize their opposition and drive them from power. In recent years this has been extremely successful and it's the cause of why we are where we are. Should the Democrats continue to avoid using such tactics themselves, given where it has gotten them? Sure, impeaching Trump will require widespread public support. Let's figure out how to get that.

All: I'm shutting off comments on this. Having said my piece, I think it best for my sanity to spend time for now on other things than this.

Math and Physics Social Media

February 4, 2017
Categories: Uncategorized

In the current situation, getting back to finding interesting news about math and/or physics to think about seems like a good idea, but I've been having trouble coming up with such news. Besides blogs, many of them listed on the right-hand margin of this one, I also follow some people on Twitter and on Google+. There are quite a few well-known physicists on Twitter at this point. On any given day you can learn something interesting from, for instance, Frank Wilczek or John Preskill (or see an epic throwdown between them).

I'm sure there are many other mathematicians and physicists on social media that I'm not aware of, and open here to hearing suggestions. Part of the problem is that I'm now so old I figure I don't even know what social media sites are out there. I hear there's this thing called Facebook, but also that it's now over as far as the younger generation is concerned. So, if you have a suggestion about where to find high quality news about math or physics on social media, whether it's on Twitter, Google+, Facebook, Live Journal, Instagram, Pinterest, Snapchat, Yik Yak, Grindr or something else I've never heard of, please let us all know in the comments.

Comments

1. **Jon Awbrey**
   February 4, 2017

   I'm not sure social media is supposed to be about super high quality. You could experiment with creating a Facebook community or group page of your own and it would have whatever focus, quality, and scope you could maintain for it. But you'd probably find that FB is more about exploration, immediacy, and yeoperson efforts at public education, in your case about math and physics, if you have the fortitude for that. I always find that communication is far harder than either discovery or invention.

2. **Peter Woit**
   February 4, 2017

   Jon Awbrey,
   To be clear, I have no interest at all myself in participating more in different social media (the blog here is already too much of a time sink). I'm just trying to find out from others what sources of information are available that I might not know about.

3. **Shecky R**
   February 4, 2017

   Will mention 3 (out of a zillion) on Twitter:
   1) Grant Sanderson, for his math videos: @3Blue1Brown
   His YouTube channel here: http://tinyurl.com/grramxt
   2) Brian Hayes, just for interesting stuff (usually, but not always math/computer science): @bit_player
   3) Erica Klarreich (usually on Quanta): @EricaKlarreich

4. **Doug McDonald**
   February 4, 2017

   I look daily at some of the Physics ones you list at right.

   But many others there seem to be extinct. Perhaps a purge?

5. **Magnema**
   February 4, 2017

   Re: Facebook: In my experience, it's one of those things which many (even young) people have and use for "functional" communication (such as group project work with someone you don't know outside of a class), but not for "social" communication. It's like e-mail – it's not something that's cool, but nor is it quite "out" (vs., say, Myspace).

6. **Cesar**
   February 4, 2017

   I'm a big fan of mailing lists.

   I know and participate in lots of them, but none about mathematics or physics. I usually get news about that from blogs (like this one) and websites like Quanta, Nature, etc.

   Searching on Google gives some results. But it appears that most lists are university-specific.
   https://encrypted.google.com/search?q=mathematics+mailing+lists
   https://encrypted.google.com/search?q=physics+mailing+lists

   We could organize a new, general mailing list for enthusiasts.
   It could be one for both physics and mathematics or 2 mailing lists for each subject.
   I would subscribe for sure!

   Anyone in the known up for the task?
   I heard good things about ezmlm.

7. **Bee**
   February 5, 2017

   I think it doesn't matter all that much which social media you use as long as your circle is large enough because stuff gets passed around anyway. Eg, I use facebook, twitter, and (to a lesser extend) G+ (I am also signed up to like a dozen other sites which I don't use though) and I follow a bunch of blogs and magazines and so on. If anything is making rounds at all, it shows up in my feeds not once but dozens of times. (And that's leaving aside the people who, several weeks later, send me the same thing by email asking if I've seen it.)

I gravitate towards facebook because in my experience the discussions work best there. I don't understand how people can have discussions on twitter, the medium just isn't designed for it. Yes, I too have heard young folks don't do facebook. Fine by me.

Of course this doesn't really address the question of all question, where to get new news from, if that's what you're after. Following conference hashtags on twitter and journal feeds is a good way to keep an eye on what's going on. For example, CQG has a blog now, and they're also on twitter. It's too technical stuff to draw a large readership, but at least for my research it's very interesting, see

https://cqgplus.com/
https://twitter.com/CQGplus

There's also of course PRL

https://twitter.com/PhysRevLett

And Nature Physics

https://twitter.com/NaturePhysics

Which I find to be very informative. On facebook, Physics Today is very strong. Other feeds, pages to follow, depending on your interest, are experiments, labs, institutions, and so on.

Just generally, I have found that journals and membership journals and experimental collaborations have a minimum amount of bullshit in their feed. With institutional accounts, there's an unavoidable amount of self-promotion. Eg, the Max Planck Institutes in Germany publish a pretty good magazine (which you can also get in print for free!), which is very well done and so on, but of course it will always tell you what great stuff MPI is doing, so you need some tolerance for that.

8. **Shantanu**
   February 5, 2017

   Peter most of the blogs on the right side are no longer active , or updated regularly.
   on fb there is Astronomers group, which is worth subscribing to for interesting news and issues and also technical group related to astrostatistics and python users in astronomy.
   (I don't know if particle physicists use any similar forum to discuss science or technical issues)

9. **Deane**
   February 5, 2017

   There's a active group of mathematicians on Facebook who engage in conversations about all the usual topics but also often discuss math. In fact, it appears that some people find it to be a more friendly environment for asking math questions than MathOverflow. However, the problem with Facebook is that there is all the other distracting stuff you have to try your best to ignore.

10. **Frank Quednau**
    February 5, 2017

    For programming, stackoverflow.com is indispensable.
    There is also http://math.stackexchange.com and https://physics.stackexchange.com.
    It doesn't fit exactly what you're looking for, but are two good quality Q&A sites on the matters.

11. **Jim Akerlund**
    February 5, 2017

    What about https://www.reddit.com/r/science/. It is moderated.

12. **martibal**
    February 6, 2017

    This is not social media, but could be of interest for those who understand french: the last lectures of Connes at Collège de France,
    http://www.college-de-france.fr/site/alain-connes/course-2017-01-26-14h30.htm
    Till the 19th of january, he talks about "geometry and the quantum". Then it goes more
    towards arithmetic.

13. **Ronan**
    February 6, 2017

    This site http://truesciphi.org/phy.html contains a list of some of the physicists on twitter

14. **Anon**
    February 6, 2017

    What has happened to blogging? Has nothing taken its place? I'm genuinely curious.

15. **tommaso dorigo**
    February 6, 2017

    Hi Peter,

    well, for one thing there's the @cmsvoices twitter account, which I manage this month (it changes every month). I am usually @dorigo

    Cheers,
    T.

16. **anon**
    February 7, 2017

    Peter, go to the Google homepage and type into the search bar: "mathematics" OR "physics", then click news and voila: plenty of fresh maths/physics news to pick from.

17. **Greg Bernhardt**
February 9, 2017

Can’t forget the original https://www.physicsforums.com

Perfectoid Woodstock

February 7, 2017
Categories: Uncategorized

Every year in Tucson the Arizona Winter School takes place, with a five day program on some topic in arithmetic geometry aimed mainly at advanced graduate students, designed to get them involved in current research-level topics. This year's topic (Perfectoid Spaces) is drawing a huge number of people there next month, with about 450 participants expected (in the past numbers were more like 100). This should be a veritable Woodstock of arithmetic geometry, with no one I've talked to quite able to figure this out, thinking that there probably weren't 450 people worldwide interested at all in arithmetic geometry. It seems everyone in the field will be there and then some.

Peter Scholze is the opening and closing act. The other lecturers who will take the stage have started to put lecture notes for their lectures on the school website.

Some are dubious that there really are 400 or so students in the world with the background necessary to understand this material. See for example MathOverflow where nfdc23 isn't very encouraging to a student who doesn't know any rigid analytic geometry, but plans to attend the AWS. In any case, I hear Tucson is quite nice in March.

At some kind of other end of the spectrum of such things, a couple months later experts will gather in Germany to discuss this field (see here). Also for about five days, at the Schloss Elmau Luxury Spa and Cultural Hideaway, the sort of place heads of state go for G7 meetings. Rooms run $600 a night or so, but in this case the tab is being picked up by the Simons Foundation. Sorry, by invitation only.

Comments

1. **Jess Riedel**
   February 8, 2017

   The end result of this, of course, is that grad students pick research topics based almost completely on perceived status rather than technical merit. By the time they have the background, they've devoted 5 years of their life specializing in a subfield, and they are too wedded to the subfield to assess it objectively. This generational inertia lets fads persist longer than they would otherwise.

2. **John Fredsted**
   February 8, 2017

   The put-down comment by nfdc23 at MathOverflow could perhaps be contrasted with the call, by Francis Su, for quite the opposite behaviour in the math community, compare To Live Your Best Life, Do Mathematics.

3. **lf**
   February 8, 2017

   As we say in French "Le ridicule ne tue pas", fortunately because otherwise that would be a real hecatomb these days in the US.

4. **anon**
   February 8, 2017

   "Business casual clothing should be worn during the symposia."

   The first time I remember hearing about dress code for a scientific meeting.

5. **lf**
   February 8, 2017

   "Business casual clothing should be worn during the symposia."

   That's probably to prevent a real Woodstock to happen.

6. **Davide Castelvecchi**
   February 8, 2017

   From what I can tell from the titles, there will be no discussion of Mochizuki's inter-universal Teichmüller theory…

7. **Jeff M**
   February 8, 2017

   Business casual? Wow. That reminds me of the first real conference I went to, at UCLA, in '91, when I was working on my thesis. My wife insisted I go out and buy nice clothes, I kept telling her "it's a math conference, no one will dress up." Suffice it to say I was better dressed than any of the professors.

8. **anon**
   February 8, 2017

   Maybe the posh conference hotel requires some level of formality so that the other guests there are not traumatised 😉

9. **lf**
   February 8, 2017

   Argh, I had not noticed that the dress code was for the Simons conference and not the winter school…thus people can dress like in Woodstock at the winter school.

   More seriously, the theme of the Simons gathering is "p-adic Hodge theory" which encompasses a larger area than the one covered by perfectoid spaces (on the geometric side), typically arithmetic applications of p-adic Hodge theory like you will find in the proof of the STW conjecture, Serre's conjecture and so on.

10. **simplicio**
    February 8, 2017

I think I'm missing some context for this story. Can someone explain (or link to an explanation) to a non-mathematician what the sudden appeal of Perfectoid Spaces?

11. **Tom Andersen**
February 8, 2017

Re: nfdc23, etc.
"Young man, in mathematics you don't understand things. You just get used to them."
– John von Neumann

Sometimes, not understanding the foundations allows one to skip to new ideas. There is a also a level of fear in every social group concerning outsider penetration.

12. **lf**
February 8, 2017

"Sometimes, not understanding the foundations allows one to skip to new ideas. There is a also a level of fear in every social group concerning outsider penetration."

Although there is some truth in this assertion, this is the typical justification all crackpots give when their proof of the Riemann hypothesis is refused because it's pretty clear they don't know the basics of analytic number theory after reading a few lines (same with Fermat and Arithmetic Geometry and so on).

13. **Peter Woit**
February 8, 2017

simplicio,
I'm in no position to explain what a "perfectoid space" is, but the context is that it's a new idea about arithmetic geometry due to Peter Scholze that in recent years has been used to solve a range of problems in that subject. For an outline of such applications, one place is Scholze's ICM talk
http://www.math.uni-bonn.de/people/scholze/ICM.pdf
As lf points out, the connection to the topic of the Simons workshop (p-adic Hodge theory) is just that there have been some applications of perfectoid spaces there. I'm guilty of putting the two topics close together because I couldn't resist the amusement value of the contrast between them.

And I should make it clear that while I'm making a bit of fun of the AWS and Simons workshop, the "ridicule" is affectionate, with no intention of trying to kill off either, they're valuable efforts (unlike when I make fun of some things going on in physics, which I really do wish could be killed off…)

February 8, 2017

@John Fredsted:

The comment I made on Math Overflow was not at all intended as a put-down, but rather as a reality check to save a person from wasting a lot of time struggling to understand papers and references on a subject when they have not yet learned much more basic things that every author of the more advanced works take as known by their readers. I have seen too many instances of students trying to leap ahead to "study" very advanced topics in mathematics without first learning something serious about the more basic contexts out of which the advanced ideas arose. There's certainly nothing wrong with skipping some steps here and there when seeking to get a sense of what a subject is about, but this is not the situation that the person was describing when mentioning that they didn't know about rigid-analytic geometry.

There are nowadays quite a number of references from which one can learn about rigid-analytic geometry and Berkovich spaces, either of which provide good preliminary experience to then try to get a feeling for the more sophisticated structures involved with creating and especially using perfectoid spaces. My point was that one absolutely have to learn something serious about at least one of those areas before making an attempt at learning about perfectoid spaces (let alone to attend a 5-day workshop on the topic). Anyone who doesn't have some reasonable familiarity with either of those frameworks for doing non-archimedean geometry has no chance to understand anything serious with perfectoid spaces that will be lectured about at the AWS.

It is akin to trying to read advanced textbooks and papers on General Relativity without prior study of undergraduate physics or multivariable calculus. When I was an undergraduate, after taking a graduate course in functional analysis (which I knew also provided the mathematical framework for quantum mechanics) I decided to try to sit in the back of the room in an undergraduate course in QM in the hope that I could learn the subject despite that I had never studied serious classical mechanics (just the simple freshman-level E&M + SR). Needless to say, my experiment was a flop.

I am not claiming that one has to go through all prior historical developments before entering a new subject, or that reading backwards can't be productive (within reason: one ought to have some knowledge of the basics). But if one is really expecting to get something out of a 5-day instructional workshop (not a semester-long course, just 5 days!) then one absolutely must learn the basics first and not rush to the seminal papers on the very advanced stuff first. That is why I said "Life is not a race".

@Tom Andersen:

I don't know if your background is in math or physics (or both), but in pure math having no understanding of the foundations of a subject (by which I mean no understanding of the more basic relevant mathematical ideas and how they are used in proofs and/or important examples, not about set-theoretic/logical foundations) makes it impossible to extract any real understanding about new ideas in more advanced areas of the subject. It may be that in physics (which I don't know much about at a technical level) one really can "skip to new ideas" in a meaningful way in an advanced topic without understanding the foundations, but in theoretical math this is basically impossible (due to the nature of the subject). The issue is not about fear of outsider penetration, but about the way the human mind digests abstract concepts.

Perhaps the example par excellence of someone who made substantial contributions to cutting-edge pure math without a systematic prior study of earlier ideas was Ramanujan. But this is the exception that proves the rule: he rediscovered on his own everything he needed from the earlier ideas of others, and his mastery of examples was singularly spectacular. So even his case fits the paradigm of how one reaches the stage of making creative new contributions to a highly-developed subject in pure math (though the road he took was one that nobody else could have traveled).

In many (though not all) topics at the cutting edge of arithmetic geometry nowadays, it is more often structural rather numerical examples that guide the development of new ideas (that is certainly the case with perfectoid spaces and how they are used), so one really needs some framework to develop intuition for organizing these sophisticated concepts in one's mind. Trying to proceed in such directions without an understanding of (relevant) foundations is not going to put one in a position to make creative use of those ideas. In fact, if the "insiders" in this area really did want to prevent outsider penetration (in terms of creative new ideas from "outsiders"), encouraging the study of the advanced work without knowing the more basic ideas out of which it emerged would be an excellent strategy. 🙂

@lf: in Tucson in March, dressing like Woodstock is encouraged!

16. **lf**

February 8, 2017

@ds: indeed, I should have guessed it, but I “prefer” the spa and the swimming pool of the Schloss Emmau…

17. **John Fredsted**
February 9, 2017

@nfdc23: Ok, point taken. But rereading your comment on MathOverflow, I still think that your message could have been conveyed in a more empathetic way. At least, if I had been the poster, I would have been put down by the very phrasing of it. But perhaps I am just being (too) sensitive.

18. **John Fredsted**
February 9, 2017

Clarification: By ‘the poster’, I mean of course ‘the original poster’, i.e., the recipient.

19. **oliver knill**
February 9, 2017

I might not be the right person to give career advise but entering the nesting ground
of giants (especially if these monsters are so young) can mean living a very competitive life. There certainly will be tears. You are the tortois running after Archilles. Once you are where Archilles was, the giants have already gone much further. Having been close to giants I know the experience: it is exciting but also humbling. It is maybe the competitive career market but both in physics as in mathematics, the herd instinct is currently particularly strong. Fortunately, both in mathematics and physics, there are many nesting grounds and some are less crowded. But the one covered in this conference seems particularly grand. Maybe its just that most of the crowd will be tourists who want to have a glimpse at the superstars in that field which rapidly appears to become classical mathematics. And like Woodstock, also math has its legendary moments. The ICM’s of 1900 or ICM 1950 (http://abel.harvard.edu/history/icm1950) must have been such, or the Woods hole conference from 1964, at a time when the index theorem was exploding. I attended once a conference /summer school at Hillerod, where lots of giants were present
http://abel.math.harvard.edu/~knill/history/hillerod Fantastic? Yes. But also a bit intimidating. I myself enjoyed once a summer school in les Houches,
http://www.math.harvard.edu/~knill/various/chamonix , where my wife participated and I actually enjoyed the tourist status very much. Now a bit older, I only can give the advise, go and enjoy as much as you can but also know about other nesting grounds where you can find one or the other leafs not yet trampled upon. Its also good to be aware of one important fact which applies to almost everybody: there are always mathematicians/physicists who are (much) better than you!

The Columbia Math department has been doing extremely well in recent years, with some wonderful mathematicians joining the department. A couple items first involving some of them:

- Kevin Hartnett at Quanta Magazine has a great article about developments in the field of technical issues in the foundations of symplectic topology. This explains work by my colleague Dusa McDuff, who together with Katrin Wehrheim has been working on such issues, trying to resolve questions raised by fundamental work of Kenji Fukaya and collaborators. For technical details, two places to start looking are here and here.

  The Hartnett story does an excellent job of showing one aspect of how research mathematics is done. Due to the complexity of the arguments needed, it's not unusual for early papers in a new field to not be completely convincing to everyone, with unresolved questions about whether proofs really are airtight. The way things are supposed to work, and how they worked here, is that as researchers better understand the subject proofs are improved, details better understood and problems fixed. Along the way there may be disagreements about whether the original arguments were incomplete or not, but almost always people end up agreeing on the final result.

  Also featured in the article is another of my Columbia colleagues, Mohammed Abouzaid, who provides characteristically wise and well thought out remarks on the story.

- Via Chandan Dalawat, I learned of an interesting CIRM video interview with another colleague, Michael Harris. The same site has this interview with Dusa McDuff, as well as a variety of other interviews in English and French.

For some other non-Columbia related links:

- The 70th birthday of Alain Connes is coming up soon, and will be celebrated with a series of public lectures and conferences on noncommutative geometry in Shanghai. This year will be the last series of lectures by Connes at the College de France. They're appearing online here, and I highly recommend them. He's taking the opportunity to start the series with a general overview of the point of view about the relationship of geometry and quantum theory that he has been developing for many years.
- For employment trends in theoretical particle physics, there are some updated graphs of data gleaned from the particle theory jobs rumor mill created by Erich Poppitz and available here. In terms of total number of jobs, there has been some recovery in the past couple years, with about 15 jobs/year, above the 10 or so common since the 2008 financial crisis (before 2008 numbers were higher, 20-25). As always, an important thing to keep in mind about this field is that this number of permanent jobs/year is a small fraction of the number of Ph.Ds. in the subject being produced each year at US universities.

  The numbers for distribution of subfields separate out "string theory" and lattice gauge theory. There have always been few jobs in lattice gauge theory, appear to be no hires in that subject for the past two years. I'm putting "string theory" in quotes, because it's very hard these days to figure out what counts as "string theory". With Poppitz's choice of what to count, hiring in string theory has recovered a bit, now around 25% of the total for the past two years, up from more like 15% typical since 2006 (earlier on the numbers in some years were around 50%).

- As pointed out here by commenter Shantanu, on Wednesday John Ellis gave a talk on Where is particle physics going? at Perimeter. I'd characterize Ellis's answer to the question as "farther down the blind alley of supersymmetry". He spins the failure to find SUSY so far at the LHC as some sort of positive argument for SUSY. The question session was dominated by questions about SUSY, with Ellis taking the attitude that there's no reason to worry about the failure so far of the fine-tuning argument for SUSY, all you need to do is "ratchet up your pain threshold". I fear that's some sort of general advice where this line of research is going.

  About the failure to find any evidence for SUSY wimps that were supposed to explain dark matter, Ellis explained that he had been working on this idea for 34 years, first writing about it in 1983, so with that much invested in it, he's not about to give up now.

Update: Davide Castelvecchi points me to another new mathematics story at Nature.

Update: One more. A profile of Roger Penrose by Philip Ball. Penrose explains that his main problems with string theory come from two sources. One is the instability problem of extra dimensions, the other is his aesthetic conviction that sticking to four space-time dimensions is a good idea since it is only in four dimensions that you get the beautiful geometry of twistors. Ball raises the interesting question of whether Penrose could have a successful scientific career if he were starting out today:

> Worst of all, the career structures and pressures facing young researchers make it increasingly hard to find the time simply to think. According to several early-career scientists interviewed by Nature, the constant need to bring in grant money, to produce papers and administer groups, leaves little time to do any research, still less indulge anything so abstract and risky as an idea.

Comments

1. **Anon**
   February 10, 2017

   Hasn't Joyce been working on this subject for years now? I was surprised not to see a mention.

2. **Shantanu**
   February 10, 2017

   Peter, one thing I was surprised to see Ellis mention is that so far no one has found a convincing connection between neutrino oscillation phenomenology and TeV scale physics (and that's why he skipped neutrino physics) Isn't this the most important question which particle physicists and string theorists should try to answer? Why is there no progress (or even concern that there is no progress) inspite of a nobel prize last year in this area?

3. **Abby yorker**
   February 10, 2017

   It is very difficult to imagine that the proof mentioned in Nature will help geophysicists in any practical way. The algorithms surely are in place and independent of detailed mathematical proofs.

   I also wonder whether it applies to areas of extreme velocity that are avoided by "raypaths". Perhaps finite bandwidth helps. Dunno.

4. **A.K.**
   February 11, 2017

not that I wanted to give here remarks which would go into any detail, but the problems in symplectic topology seem to go FAR beyond Fukaya's foundational papers. Just as an arbitrarily chosen question: did anyone here understand 'Eliashberg's existence proof on symplecic topology'? It is not 120 pages long (it is merely 10 pages or so), it doesn't contain too many technicalities, but it contains several crucial statements from singularity theory that are nowhere proven, provided with no proper links or explanation and thus give the paper a highly folkloristic character. Just to say this. Things developed with some reason the way they do.

Many approaches in 'modern' symplectic geometry were somehow 'adopted' from algebraic geometry but without its firm algebraic or systematic foundation, a firm dictionary between certain algebraic concepts and their 'analytic' counterparts was never set up, Floer theory, while easy in its idea and conception, proved to be an analytic nightmare and over the years, symplectic geometry mutated into some sort of, as I would call it, Sobolev space monster with, in compensation to the high degree of technicality, highly esoteric concepts whose existence was rather assumed than understood.

But even worse: the rise of Floer theory and Gromov-Witten theory obscured the number theoretic origins and character of quantum mechanics and mechanics, it obscured many traditional developements in quantization and physics which were far better understood than the 'new methods' that were deemed by everyone working in the field as 'hard methods' vs. all traditional methods were suddenly depreciated as (the somehow ill defined category) 'soft methods'. The common deformation theoretic background of hard and 'soft' methods was never understood, classical (real and complex) singularity theory, a tremendously rich and well understood field, was never fully incorporated or acknowledged by the 'new' methods. To understand this, a little bit knowledge of Horkheimer's and Adorno's writings on the dialectic way knowledge and science progresses would have been neccessary, with every knew theory tending to destroy the old systems of reference, but such meta research was never done.

I deeply disagree with the view that Fukaya'a papers are the main source of problems in symplectic topology, it is a highly scapegoat-defining approach to the many deeply running problems in this field.

February 12, 2017

Peter,

when listening to the lectures of Alain Connes – thank you for the link ! – I get a strange impression. It seems that this has very little to do with physics, and I am not really sure that this has a lot to do with math. It seems to me – but I may well be wrong – that he is playing around with abstract concepts in some abtsract world of thoughts. There is no real result. Less famous people that do such things are not taken seriously by the community. Another way to put my impression is the following; Connes' world is akin to that of string theorists: it is complex, interesting, but has no relation to nature.

But let me return to the first lecture, which is his motivation and advertizing one. It is really bizarre. For example, he states that the Higgs has a mass value that makes the standard model wrong at high energy – wheres enough people say just the opposite, namely that it has a mass value that makes the standard model valid up to Planck mass.
The citations of the mathematicians in the first lecture are pretty. The stories about the definition of the metre show his enthousiasm. His explanation of the reason for non-commutativity is pretty as well – but it is not physics.

I like his naive enthousiasm – but is this physics? I would be interested to hear other people's opinion about this – incuding yours, Peter. In any case, thank you for pointing this out!

6. **AC**
February 12, 2017

To see the "results" for this parts of my talks you need to reach the sixth hour where the standard model (extended to Pati-Salam) coupled to gravity appears as the spectral action on all spin 4 manifolds from irreducible representations of the higher Heisenberg relations. This is both a difficult mathematical result (using in particular the theory of immersions) and a physics result explaining "why nature is as it is". It would be invalidated by the discovery of SUZY and would have been invalidated by the dicovery of the diphoton 750 Gev. So it is physics. When one runs the scattering parameter (H^4 coupling) of the SM at Planck mass it becomes negative if the Higgs mass is too low, this is what was referred to in the talk.

7. **Friedrich**
February 12, 2017

Dear Alain,

thank you for your kind answer. I remember how enthousuastic I was when I first heard about your model about 25 years ago. I followed it ever since. Please allow me to add two points that explain what I wrote above and that dampened my enthousiasm.

Somewhere I read that your non-commutative geometry model does not lead to U(1)*SU(2)*SU(3) UNIQUELY, but that several other groups could also arise. Is this true?

A good friend of mine here in Munich showed me a text by Niels Bohr where he speaks of quantum theory stemming form h-bar as the smallest action in nature. This simple definition is a strong contrast to the very complex idea of quantization presented in your series of talks. As a physcist, I have a tendency to choose the simpler solution.

Best regards
Friedrich

8. **martibal**
February 12, 2017

Dear AC,
when you say that the discovery of the diphoton 750GeV would have invalidated the model, are you referring to the analysis of Aydemir and al (https://arxiv.org/abs/1603.01756) according to which (I quote their paper):
"even though the 750 GeV diphoton resonance can be accommodated within the NCG motivated unified Pati-Salam models, the price one has to pay is a certain amount of fine tuning in the sector involving the necessary colored scalars" .
Or are there other reasons ?

9. **Peter Woit**
February 12, 2017

Friedrich,

I don't think saying "h bar is the smallest action in nature" gets you much of even the pre-1925 "old quantum theory", much less quantum theory itself. Quantum theory as we understand it today is based on some very deep mathematics, not some simple physical intuition, and getting an even deeper understanding I think is going to require even deeper mathematics. Connes is one of very few first-class mathematicians (or physicists…) trying to do this, in a very original way. The kinds of questions he is asking and trying to find answers to are the most fundamental ones, ones most physicists seem now to have given up on, in favor of a pseudo-scientific excuse ("the multiverse did it").

I've made a few attempts to follow his ideas, each time impressed by the originality of what he is trying to do, and finding some of it quite compelling as well as providing some new insight into things at the boundary of math and physics that had always fascinated me. I'm looking forward to watching all of the latest series of lectures and trying to follow in detail, so far haven't had the time to get very far yet. As for whether he's got a predictive model that convincingly explains things the SM doesn't, I haven't understood what he is doing well enough to know. I confess to being more interested in putting time into understanding the underlying ideas and seeing what new insights I can get from them.

10. **AC**
February 12, 2017

Dear Martibal

The answer to your question is « yes ». In general the road that we
followed with my collaborators on this issue of using the new paradigm
of « spectral triples » (which could also be called « spectral geometry »)
to understand what the SM coupled to gravity is telling us about the nature
of space-time, is the one proposed by Riemann in his inaugural lecture.
There Riemann explicitly suggests that for very small distances, since the
notions of light ray and of solid body loose their meaning one should be ready
to accept that the structure is more involved than the continuum. He makes
two key points
1) "Es muss also entweder das dem Raume zu
Grunde liegende Wirkliche eine discrete Mannigfaltigkeit bilden,
oder der Grund der Massverhaltnisse ausserhalb, in darauf
wirkenden bindenen Kraften, gesucht werden » which is (badly) translated as
"Either therefore the reality which
underlies space must form a discrete manifold, or we must
seek the origin of its metric relations outside it, in the binding
forces which act upon it »
This point is fully taken up by the NCG approach where the inverse line-element
(which encodes the metric relations) exactly encodes all the forces (gravitational
and gauge bosons).
2) He continues by saying (let me skip the german):
"The answer to these questions can only be obtained by starting from
the conception of phenomena which has hitherto been justified by
experience, and which Newton assumed as a foundation, and by
making in this conception the successive changes required by
facts which it cannot explain. »
So here the key word is « successive changes » and in our experience this has been
a long struggle but each time it has been rewarding. There were quite long periods
where we were abandoning the model, saying that after all it could have been a
coincidence of some sort that it seemed to fit. But for instance it survived the neutrino
mixing (after a silent period from 98 to 2006) and more recently the wrong m_H>170 Gev
and in both cases we learned. In the first we understood the KO-dimension 6 of the
finite space (giving the fine structure) but we also rediscovered the see-saw mechanism
from the calculation (not artificially put by hands). For the wrong m_H>170 Gev we learned
our stupidity to have neglected the effect of a scalar field (not the higgs) which was there
and which we had ignored in the RG calculation.
What I have learned myself is that it is never a good idea in this stuff to try to force
a result, and the 750 Gev diphoton would have been such a case. That's for instance
why I avoided the subject when I taught my penultimate class in the College last year
in the winter of 2016!
For a long time we proceeded in the « bottom-up » manner but the recent work with
Chamseddine and Mukhanov, which is the subject of lectures #5 and #6 this year gives
a potential explanation, finally, for the slight amount of non-commutativity present and
that was the main point of this first half of my class this year!

11. **martibal**
February 12, 2017

Dear Alain, thanks for the detailed answer !

12. **Urs Schreiber**
February 13, 2017

AC wrote in small part:

> paradigm of « spectral triples » (which could also be called « spectral geometry »)

The term "spectral geometry" might have more potential than "spectral triple" to communicate to the bulk of the high energy physics community that this is a concept not alien to what they are long familiar with. Indeed the idea to encode effective target spacetime geometry in the worldvolume quantum mechanics — hence in the operator spectrum — of a quantum object that roams in it is familiar from perturbative string theory, where the only difference is that instead of a 1-dimensional worldline for a quantum particle, leading to a "spectral triple", one considers a 1+1-dimensional worldsheet, leading to what could be called a "2-spectral triple" if it were not already called a "2d SCFT".

This close relation between the Connes-Lottes-Chamseddine-Barrett approach of modelling particle physics and that of perturbative string theory has long been pointed out by people like Jürg Fröhlich and Maxim Kontsevich, with details worked out by people like Katrin Wendlandt and Yan Soibelman (here), but it seems to remain underappreciated among members of both communities.

There is a review with further pointers to the literature on *PhysicsForums-Insights* at *Spectral Standard Model and String Compactifications*.

This general relation of the underlying theory gets all the more interesting with the developments starting with Barrett's insight into the reality condition of realistic spectral triples and the result that the KO-dimension of the compact space in the Connes-Lott-Chamseddine model has to be 6, thus leading to a total KO-dimension of spacetime of d = 4 + 6 in these models (albeit seen only mod 8 by KO-theory). This of course coincides with the result of the criticial dimension found earlier in "2-spectral triples", namely in perturbative superstrings.

This interesting match seems to make it well motivated to ask whether under the point-particle reduction from 2d CFTs to spectral triples due to Fröhlich-Gawędzki, Roggenkamp-Wendland and Soibelman the Connes-Lott-Chamseddine spectral triple is indeed the point particle limit of a 2d SCFT. If so, that 2d SCFT would be a natural candidate for the UV-completion of the model, and hence potentially of realistic particle physics.

An interesting prospect, whose further examination seems to be stalled by a detachment and mutual misunderstanding of the communities on both sides of the relation.

13. **cedric bardot**
February 13, 2017

I think one important piece of information is missing (or not stressed enough by anyone here) for the readers of Peter's Blog interested in watching Connes last mathematical lectures at College de France.
To appreciate the potential physics interest of noncommutative spectral geometry one has to mention the already established connection (in arxiv.org/abs/1409.2471) between the quantization of volume in 4D Riemannian manifolds mathematically formalized by Connes with the non-dynamical scalar fields introduced by the theoretical physicist Chamseddine and cosmologist Mukhanov to account simultaneously for both dark matter and dark energy (not to mention the more implicit link with another connected idea about a limiting curvature of spacetime in 1612.05860 and 1612.05861).
To answer Friedrich question, I do not know what was the reception of the Mukhanov lecture "Non-commutative Geometry and Mimetic Dark Matter" at Pierre Fayet (French physicist well known for his contribution on supersymmetry) fest last december at ENS Paris (moriond.in2p3.fr/Fayet/program.php) but LHC and LUX data as well as numerical tests of some minimal non-supersymmetric gauge unified models with Pati-Salam structure (1412.4776 and 1612.07973) seem to confirm the message provided by the spectral noncommutative geometry : the phenomenology of our unique observable universe at the 230 meV current temperature requires, for the time being, just the standard model particle content up to an extrapolated 10^12 GeV scale leptogenesis where three right-handed Majorana neutrinos and some new Higgs brother(s) and other gauge boson(s) need to appear on stage.
So may-be it's worth focusing on measuring the Higgs couplings and top mass with the best precision before dreaming of the construction of a 100 TeV accelerator. Spending more time to the tedium computational exploration of vacua solutions of the spectral action and their astrophysical connections might be not very inspiring task at first look but who knows, may be the solution to the hierarchy problem lies there…

14. **sympathy for the symplectic**
February 13, 2017

At the webpage of Aleksey Zinger he posts further evidence of a dysfunctional foundational situation in symplectic topology. Papers there document what happened when he tried to carefully read, and then repair, the literature on the "formula" for Gromov-Witten invariants of symplectic sums. A major paper in the Annals was eventually retracted, and much other fireworks ensued.

15. **Steve Sharpe**
February 16, 2017

Just a quick comment on HET hiring, concerning the lattice breakout. Most hiring of those doing lattice field theory in the last decade has been in Nuclear Theory, and the numbers there are a bit more encouraging.

16. **Peter Woit**
February 16, 2017

Thanks Steve,
That's good to hear.

17. **colorado**
February 17, 2017

Hi Peter,

I see that there are no tenure track faculty in Columbia's math department. What's the difference between a Ritt Assistant Professor and a post doc? The teaching responsibility for a Ritt position seems little heavy. Do math departments directly hire into a tenured position after an extended post doc these days?

18. **Peter Woit**
February 17, 2017

colorado,
In math in the US (unlike physics), there are few purely non-teaching postdocs, with the standard research career path after grad school a few years in a non-tenure track job like our Ritts, then a tenure track job. Even NSF postdocs are often combined with some teaching (making it a longer position). The current teaching load for a Ritt is 2 and 1 (it was 2 and 2 way back when, when I had one). This is a lot more teaching than physicists do, on the other hand, job prospects for those coming out of these jobs are much better than for theoretical physicists.

One reason for having few if any tenure track positions is that the market for the best young people is quite competitive. If you do a search for a tenure track position you often find that the top candidates have competing offers from institutions that decide to offer them tenure to attract them, and you need to match that.

19. **AC**
February 18, 2017

Since my last lectures in the College de France are in French, I am giving the link to a paper which I am writing (and which is still evolving), it is
https://www.dropbox.com/s/8jz865ezxjwrr91/J-Kouneiher.pdf?dl=0
In particular I explain in section 3.4 the deep mathematical roots of the notion of spectral geometry (spectral triple) coming from the work of Sullivan on KO-orientations and the origin of the KO-cycles in index theory starting with papers of Atiyah and Singer in the 60's. The above paper is far from final and critical comments, missing references, etc are very useful at this point.

20. **anon**
February 20, 2017

Discussion in comments to that Quanta Magazine article seems to have gone off the rails…

21. **Peter Woit**
February 20, 2017

anon,
Yes, and an excellent illustration of a couple of important general principles that people are sometimes not aware of until it's too late:

1. The world is full of people who know nothing about the topic being discussed but want to use your comment section for their own ax-grinding. Unchecked, they will destroy any intelligent discussion.

2. Attributed to John Baez: it's not easy to ignore Lubos, but it's always worth the effort.

22. **David Roberts**
February 20, 2017

Dear AC

thank you for putting your draft online! It is very illuminating, and useful for those who grasp of spoken French is insufficient, or whose internet bandwidth is not up to the task of downloading the videos.

23. **AC**
February 21, 2017

Dear David, thanks, here is a much improved version as far as the second half of the paper goes, ie the discussion of the "quanta of geometry" in section 4. The new link is https://www.dropbox.com/s/gzrqzjvilvgwfk9/J-Kouneiher.pdf?dl=0

A Big Bang in a Little Room

February 18, 2017
Categories: Book Reviews, Fake Physics

There's a review in today's Wall Street Journal by me of Zeeya Merali's A Big Bang in a Little Room. If their version is behind a paywall you might find also find it elsewhere (for instance here). I'll reproduce parts of the review below with some comments more appropriate for the blog venue. As always, the editors at the WSJ did an excellent job of improving the first draft I sent them.

Merali has a website about the book here, and last week Nature published this review by Andreas Albrecht. Albrecht criticizes the book for "sloppy interplay between science and religion", but I think he misses the important point that the most serious problem here is the sloppiness about what is science and what isn't. When physics journals decide to publish articles like this one, it's not surprising that science writers make the mistake of taking them seriously and writing about them (Merali's first chapter is about this paper).

Here are some extracts from the review, with some comments:

> What happened at the Big Bang—or before—is an irresistible question but one that, for now, as science, lies in the realm of the purely speculative.
>
> In "A Big Bang in a Little Room," science writer Zeeya Merali turns the question around, asking instead whether physicists can create a "baby universe," born in its own Big Bang. Indeed, one prominent theorist she interviews has suggested that our own universe might be a baby universe created by a "physicist hacker," with the complex pattern of fundamental particle masses intended as some sort of message to us. thereby learning more about the beginnings of the "old" one.

The reference here is to Andrei Linde and this 1991 paper.

> explains that her interest in this topic is tied up with her religious beliefs: If we ourselves could play God and create a new universe, wouldn't that creation amount to a theological discovery, showing the likelihood that some higher intelligence was responsible for the Big Bang? She structures her narrative around interviews with prominent theoretical physicists; they mostly discuss science, but religious questions sometimes play a role, with often fascinating results. While some refuse to engage, she gets others to discuss such topics as the relation of the laws of physics to God's happiness, the possibility of a physical "consciousness field," and what the quantum mechanics of the Big Bang might indicate about the possibility of life after death and resurrection.

Don Page is the one interested in God's happiness, Abhay Ashtekar in the "consciousness field", and Andrei Linde in resurrection.

> Mr. Linde is the central figure in this story, and Ms. Merali describes him as "a showman: bombastic, passionate, and fueled by the certain belief that inflation theory, which he helped to invent, is correct." While Ms. Merali takes all of this seriously, there are very good reasons why most physicists don't. Readers of "A Big Bang in a Little Room" would be well-advised to enjoy the ride but stay skeptical. Inflationary models can to some degree be confronted with observation and tested (a topic covered in other books but not this one).

About the string theory landscape:

> Ms. Merali gives a disturbing version of this, contemplating the possibility that "string theory and inflation may be conspiring against us in such a way that we may never find evidence for them, and just have to trust in them as an act of faith."

This comes after an explanation of the anthropic multiverse point of view from HEP experimentalist Greg Landsberg, where he adds the twist of anthropics explaining why the string scale is at such high energy, and thus unobservable. The full paragraph in the book is

> In other words, the physics of string theory and inflation may be conspiring against us in such a way that we may never find evidence for them, and just have to trust in them as an act of faith. The multiverse truly works in mysterious ways!

If that paragraph doesn't make a scientist's blood run cold and see the danger physics is facing, I don't know what will. I end the review with

> In an era where "post-truth" was the word of the year, scientists and science writers need to make clear that science is not a species of theological or philosophical speculation and not about belief or entertainment value. Legitimate scientific claims are those that can be backed up with evidence, and unfortunately the wonderful and exciting story told well here contains none at all.

My concern about the topic of the book is that it's Fake Physics, not that religion is motivating the author (and likely motivating the Templeton Foundation to fund this project). A book about the religious views of physicists would be an interesting one that I'd certainly read, and the material in this book on that topic is quite interesting. One of the odder twists here is that the two blurbs from physicists promoting the book are from Sean Carroll and Martin Rees, with Carroll writing

> So you want to make your own universe. Zeeya Merali's new book won't quite give you an instruction kit—but it's the closest thing we have at the moment. A fun and mind-expanding ride through modern ideas of how universes come to be.

I don't see how you can be devoted to fighting for science against religiously-driven pseudoscience, and think that this book is one you'd like to see be the public face of what "modern ideas" about cosmology are.

Comments

1. **Jeff M**
   February 18, 2017

   So how good a journal is Modern Physics Letters A? I was thinking I could write a math paper, "Letters from the creator in mathematical objects." Have to know what journal to send it to though.

2. **tulpoeid**
   February 19, 2017

   "If that paragraph doesn't make a scientist's blood run cold and see the danger physics is facing, I don't know what will."

   Totally. Even more so if you consider that Landsberg was the physics coordinator of the CMS experiment during the Higgs discovery.

3. **Dave Miller**
   February 19, 2017

Well, Peter, I'm on your side when you say, "If that paragraph doesn't make a scientist's blood run cold and see the danger physics is facing, I don't know what will."

But, I have a sinking feeling our side is going to lose.

On the other hand, the younger generation always makes a name for itself by revolting against its elders, so, perhaps, in a couple decades, the hottest thing in physics will be angry young physicists revolting against the "anthropic principle" etc.

By the way, I haven't seen you comment yet on the article in the current Scientific American claiming that inflationary cosmology is in a lot of trouble.

Dave Miller in Sacramento

4. **a1**
February 19, 2017

Few people seem to realize that pronouncing something to be random is just saying we won't be discussing further hypotheses. So, asserting that a physical quantity is just the value of some random variable across the multiverse is not different from asserting that a god willed it to have this value in our universe. Both ways, this is an ultimate explanation without any further 'why'.

5. **Gus Bici**
February 19, 2017

"You are of this world; I am not of this world." says Jesus.

"NOTW" (i.e. Not Of This World) is a popular Christian bumper sticker. May need to print up some more for the Physics community. Amen.

6. **Mitchell Porter**
February 19, 2017

Thirty years ago, there was a fad for "third quantization" as a way to model "baby universes". Did it ever predict anything (whether right or wrong)? Did it get write-ups in the science press? And, is any of that work, an essential precursor to today's inflationary multiverse? Or was it a fundamentally separate theoretical excursion whose life and death unfolded in relative isolation?

7. **Peter Woit**
February 19, 2017

Dave Miller,
I should write about that, it's an excellent discussion of the problems of inflation, and of the more general problems I often write about here.

Mitchell Porter,

I guess you're referring to this sort of thing:
https://www.jstor.org/stable/38273
I don't think that led anywhere, it's a generalization of the idea of string field theory, from a circle (string theory) to arbitrary 3-manifolds. No one has managed to really successfully do this for the circle, and it's not at all clear to me there is any viable idea about how to even get started if you generalize to 3-manfolds, so not surprising this never went anywhere.

This has nothing to do that I can see with the eternal inflation story and the recent multiverse mania.

8. **ABC**

Original WSJ story here:

https://archive.is/dT8rA

9. **srp**
February 19, 2017

For anyone interested in the idea of creating universes in an accelerator, astrophysicist Gregory Benford's 1999 novel Cosm is pretty entertaining, though not close to his best stuff. He had the setting as the Relativistic Heavy-Ion Collider at Brookhaven.

https://www.amazon.com/Cosm-Gregory-Benford/dp/0380790521

10. **Shantanu**
February 19, 2017

Dave: Can you point me to the sciAm article?

11. **Nick M.**
February 20, 2017

Hi Shantanu,

I think Dave may be referring to this article:

https://www.scientificamerican.com/article/cosmic-inflation-theory-faces-challenges/

But, unfortunately, it's paywalled. I guess I'll have to newsstand a copy of the February 2017 Scientific American.

-Nick

12. **phil fogle**
February 20, 2017

Great review! So good to see a critic who isn't afraid to step on toes. But the war against science is ancient, and vigilance will always be called for.

At least this stuff isn't lethal, like Andrew Wakefield's pseudoscience…

13. **Dave Miller**
February 20, 2017

Shantanu,

Believe it or not, I actually read the article in a hard-copy at our local public library! (The Sacramento public library system is actually very good.)

Dave

14. **Nick M.**
February 20, 2017

Shantanu, Dave:

I think I stumbled onto a downloadable PDF copy of the article from professor Aviv Loeb's "Center for Astrophysics" webpage on the Harvard-Smithsonian website (see here).

Alternatively, go to the Harvard web address

https://www.cfa.harvard.edu/~loeb/

and scroll down to the "In The News" section, and look for the article titled "Pop Goes the Universe".

(God I hope I don't get into trouble. 😉)

15. **Mateus Araújo**
February 21, 2017

I can already see how your review will appear in the promotional material:

"Wonderful and exciting story" – Peter Woit

16. **Alan**
February 22, 2017

Wondered if you've come across Dr. Luke Barnes' work A Fortunate Universe: Life in a Finely Tuned Cosmos which seems relevant.
https://afortunateuniverse.wordpress.com/2017/01/10/talk-in-sydney-the-universe-for-beginners/
The video in there goes through 4 options, 1. physics will explain the constants (no multiverse) 2. a multiverse 3. a creator or something-like behind everything 4. we're living in a simulation.
So I guess the "physicist hacker" above could fit in 3 or 4?

As to universe creation above, what I remember (but not understand) of what Lenny Susskind says was that the config. of a Calibi-Yau space determines what universe will get created (like a "DNA") and since (my view) you can't get to that energy or specificity of configuration when you attempt to create one in a lab., it's a hopeless task to try – if the multiverse idea is correct. But even if it isn't aren't the energies out of reach?

17. **Bernhard**
February 22, 2017

@Jeff M,

I can give you my own take on what I think of MPLA from an experience a few years ago..

I was asked to be reviewer of a paper from a very good journal. On reading the article, I realized it was very bad, to the point I was not sure one could consider it really an article. It was not difficult to convince the editor that he should not publish an article of that quality, something that would hurt the journal's reputation.

A few months later, I checked the arXiv entrance for the article and saw it has been published in MPLA.

Make your own conclusion.

18. **Jeff M**
February 22, 2017

@Bernhard

Yes, there are math journals like that too 🙂

19. **Slawomir Piotr Wojcik**
March 11, 2017

I believe, I didn't read a different book, but, certainly, I have a somehow misaligned impression. It is a long time since I finished school, so I find it hard to judge what is a common scientific knowledge, but it seems to be much lower than it used to be. This chimes with what level of knowledge and curiosity the book (the author, by a sample of a book, if you let me) assumes in the reader.
On page 193, line 6 of my copy Zeeya Merali writes about Don Page commenting on why infinity of multiverses might be simpler to understand than the Universe itself: "To illustrate his point, he tells me to think of the set of whole numbers-1,2,3…" I hope, I vaguely imagine the same what a phd in cosmology would in such a case, namely something like decision problems in sets of natural numbers (https://pdfs.semanticscholar.org/ed71/ebe0eee4f88f095247c8b62ba1d3b217a68d.pdf)
The problem with this bit of text (and most of "dry remnant on a sieve" of the rest of the book – which doesn't amount to much) is that narrative and assumed (target) readers knowledge and curiosity seem to be intended to produce (and it would be a nice paper in psychology of perception if this book's an plethora of others' of the sort impact on knowledge and outlook of a reader were analyzed) a rather big collection of people who missed the hint and were left no wiser.
When read in this way (parallel way – what the author and her interlocutors know, what my knowledge allows me to decipher from the book about their intentions and what the bulk of the readers are going to make out of it) the book seems to be bursting in its seams with innuendo of a very special kind.
The real problem, which the book comes close to expose but never even tries to do so explicitly is that: Our theories are systems of conservation of information. Hence

they are good to describe a Universe that itself is such a system (in usual words “deterministic theories describe deterministic world”, but even this simple equivalence seems to be a leap too far for many and Merali doesn’t appear as keen on making leaps of this sort any easier) What if the rule of preservation of information (determinism) is of limited application? What are the limits of our knowledge and what are the implications for every individual in this entropy governed Universe? Convoluted, as it is, the book skips on the questions, the whole body of relevant research, but, by virtue of this innuendo (a false perception of mine?) works as a portent of things to come.

Various News

February 22, 2017
Categories: Multiverse Mania, Uncategorized

First some mathematics items:

- Igor Shafarevich, one of the great figures of twentieth century algebraic geometry and algebraic number theory, died this past weekend at the age of 93. Besides his many contributions to mathematics research, he was also a remarkably lucid expositor. His two volume Basic Algebraic Geometry is a wonderful introduction to that subject, his survey volume Basic Notions of Algebra emphasizes the connections to geometry, and his volume on number theory (with Borevich) struck the AMS reviewer as "delectable".

  Shafarevich was also known for his religiously-motivated nationalistic views which to many were distressingly anti-Semitic. In the spirit of respect for the recently deceased, I'll just link to a quite interesting recent discussion (very sympathetic to Shafarevich) of the issue by David Mumford here (and ruthlessly delete attempts to argue about this in the comment section).

- The AMS Notices has a set of articles in honor of Andrew Wiles and his work, which include some great explanations of the mathematics, as well as a long in-depth interview.
- For another detailed interview with a mathematician, see Quanta magazine for a piece by Siobhan Roberts about Sylvia Serfaty of the Courant Institute.

On the physics front, there's:

- For his contribution to the Why Trust a Theory? conference (see here and here), Helge Kragh has a new paper which examines the question of whether history of science can help evaluate recent claims about the need to change the way theories are assessed. He sees in the unsuccessful "vortex theory" of the late nineteenth century an analog of string theory, with many of the same claims and justifications for lack of success. He quotes as a typical example of the enthusiasm of the time:

  > I feel that we are so close with vortex theory that – in my moments of greatest optimism – I imagine that any day, the final form of the theory might drop out of the sky and land in someone's lap. But more realistically, I feel that we are now in the process of constructing a much deeper theory of anything we have had before and that … when I am too old to have any useful thoughts on the subject, younger physicists will have to decide whether we have in fact found the final theory!

  but then explains that this is actually a quote from Witten, with "string" replaced by "vortex".

- Scientific American this month has an article (also available here) about the problems with the theory of inflation. The authors end by pointing out the dangers to science of multiverse inflationary scenarios (which they call the "multimess"):

  > Some scientists accept that inflation is untestable but refuse to abandon it. They have proposed that, instead, science must change by discarding one of its defining properties: empirical testability. This notion has triggered a roller coaster of discussions about the nature of science and its possible redefinition, promoting the idea of some kind of nonempirical science.
  >
  > A common misconception is that experiments can be used to *falsify* a theory. In practice, a failing theory gets increasingly immunized against experiment by attempts to patch it. The theory becomes more highly tuned and arcane to fit new observations until it reaches a state where its explanatory power diminishes to the point that it is no longer pursued. The explanatory power of a theory is measured by the set of possibilities it excludes. More immunization means less exclusion and less power. A theory like the multimess does not exclude anything and, hence, has zero power. Declaring an empty theory as the unquestioned standard view requires some sort of assurance outside of science. Short of a professed oracle, the only alternative is to invoke authorities. History teaches us that this is the wrong road to take.

- Nautilus has an article by Juan Collar about the increasing skepticism about Wimps as dark matter candidates, and the interest in alternatives.

Update: With results from the full 13 TeV dataset just a few weeks away, SUSY enthusiasts have given up hope for the LHC. A new paper just out argues that pre-LHC claims that naturalness + SUSY implied a gluino mass upper bound of 350 GeV (the latest LHC limits are more like 1900 GeV, likely to go up next month) were misguided. According to these authors, the right number for the upper bound is 5200 GeV and the "HE-LHC with 33 TeV is required to either discover or falsify natural SUSY". So, claims that the LHC could falsify natural SUSY are no longer operative now that it has done so by earlier metrics, and such discovery or falsification is still just around the corner. All that's needed is to rebuild the LHC into a higher energy version (that's what the HE-LHC proposal is, may take a while…).

Update: Another excellent article by Natalie Wolchover at Quanta, this time about progress in studying conformal quantum field theories in higher dimensions (above 2). Definitely one of the more interesting things going on in theory at the moment. The reference in the subtitle to "geometry underlying all quantum theories" I don't think though is really justified, this is really just about conformal field theories.

There's probably lots more to be learned about these, with this conformal symmetry still not fully exploited. I'm somewhat fond of the point of view that you really shouldn't try and think of QFTs just as effective theories for some different physics at short distances. Rather, what might be going on at short distances is not some new kind of theory at the cutoff scale, but a conformal theory valid at all scales.

Update: From the comments, unfortunately two other deaths to report, those of Bert Kostant (I've written something here) and Ludwig Faddeev.

Comments

1. **Urs Schreiber**
   February 22, 2017

   The model of fuzzy dark matter, which the article by Collar refers to, with massive but ultralight axion particles of de Broglie wavelength the scale of galaxies is interesting, in that it interpolates between the extremely sucessful WIMP-style phenomenology on cosmological scale and the observed MOND-like deviation from WIMP-style dark matter on galactic scales, because on just those scales the quantum nature of these axionic particle kicks in to. That's the point amplified in much detail by Hui-Ostriker-Tremaine-Witten 16. And hence axion cosmology looks attractive, as witnessed for instance recently by the SMASH model.

   But if axions fit the data a question will remain: why axions, theoretically? As Svrcek-Witten 06 wrote way back:

   > An obvious question about the axion hypothesis is how natural it really is. Why introduce a global PQ "symmetry" if it is not actually a symmetry? What is the sense in constraining a theory so that the classical Lagrangian possesses a certain symmetry if the symmetry is actually anomalous? It could be argued that the best evidence that PQ "symmetries" are natural comes from string theory, which produces them without any contrivance.

Indeed, the funny coupling of the axion to the instanton number, which seems contrived from the point of QFT, generically drops out from string theory, as shown by entertaining little computations.

(Interestingly, it is the special properties of higher gauge fields in string theory which give the axionic behaviour in 4d: for type II its the K-theoretic nature of the RR-fields, and for HET its the Green-Schwarz mechanism on the B-field gerbe. Hence if Witten's arguments as above are right, then axionic dark matter is potentially the first direct phenomenological signature of higher gauge theory.)

2. **Peter Woit**
February 22, 2017

Urs,
I have no doubt that, if we ever find evidence for new physics that explains dark matter, no matter what that new physics is, we will be assured that it "generically drops out from string theory", just like the now-becoming-unpopular WIMPs did…

3. **Anon**
February 23, 2017

Regarding the new paper on SUSY, it says that the LHC(14) at 3000 inv fb will probe up to 2.8 TeV of gluino mass — that corresponds already to 10% fine tuning (\Delta_EW = 10) as per fig 1 in their paper (1702.06588).

Assuming nothing is found with full running of at LHC(14), the 33 TeV machine will search among models that are between 10% and 3% fine tuned (gluion mass between 2.8 and 5 TeV).

I guess this implies that, even now, LHC(14 Tev) is more likely to discover SUSY as it continues to run and search for gluinos between 1.9 TeV and 2.8 TeV which according to the authors is a region that is not 10% fine tuned. If the the LHC does not find anything in this region, the 33 TeV collider will be searching a region that is at least 10% fine tuned and is less likely to find SUSY, compared to the LHC runs between now and 3000 inv. fb.

4. **Balazs Vagvolgyi**
February 23, 2017

Dang, Scientific American and Juan Collar, inflation and strings just got burned!
In other news, the first designs for the Church of the Holy Superstring have just been submitted for review.

5. **Anonyrat**
February 24, 2017

Recent lectures on the conformal bootstrap by Simmons-Duffin

6. **Mike Weiss**
February 24, 2017

"One major question," writes Natalie Wolchover in Quanta magazine, "is how black holes manage to preserve quantum information, even as Einstein's theory says they evaporate."

Surely the last clause is in error as classical black holes in GR do not evaporate. Hawking predicted black-hole evaporation in the 1970s based on an amalgam of quantum field theory and GR.

7. **Anon**
February 25, 2017

Another unfortunate recent death is that of Bertram Kostant. I know you Peter have been interested in his ideas on Lie algebra cohomology and the symplectic Dirac operator, as well as on geometric quantization more generally.

8. **Peter Woit**
February 25, 2017

Anon,

I'm sorry to hear that, thanks for letting us know. I'll write a posting very soon about Kostant's mathematics, which has had a lot of influence on me.

9. **anon**
February 26, 2017

Yet another death: Ludvig Faddeev has passed away.

10. **Peter Woit**
February 27, 2017

anon,

Thanks for letting us know. I'll add a mention above, unfortunately I never met Fadeev and am not familiar enough with his work to write much about it.

11. **Casual reader**
February 27, 2017

Observations of spatial flatness and large-scale homogeneity required very special initial conditions for the universe. Scientists did not like that, so they came up with inflation.

Planck CMB observations require very special initial conditions for inflation. Ijjas, Steinhardt and Loeb do not like that, so they come up with a bouncing universe.

12. **lars**
March 4, 2017

"Inflation"

The universe inflated
Is really overrated
Though lack of proof is stated
The hype is unabated
Perhaps it should be traded
But those who are quite jaded
Are almost surely fated
To wait with breath that's bated
For end to things inflated

13. **Doug McDonald**
March 4, 2017

"With results from the full 13 TeV dataset just a few weeks away"

I recall a discussion late last year about a skipped meeting then, mentioning this.

Do you recall dates and places of the upcoming (presumably non-) news?

I do admit that probable SUSY or even better axions would be fun.

14. **Peter Woit**
March 4, 2017

Doug McDonald,

As far as I know, the target has been to release these results at the Moriond conferences scheduled to begin March 19th (also at the Aspen conference to begin March 20)
Watch for results to appear at
http://moriond.in2p3.fr/
http://indico.cern.ch/event/550030/
I suppose there might also be events scheduled at CERN for these announcements.

Bertram Kostant 1928-2017

February 25, 2017
Categories: Obituaries, Uncategorized

I was sorry to just hear via a comment here about the recent death of Bert Kostant, at the age of 88. MIT has a story about him here.

Kostant was a major figure in the field of representation theory, and perhaps the leading one during the second half of the twentieth century among those with a serious interest in the relations between representation theory and quantum theory. These relations have for a long time now been a deep source of fascination to me, and Kostant's work has had a great impact on how I think about the subject.

I'll just list here some of his major papers that I've spent significant amounts of time with, characterized by a few major themes:

Borel-Weil-Bott, Lie algebra cohomology, BRST and Dirac cohomology

- Lie algebra cohomology and the generalized Borel-Weil theorem. This paper has had a huge influence. Some notes from my graduate course discussing this and Borel-Weil-Bott are here.
- Symplectic reduction, BRS cohomology and infinite-dimensional Clifford algebras (with Shlomo Sternberg). If you really want to understand the mathematics underlying the BRST method, this is the place to start.
- Dirac cohomology for the Dirac operator. For the context of this and a lot more about the subject, see the book by Huang and Pandzic.

Quantization of the dual of a Lie algebra, W-algebras

The dual of a Lie algebra is a Poisson manifold, and you can ask what happens when you quantize this. For semisimple Lie algebra, reduction with respect to the nilradical is an idea that Kostant pursued, with two examples the following two papers. Applied to loop groups, this is a central idea of the geometric Langlands program. The theory of W-algebras is also an outgrowth of this.

- On Whittaker vectors and representation theory.
- Quantization and representation theory, in the volume Representation theory of Lie groups.

Geometric quantization theory and co-adjoint orbits

Starting around 1970 Kostant did a great deal of work developing the theory of "geometric quantization" and the idea of quantizing co-adjoint orbits to get representations (other figures to mention in this context are Kirillov and Souriau). Some of his papers on this are:

- Orbits, symplectic structures and representation theory.
- Orbits and quantization theory. 1970 ICM talk.
- Quantization and unitary representations. In Lecture notes in Mathematics 170.

All of the three general themes above are closely intertwined, and the relations between them indicate that there is still a lot more to be understood about how quantum theory and representation theory are related, with Kostant's work undoubtedly playing a large role in developments to come.

Comments

1. **Prof. David A. Edwards**
   February 25, 2017

   The following was the first work by a mathematician on Super-Theory:

   Graded manifolds, graded Lie theory, and prequantization, Bertram Kostant

   https://link.springer.com/chapter/10.1007/BFb0087788

2. **Peter Woit**
   February 25, 2017

   David Edwards,

   Kostant was one of the early mathematicians working on this, but there were others (for one example, Berezin-Leites on supermanifolds), so I don't think claims about "first work" that will stir up arguments from others are a good idea.

3. **David Metzler**
   March 6, 2017

   As a graduate student at MIT from 1992 to 1997, I would have been surprised to know that Kostant had actually retired in 1993—he was around the department more than most of the full-time faculty. He clearly loved his work.

Reality is Not What It Seems

March 4, 2017
Categories: Uncategorized

This Sunday's New York Times has a rather hostile review by Lisa Randall of Carlo Rovelli's popular book Reality is Not What It Seems, which has recently come out in English in the US. Rovelli responds with a Facebook post. Another similar recent book by Rovelli got a much more positive review in the NYT, his Seven Short Lessons on Physics.

I haven't written about these two books mainly because I don't think I have anything interesting to say about either of them (although if someone had asked me to review one of them I might have tried to come up with something). They're aimed very much not at physicists but at a popular audience that doesn't know much about physics. From the parts I've read they seem to do a good job of writing for such an audience, and I noticed nothing that seemed to me either objectionable or particularly unusual. Rovelli's two slightly different angles on this topic are an interest in the ancient history of speculation about physics and a background in loop quantum gravity rather than HEP theory/string theory. Instead of wading into the controversy over string theory, he just ignores it and writes about what he finds interesting.

I'm not so sure why, since to me this seems harmless if not particularly compelling, but Randall strongly objects to Rovelli's attempts to draw connections between modern physics and classical philosophy:

> Wedging old ideas into new thinking is analogous to equating thousand-dollar couture adorned with beads and feathers and then marketed as "tribal fashion" to homespun clothing with true cultural and historical relevance. Ideas about relativity or gravity in ancient times weren't the same as Einstein's theory. Art (and science) are in the details. Either elementary matter is extended or it is not. The universe existed forever, or it had a beginning. Atoms of old aren't the atoms of today. Egg and flour are not a soufflé. Without the appropriate care, it all just collapses.

She's also quite critical of the way Rovelli handles the unavoidable problem of writing about a complicated technical subject for the public:

> The beauty of physics lies in its precise statements, and that is what is essential to convey. Many readers won't have the background required to distinguish fact from speculation. Words can turn equations into poetry, but elegant language shouldn't come at the expense of understanding. Rovelli isn't the first author guilty of such romanticizing, and I don't want to take him alone to task. But when deceptively fluid science writing permits misleading interpretations to seep in, I fear that the floodgates open to more dangerous misinformation.

Here I'm a bit mystified as to why she finds Rovelli any more objectionable than any other similar author (or maybe she doesn't, and he just happened to be the lucky one to have the first such book she was asked to review in the New York Times). As should be clear from this blog and book reviews that I've written, I agree with Randall about a problem that she leads off the review with:

> Compounding the author's challenge is the need to distinguish between speculation, ideas that might be verified in the future, and what is just fanciful thinking.

However, to me it seemed that Rovelli met this challenge better than many, far better than any of the huge popular literature about supersymmetry, string theory and the multiverse. She may be right that someone not paying careful attention could get the wrong idea from Rovelli about cosmological loop quantum gravity models. It's equally true though that readers of her own books about extra dimensions, dark matter and the dinosaurs might come away not understanding exactly what the strength of evidence was for those speculations.

Note added for clarification 3/6/2017: the following is not part of the commentary on Randall's review, it's another related topic I thought readers would find interesting. The relation between the two parts is that they both have to do with the question of distinguishing solid argument/speculation, but it's not about Randall, and the context is different (communicating with other physicists versus communicating with the general public}.

On this question of how/whether physicists (here mathematicians are very, very different) make clear what is a solid argument and what is just speculation, another interesting case is that of Nima Arkani-Hamed, who came to prominence in particle theory with Randall, both of them working on extra dimensional models. Both of them got a huge amount of attention for this, from the public and from within physics, although these ideas were always highly speculative and unlikely to work out.

There's a wonderful new "Storygram" by George Musser of a great profile by Natalie Wolchover of Arkani-Hamed. It's all well worth reading, but related to the topic at hand I was struck by the following:

> Arkani-Hamed considers his tendency to speculate a personal weakness. "This is not false modesty, it's really a personal weakness, but it's true, so there's nothing I can do about it," he said. "It's important for me while I'm working on something to be very ideological about it. And then, of course, it's also important after you are done to forget the ideology and move on to another one."

Arkani-Hamed is an incredibly compelling speaker, but his talks often have struck me as putting forward very strongly some particular speculative point of view, while ignoring some of the obvious serious problems. If you're not pretty well-informed on the subject, you might get misled… From the quote above he seems to have a fair amount of self-awareness about this. Also interesting in this context is his talk last year at Cornell on The Morality of Fundamental Physics. He gives an inspiring account of the intellectual value system of theoretical physics at its best. On the other hand, he pays no attention to the very real tension between that value system and the way people actually pursue their work, often very "ideologically". For particle theory in particular and the current situation it finds itself in, this seems to me an important issue for practitioners to be thinking about.

   March 4, 2017

   "Compounding the author's challenge is the need to distinguish between speculation, ideas that might be verified in the future, and what is just fanciful thinking." OK, coming from someone like Randall, that's just funny. I seem to remember, a long time ago, physicists did actually try to stick to things that might possibly be verified. Though I shouldn't taint all physicists with that brush, I'm guessing solid state folks and the like still do. I've read a little of Rovelli's pop science stuff, and it always seemed pretty good, and quite well grounded.

2. **Douglas Natelson**
   March 4, 2017

   Yeah, the author of a book proclaiming that dark matter likely did in the dinosaurs criticizing Rovelli for lack of clarity about what is speculation seems a bit rich to me.

3. **Peter Woit**
   March 4, 2017

Jeff M.,
Rovelli's specialty is quantum gravity, and in this new book he's trying to write about this topic. The problem with such a topic is that there's no experimental evidence, and no general agreement even on what's a successful theoretical approach. I can't think of any other field of science where scientists try and write books for the public about ideas that haven't gotten any empirical backing. Even in physics, this was not the sort of thing serious physicists did before the 1990s. The problem is that, not because they want to but by necessity, physicists are working this way and people want to hear about what they are doing.

One could make a serious argument that physicists shouldn't be writing books for the general public about speculation not backed by experimental evidence, on the grounds that it's just going to mislead people. Or, one could argue that when physicists do this, they should put huge warning labels on what they are doing to make sure no one gets misled. Given Randall's own books though, she's not in a good position to make that argument. I suspect she sees herself as having put enough caveats in her books, and feels that Rovelli is not doing this, but things tend to look very different if you're writing about your own favorite idea vs. reading someone else writing about their favorite idea (which you don't at all share).

4. **Paolo**
March 5, 2017

Scientists should write for the general public. The work of "popularization" of science is of extreme importance and its utility is not only limited to the pleasing of "armchair scientists": I am actually using the books by Carlo Rovelli as short inspiring sources to motivate and engage *graduate level* students in pure mathematics (that, in the country where I work, do not usually have any technical exposure to physics beyond an introductory 1-semester elementary course as beginning undergraduates). I am also using them, with very good results, as a background reading for a weekly discussion group on mathematical physics with (well-experienced) professional mathematicians.
Clear warnings should be placed when material that is speculative in nature is presented … although everything is quite relative here since, strictly speaking, for a "rigorous" mathematical physicists most of what is currently done in theoretical physics (including standard quantum gauge field theory on 4-dimensional Minkowski space) is still mathematically not-well-founded speculation (no matter its experimental confirmation) 😉
Scientists should write … and having critical reviews should be perfectly OK as well. The problem here is, as always (as clearly stated by M.Planck's famous quote, cited by T.Kuhn), … in the "socio-pathology" of the research environment, where (for reasons of career, funding, narcissism, etc) researchers are politically fighting for the supremacy of certain "fashionable trends" and cannot tolerate the existence of dissonant opinions. The fact that speculations based on work in string theory should be considered "more scientifically founded" and "precise" compared to similar speculations based on work on loop quantum gravity (or other even less fashionable trends) seems an example.

5. **Peter Morgan**
March 5, 2017

Against your Randall quote (because she's right that one always has to pick at details), there is a beauty in the "precise statements" of physics, but to me it is a mathematical beauty. The precise mathematics of our physics is always tenuously related to the experimental data that we hope to take as the ground for our physics when we consider it in its finest details. The beauty of the human endeavor of *doing* physics is to me in searching relentlessly for formal models that are slightly less tenuously related to the experimental data and in recognizing the valor of those who constructed the very good models we already have. In physics I think of progress coming from our reimagining any or all of the mathematics, the experimental data, and the relationship between them; I take the ground of Not Even Wrong to be discussing how any of these three can fail.

6. **piscator**
March 5, 2017

Can't share your enthusiasm for that Storygram. The original piece by Wolchover had all the journalistic scepticism and critical analysis of a Profile of the Dear Leader, and Musser's piece has the same vibe.

Of course Nima is highly charismatic and fun to listen to, but physics is about results, and one would expect journalists to engage critically with the question about what Nima has really done that will still be around in thirty years.

7. **Peter Woit**
March 5, 2017

piscator,
I sympathize with your point, and I hope at some point we'll see a more critical analysis. But I think this is more of a failing of the HEP theory community than one of journalists, who aren't experts, and aren't equipped to provide such a critical analysis if there's no source for it among experts.

8. **Shantanu**
March 6, 2017

Peter , something OT but check out Stacy's blog article which discusses Dave Merritt's article
showing how the goal posts in supersymmetric dark matter have moved.
https://tritonstation.wordpress.com/2017/03/06/lcdm-has-met-the-enemy-and-it-is-itself/

9. **Thomas**
March 6, 2017

I read (well, listened to) Rovelli's book and I tend to agree with Randall's criticism of the book. I was actually rather annoyed with the whole thing and started to skip long sections. Rovelli puts way too much stock in the idea that he is traveling along a path laid out by the Greek atomists, he provides rather misleading explanations of conventional physics, and makes no attempt to explain what the difficulties with the loop quantum gravity approach are.

In this country we like no sin better than hypocrisy, and it is easy to say that this is an odd criticism from somebody who just published a book on dark matter and the dinosaurs (which was reviewed mostly favorably in the pages of the NYT). Indeed, Randall faces some of the same problems in her book. Putting a disclaimer in every other sentences would have made the book unreadable, and begs the question why it was written in the first place.

I think there is an important difference, however. By staying pretty close to how scientists actually work Randall makes it clear that this is a book about the journey, not the final answer. By focusing on the poetic connections between himself, Aristotle, and the nature of the time, Rovelli ends up writing a book that is just a little too much.

10. **Bernhard**
March 6, 2017

Thomas,

I haven't read Rovelli's book yet, but I read Randall's…. Of all people, is SHE really in position to make this kind of criticism? Chutzpah comes to mind.

11. **neil**
March 6, 2017

I just finished Rovelli's new book. I liked it a lot. Basically, it is LQG for dummies, but I appreciated Rovelli's "fluid science writing" and clear exposition of LQG. Yes, the book is a "sell job" for this approach to quantum gravity, but so what? Rovelli does not try to disguise that fact. I would defend the book against some of Randall's criticisms. I encountered no place where I found Rovelli misleading about what we actually know and what is speculation. He admits in his chapter on potential empirical confirmation that the evidence is not yet in and that "we will have to wait and see." What more should he do? I thought he made a telling point when he says that LQG does not need extra dimensions, new symmetries or new particles, just good old fashioned GR, QFT and the SM. And yes, Rovelli is a bit excessive with his sweeping connections to debates in Greek philosophy about whether the world is continuous or granular but, hey, the man is writing a book about the granularity of spacetime. I'll grant him some literary license.

12. **jimmy**
March 7, 2017

neil,

Did Rovelli mention any of the numerous arguments against LQG?

13. **martibal**
March 7, 2017

"Either elementary matter is extended or it is not. The universe existed forever, or it had a beginning. Atoms of old aren't the atoms of today."

Could add: either an electron is a particle or a field….
I am not so sure physics is working that way 🙂

14. **neil**
March 7, 2017

jimmy,

He does not. His exposition is broad and simplified and, as I said a "sell job", so he does not discuss problematic issues like computation and self-consistency checks, for example. He claims you can compute physical phenomena by "summing over spin-foams", but he doesn't give a concrete example. On issues like deriving the classical GR limit and testibility he is simply optimistic things will work out in the future. The potential tests of LQG he mentions are primarily cosmological (he expects a lot from LISA.)

As a non-expert, I was content to get a coherent explanation of how LQG is structured.

15. **Narad**
March 7, 2017

> Art (and science) are in the details. Either elementary matter is extended or it is not.

I'm pretty sure that's *ontology*, rather than either art or science.

16. **Curious Wavefunction**
March 9, 2017

I did read Rovelli's book and I don't think it's supposed to be a solid introduction to loop quantum gravity for the layman. Rovelli's style is very impressionistic, and while this works well in his previous book it doesn't really do the job in this one. At the very least, you would have to build a substantial edifice of physics to launch into a discussion of loop quantum gravity. This Rovelli does not do I think, and others seem to have done it much better. Whatever your opinion of Brian Greene's books for instance, at least he does a very good job of laying out the basic physics (QM, relativity etc.) in his books.

17. **Richard Gaylord**
March 11, 2017

I don't expect you to publish this since you seem to automatically delete any comment i make on any of your columns without any explanation to me as to why (which is your perogative since it's your blog) but the review of Rovelli's book in the Washington Post (http://www.washingtonindependentreviewofbooks.com/bookreview/reality-is-not-what-it-seems-the-journey-to-quantum-gravity) is worth reading.

18. **Richard J. Gaylord**
March 18, 2017

my comment was finally published on 3/11, long after i submitted on 3/4. Rovelli appears to have followed my suggestion in that comment (which you edited out of my comment) that he respond to Randall's review somewhere other than just on his Facebook page and he has just published a condensed version of his reply in tomorrow's NYT Sunday Book Review https://www.nytimes.com/2017/03/16/books/review/letters-to-the-editor.html?emc=edit_bk_20170317&nl=book-review&nl_art=&nlid=77068585&ref=headline&te=1

Can the Laws of Physics be Unified?

March 7, 2017
Categories: Book Reviews, Multiverse Mania

There's a new book out this week from Princeton University Press, Paul Langacker's Can the Laws of Physics Be Unified? (surely this is a mistake, but there's also an ISBN number for a 2020 volume with the same name by Tony Zee). It's part of a Princeton Frontiers in Physics series, in which all the books have titles that are questions. The other volumes all ask "How…" or "What…" questions, but the question of this volume is of a different nature, and unfortunately the book unintentionally gives the answer you would expect from Hinchliffe's rule or Betteridge's law.

This is not really a popular book, rather is accurately described by the author as "colloquium-level". Lots of equations, but not much detail explaining exactly what they mean, for that some background is needed. The first two-thirds of the book is a very good summary of the Standard Model. For more details, Langacker has a textbook, The Standard Model and Beyond, which will have a second edition coming out later this year.

The last third of the book consists of two chapters addressing the question of the title, beginning with "What Don't We Know?". Here the questions are pretty much the usual suspects:

- Why the SM spectrum, with its masses and mixing angles?
- The hierarchy problem.
- The strong CP problem.
- Quantum gravity.
- Problems rooted in the cosmological model: Baryogenesis, dark matter, dark energy and the CC,

In addition, there are problems listed that are only problems if you philosophically think that a good unified model should be more generic than the SM, leading you to ask: why no FCNC? why no EDM?, why no proton decay?

The last chapter "How will we find out?" lists the usual suspects for ideas about BSM physics: SUSY, compositeness, extra dimensions, hidden sectors, GUTS, string theory. We are told that this is a list of "many promising ideas". While in general I wouldn't argue with most of the claims of the book, here I think the author is spouting utter nonsense. The ideas he describes are ancient, many going back 40 years. In many cases they weren't promising to begin with, introducing a large and complex set of new degrees of freedom without explaining much at all about the SM. Decades of hard work by theorists and experimentalists have not been kind to these ideas. No compelling theoretical models have emerged, and experimental results have been strongly negative, with the LHC putting a large number of nails into the coffins of these ideas. They're not "promising", they're dead.

Langacker does repeatedly point out the problems such ideas have run into, but instead of leaving it at "we don't know", he unfortunately keeps bringing up as answer "the multiverse did it". On page 151 we're told the most plausible explanation for the CC is "the multiverse did it", on page 160-163 we're given "multiverse did it" anthropic explanations for interaction strengths, fermion masses, the Higgs VEV, and the CC. Pages 167-173 are a long argument for "the multiverse did it". The problem that this isn't science because it is untestable is dismissed with the argument that it "may well be correct", and maybe somebody someday will figure out a test. On page 203 we're told that string theory provides the landscape of vacua necessary to show that "the multiverse did it".

The treatment of string theory has all of the usual problems: we're assured that string theory is "conceptually simple", despite no one knowing what the theory really is. The only problem is that of the "technical details" of constructing realistic vacua. I won't go on about this, I once wrote a whole book…

In the end, while Langacker expresses the hope that "sometime in the next 10, 50, or 100 years" we will see a successful fully unified theory, there's nothing in the book that provides any reason for such a hope. There is a lot that argues against such a hope, in particular a lot of argument in favor of giving up and signing up for a multiverse pseudo-scientific endpoint for the field. I suspect the author himself doesn't realize how much the argument of the book is stacked against his expressed hope and in favor of a negative answer to the title's question.

Update: If you just can't get enough multiverse mania, you can watch Joseph Silk's talk Should We Trust a Theory? (more talk materials here). I'm not quite sure, but I think we agree that the multiverse is not currently science (he writes "The multiverse might or might not exist, but no physicist should waste his or her time chasing the unchaseable"), but not about about string theory. I have no idea what is behind his claim that "String theory has been very successful", and, since he's not a string theorist, I suspect that neither does he.

Comments

1. **Jeff M**
   March 7, 2017

   I hesitate to say this on a physics blog, but maybe the answer actually is "no."

2. **Peter Woit**
   March 7, 2017

   Jeff M,
   Well, the answer is certainly "no" if the way you approach the question is by refusing to give up on ideas that have failed, and devote your research program to the construction of pseudo-scientific justifications for why your failed idea really is right, just inherently untestable.

   Personally I don't see any reason why one day we shouldn't some day better understand the relation of space-time symmetries and internal symmetries, and thus "unify" gravitational and other forces. Maybe this is possible, maybe not, one can't know in advance. But if you decide you have an argument for impossibility, that's the end of it, and that's the existential danger for the field of "the multiverse did it".

   There's the saying in math, "theorems are proved by those who believe in them", same goes for physics: progress towards unification will come from someone who thinks it is possible, not from someone who has become convinced by "the multiverse did it" argument. Having such people write books that convince others to give up hope is even more damaging…

3. **Bee**
   March 8, 2017

   The points you list are very different in the kind of problem they pose. It might well be there isn't any explanation for the mixing matrices or masses of particles. Quantum gravity is, however, a problem of an entirely different kind – it's needed for consistency. And even if it wasn't for quantum gravity, the SM would still have a Landau pole and what physical sense does this make?

Unfortunately most of the work on unification has focused on problems that I don't think are problems at all. Eg, yes, maybe U(1)xSU(2)xSU(3) isn't pretty, not to mention chirality, but if that's the way nature works then that's that.

The multiverse is merely a conflated way to say that they're trying to answer questions that aren't scientific to begin with, it's beyond me how this has become acceptable.

4. **Mateus Araújo**
March 8, 2017

But what if it is true? I mean, there is no question that the multiverse argument is lame, but Nature has no obligation to be interesting. Or testable, for that matter.

5. **clayton**
March 8, 2017

I thought a good "understand[ing of] the relation of space-time symmetries and internal symmetries" is the reason physicists cared so much about supersymmetry — this is the only nontrivial symmetry allowed by the Coleman-Mandula theorem. Is there another possibility?

6. **chris**
March 8, 2017

Bee,

please tell me one point of experimental evidence that gravity needs to be quantized. I know of none whatsoever. And the Landau pole is a perturbative concept. Nobody yet knows how the nonperturbative RG running of QED looks.

I think our host is quite right to put all these in the same basket.

7. **Jeff M**
March 8, 2017

Peter,

I agree completely, I think I wasn't clear. Multiverse is just silly. One cannot of course eliminate it as a possibility, but that's the point, one can't do anything scientific with it. You're right if any progress is made, it will be by someone who believes it can be done, not with the multiverse. I just don't know that I think there is progress to be made (though of course I'm a mathematician, so what do I know about force unification?) I must say though I'm kind of with Chris on this, who says gravity has to be quantized? Probably just the math, but GR is truly beautiful. The SM, not so much.

8. **vmarko**
March 8, 2017

I'm surprised with the number of questions in the comments above, it's not so usual for Peter's blog. With Peter's permission, maybe I can help a little:

Mateus Araújo,

Of course nature has no obligation to be interesting, or testable. Or even self-consistent, if you ask me. But our mathematical models of nature do have that obligation. There are in general many different mathematical models which can describe nature equally successfully (infinitely many models, finite amount of experimental data). Among all of those models, we are looking for those that are self-consistent, testable and interesting. Otherwise they are useless to us. So it's a self-imposed restriction, for a good reason.

clayton,

Yes, SUSY is not the only way to circumvent the Coleman-Mandula theorem, there are others, though apparently not so popular. For example, the approach based on 2-categories (and higher), see for example 1003.4485.

chris and Jeff M,

Quantizing gravity is a requirement of self-consistency, since quantum mechanics does not tolerate being combined with anything classical. This has nothing to do with experiment, but with the axiomatic structure of the resulting theory. Namely, if one attempts to combine QM with classical GR (or classical electrodynamics, or anything else classical), one is lead to a clear-cut mathematical contradiction (violation of the superposition principle). So we either give up QM as we know it, or we give up GR as we know it. Something has to give, and of course research is being done in both directions.

HTH, 🙂
Marko

9. **Peter Woit**
March 8, 2017

Mateus Araujo,
The problem is that you need some kind of serious argument, just saying "my complicated, ugly model doesn't predict anything, so maybe the multiverse did it, let's give up" isn't one.

clayton,
Standard supersymmetric models don't unify internal and space-time symmetries. They extend the Poincare group by new spin-1/2 generators that commute with internal symmetries. This is why SUSY tells you nothing about the SM.

Bee/Chris/Jeff M.,
My take on the quantum gravity problem is that GR and the SM are based on very closely related mathematical structures: a matter particle is coupled to gravity by a connection and to the SM forces by connections. Our problem is that we don't understand the relation between these two kinds of connections. You can just say "there is none", maybe that's right. If you want to claim "let's quantize the SM connection, not the GR connection", besides consistency issues to worry about, you really should have some argument why you are treating these in a completely different fashion, other than the fact that applying a standard quantization recipe to the GR connection leads to problems.

10. **Mateus Araújo**
March 8, 2017

vmarko,

How could Nature avoid being self-consistent? I find that literally inconceivable. As for the rest of your argument, I think you have a point. It unfortunately draws a line between what Nature is and what we can say about Nature, but I guess there is no way around it.

One should, however, not be too strict about testability, otherwise one is led to ridiculous positions such as saying that we don't know whether Galileo's remains are still inside Jupiter.

chris and Jeff M,

You can't just say the gravity is classical and you don't need to quantize it. You need to actually formulate how a "non-quantum gravity" acts on atoms. The most straightforward way is to do [fails miserably](http://journals.aps.org/prl/abstract/10.1103/PhysRevLett.47.979).

http://journals.aps.org/prl/abstract/10.1103/PhysRevLett.47.979

11. **clayton**
March 8, 2017

Thanks for the replies to my question, vmarko and Peter! But, to respond to Peter, I thought that Coleman-Mandula provided a proof that there is no nontrivial product of spacetime and internal symmetries. They went on to make the (incorrect) claim there were no additional symmetries beyond the product of Poincare with internal symmetries; but this (incorrect) latter statement was, I thought, logically independent of the rest of the proof. Is this an accurate characterization? By the way, I am also confused with how the BMS "infinite dimensional" symmetry works in this respect, so my confusion is quite broad 🙂

12. **Peter Woit**
March 8, 2017

clayton,
Yes, Coleman-Mandula is a real problem, it means that there has to be a more subtle relation between internal and space-time symmetry groups than just naively finding a larger group they both fit into and making that act in a conventional way. The BMS story is a really interesting one, I haven't thought about the relation to Coleman-Mandula, but there (BMS) the group is acting non-trivially on the vacuum, which may be one reason Coleman-Mandula isn't applicable.

If you look at the history of "no-go" theorems, I think you'll find that typically sooner or later someone realizes that there is a way around one of their assumptions, so one should be very careful about drawing a conclusion from the "theorem" without paying very close attention to exactly what its assumptions are.

13. **Kurt**
March 8, 2017

It seems that the correct title of the book should have been "Did Our and My Ideas so far Allow the Laws of Physics to be Unified?" Here the answer is of course "no".

A honest summary would have clarified that the ideas in the last chapter all failed, and that a unifying ideas must differ from them.

A second honest summary would have added: Yes, the laws can be unified, because we can talk about *all of nature*. Therefore we can also talk *with precision* about all of nature. And therefore we must be able to unifiy all known laws.

It is obvious that unification is possible. But how to achieve it is not.

Whoever says the opposite is spreading disinformation.

14. **clayton**
March 8, 2017

thanks for the clear answer, Peter!

15. **Peter**
March 8, 2017

Bee, Mateus – I think the fact that the 'multiverse' argument is dressed up as a statement about reality makes one think that 'a multiverse' is a real thing, a single object which represents reality.

Given a system of (mathematical) axioms, one can deduce some statements; some statements have a truth value which is forced from the axioms (and these are not the same!). Other statements (if your axiom system is interesting) do not; they are independent. Some of these other statements have interrelations; if you fix one to true another is then forced to be also true, et cetera.

A model of a system of axioms is then an assignment of truth values to statements which is consistent (or at least is inconsistent only if the axioms themselves are inconsistent).

For example, one can take a standard set theory (ZFC say) and ask whether there exists a set of cardinality between the naturals and the reals. For ZFC this turns out to be one of those independent statements (the Continuum Hypothesis, CH, is the negative assertion); it doesn't have a defined truth value.

One can construct models of ZFC in which CH is true, others in which it's false, in either case asking 'why is it true/false' doesn't have a reasonable answer (unless you weren't looking at CH when you made your construction, anyway). It's that way because you set it that way.

Of course, one can consider the class of all models, or 'multiverse'. Then you answer 'why is CH true/false' with 'because we are in that bit of the multiverse'; same logic dressed up differently.

Now, if you take an axiom system which you think describes reality, it will have (for the same reason) many different models. These are not logically related, they cannot 'interact' because there is nothing to 'interact' with. This is the (Platonic mathematical) multiverse which is (sometimes) being used in place of an explanation in physics.

Another possibility is that our current view of `the universe' is one among a collection of interacting structures; in other words, that our current idea of 'the universe' sees only a slice through some more intricate structure of reality. That rather hypothetical 'more intricate structure' also gets called a multiverse, whereas if one posits it, what one actually asserts is a more complicated universe of which we currently (as far as we know) witness only a slice. It should be clear that two different slices through a single mathematical structure (which is a single model of an axiom system) potentially do interact and in any case are not the same thing as two different models of an axiom system. But since the same word is used for both, the two rather different concepts have been conflated.

And finally, what our host is objecting to, in these terms, is prematurely classifying statements as independent of the axiom system when we do not know this (especially since we presumably do not know the full axiom system). Incidentally, it's worth noting that an independence statement is never itself independent (one cannot logically criticise our host for asking for certainty on this point). A statement S is independent of an axiom system A if there are models of A in which S is true and others in which it is false; letting T be 'S is independent of A', if T can be true then these models exist and hence T is definitely true (though it need not have a proof in A, or indeed in any given bounded axiom system if A is reasonably complicated, so our host might not ever know why the multiverse did it).

16. **Peter Woit**
March 8, 2017

    Peter,

    The serious questions here are questions of what science is, what reliable scientific knowledge is, and how to pursue it. I don't think the kind of framework of axiom systems and models that you discuss captures the issues at all (and it has nothing at all to do with the topic of this posting).

17. **Johannes**
March 10, 2017

    Peter,

    do you believe that the laws of nature can be unified – and why?

    What is your experience: how many of the researchers in the field believe in a positive, and how many in a negative answer?

18. **Peter Woit**
March 10, 2017

    Johannes,

    Yes, in the sense that I think there is a better theory out there that we don't yet know about, which would for instance tell us something deep about the relation of space-time and internal symmetries. Part of my reason for believing this is that there are all sorts of intriguing connections between the mathematical structures involved. This does not look like the kind of situation where one understands things well enough to know why you're not going get some deep relation, it looks a lot more like a situation where something important is going on that one doesn't understand. To get some idea of the general thing I'm talking about, see my essay
    http://www.math.columbia.edu/~woit/mathphys.pdf
    but there are also much more specific ideas that I'm hoping to get to writing about after I finish work on my book (any day now…).

    I'd assume people who work on trying to find a deeper understanding of the Standard Model do so because they believe there is something there. Undoubtedly there are lots who, faced with ideas they devoted a lot of time to not working, have given up. Some go and work on other problems, a few unfortunately write books aimed at getting other people to give up too…

19. **James Cooper**
March 10, 2017

    I am not a mathemetician or a physicist or even very intelligent but I have 3 points to make

    1) It seems obvious Peter is so right on his points, especially in how much effort has been wasted in failed directions and there are directions in math that haven't been fleshed out fully yet. It is absurd to "give in" so early with this multiverse nonsense when there are things we don't even know about number theory for instance

    2) I enjoyed looking at Peter's PDF. It seems he is setting himself up to be the "I told you so" laureate when in 20 years a new Einstein comes along and inevitably shows us that the universe is just math and couldnt be any other way.:) Penrose seems to do this explicitly in his book Road To Reality

    3) Peter talks about number theory in his PDF but doesn't specifically mention the Reimann zeta function. I'm wondering if you have/have had any general thoughts on it? Again, I'm not a mathemetician, but I am fascinated by the fact that there might actually be something unrandom in prime numbers. It seems to me if there is anything fundamenal about the nature of reality it might be found in that

20. **Peter Woit**
March 10, 2017

    James Cooper,

    Thanks, you're quite right that I hope that someone smarter then me shows my prejudices about this topic to be right. Of course it's a lot easier to have the right prejudice than to successfully justify it.

    I don't have any serious ideas about the Riemann hypothesis. If we ever know why it is true, that will surely tell us something deep about number theory which very well may elucidate its connection to quantum theory (and maybe a new deep idea about quantum theory will explain why the Riemann hypothesis is true). Actually yesterday in my Fourier analysis class I went through the proof of the functional equation for the zeta function, based on using Poisson summation to first prove the functional equation for the theta function. This morning it struck me that I have no idea if there's a version of the Riemann hypothesis formulated directly as a statement about the theta function, would love to hear from anyone who can point to that.

21. **Jeff M**
March 10, 2017

    Peter,

    I cannot for the life of me remember if there's a version of the RH for the theta function, it was too long ago when I was in grad school thinking I wanted to be an analytic number theorist. I do remember there are versions of the RH for the Dirichlet L functions, the generalized RH says that the zeros for any L function have real part 1/2. L functions are just zeta but with a multiplicative character as the numerator.

22. **Peter Woit**
March 10, 2017

    Jeff M,
    A few minutes of Googling have turned up a version of this question on mathoverflow

    http://mathoverflow.net/questions/14083/modular-forms-and-the-riemann-hypothesis

I don’t see much of a satisfactory answer there though…

23. **jd**
March 10, 2017

Paper on arXiv, 1608.03679, on RH, to be published in PRL.

24. **Peter Woit**
March 10, 2017

jd and others interested in proofs of the RH,

Please, very low on the desirability list of things to do over my spring break is moderate a discussion of people’s ideas about how to prove the RH. If you have a pointer for where someone discusses what the RH says about the theta function, I would like to see that.

25. **Jeff M**
March 13, 2017

Peter,

If you’re really curious, the person to ask is Peter Sarnak, at Princeton/IAS. I assume several people at Columbia know him well. Met him at UCLA when I met you, he was a few years out of grad school then and the hot new analyst, student of Paul Cohen at Stanford. Right after that he was around the GC a lot while I was working on my thesis. FYI, as far as proofs for the RH go, i wouldn’t hold my breath….

This Time It's For Real

March 10, 2017
Categories: Quantum Theory: The Book

Several months ago I was advertising a "Final draft version" of the book I've been working on forever. A month or two after that though, I realized that I could do a more careful job with some of the quantum field theory material, bringing it in line with some standard rigorous treatments (this is all free quantum fields). So, I've been working on that for the past few months, today finally got to the end of the process of revising and improving things. My spring break starts today, and I'll be spending most of it in LA and Death Valley on vacation, blogging should be light to non-existent.

Another big improvement is that there are now some very well executed illustrations, the product of work in TikZ by Ben Dribus.

I'm quite happy with how much of the book has turned out, and would like to think that it contains a significant amount of material not readily available elsewhere, as well as a more coherent picture of the subject and its relationship to mathematics than usual. By the way, while finishing work on the chapter about quantization of relativistic scalar fields, I noticed that Jacques Distler has a very nice new discussion on his blog of the single-particle theory.

There's a chance I might still make some more last-minute changes/additions, but the current version has no mistakes I'm aware of. Any suggestions for improvements/corrections are very welcome. Springer will be publishing the book at some point, but something like the current version available now will always remain available on my website.

Update: After writing to someone to answer a question and what is and isn't in the book, and other things to read, I thought maybe I'd post here part of that answer:

> For the main topics about QM and representation theory that I cover in the book, I don't know of a better reference, even assuming an excellent math background. That's one of the main reasons I wrote the thing… The problem with other books on QM for mathematicians (e.g. Hall, which is very good on the analysis point of view) is that they don't do much from the representation theory point of view. Weyl's book was written very early, when a lot of what was going on was still unclear, I don't think it's a very good place to try and learn this material from. One topic that is in there that I don't cover at all is basically Schur-Weyl duality, but even for that arguably Weyl is not a good place to learn that theory.
>
> One thing to keep in mind about my book is that the early chapters are deceptive. I wanted to start out with very simple things, make the simplest examples accessible to as many people as possible, mathematicians or physicists. If you know basic facts about Lie groups, Lie algebras, finite dim unitary representations, Fourier analysis and how to use it to solve e.g. the heat equation, then the first quarter of the book is only going to be of interest in telling you about some applications of math you know. Mathematicians generally should be learning the basic rep theory elsewhere (lots of good books on these topics, and the main reason I'm doing many things in a mathematically sketchy way is that doing them in full would take too long, and has been done better elsewhere). In early chapters, all I'm really doing is working out very special cases of Lie groups/algebras that are rank one or products of rank one, and the irreps of sl(2,C). I never touch higher rank or general semisimple theory (would argue this actually doesn't get used much in physics, other than some simple SU(3) examples).
>
> Around chapter 12 though, things get much more non-trivial. From a high mathematical level, a lot of what's going on in the middle part of the book is the representation theory of the Heisenberg group (over R and C) and the implications of the action by the symplectic group by automorphisms (e.g. the metaplectic representation). This is done in a very detailed and concrete way, together with the relation to QM, although for some of the trickier parts of the mathematics (especially the analysis, e.g. the proof of the Stone-von Neumann theorem) I just give references. This is followed by discussing Clifford algebras, the orthogonal group and spinors (over R and C), in a very parallel way (interchanging symmetric and antisymmetric). I wish I knew of a good pure mathematics source for this material aimed at students, stripped of the quantum mechanics apparatus, but I don't. It (as well as material about reps of the Euclidean groups) is not covered in any conventional rep theory textbook I'm aware of.
>
> Much of the last third of the book, on quantum field theory, I think is just inherently quite challenging, for either mathematicians or physicists. From the representation theory point of view, the basic framework is that of an infinite dimensional Heisenberg group or Clifford algebra, but this is a difficult mathematical subject, and I think the physics point of view helps make clear why. For this stuff the rigorous treatments are quite specialized, I try and do some justice to what the main issues are and give references that provide the details.

Comments

1. **CIP**
   March 10, 2017

   I looked at a couple of sections dealing with issues that I've previously found difficult and was impressed by your directness and clarity. Looks like a winner to me!

2. **RP**
   March 10, 2017

   I think the book looks very, very impressive. I look forward to delving into it more deeply!

   One typographical pet peeve of mine, which I also notice in the current draft: 'digressions' and 'examples' are printed in cursive. This is distracting to me, since I (and most readers I think) tend to interpret cursive text as a form of emphasis. This is certainly appropriate for theorems and propositions, and perhaps for definitions, but clearly not for something like a digression.

   Anyway, many congratulations on your achievement!

3. **G. S.**
   March 10, 2017

   I'm not exactly sure how copyright works, but how can something be copyrighted 2016 but dated 2017? I get that portions of the document were previously released and copyrighted, but wouldn't the addition of new material extend the copyright of the document as a whole?

   Not sure if you want to get into a discussion of copyright law right before your trip to Death Valley, but I was curious. The book looks interesting and I'm looking forward to reading it. Thank you for posting it. Enjoy your break.

4. **Anonyrat**
   March 10, 2017

   Page 4: After calculating a final result, insert appropriate factors of ℏ can be inserted to get answers in more conventional unit systems

5. **Anonymous**
March 11, 2017

I'm really happy for you. What a magnificent piece of work.
I have one little nitpick about the usage of \left and \right.
This image explains it — http://1.1m.yt/S2j8hi.png
Not really an issue, because both have the same meaning. But I think you will agree the usage of \left(and \right) are prettier.

Congratulations.
This book is a milestone.

6. **tommaso dorigo**
March 11, 2017

Congratulations from me too Peter! This is a great work and I'm very happy you finally pulled it off!

7. **a reader**
March 11, 2017

Congratulations !
And thank you for making the final draft freely available.

8. **vmarko**
March 11, 2017

This kind of book has been missing in the landscape of QM textbooks. I've already recommended it to a few mathematicians who wanted to learn QM efficiently. Great work, congratulations!

🙂
Marko

9. **Denton Dailey**
March 11, 2017

Just started giving it a quick read. Found this on page four:

"After calculating a final result, insert appropriate factors of (h-bar) can be inserted to get answers in more conventional unit systems."

I've written a few EE texts and I know it's nearly impossible to catch all of these minor things no matter how many times you read it yourself. Will note any other issues I happen to spot, but it looks great overall.

10. **DRLunsford**
March 11, 2017

I like it. When I get the hard copy it will sit next to Weyl 🙂

-drl

11. **Anonymous**
March 11, 2017

I was curious to see the Tikz pictures and noticed one minor error in one of the captions. The caption of Figure 8.2 says "Cylindrical Coordinates". This should be "Spherical Coordinates". I also agree with the comment about the (lack of) use of \left and \right, especially when taking Lie brackets of items which involve larger delimiters, it looks much better if the outside ones are at least the same size as the inside ones. My guess is that an editor from Springer would make those changes anyway.

12. **Richard Ferguson**
March 11, 2017

Great news, Peter! Your book looks great, nothing really to nitpick on the presentation of the material. It's a very interesting and novel way to go about introducing QFT.

By the way, now that you're finished the book, do you have any research projects in Langlands or such that you're working on? Any plans for publishing papers? I would definitely be interested in reading them.

13. **DRLunsford**
March 12, 2017

Peter, don't know if you've ever been, but the journey up to Palomar Observatory from LA south toward San Diego is a great drive with a better destination. It's a strange feeling to be sitting there in the presence of the building surrounded by scrub and forest, but mindful of the Virgo Cluster..

-drl

14. **Peter Woit**
March 12, 2017

Thanks to all who have pointed out typos/typographical improvements. I've started fixing/implementing them, in particular glad to have pointed out the issue about delimiters, where I'm for now fixing the most egregious cases.

Any help of this kind is greatly appreciated, you can send me comments here or by email. If you're up for the more advanced topics of the book, you're encouraged to start looking at those, since I'm getting a lot more help with the early chapters than with the later ones. It's expected that many readers will get lost before they get to the end, but I hope some will make it all the way…

15. **Peter Woit**

March 12, 2017

DRLunsford,
I made a trip up to Palomar once, quite a long time ago and it was impressive. This trip may include a stop by Anza Borrego, which supposedly is in the midst of an unusual wildflower bloom. Palomar is nearby, maybe another visit there is indicated.

Richard Ferguson,
Definitely several research projects I now want to get to work on. The first is something I've wondered about for years, but working on this book has finally given me what looks like a way to finally get somewhere with it. We'll see soon. Another project is to finish something I started writing about Dirac cohomology and BRST. I will try and get something written and done about both of these first, since I now in principle have the background I need for them. For anything about number theory, first I have much more to learn…

16. **Martin**
March 14, 2017

With respect to paragraph 3.4 an interesting reference would be the Jaynes-Cummings model, dating from 1963, which features a two-level atom in a cavity and interacting with a single bosonic radiation mode.

17. **theoreticalminimum**
March 14, 2017

Peter,
Thanks very much for sharing a finalised version! I sure hope to find the time to read through, and learn.
In November last year, I noticed a book by Hayashi titled "Group Representation for Quantum Theory" published by Springer. Did you know about it, and would you recommend it?

18. **Cobi**
March 14, 2017

On page 573 you write that "The Hamiltonian with Einstein's equations as equations of
motion is however not of the Yang-Mills form. Applying standard perturbation
theory and renormalization methods to this Hamiltonian leads to problems with
defining the theory (it is not asymptotically free)".
Two things struck me about this and i hope you can clarify.
First of all the notes by Schwartz (http://isites.harvard.edu/fs/docs/icb.topic521209.files/QFT-Schwartz.pdf, p. 245) explain that general relativity leads to a perfectly sensible quantum field theory, at least as sensible as the standard model without gr.
On the other hand, even without coupling to general relativity the standard model is not asymptotically free due to the U(1) factor.
Thus "it is not asymptotically free" can not be the crucial obstruction.

19. **Peter Woit**
March 15, 2017

Cobi,
The topics you bring up have nothing at all to do with what I wrote, which is just pointing out that the pure Einstein theory Hamiltonian has a very different form than the pure Yang-Mills Hamiltonian, not sharing its good UV properties.

If you're looking for the usual tedious debates about quantum gravity, you really need to look elsewhere, that's not what this book is about, it's intent is to explain some very different things.

20. **R. Rosenfelder**
March 16, 2017

Dear Peter Woit,

I was surprised that you do not mention the Maslov "correction" when treating the time-dependent harmonic-oscillator propagator, i. e. the phase, which arises when the particle goes through a focal point.

Thus your eq. (23.12) in chapter 23 on page 271 is only valid for T < omega/pi; otherwise the propagator gets an additional phase.

This is covered in the standard textbook by H. Kleinert: "Path Itegrals in…", 3rd edition, p. 100 or in arXiv:1209.1315. Since the latter source may be not easily accessible to you, I recommend P. A. Horvathy's paper in quant-ph/0702236 as a detailed treatment of this caustic phenomenon.

Best regards

Roland Rosenfelder

21. **Peter Orland**
March 16, 2017

Hi Peter,

A very good beginner's treatment of the Maslov index from conjugate points is in Larry Schulman's book on path integrals (from 1981). He also has a nice elementary discussion of how a LEAST-action/arc-length principlea become an EXTREMAL principle, after passing a conjugate point.

You have plenty of other topics treated already, so this is something you could mention, without reviewing it.

22. **Peter Orland**
March 16, 2017

Hi Peter,

I just took a look at your discussion. I think you can forget about the Maslov index.

The result (23.12) is exact (the Maslov index is hidden in the answer), for the problem you consider (the simple harmonic oscillator). There is probably no need to mention

Morse theory or the Maslov index to your intended audience, unless you study more general physical systems.

23. **Peter Orland**
March 16, 2017

Scratch that… the Maslov index is definitely there in the SHO. I just checked it.

24. **Peter Orland**
March 16, 2017

… by which I mean it has to be inserted into (23.12) past the first conjugate point.

25. **Peter Woit**
March 19, 2017

theoreticalminimum,
I hadn't seen that. From the table of contents it looks like there's some overlap with what I've written, but the books are mostly pretty different. I'm traveling now, when I get back will take a closer look.

26. **Peter Woit**
March 19, 2017

Roland Rosenfelder/Peter Orland,

Thanks for pointing this out! When I get back to New York soon I'll think a bit about how much I can sensibly say about this in the book, but the existence of this phenomenon certainly needs to be mentioned.

27. **Maximillian G. Tresmond, Esq.**
March 19, 2017

Congratulations! What a great accomplishment!

28. **Austin**
March 20, 2017

At a first glance this is an impressive display of author's scholarship. The writing is clear. However, I don't know what is the purpose of a book of this size? Is is supposed to be used for a semester long material? The book seems diffuse on what chapters are considered important knowledge for the subject. What is the idea behind chapters that are just a couple of pages long?

29. **Peter Woit**
March 20, 2017

Austin,

The book roughly corresponds to a year-long course I've taught a couple times, assuming roughly a typical advanced undergraduate in math background. The later parts are much more challenging than the earlier ones. The size of chapters very roughly corresponds to a lecture (the class meant twice a week).

The goal of the book was to get to the point of explaining the basics of the quantum field theory ideas that make up the Standard Model, with the constraint of dealing just with free fields, not interactions, all in a way that emphasizes symmetries and how to think of quantum theory in terms of representation theory. There's a lot of material in early parts of the book which is not normally covered in courses at that level, but it's there because it's the simplest example of ideas and calculations which normally only are first explained in the much more complicated context of relativistic quantum field theory. I hope that this material will be useful as background for anyone studying relativistic QFT.

30. **Anon**
March 20, 2017

Hi Peter,

This is off topic but looks like Jester has won his SUSY bet with Lubos? CMS and Atlas reported their 36 fb-inv search results at Moriond 2017.

Surprised to see that blogs havent picked this up yet.

https://indico.in2p3.fr/event/13763/other-view?view=standard

cornering natural susy with 13 TeV… https://indico.in2p3.fr/event/13763/session/4/contribution/89/material/slides/0.pdf

31. **Shantanu**
March 22, 2017

OT : Peter, very curious to know your take on https://arxiv.org/abs/1703.05331
It says that no BSM physics below QG scale will be seen as pulsar timings severely constrains such bounds.

32. **Peter Woit**
March 22, 2017

Shantanu,

That claim seems highly implausible. They're making an extraordinary claim, that we have experimental access to just about any physics at arbitrarily short distance scales. That would be wonderful, but I don't see any extraordinary evidence so will wait until someone with more time on their hands figures out whether they really have something.

33. **Peter Woit**
March 22, 2017

Anon,

Will write very soon about the new LHC results.

34. **Peter Woit**
March 24, 2017

Roland Rosenfelder,

Now back from vacation and one thing I've gotten done is to add something about the issue you mentioned. From my point of view the source of this choice of phase factor is determined by analytic continuation from, so I've referred to a source that discusses it in that way. Thanks for pointing this out!

35. **Anonymous**
March 25, 2017

Why keep an empty Acknowledgements section?
I would remove it.

36. **Peter Woit**
March 25, 2017

Anonymous,

That will be the last thing to be added. I'm still getting help that I'd like to acknowledge, some from this blog…

37. **Georges E.**
March 27, 2017

Peter Woit, thanks for this wonderful book: so clear, and yet it doesn't leave anything out! A tremendous achievement.
Congrats!

38. **anon**
April 7, 2017

On page 74 you could use \left[and \right]
On page 76 it looks Φ has extra parentheses
On page 106 and 199 you could use \left(and \right)
On the exercises you could also use \left(and \right)

39. **Peter Woit**
April 7, 2017

anon,

Thanks, fixed.

New LHC Results

March 22, 2017
Categories: Experimental HEP News

This week results are being presented by the LHC experiments at the [Moriond](#) (twitter [here](#)) and [Aspen](#) conferences. While these so far have not been getting much publicity from CERN or in the media, they are quite significant, as first results from an analysis of the full dataset from the 2015+2016 run at 13 TeV, This is nearly the design energy (14 TeV) and a significant amount of data (36 inverse fb/experiment). The target for this year's run (physics to start in June) is another 45 inverse fb and we'll not start to hear about results from that until a year or so from now. For 14 TeV and significantly larger amounts of data, the wait will be until 2021 or so.

The results on searches for supersymmetry reported this week have all been negative, further pushing up the limits on possible masses of conjectured superparticles. Typical limits on gluino masses are now about 2.0 TeV (see here for the latest), up from about 1.8 TeV last summer (see here). ATLAS results are being posted here, and I believe CMS results will appear here.

This is now enough data near the design energy that some of the bets SUSY enthusiasts made years ago will now have to be paid off, in particular Lubos Motl's bet with Adam Falkowski, and David Gross's with Ken Lane (see here). A major question now facing those who have spent decades promoting SUSY extensions of the Standard Model is whether they will accept the verdict of experiment or choose a path of denialism, something that I think will be very damaging for the field. The situation last summer (see here) was not encouraging, maybe we'll soon see if more conclusive data has any effect.

If the negative news from the LHC is getting you down, for something rather different and maybe more promising, I recommend the coverage of the latest developments in neutrino physics here.

Update: Lubos has paid off his bet with Jester. Losing the bet hasn't dimmed his enthusiasm for SUSY. No news on whether David Gross has conceded his bet.

Comments

1. **new**
   March 22, 2017

   do you ever plan to publish an update to your 2005 book, updated with these latest results?

2. **Shantanu**
   March 23, 2017

   Peter I am still waiting for your post (promised after 2015 Nobel prize) on why non-0 neutrino mass is important and the impact of non-zero neutrino mass on BSM. (From John Ellis talk at PI, he mentioned that we still don't have a clue about how to connect BSM physics at TeV scale with neutrino mass measurements)

3. **flavor physics**
   March 23, 2017

   Not only neutrino physics. Also quark flavor physics too!, in particular from the LHCb experiment. There are other things than ATLAS and CMS direct searches 🙂
   Several measurements in flavor physics, none conclusive alone, seems to all point towards a change in C9 Wilson coefficient. On top of that, LNU (Lepton Non Universality) also adds some spice in flavor physics.
   See, eg, Joaquim Matias' talk @Moriond EW
   https://indico.in2p3.fr/event/13763/other-view?view=standard#2017-03-22

4. **Peter Woit**
   March 23, 2017

   new,
   No plans for anything like that now, I'd rather spend my time on other things. I just took a look at the chapter on supersymmetry in my book. It was written nearly 15 years ago, but I think stands up very well. It explains the long list of problems with SUSY extensions of the SM, and lists exactly two positive arguments for such models: one is the approximate unification of coupling constants, the other is the prediction of new weak-scale physics, observable at the LHC. That second argument is now gone, and I don't see any continuing reason for anyone to take these models seriously.

5. **chris**
   March 23, 2017

   flavor physics,

   for me the interesting thing is not the appearance of flavor "anomalies", but that LHCb has seen so few of them until now. Throughout the last decades, these anomalies came and went and it speaks for the quality of the LHCb analysis techniques that they produce so few false positives.

   I will take any bet that these "anomalies" will be gone for good before long (i.e. with the next order of magnitude increase in integrated luminosity).

6. **new**
   March 23, 2017

   In light of LHC not seeing any hints of SUSY, and your book NEW, what are the implications to string/m-theory research and debate, esp the claim that string theory does not require low-energy SUSY, and there are string vacua that are entirely non-susy?

7. **Peter Woit**
   March 23, 2017

   new,
   I don't want this to turn into the usual arguments about string theory. That said,
   the problem for string theory is that the standard response from string theorists for many years when asked "how can string theory be tested" was "by finding supersymmetry at the LHC", see for instance here
   http://www.math.columbia.edu/~woit/wordpress/?p=3864

Now that hope is gone, there really is no answer at all to this question, and claiming to have a wonderful theory of everything that makes no predictions and can't be tested is not a comfortable situation to be in.

8. **Hans**
March 24, 2017

Peter,

There is that famous graph showing that the three coupling constant unify at a certain energy when supersymmetry is taken into account. The same graph also shows that above that energy, the coupling constants diverge again. How is this second fact explained by supersymmetry fans?

9. **Graham**
March 24, 2017

Looks like Lubos is negotiating payment to Adam, possibly involving a pigeon 😉
https://twitter.com/Resonaances/status/844218605638103040

10. **Peter Woit**
March 24, 2017

Hans,
What is supposed to happen in a GUT is that there is a new Higgs-like sector that breaks the GUT symmetry to SU(3) x SU(2) x U(1). Above the GUT scale these degrees of freedom contribute and the dynamics changes. The necessity of introducing this new sector and the various problems it causes is one of the main drawbacks of GUTs.

11. **tommaso dorigo**
March 24, 2017

Hi Peter,

thanks for the link to the NeuTel blog! Indeed I concur that neutrino physics and astrophysics is where the most interesting results are going to appear in the near future…

Cheers,
T.

12. **Low Math, Meekly Interacting**
March 24, 2017

Hoping to see a post from Jester soon. His blog's been dormant for a while, causing me some worry it will be orphaned…

While the last shovel-full's of soil are being spread over SUSY's coffin, it seems worth noting the graveyard has gotten rather full these past few years. Are there ANY ideas left that are both compelling and have some hope of being tested experimentally by 21st century humans and their colliders?

13. **new**
March 24, 2017

Peter could you please clarify this scientific issue,

do the current null results based on 36fb-1 @13TEV completely falsify the hypothesis of natural SUSY, or is there still a parameter space remaining for natural SUSY, perhaps that a future proposed 100 TEV collider is required to eliminate?

14. **Peter Woit**
March 24, 2017

new,
The problem is that "natural SUSY" is not a well-defined concept. It's basically the idea that SUSY explains the weak scale (say 200 GeV), and thus implies that the SUSY-breaking scale should be roughly that. Already at the Tevatron, there were bounds above 200 GeV for gluinos and no evidence for any SUSY particles, so enthusiasts were saying "it's only "roughly", so maybe parameters are "tuned" to the extent of only being 10% of what you might expect". With the LHC results they have to say, "maybe only 1%" of expected, After nothing is found 50 years from now at a 100 TEV collider they'll say "maybe only .1%".

Besides this generic problem, there are 105 or so extra parameters in minimal SUSY models. You can try and evade LHC results by picking these to have special values making sparticles hard for experimentalists to find.

The fundamental situation though is that SUSY never provided a compelling explanation of anything about the SM, and is much, much more complicated (see my old book for details). So, not seeing anything is exactly what one would expect, and arguing for more and more implausible explanations for why your idea failed as expected is becoming more and more pathetic (and fewer and fewer are willing to go down this route).

15. **Thomas Larsson**
March 24, 2017

Sigh. I'm not sure that I want to say this, since I have found that I agree with Lubos on most things (including some politics), but I feel that I should point out that my ten-years-old theorem still holds.

Theorem [Larsson 2007]
Supersymmetry will not be discovered at the LHC.
Proof: String theory predicts supersymmetry (Witten 1984-2002). String theory predictions are always wrong. Hence supersymmetry does not exist, and will in particular not be found at the LHC. QED.
Corollary
Lubos Motl will lose his experimental-susy-by-2006 bet.

16. **Yatima**
March 26, 2017

Science/Popular article in Nautilus about the search for the 5th force spotted:

http://nautil.us/issue/46/balance/the-fifth-force-of-physics-is-hanging-by-a-thread

17. **pval**
March 27, 2017

“The chance that they are just a random statistical fluctuation is tiny, says Feng: about 1 in 100 billion.”
http://nautil.us/issue/46/balance/the-fifth-force-of-physics-is-hanging-by-a-thread

I’m going to assume this is referring to Krasznahorkay et al (2015; https://arxiv.org/abs/1504.01527). There was a lot of this “transposing the conditional” surrounding the LIGO results as well. As a layperson wrt physics I find the continued misinterpretation of p-values in physics discussions disconcerting. If the people interpreting physics data do not understand the tool they are using, how can we trust their conclusions?

Some explanation can be found at these links:
http://rationalwiki.org/wiki/Confusion_of_the_inverse
http://andrewgelman.com/2013/03/12/misunderstanding-the-p-value/

18. **Peter Woit**
March 27, 2017

Yatima/pval,
The “fifth force” story really is a different topic, and, honestly, one I personally don’t think is worth paying a lot of attention to. It’s yet another example of the general principle that “extraordinary claims require extraordinary evidence”, and the evidence here is definitely not extraordinary.

19. **emile**
March 28, 2017

pval: “If the people interpreting physics data do not understand the tool they are using, how can we trust their conclusions?”

Experimentalists in big collaborations understand p-values and you will not see a paper with such a mistake published (though students may make similar mistakes). I don’t know if Feng was correctly quoted but theorists do not work on a daily basis with statistics or the interpretation of data. Anyway, I would not decide that “physicists” can’t interpret data based on a quote from a theorist.

20. **hyd**
March 29, 2017

Ideas that do not work do not die out by themselves. They die out only after their creators die. This is what history has shown to us. So, I predict however negative the evidences to come out, those with SUSY will not stop pushing their ‘agenda’ until their last breath. Those people will keep jiggling with their models and playing all ingenuity, acting as if they were the GOD. It may well take/waste another few generations to fully quench the zeal.

21. **Peter Woit**
March 29, 2017

hyd,
Unfortunately I’m not so sure that the ideas of the supersymmetric standard model, string theory unification, and the multiverse will die out with their creators. These creators are already no longer with us or retirement age and losing influence, but their failed ideas have been rather successfully institutionalized, and several generations of younger physicists have been trained in them. Will they abandon these ideas? Will those promoting them to the public and to young people entering the profession stop doing this? So far, I’m not optimistic…

22. **GoletaBeach**
March 29, 2017

The overwhelming majority of humans alive today believe all sorts of supernatural phenomenon are real. That a tiny minority who believe in rationalism, applicable mathematics, and the scientific method held on throughout millennia of being imprisoned , burned at the stake, etc, had their ideas survive to influence modern thought is actually a remarkable story… and we scientists are still a minority.

The truth is… whatever the results of well-conceived and executed experiments, like those of the LHC, turn out to be, we all win, because we learn what Nature really is. As Luis Alvarez said about search with muons for chambers in the Egyptian Pyramids: he didn’t fail to find new chambers, is succeeded in proving there were no further chambers to speculate about.

The human dramas of betting and pilloring famous theorists who made wrong predictions may be interesting and fun, but it is just a social sideshows. SUSY might easily be correct but it might take humans another 10,000 years to discover that. Science itself doesn’t give a darn about human lifetimes.

The snickering and schadenfraude about LHC not finding SUSY is hardly a blip in that process, but to the extent that creative ideas to empirically probe SUSY and all other conjectures get inhibited by the snickering, that is unfortunate.

Independent of theorists’ ideas, hadron colliders remain the best tool to probe higher energies in actual experiments (as opposed to observations). LHC did and is doing a tremendous job, but likely we have learned that the SSC was even more important as a pathfinder than we thought in 1994. Mel Schwartz was right… he never cared much about the SUSY theorists. Go to the highest energy you can afford… that is always a compelling discovery strategy. The only role theorists really have is to run a propaganda front among the supernaturalists for what is completely obvious to experimentalists.

Unfortunately, propaganda is an issue of human drama, and it certainly is true that the propaganda can backfire.

Personally, given that the LHC was unconditionally a terrific empirical endeavor, I don’t much appreciate criticism of the over-enthusiastic theorists. Their true role was over when the LHC was well funded… they helped do that. After that, science will little note nor long remember what they said, but what the experimentalists did will be never forgotten.

23. **Peter Woit**
March 29, 2017

GoletaBeach,

It’s not “snickering”. It’s extremely important for theoretical physics that ideas that don’t get work get discarded, a disaster if they don’t, but instead become the dominant paradigm for the field. These SUSY models have always been highly problematic and heavily oversold. Pre-LHC one could argue that the “naturalness” argument justified waiting for the LHC results before abandoning them completely,. The results are now here and these models should be given a decent burial. Getting influential theorists to acknowledge that the models are dead is quite important, and the point at which they pay off their lost bet is a good time for this to happen.

For experimentalists, the issues are different. Finding the Higgs is a great achievement, but so is exploring a new energy range and finding out what's there (and what's not there). Killing off SUSY is an achievement they should be proud of. Going forward obvious goals are to do the best possible job of studying the Higgs sector, as well as to do the best and most complete job of exploring the energy range the LHC can reach. This is up to the experimentalists, but it seems to me that they should be thinking about how best to weight effort aimed at further SUSY searches versus other kinds of analyses. Fine if you like having bad models to use as propaganda, not so great if you believe your own propaganda and it blows back on you and damages your work.

If there is some way to afford it, I agree that a higher energy machine is desirable. I don't think though that bogus arguments about how such a machine is likely to find SUSY or produce black holes are going to be effective. It's not the ignorant masses that will decide whether to spend the money, but people who are a lot more sophisticated, and trying to pull the wool over their eyes with a dubious argument I think will be counterproductive.

24. **Gregor**
March 29, 2017

Peter,

why is a higher energy accelerator desirable? We have experiments that show clearly that the standard model is correct; we have calculations/theory showing that it is correct up to (almost) the Planck scale. We have no difference between theory and experiment. None.

The only thing we lack is a theory showing that the standard model is consistent with general relativity and at the same time predicts the 20 parameters of particle physics. This is a much simpler exploration, much less demanding, and well in reach in a few years time. A friend of mine would gladly take bets with real money that this scenario is correct.

With all data available, pouring money in a new machine seems an almost certain waste. A quick overview of the arguments in favor of such a machine shows that all these arguments (supersymmetry and its particles, wimps and other microscopic dark matter, more dimensions, superstrings, microscopic black holes, axions, additional generations, more Higgs bosons, fifth force, and dozens of others) have already been put aside by the LHC. Why should we look in a corner of nature when we already know quite definitely that there is nothing to be found there?

Other arguments for a machine (strong CP problem, dark matter, etc.) are based on astrophysical data, which is shaky anyway.

This "why?" question is a serious one. The hope that there is something at higher energy that can be found is based on wishful thinking, not at all on experimental data.

25. **Anonyrat**
March 30, 2017

We need high precision tests of every term in the Standard Model.

26. **Marc Nardmann**
March 30, 2017

Gregor,
you wrote: "we have calculations/theory showing that [the standard model] is correct up to (almost) the Planck scale." I would like to understand this claim: "correct" in which sense, given the lack of experimental data between the LHC and Planck scales; what kind of calculations (perturbative? at which order?); what precisely are the results. Could you give a few references?

27. **Peter Woit**
March 30, 2017

Marc Nardmann,

I assume Gregor meant "consistent", not "correct"

Gregor,

I think the argument "because it's there" is a perfectly good one for doing experiments to probe a higher energy scale. Yes, we have no good theoretical reason for expecting something new, but theorists are often wrong about such extrapolations.

Maybe the LHC will yet find something unexpected and that will give a target for what to investigate. If not, investigating the Higgs sector would be a major goal, especially measuring self-interactions of the Higgs.

The problem is not that there's no good physics to be done at higher energies, the problem is the cost. If it were $100 million, Jim Simons could finance it out of the spare change in his couch and it would be obviously worth doing. At $1 billion, it could be financed within the current budgetary envelope of CERN and also I think would obviously be worth it. The problem is that to get to a much higher energy scale, a larger ring is needed and that is going to be very expensive, $10 billion and up.

For order of magnitude $1 billion, you might be able to build the HE-LHC (same tunnel as the LHC, higher field strength magnets, doubling the energy). Again, the question is money, is that size jump in energy worth the cost?

28. **Gregor**
March 30, 2017

Peter,

I understand what you say; but we should first give 10 theorists 1 million each with the aim to find a consistent theory showing that general relativity plus the standard model is all there is (including my friend). And we should give 10 theorists 1 million each to come up with a correct theory that predicts something at higher energy.

Only if they first group finds *no* such theory, and the second group finds at least one, should we really spend 10 billion on an accelerator; at the moment the risk of not finding anything new is much too big.

After all, the LHC has "only" found the Higgs, not much else. And it confirmed the standard model. One could indeed argue (which I do not) that the last 5 years of operation of the LHC were not worth the money spent. So we will all have a tough time arguing for a new machine. Especially so if theoretical desert scenarios and new theoretical options have not been explored fully beforehand.

29. **GoletaBeach**

March 30, 2017

I suppose prior to about 1492, Europeans questioned the utility of sailing west. Peter is absolutely right: sailing west because you can is and was sufficient reason to do so. There will always be theorists who say this and that… when you have a new technology (like navigation and sailing ships in the 1400's) and can do something truly new and different (like sail long distances on the world's oceans) a fine strategy is to do everything you can to get self-appointed smart people to support you. And forget their reasons for doing so… new sources of gold were the argument in the 1400's, but in reality, the potato and a new land for Europe's malcontents were the big payoffs.

Pretty much all hadron collider experiments use the same tools whether one looks for SUSY or not… 1)look for unexpectedly large observable cross sections for every final state you can think of… (Rutherford invented this technique in 1910 or so) 2)look for missing energy (Ellis & Wooster invented this one in 1928 or so). Those are the classics. SUSY is just another excuse to re-do the classics at higher energy.

It is extremely simple radiation physics (synchrotron radiation) that leads us to hadron colliders rather than lepton colliders, although Peter is right again… precision Higgs studies at a tuned electron positron collider are an excellent idea right now. Because we can, and the analogous history of finding new physics based on small effects (charm quark mass from K0-K0bar mixing, top quark from K0-K0bar CP violation, Higgs mass from LEP precision electroweak) has been successful.

Something or another is keeping the Higgs mass so small. Something or another regulates quantum field theory at high energies. The Energy Frontier remains a good way to seek solutions to that puzzle. But as Peter says, we can't because it is just too darned expensive at the moment. Lots of people have been saying "do accelerator research" for 30+ years. The fact is people do that but maybe improvements are no easier than reductions in the cost of using neutron flux to turn lead into gold.

I'm confident in 10,000 years human kind will find a way, though. Or maybe 50,000 years. Maybe not in my lifetime or the lifetime of any blog poster here.

But at the same time… more human lives will be saved more cost-effectively right now by purchasing air-conditioners for senior citizens suffering through hot summers in St. Louis, then by spending on high energy physics. The same was true in 1400's Europe… every dollar given to Columbus would have saved more lives, in the short run, had it been spent on food for the poor. It is an eternal paradox.

Like the paradox that the very best batting average in a season of American pro baseball was 0.440. Not even 1/2 the time did Hugh Duffy get a hit! Research has a lower batting average. If anybody wants certainty in research endeavor, they really don't want to do research at all.

30. **martibal**
March 31, 2017

"I assume Gregor meant "consistent", not "correct""

And what about the instability of the Higgs vacuum ? (the fact the the quartic coupling of the Higgs become negative at high energy). Is that so much consistent ? Strictly speaking it is not a contradiction, but it is very weird, no ?

31. **Anon**
March 31, 2017

The major challenge is in writing the Lagrangian that includes neutrino masses/couplings. There is no standard way of writing the SM Lagrangian for neutrino masses/couplings. So whether it is BSM or SM, what is the Lagrangian? How can we test it? Those are the questions.

32. **Peter Woit**
March 31, 2017

Gregor,
I think we can accurately predict the results of giving $1 million to 10 theorists…

33. **B'Rat**
March 31, 2017

GoletaBeach,
I find the Columbus analogy rather bizarre. One should remember that his aim was not "let's see if there's a new continent to plunder", but "my calculations show that Asia is within reach by our ships". Too bad his contemporaries actually knew that his calculations about Earth's circumference **were wrong**, and that thus had America not existed Columbus and his sailors would have died a rather sad death in the middle of the Ocean. This explains why he found so difficult to fund his voyage. In essence, he was a *lucky idiot*.

34. **emile**
March 31, 2017

Anon: what about giving the neutrinos dirac masses with small yukawas?

35. **Ellsberg**
March 31, 2017

An interesting take on events these days: http://vixra.org/pdf/1703.0300v1.pdf

36. **GoletaBeach**
March 31, 2017

Or maybe Columbus was just utilizing advances in shipbuilding and navigation to try to do something really interesting. Of course the Talavera commission knew his crew would die of scurvy prior to reaching Japan. What they knew was… completely wrong.

Of course Columbus was a lucky idiot. And pretty much every great, truly (as opposed to bureaucratically) transformative discovery is lucky idiocy too.

There on the Berkeley campus in the early 1930's was Lawrence and his crew slaving away making medical isotopes to pay for the little bit of research they could do between midnight and 6am. When news came from Cambridge of the neutron's discovery, they realized that the neutron flux from their cyclotron exceeded that in the European setups by orders of magnitude, and they had in fact neutron activated their entire lab, but had failed to notice because they didn't hunt for radiation when the beam was off.

Perhaps they were unlucky idiots… a little more creative exploration without a good reason and they could have been lucky idiots, and discovered the neutron, which is the biggest game-changer in nuclear physics.

37. **Unmanned**

March 31, 2017

I look forward to unparticles being quickly detected and analyzed in Mr. Un's uncollider.

38. **Anon**
March 31, 2017

emite — sure you can add right handed neutrinos to the standard model and give the neutrinos small dirac masses by choosing their yukawa couplings to be very small ~10^-12.

So how do you test this?

You need to measure the Higgs Yukawa coupling to the neutrino or you can disprove the idea by showing that the neutrino is a Majorana particle and not a Dirac particle.

Alternatively, you can say that you will add 3 right handed neutrinos and include a Majorans mass terms and do the seesaw mechanism in the std model. Again you can test this by trying to find the right-handed neutrinos Majorana mass scale. But this scale may not be reachable by colliders.

Or you can say you wont add 3 right handed neutrinos but add a Higgs triplet to SM and give the left handed neutrinos small Majorana masses directly (Called Type 2 seesaw). You can test this by finding the Higgs triplet — but it could be at some very high seesaw scale that is never reachable by colliders.

Essentially the neutrino sector of SM is as untested as the neutrino sector of BSM.

In fact in BSM you may be able to think of more consequences (non-collider as well) and test for those consequences. SO BSM can be more testable than SM. For example proton decay for GUT theory, vanishing of leptonic CP phase for minimal left right symmetric model with parity (as leptonic \delta_CP contributes to strong CP phase in one loop in LR symm model).

39. **Anon**
April 1, 2017

sorry emile mis-spelt your name in the above response.

40. **Gregor**
April 2, 2017

Peter,

you are right to make fun of theorists. The LHC was sold/marketet to politicians as the machine to search for the Higgs, for supersymmetry, for dark matter and for hidden dimensions.

How would you sell the next collider, especially in the light of the last results? (1) We cannot use the same arguments any more. (2) And you need a good theory to provide arguments.

Susy and strings were wrong, but provided 3 of the 4 arguments for the LHC. On the other hand, showing that the standard model is correct and consistent is not an argument for a new machine. If the theorists cannot provide a good vision for the future, there will be no new machine.

Wasting 20 millions on 20 (or more) theoretician's salaries is much less than wasting 10 billions in a machine with the risk of getting no results. But of course your making fun of the idea is also valid! After all, we just have to look at hep-th to see that nothing is coming from that side since quite a long time. So shall we stop here?

Peter, let me ask you directly: (1) If you had 10.02 billions at your disposal for the coming 10 years, how would you spend the money? (2) What arguments would you provide?

41. **Peter Woit**
April 2, 2017

Gregor,
The problems of theoretical physics I don't think are ones that can be addressed by simply putting more money into the field. They're a different story. Redirecting money from experiment to theory will solve nothing.

Doing things like telling the public that the LHC was designed to find extra dimensions was even at the time clearly a really bad idea. It wasn't necessary to get the LHC funded, and engaging in outrageous hype like that creates a serious credibility problem next time you have a new project that needs funding. So, going forward, that will be a big problem, and doubling down with "the extra dimensions are at 10 TeV rather than the 1 TeV we thought" is unlikely to work.

The problem isn't the coming 10 years, I think experimentalists have made reasonable choices about plans for the next 10 years, with $1 billion/year the order of magnitude that is planned. At the energy frontier, it will be the HL-LHC.

The problem is the longer term. Absent some new information, I don't think HEP can successfully argue that there is a good reason to redirect resources from elsewhere and put significantly more money into the field. Maybe it can hold onto its current funding level and then there's a difficult problem of how to allocate that. How much should go to a new energy frontier machine and of what kind? People are very actively looking at the possibilities, and at some point will have to focus on the price tags and how to proceed.

42. **Frank Wilhoit**
April 2, 2017

B'Rat,

The luck of Columbus was that he came back. Just think if he hadn't — as, in hindsight, was much the likelier outcome.

43. **Darrell Burgan**
April 3, 2017

I don't suppose Motl actually admitted he was mistaken … ?

44. **Cobi**
April 3, 2017

Darrell,
the bet was 100 to 1, i.e. Motl would have won 10,000$ if SUSY were found given the current set of data. No matter how you think about Motl, there is nothing to admit after a bet of this type. In the end they made assumptions about Bayesian probabilities.

45. **Peter Woit**
April 3, 2017

Cobi,
Jester's bet I think was significant mainly in that it made clear that there were many theorists (Falkowski is a rather mainstream theorist) who not only thought that the LHC would not see SUSY, but that SUSY was already, pre-LHC, an idea that hadn't worked, so it was not only unlikely the LHC would see it, but very unlikely.

As for Lubos, when the LHC turned on, his description of the probability of seeing SUSY was that "many of us " thought it was "90% or higher", but would publicly say "60%" just to be "modest", see links here
http://www.math.columbia.edu/~woit/wordpress/?p=3864
He later revised that down to "50%".

I'll leave it to the Bayesians to explain the significance of a scientist claiming his theory predicts something specific with "90% or higher" certainty, then claims it doesn't matter, his theory is still a sure thing, when the specific prediction is falsified.

What is much more significant than what Lubos has to say is what the most influenced and respected theorists pushing SUSY now will have to say. I have in mind in particular Gross, Wilczek and Witten (although Witten as far as I know never bet anything on this).

46. **GoletaBeach**
April 3, 2017

Oops Peter… the proposers and sellers of the LHC never said the "LHC was designed to find extra dimensions".

https://press.cern/press-releases/1993/12/large-hadron-collider-presented-cern-council

Maybe some theorists who were uninvolved in the real spadework to achieve approval of the LHC came in later and cut in to the front of the parade… wouldn't be the first time.

Actually, in 1993, the SSC was sold on "no-lose" for Higgs observation. If they Higgs was not observed, you'd see strong W-W- scattering at the SSC. No lose. No mention of extra dimensions, many worlds, etc.

Then gradually precision electroweak measurements from LEP, SLC, and CDF indicated that the Higgs would be light and Atlas & CMS decided to shell out for >$100 million calorimeters to see Higgs to gamma gamma. They were right! And at the time not a few committee reviewers wailed on them, but they held fast to the need for highly segmented, fast calorimeters.

Funny how that really great story sometimes gets buried under some speculative smoke by opportunistic theorists.

47. **Peter Woit**
April 3, 2017

GoletaBeach,
I understand, the extra dimensions was theorist hype that appeared later, around 2000. For an example, see the classic New York Times article "Physicists Finally Find a Way to Test Superstring Theory"
http://www.nytimes.com/2000/04/04/science/physicists-finally-find-a-way-to-test-superstring-theory.html

48. **GoletaBeach**
April 3, 2017

Well, thanks Peter. Sure… not an experimentalist, nor an LHC advocate like Rubbia or Llewellyn-Smith even interviewed in that NYT article… and most certainly none of the machine builders themselves, or the detector leaders like Jenni or della Negra.

You have made me wonder if the "real story" of the LHC… how the US was against it due to the SSC and the SSC "No-Lose" theorem, thought to need 40 TeV in the center of mass, to see the Higgs, was proven to be irrelevant first by loop effects evaluated at the LEP/SLC/CDF energies, and then by observation of the light Higgs itself… will ever be told.

49. **tulpoeid**
April 4, 2017

"Lubos has paid off his bet with Jester."

At least with this piece of news we know that Jester is healthy and doing well. But no motivation to post even on Moriond and on April fools'? HEP not doing much the same.

50. **new**
April 4, 2017

is it premature to declare SUSY dead?

since only 36 fb-1 @ 13tev was analyzed, with additional 45 fb-1 projected this year and 3000fb-1 overlifetime, is it still possible LHC will find SUSY?

what about a future HE-LHC or 100tev collider?

51. **Anon**
April 4, 2017

new — If an electron EDM is found then there is a good chance that a future collider will see something. As CP phases in new physics generate an EDM to the electron. Currently non-observation of electron EDM by ACME collaboration, puts generic SUSY scale to be above 8-10 TeV, which is out of LHC's reach. Future improvements in sensitivity by an order of magnitude which is expected soon by ACME, and non-observation of electron EDM, will put SUSY scale above 30 TeV, out of reach of future colliders. Of course there could always be some particular SUSY models with suppression of CP phases where the electron EDM limits wont translate to limits on new Physics.

52. **Anon**
April 4, 2017

new — for reference for electron EDM impact on particle physics, please see slide 47 of https://indico.hep.anl.gov/indico/getFile.py/access?resId=0&materialId=slides&confId=791

53. **kashyap vasavada**
April 4, 2017

I understand, one of the principal difficulties that high energy experimentalists face in LHC and beyond is that, there are some hundreds of millions of event/sec and their job is to find a needle in a haystack as they say! So there is too much reliance on known theoretical models in setting up triggers etc. The reason given is that there is not enough memory to store every event. While this is true, it may be that they could be missing phenomena which are not predicted by any existing theory. Admittedly this strategy worked very well for the discovery of Higgs. But for unknown physics it may be a handicap!

54. **Peter Woit**
April 4, 2017

tulpoeid,
Yes, and this is one reason blogging here has been sparse (I'm also busy thinking about other things). Not a lot happening in HEP physics these days, with the release of LHC results getting zero attention just one aspect of the situation.

new,
The problem is that further increases in luminosity only give you relatively small increases in energy reach (given a typical model). Current limits on gluinos are about 2 TeV. I don't know the projected numbers for the energy reach of the HL-LHC, but I would guess it's something like 2.5 TeV, no more than 3 TeV. So, sure, maybe there's a gluino in between 2 and 2.5 TeV, but there's no argument for this other than wishful thinking. The only argument people had for why the LHC should see a gluino was the fine-tuning argument that said it should have already been seen at the Tevatron. Similar comments apply to the energy reach increase of next generation accelerators. Anon is also right that the idea of superpartners just above the LHC limits is in conflict with the EDM measurements (and this was true pre-LHC, so one reason Jester and others felt there was a very good bet against SUSY even then),

kashyap vasavada,
Experimentalists are well aware of this issue, of the need to set triggers and do analyses which will be sensitive to a wide range of possible new phenomena, not just something with very specific properties. The possibility that something is being missed because it's not being triggered on or not being looked for is something worth worrying about, and a good argument for considering as wide a range of models as possible, not concentrating on SUSY models.

55. **new**
April 4, 2017

anon – thanks for link i'll look forward for new results on ACME. any idea when in 2017 it will be results will be announced?

peter – given the strongest argument for SUSY is fine-tuning argument and LHC has not seen SUSY, what is the likelihood SUSY exists but is broken at some higher energy scale?

56. **Anon**
April 5, 2017

new,

Don't know, but looks like they are currently taking data. (link)

57. **new**
April 5, 2017

anon, the link you provide seems to suggest

Abstract: B2.00001 : ACME Measurement of the Electron Electric Dipole Moment
10:30 AM–11:00 AM Tuesday, June 6, 2017
Room: 306-307

Tuesday, June 6, 2017 newest results will be released

any word on the latest results on neutron and proton edm?

58. **Anon**
April 5, 2017

new,
Electron EDM implies new physics would be found at next collider — but neutron and proton EDMs do not imply this….. this is bec. the strong CP Phase \theta contributes to neutron EDM and \theta can be generated due to physics at very high scales — like the seesaw scale (which could be at 10^14 GeV) or the Planck scale.

So finding neutron EDM, while important, does not imply there will be new physics to be discovered at next collider.

Dont know when the next nEDM expts will be reporting their new results — I believe in one expt, data collection is underway (but dont know if it will increase the sensitivity by much) — several other expts are planned around the world to run in next few years to increase the sensitivity by an order of magnitude.

Some Math and Physics Interactions

April 5, 2017
Categories: Uncategorized

Quanta magazine has a new article about physicists "attacking" the Riemann Hypothesis, based on the publication in PRL of this paper. The only comment from a mathematician evaluating relevance of this to a proof of the Riemann Hypothesis basically says that he hasn't had time to look into the question.

The paper is one of various attempts to address the Riemann Hypothesis by looking at properties of a Hamiltonian quantizing the classical Hamiltonian xp. To me, the obvious problem with an attempt like this is that I don't see any use of deep ideas about either number theory or physics. The set-up involves no number theory, and a simple but non-physical Hamiltonian, with no use of significant input from physics. Without going into the details of the paper, it appears that essentially a claim is being made that the solution to the Riemann Hypothesis involves no deep ideas, just some basic facts about the analysis of some simple differential operators. Given the history of this problem, this seems like an extraordinary claim, backed by no extraordinary evidence.

I suspect that the author of the Quanta article found no experts in mathematics willing to comment publicly on this, because none found it worth the time to look carefully at the article, since it showed no engagement with the relevant mathematical issues. A huge amount of effort in mathematics over the years has gone into the study of the sort of problems that arise if you try and do the kind of thing the authors of this article want to do. Why are they not talking to experts, formulating their work in terms of well-defined mathematics of a proven sort, and referencing known results?

Maybe I'm being overly harsh here, this is not my field of expertise. Comments from experts on this definitely welcome (and those from non-experts strongly discouraged).

While these claims about the Riemann Hypothesis at Quanta look like a bad example of a math-physics interaction, a few days ago the magazine published something much more sensible, a piece by IAS director Robbert Dijkgraaf entitled Quantum Questions Inspire New Math. Dijkgraaf emphasizes the role ideas coming out of string theory and quantum field theory have had in mathematics, with two high points mirror symmetry and Seiberg-Witten duality. His choice of mirror symmetry undoubtedly has to do with the year-long program about this being held by the mathematicians at the IAS. He characterizes this subject as follows:

> It is comforting to see how mathematics has been able to absorb so much of the intuitive, often imprecise reasoning of quantum physics and string theory, and to transform many of these ideas into rigorous statements and proofs. Mathematicians are close to applying this exactitude to homological mirror symmetry, a program that vastly extends string theory's original idea of mirror symmetry. In a sense, they're writing a full dictionary of the objects that appear in the two separate mathematical worlds, including all the relations they satisfy. Remarkably, these proofs often do not follow the path that physical arguments had suggested. It is apparently not the role of mathematicians to clean up after physicists! On the contrary, in many cases completely new lines of thought had to be developed in order to find the proofs. This is further evidence of the deep and as yet undiscovered logic that underlies quantum theory and, ultimately, reality.

I very much agree with him that there's an underlying logic and mathematics of quantum theory which we have not fully understood (my book is one take on what we do understand). I hope many physicists will take the search for new discoveries along these lines to heart, with progress perhaps flowing from mathematics to physics, which could sorely use some new ideas about unification.

Update: Some comments sent to me from a mathematician that I think give a good idea of what this looks like to experts in number theory:

> The "boundary condition" is imposing an identification with zeta zeros by fiat, so the linkage of any of this to RH is basically circular. The paper at best just redefines the problem, without providing any genuine new insight. More specifically, as the experience of more than 100 years has shown, there are a zillion ways to recast RH without providing any real progress; this is yet another (if it makes any rigorous sense, which it does not yet do, yet the absence of rigor is not the reason for skepticism about the value of this paper, whatever the pedigree of the authors may be).
>
> One has to find a way of encoding the zeta function that is not tautological (unlike the case here), and that is where deep input from number theory would have to come in. This is really the essential point that all papers of this sort fail to recognize.
>
> Real insight into the structures surrounding RH have arisen over the past decades, such as the work of Grothendieck and Deligne in the function field analogue that provided a spectral interpretation through the development of striking new tools inspired by novel insights of Weil. In particular, the appearance of the appropriate zeta functions in such settings is not imposed by fiat, but is the outcome of a massive amount of highly non-trivial constructions and arguments. In another direction, compelling evidence and insight has come from the "random matrix theory" of the past couple of decades (work of Katz-Sarnak et al.) was inspired by observations originating with Dyson merged with work of the number theorist Montgomery.
>
> Number theorists making a major advance on the puzzles of quantum gravity without providing an identifiable new physical insight is about as likely as physicists making a real advance towards RH without providing an identifiable new number-theoretic insight. There is no doubt that physical insights have led to important progress in mathematics. But there is nothing in this paper to suggest it is doing anything more than providing (at best) yet another ultimately tautological reformulation by means of which no progress or insight should be expected.

Update: Another way to state the problem with this kind of approach to the RH is that without number theoretic input, it is likely to give a much too strong result (proving analogs of the RH for functions that don't satisfy the RH). For example, see the comment here (I don't know if this correct, but it explains the potential problem).

Update: Nature Physics highlights the Bender et al. paper with "Carl Bender and colleagues have paved the way to a possible solution by exploiting a connection with physics. Some wag there has categorized this work as work with subject term "interstellar medium".

Update: There's an article about the Bender et al. paper here, with extensive commentary from one of the authors, Dorje Brody, who addresses some of the questions raised here (for example, why PRL if it's not a physics topic?).

Update: Belissard has put up a short paper on the arXiv explaining the idea of the Bender et al. paper, as well as the analytical problems one runs into if one tries to get a proof of the RH in this way.

Update: One of the authors has posted on the arXiv a note with more precise details of the construction of a version of the operator discussed in the PRL paper.

Comments

1. **Anonymous**
   April 5, 2017

   The authors of this paper are humbly sharing some thoughts they have had that are relevant to the Riemann hypothesis. They are not claiming to have made profound progress. We can ignore their work if we like, there is no need to attack them. Carl Bender is awesome.

"Why are they not formulating their with in terms of well defined mathematics of a proven sort?" I assume they are simply explaining their ideas as clearly as they can.

2. **Peter Woit**
April 5, 2017

Anonymous,
Publishing in PRL (and a claim to have a worthwhile new idea about the Riemann Hypothesis) is not really an act of humility, but a claim to have something significant that people should pay attention to. I'm paying attention, and commenting on what this looks like from the point of view of the math community. It's a serious question and I think one I'm posing much more politely than most mathematicians would do privately: if they think they might have some progress towards proving the Riemann hypothesis, using tools that are not particular to physicists, but which mathematicians are experts on, why is there no engagement with mathematicians and their expertise?

3. **anon**
April 5, 2017

I'm not at all an expert, but it seems strange to me that PRL would publish a paper on such a topic. It doesn't exactly seem to be within their scope.

4. **G. S.**
April 6, 2017

While I feel the piece in Quanta is hyping things a bit too much, I think you're being a bit harsh in criticizing this paper's appearance in PRL. They appear to be making progress on a research question that has interested a number of physicists for a number of years. For example, see the 2011 review article Physics and the Riemann Hypothesis (https://arxiv.org/pdf/1101.3116.pdf). One quote from this review article which stands out to me is the following:

"The advantage of this approach would be that the huge number of ζ(s) zeros are known and quick numerical algorithms have also been developed to find further zeros, thus solving the Schrodinger equation for large energies would be unnecessary. The Riemann zeta function could play the same role in the examination of chaotic quantum systems as the harmonic oscillator does for integrable quantum systems."

That's still a bit of hyperbole, but it illustrates why someone who studies chaotic quantum systems would be interested in the article you mention. It would get them closer to a computationally-practical toy model for understanding chaotic quantum systems.

5. **Anon**
April 6, 2017

"and a simple but non-physical Hamiltonian"

There are physical systems described by PT-symmetric Hamiltonian. They describe non-isolated systems interacting with their environments, and have been studied in the laboratory, see e.g. https://journals.aps.org/prl/abstract/10.1103/PhysRevLett.103.093902.

6. **Peter Woit**
April 6, 2017

Anon,

The Hamiltonian I'm referring to is the one discussed in the paper, their equation 1, which doesn't appear in the paper you link to (or, as far as I can tell, in any other discussion of a physical system).

7. **mrj**
April 6, 2017

The story seems strongly reminiscent of one told by Paul Garrett in his notes on cuspforms (section 0.3 at http://www-users.math.umn.edu/~garrett/m/v/pseudo-cuspforms.pdf). In both cases, the zeta zeros arise as eigenvalues of some spectral problem which, alas, is not self-adjoint and therefore can't imply RH. Additionally, the problem raised by both Garrett and the linked answer at MathStackExchange is the existence of certain Dirichlet L-series which are known to not have Euler products.

8. **Doug McDonald**
April 6, 2017

Much of my research (I'm now happily retired and doing genetic genealogy) centered on quantum chaotic behavior of vibrations of molecules in size from acetaldehyde to cyclohexylaniline.
The statement quoted "The advantage of this approach would be that the huge number of ζ(s) zeros are known and quick numerical algorithms have also been developed to find further zeros, thus solving the Schrodinger equation for large energies would be unnecessary. The Riemann zeta function could play the same role in the examination of chaotic quantum systems as the harmonic oscillator does for integrable quantum systems." is interesting. However, we eventually found that no "toy" or "effective" theory ever agreed with experiment. Only very large (for their day) direct diagonalizations of the Schrodinger equation using very high order fits of potential surfaces to quantum electronic calculations did. The exact nature of the potential energy surface really mattered.

I would be astounded if this were not still true today.

9. **tomate**
April 7, 2017

The problem with this post is that it's not clear whether it's criticizing the media coverage of this paper (and of course we all agree on this), the paper itself, or the fact that it is published in PRL. After reading the post I went to the paper assuming to find the usual crazy bullshit that is usually criticized here, and instead I found a very decent paper, with a proper title, no malicious claims in the abstract, very well written and direct, and it connects to a previous line of research on the topic. So the question boils down to "is it worth PRL?", and frankly there is so much crap in PRL in recent times, this paper does not really stand out as inappropriate (and then the problem would be PRL's policies, and the good ol' times, not this paper).

Also, from the comment of your anonymous colleague mathematician I was expecting a very bizarre and ad hoc boundary condition on the eigenfunctions that would involve the zeta function itself. It turns out, instead, that the shape of the operator, the boundary condition, and the condition that the operator has to satisfy in order for the RH to hold are extremely simple. I don't think this contribution is more "circular" than are the other zillion ways to reframe the problem you mentioned, including those of the superstars in the field, one of which might eventually turn out to be the best at attacking a proof, and you never know which one it is until you got it. And after all, given your favourite set of axioms, in this sense all of mathematics is "circular".

10. **V.K.**
April 7, 2017

Jean Bellissard has weighed in on the Math Stackexchange you linked. The conclusion is devastating:

“In conclusion, the sloppyness of the definitions used but the authors leads to a complete mess. Nothing is correct in this paper.”

11. **Frank Wilhoit**
April 7, 2017

tomate:
The presence of any quantity of crap in any particular venue is NOT an argument for the addition of more.

12. **Peter Woit**
April 7, 2017

tomate,
The intent of the post was to supplement what was in the Quanta article with my take on what this looks like from the point of view of the mathematics community, something which was lacking in the article, and in all coverage of this I’d seen elsewhere. I’m not one for insisting on rigid distinctions between what is math and what is physics, but this is a case where the general motivating problem is purely mathematical, the specific questions being pursued are mathematical, and the techniques being used are mathematical (rather than physical). Why don’t the authors engage significantly with the mathematics community and its expertise on these questions and techniques? I haven’t seen anyone address this, and I suspect that many physicists don’t understand the question, because they don’t understand what mathematicians do.

The Belissard comment on math stackexchange
http://math.stackexchange.com/questions/2211278/riemann-hypothesis-is-bender-brody-m%c3%bcller-hamiltonian-a-new-line-of-attack/2222146#2222146
I think shows well what kinds of concerns this work raises with experts, why don’t the authors engage with them?

13. **tomate**
April 7, 2017

Peter and Frank,

if I understand well the Belissard argument only came up yesterday, so we cannot charge the authors of not responding to this yet. If they do it seriously, it might take several months. If a lot of such arguments show up, and a discussion starts, then the paper has served its purpose. That real knowledge does not proceed through peer-reviewed journals is a matter of fact.

Let me point out that I do not personally care at all about this paper, I have no expertise on either the RH or on advanced techniques in QM, though I am a fond amateur on both. But I like new ideas wherever they show up and I find it fascinating that often physics becomes the language by which certain branches of mathematics are inspected in a more speculative and fuzzy way, at times when so much mathematics is just a tedious and fancy-less job about defining things properly and extending by an epsilon the validity of older theorems (not everybody out there is a Connes or a Grothendieck, you know…). Despite Belissard’s argument, which is quite technical, I am quite convinced that there might be a way a more creative mathematician might make sense of these arguments.

The problem with PRL, and with publishing in general, is certainly not that these journals publish too many ideas that are out of their scope, but rather that they publish too much “socially acceptable” stuff that is well within the mainstream, maybe a tiny bit more clever than others, and that can gather a lot of consensus just because they are supported by well-established and extremely closed communities. When this happens, you see popping up a lot of very dishonest titles and abstracts, supported by unclear arguments. And this is the same in physics and in math (and I do read a lot of math papers, though in other areas).

To me, this is not the case with this paper, which I find quite honest in its assumptions and scope. I don’t like Peter’s argument that the authors did not interface with the proper community because it sounds like the rooking of a community that does not want to have too much interference with its own business. In this respect, I would propose an “evolutionary” argument: If so much great math has failed on the RH, then probably time is ripe to NOT get too much intertwined with all the mental process that got that math stuck.

14. **Peter Woit**
April 7, 2017

tomate,
I don’t think it’s a good way to do science to publish a paper in a high profile journal, and only then have experts in the subject point out well-known, serious and basic problems with what the authors are doing. Among other things, note that Belissard’s comments are probably not going to be seen by readers of the PRL paper or the arXiv preprint (as for my commentary and links, the arXiv bans trackbacks to this blog because I long ago offended certain powerful people in the physics community).

Sorry, but the attitude that you’re going to not bother to learn standard facts and acquire expertise about the topic you are doing research on, but dismiss it as “just a tedious and fancy-less job about defining things properly and extending by an epsilon” of no comparison to the power of your untutored physical intuition, is an attitude that, when there is physics involved, isn’t likely to help you get anywhere, and when there is no physics involved (as here), it’s sure not to.

15. **Maximillian G. Tresmond, Esq.**
April 7, 2017

Phys.org has also “covered” this today here: https://phys.org/news/2017-04-insight-math-million-dollar-problem-riemann.html with all the same problems Dr. Woit covered in the above-captioned post.

“I don’t think it’s a good way to do science to publish a paper in a high profile journal, and only then have experts in the subject point out well-known, serious and basic problems with what the authors are doing.”

This. I wish more academics would heed these wise words because virtually every academic field suffers from this problem. It’s beginning to impeach the credibility of academia which is the last thing this country needs right now.

16. **Anonymous**
April 9, 2017

As somebody who works on the zeta function for a living (and of course other closely related objects), I could see right away that this article is not bringing anything to the table… (Un?)fortunately mathematicians do not get to make a splash by putting forward sloppy, repetitive, not well researched approaches. I think that the authors of this paper will now be able to put in their grants that their work was advertised in Quanta, Nature, etc. and is therefore important. This incentivizes such behaviour, which is dangerous for the future of science, as it turns the objective from advancing research to making a splash with controversial (but ultimately vapid) claims.

P.S: on the analytic side, there are no new ideas in their paper, the formal inversion of the differencing operator was already known to Euler, this is how he derived the Euler Maclaurin formula, from which one can also obtain the analytic continuation of zeta. This obviously involves Bernoulli numbers and their generating function, around which, coincidentally the authors argument revolves.

17. **anon**
April 9, 2017

Articles in Quanta Magazine are usually quite good, but they do seem to be very fond of stories where some outsider(s) solve problems that have stumped specialists.

18. **Andre LeClair**
April 10, 2017

I basically agree with the points Peter is making. But I don't fault the authors. This kind of paper is essentially impossible to publish in a pure math journal. And for a problem of this magnitude, collaboration with mathematicians is difficult because they tend to be dismissive, often for good reason. The issue of rigor is important, but only a part of the problem. I think they would pay attention to a truly novel idea. Publishing in PRL for this kind of problem almost ensures that mathematicians will not pay much attention to it, which may be justified; I prefer not to weigh in on that.

Having worked on this problem over several years, I remain skeptical about the whole Hilbert-Polya idea. It's been a bit of a pipe dream, although not ruled out. It is well-known that the statistics of the zeros is conjectured to be described by random matrix theory (Montgomery). This motivated Berry-Keating in their interesting work, which did not conclusively resolve the problem. My own point of view is that the connection with random matrix theory would seem to cast doubts on Hilbert-Polya rather than support it. It would seem unlikely that a simple, non-random hamiltonian would capture the exact zeros, but that is not a rigorous counter-argument. Success would be analogous to being given an infinite list of essentially random eigenvalues and trying to reconstruct the operator that led to them. Heuristically speaking, the "randomness" of the zeros is related to the pseudo-randomness of the primes themselves. I agree with previous remarks that the fact that no deep aspects of number theory enter into their approach makes one wonder. As Peter's math colleague wrote, it appears that the construction of the model brings in too much information about the zeta function itself, via the boundary condition, so that perhaps the RH is built into the model from the beginning.

19. **Abdelmalek Abdesselam**
April 19, 2017

Peter,

It might be useful putting another update to your post since one of the authors of the PRL posted a reply on arXiv https://arxiv.org/abs/1704.04705

Malek

20. **Peter Woit**
April 19, 2017

Abdelmalek Abdesselam,

Thanks, I will add that. Glad to see this sort of thing, with precise statements so that one can see what exactly is going on.

The Social Bubble of Physics

April 7, 2017
Categories: Uncategorized

Sabine Hossenfelder is on a tear this week, with two excellent and highly provocative pieces about research practice in theoretical physics, a topic on which she has become the field's most perceptive critic.

The first is in this month's Nature Physics, entitled [Science needs reason to be trusted](). I'll quote fairly extensively so that you get the gist of her argument:

> But we have a crisis of an entirely different sort: we produce a huge amount of new theories and yet none of them is ever empirically confirmed. Let's call it the overproduction crisis. We use the approved methods of our field, see they don't work, but don't draw consequences. Like a fly hitting the window pane, we repeat ourselves over and over again, expecting different results.
>
> Some of my colleagues will disagree we have a crisis. They'll tell you that we have made great progress in the past few decades (despite nothing coming out of it), and that it's normal for progress to slow down as a field matures — this isn't the eighteenth century, and finding fundamentally new physics today isn't as simple as it used to be. Fair enough. But my issue isn't the snail's pace of progress per se, it's that the current practices in theory development signal a failure of the scientific method…
>
> If scientists are selectively exposed to information from likeminded peers, if they are punished for not attracting enough attention, if they face hurdles to leave a research area when its promise declines, they can't be counted on to be objective. That's the situation we're in today — and we have accepted it.
>
> To me, our inability — or maybe even unwillingness — to limit the influence of social and cognitive biases in scientific communities is a serious systemic failure. We don't protect the values of our discipline. The only response I see are attempts to blame others: funding agencies, higher education administrators or policy makers. But none of these parties is interested in wasting money on useless research. They rely on us, the scientists, to tell them how science works.
>
> I offered examples for the missing self-correction from my own discipline. It seems reasonable that social dynamics is more influential in areas starved of data, so the foundations of physics are probably an extreme case. But at its root, the problem affects all scientific communities. Last year, the Brexit campaign and the US presidential campaign showed us what post-factual politics looks like — a development that must be utterly disturbing for anyone with a background in science. Ignoring facts is futile. But we too are ignoring the facts: there's no evidence that intelligence provides immunity against social and cognitive biases, so their presence must be our default assumption…
>
> Scientific communities have changed dramatically in the past few decades. There are more of us, we collaborate more, and we share more information than ever before. All this amplifies social feedback, and it's naive to believe that when our communities change we don't have to update our methods too.
>
> How can we blame the public for being misinformed because they live in social bubbles if we're guilty of it too?

There's a lot of food for thought in the whole article, and it raises the important question of why the now long-standing dysfunctional situation in the field is not being widely acknowledged or addressed.

For some commentary on one aspect of the article by Chad Orzel, see [here]().

On top of this, [yesterday's blog entry at Backreaction]() was a good explanation of the black hole information paradox, coupled with an excellent sociological discussion of why this has become a topic occupying a large number of researchers. That a large number of people are working on something and they show no signs of finding anything that looks interesting has seemed to me a good reason to not pay much attention, so that's why I'm not that well-informed about exactly what has been going on in this subject. When I have thought about it, it seemed to me that there was no way to make the problem well-defined as long as one lacks a good theory of quantized space-time degrees of freedom that would tell one what was going on at the singularity and at the end-point of black hole evaporation.

Hossenfelder describes the idea that what happens at the singularity is the answer to the "paradox" as the "obvious solution". Her take on why it's not conventional wisdom is provocative:

> What happened, to make a long story short, is that Lenny Susskind wrote a dismissive paper about the idea that information is kept in black holes until late. This dismissal gave everybody else the opportunity to claim that the obvious solution doesn't work and to henceforth produce endless amounts of papers on other speculations.
>
> Excuse the cynicism, but that's my take on the situation. I'll even admit having contributed to the paper pile because that's how academia works. I too have to make a living somehow.
>
> So that's the other reason why physicists worry so much about the black hole information loss problem: Because it's speculation unconstrained by data, it's easy to write papers about it, and there are so many people working on it that citations aren't hard to come by either.

I hope this second piece too will generate some interesting debate within the field.

Note: It took about 5 minutes for this posting to attract people who want to argue about Brexit or the political situation in the US. Please don't do this, any attempts to turn the discussion to those topics will be ruthlessly deleted.

Comments

1. **Bernardo**
   April 7, 2017

   If this type of social dynamics is happening in Physics, where any given direction of research is at least driven by the goal of saying something about reality and is expected to be tested in experiments, imagine how bad the situation may be in Mathematics? It is possible that Personalities and social dynamics influence the evolution of math to such extent that, under a small perturbation, the whole field would be unrecognizable. Also, what if all math connected to this field of theoretical physics is a waste of time and, in the long run, will become completely irrelevant?

2. **Peter Woit**
   April 7, 2017

   Bernardo,

Mathematics has never been driven by experiment, so has evolved its own different standards and practices which have allowed it to make (and continue to make, unlike physics) great progress. This posting is about the situation in physics, but an interesting question I've often raised is whether physics, as it finds itself starved of the new experimental results that in the past kept it moving forward, might learn something from mathematics about how to cope. Unfortunately, this is one topic that Hossenfelder doesn't address.

3. **Bernardo**
April 7, 2017

Much if not most of mathematics is in some sense driven by applications if not experiments in the sense of discovering something new about nature. (One example is the work on wavelets for which the latest Abel prize was awarded, but of course there are many other examples.) I guess what I meant was that the situation in theoretical physics that was described in your post is the field running into a hard wall and still allowing social dynamics determine its development, while in mathematics there is no such hard wall. I grant you that mathematics keeps making great progress, but these parallels with physics makes me wonder how different mathematics would look like under different circumstances. But I wonder what you think physics can learn from mathematics?

4. **Peter Woit**
April 7, 2017

Bernardo,
I've often written about this, with one of the most important things I think mathematician's insistence on being clear about precisely what you understand and what you don't. If you don't have experiment to keep you honest, the field needs strong internal norms to keep clear the difference between what works and what doesn't (and strong internal norms to keep people honest in their evaluations of what is working and what isn't). How to change the culture of physics to move in this direction is a difficult question, especially since my impression is that most physicists at this point do not see this as a problem.

5. **G. S.**
April 7, 2017

I don't know if it's fair to generalize the problems of theoretical physics to being problems of all scientific disciplines.

Sabine's article mentions a problem common to all fields of science (reproducibility – which she admits is being addressed by the scientific community), but then pivots to the problems particular to theoretical physics. What other fields have these same problems of theoretical physics?

She mentions that "at its root, the problem affects all scientific communities", but then chooses to give an example from politics rather than from another scientific discipline.

Certainly the soft sciences (e.g., economics, sociology, etc.) have examples of theories that will not die despite a lack of testable predictions. Heck, economics is rife in theories that survive despite clear contradictory evidence (e.g., strong forms of the efficient market hypothesis).

But what about the other hard sciences? Are there similar problems in biology, chemistry, geology, meteorology, botany, engineering, computer science, material science, etc.? If so, what are they? What are the niches of those fields in which social pressure is resulting in deviation from the scientific method?

They may exist. But until the examples are given, the article would more accurately be titled "Theoretical Physicists need reason to be trusted". The generalization to all sciences is unfair.

6. **Bernardo**
April 7, 2017

Peter,
In my opinion, if physicists will try to be more like mathematicians, something precious will be lost. You sometimes must have this attitude to solve the problem by any means necessary to get to the answer, even if it takes a few more decades to make sense out of it.

7. **Peter Woit**
April 7, 2017

Bernardo,
Don't worry, based on my experience, there is no danger that theoretical physicists will take an interest anytime soon in behaving more like mathematicians and paying serious attention to the difference between what they understand and what they don't.

8. **CIP**
April 7, 2017

Particle physics today has some parallels with atomic physics in ancient Greek thought, or medicine in the Middle Ages. There just isn't good new data. I'm not sure there is a cure in our immediate future.

9. **Klavs Hansen**
April 7, 2017

It is somewhat disturbing to see physics identified with the relatively narrow field of high energy physics theory. There are a number of other disciplines that produce vast amounts of results continuously, and to identify any crisis in physics, the symptoms must be shown by at least a couple more of these fields. I don't think they are. Although, of course, a lot of the low-hanging fruit of previous centuries has been picked, and everybody finds it more difficult to discover fundamental laws of nature.

10. **neil**
April 7, 2017

Bee describes the results but not the reasons. The problem is extreme in HEP physics because the cost of discovering new experimental results has risen exponentially relative to the cost of producing new theoretical results. In other sciences, and even other fields of physics, this has not happened to the same extent. Theory is relatively cheap (paper, pencils and, hopefully, wastebaskets) so we get a lot of it, often unrelated to our ability to confirm or refute it.

11. **Wyman**
April 7, 2017

I strongly agree with Klavs Hansen here. Theoretical high-energy/particle/fundamental physics only represents a small fraction of theoretical physics as a whole. I would say that in condensed matter, there are far more open problems than there are theorists. In the past couple of decades we've seen the emergence of both highly computational condensed matter physics as well as a new focus on topological properties that has by now reached every corner of study. It's a genuinely exciting time to be a theorist working on condensed matter systems — we have so many questions and so many new tools!

12. **Anonymous**
April 7, 2017

Producing papers is part of physicist job. This is how they get paid for. Whether or not their theory can be tested is not important.

13. **Bee**
April 8, 2017

Thanks for the mention 🙂

14. **Bee**
April 8, 2017

Btw, the title of the Nature Physics comment was chosen by the editor.

@Wyman

Indeed, I have even collected some numbers here

http://backreaction.blogspot.com/2013/05/what-do-most-physicists-work-on.html

As I point out in my article, the overproduction problem is specific to the foundations of physics. But it's a symptom of a much wider problem, which is that scientists are blind to the problems in the academic system.

@neil

I mentioned this in my article, and I also explain why this argument is as tiresome as wrong.

15. **Bunsen Burner**
April 8, 2017

How in the world did the problems of physicists representing less than 1% of all physics become a crisis for the whole discipline. I see no crisis in quantum computation, condensed matter, stellar interiors, computational fluid dynamics, high precision astronomy, and thousands of other topics all more worthwhile than quantum gravity.

If the last 20 years represent a crisis in physics, then my answer is: Please God, let the crisis continue.

16. **Peter Morgan**
April 8, 2017

The foundational problems that Physics has are not limited to HEP. One of the consequences of the lack of foundational clarity in QM and of mathematical clarity in QFT is that condensed matter and other users of QM/QFT have become rather a hodgepodge of approaches. There are some patterns, which people have become used to thinking are good enough, but things could be better organized. One can read Bee's lament as about HEP becoming more hodgepodge-like, like condensed matter, etc.

17. **M**
April 8, 2017

Wyman and Burner, can you please give examples of the most interesting discoveries recently made in condensed matter and quantum computation? It seems to me that these fields have their own problems: the only future of condensed matter seems doing more complicated versions of what was understood decades ago. And quantum computation looks like a bubble, like string theory 20 years ago.

18. **Low Math, Meekly Interacting**
April 8, 2017

To be fair, the life sciences have revealed a kind if evil twin of this situation: when you are literally awash in data, when doing experiments is relatively easy because of the nearly endless array of possibilities, the result can be a vacuum almost as profound. I say "almost" because, while someone can always produce an unimportant piece of crap and boost their citation count without penalty, most truly important crap invites rapid and widespread experimental challenge. Stimulus-triggered pluripotency is a good case study of how that situation plays out. Barring those corrective reflexes, the field would be a cesspool of trivial fraud. There is simply no substitute for the ability to subject scientific hypotheses to reproducible observational challenge. Never was, never will be, ever. Humanity has proven this time and again, and the intelligence and integrity of individuals is clearly no defense against societal pressures. To the extent we surrender to the supremacy of objective reality, we make progress. To the extent we're disconnected from it, we inevitably lose our way.

19. **Bunsen Burner**
April 8, 2017

M. Seriously? Condensed matter is stagnant and quantum computation is a bubble? Perhaps rather than pollute Peter's blog with the back and forth of examples that I'm sure will never convince you, why not try asking your question on a blog by an expert in one of these fields – such as Scott Aaronson.

20. **Nick M.**

Peter Woit wrote:

April 7, 2017 at 5:54 pm

> "… This posting is about the situation in physics, but an interesting question I've often raised is whether physics, as it finds itself starved of the new experimental results that in the past kept it moving forward, might learn something from mathematics about how to cope. Unfortunately, this is one topic that Hossenfelder doesn't address."

Hi Peter! I believe that Sabine Hossenfelder may have touched upon this very topic in a blog article (dated December 8, 2016) from her "Backreaction" website titled

No, physicists have no fear of math. But they should have more respect.

Although the front portion of this article deals with an entirely different issue, the "But they [*physicists*] should have more respect [*for math*]" portion addresses the topic that you expressed concern about.

If I may quote the last few relevant paragraphs from Sabine's blog entry:

> So, I don't think physicists are afraid of math. Indeed, it sometimes worries me how much and how uncritically they love math.
>
> Math can do a lot of things for you, but in the end it's merely a device to derive consequences from assumptions. Physics isn't math, however, and physics papers don't work by theorems and proofs. Theoretical physicists pride themselves on their intuition and frequently take the freedom to shortcut mathematical proofs by drawing on experience. This, however, amounts to making additional assumptions, for example that a certain relation holds or an expansion is well-defined.
>
> That works well as long as these assumptions are used to arrive at testable predictions. In that case it matters only if the theory works, and the mathematical rigor can well be left to mathematical physicists for clean-up, which is how things went historically.
>
> But today in the foundations of physics, theory-development proceeds largely without experimental feedback. In such cases, keeping track of assumptions is crucial – otherwise it becomes impossible to tell what really follows from what. Or, I should say, it *would* be crucial because theoretical physicists are bad at this.
>
> The result is that some research areas can amass loosely connected arguments that follow from a set of assumptions that aren't written down anywhere. This might result in an entirely self-consistent construction and yet not have anything to do with reality. If the underlying assumptions aren't written down anywhere, the result is conceptual mud in which case we can't tell philosophy from mathematics.
>
> One such unwritten assumption that is widely used, for example, is the absence of finetuning or that a physical theory be "natural." This assumption isn't supported by evidence and it can't be mathematically derived. Hence, it should be treated as a hypothesis – but that isn't happening because the assumption itself isn't recognized for what it is.
>
> Another unwritten assumption is that more fundamental theories should somehow be simpler. This is reflected for example in the belief that the gauge couplings of the standard model should meet in one point. That's an assumption; it isn't supported by evidence. And yet it's not treated as a hypothesis but as a guide to theory-development.
>
> And all presently existing research on the quantization of gravity rests on the assumption that quantum theory itself remains unmodified at short distance scales. This is another assumption that isn't written down anywhere. Should that turn out to be not true, decades of research will have been useless.
>
> In lack of experimental guidance, what we need in the foundations of physics is conceptual clarity. We need rigorous math, not claims to experience, intuition, and aesthetic appeal. Don't be afraid, but we need more math.

As usual, very nicely said Sabine!

21. **Geoffrey Dixon**
April 8, 2017

Forbes just published this article:
https://www.forbes.com/sites/chadorzel/2017/04/06/why-are-there-too-many-papers-in-theoretical-physics/#68ee330d37ee
Gist:
1. There are too many theoretical particle physicists fearful of publishing anything that might jeopardize their careers;
2. There is a dearth of high sigma experimental results that could lead to "new" physics;
3. Therefore, anytime there is a glitch in some experimental result, there is a stampede of publications attempting to explain it;
4. When glitch is fixed (shown to be statistically insignificant), no one retracts or feels embarrassed by their publication(s), for everyone does it. It is socially acceptable.

I could go on and on, but I already have:

https://www.amazon.com/Fire-Night-Functioning-Maverick-Theoretical/dp/154305644X

Pay particular attention to everything after chapter, "Imagine you're a dolphin".

22. **Another Anon**
April 8, 2017

Wyman, Bunsen Burner, and all the rest of you condensed matter physicists, and fluid dynamicists, and all of you getting annoyed because you don't see a problem – seriously, this isn't about you. It's a problem with fundamental physics.

It really bugs me when people say there's no problem in physics because they've just invented a new transistor. We are talking *fundamental physics*. Please!

23. **AnonNth**
April 8, 2017

Another Anon, the problem isn't that condensed matter physicists do not see a problem with fundamental physics, but rather that high energy physicist are becoming obsolete because of the great success that condensed matter physicists are having solving fundamental AND high energy physics problems with the far more experimentally accessible mathematical and theoretical machinery of condensed matter physics.

String theorists in particular, are having a hard time saying that they just plain wrong, and seem to be unable to cope with condensed matter theory stealing their glory..

24. **Peter Woit**
April 8, 2017

All,
Will delete any more arguments between fields of physics. Yes, the problem at issue is one of certain specific fields, not all of physics, and not all of science.

Interestingly, no one seems to deny that that there is a problem…

25. **cthulhu**
April 8, 2017

G.S. asks about other fields including engineering. I'm an engineer specializing in aircraft flight control, an area which has been one of the two primary drivers of control theory over the last 50 years (the other being industrial process control). As we have pushed our aircraft designs to deliver more capabilities in numerous areas, we have demanded much more of the flight control systems, and there has developed a huge interest in design tools that give us guarantees about stability and robustness to uncertainties.

I won't go into details but will state without offering proof that these techniques have turned out to be difficult to apply in the real world, mask much of our physical understanding of what the so-called bare airframe (the aircraft without any active controls) is doing, and have over the years led to several expensive redesigns on multiple programs, affecting both investors' and taxpayers' pocket books in multiple countries; the redesigns have usually been done primarily with techniques that, while perhaps less mathematically elegant, have the distinct virtue that they have been shown to work on countless prior programs. The "modern" techniques have found a role in the analysis side of things, helping us understand the limits of our designs, and this is a valuable thing to have. Mistakes in the flight control design are probably the easiest way to cause a catastrophic accident short of pilot error.

So, my answer to the question is that yes, at least some branches of engineering have been afflicted with paths that over-promise and under-deliver, but at least for aircraft flight control we still have the ultimate Diogenes to keep us honest: does it actually fly or not?

26. **Ted**
April 8, 2017

Perhaps the best way to change the sociology/mechanics of academia is to pave a new route for the people entering the field. As a student who has been searching for a PhD research direction with promise in fundamental physics, its a depressing situation. The obscene amount of research, coupled with no significant results coming out for decades is clearly the symptom of a system that needs to start supporting academics (especially new ones) to explore new directions – and to question why our current ones aren't working. Strongly agree with what was said in the quote in the comment above – "In lack of experimental guidance, what we need in the foundations of physics is conceptual clarity".

27. **Thomas**
April 9, 2017

Peter, Bee,

the lack of new and interesting data and the overproduction of speculations, both in high-energy physics and quantum gravity, could be due to a simple reason:

Maybe there is nothing to be discovered any more in these two fields?

We all know that such a statement has been made repeatedly in the past, and it has always been wrong. But could it be correct this time? This is the touchy issue swept under the rug in all these discussions. This is the touchy issue avoided like the plague by everybody. This is the touchy issue that led to string theory, loop quantum gravity and other speculations not related to experiment but with a large number of followers.

We need an objective debate of this touchy fundamental issue, not a discussion of its side effects. Why is there no such debate? Just look at the answers to such a proposal. You will see ridicule, contempt or aggression – but no objective debate.

The world is full of smart physicists who have been trained and imbued with the conviction that there is still a lot to discover. Maybe this conviction is wrong?

28. **GoletaBeach**
April 9, 2017

Burt Richter's 1999 closing talk at the Lepton Photon discussed these issues before… https://arxiv.org/abs/hep-ex/0001012 . His talk itself used to be online… now 404. In person he was substantially more caustic toward the theory community.

"There are more of us, we collaborate more, and we share more information than ever before."

I'm not at all sure that there are more experimentalists since the 1980s… hard to tell because so many leave after PhD and postdoc… lately for high-paying data science jobs.
In the late 1990's for all sorts of telecom jobs. And a constant move to Wall Street.

Einstein did synthesize GR from only foundational notions… current theorists keep trying to pull a similar rabbit out of a hat. Somehow I don't find it surprising that all the social techniques familiar for millennia to define the "in crowd", "the outsiders", Cassandras, rebels, syncophants, etc are in play in theoretical particle physics. It is a social activity.

With luck, though, out of all the dung a really delicious mushroom might sprout.

29. **Peter Woit**
April 9, 2017

All,

I hope people will actually address the issues discussed by Sabine Hossenfelder, since I think they're interesting, and a serious discussion of what might be done to address them is important and desperately needed.

30. **Jeffrey**
April 9, 2017

Six hundred papers interpreting what turned out to be a statistical fluke? From what I gather it is irrelevant. They are getting direct deposits in their bank account anyways, why change? Who cares if was a fluke? Seriously, they could have known it was a fluke anyways, and said, "hey, we know this result is nonsense, lets publish something anyways because we need to get paid."

It would be win-win. They write up some interpretations, they get paid, the results come out as being a fluke, then they can blame the fluke on the machine. Easy. As a matter of fact it would be best for the machine to make mistakes and to have issues, and be so big that parts randomly break at intervals. Job security forever!

Sabine does not mention money in the article. Sabine can sit here and talk all day, and write up all the interesting social bubble stuff, but unless the cash stops flowing, then nothing is going to change.

31. **Tom Andersen**
April 9, 2017

Here is a situation that is happening today that is *new*. Instant worldwide intercommunication. Its of course great to have, but in theoretical physics it is also causing groupthink. No longer can a bright team work without interruption on a maverick idea for a year or three. It seems instead that papers are produced based on perceived consensus.

Without the magic of the internet and $500 long distance travel, the world of physics was different and more open to strange ideas a century ago.

32. **neil**
April 9, 2017

Why all the hand-wringing about the theorizing on the diphoton anomaly? Yes, it was low sigma but it was observed by both ATLAS and CMS. Given the importance of priority, which science has always respected, who wants to wait around for more data before trying to explain it? I don't see what harm was done.

33. **GoletaBeach**
April 9, 2017

Well, Peter, the amplification of social feedback in the theory community has widened the gulf between theory and experiment. Experimentalists just roll their eyes and when among themselves are so derogatory they make you look like a string-theory booster.

Perhaps every particle theory PhD should include a mandatory 1 year doing hardware shifts at the LHC, or on any big experimental effort.

34. **Scott Aaronson**
April 10, 2017

Hi Peter,

As someone who's often trying to get the straight dope about the topics she writes about, I appreciate Sabine's writing immensely—her bluntness, humor, and obvious relish puncturing hype strike a chord with me as they apparently do with you.

But regarding the information paradox, I think there's an actual technical point at issue, which creates a fork in the road before one enters into any questions of faddishness, sociology, etc. Namely: should the black hole entropy, which we presumably agree is governed by Bekenstein's bound, count the log of the number of orthogonal microstates? I think yes—I don't understand what entropy even MEANS if it's not counting microstates—while Sabine apparently thinks no. But crucially, if the answer is yes, then what Sabine advocates as the "obvious, inexplicably ignored" solution to the paradox—i.e., that all the information stays in the black hole, even as the latter gets microscopically tiny—is indeed ruled out. So then, unless we want to give up on unitary QM, or have the information escape through the singularity into a baby universe, as far as I can see we're indeed forced to consider the proposal that the infalling information is holographically encoded on or near the horizon, from where it can enter the radiation. So in that case, we don't need to offer a sociological explanation for why people remain so interested in the information paradox 40+ years after Hawking raised it: a scientific explanation suffices!

35. **Another Anon**
April 10, 2017

Peter will almost certainly delete my comment for being off-topic, but I agree with Scott in saying that – if the information does not escape as the black hole evaporates – how on earth can all the information that has ever fallen into a black hole be encoded into an progressively smaller, effectively infinitely small, region of space? Bee thinks the problem is solved if the singularity is removed. Surely not.

36. **spacetime**
April 10, 2017

I bit strange to read

"But we have a crisis of an entirely different sort: we produce a huge amount of new theories and yet none of them is ever empirically confirmed. Let's call it the overproduction crisis."

and

"I'll even admit having contributed to the paper pile because that's how academia works. I too have to make a living somehow."

37. **Anonyrat**
April 10, 2017

I think the "over-promise, under-deliver" problem is a bit different from the one Bee is talking about. In the information technology world, this "over-promise, under-deliver" is represented, e.g., by the Gartner Hype Cycle, the 2016 version of which can be viewed here (http://www.gartner.com/newsroom/id/3412017) (I am not affiliated with Gartner.)

Per Gartner's analysts, there is a natural progress curve, on top of which is added inflated expectations due to hype. Hype is driven by marketing, confirmation bias, novelty preference, social contagion, competitive pressure, irrational exuberance and (positively) overcoming inertia and imagination. The dangers of not understanding the hype cycle for corporations is they adopt technology too early, give up too soon on a technology, adopt too late or hang on too long to old technology. Understanding the hype cycle also opens up opportunities, which Gartner lists in some of their publications, that I won't repeat here.

The problem Bee describes has some factors in common with the technology hype cycle, such as social contagion and competitive pressure (though it is academic competition rather than commercial competition). Novelty preference may also play a role in the fad-driven research cycle of fundamental physics.

38. **Peter Woit**
April 10, 2017

Scott,
I see Sabine has responded to this on her blog, pointing to
http://backreaction.blogspot.de/2012/07/bekenstein-hawking-entropy-strong-and.html

First I should make clear that I haven't thought much about this, partly because of a personal allergy to spending a lot of time on a topic that many smart people have been active in for a long time, producing lots of papers, but no obvious progress. One aspect of this is that as this kind of thing goes on for decades, the barrier to entry to someone like me who likes to first try and understand what others have done becomes higher and higher.

As a graduate student nearly 40 years ago I spent a fair amount of time learning about Hawking radiation and was aware of the paradox, but it seemed that the framework of what was understood was not rigid enough to address the issue (in part because it was silent about "what is going on at the singularity?"). Over the years I've made periodic attempts to read up on the latest on this, but my impression has always been that this situation hasn't really changed. Yes, you can make various assumptions about what entropy is in this situation, about the Bekenstein bound, or about what "holography" is and what it implies here, and you can derive various consequences from various assumptions. But no compelling picture seems to emerge from this activity. Given this, there's a real sociological question about why this is such a popular thing to be doing. I guess the best argument for it is not that anyone is going to resolve the issue, but that thinking about this problem may lead people to something more fruitful.

Another Anon,

I just don't see how arguments like "how on earth can all the information that has ever fallen into a black hole be encoded into an progressively smaller, effectively infinitely small, region of space?" can resolve anything. At the crudest level, the singularity is a place that we don't understand, where everything has gone. Why shouldn't the answer to the paradox be there rather than at the event horizon? But my question is just as rhetorical and unscientific as yours. You need a well-defined theory to answer such questions, and that doesn't seem to exist.

39. **Lee Smolin**
    April 10, 2017

    Dear Scott and Peter,

    Sabine and I discussed in detail the issue of the meaning of the BH entropy in our arXiv:0901.3156. We argue there that the original and standard argument from Bekenstein only supports a weak form of the BH entropy which is that the surface area is a measure of the capacity of the black hole horizon as a channel for the transmission of information. The strong form, that you name, that the BH entropy is the log of the number of microstates of the interior of the horizon, is an unjustified extrapolation.

    Regarding the size of the interior of the horizon, it is understood since the early days of the subject that the volume of the interior of the horizon can be very large compared to the area, this is the so-called "bag of gold." We discuss in detail other objections and issues such as those having to do with remnants. In addition, note that there areworked out examples where the singularity is removed leading to a resolution of the paradox: Ashtekar et al's study of CGHS black holes: arXiv:0801.1811. and by Rovelli et al, Planck stars.

    The weak and strong form of the BH entropy then imply weak and strong forms for the holographic principle, as discussed in hep-th/0003056.

    Let me put the issue simply: The "conservative solution" that quantum gravity effects eliminate the singularity does indeed resolve the information paradox, as well as related puzzles such as the firewall paradox. Further, this requires no modification of standard physics at the horizon, no modification of the principle of unitarity, and no radical non-locality, but only modifies physics at singularities, where we already know we need new physics. Given this, I would think we need an extraordinary motivation to ignore this conservative and natural solution in favour of speculations that impose radical new physics on the horizon, where the curvature may be very weak.

    Thanks,

    Lee

40. **TVR**
    April 10, 2017

    If you assume that singularity forms in gravitational collapse, then you have to trace out the modes that presumably end up in the singularity and keep only the outgoing modes. That is the origin of the information loss paradox. You remove part of the original state, and then obviously something is missing, i.e. the density matrix does not describe a pure state.

    If there is no singularity, then you do not trace out any modes. Then this paper Phys.Rev.Lett. 114 (2015) no.11, 111301 practically answers the question. Most of information is not in Hawking quanta, but actually in subtle correlations between them. These correlations are described by the off-diagonal elements of the density matrix. They start off very small at the beginning, but grow as the Hawking evaporation progresses. So "information" is not released at the very end where you need Planckian physics. These correlations are able to restore unitarity. The whole process is unitary all the time, but an observer collecting only the Hawking quanta might have an impression that the information is lost.

    Note that the singularity and event horizon are much related notions. If there is no singularity, the horizon cannot be a global event horizon. If singularity is replaced by the normal region of strong gravitational fields, once enough mass is lost to evaporation, anything that was trapped inside must be released. An apparent horizon might exists for a while, but it will disappear at the end. No remnants with huge amount of "information" in them are needed.

41. **neil**
    April 10, 2017

    Does anyone know whether the Event Horizon Telescope will be able to exclude the "information released early" (firewall) possibility?

42. **reader**
    April 10, 2017

    Lee,

    This proposal has features that make it seem not so conservative after all. As is well known, if the thermality of the radiation only breaks down once the black hole becomes of Planckian mass, then the remaining object must decay over a very long timescale for its radiation to purify the full state. Indeed this timescale can be made arbitrarily long by increasing the mass of the original black hole. So this scenario requires very long lived remnants. More seriously perhaps, it seems impossible to make this work for a black hole formed in AdS. Putting aside anything to do with AdS/CFT, AdS acts like a finite sized box, so a state of radiation of total energy M_Pl has a small maximum entropy. In this case there is no way for a Planckian remnant to decay into a gas of (arbitrarily) high entropy quanta whose state would purify that of the Hawking radiation emitted earlier. So while it is logically possible for black holes to release their information in Hawking radiation in asymptotically flat space (while only modifying Planck scale physics) this seems impossible in AdS. I find that highly problematic.

43. **Giotis**
    April 10, 2017

    "When I have thought about it, it seemed to me that there was no way to make the problem well-defined as long as one lacks a good theory of quantized space-time degrees of freedom that would tell one what was going on at the singularity and at the end-point of black hole evaporation."

    Actually is the other way around.

    Your attitude with respect to the information loss paradox suggests the kind of theorist you are.

    If you still believe that information is lost or in remnants, then almost certainly you are a GRist; if on the other hand you believe that the information escapes via the Hawking radiation and to complementarity then you are almost certainly a particle/String theorist.

If you believe in Mathur's fuzzballs then you are Mathur; LOL, that was a joke, actually fuzzballs have many supporters, far far more than those believing in remnants who are indeed a small minority nowadays.

44. **Peter Woit**
April 10, 2017

Giotis,
My attitude with respect to the information loss paradox is that I don't know the answer. Don't know what kind of physicist that makes, me, maybe it makes me a mathematician…

Your schema breaking up physicists into different tribes depending on their ideological beliefs about black holes is a scary vision of the postfactual future (or present?).

45. **Zack Yezek**
April 10, 2017

It appears that this malaise is really limited to 'fundamental' or 'high energy' physics, especially 'grand unified theories' or 'quantum gravity'. And there actually IS healthy progress there, if you consider things like neutrino physics to be a part of it.

After all, the null results of the past 40 years ARE significant. Arguably the non-detection of WIMPs & SUSY are our era's versions of the Michelson-Morley experiment. The problem isn't with theorists who knock off a new model that can explain tentative new experimental results, like the CERN 750 GeV one. No, the problem is much of this "theorizing" doesn't produce useful theories. Or at least it hasn't after 40 years of research, if you define a real theory as one that makes quantitative, falsifiable predictions. SUSY, String Theory, etc. don't do that. They come in so many distinct flavors, with so many free parameters, that they basically make no hard predictions and can evade any negative experimental result.

The real solution is to draw a hard line between mathematical frameworks, hypotheses, speculations, and genuine theories. This will let people work on speculative ideas or big frameworks like SUSY, but also make it clear that there is a qualitative difference between those and genuine theories of physics like General Relativity or QCD that quantitative, testable predictions. The expectation then should be that an idea must meet certain "meta" criteria to graduate from speculation to hypothesis, and then from hypothesis to theory. This system would also make it clear that comparing things like SUSY and GR is a category error, and allow them to be judged on different criteria. That way you can really enforce a necessary, fair rule like "If your hypothesis evolve into a testable theory within 40 years, we're no longer giving it research priority".

46. **Giotis**
April 11, 2017

Right or wrong the dichotomy is there, I didn't invent it.

Check around min 1:23:10 of this video and you will understand it within the context of information loss paradox resolution proposals and remnants in particular.

https://youtu.be/3EOpHHjv5g8?t=4991

April 11, 2017

The notion that HEP should only be about finding *the* new model is an oversimplification, just as is the notion that the standard model is completely understood. There are several healthy communities working on understanding just standard model physics. This may even be the best bet of finding new physics, although it almost certainly would not be of the romantic smoking gun variety.

I agree that those areas of HEP that are in danger of forming tadpoles or vacuum bubbles in theory space should take a good hard look at themselves though. Proposed yardstick: articles starting with "recent progress…".

48. **Bernhard**
April 11, 2017

"The only response I see are attempts to blame others: funding agencies, .."

Well, meap culpa, as I'm one of those blaming "others" than. Funding agencies still determine everything. They determine which ideas are to be pursued or not and it is not as simple as saying that the reviewers are just scientists/ourselves. These agencies are more than the simple sum of the reviewers – there clear guidelines, written and not uncommonly unwritten in order to determine which persons and groups should get the funding, which ideas should be rewarded and which should be punished. Sorry to be simplistic here, but the issue 99% of the time boils to money. The reward idea pre-Higgs was the Higgs and SUSY now things are clearly shifting to dark matter. What if you're not interested in dark matter, Higgs or anything mainstream but still want to do conservative, sober physics? Sorry, but unless your CV is stellar, and sometimes even so, you're not getting the money and the following year you will obey. We all have mortgages to pay. The social problem with physics is that we cannot get rid of this model. I believe many of us would try crazier, harder things, that would take longer to publish if risking were to be rewarded. About the fact that "they don't to waste money on useless research" – define waste. Waste for them is something that attracts no attention – if something does attract attention than no matter how big the hype, it was all worth it. And what power do we actually have here (the cute idea that "they rely on us, the scientists, to tell them how science works")? We have zero power. This is a closed loop circle where people who were rewarded by this system end up being the future judges of it, doing all they can to keep the status quo. This kind of thing happens not only to theoriests, even experimentalists will be accused of having a "too narrow" program if what they're doing is not somehow connected to Higgs, SUSY or dark matter. Funding agencies taking a big chunk of the blame is the conservative answer to this problem she's failing to see.

49. **Peter Woit**
April 11, 2017

Bernhard,

It's true that changes in how decisions about funding are made could have large effects. I find it remarkable that, at least in the US, I'm unaware of any significant discussion at DOE or NSF about whether the problems of theoretical HEP physics could be addressed by changing in some way how the system of grants work.

I also haven't heard any news since December about any response to the "DOE Theory Letter" from a large fraction of US HEP theorists asking for an explanation of why grants to theorists have been cut. Unfortunately it may be that, absent any discussion of how to improve the situation, someone at the DOE has decided the thing to do is keep the system the same, just slowly defund it.

50. **X**
April 11, 2017

It has always seemed obvious to me why pure maths is not afflicted with the sociological issues discussed in the post. The reward system in maths incentivizes quality over quantity, i.e. working on hard problems that take a long time to solve rather than publishing lots of superficial 'me too' papers on the latest fad. The way it does this is through the existence of top quality journals. Publishing in one of those journals confers much greater reward than the average or mediocre journals. E.g. a single paper in Ann. Math. is worth more for a mathematician's career than countless publications in average journals. So pure mathematicians are incentivized to work on more difficult and deeper problems that can lead to publications in the top journals.

Compare this with the situation in physics. Actually HEP theory has its own unique reward system different from the rest of physics and academic science in general. In HEP theory, number of publications and citations is not actually all that important as long as the person has a respectable number of them. People don't get hired, get grants, or advance their careers by having more publications or citations than others. Instead, it all depends on how they are viewed by the 'important people' in the field. Doing good work will of course help them to be viewed positively, but it is not the only factor. In practice it matters a lot that a big shot in the field feels they have something personal at stake in whether the person succeeds or not.

This reward system in HEP theory incentives people to try to maximize the favorability of how they are viewed by the 'important people'. The first step is to get the attention of those people. This means working on whatever topic those people are working on, try to do PhD or postdocs at the institutions where those people work, etc. Obviously, people who work on other topics will have a hard time in this reward system. Jobwise they will have to try to survive on whatever scraps are left over after the 'favored' folks have been accommodated.

Note the difference with pure maths: journals play essentially no role in the reward system in HEP theory. In the major HEP journals, JHEP and Phys.Rev.D, papers making major advances are published side by side with superficial 'me too' papers. Quality control and standards for getting published are pretty minimal. So the journals that a HEP theorist publishes in says nothing about the quality of his/her work.
Even the supposedly top physics journal PRL has uneven quality in practice, and publishing in PRL will do nothing for a HEP theorist's career prospects. Without the backing of important people, PRL publications count for flat zero in HEP theory. And for someone who does have the backing of important people, it doesn't matter where they publish…

The different reward system in pure maths makes it possible for a mathematician to prove him/herself meritorious and worth supporting regardless of the topic he/she works on or whether he/she is known and viewed favorably by important mathematicians. It is enough that the person produces work of high enough quality to be published in a top maths journal such as Ann. Math. Then the career rewards will be conferred, regardless of other factors such as fashionability of the topic or how well connected the person is.
Working at a prestigious institution and having connections to important people will no doubt help a mathematician to have his/her papers taken seriously by top maths journals, but it is not essential. Unknown/unconnected mathematicians working on unfashionable topics can and do occasionally manage this too, and get the same career rewards. This possibility does not exist in HEP theory; it is simply not part of the reward system.

As for the rest of physics, and academic science in general, from what I've seen the reward system is based on a mixture of bean counting (number of publications and citations, h-index), status of the journals the person has published in (impact factors), and the views of important people in the field. At top universities the views of important people carry more weight, while at average research universities the bean count matters more. Hype and fashion seem to play a big role in getting papers published in the journals with high impact factors (Nature, Science, PNAS, PRL etc) – a very different situation that with the top maths journals. This reward system incentivizes academics to treat research as a video game where the objective is to maximize their score. This means do safe 'me too' research in hot fashionable areas that can lead to lots of publications and citations.

It seems pretty obvious that pure maths is the only field with a well-functioning reward system that creates good incentives, and I find it amusing how little interest there is in HEP theory or the rest of academic science in considering replicating the maths system in place of the obviously flawed existing systems.
One reason for this is obvious: the people who have risen to the top under the existing reward systems have no interest in replacing it with another system. They think the present system is fine – after all it allowed them to rise to the top so it must be a good one, right? 🙂
Since they are the ones running the show, there is no practical chance that things will change any time soon.

As for Bee's proposals for how to modify/improve the reward system (written on her blog, not so much in the Nature article), adding a bunch of additional metrics to assess people on along with the ones currently in use seems to me to just be more bean counting that won't change the "research as a video game" problem. People will game those metrics like they do with the current ones.

51. **Lee Smolin**
April 11, 2017

Dear Reader,

I am afraid I don't understand your logic. As we showed with Sabine in the article I mentioned, the arguments we were aware of against long lived remnants, are fallacious as they make unwarranted assumptions. This would apply also to black holes in AdS.

You assert, "Putting aside anything to do with AdS/CFT, AdS acts like a finite sized box, so a state of radiation of total energy M_Pl has a small maximum entropy." But this is contradicted by the possibility that small black holes have large interiors as in bag of gold solutions. You go on to conclude that , "there is no way for a Planckian remnant to decay into a gas of (arbitrarily) high entropy quanta whose state would purify that of the Hawking radiation emitted earlier. " Why? To the extent that the overall state is purified, the entropy is low. In any case there is no problem if the remnant doesn't decay. For example, a baby universe could form, and the quantum information ends up there. (Is there a calculation that shows that the state of a CFT cannot be dual to a baby universe?)

In any case, the published examples of singularity elimination resolving the problem, by Ashtekar et al and Rovelli et al, do not involve slow decay of remnants. Rather, as shown in detail in Rovelli et al, the Plank star explodes in a time scale of M^2, which is very short compared to the time of M^3 that the Hawking evaporation would have taken. (But still long on astrophysical time scales.) So when the Plank star explodes only 1/M of the Hawking photons have been emitted. So the process is nearly reversible and the problem of information loss never arises.

I don't think we know which of these outcomes arising from singularity resolution is correct. But I fail to see how semiclassical arguments, which assume the singularity remains, have any force once one finds that, as the calculations I mention show, quantum gravity eliminates the singularity. One cannot avoid the fact that there is a region to the future of where the singularity would have been, which contains quanta entangled with photons in the exterior. There is no singularity and this means no information is lost, whatever the fate of the region containing it. This does not contradict QM, rather it is a consequence of taking QM seriously.

Thanks,

Lee

52. **From the Mathematical "Paradise"**
April 11, 2017

I'd like to disagree with X, having seen a number of tenure cases in pure math in a highly ranked math department. We don't just count *Annals* papers, we ask for letters from other highly-ranked mathematicians – i.e., "important people". And when we do that, the same problematical sociological issues can easily muddy the waters. Somebody working on an unfashionable topic is going to get overlooked unless some miraculous discovery that affects the rest of mathematics comes out of this topic. And to make matters worse, people working on unfashionable topics are not going to get published in the *Annals*

On the other hand, it's clear that the evaluation system in mathematics is working a lot better than that in fundamental physics. But I think that's because HEP is currently "broken" in several unfortunate ways, not because the evaluation system in mathematics is different and better.

53. **reader**
April 11, 2017

Lee,
.
I should have been more clear. I hope the following clarifies matters.
.
First, the following scenario is clearly impossible: Hawking's result is accurate until the black hole radiates down to Planckian mass, and then, dictated by quantum gravity, the remaining Planckian object evaporates completely into outgoing radiation in a Planckian time, restoring the information. The obstacle is as follows. The early radiation can have a huge entropy; the total state of the radiation is pure; therefore the radiation produced by the Planckian object must also have this huge entropy. But it is impossible for a state of radiation of Planckian energy extended over a Planckian scale to have such a large entropy. A large entropy from a small energy can only be obtained if the radiation has a large spatial extent, corresponding to the long-lived remnant scenario. The same comments pertain to the decay of a black hole in AdS into a pure radiation state: no such state of Planckian energy can have the needed entropy.
.
As you correctly state, one possibility is that black hole singularity is resolved, resulting in a stable remnant that carries the information. But here there are two options. 1) The information in the remnant is hidden behind a horizon or is otherwise inaccessible to the outside world. This is really no different than information loss, as far as the outside world goes, although indeed information is preserved at large. 2) The information in the remnant is accessible by the outside world. Here one runs into the problems of infinite pair production and the like: if the remnant states interact with external degrees of freedom, then it would seems that these remnants will be produced in collisions.
.
The scenario of Rovelli: this involves a breakdown of semi-classical physics in a regime where spacetime curvature is arbitrarily small. This is a logical possibility, but clearly far more needs to be done to establish that this is a viable alternative.
.
Ashtekar: et. al: it's not clear to me what their bottom line is: a stable remnant, a long lived one…?
.
I avoided AdS/CFT so far, but you brought up whether it is compatible with information going into a baby universe. A closed baby universe has zero energy and would need to possess an arbitrarily large number of states to resolve the paradox. So the CFT would need to similarly possess a large number of zero energy states. This is not a property of, say, N=4 SYM as far as anyone knows. So AdS/CFT seems to incompatible with remnant/baby universe scenarios, although admittedly this is not a watertight argument.

54. **X**
April 12, 2017

In reply to 'Mathematical Paradise':

"people working on unfashionable topics are not going to get published in the Annals"

No doubt it's rare, but it does happen. I know an example, someone who was a former colleague in the maths dept where I worked. His PhD was from a good but not top university and afterwards he got a job at a 4-year teaching college. While there he did the work that resulted in an Annals publication (joint with his former PhD advisor). The field was Discrete/Computational Geometry, which is not a fashionable high-powered area as far as I'm aware. His work no doubt made a major advance in that area, and may have had implications for nearby areas such as algebraic geometry, but I doubt it "affected the rest of mathematics". Afterwards he was rewarded by a job at a pretty decent research university.

This kind of outcome simply can't happen in HEP theory/fundamental physics for the reasons I discussed.

55. **someone who spent time in "paradise"**
April 12, 2017

The reward system in maths incentivizes quality over quantity, i.e. working on hard problems that take a long time to solve rather than publishing lots of superficial 'me too' papers on the latest fad.

I think this is far too romantic a view. The reward structure in the math profession results in different problems than that of physics, but it has problems nonetheless.

Math is much more fragmented than physics. My advisor–who has worked in a number of different fields–told me that most mathematicians are idiots when confronted with math from outside their speciality (and he/she said this applies to him/herself). This problem is exacerbated by the fact that research math these days doesn't allow you the time to develop a broad mathematical culture: a functional analyst will probably not be able to afford learning algebraic number theory for fun, even if he/she might enjoy it and benefit from it.

So when institutions make decisions about funding, hiring, tenure, etc., it often degenerates into wrangling between various specialities: do the harmonic analysts get to hire another harmonic analyst, or do the homotopy theorists get this one?

And this is purely a question of academic politics, not of merit: are there more harmonic analysts in the department; are they cleverer bureaucratic infighters than the homotopy theorists; do they bring more grant money to the department; are they chummier with the deans, etc.

The truth-value of a theorem is objective: it is either true or false (let's leave aside undecidability for the purposes of the discussion). But the *value* of that theorem is subjective. Even within a particular discipline, there's not always expert consensus on the value of someone's work.

Regarding X's suggestion that elite journals encourage ambitious and deep work, I don't think it's true. Many, even most top mathematicians never manage to publish in such a distinguished journal as the Annals. This is exacerbated by the fact that the editors of such elite journals are very conscious of their elite status. So they're very conservative: they won't accept a paper unless they're sure it'll benefit the journal's reputation. That means many great papers are never published in those journals. Not because the work isn't good enough, but because for some reason or other, it just doesn't fit with what the editors want.

So it's a high-risk strategy to try to work on a problem famous enough to warrant publication in a top journal, especially if you don't have tenure. A young mathematician, unless he/she is very brilliant and has a high tolerance for taking risks, is not advised to try that route.

A far safer strategy is to prove more modest technical results extending the highly specialized line of research already set out by experts in your narrow field. That way those experts will recognize you, they'll praise you to their colleagues, they'll ensure your papers are published in their specialist journals, they'll write recommendations for you, they'll put your name on grant applications, and you'll be more likely to get tenure. Of course, it also means you won't break new ground or innovate very much. But if the goal is to have a career, that's the path you should probably take.

Young people are supposed to be brave and innovative and willing to gamble on big ideas because they have nothing to lose, but the incentives of academic mathematics encourage just the opposite. The pressure to publish trivial or incomplete work quickly is high and getting higher; the freedom to take time to do really deep and thorough creative work is quickly diminishing; technical prowess is increasingly valued over insight and conceptual clarity. There are exceptions to these rules, of course, but I am speaking of the norm.

The point is not whether the system produces superstars: there will always be people like Terry Tao and Peter Scholze who manage to break through to the highest level by dint of brilliance, hard work, and the luck to find the right problem at the right time. The point is whether the system can sustain a large "middle class": those researchers who are not superstars, but who make deep and important contributions.

Even those very top people depend on the contributions of many hundreds of mathematicians whose names are rarely cited. Not even Grothendieck could do it all alone!

And if the system becomes so dysfunctional that that "middle class" dies off, then eventually even the superstars won't have the material they need to produce great work. (An example is Euler's discovery of the addition formula for elliptic integrals, which was inspired by the work of Fagnano, a much lesser figure).

56. **anon**
April 12, 2017

No doubt math is fragmented, but it very hard to believe it's 'much more fragmented than physics'. Unless physics is understood to only mean fundamental theoretical physics…

57. **X**
April 12, 2017

I know of quite a few mathematicians from non-illustrious backgrounds whose research areas are not particularly fashionable but have still been able to have successful careers by publishing in high quality journals. It doesn't have to be Ann. Math.; there other journals one or two notches below that such as Adv. Math. and J. Reine. Angew. Math. which are more accessible but still recognized as high quality. When a mathematician publishes in such a journal it confers a quality stamp that is recognized throughout the maths community, including by those whose areas of specialization are completely different.

A person who has these quality stamps will generally get hired and promoted ahead of another person with better pedigree or more fashionable research area who hasn't managed to publish in journals of the same quality. This is a *great* feature of the maths reward system. Yes it does incentivize people to work on deeper problems. I've worked in maths depts, shared offices with pure mathematicians and seen first hand how trying to get published in the best journals they can is one of their main motivations when doing research.

That doesn't mean they are all trying to solve famous problems to publish in Ann.Math. But when faced with a choice between cranking out a bunch of fairly trivial papers or using the time instead to try to get one paper in a high quality journal, they choose the latter option from what I've seen. Maybe not so much at PhD level, but at postdoc level and beyond this seems to be the case.

If such 'quality stamps' were introduced in theoretical HEP/fundamental physics it would fix the sociological problems IMO.

58. **unitarity**
April 12, 2017

Dear Reader,

"Hawking's result is accurate until the black hole radiates down to Planckian mass" is exactly what is not true here. Hawking radiation is only approximately thermal. There are many ways to show this, including following the original Hawking's calculation and not taking the exact limit of t->infinity, which is anyway unrealistic for any physical external observer. Radiation becomes exactly thermal only at t = infinity, but a finite size black hole will disappear before that. Therefore, Hawking radiation was never quite thermal to begin with.

However, the real question is whether these small deviations from thermality are able to unitarize the process of black hole formation and subsequent evaporation. If there is a singularity at the center, then you are removing part of the initial state by hand. Then indeed, you really need some serious abracadabra to recover unitarity. If there is no singularity, then you do not trace out the ingoing modes. Then these modes contribute to the corrections to the original Hawking result. In that case, the deviations from thermality are able to unitarize the whole process. The corrections are locally very small, but their integrated effect is large and sufficient to purify the density matrix.

59. **Geoffrey Dixon**
April 12, 2017

No amount of downstairs gossip or griping about those comfortably ensconced upstairs will change the social order, save perhaps revolution, and even that can have no long term effect as far as stratification and exclusionary practices are concerned. The dust always settles in the same place. How many "important people" are involved in this debate? Peter and Lee are well-known, influential, and well established, but they are not the kind of "important people" discussed here. Their tomes questioning the worth of string theory pleased a lot of people – like me – but the response of the "important people" was a shrug. I've seen at least two articles extolling the virtues of being theoretically lost: it's the journey that matters, not the goal. The disruptions of a century ago were driven by mountains of incontestable data from many sources. We no longer have that, and the bombs those early pioneers gave rise to got the attention of the real power brokers. Money rained down, attracting great numbers of individuals who would otherwise never have dreamed of a life in theoretical physics. The power of vested interests increases in proportion to population. That power has withstood all attacks for 40 years.

60. **reader**
April 12, 2017

Unitarity.

If it were that simple people would not have been arguing about this for over 40 years. First, barring a gross breakdown of locality, the presence/absence of the singularity cannot possibly effect the outgoing radiation until the last stages, simply because the singularity (or whatever replaces it) is not in causal contact with the outgoing quanta, including their causal past. Of course, this Hawking radiation is not exactly thermal, but it carries a very large entropy and no small corrections to physics at the horizon can change this (a result proven by Mathur). Getting the information out in the early Hawking radiation (before the hole has shrunk to Planckian size) requires some radical new effect: nonlocality, firewall, Rovelli's bounce scenario, etc. Trouble is, all these scenarios are invented purely to solve this problem, and have little support or evidence beyond that.

61. **unitarity**
April 12, 2017

Dear Reader,

The absence of the singularity makes all the difference you need. Imagine that an object of mass M collapsed, formed an apparent horizon, but not a singularity at the center. Presumably it trapped everything within the region of the size of 2GM. If there was a singularity at the center, you would have to discard all of this trapped stuff and wait until the black hole reaches the Planck size for some unknown effects to release information about it. However, if there is no singularity, the stuff is just trapped by strong gravitational fields, and it is not lost forever. So when a black hole emits dM of its mass, only stuff within 2G(M-dM) radius will be trapped, the rest will be released right then (without waiting for Planckian physics). Therefore, information is released progressively, at first very slowly, but then faster and faster as the rate of evaporation grows and trapped region shrinks. Nothing non-local is needed here.

About Mathur's result that you mentioned, he is a very smart guy with a great amount of knowledge about this topic. The result he proved is very important, however, it is incomplete. He assumes that only the members of the Hawking virtual pair are entangled, and not the members of different pairs. The off-diagonal elements of the density matrix are exactly the interaction terms that he neglected.

62. **reader**
April 12, 2017

Unitarity,

Let's put it this way. Up until the very last stages, Hawking's computation can be carried out while making absolutely no reference to, or assumptions about, regions of large spacetime curvature. So as long as we have approximate locality and causality, any assumptions about the (non)singularity will have negligible effect on the outgoing radiation until the last stages. Therefore, if you want all the information to come out with the Hawking radiation you have two options: 1) arrange for the last gasp of radiation to carry a huge entropy to purify the full state. This is the long lived remnant scenario. 2) modify the early time radiation so that it carries a much lower entropy than Hawking predicts, noting as above that this modification is not coming from effects of high curvature, at least not in a way that anyone understands. This is the firewall/fuzzball/nonlocality/bounce scenario. They are all radical because they need to modify Hawking's computation by an O(1) amount, even though his computation appears trustworthy at face value. Nothing I am saying here is controversial.

63. **unitarity**
April 12, 2017

Dear Reader,

I mostly agree with you, up to some details that are important. Hawking flux does not have to be significantly modified. So in a way his result is robust. However, the density matrix is modified by an O(1) amount. Any local modification (say by adding the interaction terms between two emitted quanta) is small, but the integrated modification is of the order O(1), since every emitted particle is eventually entangled with any other emitted particle.

Assumption about the high curvature region is implicit. In the standard picture with the singularity, when an entangled pair is created at the horizon, a member than fell in disappears from the picture. You can't use it anymore. That is why you get the exactly thermal outgoing state (because you traced over the part of the state). But if the ingoing modes are still there, even if they are classically disconnected from the outside region, they still contribute to the emission of new Hawking quanta. After all, everyone agrees that the Hawking pair is entangled across the horizon. If the near horizon region is just Rindler, then nearby particles feel each other even across the horizon. So new Hawking quanta must "feel" what is inside the horizon, unless the black hole is an empty space with the singularity at the center.

64. **Bernardo**
April 12, 2017

X,
In some areas (such as number theory), it is enough to make decent progress like the resolution of a new special case to be published in the Annals or other top journals. In other areas, your paper better solve a major open problem to be even sent to the referees. In some areas (dynamic systems for example), a large influential name can make publishing in the top journals a completely normal state of affairs. All life is social. The good news is that none of this matters and there will always be hungry good young people pushing the envelope.

65. **Question**
April 13, 2017

Reader: "More seriously perhaps, it seems impossible to make this work for a black hole formed in AdS. Putting aside anything to do with AdS/CFT, AdS acts like a finite sized box, so a state of radiation of total energy M_Pl has a small maximum entropy. In this case there is no way for a Planckian remnant to decay into a gas of (arbitrarily) high entropy quanta whose state would purify that of the Hawking radiation emitted earlier. "

A large black hole would not evaporate away (to remnant or not) in AdS, so is there a real information paradox for large black holes in AdS? (I am not talking about firewall like arguments about smoothness of horizon, which are related, but do not concern remnants.)

If instead you are talking about a small black hole, it has an upper bound on its mass (and therefore entropy) precisely so that its can decay to radiation while increasing entropy, no? So in principle the remnant scenario could work?

I am no fan of remnants, but just trying to see where exactly the loopholes are. Thanks.

66. **reader**
April 13, 2017

Question,

A large black hole in AdS does not evaporate because the Hawking radiation reflects off the boundary back into the black hole. But one can change the boundary conditions to allow energy to flow in and out of AdS. This corresponds to coupling to an auxiliary system that collects the Hawking radiation. So one can turn on this coupling, collect the radiation until the black hole becomes small, and then turn the coupling off again. Details can be found in section 4 of arXiv:1304.6483.

67. **Question**
April 14, 2017

reader,

But wouldn't that violate the premise that you wanted, which if I understand correctly, was that there is only limited phase space available for the radiation in the box and therefore limited entropy? Isn't the system that you couple the boundary theory to, a proxy for "the region outside the box"?

In p. 20 of the paper you mentioned, they seem to have another (distinct?) argument. They keep the black hole large by pumping in energy, but the Hawking radiation couples to the auxiliary theory and eventually increases its entanglement unboundedly, which they argue is impossible. To me this sounds like enlarging the box and finding that the new box also has a finite (even if bigger) phase space available. But in any event how this is related to remnants I fail to see – the black hole stays large throughout their thought experiment.

Maybe I am missing something basic.

68. **Miki Weiss**
April 17, 2017

In the same mentioned blogpost of Dr. Hossenfelder, she writes in a response to gilkalai: “The so-called firewall problem, which isn’t a problem but just a mathematical mistake”, so this is yet another cynical description of the current situation in fundamental theoretical physics (In an older blog she explained why she considers this “Problem” to be a mistake-http://backreaction.blogspot.co.il/2015/10/black-holes-and-academic-walls.html)
Could you comment on that?

69. **Peter Woit**
April 17, 2017

Miki Weiss,
I have even less of an opinion on the “firewall problem” than on the black hole information paradox itself. If you’re interested in that, and on Sabine’s views about it, you should discuss it with her at her blog.

Quick Links

April 16, 2017
Categories: Uncategorized

A few quick items:

- I was very sorry to hear recently of the death of David Goss (obituary here), a mathematician specialist in function fields who was at Ohio State. David had a side interest in physics and was a frequent e-mail correspondent. From what I recall I first heard from him in 2004 soon after the blog started, with my first reaction when I saw the subject and From line that of wondering why David Gross wanted to discuss that particular article about physics with me.

  Over the years he often sent me links to things I hadn't heard about, with always sensible comments about them and other topics. I had the pleasure of meeting him a couple years ago, when he came to Columbia to drop off his son, who is now a student here. My condolences to his family and friends.

- The AMS has a wonderful relatively new repository of mostly expository documents called Open Math Notes. The quality of these seems to uniformly be high, and this is a great new service to the community. I hope it will grow and thrive with more contributions.
- Peter Scholze has now finished his series of talks at the IHES about his ongoing work on local Langlands, the talks are available here.
- Jean-Francois Dars and Ann Papillault have a web-site called Histoire Courtes, with short pieces in French, many of which are about math and physics research.
- The LHC is starting to come to life again after a long technical stop. Machine checkout next week, recommissioning with beam during May, physics starts again in June.
- There's a new book out with string theory predictions from Gordon Kane, called String Theory and the Real World. Kane has been writing popular pieces about string theory predictions for at least 20 years, with a 1997 piece in Physics Today telling us that string theory was "supertestable", with a gluino at 200-300 GeV. Over the years, his gluino mass predictions have moved up many times, as the older predictions get falsified. I don't have a copy of the new book, but at Google Books you can read some of it. From the pages available there I see that

  > the compactified M-theory example we will examine below predicts that gluinos will have masses of about 1.5 TeV…
  > The bottom line is that with about 40 inverse fb of data the limits on gluinos are just at the lower range of expected masses at the end of 2016.

  Right around the time the book was published, results released at Moriond (see here) claimed exclusion of gluinos up to about 2 TeV. Assumptions may be somewhat different than Kane's, but I suspect his 1.5 TeV gluino is now excluded.

Comments

1. **new**
   April 17, 2017

   since LHC latest results push gluino masses above 2tev above Gordan Kane's limit of 1.5 tev, Is there an upper limit Gordan Kane can push gluino masses ?

2. **Rob**
   April 17, 2017

   New
   The Planck scale.

3. **my Milkshake brings all the Boys to the Yard**
   April 17, 2017

   Kane must be aware of this kind of criticism. What does he say in response?

4. **Jeff M**
   April 17, 2017

   @Rob

   OK, that would be funny if it weren't true.

   Peter, thanks for the AMS link, looks great.

5. **SteveB**
   April 17, 2017

   Does someone have information on why the LHC technical shutdown was so long? 4 (or was it 5) months? Also, I occasionally used to look at the Morning Briefings on the Indico site. I could get there until last week (there was no new information for 2017), but now it brings up a CERN authentication screen — keeping me, the public, out. Anyone know why they changed their policy — or is there a new site? Here is the old one (that I found on this blog some years ago):
   https://indico.cern.ch/category/6386/
   Thankfully, the Vistars site still works:
   https://op-webtools.web.cern.ch/vistar/vistars.php?usr=LHC3

6. **Peter Woit**
   April 17, 2017

   Re Kane,

   I should have made clear that his viewpoint is a minority one among string theorists, most of whom at this point acknowledge that in its current state you can't get testable predictions out of string theory. Kane deals with this basically by saying these string theorists are ignorant, see for example page 6 of his Munich presentation, available here

   http://sites.lsa.umich.edu/gordonkane/wp-content/uploads/sites/117/2014/07/munich-final.pdf

   As far as I know he's never addressed the question of why, given so many previous failed predictions, anyone should take seriously his latest ones (few people do).

Steve B,

This was scheduled a long time ago to be a longer shutdown, an “Extended” year end technical stop. My understanding is that the main reason for this is the time needed for installation by CMS of an upgraded pixel detector, but presumably there are many other sorts of maintenance that could take advantage of the longer time period.

Once recommissioning and daily meetings start, perhaps information from these will again be available publicly. If not, LHC fans could politely ask, explaining that they appreciate getting direct news of the health of the star.

7. **MathPhys**
April 17, 2017

” Kane deals with this basically by saying these string theorists are ignorant, see for example page 6 of his Munich presentation”.

I recommend page 7 and page 8.

8. **John McAllison**
April 18, 2017

SteveB,

As Peter has pointed out, the extended year end technical stop (EYETS) was planned before 2017. This document is from Jan 2015:
https://indico.cern.ch/event/387137/contributions/1818419/subcontributions/157604/attachments/773229/1060436/YETS1516.pdf

This link gives a brief outline of what’s been going on during the technical stop:
https://home.cern/cern-people/updates/2017/03/eyets-report-2017-busy-year-ahead-accelerators

9. **Shantanu**
April 18, 2017

Peter and others:
There is supposed to be new B-physics results announced today

https://indico.cern.ch/event/580620/

10. **david_n**
April 18, 2017

Thanks for the AMS information; looks very helpful.

11. **modda**
April 18, 2017

Yes, you were right to be surprised when you thought David Gross wanted to discuss with you.

12. **Peter Woit**
April 18, 2017

Shantanu,

Tommaso convincingly makes the case for skepticism here

http://www.science20.com/tommaso_dorigo/lhcb_measures_unity_finds_06-225038

13. **Doug McDonald**
April 18, 2017

As to the morning meetings error note, this has happened before. In at least one case, it was at a time like this and they were doing some changes to the way the computer systems were do it. I would not worry for at least a few days.

14. **Tim**
April 18, 2017

Clearly, the masses of supersymmetric particles are not constant, but increase with time, as predicted by string theory and the multiverse.

15. **physicsguy**
April 18, 2017

Peter,

note that Tommaso is not an expert on flavour physics, and in fact a comment by an expert below his post very convincingly argues why what Tommaso writes does not make much sense.
Still I would not bet with Tommaso because I think the odds that it is new physics are nevertheless below 50% in my opinion, maybe 20% or so.

16. **neil**
April 19, 2017

The lepton universality tests by LHCb are quite interesting. After the 750 GeV circus, no one wants to hype a 2.5 sigma signal, but there appears to be tantalizing hints from a number of sources. I am looking forward to results from new data later this year on potential BSM physics.

17. **Sidi M.**
April 20, 2017

Hi everyone,
Thank you Peter for the Histoires courtes link, amazing audio stuff, we’ll sleep less stupid.

18. **Milkshake**
April 20, 2017

They've had 3.3 sigma signals that turned out to be nothing before.

I think Kane is wasting everyone's time. (He's always talking about his latest predictions at conferences.) Someone should have a polite discussion with him.

19. **Jim**
April 23, 2017

Hi Milkshake,

I didn't follow LHCb so closely. Can you remind me which 3.3 sigma signal turned out to be nothing?

20. **neil**
April 23, 2017

Jim

In January, LHCb reported measured violation of CP symmetry in baryon decays with significance at 3.3 standard deviations. I have not read that this "turned out to be nothing", however.

The LHCb beauty experiment results can be found here.

http://lhcb-public.web.cern.ch/lhcb-public/

21. **ronab**
April 24, 2017

@Milkshake,

"I think Kane is wasting everyone's time. (He's always talking about his latest predictions at conferences.) Someone should have a polite discussion with him."

This seems a common sentiment. But then how does he keep getting to talk at conferences? Why don't organizers just stop inviting him?

22. **Peter Woit**
April 24, 2017

ronab,

I suspect he is talking at fewer conferences these days. In any case, there's a long tradition in most fields of academia of having senior figures continue to give talks at conferences past the point anyone is paying attention to them.

Two Pet Peeves

April 20, 2017
Categories: Favorite Old Posts, Uncategorized

I was reminded of two of my pet peeves while taking a look at the appendix A of this paper. As a public service to physicists I thought I'd go on about them here, and provide some advice to the possibly confused (and use some LaTeX for a change).

Don't use the same notation for a Lie group and a Lie algebra

I noticed that Zee does this in his "Group Theory in a Nutshell for Physicists", but thought it was unusual. It seems other physicists do this too (same problem with Ramond's "Group Theory: a physicist's survey", the next book I checked). The argument seems to be that this won't confuse people, but, personally, I remember being very confused about this when I first started studying the subject, in a course with Howard Georgi. Taking a look at Georgi's book for that course (first edition) I see that what he does is basically only talk about Lie algebras. So, the fact that I was confused about Lie groups vs. Lie algebras wasn't really his fault, since he was not talking about the groups.

The general theory of Lie groups and Lie algebras is rather complicated, but (besides the trivial cases of translation and U(1)=SO(2) groups) many physicists only need to know about two Lie groups and one Lie algebra, and to keep straight the following facts about them. The groups are

- SU(2): the group of two by two unitary matrices with determinant one. These can be written in the form
  $$
  \begin{pmatrix}
  \alpha & \beta\\
  -\overline{\beta}& \overline{\alpha}
  \end{pmatrix}
  $$
  where \(\alpha\) and \(\beta\) are complex numbers satisfying \(|\alpha|^2+|\beta|^2=1\), and thus parametrizing the three-sphere: unit vectors in four real dimensional space.
- SO(3): the group of three by three orthogonal matrices with determinant one. There's no point in trying to remember some parametrization of these. Better to remember that a rotation by a counter-clockwise angle θ in the plane is given by
  $$\begin{pmatrix}
  \cos\theta & -\sin\theta\\
  \sin\theta & \cos\theta
  \end{pmatrix}$$
  and then produce your rotations in three dimensions as a product of rotations about coordinate axes, which are easy to write down. For instance a rotation about the 1-axis will be given by
  $$\begin{pmatrix}
  1&0&0\\
  0&\cos\theta & -\sin\theta\\
  0&\sin\theta & \cos\theta
  \end{pmatrix}$$

The relation between these two groups is subtle. Every element of SO(3) corresponds to two elements of SU(2). As a space, SO(3) is the three-sphere with opposite points identified. Given elements of SO(3), there is no continuous way to choose one of the corresponding elements of SU(2). Given an element of SU(2), there is an unenlightening impossible to remember formula for the corresponding element of SO(3) in terms of \(\alpha\) and \(\beta\). To really understand what's going on, you need to do something like the following: identify points in \(\mathbf R^3\) with traceless two by two self-adjoint matrices by
$$(x_1,x_2,x_3)\leftrightarrow x_1\sigma_1 +x_2\sigma_2+x_3\sigma_3=\begin{pmatrix} x_3&x_1-ix_2\\x_1+ix_2&-x_3\end{pmatrix}$$
Then the SO(3) rotation corresponding to an element of SU(2) is given by
$$\begin{pmatrix} x_3&x_1-ix_2\\x_1+ix_2&-x_3\end{pmatrix}\rightarrow \begin{pmatrix}
\alpha & \beta\\
-\overline{\beta}& \overline{\alpha}
\end{pmatrix}\begin{pmatrix} x_3&x_1-ix_2\\x_1+ix_2&-x_3\end{pmatrix} \begin{pmatrix}
\alpha & \beta\\
-\overline{\beta}& \overline{\alpha}
\end{pmatrix}^{-1}$$

Since most of the time you only care about two Lie groups, you mostly only need to think about two possible Lie algebras, and luckily they are actually the same, both isomorphic to something you know well: \(\mathbf R^3\) with the cross product. In more detail:

- su(2) or \(\mathfrak{su}(2)\): Please don't use the same notation as for the Lie group SU(2). These are traceless skew-adjoint (\(M=-M^\dagger\)) two by two complex matrices, identified with \(\mathbf R^3\) as above except for a factor of \(-\frac{i}{2}\).
  $$(x_1,x_2,x_3)\leftrightarrow -\frac{i}{2}\begin{pmatrix} x_3&x_1-ix_2\\x_1+ix_2&-x_3\end{pmatrix}$$
  Under this identification, the cross-product corresponds to the commutator of matrices.

  You get elements of the group SU(2) by exponentiating elements of its Lie algebra.

- so(3) or \(\mathfrak{so}(3)\): Please don't use the same notation as for the Lie group SO(3). These are antisymmetric three by three real matrices, identified with \(\mathbf R^3\) by

  $$(x_1,x_2,x_3)\leftrightarrow \begin{pmatrix}
  0&-x_3&x_2\\
  x_3&0 & -x_1\\
  -x_2&x_1&0
  \end{pmatrix}$$
  Under this identification, the cross-product corresponds to the commutator of matrices.

  You get elements of the group SO(3) by exponentiating elements of its Lie algebra.

If you stick to non-relativistic velocities in your physics, this is all you'll need most of the time. If you work with relativistic velocities, you'll need two more groups (either of which you can call the Lorentz group) and one more Lie algebra, these are:

- \(SL(2,\mathbf C)\): This is the group of complex two by two matrices with determinant one, i.e. complex matrices

$$\begin{pmatrix}
\alpha & \beta\\
\gamma& \delta
\end{pmatrix}$$
satisfying \(\alpha\delta-\beta\gamma=1\). That's one complex condition on four complex numbers, so this is a space of 6 real dimensions. Best to not try and visualize this; besides being six-dimensional, unlike SU(2) it goes off to infinity in many directions.

- SO(3,1): This is the group of real four by four matrices M of determinant one such that
$$M^T\begin{pmatrix}-1&0&0&0\\
0&1&0&0\\
0&0&1&0\\
0&0&0&1\end{pmatrix}M=\begin{pmatrix}-1&0&0&0\\
0&1&0&0\\
0&0&1&0\\
0&0&0&1\end{pmatrix}$$
This just means they are linear transformations of \(\mathbf R^4\) preserving the Lorentz inner product.

  Correction: *a correspondent reminds me that for the next part to be true this definition needs to be supplemented by an extra condition, since as stated SO(3,1) has two components. One version of the extra condition is to take the connected component of the identity, another is to take the component that preserves time orientation. Many use a different notation for this component to make this explicit, I'll define SO(3,1) as the connected component.*

The relation between SO(3,1) and \(SL(2,\mathbf C)\) is much the same as the relation between SO(3) and SU(2). Each element of SO(3,1) corresponds to two elements of \(SL(2,\mathbf C)\). To find the SO(3,1) group element corresponding to an \(SL(2,\mathbf C)\) group element, proceed as above, removing the "traceless" condition, so identifying \(\mathbf R^4\) with self-adjoint two by two matrices as follows
$$(x_0,x_1,x_2,x_3)\leftrightarrow\begin{pmatrix} x_0+x_3&x_1-ix_2\\x_1+ix_2&x_0-x_3\end{pmatrix}$$
The SO(3,1) action on \(\mathbf R^4\) corresponding to an element of \(SL(2,\mathbf C)\) is given by
$$\begin{pmatrix} x_0+x_3&x_1-ix_2\\x_1+ix_2&x_0-x_3\end{pmatrix}\rightarrow \begin{pmatrix}
\alpha & \beta\\
\gamma & \delta
\end{pmatrix}\begin{pmatrix} x_0+x_3&x_1-ix_2\\x_1+ix_2&x_0-x_3\end{pmatrix} \begin{pmatrix}
\alpha & \beta\\
\gamma& \delta
\end{pmatrix}^{-1}$$

As in the three-dimensional case, the Lie algebras of these two Lie groups are isomorphic. The Lie algebra of \(SL(2,\mathbf C)\) is easiest to understand (please don't use the same notation as for the Lie group, instead consider \(sl(2,\mathbf C\)) or \(\mathfrak{sl}(2,\mathbf C)\)), it is all complex traceless two by two matrices, i.e. matrices of the form
$$\begin{pmatrix}a&b\\
c&-a\end{pmatrix}$$

For the isomorphism with the Lie algebra of SO(3,1), go on to pet peeve number two and then consult a relativistic QFT book to find some form of the details.

Keep track of the difference between a Lie algebra and its complexification

This is a much subtler pet peeve than pet peeve number one. It really only comes up in one place, when physicists discuss the Lie algebra of the Lorentz group. They typically put basis elements \(J_j\) (infinitesimal rotations) and \(K_j\) (infinitesimal boosts) together by taking complex linear combinations
$$A_j=J_j+iK_j,\ \ B_j=J_j-iK_j$$
and then note that the commutation relations of the Lie algebra simplify into commutation relations for the \(A_j\) that look like the \(\mathfrak{su}(2)\) commutation relations and the same ones for the \(B_j\). They then announce that
$$SO(3,1)=SU(2) \times SU(2)$$
Besides my pet peeve number one, even if you interpret this as a statement about Lie algebras, it's not true at all. The problem is that the Lie algebras under discussion are real Lie algebras, you're just supposed to be taking real linear combinations of their elements. When you wrote down the equations for \(A_j\) and \(B_j\), you "complexified", getting elements not of \(\mathfrak{so}(3,1)\), but what a mathematician would call the complexification \(\mathfrak{so}(3,1)\otimes \mathbf C\). Really what has been shown is that
$$ \mathfrak{so}(3,1)\otimes \mathbf C = \mathfrak{sl}(2,\mathbf C) + \mathfrak{sl}(2,\mathbf C)$$

It turns out that when you complexify the Lie algebra of an orthogonal group, you get the same thing no matter what signature you start with, i.e.
$$ \mathfrak{so}(3,1)\otimes \mathbf C =\mathfrak{so}(4)\otimes \mathbf C =\mathfrak{so}(2,2)\otimes \mathbf C$$
all of which are two copies of \(\mathfrak{sl}(2,\mathbf C)\). The Lie algebras you care about are what mathematicians call different "real forms" of this and they are different for different signature. What is really true is
$$\mathfrak{so}(3,1)=\mathfrak{sl}(2,\mathbf C)$$
$$\mathfrak{so}(4)=\mathfrak {su}(2) + \mathfrak {su}(2)$$
$$\mathfrak{so}(2,2)=\mathfrak{sl}(2,R) +\mathfrak{sl}(2,R)$$

For details of all this, see my book.

Comments

1. **Maxis**
   April 21, 2017

   Is it just me, or LaTeX isn't rendering? You forgot to include the word "latex" after the dollar sign.

2. **---**
   April 21, 2017

   Re the signs and typographic errors: in the definition of SU(2) you wat $\alpha\bar{\alpha} + \beta\bar{\beta} = 1$; so that the determinant is 1. Then you also actually get the 3-sphere.

3. **Peter Woit**
   April 21, 2017

—,
Thanks, fixed.

Maxis,
I'm doing this using MathJax, works for me. If people are having trouble with this let me know.

4. **Timothy P Keller**
   April 21, 2017

   I am trying to write up some notes for a course on Lie theory and applications I would like to teach when I retire (but probably never will). Your notes are some of my best references.
   It's great that you posted this comment, and it's a wonder it's really necessary. Getting the notation right using Latex is so easy these days ….

5. **vmarko**
   April 21, 2017

   Peter,

   LaTeX isn't rendering for me either.

   Note that MathJax generally does render in my browser (if I visit my own website, or arXiv, or various other places), and everything works fine — except for your website, which just displays LaTeX source instead.

   HTH,
   Marko

6. **Jeff M**
   April 21, 2017

   Peter

   First, the LaTeX is displaying fine for me, Safari 10.1. Second, physicists really can't use different notation for the group and the algebra? In math, anything in Fraktur is the algebra. I assume this is still true, it certainly was when I took Lie Algebras in grad school in '87.

7. **Fred P**
   April 21, 2017

   My broswers (Firefox, Edge, and Chrome) does not render the Latex because it views the Latex rendering as insecure. On Chrome, I could easily turn this off.

   Looking at your page source, I see at least part of the problem:

   http://www.math.columbia.edu/department/mathjax/MathJax.js?config=TeX-AMS-MML_HTMLorMML&ver=4.7.3

   is not https, which is how I'm seeing most of this page. Note that

   https://www.math.columbia.edu/department/mathjax/MathJax.js?config=TeX-AMS-MML_HTMLorMML&ver=4.7.3

   seems like it works, but my https everywhere extension does not automatically translate that link to https – which is why the rendering wasn't working on my browsers.

8. **Peter Woit**
   April 21, 2017

   Fred P,
   I see the potential problem, changed the link to https.

   All, please let me know of any continuing problems with the Latex rendering.

9. **vmarko**
   April 21, 2017

   Yes, that fixed it, now it renders correctly for me too!

   🙂
   Marko

10. **vmarko**
    April 21, 2017

    Ok, now that I see the equations rendered correctly, shouldn't the sums be "circled", \(\oplus\), instead of an ordinary plus, \(+\), when writing sums of algebras at the end?

    I don't want to sound like a nitpick, but an algebra is also a vector space, and its addition of vectors (usually denoted with an ordinary plus sign) should be distinguished from the notion of the direct sum of two algebras. Especially if the two algebras are actually two copies of the same algebra.

    HTH, 🙂
    Marko

11. **Peter Woit**
    April 21, 2017

    Marko,
    You're probably right, but remember, here I'm trying to convince physicists that the distinctions mathematicians make are important ones….

12. **Narad**
    April 21, 2017

> Getting the notation right using Latex is so easy these days ….

Aside from remembering to type {-}\sin instead of -\sin when it's standing alone, among other things. 😉

13. **Al**
April 22, 2017

    Peter- Maybe it's ok to mention the March For Science tomorrow (Saturday):
    it's supposed to be nonpartisan and a celebration of science…
    of course barely in the background are worries about climate change, budget cuts,
    the destruction of the EPA, NIH…
    Here's TYT:
    https://www.youtube.com/watch?v=pCGFqbRC6do
    There are supposed to be marches in 500 cities worldwide.
    Information here:
    https://www.marchforscience.com/

14. **TS**
April 22, 2017

    I noticed a very minor pet peeve of mine in the book. It is really minor, so please feel free to not fill up the space under your post by publishing this comment: right after introducing "the Schrödinger equation" you call it "Schrödinger's equation." How could I not search the text after spotting an inconsistency! The text calls it "the Schrödinger equation" throughout, except for the aforementioned place, Fig. 19.1 and page 558.

    I also noted that on p. 466 you dropped the umlaut in naming the Pauli-Schrödinger equation. I actually only found this latter instance because your old-school LaTeX setup doesn't actually output the letter "ö," but instead takes \"o very literally. In other words, a search for "Schrödinger" in the pdf turns up empty, and I had to search for "Schr" instead. Thankfully, you don't cite Peskin & Schroeder all too often.

    Congrats on the book, and thanks for the explanation of the mistake in the decomposition of the Lorentz group that you gave here. That was a magic bit of common textbook lore that had puzzled me for the longest time! Too bad that I no longer do physics, and the only group that I encounter regularly these days is the Quaternion group.

15. **Art**
April 23, 2017

    In the two equations identifying R4 with 2×2 self-adjoint matrices, the signs of the x2 entries are opposite those of the R3 case (and of your book).

16. **To ask a silly question ...**
April 23, 2017

    Why do mathematicians use Fraktur for the Lie algebra so(3) when lowercase works fine?

    My suspicion is that they do it to show off their superior knowledge of fonts. Of course, this may confuse physicists into using the same notation for the Lie algebra and the Lie group, because they may not know how to use Fraktur in LaTeX and may be too lazy to bother looking it up.

17. **BCnrd**
April 23, 2017

    Dear "To ask a silly question…": Your guess for the reason that fraktur fonts are used to denote Lie algebras is incorrect. The reason is the same as why fraktur fonts are commonly used to denote ideals in commutative algebra: many concepts in abstract algebra and Lie theory were initially developed by those who worked in Germany or very closely with the German school of mathematics in the late 19th and early 20th century, among whom the fraktur font was quite common to use (unsurprisingly).

    Lie spent some early pivotal years of his professional career in Berlin, where he struck up a friendship with the German mathematician Klein that was to become very influential on the development of Lie's own work (prior to the unfortunate demise of their friendship over some priority disputes). Other early fundamental work in the subject of Lie algebras was done by Killing (also German), to say nothing of the early fundamental work in representation theory by Frobenius, Schur, and Weyl. You can read about all of this and much more in Thomas Hawkins' great book "Emergence of the Theory of Lie groups" (as well as a bit in the Historical Notes at the end of Chapters 1-3 of Bourbaki's "Lie groups and Lie algebras").

    It was due to the aftermath of World War II that German became less common as a language for math papers and the fraktur font consequently less widely seen. But the tradition was already firmly established in Lie theory and various parts of ring theory, a tradition that has remained to this day; this was widespread long before modern type-setting.

    Moreover, due to the extensive need for notation in mathematical proofs, it is a tremendous convenience that one can use g to denote an element of a Lie group G while considering proofs that involve both the Lie group and its Lie algebra $\mathfrak{g}$ at the same time while not thereby writing "g" to denote two very different things in the same discussion. The presence of many font options in LaTeX is due to the widespread notational needs of mathematicians, and not the other way around. In math papers and books, notational choices and traditions are generally made to promote clarity of discussion, not to show off.

18. **Peter Woit**
April 23, 2017

    To ask a silly question,

    As BCnrd comments, mathematicians often have a need to clearly notationally distinguish unambiguously different kinds of mathematical objects, so it's not surprising that they use more fonts and yes, are more likely to know the relevant TeX off the top of their heads.

    I understand why physicists are reluctant to use fraktur fonts, its use is culturally alien. What I can't understand is why they won't use upper vs. lower case. Why not write the Lie algebra of SU(2) as su(2)?

19. **Art**
April 24, 2017

    In your book, section 40.2, p. 448, the complexified so(3,1) "splits into a product of two sub-Lie algebras", and the equation is written with a multiplication sign. I think it should be a direct sum.

20. **Peter Woit**
April 24, 2017

Art,
Thanks. Fixed sign, and yes, for Lie algebras should be sum not product.

21. **Art**
April 24, 2017

For completeness, the same equation shows up at the end of section 40.4.

22. **Geoffrey Dixon**
April 25, 2017

SU(2) and SO(3) simplified with quaternions (H). Let X be in H, and U a unit element in H. Then
X –> UX is an SU(2) action,
X –> UXU* is SO(3).
In the former case all 4 components of X are mixed,
and in the latter only the 3 imaginary components
(U* is quaternion conjugation, and because U is
a unit quaternion, it is also the inverse of U).

There must exist some imaginary element v in H
(no real part) such that U = exp(v). The Lie algebra
of SU(2) and SO(3) is the set of such elements v.

The study of the Lie groups and algebras important
to theoretical physics is greatly simplified by using
division algebras. (Am I biased in this matter?
Hmm, let me check …)

PS: How does one exploit Latex in these comments?

23. **Peter Woit**
April 25, 2017

Geoffrey Dixon,

I do think that using quaternions and Sp(1)=Spin(3) is the best way to understand the relationship between Spin(3) and SO(3), and that's the way I do it in my book. However, this post is aimed at keeping math apparatus to a minimum for an everyday physicist, so I avoid quaternions and use two by two complex matrices instead.

You can use latex in comments, using MathJax. I should add this info to the "leave a reply" text, once I figure out how to escape the delimiters correctly. One way to convey this info is to say I'm using the default delimiters, see
http://docs.mathjax.org/en/latest/tex.html#tex-and-latex-math-delimiters

April 26, 2017

The (astro)physicists seem to be incorrigible… they write in https://arxiv.org/pdf/1704.05067.pdf , p.42:

"11)We acknowledge the pain of our more mathematically inclined readership at our deliberate, yet well-intentioned ambiguation of a group and its matrix representation. Sorry!"

25. **Peter Woit**
April 27, 2017

TG3D,
When people are having trouble figuring out the difference between a Lie group and a Lie algebra, not a good idea to tell them about representations…

26. **Steve**
April 28, 2017

Thanks, Peter, for stressing that we should always keep Lie groups and Lie algebras separate!

A perspective that I've always found clarifying is that a Lie algebra can be taken to be the tangent space to the Lie group at the identity. Of course for that to make sense you have to remember that Lie groups are manifolds that have a tangent space. But this is worth knowing because it makes obvious and intuitive some of the Lie group isomorphisms you talk about: since the group SU(2) is the double cover of the group SO(3), they are locally isomorphic and therefore have isomorphic tangent spaces. Viola! That's just another way of saying that su(2) is isomorphic to so(3). You can even give a geometrical explanation of the exponential map as a map from the tangent space (Lie algebra) to the manifold (Lie group) if you feel ambitious.

Sure, that needs more mathematical machinery than you wrote about, but I find that machinery very helpful for explicating the difference between Lie groups and Lie algebras. I've even used this to explain the difference to non-math folk using pictures!

27. **Pedant**
May 6, 2017

People who can't distinguish between a Lie group and a Lie algebra have no business calling themselves physicists or being employed as researchers. Sticking with 19th century confusions is just unprofessional and uneducated, manifesting a lack of curiosity and an intellectual laziness that shouldn't be allowed in professional contexts.

28. **Peter Woit**
May 6, 2017

pedant,
I think you're being unfair to the 19th century…

Why String Theory is Still Not Even Wrong

April 27, 2017
Categories: Fake Physics, Multiverse Mania

John Horgan recently sent me some questions, and has put them and my answers up at his Scientific American site, under the title [Why String Theory is Still Not Even Wrong](). My thanks to him for the questions and for the opportunity to summarize my take on various issues.

Comments

1. **Thomas Lee Elifritz**
   April 27, 2017

   Well done. Although I can find no mention of it in a recent arxiv article on the CMB cold spot, it appears the multiverse has somehow crept into the journalistic discussion of it … again,

2. **Peter Woit**
   April 27, 2017

   Thomas Lee Elfritz,
   Hadn't noticed that, but it's textbook "Fake Physics":

   The paper
   https://arxiv.org/abs/1704.03814
   would normally get zero public attention, and includes nothing that could seriously be taken as evidence for other universes. The authors put out a press release

   https://www.sciencedaily.com/releases/2017/04/170425124822.htm

   in which they highlight the multiverse angle:
   'Perhaps the most exciting of these is that the Cold Spot was caused by a collision between our universe and another bubble universe. If further, more detailed, analysis of CMB data proves this to be the case then the Cold Spot might be taken as the first evidence for the multiverse — and billions of other universes may exist like our own."

   Press stories then come out like this one

   http://www.dailygalaxy.com/my_weblog/2017/04/cold-spot-billions-of-light-years-across-was-caused-by-a-collision-with-another-universe-.html

   With a blaring headline:
   "'Cold Spot' Anomaly Billions of Light Years Across –"Caused By a Collision With Another Universe" "

   In deciding where to lay blame for this kind of nonsense and the damage it does to the public understanding of science, I think the bulk of it should go to the scientists involved. Look, if you put out a press release highlighting this, say things like this to reporters, you know very well what the press stories are going to look like.

3. **Thomas Lee Elifritz**
   April 27, 2017

   That sounds about right. I didn't research it that deeply. I usually just read the paper itself. But what I do is find those papers occasionally through the press, as I don't have a lot of time to pursue every lead on every search engine using every combination of keywords. It's nice to see that nowadays they at least provide a link to the papers.

   When I run into a whole slew of journalistic failures like that though, that's usually a sign that something went awry at a deeper more fundamental level and the press is just parroting that problem. Therein lies the problem, as discussed widely now here and elsewhere. What can be done about that, I don't know, except to just keep slogging.

4. **G Phillip**
   April 27, 2017

   Peter, just reading your book. I was waiting to see if all this string "theory" stuff worked out. Since it didn't, and now with the failure to find SUSY it looks like it never will, I'm digging deep into concepts I have heard of but never really taken the time to study. What a great book! I love all the HEP history. In truth I've spent as much or more time studying the concepts you mention like renormalizations and group theory on the side as I have reading, but I'm now 1/3rd through and I can say I'm impressed. My goal is to complete it with a decent understanding before your next book comes out. I found it very honorable of you to acknowledge the contributions of Lubos Motl to the book. In my opinion, everyone in the field should be so professional. I also found it enlightening that many theories along the way that were logical, self-consistent, and even elegant were disproved beyond any doubt by experimental evidence. It's a lesson we must never forget. Best.

5. **Henry Warwick**
   April 28, 2017

   I liked your interview with John Horgan. I would add that there is another critique of Bostrum et al and the Matrix theory, and that is one of infinite regress. If we are in a simulation, then there is no reason to think that the creatures controlling us in our simulation are not themselves simulations, etc. ad infinitum. Obviously, there has to be a stopping point – there has to be someone who is not a simulation running the simulation for the simulation to exist in the first place. However, given the formulation as one of computability in the Matrix theory, where any entity who can simulate can also be simulated, there is no logical reason why it can't be ad infinitum – it's turtles all the way up ! Therefore: the Matrix theory is impossible, and thinking about it is a colossal waste of time. Cheers!

6. **Magnema**
   April 28, 2017

   @Henry Warwick:
   Impossible? I think that's an implausibly strong claim. The argument does not show that we are in a simulation (in which case, yes, if that were the case with 100% certainty then we would have a problem). Rather, it shows that we should believe we are in a simulation. You could come to the conclusion that any unsimulated world will come to the wrong conclusion in such a case; however, since the premise is that most worlds are probably simulated, that is, in a sense, an "acceptable risk" to those who accept the argument – because, after all, according to their premise, they are probably right, even if uncertain.

Now, I would agree that “thinking about it is [mostly] a colossal waste of time.” However, I don’t think the philosophical argument could be refuted so easily – and I am, very generally, wary of any claim leading to “impossibility” (or “necessity”) a priori, given how often those claims have been proven wrong. (Implausibility or near-certain truth a priori, including the simulation argument, are more tolerable, if not perfect.) Non-productivity of discussion is entirely within the realm of reasonable a priori debate, though.

7. **Peter Woit**
April 28, 2017

Henry Warwick, Magnema,
Since we seem to agree thinking about the simulation argument is a waste of time, let’s not further discuss it here, OK?

8. **Tim May**
April 28, 2017

When I was in high school, there were some speculative reports in places like “Science News” and even in some issues of “Scientific American” about things like tachyons. Even by 1970 some exciting stories about black holes and wormholes.

Black holes were sort of confirmed when I was in college (Cygnus x-1) and are of course now mainstream.

There were later tales of possible magnetic monopoles. Interesting stuff.

But I never saw a “world view” based on these speculations of tachyons, wormholes, monopoles, etc. Hype was not bad at all in those days. A few speculative articles, even the famous Bryce DeWitt article/book on the “Many Worlds” interpretation of QM, but all within the basic realm of plausibility.

Not until “string theory,” going on nearly 40 years ago.

I thank some of the string theory skeptic sites, like this one, for putting a (perhaps slight) lid on the bubbling cauldron of hype.

–Tim May

9. **Justin**
April 28, 2017

I’m curious if HEP is healthier outside the US. Does anybody know if there is a better culture promoting independent thinking in Europe or does it suffer from the same problems we have here in the US?

10. **Jeff M**
April 28, 2017

Peter,

Enjoyed the piece with Horgan. The differences between physics and math are fascinating, I think fundamentally the issue is that in math you can show that something is correct, but in physics (and essentially everything else) you can only show that something is incorrect. Mathematics is the only discipline where “this is right” is a truly meaningful statement. I once argued with my father in law, who was an art professor, about which was harder to teach. He though art was, since you had no way to judge what was right. I said math was, since I had to figure out a way to get people to learn the right way to do things, I couldn’t let them do it any other way.

11. **new**
April 28, 2017

Has any string theorist like Edward Witten, Briane Greene Michio Kaku Gates et al, commented on the latest SUSY Moriond result? How does this impact string theory?

12. **Magnema**
April 28, 2017

@Peter Woit: Before I quit, I want to clarify that I meant “from the perspective of a scientist.” I think philosophers should consider it, because if it’s wrong, then why it’s wrong would be something interesting to study in that field. Like math, philosophy has different standards of argument and different paradigms for useful. OK, done talking about it now.

13. **Shantanu**
April 28, 2017

Peter, something else I would have mentioned. For many years string theorists claim to predict a dark matter candidate. Then recently Verlinde has argued that string theory dispenses with the need for dark matter. How can a theory predict two opposite hypothesis? String theorists should make up their mind about this.
(Same with principle of equivalence and I have heard similar opposing claims)

14. **Bernhard**
April 29, 2017

@Justin,

This is own take but from experience, I do not think HEP is healthier in Europe.
I can’t also not think of any fundamental differences in culture in regards to promoting independent thinking, not by a long shot. The US and Europe share, in this respect at least, the same culture and if you found yourself locked inside an US or and European institution, you would not be able to spot any differences, in my opinion. Also, the mechanisms which exist to stall independent thinking exist both in the US and Europe in the same way (like the way grant decisions are made, etc).

The US and Europe collaborate extremely closely in HEP, just look at the conferences, who attends it, who works where, etc. The geographical distance is not translated to any significant difference in scientific culture. And the rest of the world sill looks at their example for reference (including China and Japan), since historically most of the major advances came from one place or the other.

15. **Avattoir**
April 29, 2017

I’m interested in knowing Peter Woit’s view on the opening point in Jeff M’s comment:
“… math … can show … something is correct, … physics … only … that something is incorrect”.

On Jeff M's dw with his father in law, my impression is they somehow agreed to equate "harder" and "more uncertain". Surely it's not the case that teaching competence in a given field varies according to its participants' tolerance for bullshit.

16. **Tim May**
April 29, 2017

Peter, this is not directly related to this thread, but..

Tonight I saw the biopic "The Man Who Knew Infinity," about Ramanujan and Hardy (and Littlewood in a minor role). Well done. Probably not comprehensible to anyone who has not looked at infinite series and convergences.

One thing that struck me in the end credits was something along the lines of "His work is now helping us to understand black holes."

Say what? Surely he deserves even more credit for predicting the multiverse.

I looked into and found a quote from the ever-speculative (though fun to read) "New Scientist":

regarding some of Ramajun's work:

"Devised by Ken Ono of Emory University in Atlanta, Georgia, the formula concerns a type of function called a mock modular form (see main story). These functions are now used to compute the entropy of black holes. This property is linked to the startling prediction by Stephen Hawking that black holes emit radiation.

"If Ono has a really new way of characterising a mock modular form then surely it will have implications for our work," says Atish Dabholkar, who studies black holes at the French National Centre for Scientific Research in Paris. "Mock modular forms will appear more and more in physics as our understanding improves."

My thinking is that Ramanujan's work stands on its own. Co-opting him into the publicity brigade is akin to how Hardy is now being treated as a kind of father of secure credit card transactions. (And, yeah, I know about number theory and have worked in crypto since the 1980s.)

I don't dispute that some of the partition work may relate to entropy, etc. Just that claims about how Ramanujan has helped the world to understand black holes seems like journalistic hype. Probable intended for sex appeal, in the abstract sense.

17. **vmarko**
April 30, 2017

Tim May,

If you want to calculate the statistical entropy of an ordinary Schwarzschild black hole in the context of loop quantum gravity (by counting all possible ways the horizon area can be constructed from pieces which belong to the spectrum of the area operator of LQG), then you need to use one of the Ramanujan's formulas to evaluate the entropy.

It has to do with the math problem (from number theory) of counting all possible ways a large integer can be partitioned into summands, and Ramanujan was the first one to solve that problem.

HTH. 🙂
Marko

18. **Jesper**
April 30, 2017

@ Justin, Bernhard,

Although my experience with the US is limited I do think that there could be a slight difference between Europe and the US with respect to theoretical physics. I think that there is more diversity in Europe, where there are communities with a strong tilt towards mathematics, for instance algebraic QFT and those involved in noncommutative geometry. Once could also mention those working on asymptotic safety around Martin Reuter and Jan Ambjørns Dynamical Triangulations as examples – there are more. In my experience String theory is powerful in Europe, but not as powerful as it appears to be in the US. Perhaps others can confirm this.

19. **Mitchell Porter**
May 1, 2017

Tim May said

'I never saw a "world view" based on these speculations… Not until "string theory"'

String theory isn't a random speculation. It was discovered by Veneziano *before* the standard model, supersymmetry, grand unification…, in an attempt to describe hadrons. It turned out to contain fermions, gauge bosons, and gravitons, as well as being the natural endpoint of the quest to unify through symmetry. There is nothing else like it.

The only serious strategic shift that string phenomenologists face so far, is a need to abandon the idea of weak-scale supersymmetry, and that was never an implication of string theory, it was a phenomenological assumption.

20. **NoGo**
May 1, 2017

I have also read the linked interview with Witten, where he says:
"Witten: There are not any interesting competing suggestions. One reason[…] is that interesting competing ideas (twistor theory, noncommutative geometry, …) tend to be absorbed as part of a larger picture in string theory. The competing interesting ideas have been very fragmentary and have tended to gain power when absorbed in string theory."
I am curious, and will be grateful if someone in the know can comment on, were these theories really "absorbed" by string theory in some meaningful way, or it's just another conjecture about properties M theory may have when it's found, or something in between?
Thanks.

21. **Jesper**
May 1, 2017

@ NoGo,

let me comment on noncommutative geometry. The 'non-commutative geometry' aspect emerging from ST does, in my opinion, not compare to Chamseddine and Connes approach – so I would definitely not accept that NCG has simply been "absorbed" into ST.

These two approaches to understand the standard model are in fact radically different: ST proposes via the landscape that the standard model is, essentially, a random occurrence whereas NCG proposes the exact opposite, that the standard model is unique.

Generally speaking, I think that if you should have a framework, that is large enough to encompass all other existing ideas, then it will most likely be empty.

22. **Peter Woit**
May 1, 2017

Mitchell Porter,

The problem with string theorist's "strategic shift" of dismissing the failure to find SUSY or extra dimensions at the LHC as just a "phenomenological assumption" is that finding such things at the LHC was the main argument string theorists used for the last thirty years when asked "how can your theory be tested?". If they make this new "strategic shift" they will be acknowledging that there are no longer any plausible prospects for experimentally testing string theory, putting the idea of string theory unification firmly outside conventional understanding of what is science.

23. **Peter Woit**
May 1, 2017

NoGo,

The question of the relation of twistor and non-commutative geometry to string theory is an extremely complicated one, with the first problem deciding what "string theory" is. As Jesper points out, I don't think non-string theorists would agree that these ideas have been "absorbed" into string theory.

Looking at active research topics pursued by "string theorists" in recent years (for instance by looking at talks at Strings 20XX) I think one finds "string theorists" moving into other fields. A very active area for instance is the study of scattering amplitudes, and while ideas coming from string theory have had some impact, a twistor theory expert might reasonably make the claim that ideas from twistor theory have been even more important there. If "twistor theory" was a term used in the way "string theory" is, a "twistor theorist" might have a good case that "string theory" has been absorbed by "twistor theory".

Of course, this level of discourse is just playing with ill-defined words, shall we say, "not even wrong"…

24. **martibal**
May 1, 2017

Last march there have been two colloquia at ICTP in Trieste, one day by Vafa, the next day by Connes. I do not know if the videos are available, but it is difficult to imagine two approaches to theoretical physics more different.

The claim that noncommutative geometry [NCG] would have gained power once absorbed within string theory [ST] is pretty much ambiguous. If one intends "power of scientific explanation", then this claim is a nonsense. If one intends "political or sociological power", then it may be true that NCG has gained visibility within the theoretical physics community when Seiberg-Witten map was – for a while – the hot topic in ST. But this period of time is over. I do not know what ST has kept from NCG, what I do know is that research in theoretical physics inspired by NCG has kept going on, with motivations that have nothing to do with ST, and with many beautiful developments that have nothing to do with ST neither.
That gaining visibility or "media power" is not the same thing as gaining "scientific power" is the whole raison d'´être of this blog, no ?

25. **A.J.**
May 1, 2017

Noncommutative Geometry is more than just Connes' attempt to get the classical Standard Model Lagrangian by looking at the Dirac operator on a limited set of NCG spaces. It's a very general way of thinking about 'spaces'. I'd be willing to bet that when Witten said that NCG had been enriched by String theory, he was referring to the variety of nontrivial ways in which string theory realizes such noncommutative spaces. This includes the Myers Effect and various noncommutative gauge theory constructions, and also more general ideas like matrix theory. Such realizations are often powerful because they give you new ways of looking at familiar examples and suggest non-trivial relations to other concepts (e.g., the Seiberg-Witten map).

That said, Connes' specific program of connecting Standard Model dynamics to noncommutative geometry can be thought of as a special case of the superconformal QFT geometry dictionary used in string theory. Urs Schreiber has pointed this out here a few times. It's quite peculiar that enthusiasm for this model instead of string theory has become a tribal marker.

26. **Urs Schreiber**
May 1, 2017

The close relation between Connes-style NCG and perturbative superstrings has been pointed out way back in 1993 by Fröhlich and Gawędzki , has meanwhile been substantiated by theorems by Roggenkamp and Wendland, following Kontsevich and Soibelman, and has been used by Soibelman to study aspects of the string landscape in terms of spectral triples. Review and comprehensive pointers to the literature are at PhysicsForums-Insights: *Spectral Standard Model and String Compactifications*.
Apart from the technical details discussed there, one highlight is that both approaches are KK-models that do agree on the critical spacetime dimension to be 4+6 = 10 (modulo 8, because NCG only sees it modulo 8).

27. **Peter Woit**
May 1, 2017

AJ and Urs,

Looking at the document Urs links to, I see all sorts of interesting mathematics and physics, but I don't see how the perturbative superstring has all that much to do with it. As usual when I disagree with Urs, what seems to me a tenuous and not very important connection is for him a "close relation". Sorry, but all this just seems to me to be turning interesting discussion about deep mathematical structures into a waste of time ideological discussion, and I'm not in the mood to participate, or even try and properly moderate such a discussion.

28. **piscator**
May 1, 2017

Europe is less faddish than the US. The tendency for everyone to jump on the same hot idea is less. This is good when the hot idea is evanescent nonsense and less good when the hot idea is a fundamental breakthrough.

It also involves many different countries, which encourages a larger number of distinct scientific hierarchies as to styles of science and the question of what are the important problems one should ask.

But still, things are more similar than different. Everyone reads the same arxiv.

29. **Jesper**
May 1, 2017

Hi A.J. and Urs Schreiber

I don't doubt that there is are connections between noncommutative geometry and string theory – and the one with 2d SCFT is obviously interesting – but the question was whether string theory had "absorbed" noncommutative geometry. Noncommutative geometry is a very large field, mostly in mathematics but clearly also in mathematical/theoretical physics and the notion that string theory somehow captures all that doesn't make sense to me. But perhaps this is a question of semantics.

Urs, in your very nice PhysicsForum piece you end with the sentence "A very interesting question to ask therefore is: which 2d SCFTs (if any) would lift the Connes-Lott-Chamseddine-Barrett spectral triple? These would be realistic string vacua." Does that imply that it is not yet known whether the connection between the Connes-Lott-Chamseddine model and these 2d models is real?

In my view, Chamseddine and Connes' work (and others) on the standard model is an interesting observation that might point towards a unified theory of quantum gravity. The questions are where the almost commutative structure originates from and how quantum field theory/quantum gravity fits into the picture. The answer could be string theory, it could be something else – I believe that we needs as many ideas as possible.

30. **martibal**
May 2, 2017

Claiming that NCG is subsumed by ST (or gained more power thank to ST) because spectral triples might be useful to study the landscape, or because both view spacetime as a dimension 2 objects (like several other approaches to QG by the way) sounds to me a bit like claiming that Riemann integral has gained more power since it has been widely used in ST.
It is not because something is used in ST that it is "subsumed" by ST. This tendency of ST to swallow everything and deny independent interest to any ideas outside ST is unbearable, and counterproductive: first it puts the discussion on a conflictual tone, that not everybody is interests to get along with; second it is a way not to study the motivations of the other ideas, that have nothing to do with ST.
But I agree with Peter that this kind of discussion just repeats itself again and again, and is a waste of time.

31. **Giotis**
May 2, 2017

Witten obviously is referring to the early 2000 medium size Noncommutativity revolution in String theory sparked (mainly) by his by now classic paper written together with Seiberg (you need basically a strong B-field to make Noncommutativity manifesting itself)

"String Theory and Noncommutative Geometry":

http://lanl.arxiv.org/abs/hep-th/9908142v3

33. **RandomAnonymous**
May 2, 2017

^ That is a depressing amount of effort spent to reparameterise failure…

34. **Urs Schreiber**
May 3, 2017

> Urs, in your very nice PhysicsForum piece you end with the sentence "A very interesting question to ask therefore is: which 2d SCFTs (if any) would lift the Connes-Lott-Chamseddine-Barrett spectral triple? These would be realistic string vacua." Does that imply that it is not yet known whether the connection between the Connes-Lott-Chamseddine model and these 2d models is real?

Every 2d superconformal field theory yields a spectral triple as its "point particle limit". (This is a mathematical formalization of the familiar idea that we may view the quantum superstring from far away and see only its center of mass point motion, with the quantum oscillations about it appearing as different species and different internal degrees of freedom of the resulting effective spinning particle.)

But not every spectral triple necessarily needs to arise this way. Those that do would be called those that have a stringy UV-completion to a theory of perturbative quantum gravity coupled to gauge bosons and fermions.

35. **Urs Schreiber**
May 3, 2017

> Witten obviously is referring to the early 2000 medium size Noncommutativity revolution in String theory sparked (mainly) by his by now classic paper written together with Seiberg (you need basically a strong B-field to make Noncommutativity manifesting itself)

That's quite certainly what the quote was referring to, but since above the discussion quickly shifted to *Connes-style NCG*, it is worth recalling that this "spectral geometry", as it might possibly better be called, is a good bit richer than just some Moyal-noncommutativity of spacetime coordinates, and was understood to arise as the point particle limit of perturbative superstrings already in FröhlichGawędzki 93 .

One could argue that the main point of Connes-style NCG (namely: spectral triples) is not so much the non-commutativity of the algebra that is part of the triple (that's a nice side effect, that non-commutative algebras may be accomodated, too) but the main point is the Dirac-like operator in the triple (and the super-Hilbert space that, necessarily, comes with it, for it to be a linear operator on anything).

Instead, Connes-style NCG is about *extracting an effective target spacetime geometry* (possibly non-commutative, sure) *from the energy spectrum of a super-particle* (hence a spinning particle), hence to extract an effective target spacetime geometry as seen from quantum super-particles that roam in it.

This is noteworthy, since this is exactly foundational approach of perturbative superstring theory, only that there the worldline theory of that spinning particle is promoted to a worldsheet theory, since that turns out to be beneficial for the behaviour of the theory, as it provides a consistent means to incorporate interactions and counter-terms to arbitrary order (the higher string oscillation modes).

Moreover, as has been shown, this gives a richer supply of non-commutative backgrounds than Seiberg-Witten, in fact it gives a general stringy idea of how to think of the non-commutativity in a Connes-style non-commutative geometry: The non-commutativity is the remnant of the higher superstring oscillations as we pass to the superstring's point particle limit.

36. **lars**
May 10, 2017

Horgan: Do you still think string theory is "not even wrong"?

Woit: Yes. My book on the subject was written in 2003-04 and I think that it's point of view about string theory had been vindicated by what has happened since then. Experimental results from the Large Hadron Collider show no evidence of the extra dimensions or supersymmetry that string theorists had argued for as "predictions" of string theory. The internal problems of the theory are even more serious after another decade of research. These include the complexity, ugliness and lack of explanatory power of the models designed to connect string theory with known phenomena, as well as the continuing failure to come up with a consistent formulation of the theory"
— Peter Woit from linked article

You once said that "I use 'not even wrong' to refer to things that are so speculative that there would be no way ever to know whether they are right or wrong"

If that was the definition for "not even wrong" that you used when you wrote your book, I can see how an increase in the severity of the internal problems you refer to might vindicate your initial claim that string theory is "not even wrong", but it is not clear how results from the LHC could have vindicated such a claim.

"No way ever to know whether they are right or wrong" would seem to imply "no experiment".

Please note that I am not challenging your claim about the internal problems, about which I am not qualified to weigh in one way or another.

37. **Peter Woit**
May 11, 2017

lars,

I put "predictions" in quotation marks for a reason. Despite what they sometimes told the press, string theorists never had real predictions for the LHC from string theory. They did however have things they could point to which, if observed, would provide encouragement for some of the research directions that led to string theory (e.g. SUSY). It is these that have not worked out.

Theories of Everything

May 2, 2017
Categories: Book Reviews

I've written a review for the latest issue of Physics World of a short new book by Frank Close, entitled Theories of Everything. You can read the review here.

As I discuss in the review, Close explains a lot of history, and asks the question of whether we're in an analogous situation to that of the beginning of the 20th century, just before the modern physics revolutions of relativity and quantum theory. Are the cosmological constant and the lack of an accepted quantum theory of gravity indications that another revolution is to come? I hope to live long enough to find out…

Comments

indicate that this is a non-zero num
–
ber, with an order of magnitude so
big that it doesn't fit at all with what
one might expect from the Standard
Model and general relativity."

Please explain "big". I though that the (non stringy) particle physicists said "small",
by 30 or 120 orders of magnitude.

2. **Peter Woit**
May 2, 2017

Doug McDonald,
Oops, that's a mistake that seems to have crept in during the editing, and I wasn't paying enough attention in proof-reading. For "big", read "small".

3. **neil**
May 3, 2017

Despite the outstanding success of the standard model, I do not think we are in a position analogous to that of 1900 with apparently settled physics but for a couple of clouds on the horizon. Kelvin thought his clouds would eventually be explained by the "standard model" of his time. That is why he thought them mere clouds. I don't think anyone labors under that delusion today. Our clouds are looming cumulonimbus, and the big question is whether we can discover the physics needed to explain them given the limited tools available to us.

4. **Snowden**
May 3, 2017

A revolution a day keeps progress away – especially true in quantum gravity, where the revolution now is that the previous revolutions haven't gone anywhere. It is amazing that people confidently claim that properties that are true of every low energy Hamiltonian will somehow magically lead to insights about quantum gravity (http://vixra.org/abs/1703.0300)

5. **Peter Woit**
May 3, 2017

Doug McDonald,
Thanks for pointing out the problem. It's now fixed in the pdf here and online at Physics World.

6. **Pascal**
May 3, 2017

What about nonzero masses for neutrinos: is that compatible with the standard model?

7. **Low Math, Meekly Interacting**
May 3, 2017

What about dark matter? Is that not a "cloud"? I've read many an account of Einstein's doomed attempts to find a unified field theory. The general consensus being ignorance of two more forces of nature didn't exactly help his efforts to unify gravity and EM. What if dark matter completely up-ends our notion of what "matter" is? What if gravity has to be modified? Could a major part of the problem also be tied up in the answers to those questions?

8. **Peter Woit**
May 3, 2017

Pascal/LMMI,

Neutrino masses and dark matter are also possible "clouds". Unfortunately in neither case have they provided any promising hints for a revolutionary change in our best fundamental theory. This may be why Close points to the quantum gravity problem as one more likely to lead to such a change.

The problem is that all of these have received a huge amount of attention from theorists trying to interpret them as evidence for a new theory, without much to show for the effort. Maybe a very different cloud would be more promising. One of my personal favorites is the difficulty of non-perturbatively formulating chiral gauge theories such as the electroweak sector of the Standard Model.

9. **KJ**
May 3, 2017

Peter,
Your review certainly implies that your general impression of the book is favorable – you say Close is "on the right track"- but I finished the review not being sure whether or not you recommend the book, and if so, to what audience. Does Close have anything new to say about the situation that has not been covered already by some of the plethora of popular books on the Standard Model? Or is it more a case of "If you feel like you must read every popular book on quantum gravity, at least this one won't mislead you into multiverse mania".

10. **Peter Woit**
May 3, 2017

KJ,
It's a short popular book, much of which is a subset of what is covered in various longer books (including some by Close himself). He's trying to emphasize one particular question, about unification and the current state of affairs. But it is at the level of a non-technical essay, and if you've followed the issues discussed on this blog I don't think you'll find anything particularly new. My review mainly attempted to just convey the point of view of his essay, perhaps wasn't very good as a consumer guide.

Yes, one market for the book is for those who must read every popular book on fundamental physics, and for such readers I'd describe it as a sensible but unsurprising take.

11. **Low Math, Meekly Interacting**
May 4, 2017

I guess. But maybe lacking more specific observational or experimental information about the nature of dark matter is a lethal impediment, akin to operating under the assumption that EM and gravity are the only fundamental forces and then seeking to unify the forces of nature. Maybe it's just setting oneself up for certain failure? True, it's been a disappointing avenue of exploration so far, but what if it's impossible to get around nonetheless? Given the "nightmare scenario" that appears to be unfolding, I do wonder why there isn't much public discussion of such a possibility. I.e. maybe we'll never get close to completing this puzzle until we've found this one piece that's so obviously missing.

12. **AcademicLurker**
May 4, 2017

Maybe this belongs in the "Why string theory is still not even wrong" thread, but I don't want to derail the discussion there.

Peter, in your books both you and Lee Smolin dealt at length with the ways in which you thought the sociology of HEP theory was discouraging the exploration of new or unconventional approaches.

Since now post LHC new ideas seem to be more needed than ever, do you see any improvements in the sociology of the fundamental physics theory community relative to 2006?

13. **Paul**
May 4, 2017

AcademicLurker,

We are not yet in "post LHC" mode. Not by a long shot.

14. **Peter Woit**
May 4, 2017

Academic Lurker,

There have been changes in the sociology since 2006, some for the worse, some for the better. Net though I think we're worse off than in 2006.

One change for the better is increased skepticism about string theory. That string theory hasn't worked out as hoped and no longer provides a promising route to unification is now a widespread point of view in the physics community, probably even the dominant, majority one. Even lots of people who call themselves "string theorists" are now working on different ideas that have little to nothing to do with string theory.

On the still a problem front, I'd list the herd sociology of the subject. Yes, you can not work on string theory, but if you want a career you better stick to one of a small number of "hot" topics. If you have an idea that is not related to string theory or one of the latest hot topics, pursuing it is as likely to doom your career as ever.

There have unfortunately also been significant changes for the worse. The multiverse is one I go on about too much, but it's hard to over-emphasize what an awful idea it is to give up on conventional science in that way. I had some hope that negative LHC results about SUSY and extra dimensions would have a wake-up effect, but that does not seem to be happening. Those devoted to SUSY seem to be taking the line that losing their bets that they would be vindicated by the LHC is no reason to change their thinking.
Another major change for the worse I think is the way that most of the physics community seems to have decided that the reason string theory didn't work out was that it used too much mathematics (as opposed to just being a bad physical idea). The engagement with deep mathematics was one of the best aspects of string theory, and that kind of work is nowhere near as healthy as it used to be.

15. **Jesper**
May 4, 2017

Hi Peter

When you write "On the still a problem front, I'd list the herd sociology of the subject. Yes, you can not work on string theory, but if you want a career you better stick to one of a small number of "hot" topics. If you have an idea that is not related to string theory or one of the latest hot topics, pursuing it is as likely to doom your career as ever " — then I cannot agree with you more.

If this does not change then I think that young researchers must and will begin to consider alternative routes for funding. Personally (and I am not that young any longer) I have taken the consequence and am financing my research via crowdfunding. I just don't see any possibility within the academic world of theoretical physics of today to successfully — i.e. financed — pursue a research project that is both serious (which means, involves years if not decades of work) and independent of the existing power structures. I imagine that others might begin to consider alternative options too.

I don't mean to suggest that this will be easy — it is not! — but if the choice boils down to abandoning your own ideas or research altogether, then I imagine and hope that there will be some who simply refuse to accept the basic premise that research belongs in academia. In fact, there are also upsides to working outside of academia. And one thing that I have learned is that there are many people who are interested and willing to finance alternative ideas as long as they are certain that its serious research.

On another note: I agree with you on the role of mathematics in theoretical physics. In my view its possibly the most important guidance we have forward.

16. **Mitchell Porter**
May 4, 2017

Since people express so much agitation in a forum like this, about the theoretical physics establishment still pursuing its failed agendas, etc, may I point out that every month on hep-ph there are several dozen papers on models employing neither supersymmetry nor grand unification – to name two of the popular, post-1970s, beyond-standard-model research programs that are also part of the string theory edifice.

For example, there are papers on flavor symmetries, especially for the neutrino sector; and there are papers looking at rather minimal extensions of the standard model, in order to explain the extra phenomena like neutrino masses and baryon asymmetry. (An example of the latter would be the "SMASH" paper, that received a little media coverage recently.) There are always a handful of papers trying to challenge more basic conventional wisdom, in ways that look misguided. And there are still further papers which don't fit any of those categories.

I think all this would be apparent to anyone who actually checks the daily releases on arxiv. So it makes me wonder about the people who express agitation about the state of physics: who are they, and what are they angry or despairing about? Some of these people might be laypeople who only read a type of "secondary literature" – hype and anti-hype, in media and blogs. Some of these people might be theorists (amateur or professional) who have a theory of their own to push, and whose dissatisfaction is really that *their* theory doesn't get funded or isn't widely accepted. And some of these people may be part of physics culture, but are only focusing on the elite – the big institutions, the big conferences, the big-name theorists who do all the interviews. Perhaps they want these "leaders of the field" to reform themselves, not caring that there is a big wide world of universities and researchers developing a multitude of heterodox viewpoints away from the limelight.

This is just an impromptu analysis. I would like to know what it overlooks.

17. **Peter Woit**
May 4, 2017

Mitchell Porter,
hep-ph has always been mainly non string theory, with HEP phenomenologists traditionally a part of the subject opposed to string theory. The problem for hep-ph is the same now as it has been for a long time: no new -ph to study (except for experimental misfires like the 750 GeV diphoton).

If there's no new input from experiment, hopes for progress have to come from new theoretical tools and ideas, and that's supposed to be the realm of hep-th. hep-th has much less string theory on it these days, but just as many "string theorists", and it's there that the range of new ideas under consideration is problematic.

18. **Ted**
May 5, 2017

I'm curious to know: what would your advice be to young academics just starting off their careers, who want to explore new ideas? Leave academia and research independently in ones spare time? Go into a "hot" area without truly believing in it? Quit altogether?

19. **Peter Woit**
May 5, 2017

Ted,
I don't think there's any single good career strategy to suggest. Besides the making a living business, two problems with working independently are that you lose the experience of teaching a subject (which is the best way to deeply understand it) and you lose having others to regularly discuss things with. If you happen to be financially independent, it would probably be a good idea to find a high quality, friendly academic department which would allow you to have some kind of affiliation and even sometimes teach courses. Many academic departments will not turn away a qualified Ph.D. who shows up and offers to help with teaching basic courses.

If, like most people, you need a paycheck, I'd suggest trying to consider the widest range of possibilities for academic employment, looking at many institutions, many departments, many types of positions. People in the usual HEP theory career track often have narrowed possibilities because of no experience teaching.

At the very start of a career, as a graduate student, it's probably a mistake to decide that you know what the best unconventional research direction to pursue is. You need to learn your subject, and there are lots of different kinds of projects that will help with that, while making you a viable candidate for a postdoc. If you get a postdoc, you generally can spend your time doing what you want.

Where the standard career path becomes very problematic is going from such a post-doc to a longer term position, and it's in preparing for that transition that I'd suggest looking at any possibility you can think of. Trying to play the game of working on a "hot" topic you don't believe in, with the hope that this will get you tenure and freedom is something I don't think really works. Most likely you will end up just losing out to others playing the same game better than you, or after a decade of working on things you don't believe in, you'll no longer know how to work on things you do believe in.

20. **Michael Gogins**
May 5, 2017

Ted: I'm not a physicist, but I am a serious worker in a field dominated by academics, namely computer music of the sort that focuses on software synthesis and algorithmic composition, and I have concertized, published, and presented in the main venues of the field.

What I found is this. For the most part there has been no barrier to acceptance of my work arising from my not being an academic. However, I am quite clear that the quality and quantity of my work has suffered from not being in the academic context, where I would have had much more interaction with my peers, and would not have had to have a day job. I believe that even teaching helps, as one is still spending time in the thought-world of the field.

My advice to an aspiring physicist is (a) see if the lack of barrier is also the case in physics, but I wonder because there are a lot of physics crackpots and not many computer music crackpots, and (b) don't work independently if there is any way to make it work inside the academic world. But in that case, a serious theoretician would absolutely have to find a way to build a private space for the kind of deep thinking that is required. You need long stretches of just thinking and even of being quite alone. Perhaps one could keep two research tracks going — one to keep your funders and bosses happy and one to keep oneself happy. But that sounds like real overwork!

Conversely, for someone working outside academia, I think it would extremely helpful, perhaps vital, to live in a big center like New York or a major university town and try to get to know some of the leaders in the field. I have been able to do this in music, and it has been really helpful.

21. **Jeff M**
May 5, 2017

Ted : My advice for young academics. I'm a mathematician, I've been on a bunch of search committees, so I have a good idea of what the field is like for young math types. It's much worse in physics, since physics isn't a service department. At my university, we have 32 people in the math department, and 5 in physics. I would second everyone who says try to stay in academia if you really want to be part of the field, but be willing to teach anywhere. Might mean a much heavier load, many fewer connections, but it's a different world, and if you're out of it, its very hard to stay active. I know someone (in math) who did what Peter suggested, and got himself affiliated with a very good university, who didn't pay him anything. He won the lottery, so he didn't need money. But I think a lot of people in physics just dismiss the idea of teaching at a liberal arts school, or a second rank state school like mine. But you can have a good life doing it, stay active, find interesting things to do. I went to a liberal arts college, the physics professor I did most of my work with stayed very active, published, and after I left he actually started a research institute. One of the people associated with the institute won the Nobel. My son, who was at the same school this year, worked with a new physics prof, serious research degree, I have no doubt she's going to stay active. He's transferring to a research one place, I'm very curious what he's going to think of the difference

22. **Scott**
    May 5, 2017

    As a physicist, but not HEP, I always thought one of the "clouds on the horizon" was the matter/anti-matter asymmetry. Would that qualify or is there a feeling among HEP that while an issue, it is secondary.

23. **Peter Woit**
    May 5, 2017

    Scott,
    Sure, that maybe a "cloud", but one problem with that is that it depends a lot on your understanding of what happened during the big bang, so it's not a clear indication that there's something wrong with our fundamental theory of particle physics (as opposed to the details of our understanding of very early universe cosmology).

24. **Peter Woit**
    May 5, 2017

    A correspondent points out to me that the idea of quantum theory requiring replacing our understanding of space and time goes way back, with Russian physicist Matvei Bronstein discussing this already in 1936. For more about this, see

    http://blogs.scientificamerican.com/guest-blog/2011/07/14/why-is-quantum-gravity-so-hard-and-why-did-stalin-execute-the-man-who-pioneered-the-subject/

    or

    http://people.bu.edu/gorelik/cGh_Bronstein_UFN-200510_Engl.htm

25. **Chris W.**
    May 9, 2017

    The physical motivation is less clear-cut than the arguments put forth by Bronstein, but this fairly well-known quote of Einstein (on Sabine's *Backreaction*) indicates that he had been worrying about this for some time as of 1916.

26. **Thomas**
    May 10, 2017

    off-topic, but .. care for 28 000 pages of notes from Grothendiek?
    https://grothendieck.umontpellier.fr/archives-grothendieck/

Some Quick Items

May 10, 2017
Categories: Uncategorized

A few quick items, I may use this posting to add a couple more later, the next posting will discuss today's letter to Scientific American about inflation.

- Today's LHCC meeting at CERN had reports from the LHC machine and experiments. About two weeks to go before collisions and data-taking start again.
- Physics Today has a report this month on the LHeC proposal, something that has not gotten as much attention as it deserves. This is a proposal to collide protons and electrons, by building a new electron machine and a detector at a collision point with the LHC beam. Unlike proposals for a 100 TeV proton-proton machine that are getting a lot of attention, this would not push the energy frontier, but it would cost a great deal less (estimate is half a billion to a billion, vs. multiple tens of billions for the 100 TeV machine). In a few years when the question of a follow-on machine to the LHC starts to get very pressing, this idea and the HE-LHC idea (higher field magnets in the LHC tunnel, maybe doubling the energy) may get a lot more attention as the only financially viable ways forward.
- The Université de Montpellier today has started to make accessible about 18,000 pages of its archive of Grothendieck's mathematical writings. For anyone interested in Grothendieck's work, this should keep you busy for a while…

Update: A few more.

- I was sorry to hear of the recent death of Cecile DeWitt-Morette, a mathematical physicist responsible for the Les Houches physics summer school. Her books on geometry and physics (with Yvonne Choquet-Bruhat) were influential, and her more recent book with Pierre Cartier on Functional Integration contains a lot of interesting material.
- Every so often I'd wondered what the Chudnovsky brothers have been up to, some information about this emerged today.
- For a story about problems at the science magazine, Nautilus, which is having trouble transitioning from its original Templeton Foundation funding, see here.

Comments

1. **John McAllison**
   May 10, 2017

   Recently, CERN decided to stop the interested tax paying public from having a look at the morning meetings under the LHCC coordination program:
   https://indico.cern.ch/category/6740/

   So it's nice to see CERN hasn't blocked yet public access to the LHCC meetings.

   May 14, 2017

   On a mathematical note, Hironaka has a preprint on his website claiming to prove resolution of singularities in characteristic p, that it seems nobody noticed for two months because he didn't post it to the arxiv, etc.

6. **neil**
   May 14, 2017

   Out of curiosity, I looked at a few pages of Grothendieck's writings. I just wanted to witness the great man's handwriting. Transcribing and translating these 18,000 pages will be an enormous job, if that happens.

7. **Peter Woit**
   May 14, 2017

   anon,
   From what I hear, experts in the field only found out about this a few days ago, are just starting to look at the proof. It would be a great story if this turns out to be right.

8. **Matt Grayson**
   May 15, 2017

   If true, it will complete one of the more famous mathematical anecdotes of the past hundred years.

9. **David Roberts**
   May 15, 2017

   @Matt can you remind us? No doubt it's something going back to the Italian School.

10. **none**
May 15, 2017

@Roberts: @Matt is commenting on the possibility that Hironaka has also proved resolution of singularities in positive characteristic, decades after his Fields Medal winning proof in characteristic zero.

11. **none**
May 15, 2017

@Roberts: A link to Hironaka's preprint
http://www.math.harvard.edu/~hironaka/pRes.pdf

12. **David Roberts**
May 16, 2017

@none yes, but what is this famous mathematical anecdote that it would be completing? I can't recall any surrounding resolution of singularities, much less any that is a hundred years old.

A Cosmic Controversy

May 10, 2017
Categories: Favorite Old Posts, Multiverse Mania

A couple months ago Scientific American published an article by Ijjas, Steinhardt and Loeb (also available here), which I discussed a bit here. One aspect of the article was its strong challenge to multiverse mania, calling it the "multimess" and accusing multiverse explanations of being untestable and unscientific.

Yesterday Scientific American published, under the title A Cosmic Controversy, a rebuttal signed by 33 physicists, together with a response from the authors, who have also set up a webpage giving further details of their response. Undark has an article covering this: A Debate Over Cosmic Inflation (and Editing at Scientific American) Gets Heated.

As Ijjas, Steinhardt and Loeb point out on their webpage, the story of this letter is rather unusual. It was written by David Kaiser and three physicists well-known for their outspoken promotion of the multiverse (Guth, Linde and Nomura). Evidently these authors decided they needed reputational support on their side, and sought backing from other prominent names in the field (I'm curious to know who may have refused to sign if asked…). Their letter starts out with a claim to represent the "dominant paradigm in cosmology" and notes the large number of papers and researchers involved in studying inflation.

If you read carefully both sides (IS&L and GKL&N) of this, I think you'll find that they are to a large degree speaking past each other, with a major problem that of imprecision in what one means by "inflation". To the extent that there is a specific identifiable scientific disagreement, it's about whether Planck data confirms predictions of the "simplest inflationary models." IS&L write:

> The Planck satellite results—a combination of an unexpectedly small (few percent) deviation from perfect scale invariance in the pattern of hot and colds spots in the CMB and the failure to detect cosmic gravitational waves—are stunning. For the first time in more than 30 years, the simplest inflationary models, including those described in standard textbooks, are strongly disfavored by observations.

whereas GKL&N respond:

> there is a very simple class of inflationary models (technically, "single-field slow-roll" models) that all give very similar predictions for most observable quantities —predictions that were clearly enunciated decades ago. These "standard" inflationary models form a well-defined class that has been studied extensively. (IS&L have expressed strong opinions about what they consider to be the simplest models within this class, but simplicity is subjective, and we see no reason to restrict attention to such a narrow subclass.) Some of the standard inflationary models have now been ruled out by precise empirical data, and this is part of the desirable process of using observation to thin out the set of viable models. But many models in this class continue to be very successful empirically.

I take this as admission that IS&L are right that some predictions of widely advertised inflationary models have been falsified. Of course, if these had worked they would have been heavily promoted as "smoking gun" proof of inflation, as was demonstrated by the BICEP2 B-mode fiasco. After BICEP2 announced (incorrectly) evidence for B-modes, Linde claimed this was a "smoking gun" for inflation (see here) and the New York Times had a front page story about the "smoking gun" confirmation of inflation vindicating the ideas of Guth and Linde. A couple months later, before the BICEP2 result was shown to be mistaken, Guth, Linde and Starobinsky were awarded the $1 million Kavli Prize in Astrophysics.

GKL&N don't mention the sorry story of the BICEP2 B-modes, what they have to say about this is

> the levels of B-modes, which are a measure of gravitational radiation in the early universe, vary significantly within the class of standard models…
>
> The B-modes of polarization have not yet been seen, which is consistent with many, though not all, of the standard models.

About the IS&L "unexpectedly small (few percent) deviation from perfect scale invariance" all GKL&N have to say is

> The standard inflationary models… predict the statistical properties of the faint ripples that we detect in the cosmic microwave background (CMB). First, the ripples should be nearly "scale-invariant"

This doesn't seem to address at all the IS&L claims, which they make in more detail as

> The latest Planck data show that the deviation from perfect scale invariance is tiny, only a few percent, and that the average temperature variation across all spots is roughly 0.01 percent. Proponents of inflation often emphasize that it is possible to produce a pattern with these properties. Yet such statements leave out a key point: inflation allows many other patterns of hot and cold spots that are not nearly scale-invariant and that typically have a temperature variation much greater than the observed value. In other words, scale invariance is possible but so is a large deviation from scale invariance and everything in between, depending on the details of the inflationary energy density one assumes. Thus, the arrangement Planck saw cannot be taken as confirmation of inflation.

GKL&N argue for three other confirmed predictions of inflationary models:

> Second, the ripples should be "adiabatic," meaning that the perturbations are the same in all components: the ordinary matter, radiation and dark matter all fluctuate together. Third, they should be "Gaussian," which is a statement about the statistical patterns of relatively bright and dark regions. Fourth and finally, the models also make predictions for the patterns of polarization in the CMB, which can be divided into two classes, called E-modes and B-modes. The predictions for the E-modes are very similar for all standard inflationary models

On these issues I don't see anything from IS&L and would love to hear from an expert.

The main issue here comes down to the question of the flexibility vs. rigidity of inflationary models. Is the inflationary paradigm rigid enough to make solid predictions, or so flexible that it can accommodate any experimental result? GKL&N are making the case for the former, IS&L for the latter, and they point out the following quote from Guth himself:

> when asked via email if they could name any pro-inflation scientists who believe that the theory is nonetheless untestable, the trio pointed to a video of a 2014 panel during which Loeb asks Guth directly whether it's possible to do an experiment that would falsify inflation.
>
> "Well, I think inflation is a little too flexible an idea for that to make sense," Guth replied.

A fair take on all this would be to note that it's a complicated situation, and I doubt I'm the only one who would like to see an even-handed technical discussion of exactly what the "simplest" models are and a comparison of their predictions with the data. Claims to the public from one group of experts that Planck data says one thing, from others claiming it says the opposite are generating confusion here rather than clarity about the science.

I'm strongly on the side of IS&L on one issue, that of the danger of theories that invoke the multiverse as untestable explanation. I don't think though that they make a central issue clear. The simple inflationary models whose "predictions" for Planck data are being discussed involve a single inflaton field, with no understanding of how this is supposed to couple to the rest of physics. One is told that eternal inflation implies a multiverse with different physics in different universes, but in a single inflaton model this physics should just depend on a single parameter, and such a theory should be highly predictive (once you know one mass, all others are determined). What's really going on is that there is no connection at all between the simple single field models that GKL&N and IS&L are arguing about, and the widely promoted completely unpredictive string theory landscape models (involving large numbers of inflaton-type fields with dynamics that is not understood).

I think IS&L made a mistake by not pointing this out, and that Guth, Linde, Nomura and some of the signers of their letter (e.g. Carroll, Hawking, Susskind, Vilenkin) have long been guilty of promoting the defeatist pseudo-scientific idea that "evidence for inflation is evidence for a multiverse with different physics in each universe, explaining why we can't ever calculate SM parameters". By defending the predictivity of "inflation" while ignoring the "different physics in different parts of the multiverse" question, I think many signers of the GKL&N letter were missing a good opportunity to make common cause with IS&L on defending their science against an ongoing attack from some of their fellow signatories.

Update: There are sources with technical details of the arguments being made by both parties:

- For the IS&L side, see here and here.
- For the GKL&N side, see here and here.

I'll try to find time to read these carefully and try and understand exactly what claims are being made. Would love to hear from experts who may have looked at these and are better placed to evaluate what the arguments are.

This controversy continues to involve an unusual level of PR rather than science. The Stanford press office has just put out this, where Linde makes it clear that he sees this as a political and PR fight:

> Linde added that he worries about the younger generation of scientists getting the wrong impression from this story. "I don't want them to read this article and think that they are spending their time on inflationary theory in vain. But the enthusiastic support that we are receiving makes us optimistic that this is not going to happen," he said.

There's no mention in this press office story of their last press office story about Linde and inflation, which promoted the BICEP2 "smoking gun" vindication of Linde and inflation.

Some more takes on this story can be found here, here and here.

Update: Another article about this is at the Atlantic. A crucial issue here is whether inflation has now entered the realm of unfalsifiability. Given any likely new data that could appear, is there any way it could falsify inflation, or can one just come up with some version of inflation that will match it? Guth and Linde seem at times to be taking the attitude that this is fine, I take Steinhardt et al. as pointing out that this is no longer conventional science. Replacing falsifiability by arguments about how many prominent people have signed your letter is a worrisome development. From the article:

> In 2014, for example, Loeb asked Guth during a panel discussion if inflation was falsifiable—whether you could design an experiment to disprove it. Guth called that a "silly question," suggesting that inflation was an umbrella over many theories, making it very hard to knock them all out at once. The hope right now, he says, is to use observation and further theory to winnow inflation down to just one specific version.
>
> "Our point is that this kind of reasoning is inconsistent with normal science and cannot be resolved by invoking authority," Ijjas, Steinhardt, and Loeb wrote to The Atlantic.

Update: More about this from John Horgan.

Update: It seems that Andrei Linde is a Lubos Motl fan. This is getting very weird. It's not normal to respond to a scientific argument by enlisting letter writers on your behalf, even less normal to put your university press office to work on a response, and truly far out there to think that it's helpful to have Lubos announce that you have eaten from the tree of knowledge and that your opponents are imbeciles.

Update: For a sensible take on this that I think likely reflects well the views of most mainstream cosmologists, see Peter Coles.

Update: IJS have put together a Fact-Checking page. It lists the four "predictions" of inflation claimed to agree with experiment by Linde et al. and gives four references to papers published by Linde touting different "predictions" for the same quantities, predictions not agreeing with experiment.

This month's Scientific American has a bizarre cover story by Nomura on "The Quantum Multiverse", see here.

All in all, I don't know what other people's reactions to this have been, but before this started I was a lot more sympathetic to the argument that Steinhardt was treating the case for inflation unfairly.

Update: Yet more coverage trying to make sense of this, from Nick Stockton at Wired.

Comments

1. **John**
   May 10, 2017

   I found the following talk by Steinhardt, where he makes arguments similar to those in the scientific american article, particularly clear:
   http://vms.fnal.gov/asset/detail?recid=1944338

2. **Lino D'Ischia**
   May 10, 2017

   I thought this was bit ironic:
   GKL&N write:
   "Some of the standard inflationary models have now been ruled out by precise empirical data, and this is part of the desirable process of using observation to thin out the set of viable models. "

   It would seem that the multiverse puts an end to "using observation to thin out the set of viable models."

3. **Ilyas**
   May 11, 2017

I think it might also be worth pointing out the value (yet again) of Scientific American in providing a great platform for disparate views and giving them air time. These articles remind us that just because there might be a “scientific orthodoxy” does not mean it is correct. The challenge to String Theory was carried and written about very well in SA who refused to be pushed about by the orthodoxy who challenged the challenger (e.g. people such as you) by bringing together many “prominent” scientists with leading faculty positions, and effectively saying “you cannot be correct since look at all these people who occupy top positions and who support string theory – they cannot be wrong”. We should applaud SA for continuing to endorse its fine investigative tradition.

4. **Another Anon**
   May 11, 2017

   Yes, I agree with Ilyas. Publishing an article about orthodox inflation is not an interesting thing for Scientific American to do. It’s like criticising a newspaper for not printing a “nothing much happened today” on a quiet news day. The story is the challenge to the orthodoxy.

   And I know that one of the signers is privately dubious of inflation. If a bunch of big names ring you up and ask you to sign their petition, you’re going to do it.

5. **hyd**
   May 11, 2017

   Even if all the people of this generation and the preceding generations were content with the idea that the SM parameters be inexplicable but a result of playing dice, I’m sure there would be people in the next generation and the next next generation … insatiable with that idea and looking to inquire further, as history has repeatedly told us about human’s inextinguishable sense of curiosity. The attempt of silencing heretics by a bunch of big names is as amusing as ‘the 100 scientists pronouncing Einstein’s theory of relativity is wrong’.

6. **tulpoeid**
   May 11, 2017

   This wild attack from the side of theistic theories makes me sad. Statements like “the B-modes of polarization have not yet been seen, which is consistent with many, though not all, of the standard models” fill me with wrath. Keep up the good work and congratulations for putting names such as Hawking’s in the same sentence with pseudo-scientific.

7. **Jonatan**
   May 11, 2017

   I’m not a cosomologist but I’ve followed the debate between Steinhardt et al. and the pro-inflation side for a while.

   To me, the lack-of-prediction issue raised by Steinhardt is very simple, fundamental and philosophical in nature.

   As I understant it, the situation is thus: inflation provides a mathematical model/framework that CAN produce a universe like the one we see with respect to certain observables (geometry of spacetime, statistical distribution of CMB anisotropies, etc…). These are the “predictions” celebrated by GKL&N. However, quite generically (when considering quantum effects), it also produces all other possible universes with respect to these observables (the multiverse/multimess).

   Therefore it predicts everything/nothing (sounds familiar ?). How could the fact that we observe a flat, isotropic, etc universe be counted as evidence for inflation if we could have just as well observed a curved or open or anisotropic one according to inflation ? Why is this obvious and deep problem not more openly acknowledge by the prononents of inflation is beyond me.

   Steinhardt has provided technical explanations elsewhere for why this is the conclusion one should reach about the state of the inflationary paradigm at the moment, and those explanations seemed quite convincing to me. I haven’t heard any convincing counterargument to this general conclusion yet. Basically: the very concept of prediction becomes meaningless in the context of a bubbling multiverse. Peter is of course quite familiar with this epistemological fact.

   The second problem Steinhardt raises is equally damning for inflation. The fine-tuning of the initial conditions for the parameters of the inflaton field (a problem acknowledged by Sean Carroll in his blog entry on the subject) seems to be equal if not higher than the one required by standard big bang cosmology to produce a flat, isotropic universe like the one we see. I think Penrose have also mentionned that point in the past. So basically, it seems that you’re left with a choice of fine-tuning the initial conditions of standard big bang cosmology, or fine-tuning the initial conditions of a yet unknown, unseen, “inflaton” field…

   If true, this is highly ironic considering inflation was invented precisely to avoid this fine-tuning of initial conditions in standard big bang cosmology.

8. **Ben**
   May 11, 2017

   I think one of the problems is that there’s “inflation” – the idea of an early period of exponential expansion driven by something like an effective scalar field, and then there’s “inflation” – a more complete description of where that field comes from and how we got into the inflating state to begin with.

   The former seems to make testable (but maybe not unique) predictions, such as near-homogeneity, adiabatic perturbations, etc. The latter seems to screw all that up with goofy things like multiversal bubble nucleation, eternal inflation, and so on.

   So some (Steinhardt et al) argue that since attempts to come up with a complete picture of inflation wind up being non-predictive, that the whole thing is intellectually bust. Others (some of the inflation theorists) disagree on “predictivity” grounds and get into arguments about multiverse stuff. Still others (most experimentalists) would rather stay out of the weird foundational stuff, focus on “inflation” as an incomplete model for a specific epoch of history, and test the “predictions” that way.

   I think it’s hard to call the experimentalists wrong, since there’s basically no complete model of the early universe, inflationary or otherwise. Even Steinhardt is pretty clear that his pet ekpyrotic scenario has serious gaps.

9. **Shah-hid**
   May 11, 2017

   Here Dr. Neil Turok gives an epic summary of inflation’s curiosities:

   https://www.youtube.com/watch?v=g9fyn0mZEnY

10. **Pasa Dina**
    May 11, 2017

    Thanks for all the relevant links (as usual), Peter.
    The Forbes article – sigh.
    The author totally misses what the debate is about. He thinks it is about the variety of possible potentials rather than the initial conditions or multiverse. And he asserts that

everyone agrees there had to be rapid expansion, apparently missing entirely the bounce.

11. **cosmology grad student**
May 11, 2017

“One is told that eternal inflation implies a multiverse with different physics in different universes, but in a single inflaton model this physics should just depend on a single parameter, and such a theory should be highly predictive (once you know one mass, all others are determined).”

This is a key point. For a single-field slow-roll model, eternal inflation affects predictions of e.g. things you can observe in the CMB only in that instead of one particular distribution of classical spacetime geometries after inflation (drawn from a power spectrum with one particular value of e.g. spatial curvature, spectral index, “average temperature variation” = delta rho/rho, …) there is another, different distribution (instead of drawing from a fixed power spectrum at the end of inflation, there is some probability distribution of power spectra).

12. **neil**
May 11, 2017

I read somewhere, possibly here, that the strength of a theory depends as much on what it excludes as what it explains. In this debate, I think Guth et al focus on what they believe inflation theory explains whereas Ijjas et al focus on what it excludes (nothing?)

13. **skydivephil**
May 11, 2017

I am the producer of a series of films on early universe cosmology and have interviewed Guth, Nomura and many other supporters, and critics of inflation (including those that promote others models such as CCC, string gas cosmology and the pre big bang).

I am not a cosmologist but someone interested in cosmology and have spent many hours discussing these issues with some of the leading people in the field.
In our film on eternal inflation we interview George Efstathiou who gave the press conference for the cosmology results for Planck.
Efstathiou claims that the Planck data favour models of inflation that are eternal and therefore a multiverse.
you can see that 12:41 into our film here:
https://www.youtube.com/watch?v=QqjsZEZMR7I

Whats interesting is that in the ISL paper they make the same claim:
“The plateau-like potentials selected by Planck2013 are in the class of eternally inflating models,”
We asked Guth and Nomura to respond to many of the criticisms of the ISL paper and so I hope you will find our film interesting. Nomura claims a method of how to falsify eternal inflation.
What I also find interesting is that Steinhart in his paper “Cosmological Perturbations: Myths and Facts” said
“We will argue below that inflation and the cyclic model make firm predictions for the characteristic mass scale and equation of state during inflation, the spectral tilt of the scalar perturbations and the gravitational wave amplitude.”
He also states that Ns should be roughly equal to .95 in inflation , Planck measured .96 as far Im aware.
All of this was written well after it was realised that inflation led to a multiverse.
We also discuss other ways to more directly probe for the multiverse (and not just bubble collisions which we also discuss) and in other films how to probe for alternatives to inflation.

My recollection of Steinhardt and Turok’s book “Endless Universe” is that inflation makes 6 predictions and 5 have been confirmed by experiment but the last hasn’t and they predicted it would fail at the last hurdle. Hence this justifies the notion of smoking gun. But they accepted it had past the first 5. This is the prediction B mode polarisation and primordial gravitational waves. In other words one could experimentally discriminate between inflation and the Ekpyrotic cyclic model by this signal assuming its from gravitational degrees of freedom in the early universe and not primordial magnetic fields, hence a detection of this signal would rule out this cyclic model and others cyclic models (Penrose’s CCC for example).

It would not rule out all competitors to inflation though. String gas cosmology would still be in the game. But string gas cosmology (according to Ali Nayeri who we interviewed) predicts a red tilt for the power spectrum and blue tilt for the gravitational wave spectrum whereas inflation predicts both should be red tilted. There may be an exception in some inflationary models but then they would predict other non guassianties. So the picture is more complicated than the smoking gun headlines implied but I believe it has some truth. In others words different inflationary does may predict different strength of the signal but a common feature is its tilt.

I think its clear inflation has built up a large body of evidence and is the leading horse in the race to describe the early universe. However it hasn’t crossed the finishing line yet and until then it its well worth exploring other alternatives. But these other alternatives are usually cyclic models which in some sense implies a world ensemble separated in time rather than in inflating space. It seems pretty much no one in this debate is arguing for a single universe from one big bang, that is a fact. Both sides that you quote in this controversy say there were multiple big bangs; the debate is, are they separated in time or space? This is something that I think is a very profound feature of this debate.

14. **Jonatan**
May 11, 2017

Do proponents of eternal inflation assert that all bubble/pocket universes of the multiverse are flat/isotropic/scale invariant/adiabatic etc… (I guess not since Guth says that “anything that can physically happen will happen an infinite number of times”)

Because if they don’t, then I don’t see how observing any of this in this universe can count as evidence of eternal inflation. After all, someone standing in another pocket universe that is not flat/isotropic/scale invariant/adiabatic (and there would be an infinite number of those) would then be forced to conclude that eternal inflation cannot be correct if these features are true predictions of eternal inflation…

15. **Peter Woit**
May 11, 2017

All,
I’m not competent or willing to moderate a general discussion of cosmology here. If you have knowledgeable comments specifically about the topic of the posting, please contribute them, I’m going to be deleting others.

16. **Shantanu**
May 12, 2017

Peter let me make a couple of sociological points. Its again sad that none of these articles menion (or interview) Demos Kazanas even though his 1980 paper says in plain English that accelerated expansion could solve the horizon problem. Also its interesting that there are people from Harvard on both sides of this debate
cosmology grad student : I think given any observations you can concoct any model of inflation. There are even models of open inflation (despite the claim that inflation

predicts \Omega=1)

17. **Urs Schreiber**
May 12, 2017

The key point that is underappreciated in discussions here is the one that Guth et al. make in their article, where it says.

> They contend, for example, that inflation is untestable because its predictions can be changed by varying the shape of the inflationary energy density curve or the initial conditions. But the testability of a theory in no way requires that all its predictions be independent of the choice of parameters. If such parameter independence were required, then we would also have to question the status of the Standard Model, with its empirically determined particle content and 19 or more empirically determined parameters.

Indeed, this is how physical theories make predictions generally: first to fix some of the parameters to specify a model in the theory (a solution), then the remaining properties of that model are its predictions.

If one took the standpoint that the *theory* as opposed to its models is to make fairly unique predictions as such, then none of the usual theories would fit.

The usual established theories (as opposed to the models built inside them) don"t even have large finite (say of cardinality 10^500) but have usually hugely non-finite-dimensional spaces of solutions.

Those readers who really think this is controversial need to pause for a moment to think about this elementary fact.

For instance the solution space to Einstein gravity, unconstrained, is humongously infinite dimensional and says nothing specific about the observable world, it doesn't make any predictions whatsoever — not before we pick in there a very low-dimensional parameter space of models, say the 3-dimensional subspace of simple FRW models. We pick such subspaces not for some *a priori* reason, but because we match these three parameters to experimental observation. The remaining properties of the FRW models within the theory of Einstein gravity, that is the predictions of this model.

Similarly quantum field theory as such makes virtually no predictions, not before some model is specified. The best that QFT by itself can say is that the universe is described by some local Lagrangian density on some space of fields such that quantum anomalies cancel. But the moduli space of all possible field species and all possible local Lagrangians on them, that's a humongously infinite-dimensional space. No prediction is to be derived from that alone. Predictions are only being derivable once loads of parameters are specified: First we specify (by hand, because it fits observation) the local Lagrangian density to be of Einstein-Yang-Mills-Dirac-Higgs-type, then we specify the exact particle species, then their Yukawa couplings and so on. Only once all these parameters have been fixed by hand does the theory start making predictions.

With the theory of cosmic inflation it is exactly the same.

This doesn't imply that cosmic inflation is right. But this means that if you think it is wrong for *this* reason, then you would have to regard every established physical theory as wrong, too. Because they all share this feature. A physical theory does not make predictions before models have been picked inside it, and they all admit alternative models that differ drastically from the one you want to pick because it fits observation.

18. **Peter Woit**
May 12, 2017

Urs,
You continually make this claim that two completely different things are "exactly the same", I'll just point out that this FAQ applies here

http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=isnt-string-theory-just-as-predictive-as-quantum-field-theory

19. **Jonatan**
May 12, 2017

Urs,

Steinhardt's point, unless I missunderstand him, is that generically, in an eternally inflating multiverse, even once you've chosen a specific inflaton potential and parameters, because of quantum effects, the values of observables such as spacetime geometry and the statistical distribution of CMB anisotropies, will take any possible values in the ensemble of pocket universes.

If that's correct, than how can specific values for these observables in our universe be considered "predictions" of eternal inflation as they usually are ?

What should people finding themselves in a pocket with open spacetime geometry or non-gaussian distributed anisotropies be expected to conclude about eternally inflating models ?

20. **Urs Schreiber**
May 12, 2017

> spacetime geometry and the statistical distribution of CMB anisotropies, will take any possible values in the ensemble of pocket universes.
>
> If that's correct, than how can specific values for these observables in our universe be considered "predictions" of eternal inflation as they usually are ?

To repeat, this is the usual state of affairs as it has always been: We make some observations about the universe around us ("pocket universe", if you really like to say that), fit a model of our theory to that set of data and *then* make predictions for all the *remaining* observations.

This is no different from how we predict anything, say the weather. We first measure the mess that we find ourselves in, then you apply theory to that to see how it evolves.

I find it bemusing that many participants here have effectively become strong Hegelians, demanding a derivation of the entire universe from pure thought alone, without experimental input, without model building, and complaining that available physical theories are not like this. They never have been.

Maybe one day we will have such a theory, and Hegel will be vindicated. It's a logical possibility that such a theory exists. But if it does, this will be cause of awe and amazement, not something to take for granted, while as long as it does not, everything is business as usual.

21. **Urs Schreiber**
May 12, 2017

Steinhardt et. al write here:

> The Planck satellite results […] are stunning. For the first time in more than 30 years, the simplest inflationary models, including those described in standard textbooks, are strongly disfavored by observations. Of course, theorists rapidly rushed to patch the inflationary picture but at the cost of making arcane models of inflationary energy and revealing yet further problems.

In view of the [remarkble likelyhood plot] that PLANCK15 produced (fig 12 in [PLANKC 15 XX "Constraints on Inflation"]), this is an unexpected statement. Right there in the middle of the plot sits Starobinsky's R^2 inflation, the first model for inflation ever proposed. The data does not significantly discriminate between Starobinsky inflation and other plateau-type inflationary models but it does prefer this class.

22. **Peter Woit**
May 12, 2017

Urs,
Which of the following possible alternatives do you think is more likely?

1. Ijjas, Steinhardt and Loeb are ignorant about basic facts of their subject like the one you are explaining here.
2. They aren't.

Personally I'm inclined to 2, and in general to the assumption that both sides in this argument know a lot more about the subject than I do (and than you do). Given that, it might be best to pay close attention to the technical counter-arguments each is making when they discuss the same issue and see if one can figure out what the story is there, leave the accusations of incompetence and not knowing what they are talking about to Lubos.

23. **Marc Nardmann**
May 12, 2017

Urs Schreiber wrote: "But the moduli space of all possible field species and all possible local Lagrangians on them, that's a humongously infinite-dimensional space. Only once all these parameters have been fixed by hand does the theory start making predictions."

We have to specify only the particle field species (leptons, quarks, gauge bosons, Higgs), the symmetry group (spacetime symmetries and internal symmetries), and how the particle fields transform under those symmetries. (This input is essentially discrete, not "humongously infinite-dimensional".) The Lagrangian density is then the most general function that is invariant under the group action; we do not have to put it in by hand. Its renormalisable part turns out to be determined by a small number of parameters (coupling constants, masses, …). Mathematically speaking, the Lagrangian arises from a theorem, not from a definition. This is considerably less arbitrary than it sounds in your description.

24. **Jonatan**
May 12, 2017

Urs Schreiber wrote: "We make some observations about the universe around us ("pocket universe", if you really like to say that), fit a model of our theory to that set of data and then make predictions for all the remaining observations."

With all due respect, I don't think you understand what the point is. As Peter said, I doubt that Steinhardt is that mistaken about the idea he co-invented.

If the model that fit the "local" data turns out to also produce every other conceivable data set, how could you ever test whether this is the correct model ? How do you know whether what you observe is a common or very unusual case within the infinite multiverse ? This is the measure problem that Guth et al. recognize and is unresolved to this day. To repeat, what should someone living in a non-flat, non-isotropic, non-scale invariant part of the multiverse conclude about the status of inflationary cosmology ?

Sure you've got a rich mathematical framework capable of modelling anything and everything, but what have you learned about our physical reality. In my view, precisely nothing.

You seem to think that this is a common situation in science but as far I know, this unfortunate problem is entirely peculiar to both string theory and inflationary cosmology.

25. **Anonyrat**
May 12, 2017

IS&L write at one of the links in this blog post (and thus answer Urs Schreiber):

What about the comparison to the Standard Model of Particle Physics? This comparision is a false equivalency. For the Standard Model, there are definite predictions for any choice of parameters. For Inflation, there is an infinite diversity of outcomes for any choice of parameters (i.e., for any choice of the inflationary energy curve). For example, for any one choice of parameters, an infinite number of patches of space in the multiverse are produced that are not flat, not smooth, and do not have the properties astronomers observe – and there is nothing in the inflationary theory to say that one outcome is more likely than the others. The same does not apply to the Standard Model of Particle Physics.

26. **Anonyrat**
May 12, 2017

Urs Schreiber wrote:

The data does not significantly discriminate between Starobinsky inflation and other plateau-type inflationary models but it does prefer this class.

Around minute 37 of his talk here http://vms.fnal.gov/asset/detail?recid=1944338 Steinhardt addresses this point. In brief, one must rule out all models with eternal inflation.

27. **Jonatan**
May 12, 2017

Indeed, the point I'm refering to is the one Steinhardt explains in the video Anonyrat mentionned, starting at 28:45 (the part around 35:30 is particularly relevant). He also talks about the measure problem starting around 37:50.

28. **srp**

May 12, 2017

I would like Urs to either respond to Anonyrat's quotation or admit that he was wrong in his insistence that inflation models are predictive in the same sense as the SM. It directly contradicts his claim that once you put in the parameters for an inflation model you get an unambiguous prediction of everything else.

29. **qwer1304**
May 13, 2017

It'd seem that the apparent necessary entailment of multiverse (multimess) is the strongest objection to inflation (as Steinhardt says himself). In that light, it'd be interesting to hear both parties' thoughts about V.Mukhanov's (who's actually the first who worked out quantum fluctuations source of matter formation in 1981 http://www.jetpletters.ac.ru/ps/1510/article_23079.pdf) model without self-replication https://arxiv.org/pdf/1409.2335.

30. **Anonyrat**
May 13, 2017

I've been trying to come up with the most sympathetic view that I can of postmodern science. The best I can do is as follows:

The framework of classical Hamiltonian mechanics is of interest because specific Hamiltonians are highly relevant to systems we observe or build. The framework of the Schrodinger equation is relevant because specific Hamiltonians are highly relevant to the real world. The framework of Quantum Field Theory is likewise useful, because specific field theories have proven to be highly predictive.

In postmodern science, it seems that the paradigm is that the framework will give rise to a myriad of scenarios, of which the scenarios relevant to our world are few and even relatively unlikely to arise. One might tolerate this if these postmodern frameworks could say – conditional on your pocket universe having these handful of properties, here is a plethora of other things the framework predicts for your pocket universe with no wiggle room.

The problem with the postmodern framework of inflation is that there is no plethora of predictions – as I see it, there are only a handful – and the wiggle room remains immense. The problem with the postmodern framework of string theory is that even with everything we know about physics – let alone a handful of facts – as given properties, there are no testable predictions; our sum total of knowledge is insufficient to unambiguously determine the string vacuum – there are no predictions, there remains a lot of wiggle room. However, these two failures do not mean that a tolerable postmodern theory cannot exist.

31. **Anonyrat**
May 13, 2017

To complete the above thought with a metaphor: a tolerable postmodern theory of physics must produce a "discrete spectrum" of universes, not a "continuous or near-continuous spectrum", otherwise there is always wiggle room, and one would have to stipulate an infinity of facts about our universe to fix our position in the "spectrum".

32. **Peter Woit**
May 13, 2017

Anonyrat,
I don't think discrete vs. continuous is relevant. What is relevant is the explanatory power of your theory: a good theory makes lots of non-trivial testable predictions based on a small set of assumptions or choices. A bad theory is one where for each testable prediction you need a new choice or assumption. The argument here is that inflation has moved to the bad theory side: Linde is quite explicit at times that what he is doing is developing versions of inflation that can match any new observation of B-modes, of non-gaussianity, etc. This was the question Guth was being challenged on and I don't think had an answer for: is "inflation" now completely insulated from falsification, and if so, is it still science?

I don't think using the term "postmodern physics" is a great idea unless it gets a well-defined meaning, otherwise it will just get thrown around as a sort of meaningless insult (or maybe, for some people, a badge of honor…)

33. **Jonatan**
May 13, 2017

It seems to me that one common feature of both string theory and inflationary cosomology is that in both cases, a new "piece of furniture" in physical ontology was invented (the string and the inflaton field) not because they were required to make sense of new observations that couldn't be explained by the existing physical objects making up the ontology of current physical theories, but rather to improve on existing theories by way of unification, the resolution of fine-tuning issues, etc…

I wonder if this kind of liberty (one might say self-indulgence) on the part of theorists is not the common "cardinal sin" responsible for the overabundance of degrees of freedom leading to multiverses and rendering both of these ideas ultimately meaningless scientificallly speaking.

34. **Peter Woit**
May 13, 2017

Jonatan,

An important aspect of the inflation story is that it's roots are in the study of the Higgs field, and more general uses of scalar fields to make viable GUT theories. What got people excited about the idea was not just the supposed explanations of otherwise hard to understand general aspects of cosmology, but the fact that these were coming from postulating not some random new thing, but something already being used for other promising purposes. I think Guth's original dream was that the same scalar field would break GUT symmetry and provide inflation, giving two completely different sorts of evidence for it, which would be very compelling.

The "cardinal sin" of introducing new degrees of freedom unrelated to anything else to explain something occurred later, as GUTs failed to work out (there are still proposals to revive connection to known physics, identifying the inflaton with the Higgs). ILS essentially claim that this has gotten worse in recent years, with the simplest models not working out, requiring what they call "postmodern inflation". One troubling part of research into inflationary models now involves introducing large numbers of new degrees of freedom, killing the explanatory power of simple models, and yes, that's properly something "sinful".

The story of string theory is unfortunately similar, as the models of the mid 1980s were understood to be problematic, and evolved into the absurdly more complex string landscape ones.

35. **Jonatan**
May 13, 2017

Thanks Peter for reminding me about the interesting history of the field. You're right that the initial connection between the use of scalar fields in GUT and the development of inflation shows that the idea was not without broader motivations at the beggining.

What always seemed suspect to me though was the ease with which fundamental physics since the early 1980's turned to claims about the existence of new ontological entities (strings, inflaton) without any direct empirical reasons for doing so.

I mean, the intelectual path do seem different to me than the way inferences for the existence of the rest of physical ontology (particles of the standard model, four dimensional spacetime, dark energy and dark matter) were made. That is, these inferences appeared much more directly related to our empirical experience of the world. In fact required in order to make sense of this experience.

May 13, 2017

This will run the whole weekend for sure. It's on RT right now:

https://www.rt.com/news/388245-big-bang-bounce-hawking-letter/

37. **Peter Woit**
May 13, 2017

Yatima,
Thanks, good to get a take on where Putin stands on this.

I wonder if the people who signed on to this letter thought much about what they were doing, whether backing Linde in a high-profile media fight was really a good way to defend the credibility of this field of physics.

38. **Jonatan**
May 13, 2017

Briefly restated, my impression is that theories are probably much more likely to end up in a "multimess" when they are based on an ontology invoked for theoretical convenience/ambitions rather than by empirical necessity.

39. **Art**
May 13, 2017

The original ISL critique (1304.2785) identified 3 issues, and spent the least number of words on the third, the eternal inflation implied by the data-favored plateau potentials. The specific criticism here was that the agreement of the Planck data with the nominal expectations of the models was "surprising" given infinitely many opportunities for large deviations. GKN (1312.7619) responded that there's no reason to think that large deviations are probable.

By contrast, subsequent discussion is heavily weighted towards the multiverse/multimess/multi-whatever. In my view, it's deviated substantially from the original topic.

40. **Bill Kuncik**
May 13, 2017

As a layman very interested in science, I think this debate about inflation has done a good job airing and evaluating the subject issues. But I have to tell you, the manner in which it is being conducted is, least in my opinion, creating a bad public impression of the physics community.

By my observation, from BICEP, to the stage of the World Science Festival in New York, to this latest exchange in Scientific American, and much in between, the expositions, pronouncements and exchanges have simply gotten too acrimonious, too personal, and too characterized by incendiary phrasings, media grandstanding, insufficient respect for the other's position, and perhaps even for the other. By both sides, and to an extent one does not ordinarily see in such matters.

Not by everyone, to be sure. But by enough to potentially discredit the enterprise of physics in the eyes of the public, which ultimately decides whether and how much to fund that enterprise.

As was the case with BICEP, this latest episode seems to be getting legs in the general media. So while everyone understands that you all are human too, and that science is political like anything else, please press the reset button and try harder to stick to the issues. For the sake of

41. **a 1**
May 14, 2017

"we question whether the consequence of an incomplete theory
can be legitimately called a 'prediction'

That's from a really nice paper about infinitistic arguments in today's physics:
1604.06773 "The infinite turn and speculative explanations in cosmology" by Reza Tavakol and Fabio Gironi

42. **Jonas**
May 14, 2017

As mentioned above Penrose has argued that inflation would just make the fine tuning problems for the initial stage of the big bang even worse.
He gives a semi popular description of these ideas in this lecture
https://mediacentral.princeton.edu/media/Fashion%2C+Faith+and+Fantasy+in+the+New+Physics+of+the+universe+-+Lecture+3A+FANTASY/1_xbikovdr

43. **Dave G.**
May 15, 2017

I just noticed that Ijjas et al. have put up a new page on their website that they call "FACT CHECKING."
It took me a while to wade through everything. But the page provides multiple examples of papers that contradict the claim that inflation has made predictions in the past that turned out to be successful.
For each prediction, there's a list of papers that claimed that inflation could also produce the opposite result. And it looks like those papers were all written before the observations were actually made.
To make matters worse — the authors of the papers include Guth, Linde, Kaiser and Hawking.
It doesn't seem fair to claim that inflation predicted something if you also showed that the opposite was possible – you can't just forget those earlier papers.

44. **skydivephil**
May 16, 2017

Peter , Im concerned about the use of the video where Guth says inflation is not falsifiable. I have only been able to find a very short version of the discussion and no

context. do you have the whole discussion available? if so would very much like to see it.
Im primarily asking because Loeb et l's critique is more focused on eternal inflation than inflation per se and Guth and Nomura have published a paper showing how eternal inflation could be falsified. This paper is discussed by Nomura in our video about that 49 56 seconds . https://www.youtube.com/watch?v=QqjsZEZMR7I
the link to the paper is here:
https://arxiv.org/abs/1203.6876
Its true that there are version of inflation that are not eternal but according to Guth they are contrived and according to Efstahtiou they are not favoured by the data.

45. **Peter Woit**
May 16, 2017

skydivephil,
The video where Guth says that is embedded in the Undark piece and you can there see it in context. I think it's just the usual "you can't falsify a framework, only models" argument that Urs Schreiber was making above.

For the Guth/Nomura article, there's a new blog posting…

46. **skydivephil**
May 16, 2017

Thank you Peter, but the video in the Unmark piece is only 40 seconds long. What I was looking for is the whole discussion. If you have a link to that, would be very much appreciated.

47. **Peter Woit**
May 16, 2017

skydivephil,
There's a link at undark, it's to this
https://www.youtube.com/watch?v=V6rUi65qLqc&t=121m2s

48. **skydivephil**
May 16, 2017

Thank you for that Peter look forward to watching it.

49. **Alexander**
May 17, 2017

There is an approach that excludes from cosmology the problems associated with inflation, dark matter and dark energy

This Month's Hype

May 16, 2017
Categories: Multiverse Mania, This Week's Hype

It seems that a couple of the authors of the recent Cosmic Controversy letter (discussed here) are going on a campaign to embarrass the 29 physicists who were convinced to sign their letter. Andrei Linde has gone to Lubos Motl's blog to thank him for his blog entry which lauded Linde as having eaten from the biblical tree of knowledge and which denounced his critics as imbeciles. To deal with Linde and his claims, Ijjas, Steinhardt and Loeb have added a new webpage to their website called Fact Checking. It lists the four "predictions" of inflation claimed to agree with experiment by Linde et al. and gives four references to papers published by Linde touting different "predictions" for the same quantities, predictions not agreeing with experiment.

This month's Scientific American has a remarkable cover story, The Quantum Multiverse from one of the other four letter authors, Yasunori Nomura. I've seen some fairly bizarre stories about fundamental physics in Scientific American over the years, but this one sets a new standard for outrageous nonsense, and I'm wondering whether it too may cause some of the 29 co-signers of the letter co-authored by Nomura to question the wisdom of joining with him and Linde. Nomura is well known for a definite prediction based on the multiverse: in 2009 he co-authored a paper claiming that the multiverse predicted the Higgs mass would be 141 GeV +/- 2 GeV. This played a major role in the film Particle Fever. That three years later the Higgs was discovered at 125 GeV seems to have had no effect on his multiverse enthusiasm.

The new SciAm cover story is not about anything new, but is based on a 6 year old paper by Nomura discussed here. At the time I wrote about this "I'm having trouble making sense of any of these papers" and quoted Lubos's evaluation: "They're on crack". Nothing I've seen about this over the past six years seems to me to make any sense at all, including the new SciAm cover story, which just seems even more content-free and meaningless than previous efforts to explain this "multiverse interpretation of quantum mechanics". On the obvious question: how would you test this, Nomura just has this to say:

> Evidence so far indicates that the cosmos is flat, but experiments studying how distant light bends as it travels through the cosmos are likely to improve measures of the curvature of our universe by about two orders of magnitude in the next few decades. If these experiments find any amount of negative curvature, they will support the multiverse concept because, although such curvature is technically possible in a single universe, it is implausible there. Specifically, a discovery supports the quantum multiverse picture described here because it can naturally lead to curvature large enough to be detected, whereas the traditional inflationary picture of the multiverse tends to produce negative curvature many orders of magnitude smaller than we can hope to measure.

This paragraph manages to put together three different misleading and unsupported claims:

- "If these experiments find any amount of negative curvature, they will support the multiverse concept because, although such curvature is technically possible in a single universe, it is implausible there." This is just nonsense.
- "the traditional inflationary picture of the multiverse tends to produce negative curvature many orders of magnitude smaller than we can hope to measure". What is the inflationary multiverse "prediction" for negative curvature? As far as I can tell it's compatible with pretty much any level we might observe.
- "the quantum multiverse picture described here because it can naturally lead to curvature large enough to be detected." I can't find anywhere a calculation of the negative curvature expected by the "quantum multiverse picture", and I don't believe any such calculation is possible.

Given some of the outrageous hype I've seen in recent years in respectable publications, it's gotten rather hard to shock me with this sort of thing, but I do find this Scientific American cover story shocking.

Update: For some reason this was not mentioned in the SciAm article, but the paper justifying Nomura's claims about negative curvature is here.

Update: A modest proposal: Given the situation, I think someone needs to write a letter to SciAm complaining about the Nomura article and get leaders of the community to sign in support of it. They could start gathering signatures by writing to the 29 signers of the earlier letter. If these people were willing to object to the Steinhardt et al. article, they should be willing to object to the far worse Nomura article.

Comments

1. **neil**
   May 16, 2017

   "Can Quantum Mechanics Save the Cosmic Multiverse?"

   Another example of Betteridge's Law of headlines?

2. **mitch**
   May 16, 2017

   SciAm doing this kind of thing doesn't surprise me at all. SciAm today is a far cry from what it was in the 70s when I was doing my Physics degree. These days if I want to read a sensible magazine about science I pick up a copy of American Scientist from our local bookstore.

3. **Peter Woit**
   May 16, 2017

   mitch,

   Yes, SciAm has changed since the 1970s, but so has the physics community, with pseudo-scientific claims like this about the multiverse unthinkable among serious physicists back then. This does seem to me to be a new low for SciAm, not clear whether this has to do with their own efforts, or whether they're just tracking theoretical physicists downwards.

4. **Pasa Dina**
   May 16, 2017

   The IS&L Fact Checking page has a link to an important lecture from Richard Feynman [https://m.youtube.com/watch?v=0KmimDq4cSU at 5:00 minute mark].

   When I listen to Feynman's discussion of "vague theories" and then read about the multiverse, it makes me wonder what Feynman would say about the inflationary theory if he were alive today.

   It's pretty clear now that inflation was always flexible about every prediction. The IS&L page points out that Linde even used inflation to predict the universe is curved – of course, that was before astronomers showed that it is not.

5. **Peter Woit**
May 16, 2017

Pasa Dina,

Whatever the argument over “inflation” I think it’s clear what Feynman would have to say about the multiverse. It’s a ridiculous situation that objections to multiverse pseudoscience are not coming from leading figures in the theoretical physics community. It’s their job, and they’re not doing it. Instead they’re supporting this pseudoscience by signing on to a letter supporting Linde and Nomura and arguing against a perfectly sensible Scientific American article by Steinhardt and co-authors.

Given the situation, I think someone needs to write a letter to SciAm complaining about the Nomura article and get leaders of the community to sign in support of it. They could start gathering signatures by writing to the 29 signers of the earlier letter.

6. **cosmology grad student**
May 16, 2017

You may find it “nonsense”, but the argument that curvature is implausible in a single universe based on the canonical measure over the space of cosmological histories is pretty conventional at this point, see e.g. https://arxiv.org/abs/1406.3057. I don’t necessarily want to defend the rest of what Nomura is saying, though…

7. **Koenraad Van Spaendonck**
May 17, 2017

Peter Woit : ” It’s a ridiculous situation that objections to multiverse pseudoscience are not coming from leading figures in the theoretical physics community. It’s their job, and they’re not doing it. ”

Well spoken. It shows a deep lack of responsability, not only towards the public, the community who funds them, but also towards young physics students, for whom they should be an example of what a serious scientific method is all about.

Whereas now this future generation of physicists become accustomed to the notion that it is ok to make claims with an air of despotism for decades while not providing real support from observations for those claims. And that endless ‘curve fitting’ is portrayed as a professional modus operandi in this context.

One could indeed speculate about Feynman’s take on this, but what about Einstein himself ? I think he would be seriously depressed by now if he had to watch this spectacle. I believe his words were ‘It’s adding Ptolemaic epicycles all over again’.

Respect for Steinhardt&co.

Best, Koenraad

8. **Peter Woit**
May 17, 2017

cosmology grad student,

That really is complete nonsense. Carroll’s long discussion of the “natural measure on trajectories” is just the usual Hamiltonian formalism of classical mechanics. Applying it to this question is nonsense since
1. You don’t have any reason to believe classical mechanics applies.
2. You don’t know what your phase space is.
3. You don’t know what your Hamiltonian is.

That anyone considers this a “pretty conventional” argument is deeply depressing.

9. **Another Anon**
May 17, 2017

Peter Woit: “A modest proposal: Given the situation, I think someone needs to write a letter to SciAm complaining about the Nomura article and get leaders of the community to sign in support of it.”

As you have said earlier, Peter, some sort of weird lettter-writing petition is no way to settle a scientific argument.

10. **Peter Woit**
May 17, 2017

Another Anon,
Yes, but I don’t think there’s any scientific argument in the Nomura article, it’s a different sort of problem facing the physics community than a bad argument.

11. **Mitchell Porter**
May 17, 2017

Scientific American sure can pick ’em… First they give a platform to Steinhardt et al’s campaign to smear inflation as unscientific; and then they make a cover story out of the worst “idea” in multiverse theory (I don’t just mean Nomura’s paper, it’s also dumb when Bousso and Susskind, and Tegmark and Aguirre, do it).

12. **Mitchell Porter**
May 17, 2017

P.S. Just to be clear, what I mean by “the worst idea”, is the idea that the technical problems of eternal inflation (measure problem, holography) are solved by introducing the many-worlds interpretation of quantum mechanics into the mix. The proof that it’s a bad idea may be seen in the papers that try to make it work.

13. **stone**
May 17, 2017

So far all the comments seem focused on the nonsense bullshit Sci. Ame. article. But, who are backing up the writers and their followers? From where have they got the money? Should funding agencies/academic departments/media be also held culpable, in addition to those big names? Would they prosper without any social/public support?

14. **DavisHalstoy**

May 17, 2017

Great Article in the Guardian today:

https://www.theguardian.com/science/across-the-universe/2017/may/17/multiverse-have-astronomers-found-evidence-of-parallel-universes

"One of the study's authors, Professor Tom Shanks of Durham University, told the RAS, "We can't entirely rule out that the Spot is caused by an unlikely fluctuation explained by the standard [theory of the Big Bang]. But if that isn't the answer, then there are more exotic explanations. Perhaps the most exciting of these is that the Cold Spot was caused by a collision between our universe and another bubble universe. If further, more detailed, analysis … proves this to be the case then the Cold Spot might be taken as the first evidence for the multiverse."

Yes, more detailed analysis is all that is needed.

15. **Anonyrat**
May 17, 2017

Since eternal inflation was introduced in 1983 and Feynman died in 1988, he might have actually said something about it.

16. **Alain**
May 17, 2017

The fact checking is the most pedagogical presentation of the subject of cosmology that I ever saw.

17. **atreat**
May 17, 2017

Peter,

Reading through that Carroll paper and your objections I am reminded of your often repeated wish that physicists would learn more from mathematicians about process and rigor. The assumptions in the paper are not stated clearly – e.g. what we don't know – and thus the impact on conclusions is similarly unclear.

As for Feynman, if he couldn't explain it to undergrads he didn't consider it properly understood it. That is where I think he would take issue with these current theories: he would object that even more that they have no footing in experiment, they do not help us truly *understand* anything about our physical world.

In this context, I think ISL and the rebuttal are really arguing over whether inflation and the multiverse theories have actually helped us understand something real or whether we are just as muddled about the things they supposedly help to explain as before.

Endless conjectures upon assumptions upon conjectures isn't real understanding and the limitless flexibility of these theories just means conjectures and assumptions all the way down.

18. **Sesh Nadathur**
May 18, 2017

DavisHalstoy:

That quote from Tom Shanks is laughable BS. It is complete and utter nonsense, unsupported by any actual rigorous analysis in his or any other published paper, to say that the Cold Spot supports the multiverse.

In fact it is worse than that, since even the claim that the Cold Spot is 'an unlikely fluctuation' in need of any 'explanation' at all is highly dubious. Put in language that HEP people will find familiar, it is only at most a ~2.5 sigma anomaly with respect to the standard cosmological picture even without accounting for a massive 'look elsewhere' effect in the analysis; any sensible consideration of this effect and the significance completely drops away.

A couple of relevant references: https://arxiv.org/abs/0908.3988 and https://arxiv.org/abs/1408.4720 (Figure 6 in particular), among others.

19. **Peter Woit**
May 18, 2017

Thanks Sesh!

I'm wondering whether there are any examples of media stories about the multiverse that are not nonsense, or whether the only accurate possible characterization of them is by degree of nonsense (with "laughable" about the median).

20. **Jeff M**
May 18, 2017

I'm curious, what does it say about the physics community that Nomura, who is a full professor at one of the top physics departments in the world, senior researcher at one of the most prestigious labs in the world, and principal investigator at a top institute, is writing papers which make no sense? No one seems surprised. Math profs at Berkeley don't write papers which make no sense. Math profs at my university don't write papers which make no sense, and I'm not at a research one school.

21. **Yatima**
May 18, 2017

Well, who is supposed to be the consumer of all this sound and fury, signifying nothing?

To the lay public, this would look disturbingly like a bunch of quackery, and not even a particularly good one. Information about astral projection, crystal healing, communication with the dead, ghost manifestations and cold spots in the attic can be had in dedicated magazines and tradeshows without having a tedious boffin spoil the show.

22. **Peter Woit**
May 19, 2017

I noticed that the Russian government news service is running the following story about this "proof of a multiverse" and how it ties in with string theory

https://sputniknews.com/society/201705181053755094-multiverse-astronomy-research-durham-university/

The source of these “utter nonsense” stories that do great damage to the credibility of science has always mystified me.

Maybe it’s all a Russian disinformation plot, designed to destabilize the Western (scientific) establishment, by spreading fake physics, and getting leading scientists to start fighting amongst themselves, writing “open letters” and the like. I can’t think of a more plausible explanation for the SciAm Nomura article…

23. **vmarko**
May 19, 2017

Jeff M.,

“Math profs at my university don’t write papers which make no sense”

I’m not so sure. Probably not at the same level as the multiverse/multimess, but still, there is this thing with Mochizuki’s proof of the abc conjecture that nobody seems to understand, and the computer-assisted proofs of various theorems that half of the math community doesn’t consider as “proper” proofs, etc. So math is also not completely insulated from social controversies.

Peter,

“Maybe it’s all a Russian disinformation plot, designed to destabilize the Western (scientific) establishment”

If only that were true, we would have much less of a problem. But alas, I think this “disinformation plot” actually comes straight from the very Western scientific establishment itself (or one part of it), probably trying to gain celebrity status in popular media, and maybe fool others into thinking that they deserve a Nobel or something… I fear that it’s a much deeper issue than mere political propaganda.

Best, 🙂
Marko

24. **Peter Woit**
May 19, 2017

vmarko,

I fear you are right about the origin of the “disinformation plot”…

But I don’t think there is any analog in the conventional math literature of things like Nomura and his “quantum multiverse”. It’s basically a sweeping claim about what fundamental physics is, backed by no sensible non-trivial idea. To get an analog in math, it would be something like papers claiming to solve the Riemann hypothesis by some incoherent invocation of Godel. Such things do exist, but they are ignored, don’t end up in respectable journals or Scientific American. And Mochizuki/abc really is something very different.

25. **vmarko**
May 19, 2017

Well, ok, I agree that the abc conjecture thing is probably not a good example. But the physics discussions “what constitutes proper science” and math discussions “what constitutes proper proof” (in the context of computer-assisted debates) seem to have quite a lot in common. Of course, there are also big differences as well, but still…

Best, 🙂
Marko

26. **Steven Rodgers**
May 19, 2017

Off topic, but can you comment on Bill Unruh’s latest paper (https://journals.aps.org/prd/abstract/10.1103/PhysRevD.95.103504) on Dark Energy – it’s been like a week and literally none of the blogs have picked it up given how massive this thing might end up being. I’ve gone through it, and while I don’t have domain expertise to determine whether all the assumptions and approximations are strictly valid, it seems pretty easy to follow and the result is striking. No more cosmological fine tuning problem and no more dark energy, and all done with relatively simple concepts that have been lying around for decades! Best, Steve.

27. **Peter Woit**
May 19, 2017

Steven Rodgers,

Sorry, this is off-topic and you need someone more expert than me in these issues about the CC. There’s a long history of claims of ideas of how to get rid of the CC (my roommate Nathan Myrhvold was working on one more than 30 years ago), none of which ever seem to have gotten significant acceptance. You could try Sabine Hossenfelder at Backreaction…

28. **Jeff M**
May 19, 2017

vmarko

There is an issue in math over computer assisted proofs, though it’s still pretty small scale. I was actually involved with one, there’s a well known proof, due to Viswanath, that random Fibonacci sequences grow exponentially which was computer assisted, published, accepted. The basic idea was Viswanath controlled round off error. A colleague and I came up with a very elementary proof of the same fact (you could explain it to a high school student), though we only got rough bounds on the growth rate, the computer proof gave a very good estimate. We, however, could generalize to more elaborate random sequences where you not only randomize plus/minus, but you allow for multiples of previous terms. In that case we got a sharp bound for when growth can occur (which again confirmed a computer estimate for the number, by Embree and Trefalyn).

I think it’s different than Nomura though, there are serious, long term discussions of what is valid, and why or why not.

29. **anon**
May 19, 2017

Does there really still exist significant controversy about computer-assisted proofs? In my experience some mathematicians could say that a proof requiring extensive computer calculations is perhaps not very beautiful or satisfying, but I don't think that they'd call it invalid.

30. **Peter Woit**
May 19, 2017

anon,
This is getting far off-topic, but no, I don't think that computer-assisted proofs are "controversial".

The controversy here over inflation is I think very different. The question at issue is whether scientists pursuing these models have made them so flexible that they now don't solve a problem they are advertised as solving (the fine-tuning problem) and can be fit to any conceivable new data, so "inflation" has become an idea immune to falsification.

31. **Another Anon**
May 20, 2017

My reading of the letter to Scientific American by the 33 was that the target audience was purely the editors – not for public attention, with a general feeling of trying to pressurise the editors: "Don't try anything like that again if you know what's good for you". I'll say no more, but I didn't like that side of it.

32. **Mitchell Porter**
May 20, 2017

I've just had another look at Nomura's 2011 paper and I want to moderate my earlier remarks somewhat. I do think that these attempts to apply the many-worlds interpretation of quantum mechanics to cosmology are seriously flawed. But there's another side to Nomura 2011, and to Bousso & Susskind 2011, which is the concept that de Sitter universes are metastable and eventually decay into a flat supersymmetric universe. It should be possible to get rid of the Everett-like many-worlds part of the argument, and replace it with a more conventional understanding of quantum mechanics. What would be left is just a physical hypothesis that could then be discussed sensibly.

33. **Peter Woit**
May 21, 2017

Mitchell Porter,
The problem is that most proponents of the "many-worlds interpretation of quantum mechanics" claim that they just mean conventional QM (state space + Schrodinger equation) applies to the whole system including the measurement apparatus. In the case of early universe cosmology, this is pretty uncontroversial, the default assumption is that it is governed by conventional QM.

With many-worlds, if you try in the non-cosmological case to start claiming this implies branching into multiple universes, you immediately run into the problem that you don't have a useful description of the branching process or how to characterize possibilities and how to count them. This is on top of the usual problems that you don't even know what space you are trying to put a measure on.

Sure, Nomura can claim that many-worlds applies in the cosmological case, but as far as I can tell it solves no problems, just introduces more issues you don't understand. If he were able to derive anything about the real world from this, that would make it worth paying attention and seeing what he is doing. Instead this seems to be a completely ill-defined proposal that leads nowhere. Again, why is such a thing on the cover of Scientific American???

34. **Jeff M**
May 21, 2017

Peter,

When you talk about early universe cosmology, do you just mean that in the early universe essentially the whole universe has a wave function? In essence, there is no measurement apparatus? If that's it, then how do you account for the first wave function collapse? I mean why wouldn't the universe just evolve as a wave function satisfying the Schrodinger equation?

35. **Peter Shor**
May 21, 2017

Can somebody (or somebody's friends) comment on whether *Scientific American* papers in biology, chemistry, or some other non-physics field have undergone a substantial drop in quality over the last few decades. Then we'd know whether this phenomenon stems from the high-energy physics community, or from the editors of *Scientific American*.

36. **Peter Woit**
May 21, 2017

Jeff M,
The "many worlds interpretation" is basically just the claim that there is no wavefunction collapse, that you can make sense of quantum mechanics without invoking that as something separate. As far as I can tell, saying "I'm going to use the many worlds interpretation to do cosmology" is an empty statement, since that's what people already were doing, since there is no separate experimental apparatus. It's not surprising then that his supposed "prediction" is the same one already in Susskind's book about the string landscape over a decade ago.

37. **Anonyrat**
May 21, 2017

Here is a 2007 article decrying SciAm publishing an article by Peter Duesberg (full context in the article):
http://sandwalk.blogspot.com/2007/04/demise-of-scientific-american.html

38. **Anonyrat**
May 21, 2017

Here is a 2010 article concerned about a decline in the quality of SciAm coverage of climate change:
http://www.sourcewatch.org/index.php/Scientific_American

39. **Jeff M**
May 21, 2017

Peter,

So now I'm confused. From what I remember, many worlds says that when the wavefunction would collapse, it doesn't collapse, it splits, possibly into many separate wave functions. All of which go on happily evolving according to Schrodinger until they split again. So no collapse, but something takes it's place, and has an effect on the universe (which is just bigger than the normal one, since it contains many copies every time there's a split). So it eliminates collapse, that's true, but in cosmology, where people don't think about collapse I guess since there's no observer, there is a single strand in the universe, and under many worlds there are many many strands, all separate and unable to communicate with each other. And in each strand it LOOKS like the wave function collapses, right? That's the whole point, you can't possibly tell, many worlds is pure interpretation, and can't ever be shown to be false.

40. **Peter Woit**
May 21, 2017

Jeff M,
I really don't want to try and get into the details of quantum mechanical interpretation issues, and exactly what different people mean when they say "many worlds", there are lots of places you can read about that, it's a complicated story. Maybe some day I'll write a post about that, especially if I run across something that explains the issues well. As I wrote earlier, I don't see how taking those complexities into account helps at all with the conventional cosmological multiverse problems, and that's what Nomura seems to be claiming.

41. **Anon**
May 22, 2017

The reason SciAm publishes these articles is because they are losing money. Controversy sells. If academics want impartial publications they should tell their universities board of directors to form an association with other universities and buy SciAm as well as other important magazines, (they will never be cheaper then they are now). Universities are rolling in cash (look at football coaches salaries) they can afford to support these magazines. If you have an association of ten or more schools you can avoid the problems of arxiv.

42. **Peter Woit**
May 22, 2017

Anon,
These days universities (at least in the US) are looking for ways to make more money, not money-losing operations to take over. Foundations like the Simons Foundation are the organizations not looking for profit-making opportunities. They already have Quanta magazine, and maybe the way the world is going, they'll start playing the role that SciAm used to play.

43. **AcademicLurker**
May 22, 2017

I was just about to mention Quanta. Between that and their support for the arxiv, it's impressive how much the Simons Foundation has done for physics and science in general.

Nautilus is another magazine that's been successfully operating in the same space as Quanta, although I've heard that they are feeling some financial pressure lately. It's a bit depressing to think that having a billionaire patron is the only way to run a non-hype driven popular science magazine.

44. **Low Math, Meekly Interacting**
May 22, 2017

Peter is very generous to let the readership off the hook, but I think we bear some responsibility. The wisest thing to do with clickbait is ignore it, hence putting a disincentive on producing it. But does the typical reader resist that urge? Of course not. I'm just as guilty as anyone. Even when we know it's complete B.S. we find it hard to resist.

I resolve to try to do better.

45. **Roofus McLoofus**
May 22, 2017

This story has reached a mainstream outlet:
http://www.cnn.com/2017/05/14/opinions/what-explains-the-universes-cold-spot-lincoln/index.html

I'm not the least bit interested that it's a "literally cool idea": I seriously considered about the level of intellectual hygiene reaching the public. What are us outsiders missing? Should we keep our mouths shut and let this run its course?

46. **Tim**
May 22, 2017

Verlinde has now made it to ArsTechnica:

https://arstechnica.com/features/2017/05/emergent-gravity-and-dark-matter-explained-by-excited-universe/

It even mentions the false idea that glass flows, albeit slowly. The quality of popular science reporting is going down in general, I think.

47. **anon2**
May 23, 2017

Re analogous controversies in math:

In math, there is usually no real controversy about truth. That is, computer-assisted proofs are accepted as correct (maybe not enlightening), and the general notion of correctness in mathematics has not really changed since the 20s.

Instead, we mathematicians fight over "elegance", "relevance", whether "this is how you should view this". And yes, in my opinion there are entire subfields in mathematics that have lost touch with reality and produce mostly bullshit. For example the community that does "mathematical neuro-stuff", i.e. coupled oscillator networks, chimera states, etc appears to be pretty bullshit (to me). This does not mean that the claimed theorems are wrong, but it means that the "claimed motivation" is wrong: The theorem might be correct, but it is irrelevant and only pursued in order to follow the latest funding fads; it makes no progress at all for the actual questions that are claimed as motivations.

There is no shortage of true theorems in mathematics; the difficulty lies in deciding what questions to ask, and (progressing towards) answering these relevant questions.

Also, see thurston “on proof and progress in mathematics”. It is quite clear that many computer-assisted proofs provide no real insight. People can rightfully argue that generating insight is a large part of what it means to be a mathematician; hence, it makes sense to be dissatisfied with some computer-assisted proofs. On the other hand, some computer-assisted proofs contain a lot of insight!

GAMBIT

May 23, 2017
Categories: Uncategorized

The LHCP 2017 conference was held this past week in Shanghai, and among the results announced there were new negative results about SUSY from ATLAS with both ATLAS and CMS now reporting for instance limits on gluino masses of around 2 TeV. The LHC has now ruled out the existence of SUSY particles in the bulk of the mass range that will be accessible to it (recall for instance that pre-LHC, gluino mass limits were about 300 GeV or so).

Over the years there has been an ongoing effort to produce "predictions" of SUSY particle masses, based on various sorts of assumptions and various experimental data that might be sensitive to the existence of SUSY particles. One of the main efforts of this kind has been the MasterCode collaboration. Back in 2008 before the LHC started up, they were finding that the "best fit" for SUSY models implied a gluino at something like 600-750 GeV. As data has come in from the LHC (and from other experiments, such as dark matter searches), they have periodically released new "best fits", with the gluino mass moving up to stay above the increasing LHC limits.

I've been wondering how efforts like this would evolve as stronger and stronger negative results came in. The news this evening is that they seem to be evolving into something I can't comprehend. I haven't kept track of the latest MasterCode claims, but back when I was following them I had some idea what they were up to. Tonight a large collaboration called GAMBIT released a series of papers on the arXiv, which appear to be in the same tradition of the old MasterCode fits, but with a new level of complexity. The overall paper is 67 pages long and has 30 authors, and there are eight other papers of length totaling over 300 pages. The collaboration has a website with lots of other material available on it. I've tried poking around there, and for instance reading a Physics World article about GAMBIT, but I have to confess I remain baffled.

So, the SUSY phenomenology story seems to have evolved into something very large that I can't quite grasp anymore, perhaps a kind reader expert in this area can explain what is going on.

Comments

1. **Mitchell Porter**
   May 24, 2017

   It just seems to be a software library that allows you to do parameter fitting and likelihood estimation, for a variety of BSM field theories, in a standardized way.

2. **Peter Woit**
   May 24, 2017

   Mitchell Porter,
   I can see that much. What I don't understand is what is new about this, how this is different than previous efforts like MasterCode. What will this do that MasterCode didn't and why do the assumptions built into seem to be of a higher level of complexity than MasterCode?
   I guess part of what I don't understand is that I would have expected that, as stronger and stronger LHC bounds rule out more and more of these kinds of models, I'd expect people to lose interest in this kind of thing, whereas instead we seem to be seeing a larger and larger group of people working on it.

3. **Ryan**
   May 24, 2017

   Yeah and apparently these efforts are well received by the pheno community. Here are some random tweets that popped up in my timeline:

   https://twitter.com/HEPAdelaide/status/867258318770683904
   https://twitter.com/Tristan_duPree/status/867259714496757760
   https://twitter.com/suchi_kulkarni/status/867273017474375680
   https://twitter.com/SaschaCaron/status/867301364904456193

   Maybe the last tweet sums up the mindset behind this kind of work: "Yes, nice to see people moving to more complex models."

   No idea, what's nice about "more complex models". However, from a naive perspective it seems to make sense that the new bounds require more effort on the "model builder" side and thus more complex fitting codes…

4. **Peter Woit**
   May 24, 2017

   Ryan,
   Thanks. That captures part of what is confusing me here. What is the reason for "more complex models"?

5. **vmarko**
   May 24, 2017

   Peter,

   I think you are right to expect people to lose interest in this stuff, but it feels that you are a bit ahead of time. Losing interest will happen eventually. It's just that some people are hard to give up, and SUSY models will take some more time to drop out of fashion, IMO.

   Best, 🙂
   Marko

6. **Peter Woit**
   May 24, 2017

   vmarko,
   Yes, but that's not what I find hard to understand about this project. Looking at their papers I see as output various computed "likelihood" profiles of various quantities, but I find it hard to figure out what assumptions go into these and what their significance is. If the LHC tells you the gluino is above 2 TeV, what is the significance of a likelihood profile for where the mass is supposed to be above 2 TeV? More precisely, take a look at page 8 of this presentation
   https://indico.cern.ch/event/571190/contributions/2377454/attachments/1387436/2112013/Kvellestad_GAMBIT_LHC_recast.pdf
   about GAMBIT, explaining their take on how to perform a "global fit". There seems to be so many assumptions and so much complexity built into this fit that I have no

idea what it's significance would be.

I'd rather not have a discussion of the usual issues of SUSY sociology, am curious about this new development.

7. **Ben**
May 24, 2017

GAMBIT and MasterCode have overlapping capabilities – they're two different collaborations working on similar things. One difference is that GAMBIT is open source and seems to have everything up on GitHub. To some people this is a big deal. It maybe also incorporates a few extra codes that MasterCode doesn't, but that's less clear to me.

I would usually take "more complex models" to mean more complexity in the phenomenological modeling and likelihood computations, not necessarily more complexity in the fundamental theory. Usually when a theorist comes up with something new the first things one does are quick first-order calculations on what parameters are allowed. But this usually doesn't include a deep understanding of experimental systematics, cross-experiment effects, etc. That's where these sorts of codes come in.

Disclaimer: I'm not involved with either project.

8. **Jake**
May 24, 2017

Peter,

do you know the essay "Effective quantum field theories" by Georgi in "The New Physics" edited by P. Davies, where he writes about "how theoretical particle physics works as a sociological and historical phenomenon?"

It's from 1989, but I only recently stumbled upon it. I think it describes nicely the situation nowadays and it helps to understand what people are currently doing in particle physics. I quoted it, and wrote about it here: http://jakobschwichtenberg.com/making_sense/ (at the end of the post)

The most relevant part is probably: "During such periods, without experiment to excite them, theorists tend to relax back into their ground states, each doing, whatever comes most naturally. As a result, since different theorists have different skills, the field tends to fragment into little subfields."

9. **Vognet**
May 24, 2017

Peter, as an analogy GFITTER and other groups were doing similar fits for the standard model long before the Higgs was discovered, and such fits gave best fit points for a standard model Higgs mass (and other best fit points could be obtained for a non-standard higgs) that kept moving up and up as they were excluded. Now imagine a world where the limitations of technology only allowed you to go up 5 GeV at a time after passing 90 GeV, and the construction of such a machine would take a decade each time. Each decade you would get discouraged that the Higgs didn't show up around the corner yet again, and eventually blogs like yours would start saying we had it all wrong, the arguments for the Higgs being light were nonsense, updating these fits is pointless, and we should just accept that experiment is telling us so. But discouragement is a human prior placed with a human timescale and dependent on human technology; in reality the Higgs mass will be what it is independently of this. In our actual world, that it "only" took us almost half a century to discover the Higgs is fortunate but didn't have to be so, and the arguments for why the Higgs had to be there would have remained the same as what they were from the start regardless of the accumulation of null searches.

Now before you say the situation was different with the no lose theorem of the Higgs guaranteeing some discovery, I am not talking about the motivation for building a higher energy collider, I am talking about the motivation for a fit to a model beyond what is currently known to get a statistical inference on what the indirect constraints are on such a model. This is how science proceeds in the "confronting theory to data" phase, and in the hypothetical world where we go up 5 GeV every decade it would still be motivated to update fits for not just the standard model Higgs, but all kinds of non-standard Higgs models, and even higgsless models, because we still wouldn't know what lies at those energies up there, and what lies there doesn't care that naysayers are getting impatient and tired of seeing updated fits with best fit points that keep moving up.

As for GAMBIT it's just a tool for doing such statistical inferences that is routine in all areas of science from biology to astrophysics and particle physics, I'm not sure what your bafflement is at this. It's like if years ago Stephen Wolfram released a new-fangled software called Mathematica with ten example notebooks, one of which was a SUSY calculation, and you were similarly perplexed at why someone bothered writing an algebraic package to do a calculation in general that a SUSY group already did for their SUSY case before, and since you don't care much for SUSY your reaction is to ask what is the point?

10. **Peter Woit**
May 24, 2017

Vognet,
I don't really see the analogy with Gfitter, something I do more or less understand. There essentially you had a model with one undetermined parameter, lots more measurements than parameters, some of which were weakly sensitive to the undetermined parameter, so you'd expect to have some information that could be used to get a sensible "best fit" for the undetermined parameter. Gfitter was giving best fit numbers for the Higgs even without using the direct search exclusions (96 +31 -24 in 2011) and if you dug around a bit you could see which measurements had some sensitivity to the Higgs mass and were giving non-trivial information, and at what point the SM would break as direct search exclusions eliminated that range from the bottom (in 2011 the best fit using direct search exclusions was 120 +12 -5).

What's the analog for a GAMBIT "best fit" for the gluino mass? I understand that they are using direct search exclusions, but all those can do is tell me a lower bound on the gluino mass, not give a non-trivial "best fit" somewhere. What are the experimental measurements (other than direct searches) indirectly sensitive to the gluino mass that are giving non-trivial best fit information? I understand there must be some such information, but what I'm mainly saying here is that I can't get this from their description of what they are doing, since it is so complicated and the number of undetermined parameters is high. In the case of MasterCode, with a quick look at their papers I could see that they were getting information like this from certain specific deviations from the SM, eg. g-2 for the muon and see the relation to a non-trivial best fit. A similar quick look at GAMBIT just leaves me perplexed about what exactly they're doing and wondering whether there's anything going on here besides the direct search exclusion regions and artifacts of their assumptions and various choices.

11. **M**
May 24, 2017

Can somebody highlight one interesting result in these many papers?

12. **Tim**
May 24, 2017

If I understand Peter correctly, his objection is basically that among models in a particular class that are not excluded by experiment, what is the motivation for justifying that certain parameters that are compatible with experimental constraints are more probable than other parameters that are also compatible with experimental constraints?

Absent some a priori assumptions like naturalness, there is no justifiable probability metric for non-excluded theories, and the LHC results seem to be strongly hinting that naturalness, as understood prior to the LHC results, is not particularly useful in predicting future experimental results.

13. **Peter Woit**
May 24, 2017

Tim,
I need to keep emphasizing that my problem here really is the complexity of the choices being made, more than any particular choice itself. If you do a simple analysis with one or two simple choices, a human being may be able to understand how the result depends on the choices, and have an interesting discussion about the choices. In this case, when I try and read these papers, the sheer complexity of the choices being made cause me to get lost very quickly, with no feel for which choices might be important. For example, looking at the analysis done for the MSSM here,
https://arxiv.org/abs/1705.07917
right at the beginning in table 1 the authors list 7 different parameters they intend to scan over, with no particular motivation for the ranges chosen, and the priors chosen, which are listed as "flat", "hybrid" and "split hybrid". That's just the beginning, going on from there things get really complicated, and no human being I think will be capable of figuring out how the complexities being invoked are reflected in the final results.

If you have a really complicated problem, with really complicated data, it's understandable that you might get involved in very complex analyses. The question in my mind is whether going down that path here sheds light on the questions supposedly being addressed. M's question about whether this leads anywhere interesting is to the point.

14. **G. S.**
May 25, 2017

I'm guessing that the real point of this work is to provide a project for a group of high energy physicists that teaches them the skills they will need when they quit high energy physics and look for jobs in data science/machine learning/software engineering.

That seems to be the path a lot of physicists are taking these days.

15. **Mitchell Porter**
May 25, 2017

Stacy McGaugh describes the situation in astrophysics, as one in which elaborate models of galactic dark-matter dynamics come with numerous opportunities for post-hoc fine-tuning, while the many successes of a simpler, more principled theory (MOND) are relatively neglected.

I can certainly see the potential for this software package to sustain an analogous situation in high-energy physics, though perhaps it's not as clear what simpler opportunities are being missed (Koide relation, Higgs criticality?). But I wonder how flexible it is. Could this package be useful for people working on quite different models, like discrete flavor symmetries in neutrino physics?

16. **Peter Woit**
May 26, 2017

All,
MOND is off-topic here. The last thing the world needs is another source of dubious claims from non-experts about that.

17. **photongrapher**
May 26, 2017

Peter you seem to have put little time in trying to understand what they've done here. This is not just about SUSY, GAMBIT can be used for any BSM physics.

I understand the desire for a simple statement of "gluions are excluded below 2TeV", but they are taking a more nuanced approach. While the former contains a whole bunch of assumptions, their approach is trying to allow a simple way to explore what is possible in BSM theories. In the absence of BSM observations, it is necessary to be more 'complex' so that instead of making statements like:
"there is no SUSY <2TeV*"
(*where SUSY = MSSM and the LSP is all the DM.. etc),
They might be able to more concretely say:
"there is no SUSY <1TeV PERIOD"

18. **Peter Woit**
May 26, 2017

photongrapher,

Yes, I've put some but not a lot of time into trying to understand what they've done here, the question in my mind is why it might be worth putting in more time. I do understand this is meant as a general tool, not just for SUSY theories. The gluino was just taken as an illustrative example.

I also understand the use of this tool to scan for regions of SUSY parameter space not yet ruled out be experiment, assume that's always been an active area of phenomenology research with various tools available, maybe this one is better, I don't know.

What I don't understand is, for instance, most of the plots in
https://arxiv.org/abs/1705.07917
which are giving relative likelihoods and "best fits" for SUSY masses not in some corner of parameter space that people are trying to rule out, but at generic values way above the experimentally observable range. What is the point of these? Do they make any sense?

19. **Mitchell Porter**
May 30, 2017

"GAMBIT Is Incomplete But Furthers SUSY Falsification":

http://dispatchesfromturtleisland.blogspot.com/2017/05/gambit-is-incomplete-but-furthers.html

20. **Henry McFly**
May 31, 2017

Peter,

Table 3 on that paper shows the contribution of each term used in the likelihood to the total. The results are also shown separately for each mechanism that gives the correct dark matter relic density. LHC sparticle searches don't contribute since there is nothing observed yet, but Higgs discovery and b-physics do contribute a lot, so does Fermil-LAT gamma ray observations.

A Few Quick Items

May 31, 2017
Categories: Multiverse Mania, Uncategorized

I've had little time for blogging, and coincidentally, there seems to be little to blog about recently. Here though are a few quick items:

- Several people had asked me about this paper about the CC, and I had to tell them that this was not something I could evaluate. Luckily, Sabine Hossenfelder has read it and thought about it carefully, and discusses the problems with this sort of thing here. The physics community owes her a great debt.
- The LHC is back in business, with intensity starting to ramp up. You can follow progress here. This summer should see release of more results based on last year's run, results from this year's run likely will not appear until early next year.
- Inference magazine has a thoughtful piece in the latest issue by Adam Falkowski (AKA Jester) about prospects for the future of HEP physics. The same issue also has a piece by Aurélien Barrau about the implications of the failure to find the "natural" physics some expected SUSY to provide.
- Hironaka has recently put on his website a document intended to give a proof of resolution of singularities in characteristic p. For some background and links to explanations of what this is about, see mathoverflow. Evidently Hironaka has been working on this proof for quite a few years, this is the first complete version to be made public. Sometime in the next few months it should become clear whether this proof will really work, as experts get a chance to go through it carefully. If it does work, it will be a remarkable story, especially since Hironaka is now 86.
- Maybe I'm the last one to find this out, but for quite a few years now MIT has been making public detailed course materials including lecture notes from many courses in mathematics and physics.

Update: For the obligatory Multiverse Mania item, see this interview with Lord Martin Rees. Rees is rather proud of himself for leading the field of theoretical physics to embrace Multiverse Mania, quoting Frank Wilczek as claiming at the end of a conference that:

> five years ago we were a beleaguered minority, whereas now, he and I and others had led many other people into the wilderness.

Besides his belief in the multiverse, he also believes this is what we have in our future:

> I don't think Elon Musk is realistic when he imagines sending people a hundred at a time for normal life because Mars is going to be far less clement than living at the South Pole, and not many people want to do that. I don't think there will be many ordinary people who want to go, but there will be some crazy pioneers who will want to go, even if they have one-way tickets.
>
> The reason that's important is the following: Here on Earth, I suspect that we are going to want to regulate the application of genetic modification and cyborg techniques on grounds of ethics and prudence. This links with another topic I want to come to later about the risks of new technology. If we imagine these people living as pioneers on Mars, they are out of range of any terrestrial regulation. Moreover, they've got a far higher incentive to modify themselves or their descendants to adapt to this very alien and hostile environment.
>
> They will use all the techniques of genetic modification, cyborg techniques, maybe even linking or downloading themselves into machines, which, fifty years from now, will be far more powerful than they are today. The posthuman era is probably not going to start here on Earth; it will be spearheaded by these communities on Mars.

Update: Another black hole merger detection from LIGO announced today, some commentary here and here.

Comments

1. **JohnA**
   May 31, 2017

   The Falkowski article criticizes the future collider program (100 TeV pp) for:
   -) lack of clear physics target
   -) required monetary/time investment

   He instead advocates for more cheaper, faster indirect searches.

   One major (and obvious) thing his article/argument misses is the intermediate Higgs factory step in the path for a ~100 TeV pp collider.
   This is major piece of the program for both of the proposed next generation ~100 TeV colliders (CERN/China).

   Compared to his 100 TeV straw-man, the Higgs factory is a cheaper, faster indirect search with a clear and obtainable physics goal; order of magnitude, or better, improvement on higgs coupling measurements.
   It also has the advantage of being able to be recycled into a 100 TeV machine if it indirectly sees signs of new physics or we find a convincing argument for 100 TeV in the mean time.

   The decision is not 100 TeV or a bunch of indirect measurements. If there is choice to argued over, the option the future collider program is: Higgs-factor + future option on 100 TeV. Falkowski's discussion largely irrelevant as it completely neglects this real choice.

2. **Peter Woit**
   May 31, 2017

   JohnA,
   The problem is that a Higgs factory isn't cheap. The Higgs factory proposals involve the same huge tunnel as for the 100 TeV machine. The cost of the tunnel + ee machine + detectors I would think would be a significant fraction of the cost of the 100 TeV machine. I haven't seen cost estimates for either the FCC-ee or FCC-pp, but these are going to be very large numbers, and that's the problem.

   Actually I think one motivation for the FCC-ee is to divide the FCC-pp cost into two pieces and spread it out over a longer time. It's not at all clear the FCC-ee would be worth it if the plan was just to build it and then stop, rather than go on to the pp machine.

3. **Bee**
   June 1, 2017

   Thanks for the link. (That paper caused me quite some headache.)

Isn't it funny how much the two inference pieces [sound like this blogpost I wrote last year]?

4. **vmarko**
June 1, 2017

Regarding the latest CC-problem-solving paper — it seems to me that the CC problem is a social problem, rather than a physics problem. Namely, every now and then there appears a new paper proposing yet another resolution of the CC problem, so much that by now almost every hep-th physicist has their own favorite solution (myself included). And while all these papers offer worthwhile insights into the CC problem and interesting ways to resolve it, none of them produces a "Wow!" moment from the whole community, and most of the proposals end up being anticlimactic in one way or another.

At best, some part of the hep-th community (slightly larger than just the paper authors) will get excited about any particular proposal, while others will find it unsatisfactory on various grounds (mostly aesthetic), and over time everyone forgets about it until the next proposal comes along.

I don't see this paper being any different, except for a big name like Unruh making it more likely to catch some wider attention.

Everybody is waiting for a paper which will make the whole community say "Oh, look, this is how it should be answered, we were all so dumb, but now it's so obvious!". However, such a paper will never appear — not because existing proposals aren't convincing enough, but because the people in the hep-th community have various (often contradicting) ideologies, and they will never agree on which solution is satisfactory.

So the CC problem is a social problem, unlikely to ever converge to a consensus solution, no matter how ingenious proposals people offer.

Best, 🙂
Marko

June 1, 2017

Adam writes in his article:

"The possibility that the LHC will only further confirm the Standard Model is often referred to as the nightmare scenario"

I've never understood this pessimism from the physics community. The fact is, a new particle has been discovered in the Higgs, and the LHC will increasingly probe its properties over the next two decades. If nothing is found, theoretical physicists will just need to accept the completion of the periodic table for elementary particles is possibly in the distant future, as was done for the periodic table of elements recently:

http://www.futurity.org/periodic-table-new-elements-1087782-2/

6. **Low Math, Meekly Interacting**
June 1, 2017

It's hard to install your own cybernetic implants and kiss the Singularity when you're suffering from cosmic-ray-induced dementia. I don't think even crazy pioneers are going to be interested flying all the way to Mars only to live underground the great majority of the rest of their significantly shortened lives.

Multiverse mania seems to be a more general syndrome than its name would suggest.

7. **Andre T**
June 1, 2017

A Higgs factory would likely be e+ e- machine. For a a 125 GeV higgs, the production cross section is around root(s) = 250 GeV or so. (To measure Higgs BRs, gauge boson couplings). Quartic coupling is optimally measured at around 450 GeV, IIRC.
The t-tbar threshold is 350 GeV. Worth spending some luminsity there as well

This is a very viable 30 year program for a upgradeable linear collider whose cost compared to a 100 TeV machine would allow pushing the precision frontier simultaneously…

8. **Peter Woit**
June 1, 2017

Andre T,
The problem with a Higgs factory linear collider is the same problem as that of a circular collider in a 80-100km tunnel: estimates of the total ILC cost come to about $20 billion, a very big number (the yearly power costs would also be high).

The linear collider would have the advantage that you could imagine upgrading it to higher energy, the circular collider would have the advantage that you could reuse the tunnel for a 100TeV pp machine.

There are good arguments to be made for either possibility, and the ideal thing for physics would be to build both. The basic problem though is that of how to pay for such a thing.

Peter wrote:
>Maybe I'm the last one to find this out, but for quite a few years now MIT has been making public detailed course materials including lecture notes from many courses in mathematics and physics.

Peter, I'll add that my kids worked through, with my help, Anant Agarwal's "Circuits and Electronics" (edX 6.002X) and Christ Terman's "Computation Structures" (6.004X). Both courses are online videos, homework, and exams, not just course notes (Agarwal's is videos of him lecturing, Terman's is more of a PowerPoint-like format with audio of Terman speaking).

Terman is a very good teacher. Agarwarl, who is apparently the moving spirit behind the MIT series of courses (which has now become edX), is a truly brilliant teacher, in my opinion in the same league as Feynman (I took a couple of classes from Feynman as an undergrad).

Any physicist who expects to end up doing electronics (and many will after going out into the real world) should consider going through these courses. And, we should urge any bright high-schoolers we know also to work through some edX courses.

MIT, and especially Anant Agarwal, have really made a great educational breakthrough with these online courses.

The arguments and conclusion by Adam Falkowski immediately reminded me of “Six cautionary tales for scientists” by Freeman Dyson from 1988. Dyson compares 6 situations where people had to decide between a Plan A = several small projects vs. a Plan B = one huge project.

He discusses the SCC (” an extreme example of Plan B”) and concludes: “My Plan A for the future of particle physics is a program giving roughly equal emphasis to the three frontiers. Plan A should be a program of maximum flexibility, encouraging the exploitation of new tools and new discoveries wherever they may occur. To encourage work on the accuracy frontier means continuing to put major effort into new detectors to be used with existing accelerators. To encourage work on the rarity frontier means building some new accelerators which give high intensity of particles with moderate energy. After these needs are taken care of, Plan A will still include big efforts to move ahead on the energy frontier. But the guiding principle should be: more money for experiments and less for construction. Let us find out how to explore the energy frontier cheaply before we get ourselves locked into a huge construction project.”

Multiverse Politics

June 1, 2017
Categories: Multiverse Mania

The political campaign for the multiverse continues today with a piece by Amanda Gefter at Nautilus. It's a full-throated salvo from the Linde-Guth side of the multiverse propaganda war they are now waging, with Linde dismissing Steinhardt's criticism as based on "a total ignorance of what is going on". All of the quotes for the article are on the pro-multiverse side. There is a new argument from them I'd never heard before: Guth comes up with this one:

> You can create a universe from nothing—you can create infinite universes from nothing—as long as they all add up to nothing. Not only is that a deep insight, it also creates a testable prediction. "Eternal inflation certainly predicts that the average density of all conserved quantities should be zero," Guth says. "So if we ever became convinced that the universe has a nonzero density of electric charge or angular momentum, eternal inflation would no longer be an option."

The article is subtitled "Why the majority of physicists are on one side of a recent exchange of letters". One way to interpret this claim is just that 33 is more than 3, but the reason for this is clear: while Guth, Kaiser, Linde and Nomura decided to go on a political campaign, drumming up signatures on their letter, Ijjas, Loeb and Steinhardt didn't do this, but instead put together a website discussing the scientific issues.

Where the majority of physicists stand on the Guth-Linde claims is an interesting question, one that I don't think is addressed anywhere by hard numbers. My anecdotal data is that the majority of those I've ever talked to about this don't think the Guth-Linde multiverse claims are science, but don't see any reason to waste their time arguing with pseudo-science. They hope it will just go away by itself, as it becomes ever clearer that the multiverse is, scientifically, an empty idea.

Unfortunately, I don't see this going away and I think it's now doing very serious damage to physics and its public image. There's a political campaign now being waged, and one side is very determined to win and putting a lot of energy into doing so. Those on the other side need to step up and make themselves heard.

Update: Guth and Linde brought their publicity campaign to New York this past Saturday (video here) where they told a large World Science Festival audience that string theory is beautiful, it predicts the multiverse, inflation has made lots of predictions that have all worked out, and they have (more or less…) the full theory that does all this wonderful stuff. Nothing from them about any thing less than utterly glorious and well-defined about the string theory landscape/eternal inflation product they were pushing. Also on the panel were three philosophers (Jim Holt, David Albert and Barry Loewer) who did an admirable job of trying to push back by pointing out obvious inconsistencies. They at least got Guth and Linde to admit that there was this "measure problem" thing still to be fixed. Physics is in a very weird state indeed now that physicists have adopted untestable metaphysical speculation as their program, with philosophers the ones trying to engage in more normal scientific practice.

There was one multiverse skeptic, George Ellis, who unfortunately didn't engage with this and was diverted onto other topics. One string theorist was there (Veronika Hubeny), who explained about AdS/CFT duality, without anybody bringing up the fact that this has nothing at all to do with what Guth and Linde were promoting in the rest of the discussion.

   June 1, 2017

   The cynical view: As certain people saw their chances at a Nobel Prize slowly ebbing away, they decided to start a propaganda campaign to restore their chances.

   I don't know whether this is what everybody else is thinking and nobody is saying, or whether I'm just too cynical and completely off the mark here.

   But this is why giving Nobel Prizes only to experimentally confirmed results is a *great* idea.

2. **Another Anon**
   June 1, 2017

   I must say, I find something rather disappointing about major scientists trying so hard to defend their pet theories. Aren't we supposed to be involved in the search for the truth, whatever that might be? Isn't that why we all got involved in science in the first place, not for personal glorification? If you have a pet theory, and it is disproved, you should be satisfied that it is all part of the process of uncovering the truth of how the universe works. Fighting for your own theory tooth-and-nail seems very low rent.

3. **Don Terndrup**
   June 1, 2017

   Both inflation and multiverse ideas bother me when the defenders seem to treat these as firm scientific conclusions. Wouldn't it be more proper to call them both hypotheses, with various levels of supporting empirical and theoretical evidence?

4. **Peter Woit**
   June 1, 2017

   Anonymous Professor,

   I hadn't thought of that, but it makes a lot of sense. It seemed to me that Guth/Linde and their supporters were more and more engaged in a serious publicity campaign, to make a two-pronged case that inflation is settled science and the multiverse is conventional science, but I couldn't see a particularly good reason for this. They may very well feel that Steinhardt's activities threaten to deny them the Nobel that is rightly theirs, and this would explain the nature of their highly unusual response to the SciAm article (organizing a letter of support from people who might be thought to have influence with the Nobel selection committee).

5. **Adam**
   June 1, 2017

   The majority of physicists don't give a damn about this "controversy". The majority of physicists is not doing theoretical physics, and most of them are doing experiments on subject very far of inflation/cosmology or what not.
   And even among theorists, quite a few of them (me included), are not doing HEP/QG/… Reducing "physicists" to "string theorists" and affiliated is quite tiring, but I guess this is just usual business in pop science…

6. **RP**
   June 1, 2017

I am just a mathematician who is somewhat versed in the philosophy of science, but I do wonder: Does it makes sense to classify a statement X as a 'testable prediction' if the verification of X depends on scientists, at some point in time, becoming 'convinced that the universe has a nonzero density of electric charge or angular momentum'? Clearly we are not talking about things which are 'directly measurable', in any reasonable sense of the expression.

The whole idea behind falsifiability is that scientific theories should be answerable to nature in as direct a way as possible, so certainly without the interference of other theories. This is even the vital fact about scientific theories that ensures that they have real content, and are *about* something: since it is conceivable that they are false, but in fact all our experiments have shown them to be true, they tell us something real about nature.

If instead of making our theories answerable to nature, we make them answerable to just the conviction of scientists, we lose this essential quality of science. It ceases to tell us something real about nature, and only tells us something real about the ideas of scientists instead. This is *exactly* what the notions of 'testability' and 'falsifiability' were designed to avoid.

In other words, the whole notion of 'testable' is being hollowed out if it is allowed to stand in the way Guth is using it. Not just being hollowed out, I would say, but completely subverted. I think it is a terribly sad state of affairs that this type of sophistry is being peddled by a serious scientist writing for a serious public.

7. **atreat**
June 1, 2017

In the linked article, the Linde-Guth side argue that inflation is not really a theory, but rather a "class of models, a sweeping principle, a paradigm" containing a multitude of testable models. As I understand it, Linde-Guth do not disagree with Steinhardt that inflation can support any/all outcomes. Yet, they want to take credit for only those models which have continued to survive nature's verdict. They say the, "key is to figure out which model of inflation is right," but why must one of them be right?

Reading this article and then going back and reading Steinhardt's "fact checking" page where he shows all these failed paper's by Linde-Guth and company with "simple models" that have since been experimentally ruled out just leaves me with wondering what explanatory power can Linde-Guth claim of inflationary theory?

Is modern physics really just about coming up with creative mathematical paradigms describing a whole zoo of potential ways nature could go and then when a new observation is made or a new experiment conducted just shuttering that part of the zoo newly out of sync with nature's evidence? That seems… so sad. Modern physicists reduced to nature's ambulance chasers 🙁

8. **Peter Woit**
June 1, 2017

RP,
I don't think the problem with the Guth claim is the "became convinced" part, which he could easily reword in a different way that would avoid what I think bothers you.

The problem is the nature of the falsifiability claim itself. The universe as a whole is well-known to be electrically neutral, and it's very hard to imagine an experimental result that would show overall non-neutrality. So much so that I'm pretty sure no one is looking for such a thing. I'm not sure what if any experimental signal there would be for a global angular momentum of the universe, maybe there is such a thing, but as far as I know there isn't and no one is looking.

Saying that "my theory is falsifiable because X would be evidence against it" where X is something highly implausible that no one expects to see or is looking for is a standard bogus argument. To see the problem, note that I have a theory that everything that happens is determined by the Jolly Green Giant. This theory is falsifiable, because in principle by observing the CMB, one might see the written message "I'm the Jolly Red Giant, not the Jolly Green Giant".

The other problem with Guth's claim is that, if someone were to observe a global charge or angular momentum of the universe, I suspect that by the next day Linde and others would have a version of an inflationary model which produced universes with a global charge or angular momentum. Personally, if the above mentioned CMB message were found, I would just say that it really is the Jolly Green Giant, it's just that he's a Jolly Green Giant who likes to play tricks.

9. **Anonymous Professor**
June 1, 2017

This year's Nobel will probably go to LIGO. Judging by past behavior, the Nobel won't go to an astronomy/cosmology result two years in a row, so the next reasonable chance inflation has is 2019. If this is a campaign for the Nobel, it will have to be a prolonged one. So by 2019, we will probably have a good idea whether it is or not.

10. **Jeff M**
June 1, 2017

Peter,

Jolly Green Giant? I thought it was turtles all the way down.

Anonymous Prof, while I think you might well be right, I couldn't see the Nobel committee considering inflation. If that's what Linde and Guth are after, it's a false hope. I'm no big fan of the Nobel, but they have been pretty strict about experimental confirmation.

11. **Antimetrics anonymous**
June 1, 2017

Peter
Since the Anonymous Professor has raised the issue lobbying for Nobel, it is worth mentioning the other contribution of Prof Paul S.
Paul Steindhardt wrote an excellent book on " Quasicrystals" . Paul S contributed a lot to the theoretical basis of quasicrystals. In fact in one interview Dan Schectmann to a TV station told the interviewer whether anybody shared the Nobel prize with him, when he recd the phone call for the prize announcement. It was obvious he was referring to Paul S. Here is paper in Dec 1984 in PRL pf Levine and Paul S where they have cited the paper of Dans S and others.
https://journals.aps.org/prl/pdf/10.1103/PhysRevLett.53.2477
Here is the paper of Dan S and others. in November 1984

There are many more critics to the inflationary paradigm than Amanda Gefter's article claims. But some of the critics of the inflationary paradigm go too far in claiming that it should be completely abandoned and some of its advocates go too far in claiming it should be thought of as a settled science. The truth is between these two extremes and numerous critics and advocates of the inflationary paradigm fail to realize that non-eternal inflation is much easier to realize than had been previously thought. For instance, the Wikipedia article on eternal inflation points out that "A 2014 paper by Kohli and Haslam called into question the viability of the eternal inflation theory, by analyzing Linde's chaotic inflation theory in which the quantum fluctuations are modeled as Gaussian white noise [arxiv 1408.2249]. They showed that in this popular scenario, eternal inflation in fact cannot be eternal, and the random noise leads to space-time being filled with singularities. This was demonstrated by showing that solutions to the Einstein field equations diverge in a finite time. Their paper therefore concluded that the theory of eternal inflation based on random quantum fluctuations would not be a viable theory, and the resulting existence of a multiverse is still very much an open question that will require much deeper investigation". The conservation laws are certainly not evidence of eternal inflation and de-Sitter space is also unstable in quantum gravity (e.g. arxiv 1608.07237).

All of this shows that non-eternal inflation is vastly superior to eternal inflation. Eternal inflation inherits various pathologies of infinity. In an infinite cosmos there is no way to have a coherent measure (e.g. arxiv 1202.3376 and 1211.1347). This fact follows from basic Cantorian set theory. Because there are many ways to establish bijections between an infinite number of events, probabilities can be anything one wants. In these kinds of infinite situations probability questions are meaningless. For example, what fraction of the positive integers are odd? One might think it is 50 percent but it could be 75 percent if the bijection is {2} pairs with {1,3,5}, {4} pairs with {7,9,11}, and so on.

Non-eternal inflation is predictive, explanatory, has no multi-mess and no measure problems, unlike eternal inflation which has all of these problems. There are many ways to inflate the cosmos without self-reproduction. These include using some type of fluid to do the inflating (e.g. arxiv 1609.04953, 1601.04773 and 1601.05337) and multi-field inflationary models can easily be non-eternal. The weak gravity conjecture prohibits eternal inflation (e.g. arxiv 0707.3471 and 0805.4520) and the string landscape is also inconsistent with eternal inflation (e.g. arxiv 1404.5543, 1609.00385 and 1504.00056). There are also more traditional ways of doing this (e.g. arxiv 1409.2335). Although inflation theory is popular with many early universe cosmologists, it is not a standard in the same way that General Relativity, the standard model of particle physics, and the LCDM model are. The idea of a strong but short lived vacuum energy is plausible and compelling but its details are almost entirely unknown. Cosmic inflation can be thought of as a faster and stronger version of dark energy but the mechanisms of dark energy are almost completely unknown. If dark energy inflation is a sibling of cosmic inflation, perhaps related by some types of seesaw mechanisms, then it is grossly premature to claim that their details are understood in the same way that the details of General Relativity and particle physics are understood. That means, for example, there is no solid basis to claim that inflation leads to a multiverse and it is grossly premature to claim that the mechanisms postulated in traditional inflationary theory are correct explanations of nature.

There is equivalence between the two major sides in this debate because the cosmological community is not mostly nor entirely on one side in the following sense. Cosmic inflation has been quite popular in the sense that very early universe cosmologists find the idea of a short lived but strong non-zero vacuum energy compelling enough to work on. But the idea is very much under development; its practitioners certainly are not claiming that it is a finished product. So the so-called multiverse is certainly not any kind of standard. In her blog on 12/19/15 Sabine Hossenfelder wrote "But the longer the chain of inference, and the less trust you have in the theories used for inference, the less real objects become. In this layered reality the multiverse is currently at the outer fringes. It's as unreal as something can be without being plain fantasy". She also wrote in a different blog that the multiverse is something that researchers within the scientific community spend almost no time on. And the problem of inflation's initial conditions are only partly solved (e.g. arxiv 1601.01918 and 1506.07306).

It should also be pointed out that string gas cosmology is a very plausible and compelling scenario that is completely consistent with all cosmological observations (e.g. arxiv 1505.02381). String gas cosmology requires that the primordial power spectra be almost scale invariant with a slight scalar mode red tilt whereas in inflation theory the potential must be chosen such that these properties emerge (e.g. arxiv 1608.05079). And string gas cosmology can explain why there are only three large spatial dimensions: the annihilation process cannot take place in more than three dimensions (e.g. arxiv 1105.3247). But, like inflation, string gas cosmology still has lots of work to be done. And it is also possible that the correct explanation for the very early cosmos is something entirely different from all of these approaches. An experimentalist will criticize all of these approaches in that the hypothesized additional scalar fields do not have their existence empirically established. The quantas of the inflaton fields have not been observed in any particle accelerators nor have they been observed in any cosmic rays and the extra dimensions of string theory have not been empirically verified. So all of these approaches still have a long way to go.

13. **Bee**
June 2, 2017

The problem that nobody seems to want to talk about is that rather than trying to find a minimal model that explains the data and leave it at this, there are many hundreds of models for inflation all of which are almost certainly wrong because they contain too many details that aren't supported by data. As the philosophers have it, these models are severely underdetermined. (Good paper about this here.)

Theoretical physicists produce these models literally because they can make money with it. They make money with it by getting them published and then using the publications to claim it's relevant research so it'll get funded and they can hire more postdocs to crunch out more papers. It's the same reason why theorists invent dark matter particles and extensions of the standard model. It's a way to make a living.

Steinhardt & co have an issue with this because this overproduction crisis tends to crowd out alternative explanations. I agree that that's a problem, but that doesn't mean of course that Steinhardt's alternative is a better explanation for the data…

What's really missing here is a scientific criterion to draw the line and say, look, at this point in time it entirely pointless to produce further variants of speculations because the data isn't there and won't be there for decades to come. But nobody in the community has an incentive to come up with such a criterion. That's because along the line everyone makes money with this overproduction. It's for this reason I'm putting my hope on philosophers to help us out because I find this situation pretty embarrassing for my discipline.

14. **cosmology grad student**
June 2, 2017

Guth et al are not going to get a Nobel until/unless primordial B-modes are detected. The BICEP fiasco means that it'll be a long time before another group has a claim even if they're seeing hints.

The argument in the article about conserved quantities averaging to zero is dumb. The argument about inflation being able to start for generic initial conditions way overstates the argument of the cited paper. But the discussion of probabilities in a multiverse is pretty much an accurate reproduction of what almost everyone in the community–including Paul until a few years ago–believes. The measure problem is that the obvious choices of measure you might think give results that are far from the predictions of the classical theory. The fact that you need to pick a measure in the first place is just of doing quantum mechanics in a potentially infinite universe, and it doesn't really bother most people in the field.

There might be some of the scrambling for a Nobel that you perceive. But I think a lot of this is genuine frustration with Paul (+ his collaborators, but especially Paul) not grasping this fact about the measure problem, and similarly refusing to accept that it's okay for different inflationary models to make different predictions. (I think Paul has a reasonable point when he says that many simple monomial models, e.g. lamda phi^4 and m^2 phi^2, are disfavored by the lack of observed B-modes and that models like hilltop inflation which give unobservable levels of B-modes seem more contrived. But there's a big difference between that and arguing that inflation is useless because different models predict different things!)

A related note–my sense is that many people, probably even a majority, in the HEP/cosmology theory community are sympathetic to the arguments you and Paul, among others, have made against the string landscape. There's a reason almost no one works on e.g. KKLT or trying to get the Standard Model out of particular compactifications any more. So I think that it's a major tactical mistake, at the very least, to attack string theory and inflationary cosmology with the same criticisms. The community has concluded, I think mostly correctly, that they don't hold up against inflation. I suspect that the result of this is that people are going to be much more inclined to discount what you, Paul, and others have to say about string theory.

15. **Haelfix**

June 2, 2017

One of the problems with this discussion is the equivocation of the word ‘multiverse’. It really does mean many different things.
One of the initial model independent predictions of inflation was that there would be a specific pattern of correlations of the CMB on Superhorizon scales. This is now an experimental fact.. So you have a choice. Either you give up the Friedman-Robertson-Walker solution of GR as a statement about nature, you give up locality, you accept enormous cosmologically large finetunings of the initial conditions, or you do what everyone in the field does… Namely you buy yourself some time, by some sort of exponential expansion right after the big bang. Thus causally disconnected regions would have had enough time to equilibriate in the past. The upshot is that with exponential expansion, comes an exponential amount of space. This really means our horizon is really a small speck in a larger island universe.
The next version is a little more speculative. It says that b/c you have such large volumes, you have to start looking carefully at quantum processes that might be exponentially suppressed, but that would become non negligable when you analyze the system as a whole. So things like vacuum decay would become important (for instance the Higgs is currently measured to be metastable, so in such a large universe, almost assuredly you would have some sort of Higgs vacuum decay somewhere if that turns out to be true). Thus you now have an island universe with some horizons having different fundamental physics.
This then leads to the version of the multiverse that is the most speculative, namely that we are in our particular bubble with xyz finetuned constants, b/c of anthropic selection, due to the aforementioned processes taking place and eliminating most places for life.
As you can see, each version above makes really quite different statements about the laws of nature.

16. **atreat**
June 2, 2017

re “cosmology grad student”:

Linde-Guth want it both ways though; to claim the inflationary paradigm is somehow explanatory, but also a multitude of theories capable of explaining anything. That is what critics of Linde-Guth are pointing out. Admitting that the inflationary paradigm contains multitudes of theories is to admit that it contains no real explanator power. It is just a mathematical idea allowing theorists to be employed as nature’s ambulance chasers. That seems a pretty damning point for Linde-Guth…

I want to hear more about the “measurement problem” as it seems there is still huge disagreement about how to do statistics properly in an infinite multiverse. Is this the same problem of trying to do anthropic arguments in a multiverse? Ie the same as disagreements over the Boltzmann brain gedanken experiment?

17. **Peter Woit**
June 2, 2017

cosmology grad student,
I think the BICEP2 fiasco has a lot to do with this. Guth and Linde claiming “smoking gun” evidence and collecting their Kavli prize based on a wrong experimental result, then going on to claim that the evidence just doesn’t matter, inflation can give any value for r, likely encouraged Steinhardt to say something. From their point of view, I suspect that after BICEP2 they felt they were so close to a Nobel Prize they could taste it, and aren’t about to give that up.

I just don’t at all believe that the measure problem “doesn’t really bother most people in the field”, my impression is quite the opposite. What most strikes me about this whole subject though is that you don’t have a clue what space you want your measure on (unless you believe that KKLT describes the real world, which no one does).

As for the identification of string theory and inflation, I agree that there are huge terminology problems here, with no precise meaning to either term. But it’s not me who is identifying the two, it’s Linde. See
https://arxiv.org/abs/1402.0526
where for instance he writes

“the most interesting recent developments of the theory of eternal inflation are related to the theory of inflationary multiverse and string theory landscape [57, 62, 63, 64, 65, 66, 67]. These developments can be traced back to the very first paper on eternal inflation in the chaotic inflation scenario [57]. It contained the following statements, which later became the manifesto of the string landscape scenario: “As a result, our universe at present should contain an exponentially large number of mini-universes with all possible types of compactification and in all possible (metastable) vacuum states consistent with the existence of the earlier stage of inflation. If our universe would consist of one domain only (as it was believed several years ago), it would be necessary to understand why Nature has chosen just this one type of compactification, just this type of symmetry breaking, etc. At present it seems absolutely improbable that all domains contained in our exponentially large universe are of the same type. On the contrary, all types of mini-universes in which inflation is possible should be produced during the expansion of the universe, and it is unreasonable to expect that our domain is the only possible one or the best one.”

The problem is that GKLN and ISL aren’t just arguing about the conventional sort of scientific issue that arises if you have a well-defined class of models (say single-field inflaton with a simple potential) and are trying to compare them to experimental data. GKLN are explicitly saying that the potential can be arbitrarily complicated, there can be arbitrary many fields, ISL describe this as “postmodern inflation” and I think very rightly object to it as unfalsifiable pseudo-science. The GKLN letter that they got 29 others to sign onto does not specifically address this issue, but it does contain a defense of the multiverse, by implication claiming that postmodern inflation and its string theory landscape backing are part of what is being defended.

18. **Peter Woit**
June 2, 2017

Haelfix,

Yes, but Guth/Linde are very explicit about what they are defending: the multiverse in which you have different physics in each different universe, and use that as an excuse for why your models don’t predict things. This is what the controversy is about.

19. **Blake Stacey**
June 2, 2017

“So if we ever became convinced that the universe has a nonzero density of electric charge or angular momentum, eternal inflation would no longer be an option.”

I dunno. It seems to me that if the astronomers found that the net angular momentum of the observable universe is nonzero, then the eternal inflationologists would claim this as evidence for their multiverse, because it meant there must be another universe out there with opposite angular momentum to cancel everything out.

20. **Haelfix**
June 2, 2017

It is perfectly logically consistent to accept the inflationary paradigm, and even the subset of inflationary models that give rise to eternal inflation, while simultaneously questioning whether our particular bubble was anthropically selected. That’s why I reject the either/or dichotomy that’s being presented to us.

The anwer is that we simply don’t know whether our bubble was anthropically selected or not, and the details matter. I mean we could have asked the same question about the orbits of planets in our solar system and why the convenient configuration for the earth in particular . One could have imagined (before the calculations were done) that there was a mechanism during the collapse of primordial interstellar hydrogen that might have led to planets being preferentially chosen in the goldilocks zone. Of course we now know the answer for us was essentially anthropic.

We're in the exact same position with the theory of inflation, namely we need more data (gravitational wave observations in particular) to really zero in on the messy details to make statements that are more constrained.

21. **S.**
June 2, 2017

cosmology grad student,

does there exist any known case of where using the kinds of probabilistic methods that "almost everyone in the community" believe in has led to a correct prediction?

It seems to me that the practice is pure nonsense, mathematically speaking. We have as much mathematical reason to believe in conclusions reached through such arguments as we have in conclusions reached by inspecting goat entrails.

Of course, things can work empirically even without being mathematically well-defined (e.g. infinitesimals in the 17th century, parts of QFT still today). But if we don't have any empirical evidence that they actual work, the fact that lots of people believe in them is more a condemnation of the state of the field than a vindication of the method.

So is there any reason to believe that "picking a measure in the first place" actually works, rather than that it is just popular?

22. **EJM**
June 2, 2017

If the multiverse idea is correct, and there are an infinite number of universes where anything and everything is possible, then there must be a universe in which most physicists in it believe and sign a letter that the multiverse idea is incorrect.

23. **Peter Woit**
June 2, 2017

Haelfix,
The question isn't really anthropic selection, it's whether your theoretical framework is rigid enough to be useful to say something about reality, or whether it's so flexible it can never be wrong and is an empty, useless idea. The problem IJS are pointing out is that the framework GKLN are pushing appears to be compatible with any conceivable future observational results. For any value of r, Linde has a model that will give that value of r, same for other observables. He and Guth seem happy with this situation, argue that it's normal science. It's not.

S./cosmology grad student,
I really don't want to host a discussion of "the measure problem" consisting of completely ill-defined quantities and meaningless statements. If there are specific, well-defined calculations that are relevant to the issues in this controversy, fine, but spare us the nonsense if they're not.

24. **Jonatan**
June 2, 2017

I think one key point raised by IJS is that EVEN once you've picked a particular potential and fixed its parameters (selected one model within the inflationary "paradigm"), if eternal inflation apply (which seems to be so for the vast majority of cases), then you'll get an infinity of CMB observable values in the infinity of pocket/bubble universes.

If they're right, then it means that the whole inflation framework is really incapable of predicting anything and has therefore zero explanatory power.

I've never read or heard anything from GKLN directly addressing this issue, which is very suspicious to me. If IJS are wrong about that, they should very clearly point it out.

Perhaps a cosmologist could enlighten me here…

25. **Jonatan**
June 2, 2017

In other words, is it possible for a given eternaly inflating model (a particular potential with defined parameter values) to predict exactly the same CMB statistical distributions and spacetime geometry in ALL of the infinite pocket/bubble universes ?

If the answer is yes, than inflation might be said to be predictive.
If the answer is no (which is I think one of IJS's claims), than it can't.

26. **Haelfix**
June 3, 2017

It's important to distinguish two different things. There is on one hand the underdetermination of the models due to a lack of data. Basically you are given 5 observables in the CMB and you have hundreds of different inflationary potentials with parameters, some of which are allowed to vary. Therefore for any possible measurement you are possibly (but not necessarily) looking at more than one model that fits. This is the inverse problem, but note that this is really no different than any usual pheno problem in physics, and is how the standard model of particle physics came about. There was a time in the past where we didn't have enough data to really uniquely select the standard model out of the space of all field theories with undetermined parameters. Fortunately, just like the standard model we have strong constraints (renormalizability, naturalness, simplicity, slow roll etc) and so with further data collection you can really start to zero in on the right answer. Indeed, you could even falsify the whole thing, recall that the initial combination of Bicep with other measurements actually ruled out the whole inflationary paradigm.
On the other hand, there is the concern that given the large volumes of space, you might have bubbles that undergo vacuum decay (or other rare events), and so we might be living in a bubble that just happened to randomly output our observed universe with 'whatever you want'. To this second point, I would repeat my criticism above. Namely that it depends upon the details, you don't necessarily get 'anything you want', but yes the measure problem appears in this case…

27. **Peter Woit**
June 3, 2017

Haelfix,
Sorry, I'm having trouble taking this seriously enough to spend time thinking about. I don't remember hearing any inflationistas claiming "the initial combination of Bicep with other measurements actually ruled out the whole inflationary paradigm", I remember everyone congratulating Guth/Linde on their soon to be awarded Nobel prizes

for the confirmation of inflation.

As for the “it’s just like the Standard Model”, my tolerance level has dropped to zero for that rhetorical move in these arguments over theories of questionable testability.

28. **Haelfix**
June 3, 2017

So in one of the original combination plots (that no one took seriously b/c you can’t just combine data sets like that), BAO + Planck + Bicep produced a so called ‘negative running’ of the primordial power spectrum. This sort of thing would be almost impossible to find in eternal inflation.
See : http://arxiv.org/abs/1404.4614

29. **vmarko**
June 3, 2017

Haelfix,

“There was a time in the past where we didn’t have enough data to really uniquely select the standard model out of the space of all field theories with undetermined parameters.”

This is still the case — we still don’t have enough data about the neutrino sector to fix a unique Lagrangian for the SM. There is the Dirac/Majorana issue, the direct/inverse mass ordering issue, etc.

However, no sane physicist is shouting that SM is untestable because of that, because this is just a handful of unknown numbers, which moreover just barely participate in most of the experiments we can perform. In contrast, the inflation scenarios typically have an arbitrary function (the inflaton potential) in the Lagrangian, which amounts to infinitely many parameters to tune. This is untestable almost by definition, since you need an infinite number of experiments to fix the Lagrangian before you even begin testing it (and this is not the only problem with inflation). This situation is nothing like the SM nonuniqueness.

Best, 🙂
Marko

30. **Jonatan**
June 3, 2017

If IJS are right that even once a potential has been chosen and parameters fixed, eternal inflation inevitably produces a whole range of CMB observable outcomes across pocket/bubble universes, than it seems quite clear that eternal inflation is hopelessly untestable and is an empty idea.

If they’re wrong, proponents of inflation should explain clearly where and why IJS are wrong about that and clearly state that at least some eternally inflating models will produce the exact SAME CMB observable outcomes in ALL pocket universes.

Is anyone aware whether such explanation has ever been provided ?

31. **Cosmonut**
June 5, 2017

The multiple versions of inflation seem to be a trivial corollary of the fact that GR permits multiple space-time geometries. So in that sense I agree with Linde & Guth that this doesn’t automatically disqualify them.
However, people didn’t believe GR because we could somehow dream up a metric that explained the perihelion of Mercury or whatever (I daresay with enough people slogging away, we could). What happened was that the appropriate metric could be *independently deduced* from other considerations and *then* the predictions matched.
GR also permits metrics corresponding to time machines, rotating universes and so on. But nobody is loudly proclaiming that “This is a feature of the theory and we must accept the existence of time machines because other predictions of GR were valid”.
The question simply focuses on what kind of matter and energy distribution leads to such metrics and whether we can find *independent evidence* for existence of the latter.
In that respect, I am with ISL. It doesn’t suffice at all to dream up some inflation potential that makes “generic predictions”, declare victory and then insist we need to accept extrapolations like the multiverse. Until we find independent evidence of at least one scalar field and *then* deduce what it implies for cosmology, inflation must remain a provisional theory.

32. **kashyap vasavada**
June 5, 2017

I thought the main argument in favor of inflationary model was that it has three desirable features. It can explain (1) flatness (2) horizon problem and (3) lack of monopoles. Does anyone on this blog know if Steinhardt’s or anybody else’s model does this?

33. **Peter Woit**
June 5, 2017

kashyap vasavada,
I’m no expert on 1 or 2, but an obvious answer to 3 is that the Standard Model has no monopoles. 3 is only a problem if you believe in GUTs with monopoles (as Guth did when he was looking for a solution to this “problem”). There is no evidence at all for such a GUT (and by now quite a lot of evidence against), so the simplest solution to 3 is that our fundamental theory is not a GUT with monopoles.

34. **Cosmonut**
June 5, 2017

Kashyap,
Yes, Steinhardt’s model does indeed handle the flatness and horizon problem. The model has a mechanism whereby the universe is flattened and homogenized during a contracting phase of the universe, before it “bounces” (the bounce is “our” big bang)
The main problem is the bounce itself – it requires violations of GR and is just “assumed to be possible” – whereas inflation requires unobserved scalar fields, but then it’s just GR.
More details here: https://arxiv.org/pdf/1512.09010.pdf

35. **tulpoeid**
June 6, 2017

I was waiting until the next renewal date to cancel my Nautilus subscription. No need to wait anymore. The amount of money lost will be the same but the point will not be totally lost.

36. **vmarko**
June 6, 2017

Cosmonaut,

"The main problem is the bounce itself – it requires violations of GR and is just "assumed to be possible" […]"

It's not such a big stretch to imagine the violation of GR near the Big Bang moment. First, at such energies the difference between GR and Einstein-Cartan gravity becomes nontrivial, and the latter was shown by Poplawski to produce a Bounce instead of a Bang. So a rather miniscule violation of GR is quite enough. In addition, quantum corrections to GR should play a nontrivial role in such a regime, and in some models (such as loop quantum cosmology) one naturally obtains a bounce via the Friedmann equation with a small quantum correction term. So I'm not at all surprised that in string theory something similar might appear, as conjectured by Steinhardt and Turok.

Big Bounce is a quite ubiquitous concept in cosmology, you can read some history overview here:

https://en.wikipedia.org/wiki/Big_Bounce

And some of the models which feature Big Bounce also naturally resolve the flatness and horizon problems, so they are very solid alternatives to inflation.

Best, 🙂
Marko

2018 US HEP Budget

June 6, 2017
Categories: Uncategorized

HEPAP has been meeting the past couple days, with presentations available here. Much of the discussion is about the President's 2018 budget proposal recently submitted to Congress, which contains drastic cuts to all sorts of programs, including for support of scientific research. In particular the proposal is to cut the total NSF budget from \$7.5 billion to \$6.65 billion (-11.3%), and the DOE science budget from \$5.4 billion to \$4.47 billion (-17%).

At the DOE, for HEP physics, the cut would be from \$825 million to \$673 million (-18.5%). For topics less popular with the new administration the cuts are even larger, e.g. a 43% cut for biological and environmental research.

At the NSF (numbers with respect to FY 2016), the proposed cut for DMS (Mathematics) is 10.3%, for Physics 8.5% (-\$23.6 million) and for Astronomy 10.3%. The FY 2016 budget number for Physics was \$277 million, of which \$13.2 million went to HEP theory.

Budget cuts on this scale would be extreme and unheard of, requiring shutting down major planned experimental projects. For some sorts of spending, this sort of cut is painful but manageable, but cutting out 18.5% of the spending on an experimental apparatus under construction may likely mean you don't have an experiment anymore.
The HEPAP presentations are from people working for DOE/NSF and under orders to plan for these cuts and not complain about them, so I think don't reflect at all what the real implications of such cuts would be.

There's a summary of discussion here, including a discussion of last year's HEP theory letter. It sounds like nothing much has been done about that, and it may not get much attention given the current situation.

It's important though to keep in mind that this budget proposal may very well already be dead on arrival at Congress. Take a look at slide 22 of this presentation that reports that of the staffers and representatives asked about (a preliminary version of) this, only 8.4% were in favor. In recent years the US budgeting process has been quite dysfunctional, with actual budget numbers only appearing at the last minute of an opaque process leading not to a budget but to a "Continuing Resolution". I doubt anyone has any idea what is going to happen this year, with the passing of something close to this budget probably one of the least likely eventualities. Physicists and mathematicians up in arms about these proposed budget cuts need to keep in mind the context: this budget is an extremely radical proposal of an unparalleled sort, with even larger cuts aimed at groups that are far needier than scientists (for one random example, food stamps are to be cut by 25.3%). Yes, scientists should be organizing to fight this budget, but the impacts on them and their research are one of the less important reasons for doing so.

I'm setting all comments to go to moderation. If you just want to rant pro or con about the awful situation the US is now in, please do it elsewhere. If you have any actual information about the effects of this on the physics and math communities as the budget process gets underway, that would be worthwhile and interesting. Two people tweeting about this are Kyle Cranmer and Matthew Buckley.

Updates: Details of the DOE HEP budget proposal are here. It explains that about 20-25% of the research positions funded by DOE at all levels would be eliminated. There would be an "extended shutdown of the Fermilab accelerator complex".
About 1/3 of DOE HEP theory funding would be eliminated, but it would be replaced by an equal amount of funding for quantum information science as a subfield of HEP. Looks like someone in the Trump administration is a great believer in "It From Qubit"…

Update: According to this story, if this budget passes about 700 jobs at Argonne and Fermilab would be eliminated.

Comments

1. **cosmology grad student**
   June 6, 2017

   I think you're misreading what quantum information science means in this budget. On p. 180 of the budget document you linked in your update: "Increased funding will support QIS efforts in quantum computing and quantum sensor development." And the funding category that's increased is called "Computational HEP." My guess is that the increase isn't going to "It from Qubit" (which is funded by Simons not the US government) or anything like it, but more directly to nitty-gritty quantum computing. No doubt quantum info people who work on e.g. AdS/MERA or Bootstrap could try to argue that what they do falls into this category, but I doubt that's what the people who wrote this line item in the budget had in mind.

2. **Peter Woit**
   June 6, 2017

   cosmology grad student,
   That side comment was a bit tongue in cheek. I really don't know what that $14 million is for, and why it's replacing 1/3 of the HEP theory program. To me quantum information science seems a really different business than HEP, so it's unclear why it's being funded out of HEP, but there must be some set of research priorities I don't know about behind this (beside "It from Qubit").

3. **Douglas Natelson**
   June 6, 2017

   Don't overthink it. Someone likes quantum info research, and likely doesn't really understand what it is or its relationship to high energy physics beyond the money-is-fungible interrelatedness of all agency programs.

   I agree that this budget request is so out of the norm that we are basically off the edge of the map in terms of trying to figure out what Congress might do. You also left out the fun idea put forward about how to handle the proposed NIH cuts without cutting research dollars: refuse to pay indirect costs at more than 10%. Again, probably DOA in the legislature, but slashing indirect cost payments and having a flat rate rather than individual negotiations with each university likely would have appeal to some in Congress.

4. **Giulio**
   June 7, 2017

   Cutting the budget so much is certainly bad; but in the particular case of HEP theory, given that most of the money is anyway spent on things you consider "not even wrong", you should see it as money saved instead of being wasted. Or am I wrong?

5. **piscator**
   June 7, 2017

I think slashing university overheads would be an excellent idea. The growth in administrative numbers and salaries is one of the biggest problems with modern universities, and one of the ways they are funded is through the central university slice on grant income. It would be one of the rare ways of saving money and boosting the academic culture of universities simultaneously.

6. **Peter Woit**
   June 7, 2017

   Giulio,
   The amounts going to HEP theory are infinitesimal compared to other things. Most of such funding is not going to multiverse or other studies I think are completely worthless, but to often reasonable research. These days what a lot of HEP theorists are doing is actually working on QFTs with applications to topology or condensed matter.

   There is an issue about some of this funding that I've always seen as problematic, independent of the value of the research. At least in the US, spots for HEP theory graduate students are often funded this way, and the huge imbalance between the number of Ph.Ds produced and the number of permanent jobs has led to a horrific job market which I don't think is good for the field. So, I can't say that I'm strongly opposed to some cutting of Ph.D. funding in this area (or, in any area where the job market is awful).

   This is completely irrelevant to the current situation, since those pushing these cuts are not interested in targeted cutting to improve things, but in making huge across the board cuts to scientific research in general.

7. **Peter Woit**
   June 7, 2017

   piscator,
   I think the idea that removing grant money will starve the administrative beast is naive. At a certain large institution I know well and have observed closely over decades, the administration and its salary level has grown dramatically, during a period when overhead rates and grant income haven't. The way this gets paid for is not grants, but steady increases in tuition levels, radically changing the socioeconomic profile of the student body, making the institution more and more aimed at catering to the children of the wealthy.

   If overhead disappears, of the two alternatives of administrators taking pay cuts/losing their jobs, or larger tuition increases, I know which one I would bet on happening.

8. **Jeff M**
   June 7, 2017

   Piscator

   Peter is right, this has nothing to do with grants. I work at a state U, we have some grants, but nothing like the level at Columbia where Peter is. We've had just as much administrative bloat as Columbia. As far as tuition levels, when I was applying to college, back in the dark ages, full freight at Columbia was about \$7K. It's \$70K now. Inflation would justify \$25K.

9. **Rob**
   June 7, 2017

   Do I read correctly on page 188 in the detailed HEP budget proposal that the muon g-2 measurement at Fermilab is dead (if the budget passes). Or is it some type of upgrade/offshoot which is in the firing line ?

10. **Shantanu**
    June 7, 2017

    Peter, do you have any statistics on how much of DOE HEP theory funding has been invested in string theory?

11. **Peter Woit**
    June 7, 2017

    Rob,
    It looks to me like the g-2 experiment will soon be taking data, and have a measurement later this year, so this isn't a cancellation (don't know if there were plans for future upgrade).

    Shantanu,

    For a long time now different people would count different things as "string theory", so I don't think there's any sensible number of that sort, at least for the last 10-20 years.

12. **Tom Andersen**
    June 8, 2017

    I don't want to sound depressed, but a 50% budget cut to a normal bureaucratic system will result in 100% of actual work being stopped. The bureaucrats always find a way to keep their 'inner circle machine' running. One can expect linear behaviour, so a 20% cut means 40% of useful work being halted.

13. **Scott Aaronson**
    June 8, 2017

    Not that anyone making these budgets asked for my opinion, but on the small chance any of them read these comments: I'm a quantum computing person, who also happens to be a member of the It from Qubit collaboration, and quite interested recently in work at the interface between quantum information and quantum gravity. And I don't want additional funding for quantum information if it has to come out of already-strained HEP budgets.

    In general, I'm always dismayed when funders see something new and shiny (for example: a scalable quantum computer), and think they can just redirect all their resources to that, without understanding that even supposing it was all they cared about, they're less likely to get it without a healthy research ecosystem, which in this case means everything from basic physics to math to classical CS. To take a very common instance of that failure mode: you can plunk down a beautiful new interdisciplinary center at a university — but then if you don't put adequate resources into the basic needs of the individual departments that the center is supposed to be bringing together, great people won't want to be in those departments, and your center will end up as a gleaming bridge from nowhere to nowhere.

14. **Chris Herzog**
    June 9, 2017

"Yes, scientists should be organizing to fight this budget, but the impacts on them and their research are one of the less important reasons for doing so."

I wonder if it's actually one of the more important reasons for doing so. Here in Suffolk County on the eastern end of Long Island, two of the biggest employers are Brookhaven National Labs and Stony Brook University. Science research dollars from the federal government add about 500 million dollars to the local economy. Take that away, and this place becomes a summer retreat for wealthy New Yorkers and (maybe — it's not so clear) a cheaper place to live for those who work in the city and are willing to deal with a two hour commute each way.

Universities can serve as a hub for economic development in this new economy that depends so much on service, technology, and creativity. One can make a strong argument that federal research dollars are the seeds from which the local economy grows.

15. **Kev Abazajian**
June 9, 2017

My new relevant blog post, "Defending Science in the Age of Trump." http://www.314action.org/news/2017/6/9/defending-science-in-the-age-of-trump

16. **Noah Graham**
June 9, 2017

Chris Herzog — I agree that federal research dollars can be seeds for the local economy, but the problem is that the funding system tends to replant those seeds in the same, wealthy areas (e.g. Long Island). If there were more mechanisms to extend research infrastructure into less prosperous areas, both urban and rural, science would enjoy much broader political support (and cost less to carry out, as well).

17. **ronab**
June 12, 2017

"…if this budget passes about 700 jobs at Argonne and Fermilab would be eliminated."

Is there a reasonable way to extrapolate as to what this would imply for, eg, job losses at LBL, SLAC, etc.?

18. **Peter Woit**
June 12, 2017

ronab,

Not that I know of. Even the 700 number is some sort of vague guestimate.

The Dangerous Irrelevance of String Theory

June 12, 2017
Categories: Uncategorized

Eva Silverstein has a new preprint out, entitled The Dangerous Irrelevance of String Theory. The title is I guess intended to be playful, not referring to its accurate description of the current state of string theory, but to the possibility of irrelevant operators having observable effects.

The article is intended to appear in the forthcoming Cambridge University Press volume of contributions to the Munich "Why Trust a Theory?" conference held back in December 2015. The impetus behind that conference was a December 2014 article in Nature entitled Scientific method: Defend the integrity of physics. In that article, Ellis and Silk explained the problems with string theory and with the multiverse/string theory landscape.

The organizing committee for the Munich conference was chaired by Richard Dawid, a string theorist turned philosopher who has written a 2013 book, String Theory and the Scientific Method. For a fuller discussion of that book, see the linked blog post. To oversimplify, it makes the case that the proper way to react to string theory unification's failure according to the conventional understanding of the scientific method is to change our understanding of the scientific method. Much of the Munich conference was devoted to discussing that as an issue in philosophy of science.

One aspect of the Munich conference was that it was heavily weighted towards string theorists, with contributions from Dawid, David Gross, Joe Polchinski, Fernando Quevedo, Dieter Lust and Gordon Kane all promoting the idea that string theory was a success. Polchinski explained a computation that shows that string theory is 98.5% likely to be correct, going on to claim that the probability is actually higher: "something over 3 sigma" (i.e. over 99.7%). The only contribution from a physicist that I've seen that argued the case for the failure of string theory was that from Carlo Rovelli, see here. Silverstein's article says that it was commissioned by Dawid for the proceedings volume, even though she hadn't been at the meeting. I'm curious whether Dawid commissioned any contributions from string theory critics who weren't at the meeting.

Silverstein begins her article explaining how physics at a very high energy scale can in principle have observable effects. This of course is true, but the problem with string theory is that, in its landscape version, it has a hugely complicated and poorly understood high energy scale behavior, seemingly capable of producing a very wide range of possible observable effects, none of which have been seen. The article is structured as a defense of string theory, without explaining at all what the serious criticisms of string theory actually are. The list of references includes 53 items, only one critical of string theory, the Ellis/Silk Nature article. Some of the arguments she makes are:

- It is sometimes said that theory has strayed too far from experiment/observation. Historically, there are classic cases with long time delays between theory and experiment – Maxwell's and Einstein's waves being prime examples, at 25 and 100 years respectively… One thing that is certainly irrelevant to these questions is the human lifespan. Arguments of the sort 'after X number of years, string theory failed to produce Y result' are vacuous.

I think the comparison to EM or GR is pretty much absurd. For one thing it's comparing two completely different things: tests of a particular prediction of a theory (EM or GR) that made lots of other testable, confirmed predictions to the case of string theory, where there are no predictions at all. More relevant to the argument over how long to wait for an idea to pay off is that the real question is not the absolute value of the amount of progress, but the derivative: as you study the idea more carefully, do you get closer to testable progress or farther away? I don't think anybody can serious claim that, 33 years on, we're closer to a successful string theory unification proposal than we were at the start, back in 1985. I'd argue that the situation is the complete opposite: we have been steadily moving away from such success (and thus entered the realm of failure).

- About supersymmetry Silverstein writes:

> In my view, the role of supersymmetry is chronically over-emphasized in the field, and hence understandably also in the article by Ellis and Silk. The possibility of supersymmetry in nature is very interesting since it could stabilize the electroweak hierarchy, and extended supersymmetry enables controlled extrapolation to strong coupling in appropriate circumstances. Neither of these facts implies that low-energy supersymmetry is phenomenologically favored in string theory.

It is true that Silverstein has never been one of those arguing that the usual string theory scenarios with supersymmetry and 10 or 11 dimensions show that string theory is testable. See for instance her comment here back during a "String Wars" discussion in 2006. Her current take on whether string theory implies supersymmetry is just

> Much further research, both conceptual and technical, is required to obtain an accurate assessment of the dominant contributions to the string landscape.

The problem with this is that there is no sign of any possibility of progress towards deciding if the string theory landscape implies low-energy SUSY or not (quite the opposite). If you give up the assumptions of SUSY and 10/11 dimensions, you give up what little hope you had of any connection with experiment. She doesn't mention the LHC at all, especially not the negative results about supersymmetry and extra dimensions that it has produced. The significance of these negative results is not that they disconfirm a strong prediction of string theory, but that they pull the plug on the last remaining hope for connecting standard string theory unification scenarios to anything observable. Pre-LHC string theorists could make an argument that there was good reason to believe in electroweak-scale SUSY, that such a scenario fit in well with string theory unification, and that LHC discovery of SUSY would point a way forward for string theory unification. That argument is now dead. All that's left is basically the argument that "maybe a miracle will happen and we'll be vindicated" which in her version is:

> In principle one could test string theory locally. In practice, this would require discovering a smoking gun signature (such as a low string scale at colliders, or perhaps a very distinctive pattern of primordial perturbations in cosmology), and nothing particularly favors such scenarios currently.

- Silverstein's main argument is basically that string theory is valuable because it leads to the study of models that have various observable signatures that people would not otherwise look for. One example here is supersymmetry, the study of which has had a huge effect on collider physics, strongly shaping the analyses that the experimentalists perform. She gives some detailed other examples from her field of cosmology, in particular about possibly observable non-Gaussianities.

> String theory participates in empirical science in several ways. In the context of early universe cosmology, on which we have focused in this article, it helped motivate the discovery and development of mechanisms for dark energy and inflation consistent with the mathematical structure of string theory and various thought-experimental constraints. Some of these basic mechanisms had not been considered at all outside of string theory, and some not quite in the form they take there, with implications for effective field theory and data analysis that go well beyond their specifics.

I think this is the best argument to be made for "phenomenological" string theory research (as opposed to "formal" string theory, where there are other arguments). Yes, coming up with new models with unexpected observable effects is a valuable enterprise. If your speculative idea generates such things, that's well and good. The problem though is how to evaluate the situation of a speculative idea that has generated a huge number of such models, none of which has worked out. At what point do you decide that this is an unpromising line of research, better to try just about anything else? Silverstein makes the argument that

> Whether empirical or mathematical, constraints on interesting regions of theory space is valuable science. In this note we focus on string theory's role in the former.
>
> Since information theory is currently all the rage, it occurred to me that we can phrase this in that language. Information is maximized when the probabilities are equal for a set of outcomes, since one learns the most from a measurement in that case. The existence of multiple consistent theoretical possibilities implies greater information content in the measurements. Therefore, theoretical research establishing this (or constraining the possibilities) is directly relevant

> to the question of what and how much is learned from data. In certain areas, string theory plays a direct role in this process.

> The problem here is that of what is an "interesting region of theory space". At this point the failures of string theory unification strongly indicate that it's not such an interesting region. It seems likely that we'd be better off if most theorists focusing on phenomenology of this failed program were to pick something else to work on.

Update: Will Kinney has a Twitter commentary here.

Update: For another relevant recent Will Kinney Twitter storm, see here and here.

Update: Silverstein gave some lectures to the public about this at Stanford recently, video here and here, slides here. A large part of the lectures were an advertisement for string theory, with the summary at the end

> Quantum gravity (string theory) plays a subtle but important role, even contributing to our understanding of empirical measurements of early universe dynamics.

Crediting string theory with "contributing to our understanding of empirical measurements of early universe dynamics" is a peculiar way of saying that string theory produces lots of cosmological models that don't work (see a better summary by Will Kinney at the end of this presentation).

Update: Renata Kallosh is Silverstein's colleague at Stanford (and Andrei Linde's wife). In an interview here she makes much simpler and stronger claims about string cosmology than does Silverstein:

> string theory ideas help us to build cosmological models which fit the data from observations. Moreover, we have produced relatively simple predictions from string theory and related theories which will be testable with future detectors of primordial gravity waves.

I'm not sure what specifically she is referring to, but suspect that "prediction" here means something like the "predictions" of string cosmology that Kinney describes (see above) whose failure to be observed has in no way affected string cosmologists enthusiasm for the subject.

Update: For some more context about string theory inflation models and the issue of their testability, you could consult Silverstein's guest post at Lubos Motl's blog from 2014, explaining how the BICEP2 observation of that era could provide evidence for "axion monodromy inflation".

Comments

1. **Doug McDonald**
   June 12, 2017

   typo:
   "The problem with this is that there so sign of any possibility of progress"

2. **Bee**
   June 13, 2017

   I was invited to write a contribution but declined.

   The criticism you raise that there are lots of speculative models that have no known relevance for the description of nature has very little to do with string theory but is a general disease of the research area. Lots of theorists produce lots of models that have no chance of ever being tested or ruled out because that's how they earn a living. The smaller the probability of the model being ruled out in their lifetime, the better. It's basic economics. Survival of the 'fittest' resulting in the natural selection of invincible models that can forever be amended.

3. **MikeS**
   June 13, 2017

   "Historically, there are classic cases with long time delays between theory and experiment – Maxwell's and Einstein's waves being prime examples, at 25 and 100 years respectively…"

   One has to wonder at the ability of intelligent people to make this type of argument.

   Maxwell's equations validated themselves almost instantly in predicting the speed of light from a number of well established universal constants. Exactly the sort of predictive power that String Theory consistently fails to offer. And Einstein's GR was validated by Eddington within a very few years, and has been reinforced by just about every test anyone can think of in the 100 years since. Gravitational waves have never been more than a corollary to that. GR has never been reliant on LIGO, like some gravitational equivalent of the LHC, to push its sensitivity ever higher, and ever failing to see what was expected.

   I claim neither the intellect nor the background to understand the complexities of String Theory. However, when I see clearly poor arguments and comparisons such as these, then I worry that the complexities are existing on equally weak ground.

4. **Dave Miller**
   June 13, 2017

   Peter,

   You wrote, "I think the comparison to EM or GR is pretty much absurd. For one thing it's comparing two completely different things: tests of a particular prediction of a theory (EM or GR) that made lots of other testable, confirmed predictions to the case of string theory, where there are no predictions at all."

   Isn't the real problem the use of the word "theory" to refer both to EM/GR and also to string theory (the same holds for your recent posts on inflation "theory" in cosmology)? Isn't string theory (again, also inflationary cosmology) more a set of interesting speculations and suggestive calculations that might (or might not) someday lead to an actual theory than currently being a real physical theory?

   I know you have made this point again and again, and I do not want simply to be pedantic about vocabulary. But, GR, for example, was sitting there from 1915-16 with, e.g., gravitational waves a definite mathematical consequence of the theory, whether or not anyone could detect them. On the other hand, no one knows what, if any, are the consequences of string theory just because there is, so far, no such theory.

   Surely, it would be more accurate to refer to string/superstring "musings" or "speculations" (and similarly for inflationary cosmology). Words do matter.

I think I see a bit more value in such “musings” than you do: I still hope that someday an actual theory will burst forth from all the work on strings. But, alas, not yet.

All the best,

Dave

5. **Peter Woit**
June 13, 2017

DaveMiller/MikeS,

The problem is that usage among physicists has now for a very long time been that the term “theory” carries no implication of testability, being well-defined etc. Unfortunately those trying to defend science against its opponents like to insist otherwise, see for example the Wikipedia entry:
https://en.wikipedia.org/wiki/Scientific_theory
This likely leads many people to believe that “string theory” has characteristics that it doesn’t, but I know of no one trying to do anything about that misunderstanding.

The rather absurd comparison of the testability of string theory to that of EM is surprising to see, but not at all unusual in this kind of document. One would expect an argument being made in an academic context like this to make an attempt to address both sides of the argument, refer to the other side in the bibliography, and not make obviously absurd claims (one question here, are these contributions being refereed?). Instead, what’s produced is heavily ideologically-driven and one-sided. In some sense, I think the worst thing that has happened to theoretical physics over the past 25 years is this descent into ideology, something that has accelerated with the multiverse mania of the last 10-15 years.

Doug McDonald,
Thanks, fixed.

6. **Anon**
June 13, 2017

Hmm. It doesn’t look like the commenters have read the
…that you left out. This distorts
the meaning and generates like-minded comments
in this echo chamber.
The article goes right on to say in the … that most theories are
not like GR and EM, obviously referring to those
described in the article which are described
rather moderately in the main text. Anyway I
don’t see a problem with a comment about
theoretical predictions predating observations in some
famous cases, and the timescale not being
important, in context of the full article. My
problem is that the space of theories is so large,
so while I do agree that it is quite interesting in
some ways, there’s no way to test
everything in enough detail to infer much
unless we get lucky.

7. **Peter Woit**
June 13, 2017

Anon,
I don’t think anything I left out is relevant or distorts the meaning at all (the only relevant text dropped is “Of course electromagnetism and general relativity are not representative of most theoretical ideas, but the point remains valid.” which I didn’t and don’t see as having any relevance to the point I was making). The problem isn’t that she’s picking unrepresentative theoretical ideas to compare to string theory, or any issue of time-scale, but that she’s justifying the situation of string theory by claiming its like that of one of a heavily successfully tested theory (EM in its early decades).

8. **Anon**
June 13, 2017

Peter, the … is about how most ideas will be falsified or
constrained, but that is still valid science, which is a
main theme of the article. The section is about
timescales and null results. You are arguing against
a straw man here — the classic theories were not
compared to string theory, they were mentioned
in the context that even some well established
theories waited substantial periods for certain
of their predictions to be tested, the timescales
for theory and experiment not being perfectly
lined up even in that extreme case. But the paragraph you omitted
makes the contrast quite clear that the author
is making between the two cases. Seriously,
take a moment to consider less incendiary
ways of interpreting and presenting your subjects.
In this day and age, we should all make a point
of being reasonable and accurate.

9. **Peter Woit**
June 13, 2017

Anon,
I think I am being completely accurate and reasonable here. The article is explicitly a defense of string theory against the points made against it by Ellis/Silk, and string theory is explicitly referred to repeatedly in the paragraphs at issue. Claiming that there’s no comparison being made between the current situation of string theory and the situation in the past of EM/GR makes no sense.

The argument of this part of this part of the article seems to me completely straightforward: Silverstein is making the accurate point that it can take a long time to test some predictions of a theory, invoking examples from EM and GR. The absurdity is invoking these particular examples in the context of a defense of string theory research.

10. **Cosmonut**
June 13, 2017

Thanks for the very informative links to Will Kinney.
"It is not ever the case that all of a theory's predictions are empirically verified"
'True. But it would be useful to have *one*. It would be a start, anyway."

I think that one comment says it all, really. 😀

11. **skydivephil**
June 13, 2017

I am not convinced you have represented Rovelli's position correctly. I don't believe he was a saying that string theory has failed. Perhaps I have misunderstood what you were saying Peter. I think Rovelli was arguing that it had failures such as the lack of black holes, supersymmetry etc at the LHC that should reduce our credence in it. Not necessary cause us to abandon all of its ideas. I don't think he was a saying that string theory has failed . Perhaps you can point me to the relevant passage if I have that wrong.

Rovelli also seems quite happy with the idea of non empirical verification of science. he says it happens all the time. " To evaluate theories, they routinely employ a vaste array of non-empirical ar- guments, increasing or decreasing their confidence in this or that theoretical idea, before the hard test of empirical confirmation (on this, see Chapter VIII of [2]). This is the context of a "preliminary appraisal" of theories, or "weak" evaluation procedures'.

It seems to me then Rovelli is more in the middle between those that say anything that isn't testable by experiment isn't science and those that say if its theoretically plausible , that is enough. Im not sure there are many people that take these two extreme views anyway. I think Rovelli is saying non empirical appraisal is part of the scientific process and can give you some sort of "weak" status , a preliminary approval. But only experiment can give you the hard approval to turn your idea from promising proposal to accepted fact.
In Rovelli's previous appraisal of string theory he has both negative and positive things to say about it. Im sure you know the negatives but the positives were comments like

"String theory is a spectacular intellectual achievement and it might well turn out to be the right track. It is a rich and elaborate theory, that deserves to be studied further… But I think it would be a mistake to consider string the- ory as an established result about nature and therefore concentrate the attention solely on it. Also if the hopes of other research directions are realized, it would be a triumph. String theory appears of unmatched beauty to string theorists, but other ideas appear of unmatched beauty to others. What I think is important is to keep in mind that these theories are provisional.
I am not pessimistic. "

I am not seeing anything that implies he's changed his mind about this.

I also think the only game in town comment needs more careful examination. When I interviewed Abhay Ashtekar he seemed to be saying that in one sense LGQ is not a competitor to string theory and in another sense it is. LQG and string theory are both quantum theories of gravity but string theory goes much further in trying to be a unified theory. LQG does not do this and in that sense it is not a competitor to string theory. So I think one needs more care in evaluating the "only game in town" claim. In what sense was it being made ?

12. **Peter Woit**
June 13, 2017

skydivephil,
When I say "string theory has failed", I mean specifically failure as a unified theory, not that "one should abandon all its ideas" (of which there are many, of many different kinds). I don't claim Rovelli would use the same words, but the last three paragraphs of the paper I linked to list "failed predictions" of string theory and argue that that these "lower the degree of belief in string theory dramatically". I think Rovelli's "having the degree of belief in a theory lowered dramatically" can reasonably be translated into the more concise "the theory has failed". Of course "failure" is always something that comes in degrees: what I mean by a "failed idea" is one that is no longer promising. Sure, an unpromising idea may yet get revived, and some people should work on such ideas if they can't think of anything else to do.

About LQG vs. string theory, sorry but I don't think that's relevant to Silverstein's article.

13. **Will Kinney**
June 14, 2017

Peter, I'm not positive, but I suspecct Renata is referring to "alpha attractor" inflation models, which she proposed with Andrei Linde and Diederick Roest in 2013:

https://arxiv.org/abs/1310.3950

It's basically a class of non-minimally coupled scalar field models with universal behavior at strong coupling. The universality happens at strong coupling because in that limit the scalar sector becomes irrelevant, and the model asymptotically approaches Starobinsky R^2 inflation. In such a case, tensors will be at the r=0.01 level, observable with near-future observations.

Nice model, but calling it a test of string theory is a bit of a stretch, since the exact same prediction can be obtained through suitable choice of potential in a canonical scalar field model, with no reference at all to to UV physics.

14. **a 1**
June 14, 2017

The argument "you should not expect to see results in your lifetime" strikes me as identical to the advice given in religious instruction "you should not expect to see end of the world" – which people are hearing now for a third millenium in a row.

15. **Dave Miller**
June 14, 2017

Anon,

You wrote to Peter:

>You are arguing against
a straw man here — the classic theories were not
compared to string theory, they were mentioned
in the context that even some well established
theories waited substantial periods for certain
of their predictions to be tested, the timescales
for theory and experiment not being perfectly
lined up even in that extreme case.

With due respect, I think you are missing the real point here. The problem is not that string theory is a well-defined theory, just as GR was, but that it cannot yet be tested empirically for practical reasons, just as gravitational waves could not be detected for nearly a century.

The problem is quite different: GR was a perfectly well-defined theory by 1916 — it made clear, definite, and unequivocal predictions, even if some of those predictions could not be tested at the time. String theory (like inflationary cosmology) simply is not (yet) a well-defined theory that makes clear, unambiguous empirical predictions.

I.e., the problem with string theory (and inflationary cosmology) is not that we cannot test its predictions due to practical limitations but rather that it does not (yet) make any clear, definite, unambiguous predictions. The distinction is important.

I think Peter's posts do sometimes give the impression that his objection is simply that the empirical tests of string theory are taking too long in terms of time. But, he has made fairly clear that time is not the fundamental problem: the problem is that there simply is no well-defined, unambiguous theory in existence for strings (or inflationary cosmology).

Maybe that will change. I hope it will, and I am a bit more optimistic here than Peter.

But the distinction is an important one. Whether or not the solution is, as I suggested above, simply to refer to such "theories" rather as "musings" or "speculations," it is critical to keep in mind a distinction between ideas that make clear empirical predictions that *in principle* can be tested and those which do not.

Dave

16. **Peter Woit**
June 14, 2017

Thanks Will,

Linde and Kallosh do seem to have a different definition of "prediction" than most people (including Silverstein, who noticeably doesn't make claims like this about "predictions of string theory").

17. **Cosmonut**
June 14, 2017

The impression I have about the current state of affairs with "string theory":

– There is a minority of very vocal senior scientists loudly promoting the string theory landscape multimess on popular media to get publicity.

– The majority of researchers are just trying to mathematically extend "QFT in curved spacetime" in various directions.
The entire mishmash of approaches is mostly lumped together as "string theory" – which isn't really an accurate characterization.

Would that be approximately correct ?

18. **Peter Woit**
June 14, 2017

Cosmonut,
I'd agree with the first and last part. I don't think it's accurate though to describe what the majority of researchers are doing now as "just trying to mathematically extend "QFT in curved spacetime" in various directions". I don't think there is any simple way to characterize what "the majority of researchers" are doing, but lots of it has nothing to do with curved spacetime.

19. **tulpoeid**
June 18, 2017

Usually I get enraged by such writings, but, seriously now? "Historically, there are classic cases with long time delays between theory and experiment – Maxwell's and Einstein's waves being prime examples"?

It's becoming obvious to me that these people inhabit a very special and distorted space in their mind. Going on with their fervent blind belief and the more and more detached and uselessly sophisticated reasonings just brings them further away from reality — in a very everyday sense of "reality". Imho I don't care anymore for the amounts of money and arrest to science's development that they cause.

Attending pop science events and hearing the audience asking about the multiverse though when the speakers spoke about a dozen other verified wonders still makes me a little sad.

20. **Sebastian Thaler**
June 19, 2017

Meanwhile, hope springs eternal for the SUSY folks: https://www.nytimes.com/2017/06/19/science/cern-large-hadron-collider-higgs-physics.html

21. **Ra**
July 7, 2017

Dear Peter:

The problem is that: String theory is not a "theory", String theory is a paradigm, in the same way as General relativity is a paradigm, once you have a specific model (i mean: a particular solution for the field equations) you could make predictions, notice that if you pick an arbitrary solution form the landscape of general relativity, it is impossible to decide what are good observables, for example: The density parameter is a good number for a cosmological solution, but is irrelevant to try to compute that number for a gravitational wave (an allowed solution). This situation means that general relativity is unpredictable? Of course not and exactly the same happens with string theory, what is the problem with that ?

22. **Peter Woit**
July 7, 2017

Ra,

From the FAQ
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=isnt-string-theory-just-as-predictive-as-quantum-field-theory

This Time It's Really for Real

June 14, 2017
Categories: Quantum Theory: The Book

Twice now I've thought I had a finished version of the book I've been writing forever (see here and here). Each time it turned out that, the way the publishing process was going, I ended up having more time to work on the manuscript and deciding I could do better, especially with some of the basic material about quantum field theory. I do think the latest version has a much improved treatment of the basics of that subject.

This version will go off to Springer in a day or so, and they plan to publish it late this year/early next year. I'm setting up a web-page for the book, there may be more material there later.

One thing ensuring that I will stop working on this is that in a couple days I'm heading off on vacation, for a two-week or so trip to Europe. Blogging during that time is likely to be light to non-existent. Back around the Fourth of July, and looking forward to thinking about other projects, anything but this book…

Update: If you're wondering why the document length changed today, no change in content, just a minor change (improvement) in formatting.

   June 15, 2017

   A friend of mine recently finished work on a textbook. He has given everyone he knows strict instructions to remind him to say "no" if he is asked to write another one 🙂

3. **anon**
   June 15, 2017

   Peter, it's great that the book is finally going to get published, but now leaving you at the mercy of the reviews on Amazon which will be fun for the rest of us to read. If it turns out successful, there's still the future opportunity for you to improve the book later on, so I wouldn't be too obsessed about getting it too perfect at this stage. The main thing is eliminating the errors.

4. **Peter Woit**
   June 15, 2017

   anon,
   I'm not so worried about Amazon reviews. This book isn't for everyone, and I'm more aware of its faults than anyone. I do hope it will be useful to both mathematicians and physicists in providing a point of view on the relation of physics and mathematics that isn't well-described elsewhere. There are quite a few good QFT and QM books, the virtue of this one I hope is that it's explaining as clearly as possible some different things and a different point of view, supplementing other books.

   I have put quite a bit of effort into getting rid of typos and getting all the formulas correct, that's an extremely time-consuming and not very rewarding business. There are certain topics in QFT that I started to try and write about, but stopped and decided they were best left to a later time, I hope to get to some of those.

Fantastic!
I have down-loaded the final draft three or four times! No big deal, except I always
end up printing it out because I hate reading anything at all long on a screen.

Danged long it is ,-but it's one of those subjects where there is always something else to say, and I think you put in details that are quite useful to understanding, not just technical trivia.

Thanks, Tim

This Week's Hype

June 22, 2017
Categories: This Week's Hype

I'm on vacation in Europe, not in any mood to spend more time on this than just to point out that it's the same usual tedious string theory promotional operation from the same people who have been at this for decades now. We have

- A PRL publication that has nothing at all to do with string theory, preprint here. This is about a purely classical pde calculation in coupled EM + gravity.
- The researcher's university puts out a press release.
- A story then appears where the usual suspects claim this is some sort of vindication for string theory and shows their loop quantum gravity opponents are wrong. There's a lot of quite good information in the story about the actual classical calculation involved, but no indication of why one might want to be skeptical about the effort to enlist this result in the string vs. loop war.

While traveling I've seen a couple very good stories about physics online:

- A summary from Dennis Overbye about the the current status of energy frontier HEP.
- An excellent long article by Philip Ball about quantum mechanics and the measurement problem.

Comments

1. **tulpoeid**
   June 22, 2017

   I don't know what to think about the very impressive article by P.Ball.

   On one hand, it's refreshing to see a sharp attack of the metaphysical features some people try to ascribe to quantum mechanics (it's 2017 and posts on stackexchange about quantum measurement quickly get hijacked by supporters of parallel universe and even conscious observer interpretations).

   On the other, it seems to me that his enthusiasm largely consists of rephrasing of controversial terms but not necessarily their explanation. How did the described scheme explain the statistical nature of the outcomes? Maybe I missed that and I will definitely look into the decoherence theory now, but informed comments could be helpful.

   What I wonder about is how much established the status of decoherence theory is. Statements like the following sound pretty strong; are they considered mainstream in quantum optics or other fields? (Of course not being mainstream doesn't render them wrong etc.)
   "A detailed theoretical analysis of decoherence carried out by Zurek and his colleagues shows that some quantum states are better than others at producing these replicas: they leave a more robust footprint, which is to say, more copies. These robust states are the ones that we can measure, and that ultimately produce a unique classical signature from the underlying quantum morass."

2. **Charles Day**
   June 22, 2017

   Peter, your readers might be interested in this (freely accessible) Physics Today article by Ed Witten that introduced M-theory. It appeared in May 1997, two years after Witten had conjectured the existence of such a theory as a way to unify various flavors of string theory. http://physicstoday.scitation.org/doi/abs/10.1063/1.881616

3. **Peter Shor**
   June 22, 2017

   tulpocid:

   If the article is correct, then before 1996, there was no way to calculate the speed of decoherence, while today we know how to do it, and the results of the calculation match experiment. This is definitely great progress in understanding the nature of quantum mechanics and how it generates a classical-looking universe.

   On the other hand, it is not clear that this is a satisfactory resolution of the philosophical questions on the nature of quantum mechanics. Certainly, not everybody is satisfied.

4. **Peter Shor**
   June 22, 2017

   Correction to my previous comment: the article says that 1996 was when the first experiment comparing theoretical calculations of decoherence rate with experiment was done. The theory was developed over the previous decade or so. (I should have known this; I was paying attention during part of this time.)

5. **Jeff M**
   June 22, 2017

   Peter Shor,

   I'm not sure how experiments checking decoherence are even possible. Experiments of necessity involve conscious observers. Decoherence is supposed to tell you what happens in the absence of observers.

6. **tulpoeid**
   June 22, 2017

   Jeff M,
   Maybe this is why the people who achieved it won the Nobel prize 🙂

   (Whose tremendous importance was partly lost on the general audience, because it was the same year with the Higgs announcement and it's more fun to whine about the latter not getting it prematurely than explaining quantum fundamentals. But I digress.)

7. **Peter Shor**
   June 22, 2017

Jeff M:

Did you read Philip Ball's article? I quote:

> We have, at long last, a theory of measurement. What's more, it is a theory that confers no privileged status on the conscious observer, stripping away the seemingly mystical veneer from quantum mechanics.

In its simplest form, decoherence is the decay of the diagonal elements of the density matrix in the *pointer basis* (called *pointer states* in Ball's article). This is a phenomenon we believe happens with or without conscious observers (although I assume it's only been measured in their presence).

8. **Marko**
June 23, 2017

Decoherence theory is great, but do note that the consensus of the majority of the experts in the field (i.e. everyone I ever asked) is that decoherence does *not* solve the measurement problem. The reason is that QM does not give any rule to determine the pointer basis, and specifying it ad hoc in any way is actually equivalent in power to the collapse postulate itself, which we set out to explain by decoherence.

HTH, 🙂
Marko

9. **Another Anon**
June 23, 2017

Put simply, Marko, I think of decoherence as an explanation of how all the alternative quantum realities can disappear (why we could never see Schrödinger's cat alive and dead at the same time -the atoms in the cat quickly decohere) but it does not explain which of those realities we actually see, as you say – the pointer basis.

But I think just the fact that it explains how the alternate realities can disappear is damaging for the many-worlds multiverse.

10. **Low Math, Meekly Interacting**
June 23, 2017

For me, this is the kicker: "Decoherence doesn't completely neutralise (sic) the puzzle of quantum mechanics. Most importantly, although it shows how the probabilities inherent in the quantum wave function get pared down to classical-like particulars, it does not explain the issue of uniqueness: why, out of the possible outcomes of a measurement that survive decoherence, we see only one of them."

I suppose it's nice that one doesn't have to explain away an infinity of alternate realities. However, and it could very well be I've misunderstood something, it seems to me that if whatever process you invoke (Darwinian or otherwise) doesn't select a unique reality that we conscious minds perceive (and always agree on), it's not clear that progress has really been made. To my untrained eye the advantage of paring things down appears to be more psychological than anything else. Instrumentalism still seems to rule as the only truly honest way to cope.

11. **Douglas Natelson**
June 23, 2017

I think it's worth pointing out that indirect measurements of (statistically averaged) decoherence in many-body systems predate 1996 in the form of "mesoscopic" physics in metals and semiconductors. There are quantum interference corrections to electronic conduction in solids (weak localization and universal conductance fluctuations, to name two). A classic early review of weak localization is this one from 1984, and this is a broader review from 1992.

In a Feynman-Hibbs heuristic argument, in the absence of decoherence, an electron propagating from one location to another through a solid takes all possible paths. Along each of these paths, the electron wavefunction accumulates a phase proportional to the product of its wavevector (related to its kinetic energy) and the propagation distance, and with an additional "Aharonov-Bohm" phase proportional to the electronic charge and the line integral of the vector potential along the path. Scattering off static disorder along a particular trajectory can introduce additional phase shifts. The final transmission probability of the electron from initial to final location involves summing the complex amplitudes for each of these trajectories and then finding the magnitude-squared of the total amplitude. Changing a magnetic field alters the relative phases of the different trajectories, altering the probability of electron transmission and hence the electrical conduction.

With decoherence, you don't have to worry about interfering contributions from trajectories that take longer than the decoherence timescale. That ends up setting a characteristic magnetic field scale for conductance changes that can be determined experimentally. TL/DR version: By measuring the conductance (or equivalently resistance) of a metal or doped semiconductor as a function of an externally applied magnetic field, it is possible to infer the underlying decoherence timescale associated with the motion of the charge carriers. The dominant causes of decoherence for these free charge carriers are inelastic scattering processes involving lattice vibrations (at high temperatures) and electron-electron interactions (at low temperatures, say below 4.2 K) as well as spin-based (magnetic) scattering processes (also at low temperatures). The typical coherence timescale for electrons in such a system around 10 fs near room temperature, but can easily be nanoseconds or longer at cryogenic temperatures.

12. **Jan Reimers**
June 23, 2017

Marko, Peter Shor and Another Anon,

It is usually at this point that Peter accuses us being un-informed and repeating tired old arguments, but I will go out on a limb and participate anyway

Regarding the pointer basis, Nima comments on this at 55:40 in the video below. Start a 40:00 if want the full context.

https://www.youtube.com/watch?v=3bqvAIKH2Rg

The short answer as I understand it is that the pointer basis is selected by the Hamiltonian that describes the interaction between the "system" and the environment. The interactions are local, so in his example local (position) states are selected as the pointer basis rather than super-positions of position states. I don't how to extend this argument to alive and dead cats though!

It seems there are three things we need to explain

1) Selection of a pointer basis
2) Diagonalization of the reduced density matrix for the "system" **in the pointer basis** (i.e. no macroscopic entanglement)
3) Collapse of the diagonal density matrix elements to only one element as a result of a measurement.

Decoherence explains 2) and the interaction Hamiltonian explains 1). Is there a way that interaction with the environment can also explain 3)?

13. **Peter Shor**
June 23, 2017

Wow!

The comments here make me suspect that there are more people than I ever would have believed who are deeply invested in the mystical idea that consciousness has something to do with quantum mechanical dynamics.

This probably says something about human nature.

14. **Marko**
June 23, 2017

Jan Reimers,

Nima is repeating the usual locality argument for the selection of the pointer basis, which everyone talks about, but noone is able to implement effectively. So at this point it's just wishful thinking. Moreover, the locality argument can exist only on a classical spacetime manifold, and fails in a full quantum gravity setup, since the notion of locality cannot be defined on superpositions of manifolds.

So that argument doesn't really work, and cannot work, as a criterion for the pointer basis.

HTH, 🙂
Marko

15. **Mateus Araújo**
June 24, 2017

Jan Reimers and Marko,

What you say is not totally incompatible with Ball's article (which I quite liked, by the way). He explicitly says that decoherence doesn't solve the multiplicity problem (Reimers point 3), which is why most experts say that decoherence doesn't solve the measurement problem, as claimed by Marko.

Marko's reason for that is false, however. The consensus is that decoherence *does* solve the preferred basis problem, precisely as Reimers report. If you really think that no one can effectively derive the pointer basis from the interaction Hamiltonian, you had a lot of comments to write on the decoherence papers.

As for the quantum gravity argument against decoherence, come on. Using a non-existent theory to argue against an existent theory is just bizarre.

16. **Martin S.**
June 24, 2017

Regarding decoherence, the respective part of FAQs is helpful.
And regarding P.B.'s words (in the article linked in the P.W.'s post) against "spooky" stuff, does it mean that P.B. (and P.W.) disagree with Bell inequalities? AFAIK Bell inequalities hold regardless of decoherence being/not-being part of measurement.

Regarding words on Higgs boson mass in the D.O.'s text (linked in the P.W.'s post, seek the second occurrence of the word "quadrillion" there), do not they mix the originally expected Higgs mass (several times greater than lately found) with the absurd value of theoretically approached CC value?

17. **Mateus Araújo**
June 24, 2017

Martin S.:

I'm sure Philip Ball is referring to the nonlocal collapse of the wavefunction, this is what decoherence theory eliminates (in favour of a local effective collapse).

The violation of Bell inequalities is extremely well-stablished experimentally, you cannot get rid of them by playing with the theory.

18. **Martin S.**
June 24, 2017

@Mateus Araújo:
"*The violation of Bell inequalities is extremely well-stablished experimentally, you cannot get rid of them by playing with the theory*." That's what I meant; I was way too sloppy there.
"*I'm sure Philip Ball is referring to the nonlocal collapse of the wavefunction, this is what decoherence theory eliminates (in favour of a local effective collapse)*." Thanks, then according to my knowledge there must be some another nonlocal process, e.g. that choosing of single diagonal element in density matrix should be nonlocal, or we need (absolutely) nonlocal hidden variables. And that another nonlocality is the same "spooky" as nonlocality of any other process, I would say.

19. **vmarko**
June 24, 2017

Mateus Araújo,

"As for the quantum gravity argument against decoherence, come on. Using a non-existent theory to argue against an existent theory is just bizarre."

No, it's not bizarre. You cannot claim that you can resolve a fundamental problem (the pointer basis) by appealing to a semiclassical (i.e. approximate) theory, which completely ignores one very fundamental interaction in nature (gravity). At the very least, there is a potential danger that your solution may be an artifact of the approximation rather than a genuine property of a (so far unknown) complete theory.

And this is actually what happens — the proposed solution of the pointer basis problem rests on the notion of locality, which in turn relies on the notion of classical spacetime manifold, which may or may not exist in a full theory of quantum gravity. So this is the weakest point of the whole argument, and ignoring that point is what's bizarre.

Even Zurek, the father of decoherence, was aware from the very beginning that gravity may introduce trouble — in his foundational paper [1], on page 1520 he wrote: (the assumption of pairwise interactions) “is customary and clear, even though it may prevent one from even an approximate treatment of the gravitational interaction beyond its Newtonian pairwise form.” In other words, he made a disclaimer that the whole decoherence programme may fail in the presence of a tripartite interaction term in the Hamiltonian, which is precisely what relativistic gravity has.

And finally, one doesn’t need a full theory of quantum gravity to make that point. It is quite enough to know that ordinary theory relies on spacetime being classical — and in almost all QG models this assumption is violated, resurrecting the measurement problem back to its full glory.

Btw, it’s not that experts in the field aren’t aware of this. They are, but they don’t know what to do about it, and there is a lack of good ideas how to deal with such a problem (in the absence of a full QG theory). That is one of the reasons why they generally agree that decoherence doesn’t really solve the measurement problem. At least the ones I’ve talked to. 😉

HTH, 🙂
Marko

[1] W. H. Zurek, Phys. Rev. D 24, 1516 (1981).

20. **Mateus Araújo**
June 24, 2017

Marko, you are quoting a paper from 1981 to talk about the theory in 2017. This is 36 years ago. Decoherence changed from being a new idea to being a well-established theory. This inverts the roles of decoherence that has to adapt itself to quantum gravity to succeed, it is quantum gravity which must allow a decoherence-like mechanism to be taken seriously. Are you forgetting the experiments that need decoherence to be explained, including the one that got Haroche his Nobel prize?

And you don’t “ressuct the measurement problem” as soon as you drop the assumption that spacetime is classical. We knoe that classical spacetime is a very good approximation at any energy scale we can actually experiment with. If this works at all like nornal science, relaxing this assumption will make an \epsilon correction to the theory.

You have clearly been talking to different experts than me. And, as someone who works in quantum foundations, I do know a lot of experts.

21. **Mateus Araújo**
June 24, 2017

Martin S.

We don’t need a “nonlocal process”, what we need is to be able to reproduce the observed violation of Bell inequalities. And a purely quantum description of the experiment is perfectly local, the nonlocalities only appear when you start collapsing stuff.

22. **vmarko**
June 24, 2017

Mateus,

“it is quantum gravity which must allow a decoherence-like mechanism to be taken seriously”

Sure, this is a valid point of view, and may serve as a criterion for a plausible QG model. The general drought of experimental results in QG makes all such criteria fair game. But suppose sometime in the (far far) future, we start making experiments in QG, and find out that it indeed badly violates the notion of locality. That would certainly invalidate decoherence as a solution of the measurement problem, wouldn’t it? Regardless of how unlikely that may be, it certainly is a logical possibility. So it’s fair to say that the locality-based solution of the pointer basis problem is contingent on certain properties of QG, which is so far unknown, and outside of experimental realm.

“We knoe that classical spacetime is a very good approximation at any energy scale we can actually experiment with. If this works at all like nornal science, relaxing this assumption will make an \epsilon correction to the theory.”

Well, no. All experiments we can do are in our Solar system, which so far doesn’t feature any strong superpositions of the gravitational fields. That’s why classical spacetime is a good approximation. However, one can certainly imagine scenarios (typically involving a photon, a beam splitter and a black hole) where one should discuss strong superpositions of very different geometries, which behave nothing like an \epsilon correction to a classical geometry. Theory should be able to account for these situations too.

There was an analogous mishap with the assumed universal validity of the law of energy conservation (which was overwhelmingly supported by experiments), until general relativity taught us that such a law is valid only under certain circumstances, which are satisfied in our Solar system and the Milky Way, but not in general. So one has to be very careful with the reasoning you proposed above.

“You have clearly been talking to different experts than me. And, as someone who works in quantum foundations, I do know a lot of experts.”

This may be getting slightly off-topic, but just today I came back from visiting your PhD advisor in Vienna. 🙂 // I also attended the ongoing ESI workshop [2] there… // Granted, I didn’t talk to him about this particular issue (didn’t come up in the conversations, we had other stuff to cover), but I’ll make sure to do so when I visit his group again in October. So would you agree to postpone this “argument from authority” until then? 😉

Best, 🙂
Marko

23. **Martin S.**
June 24, 2017

@Mateus Araújo: Trying to be less sloppy, I mean experiments where apparatuses are spacelike separated, their outputs are real, we have choices to arrange those apparatuses locally (yeah, I had read those free-will-theorem articles), and “nonlocal” is considered as “effectively nonlocal”, admitting e.g.: speeds without limits and/or going backwards in time (sort-of the transactional interpretation), some spatial bridges in other dimensions, or whatever.
Then while decoherence is important, it leaves the *uniqueness* (as stated in the article linked in the blog post), that is point 3 at Jan Reimers’s comment, and the upper part of the FAQ part. When one is honest, the effective nonlocality occurs somewhere (to have such an experiment done), and here it is apparently pushed into that *uniqueness* part.

Thus I am unhappy about that article, since it says that there is nothing “spooky” (that is effectively nonlocal), while sweeping it under the rug, that is into the *uniqueness*. May be that I read too much into it though.

24. **Peter Shor**
June 24, 2017

@Marko:

I don’t understand your argument against decoherence and localization at all.

If you believe that the Standard Model is a very good approximation to string theory under most realistic conditions, please explain why a theory of decoherence that holds for the Standard Model wouldn’t also apply to string theory.

And if you don’t believe that the Standard Model is a very good approximation to string theory under most realistic conditions, then you’ve got even more explaining to do.

25. **Erika**
June 24, 2017

Off-topic: Peter, can you mention this in some future “quick items” post?

Besides Peter Scholze, who do you think will win the Fields Medal in 2018 (choose up to three names)? Vote here: https://vote.pollcode.com/31229277

26. **Mateus Araújo**
June 25, 2017

Martin S.,

I think you do have a point. While decoherence does give you a physical (and therefore local) explanation for the destruction of the off-diagonal elements, to get a unique result you need again some sort of collapse, which is by necessity nonlocal. And one does not even need Bell inequalities to see that, the good old EPR paradox is good enough. Consider as usual that Alice and Bob share a singlet |01> – |10>, and that Alice makes a measurement in a basis |A_0>,|A_1>. Then we rewrite the state in this basis to turn it into |A_0 A_1> – |A_1 A_0>, and the measurement (through decoherence) maps it into |A_0 A_1><A_1|, dependent on a distant change of basis.

So decoherence only gives you a way to locally kill off the off-diagonal elements; it doesn't give you a way to locally select a single outcome. Still, it is an improvement over the collapse postulate, according to which even the disappearance of the off-diagonal elements is nonlocal.

But what I was talking about is that if you stick to the quantum mechanical formalism, you'll have a completely local theory, as any physical Lagrangian is Lorentz covariant. You only get nonlocality when you do an ad-hoc modification of the quantum formalism, such as selecting unique outcomes.

Maybe you'll be interested in this paper by Brown and Timpson, which goes on precisely about how you get EPR and Bell correlations locally if you stick to the quantum formalism: https://arxiv.org/abs/1501.03521

27. **Mateus Araújo**
June 25, 2017

Marko,

I think I’ve understood why we’re failing to communicate. You expect decoherence to *always* work, even in exotic quantum gravity regimes where we’re in a superposition between being inside a black hole and outside. Whereas I’m claiming that quantum gravity must allow decoherence to work in the experimental regimes we can access today on Earth.

“That would certainly invalidate decoherence as a solution of the measurement problem, wouldn’t it?”

No, it wouldn’t. While it would be certainly be shocking if we found out that decoherence actually fails in such exotic regimes, it wouldn’t make me shed a single tear: its job is to explain the measurements we’re actually doing, and that it does with unparalleled success (its main rivals being burying your head in the sand or radically modifying quantum theory).

Getting wildly off-topic: I did not meant “talking to different experts” as an insult. I just meant that you have been probably talking to quantum gravity people, whereas I’ve been talking to quantum foundations people. Anyway, I think I’m more familiar than you with the opinion of my former PhD supervisor =). But we could just ask him, no?

28. **Martin S.**
June 25, 2017

@Mateus Araújo: regarding 1501.03521;
1) Bell’s opinions: science is not about caring of opinions; e.g. QM is quite successful regardless some dislikes by one of its early fathers, namely A. E.;
2) then that article is about the Everett interpretation: and it requires the uniqueness, that is the part that hides nonlocality inside itself;
3) an attempt to come to uniqueness without nonlocality (within E. I.) is by later (local) comparisons of results; but here (non-aligned-spins experiments) you need to get rid off some result combinations so that proper correlations are gained, and such a pruning means that some branches get killed; such a branch killing is first, strange by itself, second, you either have to kill such branches in their entirety (that is non-locally), or you need to kill anyone who tries to test it (making holes in the branches by that). then we can do an amount of such experiments together with the comparisons, and after some amount of such tests we reach a branch that either has to get killed entirely, that is together with us (in the former case), or we get killed when we try to read the results (in the latter case);
4) less naughty way of testing the outputs is via the transactional interpretation where the future is probed before actually taking one real output, that is without a need of killing us later. not arguing for it though, just mentioning it as a less terrible alternative;

PS Am not willing to argue about E. I. any more, since (according to my understanding) it solves nothing (as I described in the points above).

29. **Pascal**
June 25, 2017

I remember seeing an article on arxiv explaining why the initial condition of the universe must be taken into account to explain why the universe is classical-looking (so in particular, decoherence theory by itself would not be a good enough explanation).

The argument in a nutshell: if we start from a random, highly nonclassical state of the universe, and apply any unitary transformation (representing the evolution of the universe since the origin) then we obtain another random, highly nonclassical state.

I find this argument quite compelling but I'd be curious to know the opinion of people with a deeper understanding of physics than me.

30. **Martin S.**
June 25, 2017

@Pascal: Will not help you, especially when not having link to the text (and probably neither even with a link). If it is something like/this, I would suggest to ask Bee.

31. **Mateus Araújo**
June 25, 2017

Martin S.,

I'm afraid you have misunderstood the article. It is about how you get Bell correlations in a local way if you *don't* have uniqueness. This is what the Everett interpretation is about, not modifying quantum mechanics and trying to interpret the resulting weirdness. There is no killing involved, either of branches or experimentalists.

32. **Peter Shor**
June 25, 2017

Mateus Araújo:

… or cats.

33. **Hannes**
June 26, 2017

Peter,

my friend Chris just showed me this:
http://www.lhc-epistemologie.uni-wuppertal.de/
It is a well-funded physics-philosophy research program on the epistemology of the LHC. I really do not know what to think about it. But it exists.

34. **Anonyrat**
June 27, 2017

One of the projects of that physics-philosophy program:

Principal Investigators:
Robert Harlander (RWTH Aachen)
Adrian Wüthrich (TU Berlin)
Principal Collaborator:
Friedrich Steinle (TU Berlin)
Postdoctoral Researcher:
Daniel Mitchell (RWTH Aachen)
Doctoral Researcher:
Markus Ehberger (TU Berlin)
The sub-project A1 investigates the concept of a virtual particle from a historical point of view. This concept is an integral part of modern physics, mainly since it provides a means to interpret and describe complex quantum physical processes in comparatively simple terms. Despite of its wide use, the notion of a virtual particle appears not to be clearly defined. One of the main goals of the project is therefore to trace the origins of the concept and to follow its evolution through time. Since it is of a fundamental quantum physical nature, it is quite clear that the roots of the virtual particle concept are tied to the beginnings of quantum mechanics and quantum field theory. However, the reasons for its introduction, its further development in the context of quantum field theory, S-matrix theory, and Feynman's diagrammatic method have never been the focus of historical research. By taking up these issues, the present project aims to explain the genesis of today's terminological diversity, to bring to the fore the reasons for the apparent inconsistencies, and to further our understanding of concept formation in the physical sciences.

—
The goals are somewhat unclear to me, but if the result is to bring some precision to the various uses of "virtual particle" in the physics literature, that would be a good thing. If new experimental results are in short supply, then spending effort to elucidate the foundations of physics is worthwhile, in my opinion.

35. **Mitchell Porter**
June 27, 2017

Peter Woit said

"There's a lot of quite good information in the story about the actual classical calculation involved, but no indication of why one might want to be skeptical about the effort to enlist this result in the string vs. loop war."

Well, it's obvious why they make that connection. Vafa argues that the naked singularity goes away, exactly when you include charged matter obeying the weak gravity conjecture. String theory appears to obey the weak gravity conjecture and in some cases one can even say why. Loop quantum gravity appears to not obey the weak gravity conjecture because electromagnetic couplings are simply free parameters in that theory, there's no known mechanism that can stop you from making them weaker than the conjecture allows.

In my opinion, the main reason not to bring strings vs loops into this, is that loop quantum gravity already has so many other problems: chiral fermions, logarithmic corrections to black hole entropy, the peculiarities of polymer quantization, the very existence of a classical limit. If an alternative to string theory is desired, one could reasonably ask why we are getting the loop perspective, rather than e.g. the asymptotic safety perspective, which at least has successful empirical and mathematical predictions to its credit.

36. **An Interpreter**
June 27, 2017

Decoherence does not imply the disappearance of superposition. It just implies the disappearance of the detectability of superposition, which depends on an interference _pattern_. This is easy to see. Two points from which emanate a wave will result in maxima and minima at a screen. The interference is detectable. Add a few more points at random locations and this sign of interference disappears. The interference is still there, it is just no longer detectable by experiments in which the results of repetitions demonstrate the pattern. The pattern, from which we infer interference is gone. The interference is still there. The superposition is still there. You still need a collapse.

37. **Abby yorker**
June 28, 2017

It is easy to visualize the replication with photons. I see it as a representation of the system by successive groups of impinging photons. However, what if the pointer apparatus uses a static electromagnetic field. I am thinking of the stern gerlach apparatus. I assume photons are used somewhere, but what is the mechanism? And what codes the replications?

38. **Frank Wilhoit**
June 28, 2017

Kane's quoted comment about "realistic" searches is outrageous and should be completely discreditive.

39. **ppnl**
June 29, 2017

Why would we expect or even want a solution to the measurement problem to solve the uniqueness problem? Decoherence means that anything big, complex and connected enough to be an observer will necessarily see an approximately classical universe. What more do you want? Sure, you can't predict which classical universe you will see. But so what? In QM some things aren't predictable.

It's like a quantum version of the anthropic principle. If you exist then the universe around you must look approximately classical.

40. **Mateus Araújo**
June 29, 2017

ppnl,

The uniqueness problem is about conciliating the multiple outcomes that appear in the equations with the unique outcomes we experience. It's not about predicting the outcome: I would be perfectly happy with a random outcome that came out of the quantum dynamics. This is pretty much what is done by collapse models, and they do have a satisfactory answer to the uniqueness problem. The problem with collapse models is that they don't really match reality.

41. **ppnl**
June 29, 2017

I still don't get it. Maybe I'm just not smart enough to understand the problem.

In collapse models you have an observer (what counts as an observer?) that makes a measurement (what exactly is a measurement?) and that reduces the state of the object.

With a decoherence you have an observer (any complex connected object will do) that makes a measurement (any interaction will do even if the observer is not aware of it.) and it gets constant state reduction behind its back so to speak.

Both have multiple outcomes that appear in the equations and in both cases one is chosen. There is nothing to reconcile. What more do you want? What would the answer you seek even look like?

42. **vmarko**
June 29, 2017

So I just came back from the "Gravitational decoherence" workshop in Bad Honnef, and one of the most interesting points of the final discussion session was the lack of consensus among people regarding the unitarity of QM.

There were two main points of view, distributed roughly half-and-half among the people present there. The first half maintains that nature is obviously unitary, since all existing measurements may always be reinterpreted as unitary evolution plus the decoherence with the environment.

The second half maintains that experiments give us obviously nonunitary results, and that imposing unitarity to QM and jumping through various hoops to make all evolution unitary lacks justification (and represents an ideology).

This was basically a divide between pure QM folks (favoring formalism) and the objective collapse folks (favoring instrumentalism). The initial question (raised by me 😉) was about the experimental status and possible tests of unitarity in nature. Instead of answering the question, people got split in two groups and started arguing, based on whether they interpret experimental results as saying that nature is not unitary or as saying that decoherence is too strong to avoid.

The consensus, however, was that in the end this question is extremely hard (if at all possible) to resolve experimentally, i.e. the assumption of unitarity is apparently not falsifiable. So it doesn't really belong to physics, but to philosophy. So there you go — collapse or decoherence, take your pick, it's a metaphysical point of view. 😉

Best, 🙂
Marko

Last Week's Hype

July 6, 2017
Categories: This Week's Hype

Now back from vacation, more regular blogging should resume imminently. While away, lots of press stories about claims that LIGO could be used to get "evidence for string theory". As usual, these things can be traced back to misleading statements in a paper and the associated university press release. In this case, there had already been an initial round of hype, debunked by Sabine Hossenfelder. The new round seems to have been generated by the June 28 press release. The Guardian has a version of this, but at least there the author found someone to make the obvious point, that this is irrelevant to string theory.

Comments

1. **Jeff M**
   July 6, 2017

   I'm curious, why wouldn't the authors account for stabilization of extra dimensions? It's required, right? So an argument ignoring it is prima facie incorrect.

2. **Peter Woit**
   July 6, 2017

   Jeff M,
   For the technicalities of the actual result of the authors, better to raise the issue at Backreaction, where Sabine Hossenfelder has some expertise. What I'd like to understand is why they think it's a good idea to put out a press release invoking string theory and leading to the usual nonsense in the press.

3. **Jeff M**
   July 6, 2017

   Peter

   Will do. I wonder if the authors have anything to do with the press release.

4. **srp**
   July 17, 2017

   At least one author of the paper in question is claiming no real link to string theory, from the comments at Backreaction:

   "As the second author of the paper in question I fully agree with Olivier's comment (first comment here above), particularly with his first point. Moreover, I believe the whole point of vue of your post is a little forced. Talking about falsifying string theory on the basis of our analysis is quite a stretch, to say the least, and I don't think this viewpoint conveys the message very well or fits with the study at all. While ruling out string theory is a legitimate question to ask, I do not think one can answer it based on our simple study, which focuses on the propagation (ignoring sources and emission) and furthermore is not directly related to string theory but more genetically to extra dimensions."

5. **Peter Woit**
   July 17, 2017

   srp,
   I saw that too. A good question for this author is why he thought it was a good idea to have his university put out a press release about his paper mentioning string theory (by the way, this was done AFTER there had already been misleading press stories about string theory and this paper).

6. **srp**
   July 18, 2017

   The PR equivalent of "I just send them up and where they come down, that's not my department said Werner von Braun?"

7. **CIP**
   July 19, 2017

   Today's NYT has a story on an analog of the mixed axial-gravitational anomaly that invokes string theory:

   The experiment is also a success for string theory, a branch of esoteric mathematics that physicists have used to try to tie gravity into the Standard Model, the laws of physics that describe the other forces in the universe. But string theory has been maligned because it makes predictions that cannot be tested.

   Here, Dr. Landsteiner said, string theory was used to calculate the expected anomaly. "It puts string theory onto a firm basis as a tool for doing physics, real physics," he said. "It seems incredible even to me that all this works, falls all together and can be converted into something so down to earth as an electric current."

   Any comment?

8. **Peter Woit**
   July 19, 2017

   CIP,
   Thanks, hadn't seen that, one of the worst examples of This Week's Hype yet. Depressing that it's in the New York Times.

Various Links

July 6, 2017
Categories: Uncategorized

Some links to things that may be of interest:

- There's an excellent article at FiveThirtyEight about the issue of publicizing math research, taking as example the Atlas of Lie Groups and Representations project (which will soon be having a workshop). This kind of thing generally gets no public attention, while at the same time, one of the results of this research arguably got too much public attention (see here).
- There's a new \$1 million mathematics prize that will be awarded for the first time this fall, together with a $1 million physics prize that was awarded for the first time last year. This is called the Future Science Prize, and to get it you need to be working in China. Used to be a \$1 million prize was a big deal, now with the \$3 million Breakthrough Prizes, a mere million looks like small potatoes.
- Another way you could get a measly \$1 million would be to prove (or disprove) the Hodge conjecture. For some inspiration, see Burt Totaro's new survey of progress on the Tate conjecture (blog entry here).
- 4 gravitons has a nice posting about work by Turok and others about complexified path integrals and cosmology. The issue of the relation between Euclidean and Minkowski signature QFT is one that I think has gotten far too little attention over the years. Now that I've finished writing a book with a QFT discussion that sticks to Minkowski space, I'm hoping to work on writing something about the relation to Euclidean space.
- There's an interview with Nima Arkani-Hamed here. His talk at the recent PASCOS 2017 conference (real title is second slide "What the Hell is Going On?") gives his take on the current state of HEP, post failure of the LHC to find SUSY. He's sticking with his 2004 "Split SUSY" as his "Best Bet". I'd like to think his inspirational ending claiming that the negative LHC results are forcing people to rethink the foundations of the subject, asking again the question "What is QFT?" reflects reality, but not sure I see much of that.
- This year's LHC startup has been going well, with a new luminosity record already set, and 6 inverse fb of data already collected. For more, see here.
- Remember that "dark flow" that was supposed to be in the CMB data and evidence for the multiverse (see here)? Still not there, according to Planck (via Will Kinney).

Update: I'm sorry to hear the news of the untimely death of Maryam Mirzakhani, who was the first woman to win a Fields medal, awarded at the last ICM in 2014. Her work was described in detail at the time in this article by Curt McMullen.

Comments

1. **Jackson Clarke**
   July 7, 2017

   On rethinking the foundations of naturalness and SUSY as a potential solution, I don't think physicists need look further than the first slide of most SUSY talks, where the hierarchy problem (or the naturalness problem for the Higgs mass) is almost always described in terms of a top quark divergence and a cutoff scale. As a result, a good proportion of the field believe that the top quark itself is the problem, and the level of the naturalness problem is set by the cutoff scale alone. But this is not the case at all. In the standard model, the top quark divergence is an unphysical quantity related to the cutoff regularisation procedure, and (when new physics is added) the level of any naturalness problem is necessarily proportional to the coupling strength of that new physics (not just the scale of it). This is manifest when you only consider the renormalised parameters and not bare quantities. The latter point also seems to generalise to gravity: the lesson to learn is that scales in a theory can easily have small (and technically natural) dimensionless parameters hiding inside them.

   You (and others) might be interested in a recent blog post of mine where all this is spelled out in a way I have not seen elsewhere, and I think the field would benefit from considering. There is a sloppiness in the naturalness literature that needs addressing.

8. **David Roberts**
   July 15, 2017

   OT, but Iranian media is reporting that Maryam Mirzakhani has passed away.

9. **Mozibur Ullah**
   July 15, 2017

   This is sad news about Maryam Mirzakhani, to die so young and so soon after being awarded the Fields Medal. Rest in peace.

10. **Armin N**
    July 15, 2017

    I am genuinely shocked by her untimely passing. Not just Iran and the US lost a jewel, but humanity as a whole. My condolences to her family.

11. **tulpoeid**
    July 16, 2017

    If I am permitted to get dramatic … she bypassed two of the three obstacles that have usually kept women from entering history; she navigated a patriarchal society and she managed to combine career with family. The third one though, a more vulnerable body, caught up.

12. **Shantanu**
    July 17, 2017

    Peter, any comments about T'hooft's interview in physics today
    avaiable at DOI:10.1063/PT.6.4.20170711a

13. **Peter Woit**
    July 17, 2017

    Shantanu,
    I didn't think the interview was particularly interesting, more interesting was the news, which I hadn't heard, that he has a book out about his ideas about QM, freely available at

    http://www.springer.com/us/book/9783319412849

    The kind of thing he's trying to do is not my cup of tea (my own book about QM should make clear what point of view I'm more interested in) but others may find this more worth looking into.

14. **Low Math, Meekly Interacting**
    July 17, 2017

    I'd read about Maryam Mirzakhani with great interest (probably first in Erica Klarreich's article in Quanta). Not sure why, but news of her death made me especially sad for a total stranger whose work I don't understand. Maybe it's because my daughter was recently most tearfully upset because a boy called her stupid. Too few examples like Ms. Mirzakhani, and to lose her so young is simply tragic. I hope her legacy continues to inspire those most in need of a role model.

This Week’s Hype

July 19, 2017
Categories: This Week's Hype

Commenter CIP pointed out that today’s New York Times has one of the worst examples of string theory hype I’ve seen in a while. Based on this observation of an expected QFT anomaly effect in a condensed matter system, the NYT has an article An Experiment in Zurich Brings Us Nearer to a Black Hole’s Mysteries. Not only is the headline nonsense, but the article ends with

> The experiment is also a success for string theory, a branch of esoteric mathematics that physicists have used to try to tie gravity into the Standard Model, the laws of physics that describe the other forces in the universe. But string theory has been maligned because it makes predictions that cannot be tested.
>
> Here, Dr. Landsteiner said, string theory was used to calculate the expected anomaly. “It puts string theory onto a firm basis as a tool for doing physics, real physics,” he said. “It seems incredible even to me that all this works, falls all together and can be converted into something so down to earth as an electric current.”

There’s no connection at all to string theory here. The NYT seems to have been taken in by string theorist Landsteiner and press release hype like this, not noticing that the paper had no mention of string theory in it. The hype is timed to the paper’s publication in Nature, where the editor’s summary gets it right, referring to QFT not string theory:

> Johannes Gooth et al. now provide another intriguing connection to quantum field theory. They show that a condensed-matter analogue of curved space time can add an additional, gravitational component to the chiral anomaly in Weyl semimetals. The work opens the door to further experimental exploration of previously undetected quantum field effects.

Someone really should contact the NYT and get them to issue a correction. In particular, any string theorists who care about the credibility of their field should be doing this.

Update: For a couple more stories about this, IEEE Spectrum has Black Hole Power: How String Theory Idea Could Lead to New Thermal-Energy Harvesting Tech, Nature has Big Bang gravitational effect observed in lab crystal.

Update: The author of the NYT piece did make some changes in the last two paragraphs to make things less misleading.

Update: This has finally appeared in print today, in an abbreviated version, minus among other things the string theory business.

Comments

1. **Mitchell Porter**
   July 20, 2017

   String theory aside, is this, or is this not, an observation of an effect attributable to a gravitational anomaly?

   There’s a type of “condensed-matter hype” in which observation of monopoles, Hawking radiation, etc, is claimed, when of course the reality is just that something *analogous* to the claimed phenomenon was observed.

   What I get from skimming the theory papers is that an effective field theory for hydrodynamics in curved space-time can have a term whose coefficient is determined by the existence of the anomaly. Then I see remarks that this can still be true in flat space-time too. And finally, I see statements that in this experimental work, there’s a temperature gradient which is analogous to space-time curvature in its effects.

   So what’s going on? Is this another example of condensed-matter hype, that should be rectified by giving things their true names?

2. **Shantanu**
   July 20, 2017

   Dear readers,
   I suggest you try to write an email to the writer of this article pointing them this faux pas. On many times when Peter or others posted such hype articles I tried to find the email address of the person who wrote the article and in many cases it was hard to find. But I am guessing its easier in this case.

3. **Giulio**
   July 20, 2017

   Another piece of fake news from NYT. SO SAD!
   D.

4. **Citchell**
   July 20, 2017

   The section titled “1 Connection between the mixed axial-gravitational anomaly and thermal transport” directly references work by Landsteiner, Witten and Alvarez-Gaume, and Eguchi. Also a guy who has worked on born reprocity.

   http://www.sciencedirect.com/science/article/pii/055032138490066X
   https://en.wikipedia.org/wiki/Eguchi%E2%80%93Hanson_space
   https://en.wikipedia.org/wiki/Born_reciprocity

5. **bpv**
   July 20, 2017

   I sent a comment to the author of the article, Kenneth Chang, and he replied almost immediately with a likely pre-written email that he must be sending to everyone complaining about the article (he refers to them as “those who are outraged”).

   He basically says that he is aware of the reasons why knowladgeable people are concerned, but for most laymen the mention of string theory was just fine.

   Let me translate: He can say whatever he wants to people who have no capacity to check the truthfulness of the statements.

6. **Ed**

July 20, 2017

OT: could topological physics be the field to finally provide further insights and discoveries to break out from the stagnated situation on particle physics?
https://www.nature.com/news/the-strange-topology-that-is-reshaping-physics-1.22316

7. **Thomas**
July 20, 2017

I think your outrageous hype detector is a little too sensitive. Yes, I would prefer if the author of the NYT article adds a statement along the lines of "this result does not have immediate implications for attempts to unify the SM with gravity", but overall the article is quite accurate. In particular, I see absolutely nothing wrong with the Landsteiner quote, or with the "This work opens the door .. " quote.

People have now discovered a number of transport phenomena in flat space that are most easily determined by putting QFT in curved space. This is more than mere analogy as some commenters here seem to think. It is using QFT in curved space to implement the constraints that follow from Ward identities, anomlies, etc. As a result certain transport coefficients that look like ordinary themopower or magnetoresistance in flat space are indeed fixed by gravitational anomalies. That's pretty cool, and it is remarkable that we can now engineer condensed matter systems in which these effects are seen.

It is also the case that some of these transport coefficients that could have been discovered by Landau and Lisfschitz by analyzing the symmetry constraints for currents in hydrodynamics were in fact by analyzing holographic setups. This does mean that AdS/CFT is an efficient method to think about difficult problems in QFT.

8. **Peter Woit**
July 20, 2017

Thomas,

The problem is that this has nothing at all to do with string theory. It's purely a QFT story (as the Nature editor recognized). Going to the press with a claim "string theory was used to calculate the expected anomaly" is an intentional attempt to mislead people about the science here.

9. **Thomas**
July 20, 2017

but what if it is historically accurate?

10. **Peter Woit**
July 20, 2017

Ed,
That's a very good article that actually explains some of the real new connections between math and physics being investigated. I don't think it has anything to do with HEP physics.

11. **Peter Woit**
July 20, 2017

Thomas,
It's not in any sense "historically accurate". The anomaly calculation in the graphic associated with the article never was a "string theory calculation". It's a QFT calculation, reflecting the fundamental relation between the Dirac operator coupled to a gauge field and the index theorem. This was a major topic during the early eighties when I was a grad student, before string theory came into the picture.

12. **Thomas**
July 20, 2017

The connection to transport in flat space was discovered this way.

13. **Peter Woit**
July 20, 2017

Thomas,
Even if there is some non-trivial connection to Maldacena's AdS/CFT conjecture (which I don't see, but I'm no expert) that doesn't turn a straightforward QFT calculation into a "string theory calculation".

14. **Thomas**
July 20, 2017

The anomalous transport calculation in QFT is not straightforward, and historically it was done using AdS/CFT.

15. **Peter Woit**
July 20, 2017

Thomas,
I don't think this is relevant to the fact that the claims about "string theory calculations" in the article are flat-out incorrect, but I'm surprised that when I tried looking through the references in the paper, I find nothing about AdS/CFT. The few that refer to "holography" seem to only be using standard QFT ideas about anomalies
Can you provide references that would justify the NYT graphic as a consequence of AdS/CFT? I've spent a little time looking at the references in the paper, nothing uses AdS/CFT, the few that refer to "holography" seem to have to do not with AdS/CFT but with standard old facts about anomalies and domain walls.

16. **Chris Herzog**
July 20, 2017

Perhaps they were limited in the number of references they could include for a Nature paper. Landsteiner cites his own review article [5],
https://arxiv.org/pdf/1610.04413.pdf. Section 6 seems to be relevant to the argument of how important AdS/CFT was in the computation of anomalous transport, as is this sentence from the conclusions: "While holography can probably not claim to have discovered anomalous transport it has certainly played a major role in gaining a better understanding."

As Thomas mentions, these anomalous transport calculations are not straightforward. Mistakes in the textbooks were first noticed by doing analogous calculations in AdS/CFT.

17. **Thomas**
July 20, 2017

I think a nice historical summary of the role of AdS/CFT in anomalous transport is the intro of Son & Surowka, https://arxiv.org/abs/0906.5044 . The NYT graphic presumably refers to something like https://arxiv.org/abs/1107.0368

18. **Peter Woit**
July 20, 2017

Chris Herzog and Thomas,
Thanks for the references. I had looked at the Landsteiner review article, noticed that he invokes AdS/CFT in that one section, but I still don't see AdS/CFT getting used to explain significant. My reading of the Son/Surowka article is that their topic is effects of anomalies on relativistic hydrodynamics, that they only use AdS/CFT as a test calculation to check consistency.

From your comments it's looking to me like the only relation to AdS/CFT is that researchers in this area did analogous calculations in AdS/CFT and this may have been a useful part of the process of sorting out what was going on, but that's very different than the claim that anomalous transport is based on AdS/CFT.

19. **william e emba**
July 20, 2017

Researchers in fluid analogues to black holes (sometimes called "dumb holes") freely describe just about everything they do using the language of general relativity. The very title of https://www.nature.com/nphys/journal/v10/n11/full/nphys3104.html refers to "black hole" and "Hawking radiation". They were studying a Bose-Einstein condensate in their lab.

20. **Peter Woit**
July 20, 2017

william e emba,
Yes, but the question isn't whether GR is being used in this kind of modeling, it's whether string theory is being used, as claimed in the NYT article.

21. **Andreas Karch**
July 20, 2017

Hey Peter,

my local condensed matter colleagues here are quite adamant that the effects seen in this and similar experiments should not be interpreted as being related to the mixed gravitational field theory anomaly, so I think there are some legitimate theoretical questions one can ask about this paper. But I also think you are really trying too hard to undermine the AdS/CFT connection.

These anomalous transport coefficients have first been calculated in AdS/CFT. The relevant references are [8], [9] and [10] in the Son/Surowka paper. In the AdS/CFT calculations these particular transport coefficients only arise due to Chern-Simons terms, which are the bulk manifestation of the field theory anomalies. At that point it was obvious to many of us that there should be a purely field theory based calculation, only using anomalies, that can derive these terms. Son and Surowka knew about this. They were sitting next door to me when they started these calculations. Many of us tried to find these purely field theory based arguments and failed. Son and Surowka succeeded.

If you ask anyone serious about applying AdS/CFT to strongly coupled field theories why they are doing this, they would (hopefully) give you an answer along the lines of "AdS/CFT provides us with toy models of strongly coupled dynamics. While the field theories that have classical AdS duals are rather special, we can still learn important qualitative insights and find new ways to think about strongly coupled field theories." Once AdS/CFT stumbles on a new phenomenon in these solvable toy models, we want to go back to see whether we can understand it without the crutch of having to rely on AdS/CFT. Any result that only applies in theories with holographic dual is somewhat limited in its applications. In this sense, anomalous transport is a poster child for what AdS/CFT can be used for: a new phenomenon that had been missed completely by people studying field theory gets uncovered by studying these toy models. Once we knew what to look for, a purely field theoretic argument was found that made the AdS/CFT derivation obsolete.

This is applied AdS/CFT as it should be. Solvable examples exhibit new connections which then can be proven to be correct more generally and are not limited to the toy models that were used to uncover them.

22. **william e emba**
July 20, 2017

So? Results from XYZ are lifted to hydrodynamics and touted as such even the work is obviously not XYZ, you say this is acceptable when XYZ=GR and obnoxious hype when XYZ=string theory? I don't buy that.

I see this type of idea credit in other fields. I'm perfectly happy with the terminology "simulated annealing" or "genetic algorithms" or "evolutionary programming" or "ant-colony optimization". There's no point in hiding the inspiration, especially if more progress is expected from applying the sources.

23. **Peter Woit**
July 20, 2017

Andreas,

Many thanks for your comment, which clarifies a lot, in particular making clear to me why I was having so much trouble seeing the relation to AdS/CFT in calculations that didn't seem to be using it. I gather that the answer is that, as Thomas suggested, the relation is a historical one, with AdS/CFT research what led to a current theoretical understanding that doesn't use AdS/CFT.

I think it should be clear that my problem with the NYT article has nothing to do with any complaints about this sort of research, but with its use to obfuscate the situation of string theory as a unified theory.

Here is a question for Andreas, Thomas and Chris, about the NYT article. What do you think of the last two paragraphs of the article that I quoted? Are they scientifically justifiable or seriously misleading/incorrect? I'm making the argument to the NYT that these two paragraphs should be deleted. What say you?

24. **Peter Woit**
July 20, 2017

william e. emba,

The point is that the status of GR as a tested theory is uncontroversial, but here the invocation of string theory is explicitly being made so as to obfuscate the failure of the heavily promoted string theory unification program. Instead of acknowledging this failure (which took the form that the idea turned out to be inherently untestable), claims are made (as in the next to last paragraph of the article) that string theory is testable, and has been successfully tested. The paragraphs I quoted are the result of an intentional not very honest campaign to mislead people.

25. **Chris Herzog**
July 20, 2017

Hi Peter.

I hesitate to make a judgment about the news article and to extrapolate from what is said there to what is actually believed by the scientists involved. So often, things are misquoted or stretched in misleading ways. I know Karl, and I suspect Andreas, Karl, and I are all pretty much on the same page when it comes to AdS/CFT and the role of string theory therein. I do not have as strong a reaction to those two paragraphs as you did, and I can see my vision, perhaps in a distorted form, behind what is written there.

I see AdS/CFT as a tool for doing certain types of field theory calculations, a tool like the epsilon expansion or like lattice gauge theory or like integrable systems. AdS/CFT is at its most rigorous when embedded into a string theory. The fact that one can calculate conductivities and viscosities in maximally supersymmetric Yang-Mills for me already puts AdS/CFT and by extension string theory on a solid footing, or at least on a footing worthy of a substantial research effort. That we have learned something about anomalous transport from AdS/CFT and that anomalous transport could be seen — not in holographic systems, but nevertheless seen — in the lab is icing on the cake.

26. **william e emba**
July 20, 2017

Fair point, although from my point of view, it's success in mathematics (including that of three Fields medalists, Witten, Borcherds, Kontsevich) means it's as legitimate as GR is when making analogies. String theory has proved its chops, just not in the way the hypesters intended.

27. **Peter Woit**
July 20, 2017

william e emba,
I think it actually matters to distinguish between what has been successful about "string theory" and what has been a failure. My problem with this article is that it misleads people about this.

By the way, Witten's Fields medal was for work (Chern-Simons) on QFT, not string theory.

28. **Andreas Karch**
July 20, 2017

Hey Peter,

I am not nearly as disturbed as you are by the last two paragraphs. AdS/CFT certainly has been used "as a tool for doing physics, real physics". I think there is no doubt about it. This seems to be in the end the only thing that is really claimed. It's a tool that has its limitations (you study the wrong theory), but it works in situations where we have basically no other tools available (time dependent processes in strongly coupled theories). In detail, of course things are complicated. The stringy toy models were only part of the story. The way the second to last paragraph (talking about the standard model and unification) leads into the last paragraph (describing how string theory was useful in this situation) is open to the misinterpretation that they tested quantum gravity in the lab (which they didn't). I have different problems with the article that concern me more, but they are of a more technical nature.

29. **Peter Woit**
July 20, 2017

Chris and Andreas,

To make the question more specific, recall that the article states
"string theory has been maligned because it makes predictions that cannot be tested"
and then goes on to imply that the maligners have now been shown to be wrong, quoting Landsteiner about string theory now being on "a firm basis as a tool for doing physics". Is this or is it not highly misleading (in particular the move without any acknowledgement from string theory as a 10/11 d unified theory to gauge-gravity duality as a tool in condensed matter physics)?

I can see many good arguments for pursuing AdS/CFT as a tool for understanding strong coupling QFT, but why not sell this for what it is (and acknowledge that maybe the maligners of string theory unification were right?).

30. **william e emba**
July 20, 2017

Atiyah's laudatio of Witten mentioned three things: TQFT (which paper referred explicitly to using string theory arguments), new proof of positive energy theorem (using SUGRA), and new formulation of Morse theory (using SUSY). That's string theory enough for me.

31. **Peter Woit**
July 20, 2017

william e emba,
I've found from bitter experience that it's hopeless to argue with people about this. That Witten won the Fields medal because of his work on string theory is now a deeply entrenched alternative fact. If you are interested in real facts, recall that TQFT/SUSY/SUGRA are not string theory and take a look at
http://www.math.columbia.edu/~woit/wordpress/?p=99

32. **Matt Grayson**
July 20, 2017

I've used this analogy. If we make no distinction between Newton's theory of gravitation and the mathematical tools he developed for it, then I could say that I've put Newton's gravitation theory on a firm footing by doing a calculus problem.

33. **Jeff M**
July 20, 2017

Just to 1/3 support Peter, Witten's work on Morse theory was not string theory. That paper was the basis of my orals in grad school, so I know it well. Very nice math, nothing to do with strings. I've seen some math talks which are string theory, a few of them very interesting (Kevin Costello, on moduli spaces of Riemann surfaces, must be 20 years ago). Witten's work on Morse theory at least wasn't related.

34. **Deane Yang**
July 20, 2017

As a biased observer, I wanted to make some comments:
1) This appears to me to be a debate on semantics. Is "string theory" a (not necessarily rigorous) mathematical tool that was developed as an effort to develop a TOE? Or is "string theory" the TOE itself?
2) It appears to me that the main objection to the last two paragraphs is the concern that people who view string theory as the TOE will believe that Landsteiner's work represents progress in string theory as such.
3) On one hand, this is a valid concern that I agree with. On the other, this is not national politics. Having readers being misled on this does little harm. To me what's more important is to have more articles about science that people want to read. If poetic license is taken, I think we should try to live with it. Mentioning string theory here, even if it's a stretch, is good publicity. I know a big concern is the overfunding of string theory, but I think a bigger problem is the underfunding of scientific research.
4) Please be cognizant of the limits on what a journalist can do, including the time to research the article and the length of the article. It is hard to be precise without being dry in a 500-1000 word article. It is hard to be precise, if you are not an expert in the field and have to talk to experts who are unable to express themselves clearly to a non-expert. It is hard, period, to assess who is right and who is wrong. Even in a hard science like physics, there is a lot of subjectivity.
5) So what can you do when you don't like what an article says? Luckily, articles can still be revised even after they've been posted on the web. So you can contact the journalist and ask for a correction. However, you'll increase your chances of getting the correction made, if you make the journalist's job easier. This means trying to isolate what part of the article you'd like revised (here, it is the last two paragraphs) and suggesting new wording that's roughly the same number of words as the original wording *and* interesting to read. As someone who has tried to help Ken write about math, I know that this is really, really hard. Everything I write for him turns out to be far too long, literal, and dry. This is a huge handicap when trying to help a journalist write about science and math.
6) It's not too late to email Ken with suggested rewording. If you believe you can write the last two paragraphs in a less misleading way, please try. But it seems to me that you have to live with the quote by Landsteiner, which is not literally wrong. It's just that you want to find a way to express that Landsteiner's work was, if anything, a validation of one particular technique used in string theory, rather than string theory as a TOE.
7) By the way, if you want to see a masterful job by Ken writing about math, please read his obituary of Maryam Mirzakhani.

35. **vmarko**
July 20, 2017

Sooo, finally string theory stops being a theory about high energy physics, and moves ever more firmly into the solid state domain. It started as an effective theory of strong interactions, had one long stint as a theory of everything, and now moves on to calculating conductivities and viscosities in solid state physics. After that, what's next, maybe plasma physics and fusion reactor modeling using AdS/CFT techniques?

I'll probably have mixed feelings when the everlasting flood of papers published by string theorists moves from hep-th to cond-mat section of the arXiv. 😉 Just imagine, titles like "Electron transport characteristics in an 11D supersymmetric hexagonal crystal lattice compactified to a 3-torus with a negative cosmological constant", and similar, appearing on cond-mat… 😀

🙂
Marko

36. **Mitchell Porter**
July 20, 2017

If any of the experts are still reading… I am still trying to understand the *mechanism* of MAGA-induced (?) anomalous transport. Surely it doesn't involve virtual gravitons?! But then, how does it work?

37. **william e emba**
July 20, 2017

I personally think of SUSY/SUGRA as part of "string theory", but I'm perfectly happy if people think that is just ignorant twaddle on my part. I was not confused about the history, and our main disagreement is simply what does "string theory" mean. I completely agree that Witten was not given the Fields medal for his work *in* string theory.

So far as I know, neither Borcherds or Kontsevich did work *in* string theory, but they took what was there and ran with it. All I meant was that Witten did the same thing. For example, in his TQFT paper he explicitly mentions that his central arguments "will be quite recognizable to string theorists".

I believe we agree far more than we disagree, but in my attempts at brevity I have been unclear about my meaning. I apologize.

@Matt Grayson: considering how inconsistent the foundations of calculus were in Newton's day, there really was a time when getting calculus to work was a point in Newton's gravitational favor.

38. **Peter Woit**
July 20, 2017

Deane,

I have written to Ken with my suggestion about how to fix the article, which is pretty simple, just delete the stuff about "string theory". It seems we disagree about this. That's too bad, in general I think he and others at the NYT do a very good job of carefully covering math and physics, not always an easy task.

The fundamental problem with the NYT article is the use of the term "string theory" to mean "gauge-gravity duality calculational method", something with zero relationship to the "string theory" that is supposed to unify physics that readers have heard about, so they're going to be misled.

If you no longer know what idea "X" refers to, it becomes impossible to have a sensible conversation about "X" and things descend into the realm of ideology (are you for or against the meaningless term "X"?). My take on what's going on is that X="string theory" is in the process of becoming not a scientific term, but a clan name. This may be good for publicity purposes, but it's not good for science.

39. **David Roberts**
July 20, 2017

If one replaces occurrences of "string theory" with "the mathematics of string theory" then many problems go away.

40. **Peter Woit**
July 20, 2017

David Roberts,

I don't really think so. "the mathematics of string theory" is a really ill-defined term, and under many interpretations has little or nothing to do with the condensed matter story of this article.

41. **Dam Thanh Son**
July 20, 2017

I think it is useful to recall the relevant historical timeline.

The connection between axial-gravitational anomaly and transport (in flat space) at finite temperature, zero chemical potential was first suggested in a paper by Landsteiner, Megías, and Pena-Benitez, https://arxiv.org/abs/1103.5006. The effect was first pointed out to be possible by Neiman and Oz (arXiv:1011.5107). Landsteiner et al. suggested that the coefficient of this effect is equal to the coefficient of axial-gravitational anomaly, multiplied by temperature squared. How did they know? They constructed a simple theory in AdS5 so that the corresponding CFT4 has an axial-gravitational anomaly. Then they considered a black-brane solution, and by using AdS/CFT, found a "chiral vortical" coefficient proportional to the coefficient of the axial-gravitational anomaly.

I remember being very perplexed by the claimed connection between transport in flat space and anomaly in curved space appeared to me very strange. Not only that Surówka and I missed the coefficient in our paper (mentioned by Andreas), it was also that if we tried to correct our calculation (as Neiman and Oz did), all we could do was to restrict the coefficient to be an constant times T^2, with no indication that the constant is related to any anomaly. In contrast, naive power counting would imply that contribution of the axial-gravitational anomaly should appear at the third order in the derivative expansion, rather than at the first order, as Landsteiner et al. claimed.

For a more than a year, the issue was not understood. There was strong indication in favor of the connection from AdS/CFT, but it was not clear how general it is. If the coupling in field theory is not infinite, but only finite, would the connection still hold? The first paper explaining the connection without using AdS/CFT seems to be the one by Jensen, Loganayagam, and Yarom (arXiv:1207.5824).

What follows is my subjective opinion.

The AdS/CFT correspondence played a crucial role in this story. Without AdS5 as a laboratory, it would be highly nontrivial to see any connection between the two effects. For one, finite temperature or temperature gradient does not lead to violation of chiral charge (Spivak's argument). Then there is a mismatch between the orders of the derivatives mentioned above.

Figuratively, AdS/CFT has provided a cheap laboratory for theorists to play and to "measure" different transport coefficients of an exotic medium (like the one where particles are fermions with definite chiralities), years before it became possible to do it in a real lab.

Landsteiner's statement quoted at the end of the NYT article, in my view, is an accurate description of the role that string theory played in his and many other theorists' work. As often in condensed matter physics, whether the suggested theory is directly relevant to the experiment is a question that will take some time to completely settle.

42. **Peter Woit**
July 20, 2017

Dam Thanh Son,

Many thanks for your comment, which completely clarifies the role of AdS/CFT here.

I still however think that using the term "string theory" to describe these calculations is misleading (given that strings play no role). Why not just use a term like AdS/CFT or gauge/gravity duality? One argument for using "string theory" would be its historical role in AdS/CFT. If so though, in the usage of "string theory" in this article, we're now at two different historical removes from an actual theory of strings, and the average reader is unlikely to understand at all the relation between the "string theory" being discussed here and the "string theory" they've heard about elsewhere.

43. **Mitchell Porter**
July 21, 2017

Let me distinguish between the various complaints that have been made so far.

Peter Woit objects that a successful application of AdS/CFT to condensed matter could be mistaken for a successful application of string theory to particle physics.

William B. Emba and I object that the actual effect at work here is not literally the mixed axial-gravitational anomaly, it's some kind of thermal analogue of that.

And Boris Spivak (quoted in Nature) doesn't even think it's the thermal anomaly producing the reported results, it's some other process entirely.

Obviously Spivak's criticism is the only one of direct scientific consequence, the others pertain to how concepts are named and communicated.

But I would like to expand a little on *my* complaint. Ironically, I find the science journalism clearer on the point that this is a physical analogy, than the actual arxiv paper! (I'm referring to 1703.10682.)

I see nothing in that paper which would lead a person to think that the effects in question are not being attributed to literal gravitational anomalies. Several times, the authors write that the reader may wonder how a gravitational anomaly could be relevant in the absence of gravitation; but each time, we are told that the connection has nonetheless been established.

There must be a way to understand this which is not "consider this field theory in curved space, then consider the zero-curvature limit, and find that the gravitational anomaly coefficient is still nonzero"; but which is more like, "consider this field theory in flat space, and note this algebraic isomorphism with the zero-curvature limit of the curved-space analogue".

But it seems that if I want to understand what's really going on at the level of theory, I'll have to just keep butting my head against the original papers until enlightenment dawns.

44. **DrDave**
July 21, 2017

I don't think it matters what the NYT *thinks,* they should simply publish a response from Peter. That's good journalism. Better journalism would be to get the facts right, of course. If a paper doesn't print a well thought out, factually accurate letter, it isn't a newspaper anymore–something the Times has been struggling with.

45. **Peter Woit**
July 21, 2017

DrDave,
You're assuming I want to write a letter to the NYT for them to publish, which is not the case (I don't think the issues involved lend themselves to such a letter, and I've already wasted enough time on this). I have been in communication with the author of the article, and, given that my complaints are not about factual correctness but about misleading use of language, he's not interested in significantly changing the article.

Unlike most cases where people disagree with something in the NYT, at least in this one my point of view has gotten aired in great detail here (and opposing views also, thanks to commenters).

46. **Peter Woit**
July 21, 2017

DrDave,
Perhaps due to our email exchange, the author of the NYT piece did make some changes in the language to make things less misleading.

47. **Chris W.**
July 22, 2017

"… but for most laymen the mention of string theory was just fine."

As much as Chang, that's an editor talking.

So much of the media is worse than this where science and many other subjects are concerned. I suppose one can give the New York Times some credit for resisting the all-out competition in the race to the bottom.

48. **Peter Woit**
July 22, 2017

Chris W.,
I don't think the problem is really with the journalists, it's with the physics community. In this case the publicity for the (quite complex) scientific result seems to have largely been provided by string theorist Landsteiner, including presumably accurate quotes claiming this as a "string theory" calculation and success. And, from the comments, his colleagues in his field say they're fine with this, even if it's misleading. Other physicists need to step up and say that this is misleading and not fine. The author heard from me making this case, but is then put in a position of not knowing who to believe (a non-specialist has no hope understanding the role of string theory in AdS/CFT and the role of AdS/CFT in the calculation of this effect).

49. **Art**
July 23, 2017

This post and the comments have been educational and productive: a fair amount of history and technical detail was discussed, culminating in a revision to the original article. I hope it's at least somewhat satisfying. The only thing missing, I think, was an explanation of the change to the article, which I'm used to seeing after an edit.

50. **G Euphrates**
July 24, 2017

mea culpa.
As an ex-IRE member (Institute of Radio Engineers) I witnessed the change to IEEE (Institute of Electrical and Electronics Engineers); thus, your use of IIEE confused me.

But excellent clarification by argumentation in the comments!

51. **Peter Woit**
July 24, 2017

G Euphrates,
Thanks, I thought I had fixed that typo, now done.

52. **Art**
July 24, 2017

As of this morning, the referenced NY Times article is truncated to 4 paragraphs, with no mention of Dr. Landsteiner.

53. **Tony Zito**
August 2, 2017

Non-specialist Community College physics teacher here. Is any part of this akin to the question of whether Bekenstein discovered black hole thermodynamics, or just an interesting analogy? Is there a chance that there is any significant physical connection between this experiment and black hole physics, so that, for example, we could really learn something about event horizons by keeping this up?

54. **Peter Woit**
August 2, 2017

Tony Zito,

There's no significant connection to actual black hole physics or black hole thermodynamics here.

Summer Conferences: Physical Mathematics

July 21, 2017
Categories: Uncategorized

I've finally found some time to look around the web to see what has been happening at conferences this summer. In this blog post I'll point to a few on the math/physics interface featuring interesting talks. This area now (I think it may be Greg Moore's fault) has started to acquire the name of "Physical Mathematics", to distinguish itself from old-school "Mathematical Physics". At this point though I'd be hard-pressed to provide a useful definition of either term.

- Talks from last month's 2017 Bonn Arbeitstagung are available here. This conference was in honor of Yuri Manin and supposedly devoted to Physical Mathematics (although I suspect some of the speakers might not realize that they are doing Physical Mathematics). Dan Freed and Jacob Lurie gave two characteristically lucid series of talks, well worth watching.

  A very active area of physics these days with significant overlap with mathematics (of the sort discussed by Freed) is the study of topological superconductors and other materials in which topology plays a large role. For an introduction to this topic, Davide Castelvecchi at Nature has a new article The strange topology that is reshaping physics.

- CERN has just finished running an institute on the topic of the Geometry of String and Gauge Theories. It included a colloquium talk by Greg Moore on d=4 N=2 Field Theory and Physical Mathematics. I've always been fascinated by the d=4 N=2 super Yang-Mills theory in its "twisted" topological version. The mathematics involved is deep and amazing, and it is frustratingly close to the Standard Model…
- Pre-string math 2017 was this past week, and String Math 2017 will be next week. All sorts of interesting talks at both of these, relatively few of which have much to do with string theory. That's of course also true of Strings 2017, but I'll write about that elsewhere.

Other suggestions of interesting mathematically related summer schools with talks available are welcome. On the physics side, please wait for a succeeding blog entry on that topic.

Comments

   July 22, 2017

   I wonder if the difference is something like the difference between Physical Chemistry and Chemical Physics … the former uses Chemistry jargon while the latter used Physics jargon, but they are otherwise identical.

2. **peon**
   July 25, 2017

   Arnold Sommerfeld referred to physical mathematics in the forward to his book on Partial Differentail Equations

3. **Trent**
   September 10, 2017

   Commenting here because your Physical Mathematics post doesn't have a "leave a reply" section. (Weird, is it just my computer?).
   Kishore Marathe is the one who coined the term "Physical Mathematics". see the intro of his book "topics in physical mathematics" for some discussion of what the term means. (I take it to mean (as in mathematical physics) the drive to find the correct mathematical way to express physical theories (perfecting physics such that it becomes math), but then (unlike in mathematical physics) physical mathematicians go beyond physics and care about interesting mathematical structures inspired by physics which don't look like they describe our physical universe (as long as these structures are mathematically interesting). Some (many?) physical mathematicians even care more about the mathematical interest of the structures than the physical interest.)

What the Hell is Going On?

July 22, 2017
Categories: Uncategorized

I've looked at the talks from a few of the HEP experiment and phenomenology summer conferences. If anyone can point me to anything interesting that I've missed, please do so. The lack of new physics beyond the Higgs at the LHC has left the field in a difficult state.

One conference going on this past week and next is the IAS PiTP summer program aimed at advanced grad students and postdocs. This year the topic is HEP phenomenology, and talks are available here. If you want to understand the conventional wisdom on the state of the subject, you can watch Nima Arkani-Hamed's three and a half hour lecture (here and here) which he starts off by describing as on the topic "What the Hell is Going On?".

A lot of the first part is historical, starting off with the Georgi-Glashow GUT and the arguments for SU(5) or SO(10) GUT unification first put forward 43 years ago. He then walks the audience through the sequence of steps theorists have taken to solve the problems of such models, after an hour ending up at the landscape, spending a half an hour promoting the anthropic solution to the CC and other problems. The second part of the talk is largely devoted to making the case for his favored split SUSY models, with anthropics and the landscape taking care of their naturalness problems. By the end of the three and a half hours, Arkani-Hamed admits that this scenario is not that convincing, while arguing that it's the only thing he can see left that is consistent with the idea that theorists have been following a correct path since 1974:

> It's the only picture of the world that I know where everything that we learned experimentally and theoretically for the last 30 years has some role to play in it. But my confidence in it is not so super high, and I definitely think its worth thinking about completely radically different things.
>
> The disadvantage to the trajectory of going with what works and then changing a little and changing a little is that you might just be in the basin of attraction of the wrong idea from the start and then you'll just stay there for ever.

To me by now the evidence is overwhelming that HEP theory has been in the wrong basin of attraction for quite a while, and the overriding question is what can be done to get out of it. If you're in the wrong basin of attraction, you need to get out of it by going back to the point where you entered it and looking for another direction. I think Arkani-Hamed is right to identify the 1974 GUT hypothesis as the starting point that led the field into this wrong basin. HEP theory has progressed historically by identifying new more powerful symmetry principles. The move in 1974 was to go beyond the SM symmetries by picking a larger gauge group, then breaking it at a very high energy scale with new scalar fields. The history of the last 43 years is that this idea isn't a successful one: as this talk shows, it leads to an empty theory that explains nothing. Can one find different new ideas about symmetry that are more promising?

Comments

   July 22, 2017

   What tack would you tackle?

2. **Peter Woit**
   July 22, 2017

   Jon Awbrey,
   To me an obvious thing to do is to examine carefully the role of group representation theory (the area of mathematics that studies the implications of symmetries) in the Standard Model, and see if thinking about the Standard Model in that language can inspire new ideas. This is one of the motivations for the book that I just finished writing. I see several different directions of this sort to pursue, that's what I'm working on these days. I don't have anything definite enough to write about here. And, I don't want to turn this blog entry into a discussion forum for speculative ideas, mine or any one else's.

3. **Alex**
   July 22, 2017

   Even if you go back to pre-1974 assumptions and reevaluate everything, any new frameworks that emerge will still be of limited utility to physics until the experimentalists get something new. If the collider experiments continue to match up with the Standard Model, the searches for dipole moments and dark matter continue to find nothing, and the interesting anomalies in cosmic ray detectors and gamma ray telescopes get more mundane astrophysical explanations, then there's little or nothing to test new frameworks against.

   It could be quite intellectually fruitful for mathematics, but physics has little hope without experiments.

4. **Peter Woit**
   July 22, 2017

   Alex,
   There has been a lot of progress since 1974 in understanding the mathematical structures involved in QFT, so one is not going back to pre-1974. Yes, it would be extremely helpful if experiments break the Standard Model and provide indications of the path forward from the physics side. Bu this is not happening, and as long as this continues, coming at the problem from the more difficult path of studying the mathematics may be the only way forward. Or, one could just give up completely on HEP theory until a new experimental result comes along, and have everybody move into condensed matter theory. Actually, that seems to be where things are headed…

5. **Nakanishi**
   July 22, 2017

   I remember, though not precisely, the motto of Heisenberg: "The most conservative people can be most revolutional." QFT is quite successful; therefore, one should adhere to its proper framework as long as possible unless there appears an experimental evidence which undoubtedly contradicts with QFT. The natural representation space of QFT is the indefinite-metric Hilbert space, together with subsidiary conditions. The quantum gauge theories are successful because there exists the BRS invariance condition (the Kugo-Ojima condition). One should investigate whether or not there is any other possible subsidiary condition which guarantees the unitarity of the physical S-matrix.
   SUSY was destined to be ruined because all superpartners must be physical particles. If a supersymmetry in a wide sense could be formulated in the indefinite-metric Hilbert space with a subsidiary condition, all superpartners could become unphysical.

6. **Shantanu**
   July 22, 2017

Peter, why isn't anyone (including string theorists) trying to link theories with non-0 neutrino mass with TeV scales physics and models of EW symmetry breaking. As me and others have mentioned many times, models with see-saw mechanism etc are completely decoupled from rest of BSM physics and I don't see that situation changing.

7. **A**
July 23, 2017

In the past 10-20 years fundamental physics gave: cosmological constant, neutrino masses, higgs, inflation, cosmology, gravity waves, the fact that past ideas about naturalness seem wrong (which might indicate a cut-off less trivial than an atomic lattice). Despite the difficulties, this is much more interesting than condensed matter, a mature field that can only study more complex materials. I really hope that this is not the future of physics:
http://pyang.gatech.edu/wp-content/uploads/2017/05/feces_paper.pdf

8. **Thomas Larsson**
July 23, 2017

It is well known to experts (e.g. Pressley-Segal section 4.10) that the group of gauge transformations in Yang-Mills theory has two different types of extensions: the Mickelsson-Faddeev extension and the central extension. The MF extension is the mathematical formulation of gauge anomalies in QFT, and there is a strong mathematical reason why this extension has to vanish: it admits no non-trivial unitary representations.

In contrast, the central extension cannot arise as a gauge anomaly within the framework of QFT, because its representations depend on additional data: a privileged 1D curve in spacetime. This leaves two possibilities: either the central extension is unphysical because it is not in QFT, or one needs to modify QFT to allow for all kinds of extensions that are mathematically possible. It is no secret that I believe in the second option, and even if I didn't succeed to turn this into physics, the math is solid.

9. **David Garfinkle**
July 23, 2017

I agree that going back to the place where a wrong turn was taken and trying to take a different turn is a good idea. However, I'm not convinced that grand unification was the wrong turn. It seems to me more likely that supersymmetry and string theory were the wrong turns. One way to look at grand unification is that (1) in some sense non-abelian gauge theories have better properties than abelian ones, so one might look for a fundamental theory which does not U(1) as part of its gauge group, and (2) in quantum field theory scalar fields are not so tightly constrained as vector fields or fermion fields, so that it's easier to devise theories with lots of scalar fields and so that e.g. it might make more sense to think of theories where dark matter is a scalar field then where it is a supersymmetric partner.
I'm also not convinced that more research in representation theory is the best application of mathematics to quantum field theory. What about a more mathematically sensible way to treat the infinities that arise in quantum field theory? One way to look at this issue is the following: partial differential equations (PDE) are much more .complicated than ordinary differential equations (ODE). PDE have more degrees of freedom, and require much more mathematical machinery (Banach spaces, Sobolev norms, energy estimates, etc.) to show existence of solutions, and indeed it is only for particular PDE (hyperbolic, elliptic, parabolic) that solutions exist. Similarly, quantum field theories have more degrees of freedom than either classical field theories or quantum mechanics. It is therefore not that surprising that infinities arise, and that only some theories (the renormalizable theories) are sensible. Perhaps we need more mathematical machinery to make sense of quantum field theory so that one does not get the impression that infinities are being swept under the rug rather than dealt with.

10. **Peter Woit**
July 23, 2017

David Garfinkle,
Arkani-Hamed explains clearly the logic that non-SUSY GUTs don't work, leading to SUSY.

All,
Please, if it's not about the Arkani-Hamed talk, don't submit comments, I can't and don't want to moderate a general speculative discussion section.

11. **vmarko**
July 23, 2017

Hi Peter,

"If you're in the wrong basin of attraction, you need to get out of it by going back to the point where you entered it and looking for another direction."

This is all true, but I don't think that there is a shortage of ideas which other direction to take. The problem is a social one — convincing everybody else (or at least some part of the community) to actually start doing research in some other direction. And I don't see that happening soon, for two reasons. First, most theorists are egocentric regarding promising ideas (myself included 🙂), so they will rather have you and me follow their idea (even if they don't really have one) than they would agree to follow your or my idea themselves. Second, as usual, physics advances one funeral at a time, and there need to be quite a few of those in order to make room for a sizable number of younger people to actually be able to try out other directions.

My feeling is that lack of new BSM physics at LHC etc. is simply going to reinforce this tension between old and new ideas, as many big-name lead scientists are becoming more and more of an embarrassment in the eyes of younger generations of scientists. I believe in the end this will turn out to be a good thing, but the hep-th community will feel some pain in the meantime.

Best, 🙂
Marko

12. **Armin N**
July 23, 2017

"I don't want to turn this blog entry into a discussion forum for speculative ideas, mine or any one else's."

I understand your motivation for not wanting to do this. Would even one post, say, roughly a month, devoted to a speculative idea you find deserves more attention or investigation be too much, even if only as a riposte to those who sometimes criticize you for just pointing out the flaws in the status quo and not offering promising alternatives ideas?

13. **David Garfinkle**
July 23, 2017

In looking over that part of the Arkani-Hamed lecture it seems to me that "logic of why non-SUSY GUTs don't work" is an overstatement. He looks at things that he considers the simplest and most natural mechanisms for breaking GUTs to the standard model without using supersymmetry and concludes that those mechanisms don't work. This seems to leave open the possibility that some more complicated mechanism that doesn't look natural to Arkani-Hamed might work. In cosmology we have abundant evidence that our prejudices as to what is "natural" are a very unreliable guide. Perhaps it is time that we apply that insight to particle physics.

14. **Markus Pfleier**
July 23, 2017

Nima is probably right. Some years ago, I wrote to a Nobel Prize winner for electroweak unification (which I won't name 🙂 and asked him whether it is more correct to call it "unification" or "mixing". He answered that "unification" is not the appropriate wording; after all, there are still 2 coupling constants.

But it was electroweak "unification" that led to grand "unification". Experiments show us that there are still three coupling constants, not just one. There just is no G"U"T. There is symmetry left to be discovered. We know all elements, we know all particles, we know all symmetries.

And there is no single symmetry. The answer to the question at the end of the post is what experiments suggest: Renewed progress will be achieved as soon as the gauge interactions are kept and left separate. Renewed progress will be achieved as soon as the search for unified symmetries is abandoned.

15. **Markus Pfleier**
July 24, 2017

The sentence should have been: "There is no symmetry left to be discovered."

16. **John Baez**
July 24, 2017

Peter wrote:

> Arkani-Hamed explains clearly the logic that non-SUSY GUTs don't work, leading to SUSY.

I haven't looked at his talk, but my impression is that the non-supersymmetric SO(10) GUT is still viable if you don't mind fine-tuning: there's a [paper by Altarelli and Meloni] about this.

They write:

> We present a renormalizable non-supersymmetric grand unified SO(10) model which, at the price of a large fine tuning, is compatible with all compelling phenomenological requirements below the unification scale and thus realizes a minimal extension of the SM, unified in SO(10) and describing all known physics below the GUT mass. These requirements include coupling unification at a large enough scale to be compatible with the bounds on proton decay; a Yukawa sector in agreement with all the data on quark and lepton masses and mixings and with leptogenesis as the origin of the baryon asymmetry of the Universe; an axion arising from the Higgs sector of the model, suitable to solve the strong CP problem and to account for the observed amount of dark matter. The above constraints imposed by the data are very stringent and single out a particular breaking chain with the Pati-Salam group at an intermediate scale of about 10^11 GeV.

Is this wrong? I really like how SO(10) unifies all the fermions in each generation and neatly explains many of their properties. So, I'm hoping it's not quite dead yet.

17. **John Baez**
July 24, 2017

What's the latest word on the possible [failure of lepton universality]? This would certainly give particle physics a kick in the pants. Mark Wise says it doesn't fit into "the story line that the theorists tell", but it seems that's exactly what we need: some data that don't fit into the usual story line.

> The evidence is even harder to swallow given how far lepton universality is from theorists' expectations of where cracks in the Standard Model might show up. "There's sort of a story line that the theorists tell," Wise says, and "this isn't in the story line." What's worse, the proposed explanations for the leptons' behavior seem ad hoc and unsatisfying. "The kind of models that can fit the…anomalies don't really do anything else at first sight," Ligeti says. "For example, they don't get you any closer to understanding what dark matter might be."
>
> Still, he adds, "nature tells us how nature is." Physicists are increasingly taking note of the violations' continued persistence, and proposing new theoretical explanations. Experimentalists and theorists alike are also looking to reduce existing measurements' uncertainties. Ultimately, the biggest revelations will come when LHCb and the next version of Belle produce more data. Physicists are optimistic that within about five years not only will we know whether the effect is real, we will have an explanation for it."

18. **Peter Woit**
July 24, 2017

John,
If you look at that SO(10) paper, you'll see that what they're doing is moving up the unification scale by introducing a truly baroque set of Higgs fields and an intermediate scale. The problem here isn't really fine-tuning (which all non-SUSY GUTs have) but that to get coupling constant unification you're introducing lots of new parameters and new choices (in the Higgs sector).

This shows the generic problem with GUTs: they claim to answer the problem "why SU(3)xSU(2)xU(1)" (or at least change it to a simpler problem, "why SO(10)"), but all they really do is change the problem to "why this Higgs sector (which breaks SO(10) to SU(3)xSU(2)xU(1))?"

I agree that the fact that a generation fits precisely into the spin rep of SO(10) is a hint about something. But, Spin(10) doesn't really act on this, or, equivalently the action is"badly broken" in a way we don't understand at all. Recall that this spin rep can be constructed as the exterior algebra on 5 variables, or, if you like, 5 fermionic oscillators or 5 fermionic qubits. The fundamental problems then become: why 5? why do 3 of them behave one way, 2 another?

Yes, if the LHCb lepton universality anomaly holds up, that would be a big deal. The history so far is that all similar things have gone away, and there's no reason to think this one will be different. Unfortunately, it also doesn't seem that postulating that muons and electrons behave differently in a way that would explain the LHCb results leads to a model that explains anything else (as opposed to just adding complexity to fit this result).

19. **Peter Woit**
July 24, 2017

Armin N,

I'll keep this in mind and try and post more often about intriguing new ideas that I see. The depressing thing about the current state of HEP theory is that interesting new ideas are very few and far between.

I could also just keep repeating my own favorite intriguing ideas, which don't change much and haven't seen any progress. I happened to run across an old posting about

this from seven years ago, see
http://www.math.columbia.edu/~woit/wordpress/?p=2876
I don't think there's been significant developments on those problems since then, the first and third are motivations for things I'm working on now that the book is finished.

20. **Chris Kennedy**
July 24, 2017

Regarding the LHC, I haven't seen much discussion on the Doubly Charmed Baryon discovered and written about earlier this month? 3520 MeV with a lifetime stated to be shorter than 33 fs. Any new thoughts on that?

21. **Mark M**
July 24, 2017

Hi Peter,

In response to your "could also just keep repeating my own favorite intriguing ideas", there have been some progress in trying to formulate a non-perturbative chiral gauge theory, cf:
Nonperturbative Regulator for Chiral Gauge Theories? Grabowska, Kaplan.
Phys.Rev.Lett. 116 (2016) no.21, 211602, arXiv:1511.03649 [hep-lat]
and
Chiral solution to the Ginsparg-Wilson equation. Grabowska, Kaplan. Phys.Rev. D94 (2016) no.11, 114504 arXiv:1610.02151 [hep-lat]

22. **Peter Woit**
July 24, 2017

Mark M.,

Thanks! Taking a quick look at those papers, it's remarkable what a tricky problem this is and I think it's fair to say that it's still not clear if it is solved.

23. **srp**
July 25, 2017

In honor of the title of this post, here is the great Vince Lombardi:
https://www.youtube.com/watch?v=4V0TYIO6yv4

24. **George Rush**
July 26, 2017

Good talk from Nima Arkani-Hamed. IMHO it's basically a reaction to LHC results. They validated electroweak but cast doubt on his favorite version of SUSY. As Nima sees it the key scale is around 10^-17 cm, so he expected / hoped to see new physics here. SUSY can cancel quantum fluctuations, solving the huge CC mis-prediction and other things. But it has to do it around current LHC scale. A natural reaction to failure is to explain why anyone would, and should, have made the same mistake. (Cf. Hold 'Em players dissecting hands lost on the river to a 1 out of 46 chance.) He goes through the steps since 1974 emphasizing how each was almost inevitable. (Like the poker player proving the only sensible action on the flop was a pot-size bet.) Ties it all together by the idea of finding yourself, by small steps each very sensible, in the wrong "basin of attraction" in solution space. It makes sense and I don't mean to belittle his story. But it can be viewed as a very common reaction to the loss of what looked like a high-positive-expectation bet: justifying it.

25. **William Nelson**
July 26, 2017

Not sure how you can claim there's "overwhelming evidence" that HEP people have been on the wrong track, while also noting that there is no evidence one way or the other from experiment. Many of the same people who got it right with the SM don't think the efforts were misguided at all. Unfortunately, it comes down to opinion at this point. It's interesting to me that you emphasize mathematical studies of QFT and representation theory, both of which have been going like gangbusters in recent times. Perhaps they are not the exact type of studies that you would like to see, but you can hardly deny that there has been great progress in understand the space of QFTs and many new twists on the appearance of various kinds of representations. Many, many people other than yourself are interested in these things, so it's not clear to me exactly what you want people to do that they are not doing. It just comes out sounding like sour grapes of some sort.

26. **Yair**
July 27, 2017

Condensing the Arkani Hamed tour the force, to something like "1974 GUT was were we took the wrong turn" does injustice to the talk.

The talk was a breathtaking and brilliant attempt to cover the current situation – and to theextent any claims were made – it did provide some plausibility arguments in support of an anthropic approach.

Once a new approach (based on the Pre-1974 "wrong turn" framework) accompanied by calculations that are both consistent with the known experimental data, as well as (hopefully) some new predictions – will be officially published and peer reviewed – will it be possible to cast judgement about the heuristic claims hinted at in the comments section.

27. **Peter Woit**
July 27, 2017

William Nelson,
I've devoted far more time than is sensible to making the scientific case here and elsewhere that the string theory landscape/SUSY GUT paradigm has failed, didn't see the need to repeat it here. Characterizing things like the LHC negative SUSY results and the forty year history of countless experimental results in disagreement with SUSY/GUT/string theory expectations as "no evidence one way or the other" makes no sense unless you believe that the paradigm doesn't predict anything, which is exactly why it is a failure.

Yes, in recent years attention has returned to QFT from string theory, which is a good thing, and there's a lot of interesting mathematics going into this. My remarks about QFT and representation theory were not a complaint or sour grapes about anything, but intended as a positive response to a commenter asking what I found more promising.

Yair,
My comments about the talk obviously weren't intended to completely cover a nearly four-hour long lecture. The bulk of the talk was devoted to laying out the argument

that "if someone put a gun to his head", Arkani-Hamed's preferred scenario is the anthropic landscape, with split-SUSY, for no good reason at an energy scale just too high for the LHC to have seen it. As mentioned above, the reasons I think this is a failure are ones I go on about endlessly.

I wrote about this talk here because I think it's an unusually clear laying out of the current situation. I'd reserve the terms "breathtaking and brilliant" for a lecture with new ideas, not just a rehash of failed ones. The most interesting thing about the lecture I think was the end that I quoted, where Arkani-Hamed does bring up (without making the case for it) the obvious answer implied by his talk to the "What the Hell is Going On?" question.

28. **X**
July 28, 2017

"I've looked at the talks from a few of the HEP experiment and phenomenology summer conferences. If anyone can point me to anything interesting that I've missed, please do so. The lack of new physics beyond the Higgs at the LHC has left the field in a difficult state."

Well there's this from the recently concluded Lattice 2017 conference.
(Abstract:
I will discuss the recent B-physics results which indicate intriguing deviations from the Standards Model expectations. I will focus on several New Physics scenario which are currently being explored. I will then go through several flavor physics observables (not only those involving b-quark!) and argue that they too could provide us with access to New Physics provided the hadronic uncertainties are tamed by means of Lattice QCD.)

This kind of work is an example of what Adam Falkowski (Jester) calls the "2nd approach" to HEP – the `high precision' approach – as opposed to the `high energy' approach:
"By measuring the properties of known particles with great precision, and comparing the results to theoretical predictions, insights can be derived into physical laws at energies inaccessible to collider experiments."

The main challenge on the theoretical side is to compute the theoretical predictions with sufficiently high precision to be able to show discrepancy with the experimental results. Taking account of QCD processes is often the 'hard part' in getting the high precision theoretical predictions, so Lattice QCD is important here.

This approach is looking increasingly promising, not only IMHO but also in Falkowski's view:
"Shifting the focus away from high-energy colliders toward precision experiments may be the most efficient way to continue exploration of fundamental interactions in the decades ahead. It may even allow particle physics to emerge stronger from its current crisis."

(In the past I occasionally berated Falkowski on his Jester blog for wallowing in the lack of new developments from the 'high energy' approach to HEP while ignoring the interesting things going on in the high precision approach, so it is amusing to see that he is starting to appreciate it now…)

However, this kind of work is being done by relatively low-profile people at non-illustrious institutions, so it gets very little attention compared to the latest musings of Nima et al…

BTW, regarding the chiral gauge theory papers of Grabowska & Kaplan mentioned in a comment above, the approach seems to have been debunked (or at least shown to be very problematic) recently by Suzuki and collaborators here.

http://www.slate.com/articles/technology/future_tense/2017/07/rick_and_morty_gets_multiverse_theory_wrong_that_s_ok.html

30. **Barry Awn**
August 7, 2017

Peter, I would be interested to hear your response to Nima's comments around 1:37:14 about "… the most boring possible discussion …" in his HEP talk at the IAS PiTP summer program ("Where in the World are SUSY & WIMPS?). I found the comment at: 1:37:14 on https://www.youtube.com/watch?v=dKVXxcbJ4YY

31. **Peter Woit**
August 8, 2017

Barry Awn,
I thought that whole section of his talk was just outrageous. Given an hour to present to young researchers his take on the state of the field, he spends about 40 minutes going over laboriously exactly the same story about the CC/landscape/anthropics that those in the audience have surely heard a hundred times already (talk about boring!!), then dismisses objections with a wave of the hand as "the most boring possible.."

If, as seems increasingly all too possible, we're now at an endpoint of fundamental physics, with the field killed off by a pseudo-scientific argument ("no point in continuing, the multiverse did it"), Arkani-Hamed is one of those who will be most responsible for the situation.

32. **Jim Akerlund**
August 9, 2017

The August issue of "Notices" with the articles about gravitational waves, lists Arkani-Hamed as getting inducted into the "National Academy of Sciences". I know you get elected by current members, but does the election also include the reason the new member was elected? If so, does Arkani-Hamed reason include non-mathematical contributions, like the subject of the talks above?

33. **Peter Woit**
August 9, 2017

Jim Akerlund,
Arkani-Hamed is a physicist, not a mathematician, well-known for his work on various topics in HEP phenomenology (as well as some more recent more mathematical work on scattering amplitudes). He has an enthusiastic lecture style, likes to make dramatic, forceful claims, this is one reason he is quite influential in the field at the moment, for better and worse…

34. **Phil**
August 21, 2017

As far as new physics are concerned, strong hints actually appeared this Summer, not from the LHC, but from T2K, which excludes CP conservation in neutrino oscillations at the 95% confidence level using the latest data:
http://t2k-experiment.org/2017/08/t2k-2017-cpv/
Perhaps could be worth a new blog post?

A Few Items

July 25, 2017
Categories: Langlands, Uncategorized

Just a few items:

- The Simons Foundation has announced a new Origins of the Universe initiative, which will fund efforts to "develop testable predictions about string theory, quantum gravity and a cosmological 'Big Bounce.'" I don't think even all of Jim Simons' money will be enough to fund a real "prediction of string theory", but the fake kind can be had rather cheaply. I was interested to see in this presentation from the NSF that grants from Simons and other private sources are starting to change the way they do business:

  > One major challenge affecting Theory is the entrance of non-traditional (private philanthropic) funding sources. NSF has developed new procedures for evaluating overlapping sources of funding and introducing such evaluations into the proposal review process.

  I'm curious how they are dealing with this. If someone is being funded by Simons, will the NSF/DOE also fund them? Will the NSF/DOE stop funding fields that are being heavily financed by Simons/Templeton/Kavli? Does this have anything to with the NSF/DOE cuts in HEP theory funding of recent years?

- The latest AMS Notices has a couple of articles about gravitational radiation, see here.
- Yesterday a two week graduate summer school on automorphic forms and the Langlands program started. Lectures are being given by Kevin Buzzard and are on video here. Buzzard has set up a web-site for the lectures here.

  In his first lecture he explained that Richard Taylor's CalTech lectures in 1992 (scans of Buzzard's notes here) had a huge effect on him, and the plan of his lectures is to cover an updated version of some of the same material, ending up by getting to the latest developments, now available solely on a blog here and here. Buzzard also explained that in 1992 he devoted his time in LA to working on understanding the lectures during the week, going to raves on weekends. No news on whether MSRI is making similar arrangements for weekend activities of students in the summer school.

- Two new articles from Michael Harris: The Perfectoid Concept: Test Case for an Absent Theory and Do Mathematicians Have Responsibilities?.

Comments

1. **nikita**
   July 25, 2017

   Funding, no strings attached. Sorry, could not help.

2. **Egan**
   July 26, 2017

   The article about Perfectoid spaces from Harris is really fascinating. Easy to read for a non specialist and full of info and context.

3. **Bill**
   July 26, 2017

   Michael Harris' article was great but I did not see the point of the discussion at the end: "How much of the fanfare around Scholze is objectively legitimate, how much an effect of Scholze's obvious brilliance and unusually appealing personality, and how much just an expression of the wish to have something to celebrate, the "next big thing"?" One the one hand, nobody questions the opinion of the experts that all the textbooks on the subject will have to be rewritten. On the other hand, if the point was to put the invention of perfectoid spaces on the same level with the invention of complex numbers then the article was not very convincing.

   By the way, was the article written as the Fields medal laudatio? 🙂

4. **Peter Woit**
   July 26, 2017

   Bill,
   I don't see any attempt to argue that the invention of perfectoid spaces is on the level of the invention of complex numbers, he's just noting that our understanding of the significance of all mathematical concepts is provisionary and subject to change. While Harris does like to raise questions he then doesn't answer, this one I think gets answered (as "this is as objectively legitimate as it gets") later on.

   Yes, it does look like parts of this article could get recycled for a different purpose next year. In some sense the article has a similar goal to the expected laudatio, to make the case to non-specialists that some mathematical work is objectively important.

5. **Marc Sher**
   July 26, 2017

   I was the NSF High Energy Theory Program Director a few years ago for a year and a half. I haven't directly spoken with anyone at NSF regarding the specifics recently, but know some general practices (of NSF, not the DOE – I know nothing about the DOE). None of what I say comes from the NSF – it is my memory of what things were like a few years ago.

   "If someone is being funded by Simons, will the NSF/DOE also fund them?"
   There are plenty of people who get funding from both Simons and the NSF. It is a violation of federal law for someone to get NSF funding for a project under which they are also funded by someone else, however most physicists have several projects and can separate things out. In fact, in a grant proposal one is required not only to list current and pending support, but to discuss how that support would overlap (if any) with the work in the proposal.

   "Will the NSF/DOE stop funding fields that are being heavily financed by Simons/Templeton/Kavli?"
   Fields funded by the NSF HE Theory program are entirely determined by the proposals received. The fields of the panel members are also proportional to the fields in proposals sreceived (subject to obvious round-off issues, etc.). The NSF HET program doesn't "decide" what fields to fund.

   "Does this have anything to with the NSF/DOE cuts in HEP theory funding of recent years?"
   The NSF HEP theory budget, to the best of my knowledge, has not been cut any more than the Physics Division as a whole. I've heard that this is not the case for DOE

theory, but don’t have direct knowledge.

6. **Peter Woit**
July 26, 2017

Thanks Marc. I do wonder though what the “new procedures” are and what the thinking at NSF is about what they’re calling a “major challenge”. Given the way theorists (and their grad students and postdocs) work, it seems that it must be tricky to keep separately funded projects separate (what if a grad student funded by project A has an idea about project B?).

7. **Marc Sher**
July 26, 2017

Peter – I don’t know what the “new procedures” are. I imagine it is a “challenge” if private foundations begin steering the direction of physics, rather than having physicists do that. I don’t have an answer to that. As far as grad students changing ideas, we all understand that projects change direction (which is why NSF gives “grants” and not “contracts”) – I imagine if non-overlap morphed into overlap, the Program Director should be informed.

8. **Michael Barany**
July 29, 2017

It’s striking to see private philanthropies described as non-traditional funding sources for mathematics. Historically, NSF-style open civilian government grants are far and away the exception, and the NSF math system was itself modeled on philanthropic and military programs.

9. **Art**
July 30, 2017

From the “it could be worse” department, in today’s NYT, AI researcher Gary Marcus “look[s] with envy at my peers in high-energy physics”.

10. **jonW**
August 2, 2017

Regarding the DOE, it looks like their spending programs are completely mothballed now in any case. Just the other day there was an extremely thoroughly researched article from Vanity Fair that is very much worth reading despite its being predictably depressing: http://www.vanityfair.com/news/2017/07/department-of-energy-risks-michael-lewis

Quick Links

- For representation theory aficionados, George Lusztig has put on the arXiv a long document with comments on his papers (for a bit more about him, see this).
- For a new idea exemplifying the potential grand unification of mathematics and physics, Minhyong Kim and others have been developing arithmetic Chern-Simons theory (see here and here). There was a recent workshop on the topic, videos of talks available here.
- The editors of the Journal of Algebraic Combinatorics are leaving the Springer journal, setting up a new journal, Algebraic Combinatorics. For more about this, there's a press release, a story at Inside Higher Education, and a blog entry by Timothy Gowers.
- Landon Clay, founder of the Clay Mathematics Insitute, passed away last week, more about him available here.
- There's a profile and interview with Carlo Rovelli here.
- While Google continues to develop our new machine overlords, Google money will fund a new IAS program to address their theoretical underpinnings.

Comments

1. **Nilay**
   August 5, 2017

   Hey Peter —

   You might have posted about this already, but there was a CBMS conference in Bozeman Montana this week (http://www.math.montana.edu/cbms/), with 10 lectures by Dan Freed on applications of stable homotopy to lattice models. Arun Debray has some liveTeX'd notes here:
   https://www.ma.utexas.edu/users/a.debray/lecture_notes/topological_and_geometric_methods_in_qft.pdf

   The lectures were recorded, so those will probably be online at some point.

2. **Peter Woit**
   August 5, 2017

   Hi Nilay,

   Looks like a really interesting conference, with some great lectures on the intersection between math and physics. Thanks for writing in about it, hope you're enjoying Bozeman! I may be out there in a couple weeks (being a bit south of there on August 21 would be a good idea…)

Cosmology for the Curious

August 8, 2017
Categories: Book Reviews, Multiverse Mania

There's a new college-level textbook out, Cosmology for the Curious, targeted at physics courses designed to explain basics of cosmology to non-physics majors. The authors are Delia Perlov and Alex Vilenkin. Back in 2006 Vilenkin published a popular book promoting the multiverse, Many Worlds in One, which I wrote about at the time, making the obvious comment that there was nothing like a testable experimental prediction to be found in the book. It seemed to me then that the physics community would never take seriously an inherently untestable theory, recognizing such a thing as pseudo-science. I thought that the only reason claims like those of Vilenkin were getting any attention was that they had some novelty. Surely after a few more years of attempts to extract a prediction of some sort led to nothing, the emptiness of this sort of idea would become clear to all and everyone would lose interest.

Eleven years later I'm as baffled by what has happened to the field of fundamental physics as I'm baffled by what has happened to democracy in the US. As all attempts to extract a testable prediction from the multiverse have failed, instead of going away, pseudo-science has become ever more dominant, with a hugely successful publicity campaign (including a lot of "Fake Physics") overcoming scientific failure. Now this sort of thing is moving from speculative pop science to getting the status of accepted science, taught as such to undergraduates.

Many are worried about the status of science in our society, as it faces new challenges. I don't see how the physics community is going to continue to have any credibility with the rest of society if it sits back and allows multiverse mania to enter the canon. Non-scientists taking science classes need to be taught about the importance of always asking: what would it take to show that this theory is wrong? how do I know this is science not ideology?

Any student who reads this textbook and looks for answers to these questions in it will find just two "tests" of the multiverse proposed:

- Look for evidence of bubble collisions.
- Believe this paper, and then if you find a black hole population with a certain kind of mass spectrum, that would be evidence for the multiverse.

Of course there is no evidence for bubble collisions or such a black hole population, but these are no-lose "tests": no matter what you observe or don't observe, the multiverse "theory" can only win, it can never lose. Is it really a good idea to teach courses telling college students that this is how science works?

Comments

1. **Chris Herzog**
   August 8, 2017

   Two bubbles found they had rainbows on their curves.
   They flickered out saying:
   "It was worth being a bubble, just to have held that rainbow thirty seconds."

   –Carl Sandburg

2. **Hannes**
   August 9, 2017

   Peter, a little aside, there has been recent hints that CP violation occurs in neutrinos

   http://t2k-experiment.org/2017/08/t2k-2017-cpv/

   and commenters claim that this result might explain baroygenesis in the early universe. If that is the case, a further argument for physics beyond the standard model might be gone (you cited the article by Siegel in you blog, https://www.forbes.com/sites/startswithabang/2016/11/04/five-independent-signs-of-new-physics-in-the-universe , where the failure of the standard model to explain baryogenesis is given as one of the reasons to go beyond the standard model). Could you comment on this, maybe in another post?

3. **Peter Woit**
   August 9, 2017

   Hannes,
   The problem is that I don't know much at all about baryogenesis models, so best to leave this question to bloggers who do.

4. **Dan Winslow**
   August 9, 2017

   It's the power of instant, free mass communication, plus the seemingly ingrained predilection to hear what we want to believe rather than what is true. In both cases. The fact that 'news' is monetized by advertising makes it even worse. You can make money blathering about the multiverse, because it is cooler than not having one, and further means you can blather about anything since anything is possible. It's a perfect setup.

5. **The Observer**
   August 9, 2017

   We live in an age of great bogosity. "We each have our own truth" is the mantra of the age. Objectivity cannot be expected to survive in such an atmosphere. Believe it or not, Karl Popper's academic children began the "science is a cultural construct" movement in California a long time ago. Now, we hear the rumblings of direct attack on science and mathematics by their followers.

   It would be funny were it not so sad and so alarming.

6. **Peter Woit**
   August 9, 2017

   The Observer,
   I don't think you can blame Popper, his academic children, or a "science is a cultural construct" movement for what is going on here. Those pushing the string landscape pseudo-science are at the heart of the academic establishment and it seems that their main motivation is simply that of being unwilling to admit to failure.

7. **Mozibur Ullah**
   August 9, 2017

   I blame both the internet and the media; personally, I'm not against speculation, so long at its labelled as such; I don't think, however it's a good idea to smuggle it into a book for undergraduates without qualification.

   I also recall reading that a few physicists on discovering QM, saying we need crazy counter-intuitive ideas to make sense of QM, maybe that's set the stage for crazy ideas elsewhere, like in cosmology.

8. **Peter Woit**
   August 9, 2017

   Mozibur Ullah,
   I don't think you can blame the internet/media for this one. We're talking about a college course taught by a physicist whose views are now considered mainstream by many other physicists. This is a problem the physics community needs to face up to, not blame on others.

9. **Low Math, Meekly Interacting**
   August 9, 2017

   It's a shame, really. I found the preview chapter on Newton's laws quite enjoyable. Assuming the rest of well-established physics is covered in comparable style, I'd happily give the text a good read just for fun. There aren't too many books out there that cover such material with this balance of rigor and accessibility. But with all the anthropic multiverse garbage larding the book's final chapters, no thanks.

10. **Radioactive**
    August 10, 2017

    Is this so different from 'String Theory for Undergraduates'? Have some faith in students to be able to notice bunk when they're taught it.

11. **anon**
    August 10, 2017

    They never will change their mind, because they never have before. There were competent smart physicists from good universities looking for the luminiferous aether well into the 1930's. If anyone's noticed the people involved in these theories are starting to get quite old, they will eventually retire and new people with new idea's will take their place.

12. **Peter Woit**
    August 10, 2017

    Radioactive,
    Why do you think non physics major students will recognize the multiverse as bunk, when IAS professors don't?

    anon,
    I don't think it's true that multiverse mania is just a disease of an older generation that will die out. Many of its proponents are not that old at all. It might even be that the older generation has more skeptics, people who were around when the field was healthy and can recognize the difference between an empty idea and one that works.

    The conventional argument that we'll make progress by the old retiring and the young growing up with better ideas depends on those better ideas coming along. The really awful aspect of multiverse mania is that it's a concerted attempt to get the young to give up and not even try to find an alternative.

13. **Don Murphy**
    August 10, 2017

    I conduct "Making Sense of Science" seminars to discuss contemporary advances in science. One seminar was on the multiverse, the purpose of which was to demonstrate that some "theories" are not testable and therefore not really theories. I presented the 11 or so "theories" Brian Greene puts forward in one of his books that he says all lead to the conclusion the multiverse must exist. Most of the seminar attendees understood that the multiverse is nothing more than pseudo-science. However, to my dismay, there were some who firmly believed that the multiverse confirmed their religious views on polytheism, and human beings being resurrected as gods to rule over multiple universes. A dangerous notion for so-called mainstream science to have spawned.

14. **G. S.**
    August 10, 2017

    One saving grace here is that the material taught in physics classes for non-majors is rarely absorbed by the students. The small amount that is absorbed is quickly forgotten after the post-finals beer binge and brain dump. The books get sold online or go in a box that gets stored in the least accessible spot in a parent's garage. In ten years, 90% of the students who used this book for a college course won't remember even having taken the class, let alone the material from it.

15. **neil**
    August 10, 2017

    IMO, interest in the multiverse persists among reputable physicists because it doesn't violate any logic and offers the illusion of explaining the values of many physical constants (with the Anthropic principle) and fine tuning. It doesn't of course, but absent a real explanation it is the only interesting game in town. It also offers the illusion of testability since practically any irregularity in the CMB can be claimed to be evidence of a neighboring bubble.

16. **Peter Woit**
    August 10, 2017

    Don Murphy,
    From another side, some atheists like to have the multiverse to use against theists making a fine-tuning argument for the existence of God. They don't seem to realize that invoking an untestable theory to make such an argument puts them in a position indistinguishable from that they're arguing against (relying on belief rather than scientific evidence).

17. **Jeffrey Wolynski**
    August 10, 2017

    The more you write about it, the more popular it becomes. You are feeding the flames. You know the rule about publicity? Even bad publicity is still publicity.

18. **R. Gates**
August 10, 2017

Your point about testability and predictions is a great one but actually, there may be some evidence for evidence for bubble collisions:

https://phys.org/news/2017-05-cold-sky-collision-parallel-universe.html

19. **The Observer**
August 10, 2017

Well, you are right that Popper's academic children and the "science is a cultural construct" movement cannot really be the cause of this. They are too far separated as phenomena. It would be better had I put it that these separated phenomena have a common cause. That cause is the failure of belief in truth and the substitution of relativism.

Science has always been a phenomenon dependent on experience. I believe that it was called "speculative science" long before it was called "natural philosophy", long before Galileo, and that was exactly right, because induction is speculative. But, from the bottom side the relativists about truth have attacked truth and want to mold science as being something that, as a "cultural construct", they can reconstruct as they see fit. Does that not sound like exactly the same thing as, from the top, those in love with untestable visions of their own seeking to make it legitimate to "extend" science into a subject no longer dependent on experiment but something in which being "the only game in town", for example (in their own opinions), makes it desirable to call the creations of their own minds, divorced from experience, "science". They may be brilliant, but they have gone relativist on the ancient understanding of speculative science as something based, not on pure creativity, but experience.

Is this not, really, exactly the same phenomenon played out from below and from above.

I think that science is in danger of being crushed by a pincer movement between the relativists below, who are in the process of forming up for a politically powerful attack on science, and the relativists above, who want to reconstruct science to suit their own varius relativist redefinitions of science.

Another way to put this is: We have gone crazy.

You are doing really great and important work, but you sound a little discouraged. I would like to encourage you by suggesting strongly that you hang in there and remain the beacon of sense that you have been for many years now.

We need you.

20. **Peter Woit**
August 10, 2017

R. Gates,
These bogus claims are just endless, I've wasted far too much of my time trying to debunk them here over the years, now think that's just hopeless. It's always the same thing:

1. Scientific paper with no evidence at all for a bubble collision
https://arxiv.org/abs/1704.03814
2. Press release from university mentioning "possible evidence for multiverse"
https://www.ras.org.uk/news-and-press/2982-new-survey-hints-at-exotic-origin-for-the-cold-spot
3. Loads of press stories like the one you link to.

Everyone involved in this bullshit should just be ashamed of themselves.

Looking back, I think one reason I didn't mention this particular example on the blog is that others have done so, see

https://telescoper.wordpress.com/2017/05/19/a-spot-of-hype/

21. **Peter Woit**
August 10, 2017

Some more related to the last comment:

I wish more physicists/cosmologists/astronomers would start to do what Peter Coles did in that case. It really is part of the job of anyone in those fields who cares about the public understanding of their science.

One reason I wish this would happen is that I'm sick and tired of wasting my time on this, doing a job others should be doing. In addition, note that the reason I found the Coles blog entry was that it is linked as a trackback to the arxiv paper that started this. Trackbacks to any of my blog entries are banned by the arxiv. Historically one of the main reasons for this is that I seem to have upset Joe Polchinski by a blog entry criticizing a Bousso/Polchinski article promoting the multiverse. He then went on a campaign to ensure that my blog entries criticizing multiverse papers would never show up as links at the arXiv. So, best when others deal with this.

22. **Jeff**
August 13, 2017

The Atlantic has an interesting article (https://www.theatlantic.com/amp/article/534231/) discussing the way in which American society in general–across political, religious, and ethnic lines–has elevated personal fantasy over objective reality as "the truth". It describes both how origins of this shift can trace back to left-leaning academia as well as elements in mainstream left politics (though this is not a "both-sider" article; it clearly draws out that regarding actual party leaders, platforms, and propaganda, the American right is far deeper into fantasy than the centrist/left).

But while reading the article, I kept thinking back to this blog, and this post in particular. The article touches on domains and personality types where magically thinking hasn't taken hold: physical/empirical sciences, rationalists, the a-religious/a-spiritual. Sadly, I think the author overestimates how immune even those areas are to magical thinking.

23. **Peter Woit**

Re previous comment:

It seems that the arXiv has changed its policy and is now allowing trackbacks to my blog entries. No idea what changed or when this happened, seems to have been within the past few months.

24. **Peter Coles**
August 15, 2017

Thanks for your comments about my post at `In The Dark'.

Sadly it would be full-time job keeping up with all the misleading cosmological hype going around so I've let quite a few other papers slip!

25. **AcademicLurker**
August 16, 2017

No idea what changed or when this happened, seems to have been within the past few months.

The arxiv had their big user survey recently. Maybe there was a significant pro-Woit vote…

26. **Shantanu**
August 16, 2017

Academiclurker and Peter,
FWIW, that's exactly one of the feedbacks I gave to arxiv readers.

GR=QM?

August 10, 2017
Categories: Uncategorized, Wormhole Publicity Stunts

In recent years a hot topic in some theoretical physics circles has been the 2013 "ER=EPR" conjecture first discussed by Maldacena and Susskind here. Every so often I try and read something explaining what this is about, but all such efforts have left me unenlightened. I'm left thinking it best to wait for this to be better understood and for someone to then produce a readable exposition.

Instead of that happening, it seems that the field is moving ever forward in a post-modern direction I can't follow. Tonight the arXiv has something new from Susskind about this, where he argues that one should go beyond "ER=EPR", to "GR=QM". While the 2013 paper had very few equations, this one has none at all, and is actually written in the form not of a scientific paper, but of a letter to fellow "Qubitzers". On some sort of spectrum of precision of statements, with Bourbaki near one end, this paper is way at the other end.

Susskind starts out:

> It is said that general relativity and quantum mechanics are separate subjects that don't fit together comfortably. There is a tension, even a contradiction between them—or so one often hears. I take exception to this view. I think that exactly the opposite is true. It may be too strong to say that gravity and quantum mechanics are exactly the same thing, but those of us who are paying attention, may already sense that the two are inseparable, and that neither makes sense without the other.

I just finished writing a book about quantum mechanics, and it all seemed to me to make perfect sense without invoking gravity, but as explained above I guess I'm one of those who is not (successfully) paying attention. Another route to understanding would be to focus on the new experimental implications of the ideas. In the abstract Susskind claims that his ideas imply that we'll observe quantum gravity using quantum computers in a lab "sometime in the next decade or so". When that happens maybe this will all become clearer.

Update: Sabine Hossenfelder has a commentary on the paper here.

Comments

   August 10, 2017

   Dr. Woit,

   I'm very interested in your QM book, but I prefer bound books. Will the book be on sale?

   Thank you.

2. **Peter Woit**
   August 10, 2017

   Vik,
   Yes, I see that Springer now has a publication date of December 4.

3. **Vik**
   August 11, 2017

   "Susskind claims that his ideas imply that we'll observe quantum gravity using quantum computers in a lab 'sometime in the next decade or so'."

   Actually, you misquoted him. In his abstract, he says, "…about the possibility of seeing quantum gravity in a lab equipped with quantum computers. I expect this will become feasible sometime in the next decade or two."

   So, he uses the word "possibility" and "feasible", not "observe" as you wrote.

4. **Richard Gaylord**
   August 11, 2017

   "I'm left thinking it best to wait for this to be better understood and someone produce a readable exposition.". poorly written.

5. **Anonyrat**
   August 11, 2017

   Seems like a reductio ad absurdum proof that AdS/CFT is wrong.

6. **Anonyrat**
   August 11, 2017

   Or a side effect of the legalization of marijuana.

7. **Cobi**
   August 11, 2017

   "On some sort of spectrum of precision of statements, with Bourbaki near one end, this paper is way at the other end."
   As you mention yourself, it is not a paper but a "letter to colleagues" or, in more conventional categories, an essay.
   To take an essay as evidence that the field is moving into a "post modern" direction is somewhat dishonest.

8. **ttt**
   August 11, 2017

   So, he uses the words "possibility of seeing" , not "observe" as you wrote.

a difference without a distinction

9. **Peter Woit**
August 11, 2017

Cobi,
It's not a popular essay aimed at non-experts, thus making precise statements inappropriate. It's a letter to other experts, no reason it shouldn't contain precise statements. If you think there are any in it, perhaps you can explain what they are?

10. **atreat**
August 11, 2017

In the original ER=EPR, Susskind and Maldecena described their highly speculative conjecture like this: "In fact, we are going to take the *radical position* that in a theory
of quantum gravity they are inseparably linked, even for systems consisting of no more
than a pair of entangled particles."

I am not aware of a single experimental result that helped validate this "radical position" and yet Susskind in this latest paper suggests to others to take this "radical position" as given and then adds on another *even more radical* speculation. I think this is perhaps what Peter is referring to when he describes this research program as post modern.

Given this paper, I'm curious what this says about Susskind's String Theory work for all those years. If GR=QM it would seem Susskind now believes that String Theory is superfluous.

11. **Peter Woit**
August 11, 2017

atreat,

Good question about what the implications are for string theory.

The "post-modern" remark is less about these conjectures being "radical" than them being incomprehensible. I quite seriously have no idea whether Susskind has a new important idea that I'm not understanding because I'm not familiar with all the background and assumptions of those that he's writing for, or whether he has just stopped making sense.

12. **sdf**
August 11, 2017

How is a commentary without any precise statements acceptable as a submission to arXiv?

Apropos, would this have been regarded as acceptable as a submission to arXiv if the author's name was not Leonard Susskind or another well-known physicist?

13. **Jack Morava**
August 11, 2017

cf perhaps
https://en.wikipedia.org/wiki/Exploits_and_Opinions_of_Dr._Faustroll,_Pataphysician

14. **Daniel Hogg**
August 11, 2017

As someone who has worked in a quantum computing lab (on the experimental side), I find myself in much the same boat as Peter, being unable to confirm whether I'm not understanding Susskind's ideas, or if the ideas themselves make no sense. What I do know is that for all of the hype in the media, quantum computing is still quite primitive. Decoherence is a major obstacle, the 'computers' (if you can call them that) that we create are limited to a very small number of qubits. The papers that do produce results claiming tens of thousands of qubits seem to have fatal flaws such as a lack of distributed multipartite entanglement. So an attempt to piggyback quantum gravity onto the current 'revolution' in quantum computing needs to respect that the field is still quite limited in what we can measure/accomplish in the laboratory setting.

From the experimental side of things, what seems to be missing is an effect that is being proposed that could be measured under laboratory conditions. People in the field of quantum optical computation do not currently think about gravity because there aren't any observable interactions that we can test for (that we know of, yet). If Susskind wants to propose something that experimentalists can look for, great. As written, it comes across as too speculative.

15. **Blake Stacey**
August 11, 2017

The "ER = EPR" conjecture has the advantage that, if true, it would instantly imply the answer to one of the Millennium Prize problems, at least in the case of large N.

16. **Jeff M**
August 11, 2017

Well, I'm with sdf, how is this a legitimate submission to arXiv? Is it possible Susskind will submit it to a journal? If he does, and it's accepted, that would strike me as a very clear sign that HEP is done. On another note, Sabine is hysterical.

17. **Mitchell Porter**
August 11, 2017

EPR->ER means that where there is entanglement, there should be wormholes. There are recent papers arguing in some detail that quantum teleportation is teleportation "through the wormhole".

Susskind apparently wants people who work in quantum information to get used to the idea that quantum logic gates, etc, involve actual wormhole geometries. And the experimental frontier that he hopes to see breached, is (I think!) the creation of micro black holes *simply through the manipulation of entanglement*.

18. **Peter Woit**
August 11, 2017

Blake Stacey,
It's news to me that there's a precise formulation of ER=EPR that one could imagine proving and that would imply (I assume this is the claim) P not equal to NP. What's a reference for this?

Mitchell Porter,
I don't understand this at all. Qubits, entanglement and quantum logic gates I thought could be described precisely by QM with no need for wormholes. Is Susskind claiming that we'll see some violation of QM that indicates quantum gravity, or will what we see precisely follow QM, with Susskind's quantum gravity effects some sort of interpretation that those of us not paying attention can just ignore (and that has no known connection to actual gravity?).

19. **David Urbanik**
August 12, 2017

The "ER=EPR" solves P vs. NP comment seems like an obvious joke. If "ER=EPR", then one can cancel the E and the R to find that P = 1, so we can only have P = NP if N=1, hence showing P is not NP for "large N".

20. **Peter Woit**
August 12, 2017

Richard Gaylord,
Thanks. Improved.

21. **srp**
August 12, 2017

Peter asks: "Is Susskind claiming that we'll see some violation of QM that indicates quantum gravity, or will what we see precisely follow QM, with Susskind's quantum gravity effects some sort of interpretation that those of us not paying attention can just ignore (and that has no known connection to actual gravity?)."

From the paper: "A skeptic may argue that all of this can be explained without ever invoking bulk gravity or wormholes; plain old quantum mechanics and some condensed matter physics or quantum circuitry is enough. This is absolutely true, but I think it misses the point: Theories with gravity are always holographic and require a lower dimensional non-gravitational description. This does not mean the bulk world is not real."

22. **Friedwardt Winterberg**
August 13, 2017

GR=QM is impossible because from G(Newton's constant) and c(velocity of light) one cannot get h(Planck's constant).

23. **Blake Stacey**
August 13, 2017

Peter Woit:

Sorry, I was just making a silly joke about canceling the E and the R.

24. **Blake Stacey**
August 13, 2017

… because I work in quantum information, and I tried valiantly to get some sense out of the "ER = EPR" claim, and after all that, the best I think it deserves is silly jokes.

25. **Peter Woit**
August 13, 2017

srp,
Thanks for pointing that out.
Rereading the paper with that clarified, I think I'm finally beginning to see what Susskind is up to. By "QM" he means QM, but by "GR" he means not GR, but "hypothetical dual to QM system that we know almost nothing about" (which for some very specific QM systems in a special limit is related to GR in one dimension higher).

Those of us who aren't in the mood for completely ill-defined flights of fancy can safely continue to not pay attention. As for where this is going, it looks to me like the most optimistic scenario is that some better understanding of this kind of duality will lead to some useful approximate calculational method for some particular very complicated QM systems (by relating something in them to something in a GR calculation in one-dim higher). Then we'll see lots of new university press releases and stories in the press about "wormholes created in the lab", with claims that this is "evidence for string theory".

More interesting of course would be if this duality could be read the other way, explaining physical 4d quantum gravity in terms of a well-defined dual QFT. I don't see any indication of that happening, and Susskind's claims don't seem to have anything to do with it.

26. **Lee Smolin**
August 13, 2017

Dear Friedwardt Winterberg:

An excellent point. But you can get h from G and c if there is also assumed a fundamental length or energy scale, and vise versa. So one way to think about this could be that a QFT (h,c) whose symmetries preserve a fundamental scale (E_p), has G and hence gravity coded in it.

Lee

27. **David Roberts**
August 13, 2017

To stretch an analogy, this is the kind of thought experiment that Einstein described that lead him to the principle of equivalence and thence to GR. Except he didn't release a paper describing his thoughts about what it would be like to ride a beam of light or an elevator – he spent time learning new mathematics and wrote up a serious theory with predictions that were verifiable, and then verified.

28. **Blake Stacey**
August 13, 2017

Peter Woit (August 13, 2017 at 4:45 pm):

Your “most optimistic scenario” pretty much agrees with the most optimistic evaluation I could make. A geometric way of calculating entanglement properties in many-body systems, let’s say—that could be useful. But I strongly suspect that the further one goes down that path, the less it will look like gravity in any way, and the hope of “building spacetime out of entanglement” (to put it the way a flashy keynote at PI would) will remain as distant as ever.

29. **wolfgang**
August 15, 2017

Peter,

>> this kind of duality will lead to some useful approximate calculational method

as I understand it, an important point he makes is that the distinction between the quantum-computer CFT side and the AdS bulk part is arbitrary.
If the quantum computer(s) are sufficiently large, they may be able to communicate with observers inside the bulk.

Of course one could turn this around (I dont think he does this yet) and argue that we are just the bulk description of somebody else’s quantum computer.

30. **Mauro Claudio**
September 22, 2017

Peter Woit, have you missed this ?

Amazing statement: “teleportation … after a suitable time”.
A teleportation whit a delay!

https://arxiv.org/abs/1707.04354
Teleportation Through the Wormhole
Leonard Susskind, Ying Zhao

ER=EPR allows us to think of quantum teleportation as communication of quantum information through space-time wormholes connecting entangled systems. The conditions for teleportation render the wormhole traversable so that a quantum system entering one end of the ERB will, after a suitable time, appear at the other end. Teleportation requires the transfer of classical information outside the horizon, but the classical bit-string carries no information about the teleported system; the teleported system passes through the ERB leaving no trace outside the horizon. In general the teleported system will retain a memory of what it encountered in the wormhole. This phenomenon could be observable in a laboratory equipped with quantum computers.

31. **Peter Woit**
September 22, 2017

Mauro Claudio,

Thanks! I somehow missed that one. Surprising that this summer there weren’t a bunch of articles in the press about how quantum computers would open up wormholes suitable for teleportation.

Road Trip

August 14, 2017
Categories: Uncategorized

Blogging will be light to non-existent for the next ten days or so, as I head out west on a road trip to see next Monday's solar eclipse. Current plan is to fly to Denver tomorrow, pick up a vehicle, and head up to Wyoming the next day. If weather projections look good for the Wyoming/Idaho part of the track, that's where we'll plan to end up, likely camping out somewhere (accommodations along the track have long been booked up).

This will be the ninth eclipse I've traveled to see, and I urge anyone thinking of making a trip to the eclipse track to do so. A total solar eclipse is something quite different than a partial one, and this is a very rare opportunity to see this in the US. Besides the eclipse, a major motivation for these trips has always been that of getting to visit a more or less random place on Earth that one wouldn't otherwise have any excuse to see. I've driven quickly through Idaho and Wyoming a few times over the years, look forward to spending more time in that part of the country this coming week (unless the weather there looks bad, in which case maybe we'll end up in Oregon or Nebraska).

Some other random advice about eclipses:

- Be very careful about use of binoculars or telescopes, improper use of these at any time other than the period of totality is what can cause serious eye damage (by itself the eye is pretty good about automatically protecting itself).
- Don't put a lot of effort into photography during totality, since that's likely to lead to you spending the time you should be enjoying the experience fiddling with camera equipment (and not getting a good result anyway…). A simple thing to do is to set up a camera to take video of the overall eclipse scene as it happens, turn it on at some point then ignore it.

If you miss this one, next couple are far south in South America, there will be another chance in the US relatively soon, April 2024.

Update: Now back in New York. Had a very good view of the eclipse from a spectacular location: Stanley, Idaho, up in the Sawtooth mountains. Only not quite optimal part of the plan was camping out not not well-equipped for the the unexpected fact that it gets down to about freezing at night in that part of Idaho, even in August…

   August 14, 2017

   Peter , OT.
   TevPA talks at https://www.youtube.com/watch?v=LnjICNLvtj4 and so on
   (this one is a link to Nima's talk)

2. **Gus Bici**
   August 14, 2017

   Me & doggie driving to Idaho Falls from Tucson. Ogden UT was as close as I could get for Sunday night reservations when I booked over a month ago. Will rise early on Monday to get in the totality shadow over Idaho. If it is cloudy oh well – it will be extra dark I guess:)

3. **Abby yorker**
   August 14, 2017

   We just moved to Portlnd, OR, and so I plan to cycle into the totality swath the morning of. Driving a car would likely be unsuccessful. Portland is completely booked for the eclipse.

4. **SB**
   August 14, 2017

   And those experiencing it in an extended flat terrain look carefully for Shadow bands

5. **Chris Kennedy**
   August 15, 2017

   While you are there, if the band you're in starts playing different tunes – run like hell.

6. **Bill_K**
   August 15, 2017

   Darkened glasses are essential during the partial phases of the eclipse, but during totality, when the sun is completely covered, it's safe and desirable to take them off. If you do, the only precaution is to know in advance how long totality will last at your viewing site, so you can put the glasses back on in time!

7. **KWH**
   August 15, 2017

   I commend http://mreclipse.com to your readers, and in particular http://mreclipse.com/Totality3/TotalityCh11.html. My wife and I, who will be in Wyoming, at Glendo State Park on the morning of the eclipse, will use Shade 14 filter plates in flip-up welding goggles. Glendo is a good place to be on eclipse Monday. It's exactly on the centerline of the eclipse path and immediately next to I-25 well south of Casper. The "ticket booth" ($6) opens at 4:30 a.m. I'll be wearing or right next to a large, bright red Osprey climbing pack.

8. **neil**
   August 15, 2017

   Peter

   Be ready for huge crowds around Jackson Hole on eclipse day. Prime territory. I will be in a remote area of eastern Oregon and still expecting crowds.

   In Idaho, Craters of the Moon NM and Hells Canyon NRA are worth visiting.

Have fun and happy viewing.

9. **Koenraad Van Spaendonck**
   August 16, 2017

   Great initiative. The trip has a goal, but the goal is the trip !

10. **Eddie Dealtry**
    August 17, 2017

    Absolutely concur with the second bullet point: don't spend all the time with equipment. Spent most of the 7-minute eclipse (not far short of theoretical max) in 1973 faffing with cameras. Won't do that again.

11. **David**
    August 23, 2017

    Thanks for the advice to not worry about trying to photograph it. My wife, son, and I were in Oregon and I just set the camera to record us as we watched. The result was probably the most memorable video that I've ever made, even though the eclipse itself is never seen.

12. **Jeff Moreland**
    August 23, 2017

    Had a great view in Aurora, Nebraska, hope you had clear skies.

13. **Jerome Moore**
    August 26, 2017

    Saw it with my kid near Columbia, Missouri. Good weather and really spectacular. There were special events hosted by the university.

    @Bill_K: I was worried about that but it turns out not to be ambiguous at all. You see the flash when the sun starts to emerge, you know its time to put the eclipse shades back on.

14. **Bugannoyer**
    August 26, 2017

    I was in Madras, OR at "SolarFest", camping in the "SolarTown" tenting sites. What an amazing experience! The crowd's energy was exhilarating!

    Was slightly hazy/high cirrus clouds, but this turned out not to matter much for seeing the corona and flares. We had an Orion AstroView 120mm F5 scope with an 82 deg 44x lens that captured almost all the corona, plus 70mm 15x binocs on a tripod, and some handheld binocs (all with solar filters).

    Saw Bailey's Beads as totality exited, and pulled eyes away from the lens of the Astro View, slapped the solar filter back on the scope. One thing that was striking was how well the eye captured the solar flares (a lot of detail), compared to the best photos I've seen online. My guess is this is attributable to the eye having the separate cone receptor types, so that the red in the flares was probably selectively perceived/enhanced by the visual system. I'd be interested if anyone could say more about that.

15. **filtz**
    August 26, 2017

    Bugannoyer,

    It is safe to view totality with binoculars or telescope with proper solar filter?

    "how well the eye captured the solar flares" – Are you talking about naked eye, or eye + telescope/binoculars?

    Where did you get your Orion AstroView and binoculars? Would you recommend that telescope as a first telescope for an adult astronomy enthusiast?

    Any good resources for photographing/viewing solar eclipse? What solar filter did you use? Thank you for your post!

16. **Bugannoyer**
    August 27, 2017

    Filtz, telescopic product comment is probably OT, and so I'll be brief on that, and we should not be surprised if our moderator deletes. But in that regard, I can recommend the Orion AstroView 120st as a good value/quality-to-price, medium-range scope, which can be upgraded to a 2″ focuser and eyepieces (I'm just using the scope as equipped, with 1.25″ lenses). One caveat is the mount (German Equatorial) is heavy, so only suitable for *car* camping. I bought online.

    The 70mm binocs are Celestron, and also very good value/quality-to-price, although in this case my price was $0. They were a prize my daugher won at an Oregon Star Party a few years ago.

    At totality you view without solar filters or glasses. The brief Bailey's Beads / Flash / Diamond Ring I saw through the AstroView at 3rd contact (without filter) was probably not dangerous because of how quickly I pulled my eye away from the lens.

    The solar filters I used (when *not* at totality) I made myself from Baader Solar Film, again ordered online. You can find instructions for how to construct solar filters using this or other certified films online.

    I am not an astrophotographer myself, but I'd recommend Sky and Telescope as a good place to start; there are a ton of online resources as well.

17. **John**
    August 28, 2017

    We drove with one of the grandkids from Las Vegas to Mackay, Idaho to see the eclipse. Two minutes and 13 seconds of totality. It was amazing. Indescribable. Words and pictures don't do it justice. You really have to experience a total eclipse to understand.

18. **Nick M.**
    August 29, 2017

    Peter,

In addition to the 8th of April 2024 *total* solar eclipse, there will be an *annular* solar eclipse on the 14th of October 2023.

For 2023 see Solar Eclipse 2023,
and for 2024 see Solar Eclipse 2024.

This would be a great opportunity to witness the two types of solar eclipses that the sun and moon can put together, just one half year apart from each other, on the North American continent.

19. **Tom Dickens**
August 29, 2017

We traveled to Greenville, SC, met some family members, and had 2 min 6 sec of totality. Beautiful sight, first total eclipse we have seen.

I took pictures using an EOS 80D with 300 mm lens with Thousand Oaks filter during partial phase. Should have taken advice not to try in totality, because I missed about half of it when I kept taking pictures, and got confused by the enormity of the event! I did get a couple of decent ones..

Next time I will just watch.

This and That

August 29, 2017
Categories: Uncategorized

- The Stacks Project (see an earlier post here) had a very successful workshop in Ann Arbor earlier this month. This is a remarkable effort pioneered by Johan de Jong to produce a high quality open source reference for the field of algebraic geometry. It now is over 6000 pages, with an increasingly large number of papers citing it (according to data from Pieter Belmans, 85 citations in the arXiv so far in 2017 alone). During the workshop plans were discussed for the future of the project, with work on a new version of the project infrastructure underway (see slides and a blog post from Belmans).
- The latest AMS Notices has a wonderful article by my Barnard/Columbia colleague Dusa McDuff about her remarkable family history and reflecting on her equally remarkable mathematical career. A post earlier this year discussed a Quanta article about her recent work with Katrin Wehrheim on technical issues in the foundations of symplectic topology. Kenji Fukaya has recently written something for the Simons Center website (see here) explaining his take on this story.
- The Stanford Encyclopedia of Philosophy has a new entry about the fine-tuning problem, by Simon Friedrich.
- The LHC operators have run into some difficulty in recent weeks (reflected in the accumulated luminosity plots here and here), with problems centered around an unknown source of gas in the beam pipe at a specific location, leading to losses of the beam. Some information about this is available here. The past few days they seem to be having success running the machine with around 1500 bunches, much less than the 2500 or so of earlier in the summer. The target for the year is 40 inverse fb which may still be achieved, while more optimistic numbers that looked plausible earlier now seem less likely.

Update: Joe Polchinski has put on the arXiv a long autobiographical document, with a detailed discussion of his scientific career.

Update: As mentioned in the comments, Go Yamashita has posted a long document surveying Mochizuki's claimed proof of the abc conjecture. Experts may find that this makes it more possible to understand and check the claimed proof, we'll see.

Update: Also at the Simons Center website, there's an interview with Michael Green. It's interesting to see that in recent years his research interests have led him to getting closer to mathematics and to an appreciation of what mathematicians do. As for his claim about string theory that

> I don't think there is a substantial antagonism to it among those who have studied it, other than a few individuals who enjoy publicizing their views.

I think he's quite wrong if you properly take "it" to refer to the aspect of string theory there is widespread antagonism to among physicists, the overhyped claims about a unified theory based on string theory.

   Apropos a previous blogpost on this website, the survey of Yamashita on work of S. Mochizuki has appeared http://www.kurims.kyoto-u.ac.jp/~gokun/DOCUMENTS/abc_ver6.pdf 294 pages and claims to be self-contained.

7. **Peter Woit**
   August 31, 2017

   Klaus,
   My guess is that "brane cancer" is intended as humor on Polchinski's part. I wish him well and he's entitled to some levity about the difficult situation he is in.

   Yes, I think it's right that those are the three things he has done that have gotten the most attention and had the most impact. Unfortunately for one of them (moduli stabilization/string theory landscape/multiverse) I think the impact has been large and negative and, away from the West Coast, I suspect many of his colleagues agree with me. His discussion in his memoir of how this work affected him is remarkable.

8. **JY**
August 31, 2017

BTW, (maybe you have already known this:-)) Weinberg is going to give a talk to celebrate 50 years of SM https://indico.cern.ch/event/649760/timetable/ . Kind of curious about what he is going to say in the talk

9. **Bill**
August 31, 2017

I found Section A.4 on pages 265-266 of Yamashita's manuscript quite fascinating.

10. **Tom**
August 31, 2017

Philosopher here. I'm curious how many mathematicians, if any, suspect that Mochizuki is perpetuating a hoax. I am thinking of all the new names M. gives to concepts that are already perfectly well denoted (e.g. isomorphism); all the jargon, generally; the way a proof in one paper relies on a result from a second, which uses a definition from a third, which relies on a lemma from the first one–i.e. all the circularity; the apparent unwillingness on M.'s part to make the argument perspicuous for others; and the fact that experts are unable to understand the basic strategy of the proof. None of these features is dispositive of a hoax, but they are worrying.

Do mathematicians think that? Or is the general sentiment that M.'s work really is too brilliant and cutting-edge to understand? Or is M. likely mistaken, but working in good faith? Are mathematicians really just at a loss about what to think?

11. **Peter Woit**
September 1, 2017

Tom,
I don't know of any mathematicians who think it's a hoax, there's nothing at all to indicate that. All indications are that it's a complex argument, based upon ideas involving a lot of new mathematical constructions. The question is whether these new constructions do what Mochizuki argues that they do. Surely he is convinced of this, but others need to understand the new constructions well enough to see whether the arguments are airtight. This is a very unusual situation: usually by now other experts would have assimilated the new ideas well enough to check them, or to identify their weaknesses. Perhaps the Yamashita survey will help move this along. I think it's fair to characterize the current situation as "at a loss about what to think".

12. **sdf**
September 1, 2017

S. Mochizuki has a good pedigree and has done first-rate mathematics in the past. Furthermore there are other first-rate mathematicians who believe he is on to something. So it is rather hard to completely ignore his work, despite his unwillingness to engage properly with the community.

13. **Yatima**
September 2, 2017

Quanta Mag has a popular-science article on efforts of getting QM from a few axioms:

Quantum Theory Rebuilt From Simple Physical Principles

I remember Lucien Hardy's
Quantum Theory From Five Reasonable Axioms, and that dates back to even before the Forever War.

Axioms are not "physical principles" but "syntactic principles" though. You can just feed them to a TM-based deduction system (or better) w/o physics in sight.

QM rebuilds seem to be not particularly hard, what about QFT rebuilds?

14. **william e emba**
September 5, 2017

Spaghetti-code mathematics is, unfortunately, quite common at the highest levels. It can easily take a decade or two or three before important work gets understood, an intelligent organization is found, the proofs are actually verified, and so on. The recent Quanta article on McDuff's attempts to make sense of the foundations of symplectic geometry could have been rewritten by changing the names and theorems around.

No need to invoke *abc* paranoia.

15. **anon**
September 6, 2017

Regarding Yamashita's survey: I doubt it does very much to improve understanding of Mochizuki's work. Especially in the latter part of the survey proofs of theorems consist only of "follows from the definitions", while the theorem statements can be several pages long!

16. **Andrew**
September 7, 2017

Peter,

As far as you know, are there plans for the LHC to be upgraded in luminosity and/or energy before it shuts down completely? If so, is there already a timeline established for when these will arise and factors of increase for either luminosity and/or energy?

17. **Peter Woit**
September 7, 2017

Andrew,
There are plans to upgrade the luminosity of the LHC significantly (the "HL-LHC") and the energy slightly (from 6.5 to 7 TeV/beam), these plans go out to 2035 of so, see here:

http://lhc-commissioning.web.cern.ch/lhc-commissioning/schedule/LHC-schedule-update.pdf

I don't know of any further ideas about higher luminosity. There are post-HL-LHC plans ("HE-LHC") for a possible doubling of the energy of the beams. This would require developing new magnets and replacing much of the current LHC with them. Unclear how likely that is to happen. It would be expensive, but much less than other proposals which would require building a new, larger tunnel.

18. **asdfasdfff**
September 12, 2017

Why doesn't someone set up a wiki and have a group of mathematicians go through the Mochizuki/Yamashita presentation and confirm the theorems one by one. When they get to one they don't agree with or understand, just say "unverified". I understand this is a long proof, but where is the consensus on what's wrong exactly? I can't believe it's taking this long to get a clear answer.

19. **Peter Woit**
September 12, 2017

asdfasdfff,
Unfortunately the problem seems to be that Mochizuki's proof is written up in a form spread over many papers, very hard for anyone to go through and check step by step. One point of view on the current situation is that it is his responsibility to rewrite the proof in a form such that experts can do this. The Yamashita survey is supposed to provide a roadmap to the Mochizuki papers, outlining the logic of the proof. It is only recently available, presumably some people are trying to go through it as you suggest.

My impression from what I hear is that some of the experts who have tried to understand the proof have gotten stuck at more or less the same point. Perhaps the Yamashita survey clarifies that point, maybe not. A significant part of the problem here is a breakdown in the usual way such a situation normally gets resolved: communication between experts and the author of the proof, providing explanations satisfactory to the experts. Achieving this was a goal of a couple workshops, but these did not reach this goal, and I don't know what the current situation is for more attempts.

20. **David Roberts**
September 12, 2017

The Yamashita paper has done at least one very useful thing: it's collected the proof that one only needs to consider a very special case to prove the whole Szpiro conjecture (which implies abc). This proof (due to Mochizuki) was until now spread over several of his papers, and in Yamashita's write-up uses standard-looking arithmetic/anabelian geometry. Moreover, Yamashita provides a statement (beyond the inequality the Szpiro conjecture reduces to) that uses quite standard terminology that the IUTT papers are aiming to prove. It's small progress like this that will chip away at the monolith that is IUTT, which unfortunately is very smooth and hard.

Modern Geometry

September 4, 2017
Categories: Uncategorized

This semester I'm teaching the first semester of Modern Geometry, our year-long course on differential geometry aimed at our first-year Ph.D. students. A syllabus and some other information about the course is available [here].

In the spring semester Simon Brendle will be covering Riemannian geometry, so this gives me an excuse to spend a lot of time on aspects of differential geometry that don't use a metric. In particular, I'll cover in detail the general theory of connections and curvature, rather than starting with the Levi-Civita connection that shows up in Riemannian geometry. I'll be starting with connections on principal bundles, only later getting to connections on vector bundles. Most books do this in the other order, although [Kobayashi and Nomizu] does principal bundles first. In some sense a lot of what I'll be doing is just explicating Kobayashi and Nomizu, which is a great book, but not especially user-friendly.

A major goal of the course is to get to the point of writing down the main geometrically-motivated equations of fundamental physics and a few of their solutions as examples. This includes the Einstein eqs. of general relativity, although I'll mostly be leaving that topic to the second semester course.

Ideally I think every theoretical physicist should know enough about geometry to appreciate the geometrical basis of gauge theories and general relativity. In addition, any geometer should know about how geometry gets used in these two areas of physics. I've off and on thought about writing an outline of the subject aimed at these two audiences, and thought about writing something this semester. Thinking more about it though, at this point I'm pretty sick of expository writing (proofs of my QM book are supposed to arrive any moment…). In addition, I just took a look again at the 1980 review article by Eguchi, Gilkey and Hanson (see [here] or [here]) from which I first learned a lot of this material. It really is very good, and anything I'd write would spend a lot of time just reproducing that material.

Update: Steve Bryson sent me another excellent suggestion for a book covering these topics, aimed at the physical applications: David Bleecker's [Gauge Theory and Variational Principles].

Comments

1. **Jeff M**
   September 4, 2017

   Peter

   If you don't know it, take a look at Milnor's book on Morse Theory. In about 40 pages, he covers essentially everything anyone needs to know about Riemannian geometry. Milnor is a wonderful expositor. When I decided I wanted to do a thesis in geometric analysis, having never taken a differential geometry course (actually having never taken a geometry course of any kind, I went to a weird high school), that's where my advisor pointed me.

2. **CIP**
   September 4, 2017

   Have you looked at Thorne and Blandford's Modern Classical Physics, which is all physics but with a strong geometric orientation?

3. **Peter Woit**
   September 4, 2017

   Jeff M and CIP,

   The books you refer to emphasize classical Riemannian geometry, and I'm leaving that to Brendle. From that point of view about geometry, you really can't understand two of the most fundamental geometrical structures in modern physics:

   1. gauge fields, which are connections, but on some general principal bundle, which has nothing to do with the tangent bundle.

   2. spinor fields, which can't be constructed just using a vector bundle (the tangent bundle or its tensor bundles). To get spinors, one way is to use principal bundles: consider the principal bundle of orthonormal frames of the tangent bundle, then find a spin double cover, use the spin representation to get spinor fields (as an associated vector bundle).

   What's remarkable is that the general story about connections and curvature in Kobayashi/Nomizu was developed with completely different motivations (that of understanding the relation of geometry and symmetry groups), ended up miraculously being exactly the right formalism for fundamental physics. This is a story both physicists and mathematicians should know about.

4. **quasihumanist**
   September 4, 2017

   This is of course, not directed at you or your course, since I've never met you. However, in general, one problem many physicists have with talking to the general (pure) mathematical audience today is that they assume too much knowledge of differential equations.

   I am an extreme example, but all my knowledge of differential equations comes from teaching the standard first undergraduate course on linear ODEs, and I learned that by TAing the course, not by ever having taken it. If pressed, I might be able to recall the solution to the heat equation.

   Worse yet, as an algebraist, I usually think of a (partial) derivative as an abstract operator on elements of an algebra (over a field) that is linear, satisfies the Leibniz rule, and sends elements of the ground field to 0. Never mind limits or all that. (Actually, I'm a combinatorial algebraic geometer, which means I have colleagues tell me about statistical mechanics blah blah blah and other colleagues tell me about symplectic blah blah blah, none of which I really understand.)

   If you start talking about the Lagrangian or Hamiltonian formulation of classical mechanics, you've already lost me.

   So – this is a request for you to be nice to those mathematicians – but it's also a request for recommendations for me to pick up some of the physics point of view on differential geometry.

5. **murmur**
   September 4, 2017

Off-topic: Have you seen the autobiography of Polchinski: https://arxiv.org/abs/1708.09093?

6. **Peter Woit**
September 4, 2017

murmur,
See previous posting and comments there.

7. **Peter Woit**
September 4, 2017

quasihumanist,
The main problem with understanding gauge theory and GR, for both mathematicians and physicists, is that the differential geometry needed is rather sophisticated, and often not taught as part of the standard math curriculum, even at the graduate level. If you are comfortable with Riemannian geometry, GR is not hard. Purely as differential equations, the Einstein equations in coordinates are very complicated PDEs, but they have a fairly straightforward description in terms of the Riemann curvature tensor.

8. **CIP**
September 4, 2017

Are you thinking of writing up your notes as a sort of K&N for physicists?

9. **CIP**
September 4, 2017

Oops, sorry, I forgot that you already answered this.

10. **Thomas Larsson**
September 5, 2017

Ah. I have always liked the tensor calculus centipede being intoxicated by a plethora of indices. Although if you want the full expressiveness of tensor calculus in index-free notation, you would be intoxicated by a plethora of definitions instead.

11. **Brian Dolan**
September 5, 2017

As a physicist I too learned most of my differential geometry from Eguchi, Gilkey and Hanson's review. Kobayashi and Nomizu is a beautiful book which I now appreciate but I found it frustrating when I was learning the subject and it took me many years to understand why — it is deceptive because they prove some of the most beautiful theorems in 2 lines. The real work goes into many pages of definitions which are given almost without motivation. I guess this is a standard pure mathematics style, but I don't find it useful pedagogically. If Kobayashi and Nomizu is a work of art, Eguchi, Gilkey and Hanson is a box of paints!

12. **Jess Riedel**
September 5, 2017

"I just took a look again at the 1980 review article by Eguchi, Gilkey and Hanson…It really is very good, and anything I'd write would spend a lot of time just reproducing that material."

Think about how much easier this would be if the norm was for physicists to release all their work under a license that allowed re-use with attribution (e.g., Creative Commons ShareAlike). You could just immediately start building.

13. **Thomas**
September 5, 2017

To me, the main disconnect is that there is an extensive physics literature on instantons, monopoles, and other topological phenomena, in which many interesting phenomena are computed (instanton contribution to effective lagrangians and the OPE, axial charge diffusion in an EW plasma, defect formation in phase transitions, baryon number violation, etc), and then there is a mathematical (or mathematical physics) literature in which a beautiful formalism is laid out (bundles, forms, etc), but nothing is really computed (or if something is calculated it is done by choosing coordinates, and writing things out in components). The only case that I am really aware of where, historically, sophisticated tools played a role is the ADHM construction, although even in that case these days it is usually presented as a clever ansatz for the gauge potentials. What would be nice is a review where one can really see the power of sophisticated methods in doing calculations.

14. **Peter Woit**
September 5, 2017

Thomas,

I don't know of a review of the kind you want, maybe someone else can suggest something. In general though, I think the power of the abstract geometrical formalism is that it tells you what the general coordinate independent features of solutions will be. Sometimes, especially with enough symmetry, you can calculate these things without choosing particular coordinates. But, in any particular case, to actually calculate you may need to choose coordinates, better, coordinates adapted to the problem.

15. **Manfred Requardt**
September 6, 2017

Dear all, I remember the remark by Weinberg in his beautiful book about GR etc., i.e. that he thinks that the value of geometry in e.g. gauge theory is overtestimated. While I think he is not right, there is a grain of truth in his remark. Classical gauge theory as fibre bundle mathematics is certainly beautiful, however when quantizing the occurring fields transforms this into completely different entities. What one perhaps needs is some sort of quantum fibre bundles.

16. **TME**
September 6, 2017

Hey Peter,

After preparing for this course, have you had any thoughts about studying synthetic differential geometry?

17. **Justin**

September 6, 2017

Peter,

What are the pre-requisites for your course in real analysis, algebra, geometry, linear algebra? I've always wanted to study some differential geometry, but my background is limited to linear algebra at the level of Serge Lang, modern algebra at the level of Fraleigh, Calculus at Stewart's level, and some analysis that I vaguely remember.

18. **Peter Woit**
September 6, 2017

TME,
I don't really see the point of that, it seems to invoke a lot of abstract formalism, and get little for it. Definitely not appropriate for students.

I have been intrigued by the idea of formulating differentiable manifolds in a formalism more parallel to the definitions in terms of a sheaf of functions common in algebraic geometry and topology. Looking into this though, if you try and define the "sheaf of differentiable functions", you end up going through the same apparatus as the usual definition, to which you've just added a lot of extra formalism.

Justin,
You should start with an advanced undergraduate course in geometry, specifically one dealing with differentiable manifolds. A good typical textbook is Loring Tu's An Introduction to Manifolds. The course I'm teaching is supposed to be more advanced, assuming an undergraduate course as background.

19. **Eric Weinstein**
September 6, 2017

I'm really glad to see a shout out to EGH which functioned as a 'bible' for understanding the consequences of the Wu-Yang dictionary to which Simons and Singer also contributed. The Eguchi, Gilkey and Hanson 'article' is really an example of a phenomena we don't discuss much but which I think is fairly significant and highly conserved.

This famous article was really more of a book of a very special kind that appeared as a 'paper.' Sometimes, it becomes necessary for an entire technical field to take up a new toolkit; at those moments, it falls to someone or some group to write up the new tools as an enticement to colleagues to change their thinking. For some reason, in these situations, what gets written as a pitch or a sales job is often far clearer than what will later be written to introduce the toolkit to future students. Then, mysteriously, the old text is forgotten as new pedagogical texts attempt to reach students rather than professors. Yet, often, those more 'professional' texts aimed at students are often not as well or as deeply motivated.

As a related example, I believe I found a bound set of dusty notes from Dieudonné on Grothendieck's scheme theory written at some point early in the development of the theory that attempted to convert people used to thinking about Algebraic Varieties to think in terms of Scheme Theory. Strangely, this old book (or set of notes) seemed much clearer and better motivated than the treatment in the leading contemporary pedagogical text of the time by Robin Harthshorne. This aroused my curiosity around a simple question: do people write most clearly when pitching a new toolkit to their colleagues and in a less well motivated way once the professors have been converted?

I have since concluded that there is something magical about the early days of a new toolkit where people are thinking more clearly than they are likely to think later about the motivation for the 'kit'. As a consequence, it is often worth going back and looking for the text(s) which transitioned professors into a more modern viewpoint as they often have far more motivation and clarity than later introductory texts.

The best explanation that I can offer is this: only briefly is there a window to write for senior people (i.e. the most discerning of possible students) without fear of insulting their intelligence and while authors still remember what is counter-intuitive about the new kit. Even a short time later, people forget their beginners mind-set and thus what made the subject counter-intuitive enough to need a motivated pitch so that the new tools would be adopted.

I wish more beginning students would go back to look at those special moments where everything suddenly changed. There are very few of them in any career and each epiphany comes but once.

20. **Magnema**
September 7, 2017

@Eric Weinstein:

The difficulty I've found surround good older texts is converting their ideas to modern notation. As ideas get more solidified, notations (sometimes) improve, and make things clearer. For that reason, I think results are somewhat mixed, as with any pedagogical text. (What I've seen of the early discussion of tensor products falls into this trap somewhat. I'd imagine it'd be less large for more recently-developed fields, though.)

I also wonder if the original paper might benefit from being longer [neglecting problems and the like] for the same material (or, more precisely, the same length for less material). More time to talk about things will improve your writing for free, in some ways, although this is perhaps more true of those who would argue some variant of "read the original literature" than those who support some sort of summary paper.

That said, I do think an "updated [in notation] original" of works of that variety can sometimes be an outstanding pedagogical tool, depending, because I do agree you get better insight into the original motivation by looking at those papers.

21. **Peter Woit**
September 7, 2017

Eric,
That's an interesting comment on the EGH story. I've been kind of surprised to look around not readily find something better than that. I would have expected that over the years many people would write up versions of this material, but there aren't that many (suggestions welcome, does anyone know something that covers the material of EGH, but better?)

In this case I think part of what happened is that the 1984 advent of string theory turned attention to different areas of geometry/physics, so we ended up with people writing expository material not about gauge theory and its geometry, but about geometry of Riemann surfaces (for string world-sheets) and objects like Calabi-Yaus.

Magnema,

In this case it isn't really not-up-to-date notation that is the problem, one of the great virtues of EGH is that they use quite good modern notation.

22. **Cobi**
September 8, 2017

"In this case I think part of what happened is that the 1984 advent of string theory turned attention to different areas of geometry/physics, so we ended up with people writing expository material not about gauge theory and its geometry, but about geometry of Riemann surfaces (for string world-sheets) and objects like Calabi-Yaus."
I have the opposite impression that the mathematical structure of gauge theories is from the standard model perspective "nice to know", but became heavily utilized in the context of string theory.
To give some random examples, consider localization in non-Abelian gauged linear sigma models, the Kapustin Witten story or bundle constructions for heterotic models.
On a slightly different note i would love to understand what insights are to be gained from Urs Schreibers "higher pre-quantum geometry".
I was a bit surprised that "Modern Geometry" means classical differential geometry.

23. **Peter Woit**
September 8, 2017

Cobi,

Yes, the examples you give are random, wildly different sorts of mathematics, connections/non-connections to physics, and no connection to observed physics.

What do you think "Modern Geometry" is? Can you point to a graduate-level mathematics textbook covering whatever you think it is?

24. **Chris Grant**
September 8, 2017

"Have you looked at Thorne and Blandford's Modern Classical Physics, which is all physics but with a strong geometric orientation?"

My initial foray into this book suggests that it is very much written in physicist-speak rather than mathematician-speak.

25. **Bobito**
September 12, 2017

Look at Sternberg's recent textbook (title starts with the word "Curvature"). He makes some effort to relate differential geometry to physics.

26. **santarakshita**
September 13, 2017

Since you mention Loring Tu in one of your comments, I'd like to point out that Tu has a new textbook out on differential geometry. It seems to cover the kinds of things you want to touch upon (connections on principal bundles).

Modern Theories of Quantum Gravity

September 7, 2017
Categories: Uncategorized

Quanta magazine today has a [column by Robbert Dijkgraaf] that comes with the abstract:

> Reductionism breaks the world into elementary building blocks. Emergence finds the simple laws that arise out of complexity. These two complementary ways of viewing the universe come together in modern theories of quantum gravity.

It struck me that at this point I don't know what a "modern theory of quantum gravity" is. Much of the article is a clear explanation of the usual story of the renormalization group and effective field theory, but towards the end, when quantum gravity comes up, I have trouble following. String theory has gone from being an exciting new idea to being part of historical tradition:

> Traditional approaches to quantum gravity, such as perturbative string theory, try to find a fully consistent microscopic description of all particles and forces. Such a "final theory" necessarily includes a theory of gravitons, the elementary particles of the gravitational field.

That "reductionist" tradition is opposed to a new "emergent" holographic theory, and we're told that

> The present point of view thinks of space-time not as a starting point, but as an end point, as a natural structure that emerges out of the complexity of quantum information, much like the thermodynamics that rules our glass of water. Perhaps, in retrospect, it was not an accident that the two physical laws that Einstein liked best, thermodynamics and general relativity, have a common origin as emergent phenomena.
>
> In some ways, this surprising marriage of emergence and reductionism allows one to enjoy the best of both worlds. For physicists, beauty is found at both ends of the spectrum.

Dijkgraaf seems to be saying that a viable emergent theory of four-dimensional quantum gravity based on the complexity of quantum information has been found, but I seem to have missed this. Can someone point me to a paper describing it?

Comments

1. **NoviceAsAlways**
   September 7, 2017

   I read the Quanta article before getting to your blog post, so I really appreciate your point of 'please point out the paper that validates this claim'. As a novice, could you provide a more detailed description of where the authors leaps of logic run off the rails? Even a just basic 'this claim leads to this claim leads to this' basic rundown would be really helpful.

2. **Giulia**
   September 8, 2017

   Peter,

   he is obviously referring to Verlinde's entropic gravity. As all readers in this blog know, Verlinde repeated in a few lines what Jacobson did before him: whatever the microscopic degrees of freedom of the vacuum might be, they generate Einstein gravity if they behave like black hole horizons. Equivalently, one can say:

   If horizons have microscopic degrees of freedom, the vacuum must have as well.

   If one phrases it in this way, there is no big news in it. And one can rightly say that space is a thermodynamic entity. A deep theory of quantum gravity is not needed to make this statement; one just has to believe in black hole entropy.

3. **Mitchell Porter**
   September 8, 2017

   "a viable emergent theory of four-dimensional quantum gravity"

   I think it's called M-theory in four-dimensional anti-de-Sitter space. It emerges from a three-dimensional field theory called ABJM, and you can e.g. obtain the entropy of a black hole in the 4d theory, by an entanglement entropy calculation in the 3d theory. http://arxiv.org/abs/1705.01896

4. **Peter Woit**
   September 8, 2017

   I still don't know what Dijkgraaf is referring to:

   Mitchell Porter,
   I've never heard anyone claim ABJM as a viable physical theory of quantum gravity. In particular there's the problem that we don't live in AdS.

   Giulia,
   It's not obvious to me he's talking about Verlinde's entropic gravity. Last I heard, people at the IAS were skeptical there was any real idea there. Maybe things have changed though.

   NoviceAsAlways,
   The problem here is that I don't know exactly Dijkgraaf's "modern theory of quantum gravity" is, so I can't identify any possible leaps of logic. I'm left wondering whether it's a "postmodern theory" of quantum gravity.

5. **Chris Herzog**
   September 8, 2017

   I do not know for certain, but he may be referring to the first question that the It from Qubit Simons Foundation Collaboration Grant is trying to address: "Does spacetime emerge from entanglement?"

https://www.simonsfoundation.org/mathematics-physical-sciences/it-from-qubit/

It is probably premature claim success, but it's certainly an intriguing idea that many people take seriously — that quantum gravity could emerge from quantum information.

6. **Peter Woit**
September 8, 2017

Chris Herzog,
Your suggestion is the most plausible one so far. But if so, the "modern theories of quantum gravity" that Dijkgraaf is advertising are actually not what one would normally call a physical theory of quantum gravity, but more of a speculative general hope about some feature such a theory might someday have. It would be better if he made that clear if that's what he's writing about.

7. **Mitchell Porter**
September 8, 2017

Peter: in fact, a deformation of ABJM is holographically dual to the Nicolai-Warner critical point of N=8 supergravity, a solution of the theory whose properties did attract some phenomenological interest prior to superstrings. You yourself have expressed a liking for the idea of twisting the N=8 theory, so ABJM may be a lot closer to your own interests than you know.

However, I mention it here, not as a theory of everything, but as the main example in four dimensions, of what Dijkgraaf is talking about. The AdS5/CFT4 example (N=4 CFT) is even better understood (e.g. see David Berenstein's papers), but you asked for something with gravity in four dimensions.

These AdS theories are not immediately viable as phenomenology, because they are AdS and because they involve a special choice of fields, but they prove the viability of Dijkgraaf's concept – gravity emerging from quantum mechanics.

8. **Anon**

September 8, 2017

Art,
I hadn't really noticed the links to Quanta articles embedded in the Dijkgraaf piece. I'm suspicious that they weren't put there by Dijkgraaf himself. In particular, I wouldn't have thought that for the general idea of holography he would send people to Verlinde's work. But, who knows, I'm quite confused about what people promoting this kind of work specifically have in mind and intend to point to.

12. **Marko**
September 9, 2017

Maybe he is talking about tensor networks, which are being hyped quite a lot recently in the quantum information community (Preskill, Susskind, Carroll, etc, and a bunch of their students). But I think that tensor networks are still quite far far away from being called a theory, they are nowhere near developed enough.

Of course, none of that has ever kept anyone from hyping about the "modern theories of quantum gravity"…

🙂
Marko

13. **Low Math, Meekly Interacting**
September 9, 2017

An odd article for Quanta. Nearly 2/3 of it is devoted just to setting up the main thesis (almost half of it is a synopsis of "Powers of Ten"). So emergent gravity gets crammed into a relatively brief denouement that does little but namecheck the (seemingly) key concepts. Contrast this to, say, Frank Wilczek's anyon or entanglement articles. Like them or not, those have, at least, some actual content. Maybe Dr. Dijkgraaf had a deadline and was too busy with other things.

14. **Peter Woit**
September 9, 2017

LMMI,
The funny thing is it's not unusual in cases like this for journalists to write much more substantive pieces than scientists. I think the scientists decide it's too hard to actually explain what is going on, so stick to generalities, whereas the journalists (the good ones) at least make an attempt to convey what they've been able to understand of the story.

15. **tulpoeid**
September 10, 2017

(Partially repeating Art's remark,) it seemed to me that there's no mystery: The paragraph starting with "A complementary approach to combining gravity and quantum" links to everything the author talks about.

The alienating thing is of course that after listing the most fashionable theories of QG he pulls very hard to call them either reductionist or emergent, for not necessarily good reasons other than writing an article about these two concepts. But he doesn't seem to make mystery claims about new theories.

16. **Giulio**
September 15, 2017

I think it's clear Dijkgraaf is referring to Verlinde: the key sentence "quantum space-time, including all the particles and forces in it, emerges from a completely different "holographic" description" links to a Quanta story about Verlinde.

17. **Peter Woit**
September 15, 2017

Giulio,
All the links in the article are to other articles at Quanta. I suspect an editor at Quanta put them there, not Dijkgraaf.

18. **Moyses**
September 19, 2017

For a review, take a look at: https://academic.oup.com/ptep/article/2012/1/01A101/1556457/The-origin-of-space-time-as-seen-from-matrix-model

19. **Peter Woit**
September 19, 2017

Moyses,
I see no evidence that that proposal for how 4d spacetime emerges from the 10 d superstring is what Dijkgraaf is referring to

20. **Evan Thomas**
September 19, 2017

Peter,

Looks like I was mistaken, but you should go with my initial impression of your question, one of rhetorical sarcasm. Meaning, there is no viable "modern theory of quantum gravity" 😉

QCD at $\theta=\pi$

September 15, 2017
Categories: Uncategorized

Earlier this week Zohar Komargodski (who is now at the Simons Center) visited Columbia, and gave a wonderful talk on recent work he has been involved in that provides some new insight into a very old question about QCD. Simplifying the problem by ignoring fermions, QCD is a pure SU(3) Yang-Mills gauge theory, a simple to define QFT which has been highly resistant to decades of effort to better understand it.

One aspect of the theory is that it can be studied as a function of an angular parameter, the so-called θ-angle. Most information about the theory comes from simplifying by taking $\theta=0$, which seems to be the physically relevant value, one at which the theory is time reversal invariant. There is however another value for which the theory is time reversal invariant, $\theta=\pi$, and what happens there has always been rather mysterious.

The new ideas about this question that Komargodski talked about are in the paper [Theta, Time Reversal and Temperature] from earlier this year, joint work with Gaiotto, Kapustin and Seiberg. Much of the talk was taken up with going over the details of the toy model described in Appendix D of this paper. This is an extremely simple quantum mechanical model, that of a particle moving on a circle, where you add to the Lagrangian a term proportional to the velocity, which is where the angle θ appears. You can also think of this as a coupling to an electromagnetic field describing flux through the circle.

Even if you're put off by the difficulty of questions about quantum field theories such as QCD, I strongly recommend reading their Appendix. It's a simple and straightforward quantum mechanics story, with the new feature of a beautiful interpretation of the model in terms of a projective representation of the group O(2), or equivalently, a representation of Pin(2), a central extension of O(2). In the analogy to SU(N) Yang-Mills, it is the $\mathbf Z_N$ symmetry of the theory that gets realized projectively.

Komargodski himself commented at the beginning of the talk on the reasons that people are returning to look again at old, difficult problems about QCD. The new ideas he described are closely related to ones that are part of the recent hot topic of symmetry protected phases in condensed matter theory. It's great to see that this QFT research may not just have condensed matter applications, but seems to be leading to a renewal of interest in long-standing problems about QCD itself.

Besides the paper mentioned above, there are now quite a few others. One notable one is very recent work of Komargodski and collaborators, [Time-Reversal Breaking in QCD4, Walls and Dualities in 2+1 Dimensions].

Comments

1. **Arun Debray**
   September 16, 2017

   > a projective representation of the group O(2), or equivalently, a representation of Pin(2), a central extension of O(2)

   There are two nontrivial central extensions of O(2), called Pin^+(2) and Pin^-(2). The paper didn't seem to mention which Pin group is appearing here; do you know which one it is?

2. **Anon**
   September 16, 2017

   Thanks for posting on this. I tried looking through their paper. Will take more time to read it. But I was wondering if in the talk at Columbia whether the speaker mentioned how their works fits in with the strong CP phase or strong CP problem. Their paper doesn't explicitly mention the strong CP phase/problem.

3. **P**
   September 16, 2017

   Interesting post, thanks.

   Do you have any opinion on Arkani-Hamed's latest paper? Judging from the title it sounds pretty spectacular. Unfortunately I don't have the technical skill sett to judge the impact of the paper.

   https://arxiv.org/abs/1709.04891

4. **Peter Woit**
   September 16, 2017

   Arun Debray,

   No, I don't (since I don't know the difference between those two versions of Pin), but I'd think it's quite explicit and should be easy to figure out.

   Anon,

   No mention of the strong CP problem (other than the standard fact that it disappears for a massless fermion), no claim to have something new to say about that.

   P.

   Looks quite interesting, and I'll look at it more closely, especially since I'm quite interested in how much reps of the Poincare group tell you about QFT. Some of the claims in the abstract look much stronger than plausible, so very interesting. But, this really is off-topic, and I don't want to host a discussion of this paper here and now.

   Like the paper discussed here, another quite encouraging example of some of the best theorists around working on new ideas about 4d qft close to the Standard Model.

5. **BCnrd**
   September 17, 2017

   Peter, Arun Debray is referring to the fact that whereas the (linear algebraic) orthogonal group O(q) associated to a non-degenerate quadratic space (V,q) over a field k is insensitive (say as a subgroup of GL(V)) to replacing q with a scalar multiple cq for nonzero c, the isomorphism class of the (linear algebraic) group Pin(q) considered as a central extension of O(q) by \mu_2 is *very* sensitive to such change in q when c is a non-square in k. This sensitivity to such change in q at the level of the Pin group is a shadow of what occurs at the level of Clifford algebras: for non-square c, one doesn't see any direct link between the Clifford algebras C(V,q) and C(V,cq). For your situation, the context of interest is (V,q) positive-definite of dimension n>1 over k=R (even n=2) and c=-1.

Staying in the general setting for conceptual clarity, an obstruction to finding an isomorphism between Pin(q) and Pin(cq) as central extensions is encoded in the spinor norm O(q)(k) –> H^1(k,\mu_2) = k*/(k*)^2 that is most efficiently defined as the connecting map associated to the short exact sequence 1 –> \mu_2 –> Pin(q) –> O(q) –> 1 of (linear algebraic) groups, and is characterized most concretely by the condition that it carries the reflection r_v in any non-isotropic v (i.e., v for which q(v) is nonzero, such as any nonzero v when k=R with q definite) to q(v) mod (k*)^2. The point is that if Pin(q) and Pin(cq) are isomorphic as central extensions then the associated connecting maps (i.e., spinor norms) coincide, so then *necessarily* q(v) and c(q(v)) coincide mod (k*)^2 for any non-isotropic v. But that forces c to be a square in k! So when c is a non-square in k, we really get non-isomorphic central extensions.

Working over the real numbers, there is just one isomorphism class of positive-definite quadratic spaces of a given dimension n > 1, so one may refer to its associated Pin group as "Pin^+(n)" (considered as a central extension of O(n) by \mu_2), and refer to the one for the negative-definite variant as "Pin^{-}(n)" (also considered as a central extension of O(n) by \mu_2). Since c=-1 is not a square in R, these two central extensions of O(n) by \mu_2 are not isomorphic. (For expository simplicity I am sweeping under the rug the distinction between linear algebraic R-groups and compact Lie groups because it turns out not to be a problem in this case: see the theorem of Chevalley stated in my answer to https://mathoverflow.net/questions/6079/classification-of-compact-lie-groups/16269#16269 for a precise statement about that.)

6. **Petite Kabylie**
September 17, 2017

Will the Komargodski paper shed some light on confinement?

Thank you!

7. **Peter Woit**
September 17, 2017

BCnrd,
Thanks! I see, this is the same phenomenon that shows up in four dimensions as the fact that while Spin(3,1)=Spin(1,3), Pin(3,1) is different than Pin(1,3). This has led to some debate in the physics literature about physics being sensitive to what is usually thought of as a choice of sign convention.

Petite Kabylie,

The paper has some claims about implications for the phase diagram as a function of theta and the temperature, but not I think for what happens at theta=0, which seems to be the physically relevant value.

8. **BCnrd**
September 17, 2017

Peter, that's right. I should have also noted (for the purposes of the comparisob of spinor-norm calculations upon replacing q with cq) that the reflection r_v \in O(q) in a non-isotropic vector v is *insensitive* to replacing q with cq since by definition r_v(x) = x – (B_q(v,x)/q(v))v where B_q(v,w) = q(v+w)-q(v)-q(w) is the symmetric bilinear form associated to q. (Note this definition of B_q omits the factor of 1/2 that is sometimes used to define B_q, so B_q(v,v)=2q(v) and in particular the factor of 2 one usually sees in the definition of r_v is really lurking inside B_q).

Special Relativity and Classical Field Theory

September 22, 2017
Categories: Book Reviews

For quite a while Leonard Susskind has been giving some wonderful courses on physics under the name "The Theoretical Minimum", pitched at a level in between typical popularizations and standard advanced undergraduate courses. This is a great idea, since there is not much else of this kind, while lots of people inspired by a popular book could use something more serious to start learning what is really going on. The courses are available as Youtube lectures here.

Book versions of some of the courses have now appeared, first one (in collaboration with George Hrabovsky) about classical mechanics, then one (with Art Friedman) about quantum mechanics. I wrote a little bit about these here and here, thought they were very well done. When last in Paris I noticed that there's now a French version of these two books (with a blurb from me for the quantum mechanics one).

The third book in the series (also with Art Friedman) is about to appear. It's entitled Special Relativity and Classical Field Theory, and is in much the same successful style as the first two books. Robert Crease has a detailed and very positive review in Nature which does a good job of explaining what's in the book and which I'd mostly agree with.

The basic concept of the book is to cover special relativity and electromagnetism together, getting to the point of understanding the behavior of electric and magnetic fields under Lorentz transformations, and the Lorentz invariance properties of Maxwell's equation. Along the way, there's quite a lot of the usual sort of discussion of special relativity in terms of understanding what happens as you change reference frame, a lot of detailed working out of gymnastics with tensors, and some discussion in the Lagrangian language of the Klein-Gordon equation as a simpler case of a (classical) relativistic field theory than the Maxwell theory. Much of what is covered is clearly overkill if you just want to understand E and M, but undoubtedly is motivated by his desire to go on to general relativity in the next volume in this series.

At various points along the way, the book provides a much more detailed and leisurely explanation of crucial topics that a typical textbook would cover all too quickly. This should be very helpful for students (perhaps the majority?) who have trouble following what's going on in their textbooks or course due to not enough detail or motivation. Besides non-traditional students in a course of self-study, the book may be quite useful for conventional students as a supplement to their textbook.

One of the most annoying things someone can do while reviewing a book is to start going on about their own different take on the material, criticizing the author for not writing a very different book. So, the rest of this posting is no longer a review of the book, it's now about the very different topic of what I think about this material, nothing to do with Susskind's valuable and different approach.

This semester I'm teaching a graduate level course on geometry, and by chance the past week have been discussing exactly some of the same material about tensor fields that Susskind covers. The perspective is quite different, starting with trying to explain a coordinate-invariant point of view on what these things are, only then getting to the formalism Susskind discusses. I can't help thinking that, with all the effort Susskind (and pretty much every other physics textbook…) devotes to endless gymnastics with tensors in coordinates, they could instead be providing an understanding of the geometry behind this story. It's unfortunate that many if not most of those who study this material in physics don't ever get exposed to this point of view. Thinking in geometrical terms, the vector potential and field strength have relatively simple interpretations, and using differential forms the equations needed for the part of E and M Susskind covers are pretty much just:

$F=dA$, $dF=0$, and $d*F=*J$

Similarly, for the special relativity material, there's a danger of the basic simplicity of the story getting lost in calculations of how things appear in coordinates with respect to different reference frames. What you fundamentally need is mainly that objects are described by a (conserved in the absence of forces) energy-momentum p, which satisfies $p^2=-m^2$, with Lorentz transformations taking one such p to another. The wider principle is that things are described by solutions to wave equations, with special relativity saying that the Lorentz group takes solutions to solutions.

I'd like to believe that such a very different course and very different book would be possible, quite possibly am very wrong (I've never taught special relativity to anyone). Maybe some day someone, inspired by Susskind's project, might try to do something at a similar level, but from a more geometric point of view.

Comments

1. **Anon**
   September 22, 2017

   MIT open course ware, has a complete course on Quantum physics complete with lecture videos assignments and exams. Just started (probably won't finish). Its very good.

2. **ilovecats**
   September 22, 2017

   Do you think Penrose's book (e.g. Road to Reality) covers these topics from a more geometric angle? In any case, as a student who has been following your blog for the last 3 years, I'd love it if you sometime wrote just a couple of short articles on what you mean (books can come later :).

3. **Jim Holt**
   September 22, 2017

   Does Susskind derive EM as a gauge theory? It seems to me that conceptually this is the right way to go: getting EM from SR (instead of the other way around) by quantizing the SR equation E^2 – p^2 = m^2 to get an equation for a (complex) scalar field, and then applying the gauge principle (which can be motivated by SR) to get the EM vector potential. Fringe benefit of this top-down approach to EM: you are not shocked by the Aharanov-Bohm effect.

4. **Peter Woit**
   September 22, 2017

   ilovecats,

   Penrose's book is kind of the opposite of Susskind's. It's deeply geometrical, but at the same time really is not appropriate for beginners, many professional mathematicians and physicists find it challenging to follow.

   The main reason I haven't written up some of these things myself it that there are many other places that this has been done. For some suggestions, see

   https://mathoverflow.net/questions/72160/maxwells-equations-and-differential-forms

Jim Holt,

He does use gauge symmetry for the coupling of EM to matter, although for particles coupled to EM (gauge potential changes the action for a particle trajectory). In this book everything is classical, so he can't get coupling to EM via gauge symmetry of a wave-function. The Klein-Gordon equation is discussed, but treated as an example of a Lorentz invariant classical field (somewhat of a motivation for the classical EM Maxwell equations, not something used to describe matter).

5. **vmarko**
September 22, 2017

Usually, if you want a thorough geometric approach to SR, EM and beyond, the main reference is the MTW book. Though differential forms as such are never beginner material.

Btw, coupling EM to matter vis gauge symmetry is an entirely classical concept, i.e. classical field theory. Dirac equation is as classical as the Klein-Gordon equation, as long as you understand them as equations for fields, as opposed to relativistic QM. In fact, the whole Standard Model action is classical, together with the Higgs mechanism and all… Quantization only builds on top of that, leading to QFT.

🙂
Marko

6. **Tim May**
September 22, 2017

Peter,

I've been a daily reader of your blog for about 8-10 years, or whenever it started, since after reading your book. I've been generally skeptical of string theory for a very long time, maybe 30 years or more. (I joined Intel Corp. in 1974 as a device physics guy, working on DRAM memory chips in the early days. Took classes from Jim Hartle and Douglas Scalapino at UCSB, but am by no means a graduate-level physicist! Still, I follow it.)

Iroinically, two of my favorite physicists currently speaking are Leonard Susskind and Nima Arkani-Hamed. Though both are associated in some way with string theory, both are excellent speakers. (I could add that both are speaking a lot about things that are not directly associated with string theory. I don't think either has given up on string theory, just that their interests seem to be in other areas. While one can criticize string theory, it seems to have directly or tangentially led to some interesting other theories and some new math. A point I recall you have also made._)

I am glad that your criticisms of some aspects of string theory have not extended to criticisms of either of these two, or of Witten, Maldacena, or others. (I am not happy that a Czech blogger, whose lengthy explanations I often like, is so prone to personalizing his criticisms.)

Living only about 45 miles southeast of Stanford, outside of Santa Cruz, I have been to half a dozen or so of Susskind's talks, plus have seen him hosting a bunch of talks. Never made it to Arkani-Hamed's talks, but have greatly enjoyed his videos. Have seen the Cornell 5-part series about 2.5 times (the final two more than three times.)

Thanks!

–Tim May

7. **S**
September 23, 2017

I've had a bit of success* teaching SR to undergrads using Chapter 6 of Barrett O'Neill's wonderful book "Semi-Riemannian Geometry with Applications to Relativity." The earlier chapters do exactly what you're asking with tensors (and differential geometry), and chapter 6 is a really lovely geometric discussion of SR. (I also want to check out Gregory Naber's book, "The Geometry of Minkowski Spacetime." I know from other books that he's a wonderful writer, but I haven't had the chance to read this one yet.)

*"bit" = small sample size, not low success rate.

8. **Thomas Larsson**
September 23, 2017

Let me disagree about index-free notation being simpler than tensor calculus. Sure, you can eliminate a few indices, but OTOH you must add definitions (of d and *), and if you want to express more complicated things (upper and lower indices, symmetrized or anti-symmetrized, etc.) more definitions are needed. In the end you risk being swamped by definitions instead of indices, which does not seem like such a great advantage to me.

Moreover, finding the right definitions usually involves index manipulation. The reason why the exterior derivative is interesting is that it is a group homomorphism, which intertwines between modules of the group of coordinate transformations (i.e. if A is an antisymmetric tensor field, so is dA). If you are interested in manifolds with some extra structure, e.g. a volume, symplectic, or contact form, the relevant group preserves these structures (the algebras S_n, H_n, K_n in Sophus Lie's notation), and there are new homomorphisms, "exterior derivatives", which only need to intertwine with the relevant subalgebra of W_n.

You could perhaps look up these homomorphisms in the literature, but at least the classification of binary and higher homomorphisms is rather recent and not readily available in textbooks. Moreover, I once worked out the exterior derivatives in a case that was not yet published. Some fifteen years ago I was briefly interested in the exceptional Lie superalgebras E(3,6) and E(3,8), because there is a correspondance between these superalgebras and SU(3)xSU(2)xU(1). Kac and Rudakov had described the homomorphisms for E(3,6) but had not yet published the result for E(3,8) when I worked it out.

The point is that this was done using techniques from tensor calculus (and I proud myself of being good at index gymnastics). It could not have been done with index-free notation, because none was available for this superalgebra at the time, and probably still isn't.

9. **Peter Woit**
September 23, 2017

Thomas Larsson,
I'm not claiming that index-free notation is always the best way to calculate things. Often you need to pick a well-chosen set of coordinates and calculate using those. My point is that it is worthwhile to understand the geometrical, coordinate independent, significance of the objects one is calculating with. A good example is cases in GR where you find solutions with singularities, need to realize these are not physical singularities, but coordinate singularities.

10. **NoGo**
September 23, 2017

Have you seen “It’s About Time” by N. David Mermin?
It is (IMHO) very accessible and very geometrical introduction to Special Relativity for non-scientists. No tensors there… But it’s just SR, no electromagnetism etc.

11. **Doug McDonald**
September 23, 2017

    Its clear to me after 40 years of seeing things like this piece by Woit that the problem
    with all the “geometry” methods is that they are not taught as standard fare to
    undergraduates. I can’t understand a word of them (with the words meaning their
    specific mathematical meanings of course, not say “manifold” as its ordinary one.)
    I’ve not found a usable intro to that stuff.

    One needs at least a couple of years of digesting the math at a pliable age
    before “just using the math” for the physics.

12. **Robinson**
September 23, 2017

    I wrote Leonard Susskind some years ago to thank him for these lectures. I learned just enough to be able to vaguely follow what’s going on in modern physics at the moment. Allan Adams Open Courseware (MIT) on foundations of Quantum Mechanics is also really good.

13. **Anon**
September 23, 2017

    Perhaps of interest for index free definitions (Thorne & Blandford, Modern Classical Physics)

    http://press.princeton.edu/chapters/s10157.pdf

14. **Jeff M**
September 23, 2017

    Well, I learned special relativity out of Spacetime Physics, thereby no doubt dating myself. Perhaps even worse than one might think, since when I first read it Styx was a big band. Differential forms are wonderful, but I didn’t see them until I was a grad student in math. Learned GR the classical way, from Rindler. Lot’s of indices that I remember.

15. **Thomas Larsson**
September 23, 2017

    Peter Woit,
    I did not talk about choosing coordinates for a specific problem, but rather about expressing the same equations with or without indices. The geometrical meaning can be understood in both cases, but index-free notation requires that somebody has already worked out the right operators like d and *. In contrast, tensor calculus can be applied also in unchartered territory. The geometrical meaning of E(3|8)-invariant supergeometry might not be clear, but it was still possible to figure out the analogues of the exterior derivative using index notation.

16. **cthulhu**
September 24, 2017

    Feynman’s “Six Not-So-Easy Pieces” is mostly about Special Relativity and I liked it, but I’m looking forward to this new book too; I’ve enjoyed the other two.

    On the tensor index issue, I remember my professor for tensor calculus + calculus of variations (taught out of the engineering department for the engineering majors, not the math department) extolling the geometric interpretation for many problems – grads, divs, and curls instead of index gymnastics – at least until you have to calculate.

17. **Manfred Requardt**
September 24, 2017

    Concerning the index free notation. There exists a combination of both methods, called the abstract index notation (see e.g. the nice book of Wald). I think, at least for physicists the abstract index notation has certain advantages, in particular if you have to do some calculations.

18. **S**
September 24, 2017

    I had the opposite experience of some. I learned the index notation first, from a physicist, as an undergrad, and I had no idea what in heck he was talking about. (None of us did). It can be taught well, I’m sure, but it certainly wasn’t to us, it was only mystifying. Learning the geometric interpretation (from O’Neill, in my own case) brought clarity where there had been only mystification.

19. **Luca Ambrogioni**
September 25, 2017

    I think that the best example of a deeply geometrical textbook suitable for beginners is “Gauge Fields, Knots and Gravity” by John C. Baez. It starts by giving an insightful but somehow informal explanation of differential and Reimanian geometry and then uses it for introducing EM and GR from a purely geometrical (and topological) point of view. It is a really beautiful book.

20. **former mathematician**
September 25, 2017

    I can’t find a link, but there was a limerick circulating in the 50s, titled “LPE to DSC.” It began “A connection is simply outre when expressed in an intrinsic way.” The response, “DSC to LPE,” ended “The devil take you and Christoffel.”

21. **Jeff Moreland**
September 25, 2017

    Very Special Relativity by Sander Bais gives a good geometric introduction to SR for interested laymen.

22. **Bobito**

September 26, 2017

"I'm not claiming that index-free notation is always the best way to calculate things. Often you need to pick a well-chosen set of coordinates and calculate using those. My point is that it is worthwhile to understand the geometrical, coordinate independent, significance of the objects one is calculating with. A good example is cases in GR where you find solutions with singularities, need to realize these are not physical singularities, but coordinate singularities."

If one uses Penrose's abstract indices, indices are merely labels that indicate tensor type and symmetry (it works for spinors too), and their use requires no choice of coordinates/frames. This is all explained in detail in volume one of Penrose/Rindler. It is a mistake to confuse the use of indices with the use of coordinates. They are two different things.

23. **Mozibur Ullah**
September 26, 2017

I first learnt about general relativity from Gerochs semi-popular book General Relativity from A to B just before I left for university (to study mathematics); it's a wonderful book that uses just basic arithmetic to get to the essence of the subject.

When it came to index notation, although I could see how it worked, I couldn't see why it worked. It's only when I came across Lees book on smooth & topological manifolds that some light dawned. I also found Michors book on Natural Operations (which is freely available) an eye-opener on categorical methods to help organise the material.

Although index-free thinking is more geometric I think both skill sets are useful, otherwise physics written in index notation would not be accessible; I also think it shouldn't be forgotten that this route requires a serious investment of effort (the tangent bundle at a point p is the set of all derivations at that point!) and probably the optimum book explaining this material hasn't been written yet. It took me some time to learn, for example, that bundle and sheaf methods were, roughly speaking, dual to each other.

I don't think it's beyond the bounds of the possible to teach differential forms in high school if the right approach was taken – a practical approach; after all, in the UK, advanced students learn about the cross product in vector geometry, it's only later that I realised it was the Lie algebra of SO(3)! And of course calculus itself was once only for the cognoscenti whereas every schoolboy knows about it.

24. **Mozibur Ullah**
September 26, 2017

I'd also second Ambrogionis suggestion on Baezs 'Gauge fields, knots and gravity' as a beautifully written introductory book to differential forms in physics.

25. **Milkshake**
September 26, 2017

Are there videos of your lectures on modern Geometry?

26. **Peter Woit**
September 26, 2017

Milkshake,
Definitely not. Keep in mind that the lectures in that course are mostly the usual material and just about every math department has a similar course (with likely a more industrious and more talented lecturer…). The course webpage
http://www.math.columbia.edu/~woit/geometry2017/
shows what I'm covering and give reading suggestions. There are a lot of good textbooks on the subject at this level.

I do think a course at a bit lower level, more aimed at physicists, would be a good idea, and is not something that is so common, maybe some day I'll try and teach one. But that's not this course.

27. **Mark Weitzman**
September 27, 2017

Another interesting book on special relativity is Special Relativity in General Frames: From Particles to Astrophysics (Graduate Texts in Physics) – Eric Gourgoulhon, which doesn't just focus on inertial observers, and treats things like the Thomas precession, and Sagnac effect in an easy manner.

28. **Manfred Requardt**
September 27, 2017

As to so-called Abstract Index Notation. It is usually attributed to R.Penrose. But actually one can find it already in Laugwitz, Math.Zeitschr. 61, (1954) 100, and as far as I remember already Schouten introduced it.
But anyway, as it is not so deep an observation, it is perhaps not so important who introduced it ('invented' is perhaps to great a word) .

29. **Luca Ambrogioni**
September 27, 2017

To Manfred

I would say that the abstract index notation gets reinvented everytime someone who understands differential geometry opens a physics book. I think that most physicists writing indices have a geometrical object in mind.

You will never understand relativity if you think that R_{abcd} is "just a number".

30. **Manfred Requardt**
September 27, 2017

Dear Luca, you are absolutely wright. After all, an alternating differential form over the cotangential space is nothing but an antisymmetric tensor. On the other hand, not all geometric objects are antisymmetric, that is, are forms.

Various and Sundry

- I don't know if I ever mentioned this, but quite a while ago I replaced the "latexrender" TeX plugin being used here by a mathjax one. As I find time, I'm now going back and editing old posts to get rid of latexrender tags and make the equations more mathjax friendly. As far as comments are concerned, you can add TeX content by using standard math delimiters \$, or \$\$ for displayed math. If you want to comment about US dollars, put a backslash before your dollar signs to avoid the interpretation as TeX.

  One reason I hadn't advertised this much is that I know it's hard to get TeX right the first time, so people's comments with TeX would be likely to often not work properly. I've added a plugin that lets you edit your comment for 5 minutes after you write it. This should be useful for typos, as well as for fixing TeX problems (note that you need to refresh the page to get the math to display).

- For a philosopher's take on evaluating string theory, see this talk by James Ladyman, on Cosmic Dreams. Material on string theory is near the end, and just makes the obvious point that having no experimental evidence for the theory is a huge problem, no matter what efforts are made to change the usual way scientific theories are evaluated.
- A hot topic these days in the math community is the conjecture that local Langlands can be understood as geometric Langlands for the Fargues-Fontaine curve. My attempts to learn about this so far haven't had a lot of success, but I now have new-found hope. At Harvard there's a seminar going on this semester on the topic, and it has a website which so far features explanations of some of the mathematics involved from Jacob Lurie and Dennis Gaitsgory. In London, the London Number Theory Seminar also has a study group devoted to this topic (website here, although seems to have disappeared for the moment).
- LQP2 (Local Quantum Physics Crossroads, v.2.0) is a website that gathers various information about relativistic quantum theory.
- In November Perimeter will host what should be an interesting workshop on the question of how to make sense of the Path Integral for Gravity.
- A memorial for Maryam Mirzakhani will take place at Stanford on October 21, with a live feed available here.
- As always, Quanta magazine keeps publishing a wide range of very high quality articles about math and physics, covering different topics than everyone else. Most recently, on the math side, see an article by Erica Klarreich on Pariah Moonshine and on the physics side, Robert Henderson on possible searches for long-lived particles possibly from a "hidden sector"..

Update: Commenter sdf points out this historical article by Pierre Colmez about the Fargues-Fontaine curve, preprint of a preface to an Asterisque volume.

Comments

1. **sdf**
   September 27, 2017

   On Pierre Colmez website there is a fascinating semi-historical introduction to the FF curve. Apparently it will be the foreword to the Asterisque volume on the curve to appear.

2. **anon**
   September 27, 2017

   There's also a new preprint 1709.0743 from Scholze and in its references: Laurent Fargues and Peter Scholze, Geometrization of the local Langlands correspondence, in preparation

3. **G. S.**
   September 27, 2017

   Minor typo: "LPQ2" should be "LQP2"

4. **Peter Woit**
   September 27, 2017

   G.S.,
   Thanks, fixed.

5. **NoGo**
   September 27, 2017

   Today came an announcement that a Virgo detector together with two LIGO detectors recorded a black hole collision:
   https://www.nsf.gov/news/news_summ.jsp?cntn_id=243239
   "This discovery, announced today, is the first observation of gravitational waves by three different detectors…"

6. **Igor Khavkine**
   September 27, 2017

   So, rumors about a new GW event are confirmed! Any updates on the rumor that the a counterpart event was observed in the EM spectrum as well?

7. **aaaaaaaaa**
   September 27, 2017

   No, today's announcement seems to be about a different event.

8. **Peter Woit**
   September 27, 2017

   aaa…
   Are you sure? The NGC 4993 rumor was just a few days (Aug. 18) after this event (Aug. 14). Is NGC 4993 anywhere near the patch of sky singled out for this event?

9. **Jeff M**
   September 27, 2017

Peter

What I just heard is that there are rumors of another event, not two black holes, but a black hole and a neutron star, and that for that event there was EM confirmation. Supposedly observed a few days after this one. No comment as yet about it from either LIGO or VIRGO.

10. **AWS**
September 27, 2017

No EM counterpart for this event – from the NSF announcement:
"Being able to identify a smaller search region is important, because many compact object mergers — for example those involving neutron stars — are expected to produce broadband electromagnetic emissions in addition to gravitational waves," says Georgia Tech's Laura Cadonati, deputy spokesperson for the LIGO Scientific Collaboration. "This precision pointing information enabled 25 partner facilities to perform follow-up observations based on the LIGO-Virgo detection, but NO counterpart was identified — as expected for black holes."

11. **aaaaaaaaa**
September 28, 2017

NGC 4993 and the best localisation for GW170814 are about 100 degrees apart, unless I messed up spherical trigonometry… In any case, they're not close to each other on the sky.

12. **Igor Khavkine**
September 28, 2017

The characterization of LQP2 as a website that collects information about "relativistic quantum theory" may be overly broad. As any community website, it's content is dictated by the members of that community. But, at least historically, the focus of that community has been more narrowly the study of Algebraic Quantum Field Theory (AQFT), including also the study of QFT on Curved Spacetimes and sometimes even Non-Commutative Spacetimes using the methods/framework of AQFT. The name Local Quantum Physics actually reflects the title of the well known monograph by Rudolf Haag on this topic.

13. **David Derbes**
September 28, 2017

To follow up on Jeff M, I have a former student whom I dare not identify who might be on the LIGO team. He or she tells me, "You didn't hear it from me, but the best is yet to come." No more specific than that, but I think more and better are coming soon. Great timing! It's gotta be either the whole LIGO team or Thorne and Weiss for this year's Nobel. Nice article in the NYT by Dennis Overbye.

14. **Urs Schreiber**
September 28, 2017

Igor, on the other hand, as we have discussed, the local quantum observables of any perturbative relativistic QFT do organize into a causally local net, and so all traditional perturbative relativistic QFT is, and secretly has been all along, local QFT in the sense of the Haag-Kastler axioms. In fact the Haag-Kastler axioms (for perturbative formal power series algebras of observables) may be *derived* this way from standard relativistic QFT. (I have written out the proof in full detail here, since it is curiously non-evident from the literature as you know. Thanks again for the hints that you had provided!) Therefore it sort of makes sense and possibly is about time to conflate "local quantum physics" in the community-specific sense with traditional relativistic QFT.

15. **John**
September 28, 2017

Sabine Hossenfelder has a nice article in Forbes "https://www.forbes.com/sites/startswithabang/2017/09/28/is-the-inflationary-universe-a-scientific-theory-not-anymore/#216075e0b45e" about inflation and if it's science or not.

16. **David Roberts**
September 30, 2017

Vladimir Voevodsky has passed away…

17. **tulpoeid**
October 2, 2017

I might not be adding much to the discussion here, but Hossenfelder's article (John's link above) is so good that moves me to tears, especially the second half.

Vladimir Voevodsky 1966-2017

October 1, 2017
Categories: Obituaries

I was very sorry to hear yesterday of the announcement from the IAS of the untimely death of Vladimir Voevodsky, at the age of 51. Last year I had the chance to meet Voevodsky and talk with him for a while at the Heidelberg Leader's Forum (which I wrote about here). He was a gracious and modest person, and it was fascinating to learn a bit about what he was trying to do, and his earlier experiences doing mathematics that had led him down this path. There was no indication at that time that he was ill, and I don't know what led to his death.

Back in 2012 I wrote a blog post about him and his work, linking to various things that may be of interest if you'd like to know more about him. Among more recent sources of information, there's a video interview here, a popular article here, lecture slides here, here and here, and a piece by Siobhan Roberts which covers some of the same topics that Voevodsky told me about when I met him last year.

Update: See here for remembrances of Voevodsky on the HoTT mailing list.

Update: There will be a gathering at the IAS to remember Voevodsky this Sunday, a funeral service and conference in Moscow December 27-28, and a conference in Princeton September 29-30, 2018. More information available here.

Update: A longer obituary of Voevodsky, from the IAS.

Update: The New York Times has an obituary here. Video of the IAS gathering is available here. Especially informative and touching is the talk given there by his ex-wife Nadia Shalaby, who gave a detailed look at his life, mathematical and personal, including a frank discussion of his problems with mental illness, depression and sometimes self-destructive ways of dealing with this. Also see this story at Quanta, where Shalaby gives the cause of his death as an aneurysm.

Comments

   David Roberts,
   Thanks, fixed.

3. **Anonymous**
   October 2, 2017

   I enjoyed his wildlife photography that he linked in one interview.

4. **kris**
   October 2, 2017

   It is really sad to know that he has passed away. I had met him briefly at the IAS, at the time he was very interested in biology as well, and appeared to be planning to do some work in that direction as well. He came across as a genuinely curious and modest person, especially given his achievements. He was also a very good photographer, and some of the photos exhibited there from his collection were really very nice.

5. **Nick**
   October 7, 2017

   In 2014 I learned as a computer science student about Homotopy Type Theory, after my first year. At the time, I did not know about the basic things in this field, like lambda calculus and category theory.

   But I felt was a kind of enthousiasm, inspiritation to learn about this field and about mathematics in general.

   Very sorry to hear this. It's very sad to think what he could accomplish given more time.

2017 Nobel Prize in Physics

October 2, 2017
Categories: Uncategorized

At this point, Kip Thorne and Rainer Weiss of LIGO have (deservedly) won just about every scientific prize out there, for the first observation of gravitational waves. I don't know of anyone who doesn't believe they'll be getting the Physics Nobel tomorrow morning. With an open spot in the usual limitation to three (Ronald Drever passed away earlier this year), perhaps Barry Barish will also get the nod. Most appropriate would be to use the third slot to give an award to the entire LIGO collaboration, but it seems likely that the tradition of not honoring collaborations will continue. There will be a live webcast of the announcement at 5:45am EST available here.

Update: Congratulations to the winners. I think Natalie Wolchover speaks for all science journalists when she writes:

> Thrilled they won, thrilled not to spend this morning speed-reading about some bizarre condensed matter phenomenon.

Update: A couple things I've learned from comments and other coverage of this:

- Some physicists have no sense of humor and are either unaware of or ungrateful for the excellent job Natalie Wolchover and others at Quanta magazine have been doing in writing high-quality stories about a wider range of topics in physics than anyone else (see here and here, related here).
- All evidence is that on October 16th we'll get announcement of observation of gravitational waves with an optical counterpart, with details at this conference in Baton Rouge.

Comments

1. **J**
   October 2, 2017

   I vaguely remember that an individual could still be awarded a Nobel Prize even if he/she would pass away before announcement but after the nomination being received. So maybe Ronald Drever still got the chance. Well I may be wrong…

2. **sm**
   October 3, 2017

   I worry for a 'miscarriage of justice' if Pustovoit ('empty' Voit!) is not seriously considered. He (with Gertsenshtein) proposed, to my mind beautifully clearly, with realistic sensitivity and noise estimates the basic experimental setup (vacuumized optical paths …) and physics underpinning LIGO etc in 1962, long before anyone else in

   http://www.jetp.ac.ru/cgi-bin/dn/e_016_02_0433.pdf

   For a two page explanation how LIGO works (including an aside as to why Weber's setup could never have worked!) it takes a lot of beating.

   In the interests of historical accuracy, if nothing else, this work needs to be cited at the Nobel ceremony. Let's see!

3. **Thomas Larsson**
   October 3, 2017

   J, the winner must be alive at the time of the final decision, which happens very shortly before the announcement.

   An exception was the 2011 prize in medicine or physiology. The Nobel committee knew that Ralph Steinman was ill, checked that he was alive on Friday, the final vote and the announcement was on Monday, but Steinmann passed away on Saturday. It was then decided that he would nevertheless receive the prize posthumously, since the Nobel assembly had acted in good faith.

   I remember that I informed my wife, who is a member of the Nobel assembly, that they had awarded the prize to a dead person. She was not amused.

4. **Bernhard**
   October 3, 2017

   " but it seems likely that the tradition of not honoring collaborations will continue."

   It's typical of Swedish mentality to to give all the credit to whoever is higher up in the hierarchy and something that, as I see it, will never change. Congratulations to the winners in any case.

5. **Shantanu**
   October 3, 2017

   Peter, I think condensed matter physicists might get offended by Natalie Wolchover 's comment. I am surprised by how quick the NB was announced after the discovery (only 2 years). OTOH nu mass discovery took 17 years by that time the founder of Super-K had passed away. accelerating universe also took 13 years and discovery of CMB anisotropies took 14 years.
   So is that there are no more nobel prizes in particle physics left to be given?

6. **Mats Larsson**
   October 3, 2017

   To sm:

7. **Peter Morgan**
   October 3, 2017

Seconding Shantanu. See http://nanoscale.blogspot.com/2017/10/gravitational-radiation-for-win.html for a condensed matter physicist offering a polite clearing of the throat.

8. **Mats Larsson**
October 3, 2017

In the Nobel will it says: "…during the preceding year…"

According to the by-laws of the Nobel Foundation, §3:

"To be eligible to be considered for a prize, a written work shall have been issued in print or have been published in another form, to be decided on its own behalf by each prize-awarding body."

The discovery of the first LIGO event was published on February 11, 2016.
Thus, the discovery of GW could not be awarded in 2016.

9. **Robert Owczarek**
October 3, 2017

Replying to sn comment, in the 50s of the 20th century the theory of gravitational waves has been revived first by Hermann Bondi, then joined Pirani, Robinson, Trautman, Goldberg, Sachs and a few others. The reason for necessity of the revival was that Einstein himself almost killed the whole research by claiming that gravitational waves are probably removable by changing the reference system, and so unphysical, or, even if they are not removable, they do not transport any energy and so are undetectable, which basically means also that they are unphysical. New methods developed thanks to Petrov contribution of "objective" studies of general gravitational fields (and so finally independent of reference frames) and further expanded by the Bondi and followers allowed for finding many exact solutions of Einstein equations that describe different gravitational waves, and for studies of these waves and their sources, etc. Thus Bondi would be the first of this group who deserves the Nobel Prize, but he died in 2005. Recently died also Pirani and Robinson. Of the still alive members of this group Trautman's contribution was certainly the biggest, so he deserved to be awarded. More on that here
http://www.ams.org/publications/journals/notices/201707/rnoti-p686.pdf

10. **Peter Shor**
October 3, 2017

I think Natalie Wolchover was comparing how easy it is for journalists to explain LIGO, the 2017 Nobel Prize, as opposed to how easy it was for journalists to explain topological phases of matter, the 2016 Nobel Prize.

I'm not sure whether she was including the Higgs particle (2013 Nobel) or blue LEDs (2014 Nobel) in the comparison. I would hope not.

11. **Maurice**
October 3, 2017

I second with Shantanu's surprise that they awarded this prize so quickly. The
Nobel committee ran a risk by breaking a rule that has never been broken in previous years as far I know: the prize is only given to an experimental discovery that has at least one independent confirmation.
LIGO/VIRGO still reports serious backgrounds that they do not understand by their own account (also for the newest event GW170814).

In the likely case that LIGO/VIRGO's signals are no background, an independent confirmation is expected in the near future e.g. in the form of an astrophysical event detected with photons or neutrinos coincidentally with and from the same direction than a GW detection. The committee would have been well advised to wait until immediately after such a confirmation will be in.

Let's hope all goes well…

12. **Peter Woit**
October 3, 2017

I think Peter Shor has it right. Some of the recent Nobels have (for good reason) been given for condensed matter phenomena that have gotten little attention from journalists and are not easy to explain to the public (these two things are correlated…). Surely one should have some sympathy for science journalists expected to produce something sensible explaining the physics on a very short deadline (the Nobel doesn't do what a lot of other organizations do, give journalists embargoed information early). For gravitational waves, given the topic and the huge amount of previous public attention, writing something this morning should have been a piece of cake.

Bernard,

In the LIGO case, there is a small number of people who started the thing and had a big impact on getting it to work, so rewarding them individually is not hard to justify. On this topic, see
http://fictionalaether.blogspot.com/2017/10/woohoo-i-just-won-nobel-prize.html
and
http://backreaction.blogspot.com/2017/10/yet-another-year-in-which-you-havent.html

In cases where there are no such people in a collaboration, but the collaboration is responsible for a huge scientific discovery (e.g. the Higgs), the Nobel policy is highly problematic, likely meaning such discoveries will never get recognized by them.

13. **Peter Woit**
October 3, 2017

Shantanu,
I think Nobel's initial concept was to reward very recent work, with the prize in year X the most important development of year X-1. One problem with this is if the evidence is not overwhelming and you need separate confirmation (I don't think that's the case here, but don't want to start a debate about that). Some of the long delays can be attributed to waiting for the evidence to be overwhelming, sometimes the relative importance of the discovery is more dubious, so there's a wait until other more obviously important things have been rewarded.

I don't want to turn the discussion to HEP and its problems of lack of unexpected discoveries. If the LHC discovers anything unexpected that violates the Standard Model there should be a quick prize (except for the problem that the discovery may have been made by too many people…)

14. **Douglas Natelson**
October 3, 2017

To clarify, I fully recognize that Natalie Wolchover's remark was likely meant to be both humorous and a comment on how hard it can be to explain some CM topics. It is a rather weird situation where talking about dark lepton sectors or black hole firewalls or emergent quantum gravity is somehow viewed as more accessible than much of CMP, but that's where we are. This is a pet issue of mine, and clearly there is more work to do.

15. **simplicio**
October 3, 2017

Is there a generally known (or common guess) for why the prize has never been awarded for the discovery or study of Dark Matter? It seems to stick out as the only fundamental physics discovery developed in the latter half of the 20th century not to get a prize. And especially given fundamental physics discoveries have come at a rate of far less than 1/yr, its not like there just hasn't been any room to fit it in.

16. **Shantanu**
October 3, 2017

Peter (or others), do you remember how much interest the 1993 Nobel prize in Physics (which was also for GWs) generated among journalists/physicists/audience compared to 2017 one?
Would be curious to know
Thanks

17. **HEP theorist**
October 3, 2017

Douglas Natelson,

I think that condensed matter theorists have a culture of valuing very technical insights and computations, and being very upfront about it. There is nothing wrong with this. In fact it's pretty admirable. But it has an unfortunate side effect. Compare power-points written by leaders in condensed matter theory vs leaders in high energy theory. The former always have very busy slides, many plots with tiny fonts, many diagrams. The latter like masking computations and giving elegant sound bites. (Not saying there are no computations behind them!) It's no wonder that the latter is more easily picked up by science journalists. It's a credit to the Nobel team for not succumbing too easily to media pressure and for valuing condensed matter research.

18. **Peter Woit**
October 3, 2017

Shantanu,

My impression is that the actual physics Nobel awards get much the same amount of attention, independent of the topic. It's usually just a one day story, similar amount of media coverage. I don't remember 1993, different times, different kind of press. but I bet most of the press covered it. The result itself got much less attention, since it was indirect and much less spectacular.

19. **David Derbes**
October 3, 2017

This may be old news but it was brand new to me. In the Nobel press release for technical readers, there are a number of references, including a simply wonderful set of conference notes from the legendary GR conference at Chapel Hill in 1957, put together six years ago by the peerless and irreplaceable Cécile Morette DeWitt, UT Austin, and Dean Rickles, U of Sydney. The Nobel folks suggest that this conference was the seed that led to LIGO, particularly Feynman's terrific thought experiment with beads on a wire, arguing very forcefully that gravitational waves would carry energy and could in principle be measured. Most if not all of the founding fathers and mothers are there: Felix Pirani, Hermann Bondi, Andrej Trautman, André Lichnerowicz, Joe Weber, Wheeler, Feynman, Dicke, Bryce S. DeWitt and so on. A wonderful gathering, sometimes thought of as the Shelter Island of general relativity, wonderfully rendered: http://www.edition-open-sources.org/sources/5.

I think the Nobel people tried very hard to recognize the many pioneers of this great achievement.

20. **piscator**
October 3, 2017

simplicio:

I would think the reasons are

(A) The Nobel Prize committee is historically conservative, and it is not 100% nailed down that dark matter as such exists – there are alternative proposals such as MOND, even if most do not agree with it.

(B) The history of dark matter is that the evidence with the longest history (velocity dispersions/rotations curves, Zwicky, then Rubin&Ford + some others whose names I forget (in the review by Bertone)) is most vulnerable to the MOND objection, whereas the cosmological arguments for dark matter are later (and so would have less claim to a prize).

That said, in terms of something having a large observable effect of the universe, my view is that if the Nobel Committee felt that the evidence for dark energy was enough for a Nobel Prize, then they should have awarded one for 'dark matter' first (or something that at least behaves like it).

21. **Bernhard**
October 3, 2017

Peter,

Even in the case of the large LHC collaborations, you can go back and would find a rather small number of people who started it and were authors of the letter of intent of the experiments.

I'm not sure what it means to "start and experiment". So many things can and do go wrong while trying to collect the data that it takes several other intelligent people to get that first inspiration/idea into something real.

It's not that Thorne at al, didn't deserve the prize or that some random postdoc should had won, but the fact that the scientific work that mas done, was done by a collaboration and it is this collaboration that did the work that led to the discovery. Irrespective of the fact that Thorne et al, as individuals certainly deserve the prize, so does LIGO. And LIGO did not win any prize. Morally yeas, technically no.

I'm all for, let's stop this Nobel nonsense, and focus on the science. But as long as we are going to keep talking about it, which is likely to happen, than we should try to get it right. And the Nobel is not getting it right, for stupid conservative reasons.

22. **william e emba**
October 3, 2017

One thing I don't like is that they don't like to give awards for experimental discoveries of significant mysteries until the mystery is explained. Davis had to wait decades for the explanation of the missing solar neutrinos, and Bahcall was unfortunately left out, again.

They could have awarded Rubin for discovering dark matter, while phrasing it in a way that did not commit the committee to any particular interpretation. That they did not is a disgrace.

I suspect the reason for not awarding the prize for LIGO last year was simply that no one from LIGO was nominated. I once read somewhere that there was a January deadline, which was why Bednorz and Müller got the award, but not Chu.

I almost wonder if the joint Virgo observation was rushed into print just to sweeten the committee's laudatio.

If I remember correctly, Nobel's will specifies that most of the prizes are to individuals, at most three at a time, with Peace allowed to go to organizations.

23. **Daniel Mittleman**
October 3, 2017

I'm not at all surprised by the rapidity of the Nobel committee's response to this discovery. There seems to be little doubt that it's correct. There also seems to be little dispute that it's a Big Deal, of the sort that clearly deserves this level of recognition. And the people who most deserve the prize aren't young (indeed, one already died, as mentioned above). So why wait? I think this was a no-brainer, frankly, and hardly without historical precedent. Not that I'm biased…

On the other hand, I agree with Doug: it's somehow quite amusing, in a sad sort of way, that journalists think general relativity is easier to explain than, well, anything.

24. **DrDave**
October 3, 2017

There's always some second guessing in respect to the Nobel prizes, and there will always be people left out, but certainly these are good choices. The real winners here are scientists who have new avenues of research as well as those who will be inspired to create new and creative experiments to actually test things. Big victory for testability.

25. **MathPhys**
October 3, 2017

Well done, Kip Thorne.

PS I grew up reading Misner, Thorne and Wheeler.

26. **David Metzler**
October 3, 2017

In Weiss's remarks at the MIT press conference, he refers multiple times, obliquely, I might even say winkingly, to more news coming on October 16, with reference to neutron stars. Each time got a big laugh from the other LIGO members. So it looks like those rumors are true. Exciting!

27. **A**
October 4, 2017

simplicio, the Nobel prize for Dark Matter will be given when/if DM will be detected non-gravitationally. A posteriori Zwicky would have deserved a Nobel prize for DM. Just like Einstein would have deserved this Nobel prize. For the future, Nobel prizes for inflation and for inflationary perturbations would be more appropriate than prizes for topics that require speed-reading

28. **Robert Owczarek**
October 4, 2017

David Derbes
To make things straight: Unfortunately, Andrzej Trautman had not participated in the conference, which certainly was great even without his participation.
With all your respect, although arguments by Feynman were impressive, they were much weaker than what in the next few years did Bondi et al.
Also, I do not see how the pioneers of the research in gravitational waves were recognized by the Nobel committee if none of them got the award.

General discussion:
Of course awarding the discovery, which is really of great importance and will influence the fututre development of astrophysics and physics in general in profound way, as I believe it will, is a very good and expected decision.

29. **Shantanu**
October 4, 2017

David, I agree with Robert So far no theorist (other than Kip) has got a nobel on gravitational waves whereas 4 experimentalists have got it in (1993 and 2017). Once can argue Damour deserves one for his theoretical contribution to both endeavours.

30. **piscator**
October 4, 2017

The nonsense about awarding Nobel prizes to collaborations should be knocked on the head.

In addition to the many other bad reasons, even the stated positive aim – to recognise that science is a collaborative process – fails badly, by excluding people with very significant contributions to a discovery while making Nobel prize winners of extremely junior people who have done precious little other than become a member of a certain collaboration.

For the specific case of gravitational waves, a major element to the discovery is the ability to identify the waveforms, which comes from being able to follow numerical relativity all the way until the merged system settles down. But e.g. Pretorius, who transformed this field, is not a part of LIGO – and so would be excluded under this policy.

For the case of the Higgs, the LHC beam was manifestly key to the discovery – but CERN's accelerator division is not part of the experimental collaborations such as ATLAS or CMS. Furthermore, an essential part of this discovery again lies in unheralded work on theoretical predictions for QCD and electroweak backgrounds or the development of Monte Carlo generators – all done by those who are generally not part of the collaborations that get to announce discovery.

So, yes, science is collaborative but yes, some people contribute a lot more than others. The Nobel Prize has kept its reputation over a long period because those involved do a good job of ensuring that those who win have made major contributions.

31. **Peter Erwin**
October 4, 2017

simplicio:

To repeat and amplify a bit on what piscator, william e emba, and A said: I think there are two strikes against dark matter when it comes to Nobel Prizes.

1. It's originally a discovery in astronomy (i.e., the work by Vera Rubin, Albert Bosma, and others), and Nobel Prizes are very rarely awarded for work in astronomy. Consider the fact that there have been no Nobel Prizes for the discovery of extrasolar planets, or the fact that Hubble never got one for discovering the expansion of the universe. I suspect that for many years the argument would have been something like "Well, that's just something weird about galaxies, that not really *physics*, is it?"

2. The Noble committee seems not to like giving out prizes for *unsolved mysteries*. We still don't know what dark matter *is*: Is it (the most popular explanation) an undiscovered nonbaryonic particle? (What *kind* of particle?) Is it mass in some other form, like primordial black holes? Is it not mass at all, but an indication that our theory of gravity needs to be replaced? Etc. (Any one of those would probably be worth a Nobel, but the committee probably doesn't want to give out an award for the wrong reason.)

The missing solar neutrino problem is, I think, a good example. Evidence for this first appeared in the 1960s, and only accumulated in strength and replicability over time. But the actual prize wasn't awarded (in 2002) until after evidence for the solution in the form of nonzero neutrino mass and neutrino oscillations was obtained.

(The discovery of pulsars is also a good example, because even though they were initially a complete mystery, the correct solution — rotating, magnetized neutron stars — was worked out very rapidly.)

The Nobel for discovery of dark energy via supernova measurements is arguably the only modern counterexample (the 1937 award for discovery of cosmic rays is a much earlier one) — except that it *does* work perfectly well as confirmation of a longstanding theoretical prediction, in the form of the cosmological constant. (It also helped resolve some issues with the age of the universe, which was probably a bonus.)

32. **Bernhard**
October 4, 2017

piscator,

What you wrote is utter and complete nonsense.

The only thing preventing the Nobel committee from awarding collaborations is tradition. And it is only this tradition that prevents collaborations from getting a prize. A prize for a collaboration would not make some random person in the collaboration make the claim that they won the Nobel, only that they worked in a Nobel winning experiment, which tells nothing about them.

About "some people contributed more than others", please you are stating the obvious, and anyone working in a collaboration knows that. There is however a VERY long way between this statement and the conclusion that because of this plain statement we should just award spokespersons.

The Nobel committee has actually track-record of doing an awful job because of this tradition of rewarding bosses only, even when large collaborations are not the matter (Cesar Lattes comes to mind). And are you seriously suggesting Takaaki Kajita and not the Super-Kamiokande Collaboration that deserved the Nobel for neutrino oscillations? Oh please!

LIGO is an entity in itself and there is absolutely nothing absurd in giving the prize to it. To the very least, they could follow the lead from the Breakthrough Prize and mention the collaborators too, even if given more credit to the seniors:
https://breakthroughprize.org/Laureates/1/P4

33. **piscator**
October 4, 2017

Bernhard,

>>A prize for a collaboration would not make some random person in the >>collaboration make the claim that they won the Nobel,

funnily enough, if you look at CVs (enough available online) of LIGO members you will find them listing the Gruber Prize, Breakthrough Prize, etc under their 'Awards' sections.

Of course I am not saying that prizes should only go to spokespersons. Some spokespersons are just good managers. Prizes should go to people who have been transformative. van der Meer won the Nobel Prize for the discovery of the W/Z even though he wasn't in the collaborations, because stochastic cooling was a transformative contribution that was central to the discovery.

The drive to visualise, initiate and build up a large collaboration focused on a particular topic can be transformative and fully deserving of a Nobel Prize. This isn't just in academia – to say that Google has X thousand employees doesn't obscure the centrality of Brin and Page. As I don't know any of the history of Super-K I'm not going to comment on Kajita and whether this would be an accurate description.

For the Higgs, what you suggest would exclude people like Lyn Evans and various CERN D-Gs who ensured the LHC happened in the first place, while including graduate students who were in ATLAS/CMS for a couple of years and spent zero time on Higgs searches.

The Milner prizes are textbook examples of how to do prizes badly, and I am surprised you regard them as a model.

34. **Bernhard**
October 4, 2017

pisctor,

Yes, I know of people who list the Breakthrough prize in their CVs. Actually, I gave not so long ago feedback to a student that was applying for a job to remove it, because it looked really silly. The fact that young people will want to do that is another thing, and comes out of naivety because they fool nobody worth fooling. It still argues not against awarding a collaboration.

In case of the the Higgs, what I would argue is that the half of the prize could have been given to ATLAS, CMS and the LHC and the other half split between Higgs and Englert. This would have awarded theory and experiment in a fair way.

I agree, there is lots of things wrong with the Milner prizes, and I personally think they do more harm than good. BUT, awarding the experimental collaborations is about maybe the only thing that they got right and that they Nobel is incapable of seeing. It has in the end more to do with the seniority and Swedish mentality of the people who control the prize than anything tangible concerning a transformative contribution to an experiment.

35. **Bernhard**
October 4, 2017

By the way, I recommend reading:

https://www.theatlantic.com/science/archive/2017/10/the-absurdity-of-the-nobel-prizes-in-science/541863/

36. **Fred P**
October 4, 2017

@Bernhard- "The only thing preventing the Nobel committee from awarding collaborations is tradition."

Statue 4 of the Nobel foundation appears to preclude collaborations.

The Nobel foundation statue 4:
"§ 4.
A prize amount may be equally divided between two works, each of which is considered to merit a prize. If a work that is being rewarded has been produced by two or three persons, the prize shall be awarded to them jointly. In no case may a prize amount be divided between more than three persons…" source:
https://www.nobelprize.org/nobel_organizations/nobelfoundation/statutes.html#par7

As a note, it looks like this could be changed – see Statute 22.

37. **Bernhard**
October 4, 2017

Fred P,

this rule can be bent simply by considering the collaboration as a single entity, like is is done for the piece prize (e.g. awarding the UN). It's not a stretch of the imagination.

38. **william e emba**
October 4, 2017

I've looked some things up.

Nobel's will specifies one person per prize for up to "two works". The first Peace prize was to two people. There were multiple winners for several early Physics prizes, and there was an early institutional Peace prize. Literature, for some reason, has only given a joint award twice. The Nobel Foundation gives each prize-awarding group the authority to award organizations. I would guess that there were no organizations in non-Peace categories worth thinking about for decades, and the awards have achieved a certain reputation they don't want to tinker with.

Originally nominations were restricted to the living, and awards could be given to someone who died afterwards. This happened twice. The Foundation changed this in 1974. The Steinman family deliberately did not announce his death at first; I don't recall anything about the Academy inquiring if he was alive. (The only inquiry I have heard of was whether Nash could cope with the unusual attention he would be subject to.) It's believed that there was no 1948 Peace prize because Gandhi was assassinated January 30 that year. Had he been killed two days later, he would have been eligible.

39. **aaaaaaaaa**
October 4, 2017

Fred P,

The fourth statute also says:
"Each prize-awarding body shall be competent to decide whether the prize it is entitled to award may be conferred upon an institution or association."

It seems to me that this explicitly says that, for example, LIGO as a whole could be eligible for the prize.

40. **AcademicLurker**
October 4, 2017

This discussion might be past its sell-by date, but I guess I'll jump in anyway.

I'm skeptical of complaints, like the one in the linked Atlantic piece, the the Nobel prize "distorts how science is done". Very few people work on the things they do because they expect to get a Nobel prize for it. One of the cryo-EM winners announced this morning won for the years he spent figuring out how to get water to form a glass instead of crystals during the freezing process that's part of sample preparation. I doubt he was thinking "Stockholm, here I come!" during that work.

As Ed Yong notes, none of the issues with the Nobel would matter if the prize weren't such a big deal. I'm betting, and I could be wrong, the the "big deal"-ness of the Nobel would start to diminish if it were awarded to institutions instead of individuals. Which would be too bad. One guaranteed high profile week for science per year isn't all that much as it is.

Football and baseball are also collective enterprises, but MVP awards and the Heisman trophy don't seem to generate quite so many complaints.

41. **David Derbes**
October 4, 2017

@Robert Owczarek:

Thank you for the correction re: Trautman. I clearly didn't read the conference proceedings carefully enough. With respect to the Nobel Committee recognizing the pioneers, I did not mean to suggest that all who might have deserved a part of the prize had gotten it. The rule of three prevents that. I was trying to say that in their press releases, they seemed to me to have tried hard not to slight anyone. That's a good thing. With respect to Feynman's argument, I am not saying that it turned the tide; I don't know enough about the history of gravitational radiation research. But that's my impression of what the Nobel press release said.

@Shantanu:

It's true that experiment has been rewarded four times to theory's once, if you count Hulse-Taylor (appropriately). But on the whole the Nobel folks seem to me to favor experiment over theory in general, and I don't fault them for that, notwithstanding my own theoretical upbringing. I think Thorne was actually a little sorry that the entire LIGO team didn't get the prize. I remember in the weeks before Englert-Higgs, someone asked the Nobel Physics folks if they felt the ATLAS-CMS teams were disqualified. I believe the answer was no, that in principle a team with N >> 3 could win it (as has happened repeatedly with the Peace Prize: Doctors Without Borders, the Irish Mothers, and so on). It's a shame that ATLAS-CMS didn't also win for the Higgs discovery, and a shame that other theorists besides Thorne haven't also won for gravitational radiation, but there are always losers in these prizes. Specifically, Robert Brout and Ron Drever lost out because of death. That really stinks, in my opinion, though I am glad Barry Barish won (as predicted skillfully by Peter W.).

42. **Paul**
October 5, 2017

Weiss alluded to a new announcement on Oct. 16. See 8:40 in this video, and also around 16:40:

https://www.youtube.com/watch?v=eJMOzmwYT8A

43. **Shantanu**
October 5, 2017

Peter, since no one has mentioned this, I should point out that cancellation of SSC proved to be a blessing in disguise for LIGO as many people (starting from/inspired by Barry) shifted to LIGO
after their phd/postdocs in experimental HEP.
This is despite that the fact that LIGO project involves completely classical GR and astrophysics (a topic which I doubt many HEP experimentalists knew much about in grad school). Even the nuts and blots issues needed for working on LIGO such as control theory, digital signal processing, time-domain digital filtering is never taught in Physics grad school and is completely decoupled from HEP (which deals with discrete triggers or events).

44. **Laurence B Lurio**
October 5, 2017

On the subject of being able to explain last years Nobel prize on topological physics, there was an article in December 2016 Physics today by Sung Chang which put this obscure condensed matter theory into context and really did a good job of explaining why it deserved a Nobel. Of course, this still isn't an explanation at the popular science level which journalists might like, but perhaps more articles like this might have made Feynman change his mind about canceling his subscription.

45. **cedric bardot**
October 5, 2017

A nice way to celebrate the end of the Noble prize annoucement season and "Fête de la science 2017" … Go to Baton Rouge, Lousiana on October 16th?

Upcoming conference :
IAU symposium on Gravitational Wave Astrophysics: Early Results from GW Searches and Electromagnetic Counterpart, 16 – 19 oct. 2017 at Baton Rouge, Lousiana

Rainer Weiss said at a press conference at MIT on October the 3rd :
"…We opened a new field in astronomy and astrophysics… Einstein's waves are interesting and the fact that you can directly detect them is important but the real pay-off is gonna be in the future… it's already happened the pay off in some regards and more of will happen on october 16th I won't tell where it is but I can tell you there is more there… We've seen balck holes which is already wonderful but we also expect to see the merger o neutron stars and that was the thingthat that gave the field a certain credibility when it was discovered that there are pairs of neutron stars in our galaxy and people stopped laughing at us when that was found out … now the big question is how often does it happen that two neutron stars are smashing each other well … I won't say anymore all this is reserved and the thing is that from that people will learn if we have done it right we'll learn much more than just from gravity … you'll learn a lot about nuclear physics a lot of facts about equation of state of nuclear physics… how stiff is nuclear matter, you'll also learn probably how heavy elements are made, all of this is reserved for the future…"

46. **Michael John Sarnowski**
October 5, 2017

An honorable mention should go to Professor of physics, Jolien Creighton, from the University of Wisconsin, Milwaukee, who has been working on LIGO many years. Very smart man.

47. **Paul**
October 5, 2017

Quote from Robert Byer at a photonics conference not long ago. Interesting detail about the LIGO laser systems, but also:

'And Byer hinted that the coming month may see still more impressive results in the quest for gravitational waves and "multimessenger astronomy." Specifically, Byer offered a quick teaser of an upcoming news conference that the LIGO team will hold on 16 October to announce a new result. While Byer couldn't reveal the content, what he did say suggested that his particular presser will be a don't-miss event. "I'm willing to admit," Byer said, concluding his talk, "that what they will announce will be one of the most important events in the history of astrophysics."'

48. **Yatima**
October 7, 2017

"that what they will announce will be one of the most important events in the history of astrophysics."

Well, the last 20 years have been quite exciting already. I hope they won't be announcing that we are at the business end of an upcoming in-galaxy gamma-ray burster.

49. **Kyle MacDonald**
October 10, 2017

Was it just Wolchover's tweet that provoked that rant from Orzel? How could anyone within earshot of the popular science press not recognize that she's been writing about LIGO essentially every few weeks for the last several years and is glad to have a topic she can write about competently in a hurry?

50. **Peter Woit**
October 10, 2017

Kyle MacDonald,
I think it's exactly that the popular science press writes about LIGO every few weeks and not about other topics in physics that is what provoked the rant. Wolchover though is an example of someone who does regularly cover topics beyond the high profile things like LIGO.

51. **Kyle MacDonald**
October 10, 2017

Peter,

Ah, okay. That's an easier frustration to understand. I couldn't see how someone could possibly mistake 1) relief that the big annual write-it-in-three-hours physics story is this year already familiar to both science writers and their audiences for 2) general journalistic laziness. Agreed that it's a thoroughly unfair criticism to make of Wolchover specifically, but I also have sympathy with the general point that some topics get a lot of coverage simply because they've already had a lot of coverage.

52. **aaaaaaaaa**
October 12, 2017

Press conferences about the GW observation with EM counterpart seem to start 16:00 CEST/9:00 EDT in several places (at least at the National Press Club in Washington DC and ESO HQ in Garching) on Monday. The announcement says that some 70 observatories took part in the observations, so no wonder there were some leaks.

The Big Bang Theory and the Death of SUSY

October 5, 2017
Categories: Uncategorized

If you're a fan of The Big Bang Theory, perhaps you've seen the latest episode, *The Retraction Reaction*. If not, you might be interested in the following transcript (taken from here). The show has always done a good job of getting the science right, for an interview with their physics consultant David Saltzberg, see here.

The episode begins with a Science Friday interview of physicist Leonard Hofstadter by Ira Flatow:

> FLATOW: So, it has been five years since the discovery of the Higgs boson– what's the next big thing gonna be?
>
> LEONARD: Wow, that's hard to say. There's so much going on. We've been collecting tons of data that could revolutionize the way we understand the universe. For instance, there's a particle called a squark, which could prove supersymmetry.
>
> FLATOW: That is interesting. Have you found it?
>
> LEONARD: What, the squark?
>
> FLATOW: Yes.
>
> LEONARD: No, no. Wouldn't that be exciting? But we're also looking for the selectron, the gluino and the neutralino.
>
> FLATOW: Well, and have you found that?
>
> LEONARD: No. Another fun sidenote– I went to high school with a girl named Theresa Gluino, but it didn't cost $2 billion to find her. She was smoking behind the gym. (laughs)
>
> FLATOW: So, what have you found?
>
> LEONARD: Uh, nothing, actually. We've got the best equipment and the best minds all working on it. Although, some days I'm, like, ugh we've spent so much money. Why haven't we found anything? What are we doing?

After a segment in which neuroscientist Amy explains that she doesn't tell physicist boyfriend Sheldon about her new lab equipment since

> AMY: We've been getting so much more funding than physics, he's been a little sensitive.

another scene features Leonard called into the office of a university administrator:

> LEONARD: I have to say I'm a little nervous.
>
> Ms. DAVIS: You should be.
>
> LEONARD: Look, I know I screwed up, but it was only one interview.
> How much damage could it have caused?
>
> Ms. DAVIS: Would you like for me to read you the e-mails from donors asking why are they giving us money if physics is a dead end?
>
> LEONARD: I didn't say it was a dead end. I just said that I was worried it might be.
>
> Ms. DAVIS: So if I just said I was worried you might not have a job next week, how would you feel?
>
> LEONARD: Light-headed, and glad you asked me to sit down. Okay, just tell me what I can do.
>
> Ms. DAVIS: I'm gonna need you to make a statement saying that you misspoke, and that you're confident the physics community is close to a major breakthrough.
>
> LEONARD: You want me to lie.
>
> Ms. DAVIS: Look, Dr. Hofstadter, I'm counting on you. I think that you are the smartest physicist at this university.
>
> LEONARD: Really?
>
> Ms. DAVIS: See? Lies. They're not that hard.

Leonard then has this exchange with Penny:

> PENNY: Hey, come on, look, you said a few dumb things on the radio– what is the worst that could happen?
>
> LEONARD: I may get fired.
>
> PENNY: Okay, well, even if you did, you could find another job.
>
> LEONARD: Yeah, who wouldn't want to hire the physicist who publicly said physics is dead? Well, I wouldn't put that under "special skills". I can fix it, I just need to write a retraction I don't believe in– basically sell out to keep my job.
>
> PENNY: Great, I'll leave you to it.

He then goes to talk to string theorist Sheldon Cooper:

> LEONARD: Sheldon, it's me.
>
> SHELDON: What?
>
> LEONARD: Look, I know you're mad, but I have to write a statement that says the physics community is close to a breakthrough, and since you actually believe

> that, I could really use your help.
>
> SHELDON: Sorry, I can't.
>
> LEONARD: Come on, don't be like that.
>
> SHELDON: What? Look. (sighs) Not all science pans out. You know, we've been hoping supersymmetry was true for decades, and finally, we built the Large Hadron Collider, which is supposed to prove it by finding these new particles, and it-it hasn't. And maybe supersymmetry, our last big idea, is simply wrong.
>
> LEONARD: Well, that sounds awful. Now I get why everyone hates me.

Penny later comes in:

> PENNY: So you guys are upset because the collider thing disproved your theories?
>
> LEONARD: It's worse than that. It hasn't found anything in years, so we don't know if we're right, we don't know if we're wrong. We don't know where to go next…
>
> PENNY: Come on. You guys are physicists. Okay? You're always gonna be physicists. And sure, sometimes, the physics is hard, but isn't that what makes it boring?

The episode ends with a visit to the grave of Richard Feynman, and a reference to Feynman's story about how he got himself out of a slump in his work when he was at Cornell:

> WOLOWITZ: He did so much. And here we are, stuck and letting him down. You know, Feynman used to say he didn't do physics for the glory or the awards, but just for the fun of it. He was right. Physics is only dead when we stop being excited about it.

All in all, a pretty accurate portrayal of the situation in high energy physics theory, with a reasonable take on what to do about it.

Update: A correspondent points me to a rather Leonard Hofstadter-ish interview with Steven Weinberg back in 2011, where he says:

> It may be that they'll only discover the Higgs boson and nothing else, and we'll be left looking at our toes and wondering what we're going to do next. There may be nothing really new that can be reached with the LHC,
>
> I have fears… If all they discover is a Higgs boson with roughly the properties that the theory predicts and nothing else, I don't know where the field is going to go.

When asked a rather Ira Flatow-ish question: "Wouldn't you say to a young person that now would be a very exciting time to go into physics?" his answer is

> Whether or not it would be a good career move depends on what they are going to discover.
>
> If all they discover is the Higgs boson and it has the properties we expect, then No, I would say that the theorists are going to be very glum.

Comments

1. **Michael John Sarnowski**
   October 6, 2017

   Hilarious. Very funny story.

2. **Casey Leedom**
   October 6, 2017

   And for once, I truly wish Word less supported "like"s. Yeah, I know, it only works on the discredited social media circuit, but still …

   Casey

3. **A**
   October 6, 2017

   Altought Michelson-Morely were unhappy, but not finding what theorists expected has been a more revolutionary breakthrough than finding it

4. **Enrico**
   October 6, 2017

   A: I agree, not finding what theorists expected is a breakthrough. The next logical step is that theorists stop working on theories proven wrong. Does it make sense to work on aether after you know the results of the Michelson-Morely experiment?

5. **MikeS**
   October 6, 2017

   The Michelson-Morely experiment had the great advantage of demonstrating a clear negative result.
   The LHC seems to have brought us to the edge of a desert with no way of knowing what wonders may lie beyond the horizon, or if it's just desert all the way.

6. **Antimetrics Anonymous**
   October 6, 2017

   Peter
   Do you think metrics madness has caused this problem in physics ? . For example here is sample of the madness below.
   Einstein has h-index 108 66 in this google scholar index.
   from this web site https://scholar.google.com/citations?user=qc6CJjYAAAAJ
   Feynman has h-index 61 46 from the web site below.
   https://scholar.google.com/citations?user=B7vSqZsAAAAJ
   Do high energy physicists, want to prop up their indexes to get grants, promotion and in the process cut a sorry figure like Leonard H ?

7. **Peter Woit**
   October 6, 2017

   AA,
   There are lots of ways the incentives in academia are problematic and I don't want to start a general discussion of them here. I don't think the h-index thing is the biggest problem. The TV show gets right what the biggest problem for HEP is: lack of new experiment hints pointing a way forward coupled with refusal to acknowledge failure of dominant research programs (SUSY and string theory). I think it accurately portrays the current situation: people are aware of the problem, but don't want to admit failure publicly, fearing the implications of this for the field and for their careers.

8. **Jim Douglas**
   October 6, 2017

   "And sure, sometimes, the physics is hard, but isn't that what makes it boring?"
   That absurdly funny question so profoundy captures the attitude of the public towards mathematics, science and engineering. I've often felt this explains much of why superstrings / supersymmetry / Multiverse research still gets funding: the names, particularly "super" makes those subjects so sexy sounding in a field that is perceived as bone dry. Quantum Field Theory and especially Standard Model are so dull sounding. It was a careless catastrophy naming the world's most stunning theory the dreary "Standard Model". We need sexier names for genuinely scinetific theories. SuperDirac theory might do the trick for the SM. Germanely, "Big Bang" as a theory name is spot on, it's a fantastic name. Fred Hoyle is a hero. By wonderfully irony, he boosted the theory by giving it a fantastic name. The LHC is a ridiculously name. The Superconducting Super Collider was so much more fun! These things matter if you want funding and coverage in the media. Unless you're the SSC of course.

9. **Chris Kennedy**
   October 6, 2017

   Peter Woit (of Columbia University) has been trying to tell us the truth about SUSY for quite some time. Now Big Bang Theory (aired by Columbia Broadcasting System) has used humor to inject the same reality. Could there be a Columbia connection???

10. **zzz**
    October 6, 2017

    and Columbus day is next monday…

11. **Simon**
    October 6, 2017

    This is a common, but very particle physics-centric view of physics – it makes no difference to the vast majority of physics if SUSY is right or wrong (I'm an astrophysicist and finding (or not) the Higgs made zero difference to my research). Most of physics is advancing and discovering very nicely thank you very much… and ready and waiting to get its hands on all that juicy funding as particle physics hits a dead end…

12. **Anonymous**
    October 6, 2017

    Physics will never die, only physicists will. Historically we didn't have major breakthrough coming left and right. Instead, it is more like the case that it takes generations of physicists to explore extensive before one is shown up.

    A side note, while people are talking about unexpected hints from experimental sides, it might be worthy to note that almost all direct searches for BSM at LHC is based on and optimized on a particular model, which is very likely not correct by itself. Also it has this saying that no new physics can be discovered without a model at hadron collider, giving the enormous production rate of SM processes. It might not be a coincidence between this saying and this fact of experimental results.

    October 6, 2017

    It's a shame there no mathematicians in The Big Bang Theory. They get the gist and types of interaction between hep, engineers, cosmologists, biologists, etc. It would be interesting to see their take on mathematicians.

15. **Igor Khavkine**
    October 7, 2017

    I think that was a good episode. They found a way to reflect the truth and make it funny. From my point of view, there was also bitter-sweetness to it, because they missed a chance to make it even better. I will echo Simon's comment and point out that they could have done a better job of distinguishing between Physics and Beyond-Standard-Model-Fundamental-Particle-Physics. What I think would have killed multiple birds with one stone is if, at the end, the despondent protagonists ran into one of their colleagues who when prompted easily rattled off a whole string of current *non-speculative* research topics that are both *highly successful* and show *great potential* for future development. It's not like there's a lack of those, at least when looking beyond Beyond-Standard-Model-Fundamental-Particle-Physics.

16. **tulpoeid**
    October 7, 2017

    Gold.

    PS: @Simon, unfortunately academia seems to gather several types with the perspective of "the Higgs made zero difference to my research". I.e. researchers who don't care about monumental discoveries related to the deepest foundations of humankind's scientific worldview and I'm pompous on purpose, as long as their lab is unaffected. Even though you beg to differ, this is not much different than caring for a failed theory only because it allows one to publish.

17. **Anonyrat**
    October 8, 2017

    Glad you noticed this episode of Big Bang Theory. When I watched the broadcast, I immediately thought of Not Even Wrong.

18. **Frank Wilhoit**
    October 8, 2017

There is a deep confusion here, on the part of the as-portrayed academic authorities, between process and results. Results can invalidate theories — that's the process. Results cannot invalidate the process. Protecting the theories from the process invalidates the process. To an outsider it looks like the theories, or the results, are the exciting things. No: it is the process that makes the theories, or the results, exciting.

The bad reasoning runs somewhat thus: pure science eventually led to nuclear weapons; nuclear weapons won the last war; the Next Big Thing will either win the next war, or, if there doesn't just happen to be a war on right then, it may make a metric muckton of money. But if it isn't even going to do that, then screw it sideways.

Someone once disparaged my discipline, in a public forum, by sneering at the mythical phenomenon of things being "analyzed to death". I retorted that everything he possessed and used had been analyzed to life.

19. **Jerome Moore**
October 8, 2017

Simon,

I'm still waiting on the "juicy funding" to come to my field since the cancellation of the SSC. The size of the pie isn't fixed, and there are positive-valued coupling constants for funding between fields of research at the macroscale.

What research directions there are and should be for given fields are fantastic questions that people like Peter are asking. Undermining entire fields, however, is done at our collective peril.

20. **Bernhard**
October 8, 2017

Peter,

About SUSY, but not really to do with the BBT…. Have you had a look at what's written on Wikipedia lately on it's current status? Pretty interesting and advocates SUSY is alive an well, just waiting for a new e+e- collider (I'll copy/paste all since it might change):

"The LHC result seemed problematic for the minimal supersymmetric model, as the value of 125 GeV is relatively large for the model and can only be achieved with large radiative loop corrections from top squarks, which many theorists had considered to be "unnatural" (see naturalness and fine tuning).[43]

This "naturalness" crisis turned out to be premature[11] in that one set of naturalness calculations were performed in multi-parameter effective theories which didn't allow for intrinsic cancellations which must occur in a more fundamental theory.[citation needed] Other calculations, indicating the need for light top squarks, neglected terms in the renormalization group equations that could lead to radiatively-driven naturalness[12] (wherein radiative corrections drive certain SUSY breaking terms from unnatural high scale values to natural values at the weak scale). It is now understood that top squarks can range up to 3 TeV and gluinos up to 5 TeV with little cost to naturalness so that LHC searches have only begun to explore the natural SUSY parameter space. On the other hand, it is also understood that higgsinos, the superpartners of Higgs bosons, are required to lie between 100-300 GeV, the closer to 100 GeV the better. Such light higgsinos are difficult, though perhaps not impossible, to see at LHC. However, they would easily be seen at an e+e- collider operating at energies above higgsino pair production threshold (such as the International Linear Collider, or ILC, proposed for construction in Japan)."

21. **Peter Woit**
October 8, 2017

Thanks Bernhard,
That's pathetic. Interesting to note that Wikipedia knows the Higgsino mass (they say the pair production threshold is at 500-600 GeV.

22. **N. Bhonka**
October 9, 2017

I think the physics community must realize that it is no longer the era before 1950's. The 'physics' of that era has been taken over mostly by computer science and some fields in engineering. The best students after high school like go to in these fields. And, partly because these fields are more lucrative also. Without sounding rude, in general, it is the bottom rung of the 'scientific pool' that makes its place in physics and mathematics these days. No wonder one sees the same toeing the line, little new ideas in physics.

Besides the possible exception of Peter Woit, and a handful others, you can talk to any physicist and the uniformity (read lack of new thought) of opinions expressed is astounding and quite unnerving. It seems like few, new and fresh ideas.

23. **Alain Blondel**
October 9, 2017

Even "particle physics" is much larger than SUSY and the LHC. BSM physics has actually been found and was rewarded the Nobel prize in 2015: neutrinos have mass.

The reason this is interesting is that some big observation-based questions to particle physics are as follows:
— the fact that the Universe is made of matter and not of anti-matter
— the existence of dark matter which cannot be one of the established Standard Model particles
— the fact that neutrinos have mass that is so much smaller that the other fermion particles.

All three can possibly be solved simultaneously by giving each neutrino family (e, mu, tau) two distinct mass terms,
— a 'Dirac mass term' just like the other particles, which connects a left spinning particle to a right spinning one.
— a 'Majorana mass term' which connects a left spinning neutrinos to the right spinning anti-neutrino. Such a term transforming particle into antiparticle cannot exist for charged particles because of the charge conservation; it can be present for neutrinos which have no charge.

The result of this is the existence of three heavy right handed neutrinos which happen to be nearly sterile…(they would interact million or more times less than the usual neutrinos) ah! they could be dark matter and generate the matter asymmetry (or not). Now there is something very neat in this: we need right handed neutrinos to complete the picture from the very moment that neutrinos have a mass. (there are more complicated scenarios to play their role but minimal is always more attractive)

So far this type of research has been dubbed 'exotic' in the LHC collaborations, I think because it was not in the initial research plan, but maybe also because that discovery of massive neutrinos is beyond the usual Supersymmetric BSM, and also because the so-far standard "next step in particle physics", the linear collider, can do little about it.

However this 'neutrinos are just missing energy ' attitude is in the process of changing at the LHC and in planning future experiments and colliders; the search for right-handed neutrinos is becoming a subject of focus.

Of course this is so far only a possible ‘natural’ solution of the neutrino questions, but any statement that no physics beyond the standard model has been found is just a sign of ignorance.

NB: Super-symmetry can also answer these questions, at the cost of being very considerably non-economical — and getting us in trouble in a nearly infinite number of ways, too.

24. **Cormac O Rafferty**
October 10, 2017

“The show has always done a good job of getting the science right”. Does it?
I spotted two very basic errors
(i) “there’s a particle called a squark, which could prove supersymmetry”
There is a world of difference between “give support for ” and “prove”. This is very basic stuff I would expect the program advisors and PW to know.
(ii) the general theme of the piece is that because certain particles have not turned up, SUSY must be dead. A great many science journalists , and PW, have been flogging making this statement for years now. It should be obvious that it is an overstatement. All we can say is that certain models have been ruled out.
That’s 2 basic misunderstandings of how science is done, in one passage…

25. **srp**
October 10, 2017

The only problem with the BBT episode is that they previously established (and told countless jokes based on the fact that) Leonard is not a HEP theorist but some sort of tabletop experimentalist (I think condensed matter or atomic physics) who uses lasers in his work. So Leonard should have been as cheerful as many of the non-HEP commenters above.

26. **Peter Woit**
October 10, 2017

Alain Blondel,
I’ve been guilty sometimes of the shorthand of referring to the current situation as “nothing beyond the Standard Model”, partly because the neutrino mass situation is complicated and can be accommodated by relatively straightforward extension of the SM. So given only a few words to work with, “we have seen BSM physics” seems about as misleading to non-experts as “we have not seen BSM physics”. I agree though that this issue of understanding right-handed neutrino fields and the neutrino sector in general is the most promising area where something is going on that we don’t understand well. I’m very interested to hear of the possibility of looking for something new in this sector at colliders. What specifically did you have in mind, and can you give any references?

27. **Anon**
October 11, 2017

Hi Peter,

There is no “straightforward” or an accepted minimal (or a standard) way of accommodating the neutrino mass in the Standard Model Lagrangian — it can be written as a
i) Dirac neutrino by adding right handed neutrinos, or
ii) Majorana neutrino with Type 1 seesaw term by adding right handed neutrinos or
iii) Majorana neutrino with Type 2 seesaw term by not adding a right handed neutrinos but instead adding a Higgs triplet field that couple to the existing left-handed neutrinos.

Therefore the standard practice seems to be not to do any of the above — thereby not putting the neutrino term in SM Lagrangian – but instead to state the PMNS matrix and neutrino mass squared differences as an addendum.

Which leaves the SM in the same or even in a worse boat than say the minimal left-right symmetric model, where there is a standard accepted Lagrangian that includes (in fact it predicts) the right handed neutrino. So in the standard LR model you would write down the Lagrangian, and not put the PMNS matrix in the addendum.

The issue with colliders for something new in neutrino physics is that the canonical seesaw scale (M_R or mass of right handed neutrino) is 10^14 GeV. That is the scale we get with order 1 Yukawa couplings (h ~ 1) from observed small neutrino masses (m_nu) and weak scale (v). M_R = h^2 v^2/m_nu

This scale is short of the GUT scale and Planck scale, and appears to be the seesaw scale for new physics. One may have to look for non-collider experiments for more info on the neutrinos.

Of course if h is smaller than 10^-5 for all the 3 generations of neutrinos, then the neutrino physics maybe at the colliders. But that maybe wishful thinking.

28. **Anon**
October 11, 2017

We should also remember that the Standard Model had actually predicted that the left-handed neutrino would be massless. This was a prediction it made for the mass of a known particle. And this is unlike the discovery of additional generations that were unknown particles.

29. **Peter Woit**
October 11, 2017

Anon,

Thanks for the comment. To clarify what I had in mind, I think of just adding right-handed neutrinos and Dirac mass terms as a “straightforward” extension of the Standard Model, one that it is a bit misleading to describe as “BSM”. The possibility of Majorana mass terms makes the whole subject much more interesting, and such mass terms and a seesaw mechanism would deserve to be called a “BSM” phenomenon. But, as far as I know, we currently have no evidence for this latter possibility.

30. **Anon**
October 11, 2017

Hi Peter,

I dont think adding right-handed neutrinos and only Dirac mass terms is “straightforward” 🙂 — in fact it may be taking you on the path nature did not pick.

This is because once you add the right-handed neutrino the most general SM Lagrangian will have Majorana masses for the right-handed neutrino. So you are setting the Majorana masses to zero by imposing a B-L symmetry which is ad hoc. In the original SM without right handed neutrinos B-L symmetry has an anamoly.

Another issue is that if neutrino is a Dirac particle then it can have an electric charge that is fractional and very small — its electric charge becomes a parameter that we have to determine by experiments and is not necessarily zero. In the std model the electric charge is quantized only if the neutrino also has a Majorana mass term. Only if the electric charge is quantized, do we know from theory that the electric charge of neutrino is zero.

Of course the experimental bound on neutrino's electric charge is very very small. But the electric charge of the neutrino is an additional parameter of the std model with Dirac neutrinos.

31. **John**
October 12, 2017

In the show it was mentioned how Leonard had to redeem himself about saying SUSY might not be found. Well Forbes did something just like that with an article by Ethan Siegel titled: "The Multiverse is Inevitable, And We're Living In It". He goes on to write: "the Multiverse is a theoretical prediction that comes out of the laws of physics as they're best understood today. It's perhaps even an inevitable consequence of those laws: if you have an inflationary Universe governed by quantum physics, this is something you're pretty much destined to wind up with."

32. **Peter Woit**
October 12, 2017

John,
At least Siegel doesn't repeat the usual dangerous pseudoscience about the multiverse showing that physical constants are environmental. In his explanation our "best theory" predicts lots more universes with the same physics as our own, something we can't ever check so is metaphysics rather than science. That's accurate enough, although calling a single field inflaton model with no understanding of the potential or of how it couples to matter a "best theory" is pretty misleading, in that it's more of a toy model than a theory.

All: a correspondent pointed me to an interview with Weinberg very much like the one on the TV show, I added some material to the posting about that.

33. **Curious Wavefunction**
October 12, 2017

The episode was funny and real, but I was disappointed that it played into the belief that particle physics is the only physics worth doing and that if it's at a dead end, physics as a whole must be at a dead end. I think this is exactly the criticism that people like Chad Orzel have had. There's plenty of excitement in other areas of physics like condensed matter and biophysics which somehow is never discussed in these discussions pertaining to the "death of physics".

34. **Mark Roulo**
October 15, 2017

This post reminds me of a (possibly fictional) exchange that Charlie Munger (Warren Buffet's long time business partner) reported between Charlie's old business partner, Ed Hoskins, and a fishing guide up in Minnesota:

> "Are any muskies caught in this lake?" asked Hoskins
> "More muskies are caught in this lake than in any other lake in Minesota. This lake is famous for muskies."
> "How long have you been fishing here?"
> "Nineteen years."
> "How many muskies have you caught?"
> "None"

Various Topics in Interpretation of Quantum Mechanics

October 11, 2017
Categories: Quantum Mechanics

A couple of recent discussions about quantum mechanics that may be of interest:

- There's a recent paper out by Don Weingarten that looks looks like it might have a different take on the fundamental "many-worlds" problem of, as he writes:

  > how in principle the definite positions of the macroscopic world emerge from the microscopic matter of which it is composed, which has only wave functions but not definite positions.

  My naive feeling about this has always been that the answer should lie in a full understanding of the initial state of the measurement apparatus (+ environment), that it is our imperfect probabilistic understanding of the initial state that limits us to a probabilistic understanding of the final state. I found Weingarten's investigation of this intriguing, although I'm not sure that the language of "hidden variables" is a good one here, given the use of that language in other kinds of proposals. By the way, Weingarten is an ex-lattice gauge theorist who I had the pleasure of first meeting long ago during his lattice gauge theory days. He at some point left physics to go work for a hedge fund, I believe he's still in that business now.

  Luckily for all of us, Jess Riedel has looked at the paper and written up some detailed Comments on Weingarten's Preferred Branch, which I suggest that anyone interested in this topic look at. Discussion would best be at his blog, a much better informed source than this one.

- Gerard 't Hooft has a remarkable recent preprint about quantum mechanics, with the provocative title of Free Will in the Theory of Everything. I fear that the sort of argument he's engaging in, trying to ground physics in very human intuitions about how the world should work, is not my cup of tea at all. Instead, what has always fascinated me about quantum mechanics has always been its grounding in very deep mathematical ideas, and the surprising way in which it challenges our conventional intuitions by telling us about an unexpected new way to think about physics at a fundamental level.

  For more discussion of the paper, there are Facebook posts by Tim Maudlin here and here in which he argues with 't Hooft. I confess that I wasn't so sure whether to take the time to read these, and after a short attempt gave up, unable to figure out precisely what the argument was about (and put off by Maudlin's style of argument. Do philosophers really normally behave like that?). Links provided here in case you have more interest in this than I do, or better luck getting something out of it.

Comments

1. **vmarko**
   October 11, 2017

   I won't judge Maudlin's style of discussing, nor do I know if other philosophers have similar style or not. But as far as the content of the discussion goes (at least the parts in the above links), I believe the following is the crux of the matter.

   Prof. 't Hooft seems to be fighting against a theorem (Bell's theorem). Tim Maudlin has studied the theorem top-to-bottom, upside-down and inside-out, and serves as a voice for the theorem to push back.

   In short, Prof. 't Hooft's argument is that one can have a violation of Bell's inequality in a local deterministic theory if one additionally imposes the law of "conservation of ontology" (I don't want to go into a technical specification what this means). Maudlin's counterargument is that, if one does impose that conservation law, then that law must be non-local (as per Bell's theorem), rendering the full theory nonlocal.

   And then there are a gazillion of off-topic sideway arguments going back and forth, which are ultimately irrelevant for the above argument. But the bottomline seems to be the above.

   IMO, I fear that Prof. 't Hooft is on the loosing side here — while fighting against a theorem can be very instructive, insightful and educational, eventually it has to fail.

   The short abstract of the whole discussion can be found in the second Maudlin's facebook post, near the end, in the allegorical dialogue between Vladimir and Estragon.

   HTH, 🙂
   Marko

2. **Tom Andersen**
   October 11, 2017

   It seems that until quantum mechanics has an experimental problem, the arguments about how to solve the measurement problem are going to be difficult to pick from. That's why experimental results like Vinante2016 https://arxiv.org/abs/1611.09776 are the most interesting (to me).

3. **a**
   October 12, 2017

   I read most of the exchange but was hampered by my ignorance of the meaning of "ontological state". Google didn't help me. Can anyone provide a definition?

4. **vmarko**
   October 12, 2017

   a,

   The notion and some properties of ontological states are on page 15 of Prof. 't Hooft's arXiv paper.

   HTH, 🙂
   Marko

5. **Dave Miller**
   October 12, 2017

   Peter,

I read all the way through both of the (long!) posts. And, I have read enough stuff by a lot of philosophers that I can answer your question: “Do philosophers really normally behave like that?”

No. Maudlin is much more comprehensible and much more knowledgeable about science than most philosophers I have read. I suppose the obvious example for incomprehensibility is Hegel (whom I thankfully have not read!), but Maudlin is more comprehensible even than most twentieth-century “analytic” philosophers. As for his knowledge of science, compare Maudlin to Popper’s writings on QM or J. L. Mackie’s various papers on science: both Popper and Mackie are very comprehensible, usually, and often insightful, but they got all mixed up when they wrote about science.

I know a fair amount about Bell’s work, and Maudlin quite accurately describes that work.

The difference between Maudlin and ‘t Hooft can be summarized very easily:

1) ‘t Hooft uses “locality” to refer to equal-time commutation relations, as is common among physicists. Maudlin uses “locality” in a more general sense defined by John Bell that applies to a much broader class of theories, including ones in which ETCRs make no sense. ‘t Hooft seems fairly clearly not to understand that Bell’s sense of the word is not the same as his.

2) ‘t Hooft, Maudlin, Bell, and pretty much everyone who has carefully thought about this agrees that a sort of “superdeterminism” is logically possible in which what experimenters choose to measure is pre-ordained from the beginning of the universe and that, in principle, this would sort of allow one to evade Bell’s theorem. Maudlin (and most other people who have considered this possibility) think this idea is infinitely bizarre. ‘t Hooft disagrees.

On point 2, I am personally with Maudlin, but ‘t Hooft could prove us both wrong if he could come up with any sort of actual concrete comprehensible theory which is superdeterministic and which reproduces the sort of results by which QM violates Bell’s theorem.

So far, ‘t Hooft has not done so.

I’m pretty sure he never will, but then I have been surprised before.

Dave

6. **SteveB**
October 12, 2017

‘t Hooft’s new, free book explains a lot of his thinking and the “ontological state”. Given his assumptions, it seems he can argue against Bell. The book is: The Cellular Automaton Interpretation of Quantum Mechanics

http://www.springer.com/us/book/9783319412849

7. **Tim Maudlin**
October 12, 2017

Ah, well. Style is a matter of taste. For what it is worth, after many decades of people trying to tell ‘t Hooft that his whole project is doomed by Bell’s theorem, he got engaged enough in this discussion to actually sort out that he has been using some terminology (in particular “superdeterminism”) in a completely idiosyncratic way, which has meant that everyone has been talking past each other for these many years. Everything is becoming clarified.

It’s actually the first time I have written anyone a play in order to make a point. I’m rather proud of it.

8. **Dave Miller**
October 12, 2017

Hi, Tim. I’m not quite sure the play worked — but then I did not really like the original by Sam Beckett, either.

Yes, I think ‘t Hooft just does not understand that he is just using terms differently from many people interested in the subject, although I think the main problem is the two different meanings of “locality”: i.e., I think it is clear enough what is going on with “superdeterminism.”

Anyway, congratulations to both you and ‘t Hooft for trying to get through the communication problems. And, just maybe ‘t Hooft will come up with something and surprise both you and me: betting against Gerard ‘t Hooft is not the safest of bets!

Dave Miller

9. **Manfred Requardt**
October 13, 2017

I think, Peter is right. It is evident that the microscopic conditions of the initial state of measurement instrument and environment are only incompletely known and hence the outcome will be of a stochastical nature. Furthermore, what Bell really tells us is that quantum theory and the micro state of quantum space time are intrinsically non-local. This can also be learned from e.g. Black Hole physics. This kind of non-locality is however not of an ordinary nature.

10. **Scott**
October 13, 2017

Hi Peter. Sorry this is off topic but just wanted to let you know
about a recent pro multiverse article. https://www.forbes.com/sites/startswithabang/2017/10/12/the-multiverse-is-inevitable-and-were-living-in-it/

11. **feynman fan**
October 13, 2017

Peter, have you read Feynman’s interpretation in his 1985 book “qed” (not to be confused for the 1965 book written before he discussed the problem with David Bohm). In it, while ignoring Bohm’s pilot wave, Feynman argues that the path integral of qft explains the wave function collapse in 1st quantization. I’ve never seen any discussion of this on any high profile site.

Basically, the different possible interactions of long-lived (on mass shell) particles with random field quanta manifestations in the vacuum provide a physical mechanism for indeterminacy. A short-lived pair production loop near the path of an electron’s orbit will affect that path, causing indeterminacy. Thus, Feynman comments (in a footnote!) the uncertainty principle of 1st quantization is explained by taking as real possibilities the many different interactions possible between electrons (or other particles) and randomly occurring vacuum particles!

12. **Peter Woit**
October 13, 2017

feynman fan,
I hadn't seen that claim from Feynman (or anyone else) that QFT automatically solves the measurement problem. Doesn't sound plausible at all….

13. **feynman fan**
October 14, 2017

Peter: please see figure 65 in the 1985 book called QED by Feynman to be convinced!

Discrete Coulomb field quanta exchanges cause indeterministic electron orbits, in that analysis:

'I would like to put the uncertainty principle in its historical place … If you get rid of all the old-fashioned ideas and instead use the ideas that I'm explaining in these lectures – adding [amplitudes for all possible paths, by way of the path integral] for all the ways an event can happen – there is no need for an uncertainty principle!' – Richard P. Feynman, QED, pp. 55-56.

'… when seen on a large scale, they travel like particles, on definite paths. But on a small scale, such as inside an atom, the space is so small that there is no main path, no "orbit"; there are all sorts of ways the electron could go, each with an amplitude. … we have to sum the [wavefunction amplitudes for each possible path] to predict where an electron is likely to be.' – Richard P. Feynman, QED, pp. 84-5.

14. **Low Math, Meekly Interacting**
October 14, 2017

Apologies if this isn't apropos.

I watched this interview maybe a year ago, and the statement above jogged my memory. Check out around 8:55 (and a little before for some background). I believe what Gell Mann is saying may be along the lines of what feynman fan is proposing. If I understand correctly, what Gell Mann is speculating on is the notion that the path integral isn't just a tool for calculating. It is, in some sense, fundamental.

I have no opinion on this, nor the intellect to rightly have one. Just thought it might be interesting to note.

https://www.youtube.com/watch?v=f-OFP5tNtMY

15. **Peter Woit**
October 14, 2017

feymanfan and LMMI,
I don't think the fact that you can formulate QM in a path integral formalism solves the measurement problem. If you interpret the path integral as a probability measure, one problem is that you need to do this in imaginary time, another is that this tells you about the wave function, whereas in measurement theory what governs the probability is the norm-squared of the wavefunction.

16. **feynman fan**
October 14, 2017

Feynman (in Fig 65 of QED) uses Euclidean space for the path integral. All he is saying is that the measurement problem of "wavefunction collapse" in QM is fake news because:

1. There is a separate wavefunction amplitude for each Moller scattering event in the interaction of the Coulomb field for a particle in QFT, whereas there is only a single wavefunction in QM because QM falsely uses a classical Coulomb field.

2. To solve the measurement problem, simply replace the classical Coulomb field potential in the Hamiltonian of QM with a proper Moller scattering QFT path integral, and you will no longer have a single wavefunction collapse paradox. Instead, you will see that you are dealing with numerous wavefunction amplitudes via the corrected (truly quantized) Coulomb field. If you try to "measure" the position of the electron, that measurement involves using a quantum field, and adds another Feynman interaction diagram (with its own wavefunction amplitude)!

17. **Dave Miller**
October 15, 2017

feynman fan,

I took Quantum Mechanics from Feynman in the 1974-75 academic year and then took Intro to Elementary Particle Physics from him in the 1975-76 year.

He never offered the interpretation you are attributing to him.

He was, in fact, not much interested in the "measurement problem" one way or another (I tried to get him interested, to no avail).

What you have quoted is just the common-sense stuff about the path integral that all competent physicists have known about for decades. Sorry, but the "measurement problem" refers to something else. (And I am pretty sure Peter does not want me or anyone else to give you a tutorial on all this in this comments section!)

18. **tulpoeid**
October 17, 2017

Comments by Miller and Maudlin above say that it is now realized that 't Hooft uses a definition of "superdeterminism" which is different than others', the latter being that everything was fixed at genesis (I guess?).

I am mildly surprised, since the different definition seems to be known for some time now; Hossenfelder wrote the following and also, in a funny coincidence, I was told about this definition by an unrelated colleague last week:

"But really, this is a very misleading interpretation of superdeterminism. All that superdeterminism means is that a state cannot be prepared independently of the detector settings. That's non-local of course, but it's non-local in a soft way, in the sense that it's a correlation but doesn't necessarily imply a 'spooky' action at a distance because the backwards lightcones of the detector and state (in a reasonable universe) intersect anyway."
http://backreaction.blogspot.co.uk/2013/10/testing-conspiracy-theories.html

Note though that in http://backreaction.blogspot.co.uk/2016/01/free-will-is-dead-lets-bury-it.html she says that they themselves might not even agree on what they mean 🙂

Imho both cases are definitely not worthy spending time and money on, I'm just mentioning it in the context of this discussion (which proves more absorbing than it ought to!).

50 Years of Electroweak Unification

October 14, 2017
Categories: Uncategorized

The 50th anniversary of electroweak unification is coming up in a couple days, since Weinberg's A Model of Leptons paper was submitted to PRL on October 17, 1967. For many years this was the most heavily cited HEP paper of all time, although once HEP theory entered its "All AdS/CFT, all the time" phase, at some point it was eclipsed by the 1997 Maldacena paper (as of today it's 13118 Maldacena vs. 10875 Weinberg). Another notable fact about the 1967 paper is that it was completely ignored when published, only cited twice from 1967 to 1971.

The latest CERN Courier has (from Frank Close) a detailed history of the paper and how it came about. It also contains a long interview with Weinberg. It's interesting to compare his comments about the current state of HEP with the ones from 2011 (see here), where he predicted that "If all they discover is the Higgs boson and it has the properties we expect, then No, I would say that the theorists are going to be very glum."

Today he puts some hope in a non-renormalizable Majorana mass term for neutrinos as evidence for new physics. As for the future:

> As to what is the true high-energy theory of elementary particles, Weinberg says string theory is still the best hope we have. "I am glad people are working on string theory and trying to explore it, although I notice that the smart guys such as Witten seem to have turned their attention to solid-state physics lately. Maybe that's a sign that they are giving up, but I hope not."

On this last sentiment, I have the opposite hope. He also shares what I think is a common hope for what will save the field (a smart graduate student with a new idea):

> Weinberg also still holds hope that one day a paper posted in the arXiv preprint server by some previously unknown graduate student will turn the SM on its head – a 21st century model of particles "that incorporates dark matter and dark energy and has all the hallmarks of being a correct theory, using ideas no one had thought of before".

Perhaps current training of graduate students in theory should be rethought, to optimize for this.

Update: A colloquium talk by Weinberg on this topic will be live-streamed here on October 17.

Comments

1. **Low Math, Meekly Interacting**
   October 14, 2017

   Weinberg must be aware of his great fortune: He was alive during a period when his theories about fundamental physics could be subjected to rigorous empirical challenge, and either survive or not. I am lucky to have been alive to see "the" Higgs boson discovered. To have been born later may mean to have been born after the end of that era of fundamental discovery.

2. **Art**
   October 14, 2017

   From Close's article: 1) "QED is perhaps the simplest example of a general class of "non-abelian gauge theories"". Um, QED is abelian, right? 2) "it shows how it is easier to be Beethoven or Shakespeare than to be Steven Weinberg". Quite a stupid statement, no?

3. **vmarko**
   October 14, 2017

   I am a bit surprised by the article of Frank Close. It's all about Weinberg, mentioning only in passing that Glashow and Salam&Ward had figured out the SU(2)xU(1) symmetry no less than eight years earlier, in 1959. What Weinberg actually did in the 1967 paper was to combine this with the Higgs mechanism in order to break the symmetry spontaneously. And yes, Weinberg does quote one of the Glashow papers (in a slightly dismissive tone), so at least he did know about it, and most probably read it.

   I don't want to put off Weinberg's contribution to EW model, but I think Close doesn't do justice to Glashow and Salam, let alone Ward.

   Best, 🙂
   Marko

4. **Benson Woo**
   October 14, 2017

   It was wonderful to read Frank Close's account of the history of Weinberg's paper, especially the epiphany Weinberg had while driving his red Camaro to MIT. What if he had been doing something different that Sept 1967 day? These behind the scenes stories of how discoveries get made happen all the time.

5. **physicsphile**
   October 15, 2017

   Very nice articles. I was surprised to read that Weinberg works with the TV on! I would find that too distracting.

6. **Frog Leg**
   October 16, 2017

   "Weinberg also still holds hope that one day a paper posted in the arXiv preprint server by some previously unknown graduate student will turn the SM on its head – a 21st century model of particles "that incorporates dark matter and dark energy and has all the hallmarks of being a correct theory, using ideas no one had thought of before"."

   "Perhaps current training of graduate students in theory should be rethought, to optimize for this."

   I apologize if you've covered this before, but how do you think would graduate training be different from today?

7. **Peter Woit**

October 16, 2017

Frog Leg,

This really is a different and large topic, better for another time, but some obvious ideas are:

1. the parts of the usual graduate training that traditionally have been devoted to getting students up to speed on the most "advanced" topics (in HEP theory: e.g. GUTS, SUSY extensions of the SM, superstring theory) should be deemphasized, in favor or explaining what problems those ran into, why they haven't worked.

2. instead of rushing through the fundamentals of basic tools like QFT, it might be a good idea to devote more time to those and give students a better chance to become familiar with the trickier parts of those fundamentals. This is more likely to make it possible for someone approaching the subject with a fresh perspective to possibly come up with a new and successful fundamental idea.

8. **David Derbes**
October 16, 2017

@vmarko:

The CERN Courier article is an edited excerpt from Close's *The Infinity Puzzle*. The article focused on Weinberg, but the book doesn't. Salam, Ward, Glashow, Schwinger and many others (specifically 't Hooft and Veltman, and Higgs, Englert, Brout, Guralnik, Hagen and Kibble) are mentioned and receive large credit at various places in the book for work on the electroweak theory. You or I might weigh credit differently from Close, but nothing he wrote struck me as unfair while I was reading the book.

9. **Ilyas**
October 16, 2017

@vmarko and @David Derbes

David, you make a good point about Close's book (the source of the excerpt). There is a view that Close is somewhat negative about Salam in the context of the way in which he (Salam) was the third person that the Nobel committee chose. I dont know if you have seen the Noorman Dombey article (https://arxiv.org/pdf/1109.1972.pdf) but it is an interesting additional part of that little side-story around electroweak unification and who should (or should not) be credited. There are a few nice pieces written on the overall topic, but regardless of the negativity around Salam I like Close's book. Its really well written, and it does not cut corners in trying to be "popular".

10. **Peter Woit**
October 16, 2017

Ilyas and others,
The Dombey article was discussed extensively here back in 2011
http://www.math.columbia.edu/~woit/wordpress/?p=3972
and the Close book a couple months later:
http://www.math.columbia.edu/~woit/wordpress/?p=4181

11. **a reader**
October 17, 2017

Steven Weinberg is a true giant, but his closing remarks, that "the actual work is so, well…it's so chillingly non-human. I need to feel that I am still part of the human race while I'm doing it," were a bit of an anticlimax. As Ulysses says in Dante's Inferno, "considerate la vostra semenza: fatti non foste a viver come bruti ma per seguir virtute e canoscenza." Rather than being "chillingly non-human," physicists' actual work is eminently human, and it is something our species can be proud of.

12. **piscator**
October 17, 2017

a reader: I took exactly the opposite message. Given how technically algebraically oppressive Weinberg's textbooks are (I know how good he is, but the style just doesn't work for me) I find more than slightly amusing the fact that they may have been written to a backdrop of old films or cheap TV.

13. **David Brown**
October 20, 2017

In the livestream "Reminiscences of the Standard Model" by Weinberg, he made an interesting comment (around 1:18:15 in the YouTube video) concerning the work of string theorists, "… they haven't settled down to any particular theory, and we don't know whether that works anyway. I hope it does."

14. **Lucimário Custódio**
October 21, 2017

Yesterday Steven Weinberg gave a online lecture, "The Rise of the Standard Models", invited by the brazilian physics society. Here's the youtube link:

https://www.youtube.com/watch?v=DG3OqvdjnA4

15. **paddy**
October 21, 2017

piscator,
Despite his personality, I found (as a student 40+ years ago) Weinberg's didactic "algebraic" approach informative. Mathematical and example driven texts are helpful for those of us who are not geniuses.

16. **Fiona**
October 22, 2017

Peter, maybe this preprint https://arxiv.org/abs/1710.06149 is of interest and worth a comment? They propose the "conformal standard model", an extension of the standard model up to Planck scale without susy and without loops.

Shut Up and Calculate!?

October 17, 2017
Categories: Multiverse Mania

I noticed recently that Nima Arkani-Hamed was giving a talk at Cornell, with the title Three Cheers For "Shut Up And Calculate!" In Fundamental Physics. No idea whether or not video is now or will become available.

From the abstract one can more or less guess what sort of argument he likely was making, and it's one I'm mostly in agreement with. "Shut Up and Calculate!" is pretty much my unspoken reaction to almost everything I read purporting to be about foundational issues in quantum mechanics. I have in mind in particular discussions of the measurement problem, which often consist of endless natural language text where one struggles to figure out exactly what the author is claiming. An actual calculation showing what happens in a precise mathematical model of a "measurement" would be extremely helpful and likely make much clearer exactly what the problem is (or, sometimes, whether or not there even is a problem…). Such calculations are all too few in a huge literature.

Over the last few years, while teaching and writing a book about the mathematics of quantum mechanics, the tedious exercise of trying to get all signs right in calculations has sometimes turned out to be quite illuminating, with tracking down a mysterious inconsistency of minus sign leading me to realize that I wasn't thinking correctly about what I was doing. I'm all too aware that this kind of calculational effort is something I too often avoid through laziness, in favor trying to see my way through a problem in some way that avoids calculation.

On the other hand, I'm not quite ready to sign up for "Three Cheers", might just stick to "Two Cheers". For a perfect example of what's wrong with the "Shut Up and Calculate!" philosophy, one can take a look at the forthcoming Workshop on Data Science and String Theory planned for Northeastern in a month or so. They have a Goals and Vision statement which tells us that they plan to:

> treat the landscape as what it clearly is: a big data problem. In fact, the data that arise in string theory may be some of the largest in science.

About being the "largest", I think they're right. The traditional number of 10^{500} string theory vacua has now been replaced by $10^{272,000}$ (and I think this is per geometry. With 10^{755} geometries the number should be $10^{272,755}$). It's also the case that "big data" is now about the trendiest topic around, and surely there are lots of new calculational techniques available.

The problem with all this is pretty obvious: what if your "data set" is huge but meaningless, with nothing in it of any significance for the problem you are interested in (explaining the Standard Model)? This is not a new project, it's an outgrowth of the String Vacuum Project, which I wrote about here, here and here. This started with a 2005 funding proposal, ended up getting funded by the NSF during 2010-2014. From the beginning there were obvious reasons this sort of calculational activity couldn't lead to anything interesting, and as far as I can tell, nothing of any value came out of it.

For an opposite take to mine on all this, see the paper Big Numbers in String Theory, by Bert Schellekens. It contains an odd June 2017 preface explaining that it was supposed to be part of special issue of *Advances in High Energy Physics* devoted to "Big Data" in particle and string phenomenology ("all the ways we use high performance computing in addressing issues in high energy physics, and (in particular) the construction of databases of string vacua"). This issue was cancelled "as requested by the Guest Editors". I wonder what the reason for this cancellation was, in particular whether it had anything to do with part of the topic of the special issue being considered by some to be obvious nonsense.

Comments

1. **paddy**
   October 17, 2017

   As an adherent of the shut-up-and-calculate school of thought, I was once asked how then to think of Schroedinger's cat. My answer: I don't, I'm a dog person.

2. **Armin**
   October 17, 2017

   "…the tedious exercise of trying to get all signs right in calculations has sometimes turned out to be quite illuminating, with tracking down a mysterious inconsistency of minus sign leading me to realize that I wasn't thinking correctly about what I was doing."

   Could you please elaborate a little? What was the "mysterious inconsistency"? the nature of the "illumination"? How does it relate to "shut up and calculate"?

   As stated, the paragraph gives the impression you are implying that many interpretational problems of quantum mechanics simply evaporate if one just does the calculations properly. Is that what you meant?

3. **Peter Woit**
   October 17, 2017

   Armin,
   The second paragraph was the one referring to interpretational problems of quantum mechanics, and it's there that I'm suspicious that some problems disappear if you start to look carefully at and actually calculate what is happening when you have a specific system that is "performing a measurement". For the kind of all too rare thing I have in mind, an example would be
   http://blog.jessriedel.com/2017/10/12/models-of-decoherence-and-branching/

   In my class and in my book there's nothing about the measurement problem or interpretational issues, the topic is the mathematical structure of the subject, and that's what I was referring to in the third paragraph. In that case, finding a minus sign made clear to me that I really needed to be using the dual of a vector space at some point when I thought I needed to be using the vector space itself. The clarification was just one of the mathematical structure of the problem, had nothing to do with interpretational issues.

4. **Mike McCracken**
   October 17, 2017

   Hi, Peter,

   Sorry to focus on a parenthetical here, but I'm intrigued by the following:
   "(and I think this is per geometry. With \$10^{755}\$ geometries the number should be \$10^{272,755}\$.)" Can you elaborate on this or provide a link? I'm not interested

in strings, but this sounds like a deep geometric idea on which I'm obviously ignorant.

Thanks,
Mike

5. **Peter Woit**
October 17, 2017

Mike McCracken,
You can find references in
https://arxiv.org/abs/1707.00655
No, there is no "deep geometric idea" here, just some complicated, ugly and uninteresting constructions. I wouldn't advise spending time on looking into the details of this, I'm certainly not going to.

6. **Bee**
October 18, 2017

No no, "big data" is so yesterday. Today is "deep learning" and "neural networks." Wait for it!

7. **Luca**
October 18, 2017

Yep, and the most amazing trait of the Deep Learning techniques is that algorithms can give you the right answer, but it's impossible to understand why you've got that particular answer. In the end one could find the right vacuum from a zillion of possibilities and still having absolutely no explanation at all.

8. **tulpoeid**
October 18, 2017

Yep, and tomorrow's thing is emergent computation. It could run on the landscape and realize that all solutions point to only one viable one, namely Standard Model with QFT. It would be a triumph of strings' predictive power.

9. **Dave Miller**
October 18, 2017

Peter,

As someone with an interest going back decades in the foundations of quantum mechanics, I generally agree. Your recent post regarding the Maudlin-'t Hooft discussion is a case in point: *logically* something along the lines of what 't Hooft proposes might be possible. But until he or someone actually gives at least a toy model… well, it is very difficult to evaluate his Big Idea.

On the other hand, if no one ever gives any thought to "superdeterminism," "retrocausation," etc., we might fail to trigger the random thoughts that eventuate in a real theory. Einstein did, after all, get a lot of mileage out of his youthful curiosity about what it would be like to ride a light wave!

I don't think decoherence will solve the "measurement problem," but, like you, I think it is worth pursuing to sharpen our intuition and understanding of the deeper issues. And — who knows? — maybe the big contribution of string theory will be to sharpen thoughts about temporality, causation, etc. Polchinski suggested something along those lines some years ago, I think in his Rev. Mod. Phys. article.

Dave

10. **Atreat**
October 18, 2017

Here is the problem: "shut up and calculate" reduces to "shut up" if you don't know how to calculate. And in the case of quantum interpretations that leaves everyone silent.

A better slogan might be, "By all means keep talking, but in the absence of the ability to calculate let's not fool ourselves that we are close to a solution."

11. **Adrian C Keister**
October 18, 2017

As a "hype iconoclast", you might be interested to know, in the unlikely case you don't already, that there is just as much empty hype in "big data" as there is in string theory, SUSY, etc. Probably more, actually. As you mentioned, if there's no inherent meaning in the data, you can run it through fancy algorithms all day long and produce absolutely no new insights whatsoever.

@Atreat: Your "better slogan" is certainly better, but I'm just not sure it's got that catchiness we expect of meaningless slogans. You should work on that.

12. **Peter Woit**
October 18, 2017

Bee,
They're on it.

"In comparison, a renewed thrust to study the landscape (articulated e.g. at String Phenomenology 2017) has many of the same goals as the SVP but places an increased emphasis on using modern techniques in data science to study the landscape. This approach is worth pursuing since the past decade has seen rapid advances in the areas of machine learning, distributed artificial intelligence, and generative adversarial networks. "

"generative adversarial networks" sounds like the latest thing, right out of Blade Runner 2049….

13. **Tim Maudlin**
October 18, 2017

This is a very telling sentence: "I have in mind in particular discussions of the measurement problem, which often consist of endless natural language text where one struggles to figure out exactly what the author is claiming."

Now I understand why you don't my style. It all natural language and no math. Indeed, I have often said that the way many physicists read papers is the exact complement to how I read them: they read the equations and skip the prose and I read the prose and skip the equations. I figure they have not made a mathematical mistake, and the whole issue is *how the mathematics is being used as a way to represent physical reality*. A piece of mathematics is just that: a piece of mathematics. It isn't, by itself, a physical theory. And it doesn't magically become a physical theory by just explaining how to use it to make some predictions. Then it is part of a predictive apparatus. To become a physical theory, or rather be part of a physical theory, a mathematical formalism has to be interpreted, or, as I say, accompanied by a commentary. The commentary explains exactly what is being posited to exist by the theory (the ontology) and how that is being represented by the mathematics. To take is simple example, the usual mathematical formalism of classical electromagnetism can be used to express completely different physical theories depending on whether one takes the (mathematical) electric and magnetic fields to represent something physically real or the scalar and vector potentials to represent something physically real. And no amount of staring at the math will tell you. That is in the prose commentary.

There is an extremely effective predictive apparatus called "quantum theory" that is not, in the sense I just articulated, a physical theory at all. So much of the discussion in foundations of quantum theory is about the commentary, not the math. If you are struggling through the prose (which in many cases can be obscure and poorly expressed because the ideas being defended are simply unclear) you are struggling though the essential part. Looking for equations will not be much help.

John Bell, in "Against 'Measurement'", clearly explained the problems with standard presentations of the quantum theory. The problems are not in the math, they are in the prose. And on the other side, a theory like Bohmian mechanics, which completely solves the measurement problem, is not appreciated at all because there is no change to the math of Schrödinger's equation. There is, of course, one extra equation, the guidance equation, but to appreciate its significance you have to read the prose. And then there is a lot of detailed mathematical analysis of those equations that has been worked out over 40 years that almost no one is even aware of or reads.

This is a mess. But the way out of the mess is not to give even one cheer for "Shut Up and Calculate". Pablo Echenique-Robba had it much closer to the mark in the title of his paper: "Shut up and let me think. Or why you should work on the foundations of quantum mechanics as much as you please."

14. **Frederica**
October 18, 2017

Peter,

there are quite a number of calculations of decoherence times, and measurements of the values. Are they not convincing for you?

15. **Peter Woit**
October 18, 2017

Tim Maudlin,
The earlier objection to your style was about something different, things like : "And for years and years 't Hooft gives replies that only verify that he has not understood Bell's work and keeps at it."

About arguments over interpretations, I understand this has nothing to do with the mathematical formalism. My problem when I start reading such arguments often has to do with imprecision of language: when you and 't Hooft are using the term "superdeterminism", what exactly are you talking about? Of course part of my problem is a lack of expertise, insufficient time spent immersed in these debates and thus insufficiently aware of conventions for exactly how terms are used and ambiguities resolved. My sympathy here with "shut up and calculate!" is that often when I can't tell exactly what argument is being made, my high school English teacher's demand "Be specific, give examples!" comes to mind. Extremely helpful often would be not necessarily equations, but an explanation of what the issue is in the context of a specific physical measurement process.

Frederica,
I have no problem with calculations relevant to interpretational issues, I'm just saying that many interpretational debates I read could be clarified a lot by reference to specific calculations (see above).

16. **Tim Maudlin**
October 18, 2017

Peter,

You will be glad to know that as a consequence of this discussion I have recommended dropping the word "superdeterminism" in favor of "hyperfine tuning", which is fine tuning of the initial conditions of a theory not just to some macrostate (e.g. the Past Hypothesis) but to a microscopically specified set of states. I think it is a more descriptive term. In fact, I offered a whole set of exact definitions.

As to the particular sentence of mine you cite, I am puzzled. It is blunt, but accurate. The title of your blog is also blunt, but accurate. But maybe it's not worth the effort to figure out your problem here.

17. **vmarko**
October 18, 2017

Regarding the interpretations of quantum mechanics, they are always in the prose (as Tim says), but this is basically by definition, since interpretations should all agree on the math, and hence the math is the same in each interpretation. If two models do not agree on the math, then they are different theories rather than different interpretations.

But the measurement problem is not an interpretational issue, it is rather a bit more serious. QM as a theory, both the math and the prose included, fails to tell us which processes constitute measurements (and, say, lead to the collapse of the wavefunction) and which don't. The notion of measurement is always introduced intuitively, on a case-by-case basis, and plugged into the QM formalism by fiat, for every particular situation. Either by saying that the wavefunction collapses at some random moment of evolution, or by specifying the pointer basis for the decoherence and picking one particular vector from it, or by saying that this particular beable was detected in the apparatus, or otherwise. I agree with Peter that just speaking in prose about the measurement problem is not enough, and that one should instead write some equations that produce an actual model for the measurement process. And it should be clear that these equations should supplement QM, rather than be derived from it. Simply talking prose about it will never fill in for such equations.

HTH, 🙂
Marko

18. **Robert A.Wilson**
October 18, 2017

As an amateur in the field, I find the maxim "shut up and listen to the experts squabble" very useful. It does not take all that much listening to distinguish the experts who have thought deeply, but may ultimately be misguided, from those who shout loudly but have nothing to say.

19. **a1**
October 18, 2017

Reading "How the Hippies saved Physics' could remind you of some things the Calculators missed (not just the fun). And, by the way, the post/review/ from 2011 seems more nuanced than today's.

20. **Peter Woit**
October 18, 2017

a1 is referring to this
http://www.math.columbia.edu/~woit/wordpress/?p=3785

21. **Robert A.Wilson**
October 18, 2017

On a more serious, but less important, note, several comments above make the distinctions between mathematical errors, physical errors, and interpretational errors. All three need to be addressed. As a mathematician, I am best qualified to comment on the mathematical errors. In the way the standard model is routinely explained, there are many serious mathematical errors. Many of these have been pointed out in this blog, such as the particularly egregious "so(3,1)=su(2)+su(2)". Physicists rightly question whether this really makes any difference. And if you just "shut up and calculate" then most of the time the answer is no, it makes no difference. Clearly, the standard model works, and the calculations give the right answer. Most of the time. But this doesn't address the issue. Much of the physical argument is based on an inconsistent, not to say incoherent, interpretation of the mathematics. What should a mathematician who is concerned about this do? If he says "the mathematics is wrong", he is told "it doesn't matter, it works"; if he says "the physical interpretation is wrong", he is told "shut up, what do you know about it?". And heaven help him if he tries to say "the physics is wrong"! But if we are ever to solve this problem, we have to start from the assumption that probably all three are wrong, and start listening to constructive suggestions for what to do about it. In particular I whole-heartedly agree with Peter that getting the signs right is an educative experience, that is not about getting the right answer, but about understanding the nature of the underlying model, and, dare I say it, reality. I don't think anyone could say it doesn't matter whether the Lorentz group is SO(3,1) or SO(4).

22. **tulpoeid**
October 18, 2017

(Tim Maudlin, he refers to your tone verging on the sarcastic and even conceivably impolite.)

23. **a**
October 19, 2017

I think most agree that t'Hooft was one of the greatest physicists of the latter half of the 20th century. And apparently he is one of the most straightforward and honest people you'll see on the web, judging by his comments. But it looked to me like he was thinking a little fuzzily on the quantum interpretation business. Yes, the commentary was, um, rude, and I doubt t'Hooft would have taken that tone even in his heyday (which included some decidely modern topics) but the comments made some sense and were helpful (to me, at least, a nonexpert) in sorting through the issues. It also motivated me to reaquaint myself with Bell's papers (ok…basically just speakable and unspeakable); his style is very appealing (for example, he was a great Einstein fan but maybe not so much Bohr, as was made clear in the very amusing first appendix to Bertlmann's socks).

24. **Tim Maudlin**
October 19, 2017

Tulopoid: Yes, it is. So is "Not Even Wrong": it means that a theory is so confused that you can't even say that it is false because it doesn't say anything coherent. Indeed, the overall tone of my original post—which was not addressed directly to Prof. 't Hooft but at a wide swatch of the field—should come across as extremely exasperated because I was, and am, extremely exasperated. Literally years of theoretical effort has been wasted because people do not understand Bell's Theorem, which is nearly a mathematical triviality. The sociology of how this could happen is long and complicated, but the effect is there. And the systematic confusion of the notion of a "free variable" in a physical theory with the notion of "free will" as it applies to humans is so obvious as to be inexcusable. Just as Prof. Woit got rightly exasperated by the dominance of string theory in theoretical physics, people who work in the foundations of physics are exasperated that the most important and often simplest results in that field are systematically misreported and misunderstood.

It was not my intention, but if some naked exasperation (including occasional sarcasm) manages to bring some attention and light to these issues, that is a good thing. Certainly the very measured and elegant and immaculately careful and concise writing of Bell himself didn't do the trick. Sometimes people have to hit by a 2×4 to pay attention. That would have been beneath Bell, but I admit it is not beneath me.

25. **Dave Miller**
October 19, 2017

Re Bee's and Peter's comments on "deep learning" and physics: An interesting paper was posted on the arXiv earlier this year entitled Deep-Learning the Landscape! Despite the provocative title, this was basically an exercise at using deep neural nets (AKA multi-layer perceptrons) to "learn" various calculated quantities in algebraic geometry (specifically concerning Calabi-Yau manifolds).

The paper looks legit, and the results are interesting, though I think it is fair to say that the paper shows that neural nets are not yet ready to replace human mathematicians!

26. **tulpoeid**
October 19, 2017

(Maudlin: I see, I think this point was worth clarifying.)

27. **Chris W.**
October 19, 2017

Speaking of deep learning, see yesterday's news from Google's DeepMind team on AlphaGo Zero.

Echoing Luca's comment, the recurring question with such accomplishments is how and when they are useful. With AlphaGo, Go players can study and learn from the strategies that it discovers. That the strategies are useful and effective is readily verifiable, and this is obviously essential to AlphaGo's learning process. The fact that its learning—its experimentation—takes place in a completely automated way within a self-contained simulation environment on a high performance computing platform makes the process extremely rapid in human terms.

Leaving aside the problematic motivations for even attempting to apply such techniques to understanding the string theory landscape, how much of the above can be said to apply to physics? Obviously, if part of the learning involves doing actual experiments with real physical systems then it can't help be much slower, and subject to all the constraints that human experimentalists face every day. Learning non-trivial things about the physical world is much harder than learning something as artificial and well-structured as a board game.

By the way, I completely agree about the current level of hype in "big data". When commercial applications and marketing get involved, the amount of BS in circulation always rises precipitously.

28. **JoKing**
October 19, 2017

Hey Tim Maudlin,

You see, the reason that physicists when pressed won't posit any ontology for their equations is that this is not only not the most important part of what you might conceive of as a physical theory, but that it is in fact totally redundant and misplaced.

To give any credence to that statement that "such and such entity exists and this is how it is represented in the equations", you have to say what effect that entity will have in the real world. (Or else what do you mean?) Without an operational prescription, that statement is physically totally empty and can at best be viewed as a purely mathematical existential quantification.

What's more, the physical theory known as quantum mechanics in fact forbids you of talking about the physical reality of many of the objects you talk about when explaining what you think Bell did. (And I think Mermin now understands that meaning of "shut up" as well.)

My point is indeed that your grief with the physics community arises very early on from your epistemological misconception of a "physical theory" rather than from their misunderstanding of Bell.

29. **Bill Bailey**
October 19, 2017

Tim Maudlin,
There are many things natural language can't get at that math can. The math needs no prose commentary because the math is telling you what the abstract relationships are itself. Physicists read the equations to understand what is going on without needing a running prose commentary. Some things like "free will" are metaphysical speculations that may actually be incoherent under precise examination based on the structure of the mathematical relationships that physicists discover. These problems like "the measurement problem" may only arise because one wants to force a translation between our prose language and the mathematics. One may be introducing problems that are not there. But that's in your area. The dissolution of paradoxes and confusions.

30. **Peter Shor**
October 19, 2017

Peter,

My take on the "shut up and calculate" philosophy is that it's one of the reasons that quantum computation and information was not discovered by mainstream physicists, but by the motley crew of non-mainstream physicists, computer scientists, mathematicians, and semi-crackpots who discovered it. (And for the curious, I'm not going to say who I think falls into which category.)

And maybe you should consider whether "shut up and calculate" might not be a reason that people haven't spent more time studying quantum field theory deeply, the way that you are advocating.

On the other hand, I am also convinced that studying the foundations of quantum mechanics in the manner that many people have been doing it is a waste of time. But I believe the "shut up and calculate" philosophy's influence has been much broader and more negative than that.

31. **F4**
October 19, 2017

I attended Arkani-Hamed's talk (though when prompted by this post I realized that I recall shockingly few details about it now (something for which my memory is solely to blame); I also had to leave just as he was finishing skipping through the roughly sixty (?) percent of the slides that he didn't discuss at all).

Hopefully any recording made will be decent: he was forced to suffer some inexplicable (and inexcusable, I would say) technical difficulties before commencing, had to resort to standing directly in front of the lectern microphone, and eventually seemed to give up or forget and so spent most of the talk perambulating around the front of the hall sans amplification.

Anyway: I thought that he made it fairly clear at the beginning that both a rigorous shut-up-and-calculate pragmatism and a broader philosophical vision are necessary for real scientific progress. But indeed speculation must be grounded: a segment of the talk concerned Einstein's perserverance in improving his mathematical knowledge and his spurious justification of failed pre-GR proposals with a variety of philosophical principles. Arkani-Hamed also said that getting the mathematics of a concept right can be a (more or less) combinatoric exercise once you have delivered yourself into the right theoretical attractor space.

I don't remember much if anything said about applications to string theory in particular but then again he seemed to be ready to talk for at least two more hours than the time allotted.

32. **Tim Maudlin**
October 20, 2017

JoKing,

The question is not how a physical theory with clear ontological postulates (i.e. saying clearly what physically exists according to the theory) has any trouble at all with making empirical predictions, it is just the opposite: how can you derive empirical predictions from a theory that make no clear posits about what exists?

Quantum theory does not "forbid you from talking about" anything. How could it? I mean what is quantum mechanics going to do to me if I insist on talking about things like what really exists at microscope? Bohmian mechanics, for example, says that point particles do. And that tables and chairs and cats and people are composed out of point particles. And how the point particles move (what exists and how it behaves). So it automatically makes predictions about tables and chairs and cats and "measuring apparatuses" without having to mention "measurement" or any other problematic notion.

My conception of a proper physical theory as postulating what exists and how it behaves has zero epistemology built into it. It just isn't an epistemological thesis of any kind. So you are confused there.

33. **Tim Maudlin**
October 20, 2017

Bill Bailey,

A piece of mathematics without some indication of how it is being used as a mathematical representation of something physical just isn't, and can't be, a physical theory of anything. I mean, how could you tell even what it is supposed to be a theory of, what phenomena it is supposed to account for? How could you get experimental evidence for or against it? That extra information comes in the commentary. It is given in natural language, not mathematics.

As a simple example: take the mathematical formalism of classical E & M. Accompanied by the commentary: "The mathematical E and B vector fields represent the physically real electric and magnetic fields; the mathematical A vector and phi scalar potentials are mere mathematical conveniences that represent nothing physical" that math has one sort of physical significance. Accompanied by this commentary: The A vector field and phi scalar field represent physically real things, and the E and B fields are just mathematical conveniences" the very same math underlies a completely different theory.

I hope this helps make the point.

34. **Manfred Requardt**
October 20, 2017

I think Peter Shor is right. I know many mathematicians who think they do understand quantum mechanics if they understand the Schroedinger equation. Mathematics is only an important tool in natural science. Most of our important ideas arise in form of images and words. As far as I can see, many of our greatest colleagues were not of the shut up and calculate type (e.g. Einstein, Bohr, Heisenberg). I believe the really deep problems can never be found by shut up and calculate.

35. **André**
October 20, 2017

JoKing:
I think, "operational prescription" is just a euphemistic way of saying "shut up and calculate". It's of course nice to have a mathematical model that tells you what reading (with which probability) you will get from a photodetector under certain initial conditions, but at the end of the day most physicists will probably agree that the photodetector itself is built of atoms that need to be described quantum mechanically. So, from my point of view, it seems clear that the "operational prescription" can't be more than an effective theory.
Effective theories can be very useful, thermodynamics, for example, has quite a lot of applications for which it is completely irrelevant to understand the microscopic definition of temperature, entropy, etc., but if you want to gain some deeper understanding of the world, you will eventually end up asking what exactly these quantities are.
The way I see it, the measurement problem is pretty much at the same level. Quantum theory is a perfectly predictive theory for the outcome of specific experiments, but it doesn't teach us anything about what is "really" going on at a deeper level.
Also, I disagree that quantum mechanics forbids us from talking about the physical reality of objects. It is just that the real objects in (Copenhagen) quantum mechanics are very odd ones: the measurement devices/outcomes.

What I don't understand – and this is a purely sociological and not a scientific observation – is how many physicists are totally obsessive about the assumption that quantum theory must somehow be the end of the story, and not just some limit of some more elegant underlying theory. This is against everything we should have learned from the history of science, and somehow against the very idea of science.

36. **André**
October 20, 2017

Tim:
Although I very much agree with your point of view and enjoyed reading your conversation with 't Hooft, a question regarding your example for classical EM:
I could just consider a concrete set-up, say a Hall probe in an EM field, and have a perfectly well defined mathematical formalism that tells me: given this experimental set-up, my B-probe will show the value 0.5 Tesla (e.g.). For this, I don't have to give any reality to either E and B or A and phi.
Of course, you would still need a commentary, namely stating that the output of your mathematical algorithm gives you the reading of your B-probe, but I would still be interested about your view on such an approach, since I think it is pretty much what many physicists have in mind when they argue like JoKing and Bill Bailey.

37. **Bee**
October 20, 2017

@Dave Miller,

Thanks for the reference, looks interesting!

38. **Bee**
October 20, 2017

@Tim Maudlin,

Replacing one word with another word is not a definition.

39. **Urs Schreiber**
October 20, 2017

> To become a physical theory, or rather be part of a physical theory, a mathematical formalism has to be interpreted, or, as I say, accompanied by a commentary.

An established term for this in the philosophy of physics is *coordination*.

40. **Peter Woit**
October 20, 2017

All,
Sorry, but I have to cut off further attempts to use this as an interpretation of quantum mechanics discussion board, in effect telling people to shut up. I've been trying to delete those (many) comments that don't appear to make an argument worth reading, but have now had enough. Whatever my sins, I don't deserve having to moderate a discussion of exactly the sort I was criticizing as a waste of time.

41. **onlygamintwn**

October 21, 2017

You should take a look at https://arxiv.org/abs/1709.03554
since you are taking about string vacua or numbers like 10^{whatever}.

42. **Mateus Araújo**
October 23, 2017

Prof. Woit,

I have to peacefully disagree with your assertion that the measurement problem is somehow a ill-posed natural language problem. It is mathematical.

Consider a quantum system in the state \ket{\psi_0}. Then a measurement happens, taking it to the state \ket{\psi_1}. What is the evolution from \ket{\psi_0} to \ket{\psi_1}? Is it a projection? Is it a unitary transformation? It's easy to prove that these alternatives are mathematically incompatible, so it can't be both (I guess you already know this, but I'd be happy to provide a proof if you're interested).

Of course it might be even something else, but I guess you are even less interested in this possibility than you are in the foundations of quantum mechanics.

43. **Peter Woit**
October 23, 2017

Mateus Araujo,
I never said the measurement problem is an ill-posed natural language problem. My comment was that many natural language discussions of it don't seem to me to touch the actual problem. When I try and read many such discussions I soon get lost, unsure exactly what the author is saying, and thus whether a real problem is getting addressed. There are also plenty of examples where the author writes unambiguously, perhaps using a mathematical formalism to achieve precision. Typically in such cases I can at least understand what is being said, and when the author moves to discussing something I don't think is interesting or relevant, I know when to get off the bus.

My positive take on "shut up and calculate" here is that it would often be useful if someone making a claim to say something new about the measurement problem would discuss an actual measurement instead of making imprecise claims about all "measurements" (including being imprecise about what a "measurement" is). Pick an actual physical system and work out what happens (i.e. "calculate"), showing where the "problem" occurs and explaining what you have to say that's new and enlightening about this problem. When I see this kind of activity, I can follow it, and often learn something interesting, often that the "problem" has some different aspect that wasn't obvious to me before.

44. **Mateus Araújo**
October 23, 2017

Prof. Woit,

Indeed, that is what you had written. Sorry for misunderstanding you.

I think saying something *new* about the measurement problem is close to being a literal impossibility, due to the sheer amount of literature written about it. As a corollary, the solution to the measurement problem has already been written, but finding it in the literature is also nigh impossible, due to this "Library of Babel" situation.

Nevertheless, I disagree with you that making some precise calculation about some specific physical system would be of any help. I've actually met a guy in a conference that claimed that he had solved the measurement problem by doing exactly this. This is his paper. It does make a nice mathematical model of a measurement, up to where the outcome should be produced, where he writes some stuff that I read as "then a miracle occurs".

The problem is that this sort of details hardly matters, the points about which there is disagreement are much more general features of the measurement process. This paper by Maudlin, for example, discusses in a rigorous way what the features are and where there is disagreement. I think that if your solution doesn't address the problems he is bringing up then you are completely missing the point (and yes, it makes me feel dirty to agree with Maudlin on something).

45. **Robinson**
October 23, 2017

A comment section with a Tim Maudlin observable… A pleasure to read.

46. **Doug McDonald**
October 23, 2017

An earlier comment had a pointer to this blog:
http://blog.jessriedel.com/2017/10/12/models-of-decoherence-and-branching/

An even better discussion, really definitive as blogs go, is
http://blog.jessriedel.com/2016/11/12/how-to-think-about-quantum-mechanics-part-0-measurements-are-about-bases/

especially in part 4.

I'm completely shut up by that blog series.

47. **Curious Mayhem**
October 23, 2017

Isn't the whole "shut up and calculate" ethos just an extension of what Lee Smolin was complaining about when he criticized the whole field has having degenerated into virtuoso but mindless calculation mixed with a lot of hand-waving? You know, as in, no one is thinking about anything physically?

We're a long way from Einstein thinking up the invariance of light rays or the Equivalence Principle, or the pioneers of quantum mechanics struggling with classical variables in the face of the quantum of action, or Feynman's insight that yielded the path integral. All of those required formidable mathematics to implement. But the original insights were not mathematical.

48. **Jeff M**
October 23, 2017

Curious

Lee was trained by the same physicist I was, before I went over to the dark side (math). Herb was brilliant, but no computationalist. He was always very physically motivated, and interested in why things were the way they were. He went on to be very involved in quantum teleportation stuff, despite teaching at a small liberal arts college. My perspective now is somewhat different, but the hand waving drives me nuts, mathematician that I am.

49. **Peter Woit**
October 23, 2017

Curious Mayhem,
To a large extent, I disagree with Lee about this, and agree with Arkani-Hamed. I think the problem with string theory is not too much virtuoso math, but that it's a wrong physical idea about unification. The physical idea impressed a lot of people, but when you try and write down a fully consistent theory and calculate anything meaningful you find that you can't . It's the physical idea that is leading you down the wrong path, the actual calculations implementing it that show that this is the wrong path. Of course, once your calculations have shown you you're on the wrong path, one possible reaction is to ignore this and do more calculations, which is what the string vacuum people are doing, showing that calculations are not always the answer.

50. **Mateus Araújo**
October 24, 2017

Robinson,

I think Maudlin is actually a beable.

51. **Jeff M**
October 24, 2017

Peter,

I think you're right that string theory is based on an incorrect physical idea, but I don't think that's what Smolin is talking about. He's pointing out that the physical idea isn't even talked about anymore, and hasn't been for a long time. It's just a bunch of physicists spitting out meaningless calculations, many of which aren't even properly done. Continuing to do that, which is what Arkani-Hamed is suggesting, won't get anyone anywhere. And unfortunately I don't think physicists (well, string theorists) think that the calculations they're doing show they're on the wrong path, precisely the opposite. Look at all the possibilities! It's not that there isn't interesting math, there is, but it's not the physicists who are doing it, and it has no relation to the physical world. I should give credit to the physics folks for pointing out an interesting direction for mathematicians to look in, I think honestly much of that was Witten, who has remarkable mathematical insight, there's a reason he won a Fields.

52. **Peter Woit**
October 24, 2017

Jeff M,
I don't think it's meaningful or helpful at this point to globally say "string theorists are doing X" and criticize that, there's a huge range of things of different value being worked on by "string theorists", most of which have nothing at all to do with the original physical idea of quantizing a 1-d extended "string".

To me one of the most bizarre aspects of the current situation is the inversion of attitudes among prominent string theorists (note that Arkani-Hamed has never really been a "string theorist", he comes from a different background) over the past decade. Back when our books came out in 2006, the criticism from string theorists of Lee and some other people doing LQG was basically that they were woolly-thinkers, going on about Einstein and how you just needed some vague revolutionary "physical" idea, while string theorists had a real theory and could do real calculations. Nowadays, many of the most influential people among "string theorists" (of those who haven't completely abandoned the subject for field theory and condensed matter) are engaged in pursuit of a vague but impressive sounding "physical" idea that somehow a theory of quantum gravity can be found based on general ideas about entanglement and quantum mechanics. This looks to me like exactly the sort of thing Lee's string theory critics had in mind a decade ago when they were criticizing him and the LQG people (those LQG people as far as I can tell are now mostly doing detailed calculations…)

One thing I'd love to know is who exactly Arkani-Hamed had in mind when he decided that he should give this talk. Who does he want to "Shut up"? I suspect Lee was one such person, but what does he think for instance of Susskind, who doesn't appear to be calculating anything anymore? What does he make of "calculations" like "ER=EPR" or "GR=QM"?

53. **Mark Hillery**
October 24, 2017

For those interested in some recent thinking about quantum measurements, which includes calculations, I suggest having a look a What happens in a measurement? by Steven Weinberg, Phys. Rev. A 93, 032124 (2016).

54. **Kris Krogh**
October 24, 2017

Mark,

Thanks for the Weinberg reference. Working along similar lines with the Lindblad master equation, Apoorva Patel and Parveen Kumar have produced what appears to me a spectacular new result, with realistic prospects for experimental tests:

https://arxiv.org/abs/1509.08253
https://arxiv.org/abs/1412.1312

55. **Daniel Tung**
October 24, 2017

In the style of Einstein's comment on science and religion,
Calculations without physical idea is blind; ideas without calculations are lame.

56. **Curious Mayhem**
October 24, 2017

Peter,

I suppose the original physical idea behind strings is at fault here. Once the failure became apparent, around 1990, the solution from the string establishment was more calculations. There were further physical insights (like AdS, conformal symmetry, etc.). But these were tangential to the original unification program that gave rise to the popularity of strings in the first place, in the 1980s.

Perhaps a better way to say it is that a certain style of “math jock” theoretical physics, combined with the previous successes of symmetry-based unification, led to the feeling that just driving further in that direction — without careful study of the map — would soon lead to the “end of physics.” This path was never devoid of physical ideas. But string theory did not incorporate a new and deep breakthrough physical principle that could be turned into a coherent theory. Very different from gauge theory, chiral symmetry, spontaneous symmetry breaking, or the spawn of superconductivity and the Goldstone-Higgs complex. The latter ideas were “pretty,” but mainly, they were simple, general, and powerful. Granted a limited pool of assumptions, you can go very far with these — hallmarks of the best scientific ideas.

Searching my memory of graduate school in the 80s, I’m trying to remember what it was that entranced us about strings. (I never worked in strings directly, just around the periphery, back when theory included phenomenology, an essentially dead subject now.) The first memory I have is “anomalies cancel! anomalies cancel!” Within the following year or so, we learned that strings incorporated higher dimensions (like Kaluza-Klein), groups that extended unification groups we already knew (like E8 and SO(32)), and supersymmetry and supergravity. These were already well-known topics.

The funky string diagrams were fun. But what convinced us was the fact that strings seemed like an extension of a familiar road that we’d been traveling on for a decade+ anyway, just with some weird and unexpected twists. The fact that it did NOT propose a radically new physical idea seemed sensible and attractive.

57. **Jake**
October 24, 2017

re: the deep learning talk from last page, the difference between ‘deep learning hype’ and ‘big data hype’ is that *deep learning actually works*, at least sometimes. Yes, there are major unanswered questions about many aspects (such as interpretability), but all that means is there’s a big gulf between experimental results and theory, a situation that should not be too foreign to people reading this of all blogs.

58. **Robert A. Wilson**
October 25, 2017

Manfred Requardt,

You say that some mathematicians think they understand quantum mechanics because they (think they) understand Schroedinger’s equation. When I was an undergraduate 40 years ago, I knew that I did not understand quantum mechanics, because I knew that I did not understand Schroedinger’s equation. This has not changed: I still do not understand quantum mechanics, and I still do not understand Schroedinger’s equation, although I am perfectly able to shut up and do the calculations if I want to. What *has* changed for me in the last 40 years is that I now know that nobody else *really* understands Schroedinger’s equation either, although many people think they do, or at least say they do.

59. **Robert A. Wilson**
October 25, 2017

Peter,
23 Oct 11.11pm. I agree. Physical ideas lead to math, you do the math, it doesn’t work, you revise the physical idea, and/or you revise the physics-math interface, and you go round again. And again. And again. Fifty years of ignoring the basic misconceptions and calculating forever in the wrong model is a complete waste of time. New physical ideas are two-a-penny, but mostly they are counterfeit, and the genuine ones are very rare and precious. Distinguishing the two is the hard part, and most are thrown away before being properly examined, so it is likely that there are some genuine ones out there that are not recognised as such. Mathematics is also cheap, but again, choosing the right mathematics is very, very difficult and expensive. It seems to me that the current strategy amounts to going to a car boot sale and picking up a bit of mathematics or any old junk in the hope that it will solve the problem. The chances are zilch. I have no solution to the problems, but I know where you have to start: get real mathematicians involved in the search. It is essential to have a genuine two-way dialogue between the physical ideas and the mathematics that expresses those ideas. But choosing the right mathematicians is also very very hard. The evidence of the past thirty years is you’ve consistently picked the wrong ones. Hahaha! “You’re very clever, young man, but it’s turtles all the way down!” Throw the dice, start again, pick some clever people at random, give them tenure *before* they’ve proved themselves. That’s the only way you’ll not only get the really innovative ideas you need, but also get someone committed and able to work on them. You’ll give tenure to 99 people who after 40 years come up with nothing, but you may also have hit on the one person who is worth 100000.
This is venture capitalism on the most extreme scale of risk, and it is necessary to approach it in that spirit. Build a team of 3 or 4, or 6 or 8, extremely clever and open-minded people, spanning particle physics, relativity, cosmology, mathematics, and leave them alone and give them everything they need for their entire careers, to argue among themselves until they resolve their differences. Treat them like a jury, and refuse to let them out until they come to a unanimous decision. Above all, do not interfere in any way in their deliberations, and do not give them a time limit. And maybe repeat the exercise a few times in parallel, up to the limit of the desired investment. Ah well, utopia is a beautiful place, today’s political reality is a very different kettle of fish.

60. **Peter Orland**
October 25, 2017

Robert A. Wilson,

As someone who has done (or tried to do) research in particle theory for a long time, I am convinced that there are no fixes of the sort that you recommend.

If it were simply a matter of building the right sort of team or looking for specifically qualified people, it would have already worked.

There is no simple path to creative achievement. Creative people have to find the way themselves. Good ideas are a matter of luck, talent and knowledge in that order. In my limited experience, planning is an obstacle, not an incentive!

61. **Robert A. Wilson**
October 25, 2017

Peter Orland,
You are right, of course, I was merely venting my frustration with the current system, not really proposing an alternative. “Luck, talent and knowledge in that order”, definitely in that order. You can’t control luck, and you can only vaguely spot talent, so the system is based largely on assessing knowledge. And that is where the systematic biases cause the most damage, because you cannot know in advance what combination of knowledge is going to trigger the key insight that leads to the big breakthrough. You need to allow for input from unexpected directions, and I admit I don’t know how to do that. But you are surely right that less planning rather than more, is the way to go.

Short Items

October 24, 2017
Categories: Uncategorized

A few short items:

- My graduate school roommate Nathan Myhrvold has a new book coming out this month, a five-volume series about the science of bread, based on several years of research into the subject at his laboratory near Seattle. Robert Crease has gone out to visit, and gives a wonderful detailed report on The physics of bread in this month's Physics World.
- An article at FQXI on multiverse research they are funding seemed to finally give me an understanding of what this is all about:

  > These are the two conceptually hardest questions in cosmology, according to Raphael Bousso, a theoretical physicist at the University of California, Berkeley. They go to the core of what it means to exist as a human being making sense of the universe we find ourselves in. And, he adds, unfortunately, there is very little physical knowledge to go on when it comes to working out the answer.
  >
  > Undaunted by the lack of tools to help them, theatrical physicists Eugene Lim of King's College London, UK, and Richard Easther of the University of Auckland, New Zealand, are…

  This all of a sudden made things clear: what is going on is "theatrical physics", not "theoretical physics". Going on like this about the multiverse is performance art.

  Unfortunately I just noticed that this page has been edited (new version here), removing the enlightening characterization of what this is about.

- I'm glad to see that Natalie Wolchover has just won an AIP award for her writing about physics, in particular for a piece on how physicists are dealing with the "nightmare scenario". While she's perhaps the best professional journalist writing about these topics, for coverage of this from a professional physicist, the best you can find is Sabine Hossenfelder's blogging at Backreaction. I'm pleased to hear that the two of them will be appearing at an event here next month in NYC, talking about Making Sense of Mind-Blowing Physics at NYU on Nov. 16.

Update: Sabine Hossenfelder has a book coming out next year, which should be fascinating (although I suspect I'll have something to disagree with…).

Gian Francesco Giudice has a long essay about the status of particle physics, post-negative LHC results. For better and worse, I think it captures well the view of many mainstream theorists.

Comments

1. **Matty**
   October 25, 2017

   I totally agree with you regarding the "theatrics" of that FQXI piece on the multiverse.

   One of the reasons I dislike the inflationary multiverse paradigm is because it just seems like an excuse for failure, as you have noted before – to drag philosophical speculation, however empirically based and explanatory or elegant in nature it might be (and I recognize that the multiverse might not even be elegant or explanatory!), into scientific discussion. It amounts to this sort of reasoning imho,

   "Oh well, our ability to test high energy physics is approaching its limits: we can't seem to calculate the observed value of the cosmological constant and supersymmetry may not be found at the LHC to explain the mass of the Higgs, so yeah – the multiverse must have did it! And even if we can't actually test it because of the particle horizon etc. that's no big deal, we should just accept it as the explanation anyway because it accounts for the data and seems to be the only game in town".

   Umm. Is that how scientific inquiry really worked in the past? From the Aristotelian notion of unmoved movers, the Geocentric model of the universe to Fred Hoyle's Steady State theory, science has ultimately lived or died in terms of testable predictions. Each of these models was ultimately falsified by tested theories (i.e. the discovery of inertia/momentum, heliocentrism, the cosmic microwave background validating the Big Bang).

   Now we appear to be left with "there is very little physical knowledge to go on when it comes to working out the answer" so BINGO, must be multiverse.

2. **Peter Woit**
   October 25, 2017

   Matty,
   Unfortunately I don't think the explanation for the sad story of the multiverse is that physicists have been inspired to become performance artists. Whatever the true reason is, it's a much more depressing situation…

3. **Matty**
   October 25, 2017

   It was an amusing Freudian slip though! But yes, the reality does appear to be more depressing……

4. **Natalie Wolchover**
   October 25, 2017

   Thank you, Peter, much appreciated! See you at the NYU event, perhaps.

5. **neil**
   October 25, 2017

   Also, there is an interesting article in SciAm by Guy Wilkinson on beauty experiments at LHC and elsewhere.

6. **Robinson**
   October 31, 2017

   Giudice's paper was a pleasure to read. Thanks for that.

7. **Jacob Pearce**
   November 15, 2017

   Hi Peter,
   I enjoyed the 'theatrical physics' comment re the multiverse.
   I've got an article in MIT's Perspectives on Science journal entitled:
   "Why These Laws?"—Multiverse Discourse as a Scene of Response.
   http://www.mitpressjournals.org/doi/abs/10.1162/POSC_a_00245
   It's open access. Think you and your readers might find it of interest.
   Cheers

This Week's Hype

October 26, 2017
Categories: This Week's Hype

Yet another entry in the long line of nonsensical hype about fundamental physics driven by misleading university press releases is today's news that CERN Scientists Conclude that the Universe Should Not Exist. Tracking this back through various press stories (see here, here and here), one finds that the original source, as always, is a university press release designed to mislead journalists. In this case it's Riddle of matter remains unsolved from Johannes Gutenberg University Mainz, a press release designed to promote this paper in Nature.

The paper reports a nice experimental result, a measurement of the antiproton magnetic moment showing no measurable difference with the proton magnetic moment. This is a test of CPT invariance, which everyone expects to be a fundamental property of any quantum field theory. The hype in the press release confuses CPT invariance with CP invariance. We know that physics is not CP invariant, with an open problem that of whether the currently known sources of CP non-invariance are large enough to produce in cosmological models the observed excess of baryons over antibaryons. An accurate version of the press release would be: "experiment finds expected CPT invariance, says nothing about the CP problem."

If this experiment had found CPT non-invariance, the implications for early universe baryon-antibaryon asymmetry would have been of minor interest compared to the revolutionary discovery that a fundamental theorem of quantum field theory was violated, shattering our understanding of fundamental physics in terms of quantum field theory.

Comments

1. **murmur**
   October 26, 2017

   Who writes these press releases? I doubt the authors of the paper would so willfully misrepresent their work.

2. **Davide Castelvecchi**
   October 26, 2017

   Another type of statement that one finds very often in press releases – so often, in fact, that some physicists have started to believe it – is that experiments on actual CP violation, like BaBar, "produce more matter than antimatter". This is usually based on the production rate of B mesons versus that of their antiparticles. Trouble is, these mesons are neither matter nor antimatter: they are each made of a quark and an antiquark 🙂

3. **vmarko**
   October 26, 2017

   murmur,

   Apparently the first author of the paper, Christian Smorra, got confused between CPT and CP symmetries. At the end of the press release it says:

   'This consistency is a confirmation of the CPT symmetry, which states that the universe is composed of a fundamental symmetry between particles and antiparticles. "All of our observations find a complete symmetry between matter and antimatter, which is why the universe should not actually exist," explained Christian Smorra, first author of the study. "An asymmetry must exist here somewhere but we simply do not understand where the difference is. What is the source of the symmetry break?".'

   It looks like he was explicitly quoted to have said that. I can understand that we all make mistakes, but these days one should really be extra careful not to say something too stupid in an interview for the media. Why is he even talking about matter-antimatter asymmetry in the context of his paper, when CPT invariance has nothing whatsoever to do with it? I'd say this is the author's fault, in the end.

   Best, 🙂
   Marko

4. **Peter Woit**
   October 26, 2017

   murmur,
   Such press releases are generally not written by physicists themselves but by university communications staff. Usually a press release of this kind would be reviewed by the scientists before going out. Even if that were not the case I can't imagine that a university wouldn't take down a press release about work by one of their faculty if the faculty member complained that it was misleading. This press release has been up for nearly a week, so the physicists involved presumably haven't complained. As vmarko points out, one of them is quoted quite explicitly confusing CPT and CP.

   Davide,
   Never noticed that, thanks for pointing it out (although for that a defence of poetic license might be reasonable…)

5. **Davide Castelvecchi**
   October 26, 2017

   I don't know how they do it in Mainz, but when I used to work for the AIP and wrote press releases I would interview sources the way a journalist would. And I would not edit their quotes without their permission.

6. **NoGo**
   October 26, 2017

   Maybe this is normal for such press releases, I don't know, but parts of this one don't look like written by people who have a clue about physics, more like the worse kind of articles about science in mainstream press… "A total of 16 antiprotons were used and some of them were cooled to approximately absolute zero or minus 273 degrees Celsius."

7. **vmarko**
   October 26, 2017

Peter,

“This press release has been up for nearly a week, so the physicists involved presumably haven’t complained.”

Most of the authors of the Nature paper are postdocs, PhD students and master students. Ulmer is the principal investigator, and (after a cursory look) only Yamazaki, Walz and Blaum are senior scientists, AFAICS. So when the paper’s first author (Smorra, an ex-postdoc of Ulmer) says something misleading in an inverview, there aren’t so many people in their team who will notice it and complain.

However, after this much media hype, I guess one of the seniors did have a talk with Smorra about the difference between CPT and CP symmetries. Or should have had. 😉

Best, 🙂
Marko

8. **Lowell Brown**
October 27, 2017

It is a wonderful paper because they quote two of my papers.

9. **Mark**
October 27, 2017

“All of our observations find a complete symmetry between matter and antimatter, which is why the universe should not actually exist,” explained Christian Smorra, first author of the study. “An asymmetry must exist here somewhere but we simply do not understand where the difference is. What is the source of the symmetry break?”.’

Even if he did mean CP symmetries, this is still misleading. Last time I checked there is a plethora of measurements showing CP violation in the field. The statement implies the opposite (though maybe he meant “our” to be more literal and to mean his experiment – but then the latter part of the quote makes no sense).

10. **Anon**
October 27, 2017

Hi Peter

Thanks for your post as always.

You had written, “We know that physics is not CP invariant, with an open problem that of whether the currently known sources of CP non-invariance are large enough to produce in cosmological models the observed excess of baryons over antibaryons.”

Am curious why you think this is an open problem. Isn’t it the consensus that the CKM CP phase is insufficient — for example it vanishes if any 2 quarks have degenerate masses or if any of the CKM mixing elements are zero… which basically implies that the CKM phase is multiplied by a factor 10^-20 or so in baryon asymmetry calculations.

see for example https://arxiv.org/pdf/hep-ph/9404302.pdf

11. **Attavoir**
October 27, 2017

‘Insufficient Strangeness, Also Reality, Dooms Effort At Bizarre Equivalence’

12. **Peter Woit**
October 27, 2017

Anon,
Yes, that’s true about the CKM CP phase. What I had in mind though were things like whatever is giving neutrino mass terms (no, I don’t want to engage in the same argument over whether this is SM…) or some exotic mechanism in a cosmological model for getting larger baryogenesis. In any case that sentence was just intended to indicate the problem, not provide a complete characterization.

13. **Anon**
October 27, 2017

Hi Peter,

Yeah but the CP phase in the neutrino or leptonic sector has not yet been discovered or experimentally established. It is not a “currently known source of CP non-invariance”

Moreover, if it is experimentally discovered, and if the neutrinos are Dirac neutrinos (with no Majorana mass terms), it will be exactly analogous to the CKM phase and insufficient for Baryogenesis.

14. **Birgit Dannsmann**
October 28, 2017

Peter,

one more twist to the story. A few years ago I tried to find a reliable source for the statement that “CKM/usual CP violation is not sufficient for baryogenesis”.

I found none. I might have missed something. There is the clear possibility that this statement is similar to the famous one “Bumblebees should not be able to fly” which was all over books decades ago, and which nobody had actually ever proved or even said.

Or do you know a definite source?

15. **Marc Nardmann**
October 28, 2017

@Birgit Dannsmann:

There is an article by Huet and Schechtmann from 1994 (arXiv:hep-ph/9404302, DOI 10.1103/PhysRevD.51.379) that claims to explain why the CKM matrix is not sufficient for the observed amount of baryogenesis. I assume you saw this paper when you looked for a reliable source (it is currently Google result #3 for "CKM baryogenesis"), and found it unconvincing. Why, and what do you demand from a reliable source?

16. **Peter Woit**
October 28, 2017

All,
For a review article that has a lot about the question of relevance of SM CP violation to baryon asymmetry, see here:

https://arxiv.org/abs/1204.4186

17. **Birgit Dannsmann**
October 28, 2017

Peter, thank you for the link. The opposite view, surely a minority, is

T. Brauner – CP violation and electroweak baryogenesis in the
Standard Model- EPJ Web of Conferences vol. 70, 00078 (2014).

which seems to claim that there might be a way to explain the asymmetry with the standard model.

18. **Marc Nardmann**
October 28, 2017

[Correction: by "Huet and Schechtmann" above, I meant "Huet and Sather".]

In arXiv:1208.4607 (§5 and Figure 6), the authors argue that baryogenesis (and simultaneously dark matter) can be explained in the so-called "neutrino minimal Standard Model" νMSM, i.e. in the obvious and natural extension of the Standard Model by three right-handed neutrinos. They say that in the νMSM, the baryon asymmetry of the universe is mainly caused by oscillations of these sterile neutrinos. Hence baryogenesis can be explained without any new physics above the electroweak energy scale, but the contribution of the CKM matrix is negligible.

19. **Curious Mayhem**
October 29, 2017

There remains SM EW baryogenesis (conserving B-L, but neither separately), which requires a strongly first-order EW phase transition. No one has been able to make it work convincingly, and the observed Higgs and top quark masses make it hard. The idea has been around since the 1980s.

Extending the MSM with RH neutrinos and getting leptogenesis is also not new. It can be made to work in some models, combined with EW phase transition baryogenesis. First you get lepton asymmetry; the phase transition with the B and L anomalous currents later gets you baryogenesis.

20. **George S Williams**
November 4, 2017

Physics Today published a commentary on this- Antimatter measurement draws unjustified hype. Some of the ways 'journalism' responded to the actual story are truly creative.

Maybe this should be Next Week's Hype- The Subatomic Discovery That Physicists Considered Keeping Secret. The article is both sensational and riddled with errors.

21. **Hal Porter**
November 4, 2017

As a sometime "science/technical" writer (though definitely not focusing on particle physics), I am shocked that so many journalist underlined matter/antimatter symmetrical annhilation as some new issue. My memory may be imperfect, but I seem to remember articles in the consumer literature (Isaac Asimov, Scientific American?) discussing the anomalous existence of matter in high school (1961-65). This undoubted reality, however, was taken as merely underlining the incompleteness of our understanding of physical processes. A lot has happened since then, of course, but the basic insight hardly seems new, and was possible meant by the scientist quoted as an offhand (almost joking?) comment. Did none of the journalist ever think to give him or her a call? Fact checking? The actual experiment strikes me as an inherently remarkable achievement.

22. **Al**
November 6, 2017

Way way way off topic, but Yuri Milner of Breakthrough Prize fame has just made headlines as a Russian oligarch connected to Putin, exposed now due to huge new "Paradise Paper" leaks from Appleby, an offshore investment (read money laundering?) company."Behind Mr. Milner's investments in Facebook and Twitter were hundreds of millions of dollars from the Kremlin.", and "Among Mr. Milner's current investments is a real estate venture founded and partly owned by Jared Kushner…."–
from the NYT on Milner investments:
https://www.nytimes.com/2017/11/05/world/yuri-milner-facebook-twitter-russia.html
and here is Democracy Now on the Paradise Papers:
http://www.truth-out.org/news/item/42507-paradise-papers-millions-of-leaked-docs-reveal-shady-ties-and-tax-evasion-by-trump-s-inner-circle

23. **Al**
November 8, 2017

Along the same lines: Democracy Now (Nov 7 and 8) has a report based on the Guardian's
reports on the Paradise Papers, focussing on Robert Mercer's use of tax havens
to pay for Bannon's alt right-pro Trump propaganda,
https://www.youtube.com/watch?v=3Cpcggv4v-Y
but also on Jim Simons. They mention that Simons apparently just forced out Mercer as head of Renaissance Technologies. Here are links to the articles:
from CNBC:
https://www.cnbc.com/2017/11/07/mercer-reportedly-pushed-out-of-renaissance-by-simons.html

Quantum Theory, Groups and Representations

November 11, 2017
Categories: Quantum Theory: The Book

While I was away last week on vacation, it seems that Springer has published my book on quantum mechanics and representation theory (previously discussed in various blog posts). The Springer page is here, your institution may provide access to the content (and a $24.99 MyCopy softcover) at the Springer Link page for the book. I've retained copyright for the content of the book and a version with essentially the same content as the Springer version is available from my website here. The Springer version has their formatting, copy-editing and metadata. The Amazon webpage for the book (if you're in the mood to write a review there, feel free) is here.

I haven't yet seen a physical copy of the book, don't know how long it will take for them to start printing copies. From people at Springer I learned last year that they no longer print and store copies of such books, they're now always printed on demand (with the quality of the printing dependent on where you order your book from, German printers are quite good I hear..).

Just before leaving on vacation, I gave an introductory talk on some of the themes of the book at LaGuardia Community College (slides here). This week I'll be giving a similar talk at a math department colloquium at Queensborough Community College this Wednesday (1 pm, Science building, S-213).

Comments

   November 11, 2017

   Congratulations, Peter.

2. **Peter Orland**
   November 11, 2017

   Congratulations on finishing this project Peter.

3. **Lino D'Ischia**
   November 11, 2017

   Enjoyed your slide presentation. Very informative. Gives you a great 'bird's-eye-view' of the relation between CM and QM.

   On the slides: viewing it as a "continous" pdf, I found myself starting at the top of each slide, and not being able to focus in immediately on the 'added' portion. Watching your slide presentation may make that all go away; but, if not, then maybe the newest addition to a slide can be 'shaded,' or the older portion 'shaded.' Just a suggestion.

4. **Lino D'Ischia**
   November 11, 2017

   BTW, I've already said it, but, once again: Congratulations on your new publication!

5. **Jess Riedel**
   November 11, 2017

   Congrats Peter! And thanks especially for releasing the free version (and going through the hassle of retaining the copyright and so forth).

6. **Douglas Natelson**
   November 12, 2017

   Congratulations! I'm adding it to my list of future reading material (a list whose source term seems to be eclipsing its sink term these days, unfortunately).

7. **Peter Woit**
   November 12, 2017

   Lino D'Ischia,
   Thanks. I had intended to post the version you don't step through, just replaced the file by the intended one, should be easier for people to read through if they want.

8. **Hossein Ehteshami**
   November 13, 2017

   Nice! My university has the subscription for Springer and I ordered a MyCopy softcover version. In the receipt, I see that it is not available yet and it will be printed approximately on 16th of November. I hope soon Springer prints it and I get my copy of this nice book 🙂

9. **a reader**
   November 21, 2017

   My copy of your book got delivered this morning – here in Denmark. It looks very nice. Congratulations!

10. **Peter Woit**
    November 21, 2017

    a reader,
    Thanks! I also got a bunch of copies late last week, was pleased to see how the actual physical books turned out.

Where the Money Comes From

November 11, 2017
Categories: Uncategorized

Since returning from a vacation partly spent isolated from the internet, I've been catching up and noticed that some of the most prominent sources of funding for math and physics research have been making the news:

- The New York Times and other sources have extensive reports based on leaked records from an offshore law firm that specializes in helping you avoid inconvenient US tax and reporting requirements. The story starts out with the example of Jim Simons, who has become the largest non-governmental funder of math and physics research. His Simons Foundation has been doing an excellent job of providing such funding. They have about \$3 billion in assets, annual income of around \$500 million. The Times reports that Simons (with a net worth of about \$18.5 billion) has an offshore version of the Foundation, the Simons Foundation International, with assets of \$8 billion, dwarfing the onshore version.
- The assets of these Foundations are presumably largely invested in the secretive and extremely successful Renaissance Technologies hedge fund, which also is the employer of quite a few physicists and mathematicians. I've asked many people over the years, but have never found anyone who knows (or will admit to knowing) what it is that RenTech does that is so successful. A peculiar aspect of the coming age of private math/physics research funding is that no one getting this funding really knows where the money comes from.

  In other news while I was away the CEO of RenTech, Robert Mercer, was finally induced to leave. Mercer had drawn a lot of attention recently since he in recent years has been taking the opposite tack to Simons, funding institutions devoted to promoting untruth over truth (e.g. Breitbart News), achieving fantastic success last year. He also has branched out from doing whatever secretive things RenTech does to make mountains of money using computers and data, starting up a firm called Cambridge Analytica, a firm involved in secretively using computers and data to undermine democracy in the US and elsewhere. I had been wondering for quite a while what Simons thought of Mercer's activities. My understanding of highly-paid finance jobs was that your employer pays you a lot of money in return for having your full attention and devotion to not having negative stories about them come to public attention, so Mercer's continued employment was surprising. It seems that Simons finally had enough, after realizing how much damage Mercer was doing to his firm, in particular by creating a situation that would discourage many people from wanting to work there (there also was a campaign underway to get institutions to divest from investments with RenTech).

- Another high profile source of funding for math and physics, in this case for cash prizes to mathematicians and physicists, has been venture capitalist Yuri Milner, with his Breakthrough Prize organization. New prizes will be announced in three weeks at a December 3 prize ceremony (I also believe there will be an associated Breakthrough Prize symposium held at Stanford shortly thereafter). It has always been well-known that much of Milner's wealth derived from investments in Facebook and Twitter. Less well-known and recently revealed was that a major source of the funds for these investments was Russian state organizations closely tied to Vladimir Putin.
- Turning to sources of public funding, there's not very positive news about a possible ILC collider in Japan, with reports of a cutback of the proposal from a 500 GeV to a 250 GeV machine (which would still cost about $7 billion).
- Foreign policy magazine has an article discussing the proposal for a huge new collider in China (discussed here). The point of view of the article is quite critical of the idea of locating a huge new project in a country with an increasingly authoritarian regime:

  > China's next-generation supercollider will unlock secrets of the universe — and destroy the ideals of the scientists running it.

  Luckily, for another more local prominent large country with an increasingly authoritarian and xenophobic regime, the issue of a possible problem with locating an international collider project there isn't likely to come up since its leaders have no interest in funding such projects.

Comments

   November 11, 2017

   Evidently, Mercer is going to be replaced by someone else in the inner circle. I wonder what the consequences will be…

2. **CIP**
   November 11, 2017

   Hmmm? Maybe Milner's vast investment in string theory is part of Putin's plot to divide the West;-)

3. **Matt Grayson**
   November 11, 2017

   To the extent that there are Finance Koans, my favorite is "One trader goes long, the other goes short. They both make money." The point, of course, is that any trade has an entry and an exit. People always forget about the exit. The hardest part of trading is knowing when to get out of a trade, and having the discipline to get out when your knowledge or algorithm tells you to.

   I have no special insight into Renaissance, having answered "No" to the first interview question: "Would you move to Stony Brook?", but I think discipline has as much to do with their success as superior analytics.

6. **David Brown**
   November 12, 2017

   2 from Twain:
   (1) Honesty is the best policy — when there is money in it.

(2) Virtue never has been as respectable as money.

7. **Peter Woit**
   November 12, 2017

   Shantanu,
   Thanks for pointing that out, I hadn't heard about it. Quite possibly I will go out there for that. Interesting that an event covering a "scientific controversy" is being planned, with only one side of the controversy represented…

8. **Rick Angell**
   November 13, 2017

   I think Mercer is leaving his management role at Renaissance, but continuing work in their models/algo division

9. **Anonyrat**
   November 15, 2017

   Talking about funding, the Republican tax bill will make graduate tuition waivers taxable. The effect on graduate students at Carnegie-Mellon below – I imagine it will be the same for physics and mathematics students. I don't think any number of billionaires throwing in funding can/will help with this. If the tax bill passes, it will be the end of the American research university, in my opinion.

   https://www.wired.com/story/grad-students-are-freaking-out-about-the-gops-tax-plan-they-should-be/

   > "The annual stipend for a PhD student in Carnegie Mellon's school of computer science is about \$32,400. The university covers the student's \$43,000 tuition, in exchange for the research she conducts and the courses she teaches. Under current law, the government taxes only a student's stipend; the waived tuition is not taken into account. But under the GOP bill, her annual taxable income would rise from \$32,400 to \$76,234. Even factoring in new deductions also included in the proposal, the CMU document estimates her taxes would amount to \$10,209 per year—nearly four times the amount under current law. That would slash her net annual stipend by 25 percent, from \$29,566 to \$22,191."

10. **Anonyrat**
    November 15, 2017

    The Council of Graduate Schools has a worksheet (PDF) with a number of scenarios of the impact of the tax proposals on graduate students.
    http://cgsnet.org/ckfinder/userfiles/files/CGS_Tax_Reform_Scenarios(1).pdf
    or
    https://goo.gl/2qReAb

    Their main page on this topic is here:
    http://cgsnet.org/tax-reform-resources

11. **Peter Woit**
    November 15, 2017

    Anonyrat,
    There are massive, \$1.5 trillion scale public policy problems with this tax legislation (and no, I won't host a discussion of these here). I think academics are making a huge mistake to focus on this tuition issue instead of fighting the real problems. They look like they have no interest in anything beyond their very parochial concerns. The fact that universities charge Ph.D. students some often huge level of tuition, and then immediately turn around and give it back to them has always been a somewhat dubious piece of accounting. The supposed tax legislation problem for the students should be solvable if necessary (I doubt it will be) by reducing tuition numbers to zero for Ph.D. students the university doesn't collect tuition from. Yes, I'm sure this creates a secondary effect of indirect budgetary problems for the universities, but then focus should be on those.

    One thing I've been wondering about is what the current budgetary situation for physics/math research actually is. A new fiscal year has started, and as far as I can tell as usual there is no budget. The Trump budget announced earlier this year seems to have been dead on arrival but I haven't heard what the real budget for the current year is looking like.

12. **Anonyrat**
    November 16, 2017

    Assuming the desired outcome is that if a Google or Apple sponsors an employee's PhD, they don't get to pay zero tuition, then whatever tuition is charged in such cases, is the value that the Research or Teaching assistant PhD student is getting as a gift or as compensation, and tax will have to be paid.

    The Senate bill preserves tuition waiver tax deductions, while the House bill does not.

    In the meantime, both House and Senate versions of tax reform legislation would impose a 1.4% tax on investment income at private schools with endowments worth at least \$250,000 per full-time student. The tax would affect up to 70 schools and raise an estimated \$2.5 billion over a decade.

13. **Anonyrat**
    November 16, 2017

    https://www.collegeraptor.com/college-rankings/details/EndowmentPerStudent
    Columbia University with an endowment at \$337,580 per student will be subject to the 1.4% tax.

14. **Peter Woit**
    November 16, 2017

    Anonyrat,
    On the list of awful things about this legislation, the fact that my employer might have to pay a 1.4% tax on investment income is pretty far down the list.

    To the extent there are organizations or grants actually paying Ph.D. tuition, that could be a significant budgetary problem. About Apple or Google not so much. These two companies have obscene amounts of money available, should have no trouble making sure that any employees they want to pay tuition for will be able to feed their families.

15. **Anonyrat**
    November 17, 2017

Just keeping on topic about funding for math, physics, academics.

Various Stuff

November 12, 2017
Categories: Uncategorized

A few links that may be of interest. Mathematics first:

- A seminar "Lectures Grothendieckiennes" on the mathematical ideas of Alexander Grothendieck is taking place this year in Paris, and has just recently started up.
- My ex-Columbia colleague Jeff Achter is one of the authors of an unusual new math paper: Hasse-Witt and Cartier-Manin matrices: A warning and a request. The paper points out that papers of Manin at some points confused an operator and its dual, leading to potential sign errors in later papers that reference Manin's results. I'm quite sympathetic to the problem, having at various points fallen victim to similar confusions while writing my book (I hope they have all been resolved in the final version, wouldn't bet anything really valuable on it…).
- Nature has an excellent obituary of Vladimir Voevodsky, written by Dan Grayson.

On the physics side:

- The LHC has now ended data-taking at 13 TeV for the year (a recent summary is here) and will start up again next spring. The machine ended up delivering about 50 inverse fb each to CMS/ATLAS (bettering the goal of 45), of which about 45 was recorded. Results published so far typically use 36 inverse fb from previous year's data, so next year we should start seeing results based on a total 13 TeV data set of up to 80 inverse fb.
- Still no WIMPs. Frank Wilczek surveys searches for his favorite dark matter alternative here.
- At Big Think, Eric Weinstein has a take on what's gone wrong with theoretical physics over the past 40 years that I'm mostly in agreement with.

Comments

1. **Reimagine Physics**
   November 13, 2017

   Eric Weinstein's analysis is spot on. Does anyone know which Arkani-Hamed talk is he is talking about?

2. **Mozibur Rahman Ullah**
   November 13, 2017

   I liked Weinsteins bon mot – that we've ended up geometrising the quantum rather than quantising the geometric. I get that sense too, and that seems like an over-arching theme in that Grothendiecks work showed how we could geometrise number theory.

   Given that quantum mechanics was kick-started by experimental findings I do think more prominence should be given to just how far out of reach Planck-scale physics is experimentally.

   Is there any hope that improved sensitivity with LIGO might help there? after all one might suspect two black holes smashing into another might generate findings relevant to quantum gravity.

   Another point worth adding is that this desert isn't unprecedented, if one takes the perspective that science began with Greek antiquity then there was great arid period of roughly two millenia before a new constellation of ideas intertwining with the old began modern physics.

3. **srp**
   November 13, 2017

   Surprised nobody has noted the resonance between the second and third bullet points in Peter's post. Voevodsky expressed concern for exactly such problems in motivating his use of proof assistants and development of type theory.

4. **Bobito**
   November 14, 2017

   Note that the conclusion of the Achter paper is basically that the error has not caused widespread problems because most users have corrected it before using it, or not used cases in which it mattered.

5. **Pascal**
   November 14, 2017

   I find it puzzling that Eric Weinstein does not even consider new experimental discoveries as a source of progress. It's no wonder that new generations of theoretical physiscists have a hard time "making contact with physical reality" when all or almost all of the known facts about physical reality are already explained by well established theories!

6. **Peter Woit**
   November 14, 2017

   Pascal,
   Unexpected new experimental discoveries would of course change the situation, the problem is that we haven't been seeing any. In the past it is these that have been most often the source of inspiration driving theoretical progress. Now that the LHC has been running for a while without finding anything new at 13TeV, it seems all too possible there won't be energy frontier discoveries from the LHC (and anything higher energy is a long ways off). One attitude is that theory can't make progress without such input, and if you adopt that, best thing for HEP theorists to do is to change fields (lots are, going into condensed matter or quantum information theory). I think the question Eric is interested in is whether there's an alternative to giving up for now.

7. **Peter Orland**
   November 14, 2017

   "One attitude is that theory can't make progress without such input, and if you adopt that, best thing for HEP theorists to do is to change fields (lots are, going into condensed matter or quantum information theory)."

   Or, alternatively, they can try to solve hard problems in the territory of QFT, where the wise fear to tread…

8. **Douglas J. Keenan**

@Scott Marks: it didn't happen.

Breakthrough Prize 2018

November 16, 2017
Categories: Uncategorized

The Breakthrough Prizes for 2018 will be awarded at a ceremony on December 3, I believe at the usual NASA Hangar 1 in Mountain View. The next day Stanford will host the 2018 Breakthrough Prize symposium, which one will be able to watch live from the Breakthrough Prize Facebook page.

The symposium schedule is available here, and while it does not list the Prize awardees, it does appear to list the titles of the talks. From this it looks like the math \$3 million will go to a geometer, who will talk about "Geometry at Higher Dimensions". There may be several \$100,000 New Horizons Prizes for younger mathematicians, but at least one will be to an analytic number theorist, who will talk about "Analytic Number Theory in Everyday Life".

For the \$3 million physics prize, it looks like it is going to be split five ways and go to cosmologists/astrophysicists. The talks by laureates are "The Next Decade in Cosmology", "Gravitational Waves and Cosmology", "Search for Extraterrestrial Intelligence", "A New Instrument for Listening to the Universe" and "The Beginning and End of the Universe".

Update: Some details about the prize ceremony here. Perhaps there really is a problem with the public understanding of mathematics:

> This year, a total of seven \$3 million prizes will be awarded – five in life sciences, one in fundamental physics, two in mathematics.

Update: The \$3 million for physics went to the WMAP team. For mathematics, it was Hacon and McKernan. The posted titles for the mathematics prize winners were a red herring, they have been changed to "A Tour of Algebraic Geometry" (McKernan) and "Sphere Packing in High Dimensions" (Viazovska).

Comments

1. **L(s,\chi)**
   November 16, 2017

   Viazovska? (She actually could be either one…)

2. **Bill**
   November 16, 2017

   Did they really just post the talk titles? 🙂
   Horizons in math: James Maynard.
   Breakthrough in math: Simon Brendle (http://annals.math.princeton.edu/articles/11346)

3. **Trent**
   November 16, 2017

   My guess for the breakthrough is Simon Brendle too.

4. **tulpoeid**
   November 17, 2017

   From the panel discussions, "And in mathematics, we have scratched the surface of a perhaps infinite world of structure."
   By the sound of it this refers to some established recent development. What would that be?

5. **Peter Woit**
   November 17, 2017

   tulpoeid,
   I think that's just generic inspirational verbiage, could be used to refer to anything, know of nothing that it seems particularly apt for. On the other hand, the talk titles are not generic but rather specific, and perhaps Bill is interpreting the math ones correctly.

6. **Bill**
   November 17, 2017

   Another question is whether Peter Scholze would have accepted the Breakthrough prize if they haven't insulted him by offering the Horizons prize.

7. **Peter Woit**
   November 17, 2017

   Bill,

   While Scholze has never publicly explained why he turned down the money (in essence choosing just to ignore Milner-Zuckerberg and go about his business) I doubt it was because it was too little money. By turning down 100K, he ensured that they wouldn't try that again, and also wouldn't award him the \$3 million likely to come a few years later. He deserves some sort of award for this…

8. **Bill**
   November 17, 2017

   Peter, perhaps, his decision was driven by the wish to avoid this type of spectacle: https://youtu.be/eNgUQlpc1m0

9. **sdf**
   November 21, 2017

   Maybe it is wishful thinking that Scholze refused because these type of prizes are obnoxious—giving a large cheque to one person when they could be used to endow X number of fellowships, scholarships etc… I daresay this world needs more of James Simons and less of these Yuri Milner types.

10. **Anonymous**
November 21, 2017

“Geometry at Higher Dimensions”

It should be Hacon and McKernan?

11. **boris**
November 22, 2017

Gromov!

12. **Bill**
November 26, 2017

Peter, it looks like they’ve already corrected their press release. However, could this indicate that Hacon and McKernan are really the winners, sharing one prize?

13. **Peter Woit**
November 26, 2017

Bill,
I forgot to include the link to where I got that from, added it now, that source still has 7=8. The schedule refers to 5 different 2018 physics laureates, so that prize is being split. It only refers to 1 math laureate. Maybe there are others who aren’t speaking. I have no inside information, but your initial conjecture looks more convincing to me than Hacon/McKernan.

14. **Bill**
November 26, 2017

The official press release says 7=7: https://breakthroughprize.org/News/39

I understand why broadwayworld.com cares about this, but why not nfl.com?

15. **Bill**
November 28, 2017

http://smf.emath.fr/content/prix-fermat-2017

16. **AGCGDG**
December 3, 2017

2018 BREAKTHROUGH PRIZE IN MATHEMATICS AWARDED TO SCIENTISTS

CHRISTOPHER HACON
JAMES MCKERNAN

17. **AGCGDG**
December 3, 2017

New Horizons in Mathematics Prizes Awarded to Aaron Naber, Maryna Viazovska, Zhiwei Yun, and Wei Zhang.

18. **Bill**
December 4, 2017

I wonder why they don’t award 3 million to both mathematicians? (Although UCSD and Utah press releases say that their corresponding faculty member won 3 million, which does not add up to 22 million.)

Various Physics News

November 20, 2017
Categories: Uncategorized

First, two local events, involving well-known physics bloggers:

- Last Thursday I had the pleasure of attending an event at NYU featuring Sabine Hossenfelder and Natalie Wolchover in conversation. You can watch this for yourself here . If you're not following Hossenfelder on her blog and at Twitter (and planning to read her forthcoming book), as well as reading Wolchover's reporting at Quanta magazine, you should be.
- Next week there will be an event out in Brooklyn advertised as covering the Scientific Controversy over string theory. The idea seems to be to address this controversy by bringing to the public two well-known and very vocal proponents of one side of it.

For a Q and A with another well-known physics blogger, there's Tommaso Dorigo at Physics Today.

For a couple of encouraging indications that the theoretical physics community may finally be taking seriously the need to give up on failed thinking and try something new, there's

- A conference next month in Italy on Weird Theoretical Ideas (Thinking outside the box).
- An interesting talk at a recent IPMU conference by Yuji Tachikawa. I like his conclusion:

> Basically, all the textbooks on quantum field theories out there use an old framework that is simply too narrow, in that it assumes the existence of a Lagrangian.
>
> This is a serious issue, because when you try to come up e.g. with a theory beyond the Standard Model, people habitually start by writing a Lagrangian … but that might be putting too strong an assumption.
>
> We need to do something

In General Relativity related news, there's a new edition out of Misner, Thorne and Wheeler, the book from which many of us learned both geometry and GR. It comes with new prefaces from David Kaiser as well as Misner and Thorne (which an appropriate search on the Amazon preview might show you…). In other Wheeler-related news, Paul Halpern has a new book out, The Quantum Labyrinth, which tells the entangled stories of Feynman and Wheeler.

Finally, also GR related, the Perimeter Institute has announced the formation of a new cosmology-focused "Centre for the Universe", funded by an anonymous 10-year $25 million donation. It will be led by cosmologist Neil Turok, who is soon to step down as director of Perimeter.

   November 21, 2017

   Has David Gross paid off his bet?

3. **tulpoeid**
   November 21, 2017

   I'm sorry if I'm missing it, and a joke explained is not a joke, but is the "encouraging indication" re Tachikawa a joke? Because his argument and conclusion sound like trying to give a little extra breathing room to susy and strings. (Although I'm not sure that string theorists have by now written down a Lagrangian, I stopped following this some time ago.)

4. **Peter Woit**
   November 21, 2017

   tulpoeid,
   Not a joke at all, although my sympathy with the point being made may come from a different origin than Tachikawa's. I do think it's a serious and important point: maybe a lot of our problem is that we're wedded to a too narrow conception of how to produce QFTs (choose a Lagrangian function, turn path integral or canonical quantization crank). Maybe the SM is the best one can do within this framework, to do better you need a wider notion of what a QFT is. One reason I stayed away from the Lagrangian formalism in my recent book was precisely because for the analysis of quantum theories in terms of representation theory, the Hamiltonian formalism is much more appropriate. Perhaps there is a representation-theoretic framework for understanding QFTs where some things become clear which are hard to impossible to see in the usual Lagrangian formalism.

   This is a question about QFTs and how to formulate them, pretty much irrelevant to string theory, which Tachikawa doesn't even mention.

5. **boop**
   November 21, 2017

   I am just a layman and picked the Tachikawa link as the one I was going to read through, and I thought it was sort of a win for string theory and was wondered too what you would think. On slide 29 they say "where genuinely N=3 theories were found, using string theory." I took that to mean this was one of the first theories found to break the lagrangian view and so maybe it was a nice, as you sometimes allow, mathematical use of strings.

6. **Peter Woit**
   November 21, 2017

   boop,

All sorts of interesting QFT phenomena have turned up when people have been looking into questions coming out of string theory. Categorizing new ideas as to whether they're "a win for string theory" or not is just reducing everything to uninteresting ideology and sloganeering (and to his credit, Tachikawa isn't doing this).

The actual example Tachikawa gives here (an N=3 4d SUSY QFT) is a rather complicated one and doesn't look in and of itself very interesting. More interesting is the question of finding new ways to identify and study such QFTs. Sure, you may be able to find them by string theory methods, but people have been trying that for a long time. If you could find other, more insightful, methods that would be more promising.

7. **neil**
   November 21, 2017

   The paragraph describing Sci Con #13 reads like it could have been written in 1994.

8. **vmarko**
   November 22, 2017

   I'm slightly confused by all the noise regarding Lagrangian formalism. I don't see anything really fundamental in using (or not using) a Lagrangian — it's just a piece of mathematical formalism, convenient for some purposes, and less so for other purposes.

   The question whether a Lagrangian for a given theory exists can be answered in a pretty trivial way. Given any set of partial differential equations (that describe your classical field theory), one can always construct a Lagrangian to reproduce those equations by extremizing the action. Just write the Lagrangian as the LHS of your differential equation times a Lagrange multiplier, and you're done. Of course, introducing Lagrange multipliers as auxiliary fields into the theory is the price one pays for having a Lagrangian, but this can always be done if you want to work in a Lagrangian formalism.

   So, if one can rewrite any classical field theory as a Lagrangian theory, what's all the fuss about?

   Best, 🙂
   Marko

9. **Jon Forrest**
   November 22, 2017

   I watched the video of the NYU presentation. It was very enjoyable but it was almost spoiled by Robert Lee Hotz, the white-haired interviewer. He commits the cardinal sin of interviewing, which is being more interested in showing his own cleverness than interacting with the people being interviewed. He interviews as if he's being paid by the word, and there are several times when he rudely interrupts what the interviewees are saying. Sad.

   On the other hand, both interviewees had some very good responses, and showed their way of thinking about scientific writing.

10. **Peter Woit**
    November 22, 2017

    vmarko,
    The issue is quantization. Are there interesting QFTs that are not in any known sense the "quantization" of a classical field field theory? The standard way of thinking about such things is that they're strongly coupled QFTs that don't have parameters that can be taken to some weakly-coupled limit where you do expect a usual relation to a classical field theory.

11. **kashyap vasavada**
    November 22, 2017

    Can you elaborate what you can do in QFT without Lagrangian or Hamiltonian? Do you calculate S matrix directly?

12. **Peter Woit**
    November 22, 2017

    kashyap vasavada,
    That's the problem, we don't have much in the way of methods to produce such non-Lagrangian theories. One way to characterize them would be in terms of an S-matrix. I believe this is one motivation for some of the work on amplitudes. S-matrix theory has a long history of pursuing the idea of trying to go even further, getting rid not just of Lagrangians, but also quantum fields.

13. **Urs Schreiber**
    November 22, 2017

    vmarko, not every differential equation is the EL-equation of a Lagrangian, not even locally. The obstruction is measured by the cohomology of the Euler-Lagrange complex in degree "spacetime dimension +1" (an argument that for linear PDEs was made way back by Helmholtz). Examples of non-Lagrangian QFTs are the chiral WZW model (which is "one chiral half" of a Lagrangian theory) and generally self-dual higher gauge theories. (However, these non-Lagrangian theories are thought to be holographic boundary theories of Lagrangian theories.)

    The beauty of Lagrangian field theory is that it comes with its own covariant phase space. This is really what makes rigorous pQFT tick. We are running a series on this over at PhysicsForums Insights here.

14. **vmarko**
    November 22, 2017

    Hi Peter,

    "The issue is quantization. Are there interesting QFTs that are not in any known sense the "quantization" of a classical field field theory?"

    This seems to be a completely separate issue, having nothing to do with Lagrangian formalism. You can also ask the same question for QFT's which do not have a well-defined Hamiltonian. For example, a QFT which lives on a spacetime manifold which does not have $\Sigma\times \mathbb{R}$ topology, so that you cannot introduce the foliation into space and time, and consequently no Hamiltonian.

    I don't see the existence of such QFT's to be an argument against the Largrangian or Hamiltonian formalisms.

    "The standard way of thinking about such things is that they're strongly coupled QFTs that don't have parameters that can be taken to some weakly-coupled limit where you do expect a usual relation to a classical field theory."

You mean a QFT without a well-defined classical limit, i.e. when $\hbar$ is not allowed to go to zero for some reason? While I agree that this would be an interesting object to study in itself, I don't really see how would such a QFT be relevant to realistic physics?

Best, 🙂
Marko

15. **vmarko**
November 22, 2017

Hi Urs,

Thanks for the links, I'll take a look at the PF in detail.

I don't think I understand your argument. Say I have a differential equation $D(f)=0$, and I define a Lagrangian as $L=\lambda D(f)$, where λ is the Lagrange multiplier. One of the Euler-Lagrange equations of motion will always be the above differential equation, obtained by the variation of the Lagrangian in λ. The other equations (obtained as variations in f) will give other equations involving λ, to complete the set of EL-equations. In the end the set of solutions to the system of EL-equations should be equivalent to the set of solutions of the original differential equation.

Granted, the construction above actually extends the number of fields you have in the theory, and with it the phase space structure etc., but I don't see any choice of $D(f)$ where such a construction would be impossible. What am I missing?

Note, the existence of the action is another matter, I agree that integrating the Lagrangian over some manifold may depend on the nontrivial topology of the manifold etc. so that the action may fail to be well defined in general, or may be always equal to zero or whatever. But for the Lagrangian itself I don't really see what can go wrong?

Best, 🙂
Marko

16. **lun**
November 23, 2017

The complete S matrix of quarks and gluons within QCD will teach you very little about QCD as it is really observed. An S-matrix does not make a theory, an S-matrix and a vacuum state do.
If a string theory solution low energy limit gives "a theory without a lagrangian, but with a hamiltonian and an S-matrix", I would be skeptical that configuration is "physically consistent" and that thing is a real field theory (than again, Tachikawa cannot give a definition of this)

17. **Art**
November 23, 2017

Re the NYU conversation, I thought the moderator did a fine job of accomodating a mostly taciturn Dr H. There would have been precious little conversation without him.

18. **Peter Orland**
November 23, 2017

Marko: The variational functional you propose for the diffusion equation is not bounded from below, hence pathological. Since the Lagrange multiplier and the diffusion field are independent, you can imagine that the time derivative of one is large and positive in the same region where the other field is negative. This pertains to any action of real fields, first order in derivatives.

To all: Bootstrap methods, which assume no Lagrangian have proven their value, but many of their applications (conformal field theory, integrable bootstrap) are to models for which an action or Hamiltonian is known. What isn't understood in most cases (a major exception is the Ising model's spin correlation functions in 2D) is how to relate one formalism from the other. A real problem in stat. mech. is making this connection. In a sense this means trying to reconstruct the Lagrangian/Hamiltonian field theory from the axiomatic field theory.

For example, in some bootstrap theories, we know some or even all of the form factors, hence something about correlation functions. Getting the equations of motion, much less the Lagrangian from this is hard (one of my own research goals is to reconstruct the Lagrangian from exact form factors for the large-N principal chiral model. This doesn't make my life easy).

If we were lucky enough to get a nice bootstrap/axiomatic theory of QCD, there would remain the question of whether it is REALLY QCD. On the other hand, it is not clear we should care, at least as far as phenomenology is concerned.

19. **Andy**
November 24, 2017

"For a couple of encouraging indications that the theoretical physics community may finally be taking seriously the need to give up on failed thinking and try something new"

The titles of the more formal talks at the Italy conference look to me like just more of the same old failed thinking, only not of the mainstream variety.

20. **vmarko**
November 24, 2017

Peter Orland,

"The variational functional you propose for the diffusion equation is not bounded from below, hence pathological."

I never mentioned the diffusion equation, but regardless… The requirement that the Lagrangian be bounded from below is something one may or may not care about, but there is nothing pathological about it. The scalar curvature in the Lagrangian of GR is not bounded from below either, but I wouldn't call the Einstein-Hilbert action "pathological" in any sense. Another example would be a BF theory, which is also not bounded from below. I could probably dig up more examples.

On a more general note, I think we need to separate the issue of the existence of the Lagrangian from issues related to the wishlist of properties we want a corresponding QFT to satisfy. The Lagrangian is a *classical* quantity, and its existence or nonexistence has nothing a priori to do with quantization. And even if one is predominantly interested in quantization itself, I don't see why the non-existence of a classical Lagrangian would be of any benefit to the construction and analysis of QFT's.

The only statement in this thread so far that makes sense to me is from Peter Woit, arguing that a QFT with no well-defined classical limit may have no Lagrangian associated to it. But such QFTs are hardly relevant for physics, I cannot think of a situation where such a QFT would be in any way connected to the real world. So interesting mathematics aside, why study those in the first place?

Best, 🙂
Marko

21. **Peter Orland**
November 24, 2017

"The scalar curvature in the Lagrangian of GR is not bounded from below either, but I wouldn't call the Einstein-Hilbert action "pathological" in any sense. "

Quantum gravity (even with a UV cut-off) IS pathological with signature ++++. Not with signature -+++. There were fights over this very issue by quantum gravity people (which I watched from the sidelines) in the eighties. Hawking was arguing that the right analytic continuation could be used to make sense of ++++, but other quantum gravity types appeared unconvinced.

If an action is unbounded from below, there is generally no ground state in the quantum theory. Exceptions are situations where the phase space volume around minus infinity is small enough (like the hydrogen atom).

22. **vmarko**
November 24, 2017

Peter Orland,

I'd say that the "pathology" of the Lagrangian which is not bounded from below is actually a shortcoming of the possible QFT description, rather than the shortcoming of the Lagrangian itself. In other words, the quantization of such a Lagrangian cannot be done within the framework of QFT — which is a problem of QFT, not of the Lagrangian. There are other quantization frameworks out there…

In particular, the existence of the ground state is one of the "wishlist" things that one may or may not care about when one discusses QFTs, in particular perturbative QFTs. Another example would be the lack of a unique ground state in QFTs in curved spacetime. If anything, these are shortcomings of the perturbative QFT formalism — if you require minimum energy in the theory, or a global Poincare symmetry of the background spacetime, you simply limit yourself to a certain subset of theories where these properties can be satisfied, while the theories where these properties cannot be satisfied (such as GR) become out-of-scope for your QFT description. That's why nobody really expects quantum gravity to be a QFT, nor (as a consequence of QG) does anybody expect that QFT should be a fundamental description of nature. Today people are slowly getting disenchanted by QFTs and start talking more and more about *effective* QFTs, with the understanding that a QFT is just an approximate description of reality, while at a fundamental level there should be some non-QFT type of theory.

But all this has nothing to do with the existence of the classical Lagrangian, given some classical differential equations of motion. It is a completely separate issue, and should be kept separate, IMO.

Best, 🙂
Marko

23. **Peter Orland**
November 24, 2017

Well, I don't understand why unstable Lagrangians are useful, even classically. The problem goes beyond quantum mechanics. Maybe there are some weird examples where you never worry the instability, but you are messing with foundational stuff here.

If you allow actions to be unbounded from below, you are inviting all sorts of trouble, unless you have a parameter to squelch the instability (like a small value of 1/N, some Sobolev inequality removing the instability, etc.).

Invoking effective QFT's seems like a red herring. No matter what the more fundamental theory is, it had better be consistent. Theories without ground states aren't. Even serious axiomatisists (Streater and Wightman, for example) demand a ground state. S matrix theorists (if there are any still out there) do too; there is a vacuum associated with no particles.

24. **Urs Schreiber**
November 24, 2017

vmarko,

the proposal you make (if I follow what you mean) does not just add more fields and field equations, but it leads to a different phase space structure and hence to inequivalent field theories. Consider this for the simple case of the free real scalar field. Your prescription does not just yield a second field (your would-be "Lagrange multiplier") which has EOMs of a second scalar field, but the canonical momentum of the original field now becomes the derivative of the "Lagrange multiplier" field and vice versa. Hence the resulting field theory is not the original field theory plus extra stuff.

25. **vmarko**
November 25, 2017

Hi Urs,

Ok, in general, if your original equation cannot be derived from a Lagrangian on its own, I don't know how can you construct a Hamiltonian, nor the phase space. In that case, the phase space structure coming from my proposed Lagrangian is as good as any, since it has nothing to compare to.

On the other hand, in the case of the real scalar field that you mention, there do exist "traditional" Lagrangian, Hamiltonian and phase space, and can be compared to the Lagrangian I proposed. In that case, the EL-EoMs give rise to the original EoM for the scalar field plus another EoM for the multiplier, and the corresponding phase space structure indeed appears different than the original one. However, I suspect that there is a canonical transformation that will restore the usual canonical variables describing two noninteracting scalar fields. Therefore, the "traditional" classical theory is a subset of the new theory, since I merely added one more scalar field which does not interact with the original one. After that, quantization gives you the standard quantum theory for the old scalar field plus the new auxiliary scalar field. So the procedure merely extends the theory, without changing any physics of the old theory.

But the main advantage of the approach I propose comes about when the original differential equation does *not* have a well-defined Lagrangian (and consequently the Hamiltonian and the phase space, constructed from the Lagrangian in the standard way). In that case, my point is that one can still manage to define a Lagrangian, at the expense of introducing an auxiliary degree of freedom. In my eyes, having a Lagrangian is an advantage of that approach.

Anyway, these days it is common practice for physicists to introduce new auxiliary fields whenever they please, it's not a controversial step to make, IMO.

Best, 🙂
Marko

26. **Mozibur R Ullah**
November 27, 2017

I too thought the interviewer did a great job in getting a conversation going, I didn't notice that he was particularly hogging the conversation or being overtly 'clever', and as he points out right at the beginning Dr H is jet-lagged, hence taciturnity.

I'm a little disappointed that the conference calling for 'new thinking' doesn't mention causal nets which I find interesting, because (apparently) it admits Presentism as well as general covariance, which on the face of it, seem to be at odds.

27. **Urs Schreiber**
November 29, 2017

Dear vmarko,

I do see your point. But I still want to caution that a field theory is more than its equations of motion, and that in this respect the sectors of field theories that you propose are peculiar, to say the least.

The point about phase space structure that I made above in the example of the free scalar field applies more generally: In your proposal to consider Lagrangians of the form L = lambda P[phi] for P any given differential operator on a field phi, the canonical momenta of phi end up involving the would-be "Lagrange parameter" lambda, and conversely. Specifically in the case that P[phi] is linear, then the canonical momenta for phi are proportional to (derivatives) of lambda and independent of phi.

This in turn implies that the propagators between the phi-s are trivial, because these come from the Poisson bracket pairing.

So if you consider, for linear PDE P, the Lagrangian L = lambda P[phi] and then restrict attention to observables involving only phi, not lambda, then the theory looks entirely like the classical field theory defined by P[phi] = 0.

While I agree that one can consider this situation, its peculiarity makes it be not a counter argument to the claim that it is a special property of a field theory to be Lagrangian, i think.

Notice the similarity between your proposal and the very issue of the non-Lagrangian chiral WZW model ("self-dual boson" in the abelian case, the 2d toy version of that (2,0) superconformal 6d self-dual higher gauge theory that is discussed elsewhere):

Here one may start out with the Lagrangian field theory in 2d that turns out to split into two chiral halfs and then observe that each chiral part is a viable quantum field theory in itself (current algebra). Now even though there is a Lagrangian around which gives the two chiral halfs together, possibly suggesting to regard the other half as an "auxiliary field", the point is still that either one by itself is not Lagrangian; and this is what makes self-dual higher gauge theories and their holographic/boundary relation to Chern-Simons theories interesting.

Theorists Without a Theory

November 24, 2017
Categories: Favorite Old Posts, Multiverse Mania

I had been intending to write something here on the blog about this essay by George Ellis, so when I was contacted by someone at Inference about writing a letter in response, I did so for publication there. It has now appeared in their latest issue, with the title Theorists Without a Theory.

The topic is one I've addressed here all too often, but the main point I was trying to make is perhaps a new one. When I was writing here about the controversy over inflation one thing that struck me was that the pro-inflation side was responding to arguments that their theory didn't solve the problem it was supposed to by in effect saying "the real theory is much more complicated" (see the paragraph beginning "Besides our disagreement…" on page 3 here). One way of seeing part of what is going on here is that most of what gets advertised as "theories" of inflation are actually more appropriately described as toy models. They involve a single inflaton field with a simple potential and unknown couplings to matter, intended as a toy model for the real theory (which will have lots of fields, complicated potentials and specified couplings to matter). An aspect of the controversy is one side pointing out that this theory doesn't solve problems it is supposed to solve, with the other side arguing that it's just a toy model.

People sometimes note that there's a terminological problem with "string theory", in that the public is often told that "theories" are solidly tested parts of science, which is not true in this case. The actual usage among physicists is different though, with "theory" often used to mean a specific mathematical model or set of models, with no implicit claim of a successful experimental test. A lot of the problem with the usage "string theory" is that no one knows what the actual theory is: it's a conjecture that a theory with certain specific limits exists. The main point I was trying to make in this piece is that to a large degree the arguments over the scientific status of string theory (and of its supposed landscape and multiverse) revolving around its lack of testability are moot, since the underlying problem is something different: that there is no real theory to argue about. String theorists often try and evade this problem by a terminological shift: string theory is not a "theory", it's a "framework". "Framework" is a much more ill-defined term than the already ill-defined "theory". A theorist who says "I have a framework, not a theory" is actually saying nothing more than that they are a theorist without a theory.

Comments

1. **Reader297**
   November 24, 2017

   Genuine question, out of pure curiosity: From this perspective, would you consider "the old quantum theory" to have been a theory? (https://en.wikipedia.org/wiki/Old_quantum_theory) Or a collection of "toy models"? Or a "framework"? Clearly it played an important historical role in the eventual development of what became the standard Dirac-von Neumann formulation of quantum theory.

   Obviously the analogy with inflation is not perfect. No analogy ever is. But there are some interesting parallels. (And, for the record, I'm asking solely about the analogy with inflation, which is connected with experiments and observations. I'm not attempting to create an analogy with string theory.)

2. **Peter Woit**
   November 24, 2017

   Reader 287,
   I honestly don't know what a "framework" is, it's a term that as far as I can tell only gets used in theoretical physics as part of bogus arguments about string theory vs. QFT.
   The old quantum theory was a theory, albeit an incomplete and inaccurate one, although one that was clearly capturing part of the story because it gave very non-trivial predictions that were close to observed results in some cases. I don't see any relation of that story to string theory, and little if any to usual inflation models.

3. **Reader297**
   November 24, 2017

   Granted, it was way easier to do arbitrarily many replicable measurements of small systems than of the whole universe! But we do have a lot of cosmological data. Am I wrong in thinking that inflation can give an explanation for many of these data points, including the scale-invariance of fluctuations in the CMB, and all within basically standard GR plus some scalar fields and small quantum corrections?

   I'm also rather curious about whether you have an opinion about where inflation stands. Perhaps you've maintained a wise level of ambiguity! But do you feel inflation is on par with string theory in terms of being not even wrong, disconnected from experiment, and a wrong direction that people should turn away from?

4. **Alan**
   November 25, 2017

   So what's the way forward? We know Prof. Ellis doesn't think naturalism is the final framework (I've read some of his eloquent writings on this) and some multiverse proponents think naturalism *is* the right path. Therefore … ?

5. **Peter Woit**
   November 25, 2017

   Reader297,
   I don't think that problems with the theory of inflation are anywhere near as severe as the situation with the complete failure of string theory as a unified theory. Looking at the arguments discussed in the posting linked to above, the situation is complicated and I'm well aware I'm not a cosmologist.

   Sometimes inflationary theory proponents claim evidence for a theory that will produce a multiverse and different physics in each universe. I think it's important to point out that when they do this, they don't have an actual theory that does what they claim, certainly not a testable one. If you look into such claims, they rely upon failed ideas from string theory.

6. **Peter Woit**
   November 25, 2017

   Alan,
   I don't think any of this is relevant to debates over "naturalism" and theology. If you're looking for answers to such questions in theories of inflaton fields, I think you're making a category mistake.

   As for people who claim that they're furthering the cause of naturalism by promoting an untestable scientific theory based on a failed research program, justified by appeals to authority, I think they're making a really huge mistake. If you make this an argument about which untestable idea one should believe, most people are going to quite sensibly chose the church of their ancestors over Lenny Susskind.

7. **Alan**
   November 27, 2017

   Thanks for reply Peter. I was hoping some might take up the baton a bit. I'm really hoping one day for something really meaningful through and through (and I have a physics degree) and see little in the multiverse (though never understood it to be a reaction against theological issues) that impacts on my (irreducibly meaningful) dot of an existence. I smiled at your last point. Best.

8. **NoviceAsAlways**
   November 27, 2017

   The 'String Hypothesis' then! Would that be a fair assessment?

9. **Curious Mayhem**
   December 1, 2017

   Inflation is a real theory, implemented as a series of toy models, but generalizable to more complex models. It's exactly like gauge theory in the 1960s: a great general idea, implementable in an infinity of working models, waiting for specific implementation consistent with observation.

   Inflation is compatible with different "patches" of spacetime having different symmetry breakings. What that has to do with the string "multiverse" has never been clear to me.

   Anyway, inflation, unlike strings/M-theory, provides an economical explanation for a series of otherwise "accidental" observations and makes a general prediction for the form of the primordial fluctuation spectrum that so far is in good agreement with observation. It's a pretty successful idea. It's doubtful we'll ever have a fully detailed theory of it, however, because it applies to regime we'll probably never have access to, like evolutionary biologists trying to figure out how life originated. But who knows?

A Physicist's Physicist Ponders the Nature of Reality

November 28, 2017
Categories: Uncategorized

Quanta magazine has an interesting new piece up, an interview of Witten by Natalie Wolchover.

One topic covered in the interview is the question discussed in a recent posting, that of whether a different formulation of QFT exists, one not based on a choice of Lagrangian. Here Witten is non-committal, leaning to the idea such a thing might exist only in special cases:

> Now, Nati Seiberg would possibly tell you that he has faith that there's a better formulation of quantum field theory that we don't know about that would make everything clearer. I'm not sure how much you should expect that to exist. That would be a dream, but it might be too much to hope for; I really don't know…
>
> I find it hard to believe there's a new formulation that's universal. I think it's too much to hope for. I could point to theories where the standard approach really seems inadequate, so at least for those classes of quantum field theories, you could hope for a new formulation. But I really can't imagine what it would be.

The standard example of where such a formulation might be needed is the 6d superconformal (2,0) theory, about which Witten says:

> From the (2,0) theory's existence and main properties, you can deduce an incredible amount about what happens in lower dimensions. An awful lot of important dualities in four and fewer dimensions follow from this six-dimensional theory and its properties. However, whereas what we know about quantum field theory is normally from quantizing a classical field theory, there's no reasonable classical starting point of the (2,0) theory.

About the current state of M-theory, there's this exchange:

You proposed M-theory 22 years ago. What are its prospects today?

> Personally, I thought it was extremely clear it existed 22 years ago, but the level of confidence has got to be much higher today because AdS/CFT has given us precise definitions, at least in AdS space-time geometries. I think our understanding of what it is, though, is still very hazy. AdS/CFT and whatever's come from it is the main new perspective compared to 22 years ago, but I think it's perfectly possible that AdS/CFT is only one side of a multifaceted story. There might be other equally important facets.

What's an example of something else we might need?

> Maybe a bulk description of the quantum properties of space-time itself, rather than a holographic boundary description. There hasn't been much progress in a long time in getting a better bulk description. And I think that might be because the answer is of a different kind than anything we're used to. That would be my guess.

Are you willing to speculate about how it would be different?

> I really doubt I can say anything useful. I guess I suspect that there's an extra layer of abstractness compared to what we're used to. I tend to think that there isn't a precise quantum description of space-time — except in the types of situations where we know that there is, such as in AdS space. I tend to think, otherwise, things are a little bit murkier than an exact quantum description. But I can't say anything useful.

The hope of 22 years ago was that it was non-perturbative string theory which would provide the desired "description of the quantum properties of space-time itself". Over the years though studies of gauge-gravity duality have moved away from the use of string theory to provide this bulk description. Witten's take on the current situation: "There hasn't been much progress in a long time in getting a better bulk description. And I think that might be because the answer is of a different kind than anything we're used to." seems reasonable.

It's interesting to hear that Witten was going back to Wheeler to see if he had any inspiration to offer the current "It from Qubit" program. This requires a patience for the "vague but inspirational" that Witten has more of these days than he used to:

Why do you have more patience for such things now?

> I think when I was younger I always thought the next thing I did might be the best thing in my life. But at this point in life I'm less persuaded of that. If I waste a little time reading somebody's essay, it doesn't seem that bad.

This patience is not infinite though: among Witten's many admirable qualities are the way he responds to:

Do you have any ideas about the meaning of existence?

> No.

Comments

1. **Davide Castelvecchi**
   November 28, 2017

   What does it mean for a theory to not have a Lagrangian? That its solutions do not satisfy a variational principle?

2. **Peter Woit**
   November 28, 2017

   Davide,
   From one point of view a QFT, like any quantum theory, is some algebra of operators acting on some state space, perhaps with some interesting group acting by automorphisms on the algebra. The usual way to produce such a thing is to start with classical fields, a Lagrangian and a group acting leaving the Lagrangian invariant. Then, produce matrix elements of the operators by either
   1. Computing a path integral using the Lagrangian to get the action and thus a "measure"
   2. Using a variational principle and the Lagrangian to produce an equation of motion, taking as phase space the space of solutions, quantizing by "canonical quantization", or maybe geometric quantization.

   It seems that for the 6d (2,0) superconformal theory there is an appropriate operator algebra, but no known Lagrangian that would give this algebra using 1. or 2.

Unlike Witten, I'm more willing to speculate, and very fond of the philosophy that interesting quantum systems are sometimes understandable as representations of some group or algebra, accessible via the methods of representation theory. I'd guess that there are various cases where such methods can produce representations that are not of a sort that the standard methods 1. or 2. can produce (or, that they can't produce in a conventional way: physicists may be able to expand their usual ways of doing 1 or 2 to accommodate more possibilities, and end up with something they still might call a "Lagrangian".)

3. **John**
November 28, 2017

Can anyone please explain this response to me:
"Personally, I thought it was extremely clear it existed 22 years ago, but the level of confidence has got to be much higher today because AdS/CFT has given us precise definitions, at least in AdS space-time geometries. I think our understanding of what it is, though, is still very hazy. "

It seems he is claiming M-Theory has an even higher level of confidence today than 22 years ago but then says his understanding of what M-Theory even is has become very hazy. How can you have even more confidence in something that you understand even less?

4. **Peter Woit**
November 28, 2017

John,
"M-theory" is basically a conjecture that there's an unknown theory that behaves in a certain way in certain limits. I think what he's saying is that we understand the behavior in some of these limits much better, in a way that agrees with the conjecture. Away from the limits, at a generic point, nothing people have tried has really worked, thus the "still very hazy".

One thing that I've never really understood is the often-expressed claim that M-theory is "unique", even though one doesn't know what it is.

5. **Anonyrat**
November 28, 2017

Gregory Moore's Felix Klein lectures for 2012 (PDF file: http://www.physics.rutgers.edu/~gmoore/FelixKleinLectureNotes.pdf) has the following, has the situation changed in the last five years?

Quote:

In what follows we try to explain the reasons many string theorists believe in the existence of the remarkable (2, 0) superconformal field theories. In §??? we attempt to write down with some precision the ground rules physicists use when speculating about these theories.

Mathematicians will find this discussion extremely frustrating. A mathematician could well ask: "Is this mathematics?" The answer is "No." It is not even physical mathematics. The relevant question is "Can it be turned into mathematics?"

End quote

6. **Peter Woit**
November 28, 2017

Anonyrat,
I don't think much has changed concerning what is known about the underlying theory since those lectures. There may very well be important developments I'm unaware of though. The Moore lectures give an excellent overview about what is known about this still not understood theory. See sections 6.6 and 6.7 for this.

7. **Nakanishi**
November 28, 2017

Peter,
In discussing QFT without Lagrangian, why do you neglect the axiomatic QFT, such as the Wightman theory, the algebraic QFT of Haag et al., etc. ? As a typical example, I take the 2-dimensional massless scalar field thoery: both scalar field and its dual field satisfy the 2-dim. d'Alembert equation. While if the existence of the Lagrangian is assumed, both fields cannot have independent degree of freedom so that the duality is necessarily broken, if one admits to formulate the theory in the Wightman framework, it is possible to realize the complete duality. But I, personally, prefer the Lagrangian formalism.

8. **Peter Woit**
November 28, 2017

Nakanishi,
I'm not trying to discuss what the right general framework for QFT should be (because I don't know…). I'm just noting the fact that Tachikawa, Seiberg, and Witten, very much mainstream theorists, have each been publicly discussing the idea that the standard textbook way theorists are trained to produce QFTs, by starting with a Lagrangian, doesn't produce all the QFTs they are interested in. This kind of public acknowledgement that maybe one should be rethinking the foundations of QFT, looking at different fundamental formulations than the Lagrangian one, seems to me a positive development.

9. **Dan**
November 28, 2017

Davide #1, check out Yuji Tachikawa's awesome talk slides http://indico.ipmu.jp/indico/event/134/contribution/17/material/slides/0.pdf (this was linked to a few posts back on this blog)

10. **Nakanishi**
November 28, 2017

Peter
I am just pointing out that the axiomatic approach provides us a broader framework for QFT, which is independent of Lagrangian. It is irrelevant to whether or not the three persons you quoted are "mainstream" theorists. Probably, they forget to mention the axiomatic QFT.

11. **piscator**
November 29, 2017

Interesting title. There are many ways I would describe Witten, but 'physicist's physicist' would never be one of them.

12. **Peter Woit**
November 29, 2017

piscator,
I think what was meant was “theoretical physicist’s theoretical physicist”….

13. **Low Math, Meekly Interacting**
November 29, 2017

Reportedly Sheldon Glashow already bestowed the “physicist’s physicist”title on Sidney Coleman.

The way I see Witten often described, he sounds more like some near-miraculous alien intelligence inhabiting a human body.

14. **Anonyrat**
November 29, 2017

The aforementioned slides of the talk by Yuji Tachikawa is about the unsatisfactory state of QFT, and says that axiomatic QFT is too broad and generic to carry out the calculation of the anomalous magnetic moment of the electron.

15. **ronab**
November 29, 2017

Peter,
Are you saying that there exist QFT’s that can be proven to have no Lagrangian formulation, or simply that there are some QFT’s whose Lagranian is not currently known?

(By ‘proven’ I mean at a physics level of rigor, Coleman-Mandula rigor, say.)

16. **Peter Woit**
November 29, 2017

ronab,
The conjectured 6d superconformal theory discussed here comes with a physics argument why it shouldn’t have a Lagrangian. Lacking a real definition of that theory though one has no way of knowing if, once defined, there won’t be something you could interpret as its Lagrangian.

17. **vmarko**
November 30, 2017

In principle, if you know how to write down a partition function (with sources) for your QFT, you can take the logarithm of that to get the energy functional, and then do a Legendre transformation to obtain an effective action functional. Then, assuming that $\hbar$ exists as a deformation parameter in your QFT, it will sit somewhere in the effective action — then you can study the limit $\hbar\to 0$ for the effective action, and the result can be provisionally called “classical action”. Then you define a Lagrangian as the kernel of that action.

So in cases where your QFT is defined in the language where the above procedure can be performed, eventually you end up with *a* Lagrangian. The question whether this Lagrangian is *the* Lagrangian of your QFT (in the sense that the initial partition function can be reconstructed from that Lagrangian using some quantization scheme) is of course nontrivial, and the answer usually needs to be studied on a case-by-case basis.

That’s how I’d like to understand this whole story.

HTH, 🙂
Marko

18. **GoletaBeach**
November 30, 2017

Witten is of course an exceptional researcher, but really a Physicists’s Mathematician.

Fermi… who hand built capacitors and small rolling tables for the Chicago Cyclotron, and who estimated the Trinity yield from casting torn up paper in the air just before the blast wave hit, and used the displacement in the fall to the ground.. of who Feynman said, “he was like me, only ten times better at it”… now he was a Physicist’s Physicist.

Of course, these names and qualifiers don’t really matter. But Fermi’s collected works, and his family of mentorees, dwarf in breadth and depth any other physicist I can think of, including Einstein. Good these days to remember… he mentored the only woman other than Marie Curie to win a Nobel Prize in Physics.

19. **sdf**
November 30, 2017

Resorting to saying there may be no Lagrangian is akin to saying instead of tinkering with the recipe let’s blame the pot, in my view.

Is the only justification for the “no lagrangian” business the 6d superconformal theory? Because that seems to me to be far from sufficient.

20. **Peter Woit**
November 30, 2017

sdf,
The 6d theory is one of the reasons Witten and others have started publicly asking the question of whether our usual Lagrangian-based understanding of QFT is too limited, but I think there are other reasons to be asking this question. For instance, one thing to notice about a lot of studies of 2d conformal field theory is that the way you get detailed information about these theories is by studying representations of certain infinite dimensional groups (Virasoro and loop groups). The theory may also have a Lagrangian, but this isn’t anything particularly useful for studying the theory. It may be that there’s always some way to assign a “Lagrangian” to a theory (as vmarko does above for instance), but that this in some cases won’t uniquely characterize the theory or tell you anything useful about it.

21. **Low Math, Meekly Interacting**
December 1, 2017

Probably you've already seen this, but if not: Since the interaction of cutting-edge mathematics and physics is of particular interest, the latest Quanta article about Minhyong Kim seems worth a look.

My limited knowledge of the subject would lead me to believe that something like the specific "action" principle he is searching for might relate somehow to this discussion of Lagrangians.

22. **Jeroen**
December 4, 2017

Dear Peter,

I would like to understand a bit more about 'the philosophy that interesting quantum systems are sometimes understandable as representations of some group or algebra, accessible via the methods of representation theory'.

I've read part of your book and wanted to ask whether you have ever done something with 'dualities' between different quantum field theories in the context of representation theory. For 1+1 dimensional bosonization, this seems to be well understood in some cases. The free and massless fermions and bosons are for example related to the unique irreducible representation of the Virasoro and Kac-Moody algebra's that specify these theories. I was wondering whether it is known how one can find the exact relation between the fermionic and bosonic degrees of freedom just from representation theoretic arguments, and whether it is known how this works generalizes to the massive interacting cases.

In the case of 3+1 dimensional (supersymmetric) Yang-Mills theories, the partition function can be written as a theta function. S-duality (when we look at the partition function as a path integral) then seems to be related to a 'functional Fourier-transformation' being performed on this partition function. I don't know enough about the way modular forms transform under Fourier transformations and how this generalizes in this case… I tried to read part of the notes by Edward Frenkel on the Langlands programme (though it's a bit too mathematical for me) hoping this would explain a bit more about how the representations of the original Lagrangian are transformed under this 'functional Fourier transform' into representations of the Langlands dual group that describes the S-dual theory.

I am very interested whether you ever wrote something about dualities in the context of representation theory, or if you could give me a few hints or articles in the right direction?

Many thanks.

23. **Peter Woit**
December 4, 2017

Jeroen,

What's interesting to mathematicians about these QFT dualities is that many of them don't correspond to anything well-understood in mathematics (in particular in representation theory). For T dualities there is a clear understanding of their origin (both in math and physics), which is the usual story of Fourier series and the Abelian Fourier transform.

For S dualities, you can often interpret them as part of a modular group action and thus the story of modular forms, but this is exactly where the representation theory issues get very deep and poorly understood. It's important to realize that there is a lot of mystery at the heart of the Langlands program and thus these issues. It's not that mathematicians have a simple idea about why such things should be true, and are just having trouble making things rigorous.

The geometric Langlands program and its Langlands duality is about very non-trivial structure of spaces of bundles and connections over Riemann surfaces, it was formulated partly by looking for the geometric analog of the number theory Langlands program. Witten related this to S-duality of 4d QFTs, but this just relates two different mysteries. The only conceptual explanation of the S-duality I know of is based on starting with the existence of a superconformal 6d theory, compactifying on a torus, and getting the modular group action using the torus. This explanation is yet a different kind of mystery, the existence of this 6d QFT.

So, sorry this isn't much of an answer, just an indication of how pursuing the connections between math and physics based on S-duality leads to relations between deep mysteries, but no truly satisfactory explanation of these mysteries.

24. **Peter Woit**
December 4, 2017

Jeroen,
Also, forgot to make this clear: I haven't written anything about this. In the book I wrote I decided to not try and say anything about conformal field theory. That would require a whole other volume, and it's a subject where there's already an extensive literature from the representation theory point of view, in which you likely could find discussion of cases of dualities that are well understood.

25. **Urs Schreiber**
December 5, 2017

The quick way to see that there is an issue with the (2,0)-superconformal field theory in 6d to be Lagrangian is to observe that it involves a self-dual 2-form higher gauge field B, meaning that the 3-form field strength H = dB is proportional to its own Hodge dual star H, which means that the would-be kinetic Lagrangian H /\ star H vanishes identically.

This is one example in a hierarchy of self-dual higher gauge theories which in 2d starts with the chiral boson and in 10d continues with the self-dual RR-fields. All these share the same issue with being Lagrangian, and all of them are either known or conjectured to be defined instead as the holographic boundary theory in one dimension higher which *is* Lagrangian. For the chiral boson this is abelian 3d Chern-Simons theory, for the 6d theory it is AdS7/CFT6 duality, and specifically for the self-dual higher gauge sector inside the 6d theory it is 7d Chern-Simons theory, and for the 10d self-dual RR fields there is a proposal in terms of an 11-dimension Chern-Simons theory whose fields are differential K-cocycles.

But generally, that not every field theory is Lagrangian is an old hat, this was fully understood for free field theories by Helmholtz way back in 1887. In his honor the corresponding obstruction for the general case is known today as the cohomology of the Helmholtz operator, which is one of the differentials in the Euler-Lagrange complex that controls all things variational. A good introductory discussion to these matters is in Anderson's book *The variational bicomplex*, see p. viii of the introduction.

Secret Link Uncovered Between Pure Math and Physics

December 1, 2017
Categories: Uncategorized

There's a very intriguing new article out today by Kevin Hartnett at Quanta magazine, entitled Secret Link Uncovered Between Pure Math and Physics (also a video here). It's about ideas relating number theory and physics from arithmetic geometer Minhyong Kim. He's evidently on tour talking about them, with two talks on Gauge theory in arithmetic and a colloquium talk on "Gauge theory in geometry and number theory" in Heidelberg, and a talk on Gauge theory in arithmetic geometry in Paris.

In recent years Kim has been working on what he calls "arithmetic Chern-Simons" theory. For details about this, there are papers here, here, here and here, a workshop here, talks here and here. These ideas grew out of a beautiful and well-known analogy between topology and number theory that goes under the name "Arithmetic Topology". For more about this, see the book Knots and Primes by Morishita, or the course notes by Chao Li and Charmaine Sia.

While these ideas look quite interesting and I have some idea what they're about, the Quanta story seems to indicate that Kim has something new, an idea about "Diophantine gauge theory" going beyond the arithmetic Chern-Simons business, and with potential applications to deep problems in arithmetic geometry. Unfortunately the mathematical background here is beyond me (you can try to look at Jordan Ellenberg here, and this earlier paper of Kim's), and as far as I can tell, the only source for details on the conjectured relations to gauge theory is Kim's recent talks, which aren't documented anywhere I can see.

I'm sure we'll be hearing more about this as time goes on. It joins a host of other ideas relating gauge theory and number theory (in the context for instance of the Langlands program), and promises deeper links to come between fundamental ideas about physics and about mathematics.

Update: Some personal background on this story from John Baez.

Update: More about this story here, including a discussion of the use of Kim's methods to deal with the "Cursed Curve".

Update: Reddit has a report of the Heidelberg talk here, unfortunately giving just enough information about the talk to make it sound very interesting, too little to figure out what the ideas discussed actually were. For yet more frustration on this front, Kim gave a general talk on the subject last year here with video supposedly available, but no browser I've tried can access it. I do hope we'll soon see slides, notes, a paper, something, anything, so we can figure out what the Quanta article actually was about.

Update: Kim now has a paper out explaining these new ideas: Arithmetic Gauge Theory: A Brief Introduction.

   "What I started out trying to find" was a least-action principle for the mathematical setting, he [Minhyong Kim] wrote in an email. "I still don't quite have it. But I am pretty confident it's there."

   Then shouldn't the title be "Secret Link Conjectured Between Pure Math and Physics" or even "Secret Analogy Conjectured Between Pure Math and Physics"?

   Or probably the title refers to the fact that Minhyong Kim is finally revealing/uncovering a link between pure math and physics he had in his head for a while. Then the title is a clickbait.

2. **CIP**
   December 1, 2017

   I don't know anything about the math, but I love the headline.

3. **Low Math, Meekly Interacting**
   December 1, 2017

   I thought the article was extremely interesting and clear. For whatever reason, this one grabbed me like few others of its kind. The notion that somehow there's something analogous to finding rational solutions to Diophantine equations in the way nature "finds" the classical path of a light beam is kind of mind-blowing.

4. **Yatima**
   December 2, 2017

   "Principle of Least Action now considered for use in Number Theory" perchance?

5. **Arun Debray**
   December 2, 2017

   Thanks for blogging about this!

   One question I've wanted to know about arithmetic Chern-Simons theory is: in topology, Chern-Simons theory manifests in many different ways (e.g. path integrals, 3-manifold invariants, functors out of a cobordism category), so arithmetic Chern-Simons must carry over some subset of those things into number theory. Which parts have been brought over, and how much of the rest of the story is expected to apply to the number-theoretic side?

   I know very little number theory, but looking at these papers, it looks like thus far, Kim and his collaborators have constructed the analogue of the classical Dijkgraaf-Witten action. Has there been discussion of quantizing this action? What could the analogue of functorial TQFT for this action look like?

6. **Peter Woit**
   December 2, 2017

   Arun Debray,
   Good questions. From looking at the papers a bit, there's no quantization or TQFT here that I can see, this is quite a different story than the Witten-CS QFT one. What appears is just the analog of the classical action of Chern-Simons (Abelian case), with the novelty coming from the arithmetic context,

7. **Arun Debray**

December 3, 2017

Ah, ok. Thanks!

8. **Mathematician passing by**
December 3, 2017

To me, this has much the same look as the "hype" you complain about.
I would be much more sceptical about mathematical PR: here and elsewhere, you seem surprisingly willing to accept it at face value.

9. **boop**
December 3, 2017

Baez made [a nice google plus post expanding on this]()

10. **Peter Woit**
December 3, 2017

Mathematician passing by,

I'd agree that the title of the piece is over the top, but the Quanta article on the whole I think gives a non-hyped take on a complicated story. The last section of the article both presents Kim's hopes and skepticism from others, explaining well the current situation. It is difficult for others to evaluate this right now, since Kim has not (at least in print that I know of) explained either how gauge theory ideas motivated his earlier solid mathematical results, or what the conjectured variational problem he has in mind is.

I don't think this is at all like the typical physics hype that I complain about, which generally deals with bogus claims being made about failed ideas that have been around for over 30 years, and studied in detail by thousands of scientists. Whether Kim really has something or not, we'll see, but he has a significant amount of credibility (unlike other common cases of physicists or mathematicians making non-credible personal claims for a new idea, which I tend to ignore and not bring up here).

11. **Skeptikal mathematician**
December 4, 2017

As a mathematician not working in number theory or geometry, my impression is that this is exactly the kind of hype we are used to in geometry and number theory, which has elevated these subjects to an over-inflated status, much like string theory, and has resulted in other branches of mathematics being starved of funds, and of bright minds, and going out of fashion. It is not a theorem, not even a conjecture, just a vague idea. It might lead somewhere spectacular, of course, but mathematicians are only impressed by proofs, not by speculation.

12. **Someone who used to work in number theory**
December 5, 2017

I wholeheartedly concur with the contributions from the two mathematicians. I think Minhyong Kim is an awesome mathematician, but even before his coming-out as a physics-minded number theorist, his work tended to gear towards grand programmes and sweeping conjectures. There is nothing inherently wrong with that, but we can't all be Grothendieck, dreaming up a bunch of mysterious connections and slowly working towards a grand materialization 10, 20 years down the road. And even in Grothendieck's case it didn't all quite work out as planned. The whole field of number theory, and arithmetic geometry more generally, is absolutely littered with unproven conjectures and half-fulfilled dreams, and in my humble view no-one should be encouraged to add to this castle in the sky.

As for me, I am practicing what I preach, and now working in a field where I see concrete results everyday, and where moreover I don't have to engage in mental gymnastics to justify the fact that people are giving me money for my labours.

13. **Trent**
December 8, 2017

I can access the cgp video on safari and also on my iPhone. (There are tons of interesting videos on that site too btw, so it is very much worth figuring out how to access it.)

14. **Peter Woit**
December 8, 2017

Trent,
Thanks. With Safari I at least got a frozen screen of video with the title slide, the Kim talk looks like it was about the arithmetic Chern-Simons stuff, not the more recent ideas. I can't stand the idea of trying to watch a math talk on my phone, I'm too old for that.

15. **Peter Woit**
December 8, 2017

Tried Safari again on the Kim talk, and managed to get a few screens showing later slides, which looked quite interesting. But staring at the frozen screen got old after a while. Got so desperate I tried the phone, but that doesn't work at all. This is really maddening.

16. **Bill**
December 8, 2017

On Safari worked fine for me: https://goo.gl/JtyBxu

17. **John Baez**

>
> People have looked at the quantization too; a good reference is [Analogies between knots and primes, 3-manifolds and number rings]() by Masanori Morishita.
>
> The basic idea is that the Galois group of Q is like the fundamental group of Spec(Z), since it acts as "deck transformations" of the "universal cover" of Spec(Z),

which is the spectrum of the algebraic integers in the algebraic completion of Q. Going further with this analogy, representations of the Galois group of Q are like flat vector bundles over Spec(Z), since flat vector bundles over a space correspond to representations of its fundamental group. And since Spec(Z) is 3-dimensional from the viewpoint of etale cohomology, while Spec(Z/p) is 1-dimensional for any prime p, and we have a map Spec(Z/p) -> Spec(Z), we should think of Spec(Z) as being a bit like a 3-manifold, and each prime as giving a knot in this 3-manifold.

(All this generalizes to arbitrary algebraic number fields, too.)

Since Chern-Simons theory is a topological quantum field theory involving flat vector bundles on a 3-manifold, and it gives invariants of knots and links in 3-manifolds, it's irresistibly tempting to create an "arithmetic Chern-Simons theory" that gives invariants for primes or collections of primes.

The first success of this viewpoint is that the "Gauss sum" formula for the Legendre symbol of a pair of primes can be seen as analogous to the path integral for the vacum expectation of the product of Wilson loops for a pair of knots in U(1) Chern-Simons theory, which is a Gaussian integral. Yes, the Gauss sum looks like a discretized Gaussian integral! And this vacuum expectation is basically just the linking number!

Thus, quadratic reciprocity, which says how the Legendre symbol changes when you switch the two primes, becomes the usual symmetry of the linking number under switching the two knots.

18. **David Roberts**
December 21, 2017

MK has a new paper out, on this: "Arithmetic Gauge Theory: A Brief Introduction", arXiv:1712.07602

19. **Urs Schreiber**
December 21, 2017

There are more such analogies:

1) the differential geometric analog of Artin L-functions is clearly the Ruelle/Selberg zeta functions;

2) the Ruelle/Selberg zeta functions are known (I, II) to serve to express both Reidemeister torsion as well as the eta invariant;

3) these are of course the factors in the perturbative Chern-Simons quantum invariant (here).

Under this identification, all the zeta-. eta-. theta-, and L-functions in physics and number theory fit neatly into a dictionary.

Scientific Controversy No. 13

December 2, 2017
Categories: Uncategorized

I made the mistake yesterday evening of spending it out in Red Hook, at an event billed as addressing the scientific controversy over string theory. The venue was an arts space called Pioneer Works, the brain-child of artist Dustin Yellin (whose formative early experience with physics is described here). The event was sold out (tickets were free, courtesy of the Simons Foundation), and drew a huge crowd of several hundred, mostly twenty-something Brooklyn hipsters.

The guests brought in to discuss the controversy were David Gross and Clifford Johnson, and the moderator was Janna Levin. Levin began the discussion by asking the two of them where they stood on string theory: pro, con or agnostic? This flustered Gross a bit (he's one of the world's most well-known and vigorous proponents of string theory) and Levin somehow took this as meaning that he was agnostic. Finally Gross clarified things by saying something like "I've been married to string theory for 50 years, not going to leave her now".

Things then moved on to the usual well-worn hype about GUTs, string theory and unification. The LHC made a quick appearance, with no mention of falsified string theory "predictions" of supersymmetry. Instead Johnson characterized the discovery of the Higgs as somehow a vindication for this unification program. Gross went on to explain that unfortunately testing string theory requires going to the Planck scale where strings would be obvious, but that this was out of the question with any conceivable technology.

Besides being immune to experimental test, Gross also described string/M-theory as not a theory at all, since we don't know its equations or principles (according to him, it's a "framework", see here). The conversation then degenerated into a long and meandering discussion of the black hole information paradox (to her credit, Levin countered Gross's claim that string theory successfully explained it by reminding him of Polchinski and the firewall business).

The Q and A session consisted of a series of mostly crackpot questions from the audience. Johnson responded to a woman saying she thought that we were oscillating between two universes by telling her that she could see she was wrong by testing her theory. The sudden appearance of testability as a criterion to shoot down vague ideas surely confused her.

On a positive note, neither Johnson nor Gross were interested in promoting the multiverse, and the audience was spared that.

Johnson has a new book out called The Dialogues, written in graphic novel form. My previous experience with him was a rather unpleasant one more than ten years ago, after the publication of my book. He wrote a long sequence of blog posts about what he called the "Storm in a Teacup", attacking Smolin and me and our books. Attempts to discuss the issues involved with him in the comment section there were confusing at first, until things finally became clear when he explained that he was refusing to read my book or Smolin's. Dialogue about science was not something he seemed interested in if it involved uncomfortable criticism of string theory.

His book addresses this controversy with a panel in which the physicist figure explains:

> Frankly, that's mostly driven by the press, and a few attention-seeking individuals. Most people have a more nuanced view… It just does not sell newspapers or books.

On the question of "attention-seeking", one might want to consult Johnson's forty-plus long series of blog postings about his participation and appearance in TV and movie programs. As far as books go, in an end-note for this panel Brian Greene's *The Elegant Universe* is recommended. After the Q and A, a long line formed for people to hand their credit cards over to an assistant, then get a copy of Johnson's book and have it signed.

Comments

1. **Richard Gaylord**
   December 2, 2017

   your view of Johnson seems clear (it's not favorable). can you give us review of Johnson's book?

2. **Peter Woit**
   December 2, 2017

   Richard Gaylord,

   I did at least read it (granted, that only took about 15 minutes), but, no, I don't have any interest in writing a review. For one thing, I've no interest in the graphic novel format. I stopped reading comics when I was about 12, other than some R. Crumb never picked one up after that. If you do like graphic novels, from the blog entries at his blog you can probably figure out if you'll like this one.

3. **Bee**
   December 3, 2017

   Why didn't you ask a question? Or if you had, what would your question have been?

4. **tulpoeid**
   December 3, 2017

   "I made the mistake" — apparently you didn't, being there and reporting is useful, at least for those of us whose nerves couldn't have stand so.
   "It just does not sell" — does this include research grants and prestigious multimillion dollar awards?
   "The sudden appearance of testability as a criterion to shoot down vague ideas surely confused her" — this must be one of my all-time favourites on here.

5. **Mika**
   December 3, 2017

   Have you read The Elegant Universe and if so, would you recommend it (or other books by Greene) to a layperson?

6. **Hetzen**
   December 3, 2017

   After barely managing to finish The Elegant Universe. I felt if I was being told the same sentence over and over without being any the wiser on what it was. It was me walking away dissatisfied with that book that made me find Peter Woit's and subsequently finding this blog.

7. **Peter Woit**
   December 3, 2017

   Bee,
   I considered it, but decided not to try for several reasons, including a distaste for people using question sessions to put forward their own agenda, the fact that, whatever Johnson thinks, I'm rather the opposite of attention-seeking, and listening to this had left me disgusted and depressed. Thinking back on it, I still don't see how a serious counter-argument could have credibly been made by joining the line of people intent on airing their crackpot ideas.

   On the other hand, alerting the Simons Foundation about how their money is being used might be a good idea…

8. **Peter Woit**
   December 3, 2017

   Mika/Hetzen,
   The mention of The Elegant Universe was just there since it made clear that Johnson was not criticizing pro-string theory books, I don't want to start a discussion of it here. But yes, of course I've read it, and one motivation for my own book was the feeling that the public then, as now, deserves to hear both sides of a debate

String Theory Fails Another Test

December 6, 2017
Categories: Uncategorized

Back in 2004, the KITP put out a press release (which I wrote about in an early blog post here) announcing that "Newly Devised Test May Confirm Strings as Fundamental Constituent of Matter, Energy". The press release announced that Polchinski and collaborators had found "the most viable test to date for determining whether string theory is on the right track", that this test would be performed by LIGO, which "could provide support for string theory within two years."

This got a lot of attention and was often quoted as evidence that string theory was testable science. In a 2007 article in Physics World, David Gross answers string theory critics with:

> String theory is full of qualitative predictions, such as the production of black holes at the LHC or cosmic strings in the sky, and this level of prediction is perfectly acceptable in almost every other field of science," he says. "It's only in particle physics that a theory can be thrown out if the 10th decimal place of a prediction doesn't agree with experiment."

LIGO never found any evidence of cosmic strings within two years after 2004, and now the vastly more sensitive Advanced LIGO experiment has just released results of a search. As expected, the results are negative.

Any guess on the probability of a KITP press release announcing that string theory has failed an experimental test? Or of an acknowledgement by Gross that all the "qualitative predictions" of string theory he was using to justify it ten years ago have now all failed, so, by the standard of "every other field of science", it should be abandoned?

Comments

1. **Lino D'Ischia**
   December 6, 2017

   The last sentence of the abstract of the linked paper says: "Finally, we show that the data sets exclude large parts of the parameter space of the three loop distribution models we consider."

   How severely constrained are they? That is, is this just a nice way of saying cosmic strings don't exist?

2. **Peter Woit**
   December 6, 2017

   Lino D'Ischia,
   It's always the same story, talking about string theory "tests" or "predictions" is just a way of misusing words to mislead people. If that wasn't clear back in 2004, it should be clear now, after the "tests" are over and the "predictions" have been falsified. This hasn't changed the opinions of those making these "predictions" (Polchinski says string theory "over 99.7%" likely to be true, Gross last Friday said he's still wedded to the idea).

   String theory as a theory of unification predicts (in the usual scientific sense of the word) nothing about anything. You can't rule out the cosmic strings of superstring theory, because the theory is so unconstrained that you can evade any conceivable negative experimental result, by just saying, "there really are cosmic strings, it's just that their properties make them unobservable by the current version of LIGO"

3. **Verissimo**
   December 6, 2017

   Every post like this takes 30 minutes off the life of some random string theorist somewhere around the globe.

4. **Yatima**
   December 6, 2017

   I don't understand this at all.

   From the abstract:

   Cosmic strings are topological defects which can be formed in GUT-scale phase transitions in the early universe. They are also predicted to form in the context of string theory.

   Cosmic strings (which I first read about in the 80s in SciAm IIRC) have scant to do with String Theory. And even if they had been detected, this would STILL say nothing about String Theory as the implication works the wrong way.

   And maybe it would say nothing about GUTs either.

   Is elementary logic still on the program nowadays?

5. **David Appell**
   December 6, 2017

   I have the same question as Yatima — are cosmic strings the same as string theory strings?

6. **Anon**
   December 6, 2017

   A concise description of cosmic strings generated during inflation independent of string theory:

   http://www.theory.caltech.edu/~preskill/pubs/preskill-1996-vilenkin.pdf

7. **Peter Woit**
   December 6, 2017

Yatima/David,
The history is that such things were first considered (late 70s) in the context of GUTs, where you can have string-like gauge/higgs-field configurations that may be stable for topological reasons, depending on the ingredients of your GUT (this doesn't happen for the ingredients of the Standard Model).

In 2003, in arXiv:hep-th/0312067 the authors came up with some string theory models with metastable fundamental strings (using complicated configurations, along the lines of the "string vacua" that supposedly stabilize moduli). Remember, in this game of Rube Goldberg models, you can get pretty much anything you want, why not large metastable fundamental superstrings?

String theory proponents then went to work claiming that, if you found cosmic strings, and you could study them in enough detail to see whether they were GUT strings or these fundamental ones, then you would have "evidence" for string theory. The KITP press release was part of this publicity campaign, timed to coincide with publication of the 2003 paper. From then on, this regularly appeared as a "test" or "prediction" of string theory. The "could you even tell if your cosmic string was a GUT one or a superstring one?" question rarely got mentioned.

I don't see any point in wasting any time going over the details of this particular hype campaign and the supposed science behind it (probably it appears in a dozen or so of the posts on this blog). The fact that falsification of these "predictions" hasn't changed one iota the faith in string theory of the people promoting them is good reason not to take this supposed science seriously. If the people behind these ideas don't, why should you?

8. **Lino D'Ischia**
   December 7, 2017

   "The fact that falsification of these "predictions" hasn't changed one iota the faith in string theory of the people promoting them is good reason not to take this supposed science seriously."

   It stops looking like science, doesn't it?

9. **Shantanu**
   December 8, 2017

   Peter: maybe you (or someone else) should forward this or ask this question to KITP PR folks and whether string theory has been falsified?

10. **Kea**
    December 17, 2017

    The only thing that will bring down string theory is a full theory of quantum gravity that shows precisely how string theory fits into the theory as a physically-not-very-relevant piece of structure, say like bubble graphs for scattering amplitudes.

The Last Refuge of Cowards

December 6, 2017
Categories: Multiverse Mania

The talks and panel discussions from the 2018 Breakthrough Prize symposium are available via Facebook video. They ended with the following, from prize winner David Spergel:

> Well, alright, I'm going to say something that I probably shouldn't say in Palo Alto. I don't think the multiverse is a testable and interesting scientific hypothesis. I think it doesn't explain anything.
>
> The way the multiverse tends to be used is together with the anthropic principle. The idea is that the universe is the way it is because that's the way we get to live in it. I find the multiverse solutions to these problems, it's a lot like if you ask me "why am I wearing a black shirt today". My answer would be: "you wouldn't have asked the question if I wasn't wearing a black shirt". That's not a satisfactory answer.
>
> The way we have advanced in science is by falsifiability. By developing hypotheses, testing them (that's why we do experiments) and ruling things out.
>
> Ideas that are not testable, it's interesting metaphysics, perhaps interesting for philosophers. What has driven four hundred years of scientific progress is the fact that ideas can be wrong. And, the multiverse, I think is kind of the last refuge of cowards… That's why it's great to have tenure.

Comments

1. **Petero**
   December 6, 2017

   This sentence of the quote looks a bit mangled:
   By developing hypotheses, testing them, that's what why we do experiments, and ruling things out

2. **Peter Woit**
   December 6, 2017

   Petero,

   Thanks, fixed.

3. **paddy**
   December 6, 2017

   David Spergel: Bravo! Especially for avoiding hair-splitting and angels-on-the-head-of-a-pin stuff over falsifiability. We all know it when we see it.

4. **Pierre**
   December 6, 2017

   It's not even philosophy or metaphysics; that's an ignorant slur.

   Philosophers have usually engaged in metaphysics in order to ground moral arguments. That's a hell of a lot more honest, interesting, and better motivated than the tautological sleight-of-hand upon which the multiverse rests.

5. **Paul**
   December 6, 2017

   Am I correct in thinking that the Multiverse hypothesis is partly based on geometries of the String Theory?
   Would the proponents of Multiverse base their pro-position on the belief that String Theory is a proven theory?

6. **Peter Woit**
   December 6, 2017

   Paul,
   Yes.

   http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=why-do-you-describe-the-multiverse-as-pseudo-science

7. **Cookie**
   December 6, 2017

   Peter,

   Can one in principle find the correct string theory vacuum if you perform Planck scale experiments? Aren't there any generic string theory predictions you can in principle test if you can perform those ultra high energy experiments, like extra dimensions or string-like or Brane-like behavior? In principle at least?

8. **Peter Woit**
   December 7, 2017

   Cookie,
   No.

   All, enough about string theory. Spergel sensibly thought it not worth even mentioning.

9. **Cookie**
   December 7, 2017

Why not? If there's a reference you can refer me to, that would be much appreciated! I've always thought that you could in principle test things with Planck scale experiments.

10. **Casey Leedom**
December 7, 2017

Man, I am so sorry that I didn't go to see the award ceremony now. I've got to get on Stanford's Physics Seminar email list …

11. **Casey Leedom**
December 7, 2017

By the way, for those of you who want to listen to the comment that Peter quoted, it's in the "panel discussions" link at 1:25:56 …

12. **Peter Woit**
December 7, 2017

Cookie,
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=doesnt-string-theory-make-predictions-at-very-high-energy

13. **Peter Woit**
December 7, 2017

Casey Leedom,
You can't get into the actual awards ceremony unless you are a Hollywood starlet or one of our Silicon Valley overlords. The symposium I gather was open to the public.

14. **Alan**
December 7, 2017

Spergel does say about learning from "string theory colleagues" after 1h 15 minutes in relation to duality (linking the small and the large). Yet string theory implies a multiverse? All those vacua? His mention of the anthropic principle and his shirt is just the weak anthropic principle so I didn't think that was very deep.
I also think it was David Bohm who said it took 2000 years of theoretical and experimental content before Democritus' idea of atoms got confirmed. So more time needed for the multiverse?

15. **Peter Woit**
December 7, 2017

Alan,
I think Spergel is well-informed about the question of testability of multiverse models, not just some naive guy who isn't happy with anthropics.

16. **BCnrd**
December 7, 2017

Alan:

The fact that some things took 2000 years doesn't carry as much weight as it may seem to, since it isn't as if during most of that time there was a vibrant scientific community working on the task (though there was some scientific work happening during some periods outside Europe). It's sort of like when Gauss solved a 2000-year-old problem at age 19 by figuring out which regular polygons can be constructed by a straightedge and compass: definitely a landmark accomplishment, but in the intervening 2000 years between Gauss and the ancient Greeks there wasn't exactly a vibrant community of mathematicians working on that problem, what with the Dark Ages and the absence of an adequate algebraic language and so on.

And with the size of the community of scientists that has developed during the 20th century up to today, as well as the funding mechanisms (such as they are…) one can reasonably expect rates of progress to be way faster than anything during earlier centuries and epochs (though coming up with good new ideas remains as challenging as always).

17. **Philip Gibbs**
December 7, 2017

Why does he think that the universe owes him an answer that would satisfy him? Some people don't like the uncertainty of quantum mechanics because it does not satisfy them, but the universe stubbornly refuses to change its rules.

As for falsfiability, when someone has a complete theory of quantum gravity that is falsifiable and not falsified using current technology, then they can level that criticism. Meanwhile those who think multiverses of various sorts could be part of how the universe might work, probably won't stop thinking about it just because other people tell them that they don't like it for philosophical reasons.

18. **Peter Woit**
December 7, 2017

Philip Gibbs,
Where do you see him saying that? Spergel is one of the best cosmologists in the world, expert on the issue of what you can test experimentally about cosmology and how to do it. He's making the uncontroversial point that if it can't be tested experimentally it is not conventional science. His description of theorists who promote their own ideas that cannot be tested by confrontation with experiment as "cowards" (because they can never lose) is a pointed one, but it's a characterization that many if not most of his colleagues would agree with privately.

19. **tulpoeid**
December 7, 2017

It's not philosophical reasons, it's epistemological.
By the way, comparing Democritus who had to try and derive nature's law through human senses (which means arriving at a right answer merely by chance) with privileged physicists of the 21st century … should I say more?
Spergel made my day and I'll drink a glass to his health. Although it's depressing to realize that stating the obvious makes headlines nowadays.

20. **Philip Gibbs**
December 7, 2017

Last time I checked epistemology was considered a sub-branch of philosophy.

21. **The Observer**
December 7, 2017

BCnrd,

"The fact that some things took 2000 years doesn't carry as much weight as it may seem to, since it isn't as if during most of that time there was a vibrant scientific community working on the task (though there was some scientific work happening during some periods outside Europe)."

There is also an "unlikeliness" that is ignored in choosing something like Gauss's construction, after the fact, in that most of the ideas that were worked on 2000 years ago were wrong. They were so wrong that we have never heard of them. Some of them may have been so bad that they were "not even wrong". Most ideas are bad ideas. Most music is bad music. Most fiction is bad fiction. So the Gauss example has an "unlikeliness" problem, a good metaphor for the way unlikeliness plagues these wild, escapist, ideas of "physics" today.

Also, who was working on the construction of a 19 sided polynomial 2000 years ago anyway? That was not a problem that took 2000 years to solve. It was an idea Gauss had of his own and solved, presumably, very quickly. Same goes for Democritus (and Lucretius). No one spent 2,000 years trying to prove it. It was not a project of research, just speculation. Modern atomic theory didn't arise by guys who read Lucretius and decided to try and prove it. The idea rose *de novo* with the scientific investigations of the modern era. After that, it was commented that Democritus and Lucretius had come up with the idea in ancient days but they in no way founded or inspired the modern research program. There was no connection at all.

But I like Steinhardt's description of the anthropic principle.

"Yuck!" (see his Fermilab presentation of 15 months ago)

22. **tulpoeid**
December 8, 2017

Philip Gibbs,
You used uncertainty as an example. Let's say that I don't like the notion very much, but it is well proven by now. Then, I don't like it philosophically but nothing can be done about that.
On the other hand, demanding continued funding and respect on the basis that we can't dismiss what can't be either proven or falsified, speaks about a way of defining how science should work (epistemology). It's not a matter of taste and it has some very real repercussions, and this is what the post is about.

23. **Alan**
December 8, 2017

The Observer, Steinhardt may say "Yuck" in relation to the Anthropic Principle but really it's misnamed anyway and to do with the inevitability of life of *some kind* in this universe. No matter we get wiped out in a cataclysm, something else will prevail somewhere in the universe into it's far BY-old future. The question is, is this significant? Science fact essentially meets a valid philosophical question.

Peter, I don't really get that Spergel talks of learning from "string theory colleagues" and yet doesn't like the multiverse – which I thought was kind of inevitable from ST. I mean, if the multiverse is kind of forced theoretically (is it?) then is it the string theorists fault?

BCnrd, But I thought the point was well made. I'd guess many good thinkers over those 2000 years were pondering Democritus' idea on atoms and were wondering how to test it.

24. **Peter Woit**
December 8, 2017

Alan,

"String theory" now refers to a huge variety of different sorts of activities, and I think Spergel was referring to ideas about dualities, which have nothing to do with the multiverse.

About "string theory implies the multiverse" claims: string theory unification is a failed idea that predicts nothing. It is compatible with pretty much anything, including a multiverse or no multiverse.

25. **Casey Leedom**
December 8, 2017

Peter,

Thanks for letting me know about the difficulty getting into the awards ceremony. Too bad, but personally, I think I would enjoy the symposium more.

I've recently started going to a bunch of the Stanford Bio-X talks and they've been great. I have no idea why I've lived this long in Palo Alto and not taken advantage of the many and various free talks at Stanford. Oh well, better late than never I suppose.

Casey

26. **Lowell Brown**
December 8, 2017

I do not think that 2,000 years in the past has anything to do with 2,000 years in the future. On must relate past to future years by many scale factors. For example, one should divide the year by the number of scientists living in that year. And divide by the large and multiply by the small energies that can be measured. Same for distances and times. Divide by the number of communication links. Divide by the knowledge acquired in some measure. So, allowing for my crazy big factors, maybe 2,000 years in the past is 2 or 20 years in the future.

27. **Philip Gibbs**
December 9, 2017

"Multiverse" is a word that covers may different ideas in physics. Since Spergel is a cosmologist he may be thinking mostly of the multiverse version of eternal inflation. This is a very incomplete theory built on several layers of speculation. I don't favour it myself and agree with those who say that it has been overhyped. I don't think the logic in support of it is particularly good, but I accept that some version of it could be correct and don't see why others should stop thinking about it.

The multiverse idea can however also be used to refer to anything from ordinary Hilbert space in quantum mechanics up to the Mathematical Universe of Tegmark. Even the anthropic principle means different things to different people and is obviously a broad philosophical principle rather than a specific physical theory. It is easy for someone to conflate the issues by talking about the multiverse without being clear about which of these things they actually mean. A more concrete question is whether the vacuum state with the spectrum of particles we know is a unique consequence of some fundamental theory, or one of several possible outcomes whose selection involved an element of historical chance. I think this is a perfectly scientific question. It could only be answered in the context of some theory that we do not have yet. It is difficult to see how it could ever be tested or falsified directly, but a satisfactory answer may be given by a theory that is perfectly testable in other ways.

At this time phenomenology beyond the standard models is very scant and quantum gravity phenomenology is non-existent. I don't think epistemology or any other branch of philosophy can be applied to answer questions like that. The scientific method determines the soundness of the way scientists operate but it does not offer definitive answers to scientific questions. It is only right that physicists are allowed to explore all options mathematically until the observational prospect improves. Opposing philosophical principles have always played a part in the directions theorists go. Any theory of quantum gravity you could imagine would not be falsifiable while quantum gravity phenomena are inaccessible to experiment, so that kind of criticism is void.

It is sometimes argued that lack of funding and the influence of a small section of elite theorists is stopping people from exploring all the alternatives, but I suspect that if good new ideas are waiting they will be found sooner or later despite what anyone says. Everyone is free to express their opinions and explore the directions they favour, but it is not helpful to deliver polemic speeches that criticise other people for following the path they find most promising. Surely Spergle is sufficiently competent and well placed to coach his own students to help him research any direction he wants to go in.

28. **Jernej Satler**
December 9, 2017

David. Braaaavo!

29. **R LeVitt**
December 9, 2017

Well, alright, I'm going to say something that I probably shouldn't say here. I don't think the monoverse is a testable and interesting scientific hypothesis. ;^)

My point being, we have exactly zero evidence that our Universe is a singleton. The hypothesis that our cosmos is unique seems an unprovable idea with no data supporting it. As the old saying goes, "Absence of evidence is not evidence of absence." Which in my view makes the monoverse and multiverse more or less equivalent from an empirical point of view.

If I understand the problem correctly, the problem of one or many cannot be resolved by experiment. If so, theoretical ideas may give us the only hints, however tenuous.

30. **a1**
December 10, 2017

@RLeVitt: multiverse vs. monoverse, who wears the burden of proof?
Universal statements are falsifiable, existential statements are verifiable.

31. **Fabien Besnard**
December 10, 2017

I would just like to stress that there is a huge leap between saying that
1) String theory multiverse is not justified because string theory isn't,

and

2) no scientific theory whatsoever may contain reference to a multiverse.

While the first statement seems to me to be an accurate description of the current situation, I see the second one as a dogmatic position which can potentially hinders scientific progress.

32. **William Astley**
December 10, 2017

An infinite number of patches with infinite diversity possibilities is also a problem for 'inflation'.

If it is theoretically possible for there to be good inflation (Inflation is the name for the 100,000 times faster than the speed of light expansion of space by the hypothesized inflaton field immediately after the BB event) then there would also be bad inflation.

http://physics.princeton.edu/~cosmo/sciam/

"What do you mean? Inflation has two major problems: First of all, we have learned that inflation is highly sensitive to initial conditions. This is the opposite of what everyone thought originally. For example, in the 1990s, by considering different initial conditions and parameters, Linde (and others) championed models of inflation that would lead to an open universe rather than a flat universe, because, at the time, observations seemed to point that way."

"Second, we have also learned that inflation generically produces a multiverse ("multimess") of outcomes – literally an infinite number of patches with an infinite diversity of possibilities – and there is currently no criterion to prefer one possibility over another. As Guth has put it, "In an eternally inflating universe, anything that can happen will happen; in fact, it will happen an infinite number of times. Thus, the question of what is possible becomes trivial—anything is possible […] The fraction of universes with any particular property is therefore equal to infinity divided by infinity—a meaningless ratio." See, highlighted text in the Conclusion section of Guth's paper published in J.Phys. A40, 2007 (LINK). In other words, there is nothing that says that what we observe in our patch is typical or could be predicted a priori on the basis of the theory."

33. **Peter Woit**
December 10, 2017

Spergel clearly was referring to the cosmological multiverse, and I'm sure he would say that claims there is only one universe are just as unscientific as multiverse claims. And I doubt he intends to criticize theorists for working on whatever they want, the problem is when they decide to start selling untestable ideas to the public to further their agenda.

34. **R LeVitt**
December 10, 2017

@ai: My point was that neither the multiverse nor the monoverse ideas are falsifiable at present, if ever. The only existential, verifiable statement we can make is that there is at minimum one Universe.

As for burdens of proof, nature doesn't require them–and is under no obligation to make all her secrets known to us.

35. **Peter Woit**
December 10, 2017

All,
Unless you have something substantive to say about the Spergel story, please don't add to this comment section. Most attempts to argue about the multiverse do nothing but reinforce Spergel's point that nothing is being explained and we're best off without such arguments.

36. **JimV**
December 23, 2017

It is probably too late, since I just saw this post today (which is my fault), so if this comment isn't accepted so be it.

My thought on the multiverse/Anthropic answer to fine-tuning is that yes, it could promote some sort of understanding because it supplies a mechanism, and once one has a mechanism it is easier to explain a concept. Sort of like when Feynman was asked what he would like to pass on as a starting point to another civilization (or something like that) and he said the concept that matter is composed of tiny bits that are sticky when close together (or something like that). That example is not completely on-point because it's true and can be tested, but just the availability of the multiverse idea is, to me, sufficient to counter fine-tuning arguments. It demonstrates that there is another logically-possible alternative, whether that alternative is testable and/or true or not.

And I like to have a mechanism. It makes things so much clearer if I can see how something could occur even if I don't know whether it occurs. So I'm glad the multiverse concept exists. Granted, we always should preface such speculations with "I don't know if this is true", but isn't it fun to speculate?

This Week's Hype/Fake Physics

December 11, 2017
Categories: Fake Physics, This Week's Hype

On the Fake Physics front, Jerry Coyne at Why Evolution is True has a post claiming New evidence for the multiverse-and its implications. You would think that recent history should have made clear the danger of using Youtube videos as a reliable source of information, but this posting is based mainly upon a Youtube video, one that claims Evidence for a Multiverse in NASA and ESA Satellite Data? (Coyne seems to have missed the question-mark).

As usual, a large part of the problem here is people looking for material helpful to their arguments, without worrying much about whether the material is accurate or not. In Coyne's case, he wants to counter the theological fine-tuning argument with the multiverse counter-argument, which requires a multiverse with a wide variety of different physical laws. The Youtube video he found makes the standard tenuous argument that the CMB provides evidence for inflation, inflation should be eternal, thus there should be a multiverse. As I explained in detail here, the models of inflation one supposedly has "evidence" for are not models that lead to the kind of multiverse of different physical laws that Coyne needs for his argument with religion.

I should make it clear that I'm on Coyne's side in the argument of evolution vs. religion, but scientists arguing on the basis of science should take care that they're using good science if they don't want to discredit themselves. And, as a general rule for anyone who cares about what's true and what isn't, looking for things on Facebook or Youtube that help your side of an argument is now an extremely bad idea.

The question of how to stand up for truth in a post-truth era was the main topic of this year's Nobel Week Dialogue (video here). David Gross gave a rousing and inspirational talk on Truth and the Scientific Method (starting about 36:30), which ended with the assurance that "Science will survive Donald J. Trump and his ilk", because of its rigorous honesty and grounding in experimental testability. Gross is someone well-aware of the multiverse Fake Physics danger, although he didn't mention it. I'd feel a lot better about his Stockholm talk though if I hadn't just recently attended this disturbing one.

Update: Some more fake physics today, from the Russians, courtesy of Sputnik News. See here for propaganda about "a testable theory on how matter behaves inside a black hole" which is also supposed to describe quark-gluon plasmas at the LHC and RHIC . This is all based on this paper, which has no such thing.

Comments

1. **Daniel Tung**
   December 11, 2017

   Regarding the part of your Inference article on inflation and multiverse, isn't it that eternal inflation itself, without any input from superstring theory, already implies the idea of multiverse? This is also why Paul Steinhardt and a few others oppose it so strongly.

2. **Peter Woit**
   December 12, 2017

   Daniel Tung,
   In my article I was trying to point out that actual models of eternal inflation being advertised on this Youtube video and elsewhere are single inflaton field models with a simple potential, which produce a multiverse of universes with the same physics. To get a multiverse of universes with different physics, you need something much more complicated, and this is where string theory gets brought in.

   Steinhardt's objections to eternal inflation were discussed in detail here
   http://www.math.columbia.edu/~woit/wordpress/?p=9289
   I think they're essentially the same as Spergel's (and shared by most physicists): if your theory is unfalsifiable, you're not doing science, and that's what's going on here.

3. **Palmer**
   December 22, 2017

   Peter, you talk about the danger of using youtube videos as a reliable source of information. But this seems like too broad a brush to be taken seriously. Are all youtube videos to be treated equally? Why is a youtube video necessarily any less reliable than a blog post?
   In the case of the video linked to by Coyne, it's an interview with George Efstathiou
   who is not just a cosmologist but an award winning CMB Specialist and the spoke person for the European Space Agency's Planck CMB probe. Why should i take a blog post written by a non cosmologist more seriously than a video interview of this more than qualified cosmologist?

   You claim "The Youtube video he found makes the standard tenuous argument that the CMB provides evidence for inflation, inflation should be eternal, thus there should be a multiverse."I think there is a more to the video than what you imply. The question asked of Efstatuhiou was not just is there evidence for inflation and is inflation eternal? But whether or not the Planck data favours models of inflation that are eternal.His answer is yes and that this leads us to a multiverse. He even said this was the most important result from Planck. Now if you want to disagree with Efstathiou on this you need to give us a reason why he is wrong. To simply say he said it on a youtube video and hence dismiss it won't do.

   If we look more deeply at the debate over inflation and the multiverse. Both sides of this debate seem to agree with Efstathiou. Note Steinhardt and his colleagues said in this paper:
   https://arxiv.org/pdf/1304.2785.pdf
   "The plateau-like potentials selected by Planck2013 are in the class of eternally inflating models, so the multiverse and its effects on predictions must be considered. "
   Guth and his colleagues replied:
   https://arxiv.org/abs/1312.7619
   "First, they argue that the plateau potentials favored by Planck will lead to eternal inflation, and hence the measure problem [40]. We agree that if the observable inflation occurred on a plateau-like potential, eternal inflation seems very likely."
   What is in this video? It's Efstahtioua claiming that these flat potential models favoured by Planck produce a multiverse. Something then that many other cosmologists seem to agree with. And yet again not just any old cosmologists, but the very ones you have quoted in the past. It's a claim not just on youtube but in the peer reviewed literature.
   .
   As to your comment that "the models of inflation one supposedly has "evidence" for are not models that lead to the kind of multiverse of different physical laws that Coyne needs for his argument with religion.". i think this is a poorly informed statement. Have you ever watched a debate between a theologian and an atheist on fine tuning? Did you watch Caroll versus Craig? The theologian often argues that fine tuning is explained by necessity, chance or design. How do they rule out necessity? By appealing to string theory and its landscape.

Now I'm with you on this Peter, there is no evidence for string theory so there is no reason from the perspective of fine tuning alone, to rule out necessity and invoke a multiverse. But as Craig appeals to string theory to rule out necessity then Coyne can use this evidence for the multiverse to rebut him. If Craig wants to doubt string theory then Coyne can raise the possibility of necessity. Its seems then that this "evidence" is relevant to the debates Coyne has in mind and so he is wise to quote it. Out of 1) necessity 2) a multiverse or 3) design by an immaterial mind. it seems like the multiverse is the only one with any evidence in favour of it. I agree the many pocket universes of eternal inflation might turn out to be all the same without different constants. This would a very boring multiverse yes. But surely the existence of many pocket universes ups the probability that 2 is the right solution and given the complete lack of any evidence for necessity of immaterial minds it seems that is all Coyne needs.

If you want to help Coyne and his fellow travellers refute The Trump supporting Craig and his acolytes it might be helpful to explain how you deal with the fine tuning argument yourself. Criticising Coyne for quoting a well respected cosmologist without providing any reason to doubt them other than the claim is being made on youtube does not seem like a well thought out response to me.

4. **Peter Woit**
December 22, 2017

Herbert Palmer,
You completely ignore the main point I keep on repeating: the "eternal inflation" single-field inflaton models for which (tenuous) evidence is claimed do not give you the kind of multiverse you want for your arguments with theologians (to get this you need something much more complicated, like string landscape models, for which you have no evidence at all).

No, I haven't watched Carroll vs. Craig, I think that kind of thing is a complete waste of time. For those who think it is worthwhile, if you want to invoke scientifically untestable ideas about a multiverse as a possible explanation for fine-tuning, you can do so if you want, they're just as good as what the theologians have. Just don't claim that CMB measurements provide scientific evidence for this, because it's not true.

Sorry, but I just don't understand why anyone who wants to engage in these arguments thinks it's a good idea to abandon the high ground of actual, tested science and start invoking untestable pseudo-science and misleading claims of evidence that's not there. I don't see at all why that's either necessary or desirable: why sell the public on fake physics because you find it convenient to make a debating point in a tedious argument?

5. **Pete Best**
December 24, 2017

https://www.forbes.com/sites/startswithabang/2017/05/11/what-if-cosmic-inflation-is-wrong/

Peter, this article spells out the conflicting opinions on inflation. There is data and reasoning to back it up so it's not merely fake physics as you appear to be suggesting. Sure it's not full proof (what science is?) but alternatives to inflation and the issues it addresses are no better or worse than inflation.

So although inflation has its critics and is slated as not science by your good as well as others it does have data from Planck and it does therefore have more merit than you appear to be suggesting I am suggesting. Inflation may have too many models and hence can predict anything but the data leans towards some form of inflation did take place.

6. **Peter Woit**
December 24, 2017

Pete Best,
This posting is not about inflation, but about Jerry Coyne's article claiming "evidence for the multiverse and its implications" (the implication for him is the multiverse argument against theologians invoking a deity responsible for fine-tuning). The "Fake Physics" is the multiverse of universes with different physics that Coyne wants for his side of the argument. There is zero evidence for such a thing.

7. **Palmer**
December 27, 2017

Hello Peter, thanks for taking the time to reply. I do feel your reply misses the mark though. Your only complaint left standing seemed to be that the evidence is not for the type of multiverse that Coyne needs to dispute the theistic fine tuning argument. But then you admit you haven't spent any time researching what points are actually used by theists to make these arguments. But as I explained to you in my post , had you watched such debates, you would know that theists need string theory (or something else like it that can change the constants of nature) in order to support a key premise in their argument.
Here is a quote from the Bill Craig in his debate with Sean Carroll.

https://www.reasonablefaith.org/media/debates/god-and-cosmology-the-existence-of-god-in-light-of-contemporary-cosmol/

"Now there are three possibilities debated in the literature for explaining the presence of this remarkable fine-tuning: physical necessity, chance, or design. The question then is: Which of these three alternatives is the most plausible? On the basis of the evidence we may argue:
1. The fine-tuning of the universe is due to either physical necessity, chance, or design.
2. It is not due to physical necessity or chance.
3. Therefore, it is due to design.
Physical Necessity?
Consider the first alternative, physical necessity.
This alternative seems extraordinarily implausible because the constants and quantities are independent of the laws of nature. The laws of nature are consistent with a wide range of values for these constants and quantities. For example, the most promising candidate for a Theory of Everything (T.O.E.) to date, super-string theory or M-Theory, allows a "cosmic landscape" of around 10500 different universes governed by the present laws of nature, so that it does nothing to render the observed values of the constants and quantities physically necessary."

Or consider another example from IS There A God.Info

http://www.is-there-a-god.info/clues/teleological/

"Currently the most promising possibility for a ToE is string theory, but Stephen Hawking said: "Does string theory predict the state of the universe? The answer is that it does not." In other words, string theory does not provide the physical necessity for the universal fine-tuning."

So you see that the theist needs string theory to rule out necessity. Coyne does not need string theory. If it turns out that string theory is false then necessity cannot be ruled out by the theist. And so they can't follow through to the conclusion of God. If string theory is right (or at least the landscape or something like it) then Coyne needs something to generate multiple worlds to populate the landscape. The multiple bubble universes of eternal inflation seem like a good candidate. However if string theory is right in that the constants of nature could easily be different but there's no way to generate multiple worlds, only then Coyne is in trouble. So evidence for other bubble universes supports Coyne's case whether or not these other bubble universes have the same or different properties to our own. You are just wrong about what is needed in these debates from Coyne's point of view. And the reason you are wrong is , by your own admission, you don't pay attention to the said debates. The Carroll/Craig debate is considered the number one debate on this topic by most in my experience of attending these sorts of debate environments. So that fact you haven't watched even that one, is very telling.

Moreover Coyne never claimed any evidence for the string theory landscape and neither did the video. If you look up the word multiverse in the dictionary it does not mention the string theory landscape . Here is the OED's definition:

https://en.oxforddictionaries.com/definition/multiverse
"A hypothetical space or realm consisting of a number of universes, of which our own universe is only one."
Bubble universes of eternal inflation seems to fit that, even if its a boring multiverse where they all have the same values.

So there is absolutely nothing fake about claiming evidence for eternal inflation and calling that a multiverse.

Coyne himself acknowledges there are different ways to conceive a multiverse. Coyne also brings up caveats about why the evidence presented is not decisive "Now, according to this video, we've gotten some evidence for the multiverse, though our Official Website Physicist™ notes (see below) that the new evidence isn't terribly decisive."
The video itself mentions that inflation could still be wrong or perhaps misunderstood and gives caveats about why the evidence presented might not show the multiverse to be true.The video itself had a question mark at the end and you said "Coyne seems to have missed the question-mark Coyne published". But those caveats that were on the video are in his post. So if anyone was missing something, it is you. What you see then in both the video and Coyne's blog post then is yes excitement about potential evidence for a multiverse, but also nuance, caveats and thoughtful discussion.
All of which are absent from your blog post.
You made accusations about fake news, dubious sources and comparisons with Donald Trump. None of this stands up to scrutiny.
And one of the most prominent intelligent design blogs is already using your blog post to rubbish their arch critic Coyne.
https://uncommondescent.com/fine-tuning/peter-woit-on-whats-wrong-with-jerry-coynes-argument-for-a-multiverse/

I suggest you need to provide some sort of apology or retraction. I loved your book "Not Even Wrong" but now it seems that you are the one using hyperbole that is not supported by the evidence.

8. **Peter Woit**
December 27, 2017

Palmer,

Sorry, but I'm not going to waste more time involved with the mountain of stupidity of intelligent designers, http://www.is-there-a-god.info, Bill Craig etc. If you, Coyne, Carroll or anyone else wants to spend their time this way, it's a free country. But, the fact of the matter is that CMB observations do not provide any significant scientific evidence for the argument you want to make. Taking stuff off Youtube to make a bogus scientific argument against the believers does nothing but discredit science and scientists. You and Coyne should just stop doing it. You have plenty of perfectly good arguments, why discredit science by making a bad one?

9. **Palmer**
December 30, 2017

But you haven't shown any evidence of any bogus science. All you have is a straw man argument. You are claiming no evidence for a string landscape. But no one is claiming evidence for the string landscape. You say you need the string theory landscape to make the point in the debate. But these are debates you admit you have never watched. So I explained why the string landscape is actually irrelevant and your response is just to ignore my argument and make the same accusation.

So to repeat, the string landscape is irrelevant , it is not needed, you are wrong. Why are you wrong? Because the theists usually claims fine tuning is explained by either necessity, chance or design. The theist uses the string landscape to rule out necessity as a possible explanation for the constants of nature. If you watched the Caroll/Criag debate or others you would know this. If the string theory landscape is right but eternal inflation (or something like it) is false, then there is no way to populate the landscape and the theist can rule out necessity and chance and claim design is the winner. But if we have someway to populate the landscape, and eternal inflation would seem to do the job, then chance cannot be ruled out. And if the string landscape is false then necessity can't be ruled out either. So the theist needs the string theory landscape to be true and eternal inflation to be false. As long as they are wrong about one of those things, their argument fails.

The evidence Coyne points to then does help his case. Is it a knockdown piece evidence ? No, but he never claimed it was. It's something that helps his case, nothing more, nothing less. Please don't argue against a straw man. As far as I can see, out of necessity, a multiverse or design by an immaterial mind, the multiverse is the only one that has even a shred of evidence in favour of it. If you have evidence for some other option, let's see it.

If you are going to tell us whats useful in a debate against the ID crowd it would be helpful if you actually did so, rather than telling us what not to say. It would be helpful if you knew what these people actually said rather just imagining what is said. I read your blog a lot, but I don't think I've ever seen you give what you think is the correct response to the fine tuning argument. Why is that? Maybe i missed it. But it's too easy to criticise someone else when you have having zero to offer in their place. Why don't you watch the debate and tell us how you would reply? oh yes i forgot its beneath you. This "higher than thou" attitude is actually what gives science a bad name. Meanwhile the religious right are on campuses, promoting their videos online and making their arguments which some people find persuasive or those that already persuaded find empowering. And your preferred strategy is to say nothing to counter them. I'm not convinced that has worked out well. Now they in power and using that power to attack science.

10. **Peter Woit**
December 30, 2017

Palmer,
The problem is that the "evidence" Coyne is trying to use is not evidence for a of model of inflation that populates a landscape, it's evidence for a model of inflation with no landscape. If you believe the model that supposedly this is evidence for, you predict a multiverse of universes with exactly the same fine-tuning problem you started with. Claiming evidence here for the different kind of multiverse you want is just misleading and dishonest, and the way Coyne is doing it (via promoting a dubious Youtube video) is a really bad idea. Defending this kind of activity just discredits the naturalist side of the debate with theologians. You should be arguing with Coyne and getting him to stop, not arguing with me.

I don't engage with these theological debates because I don't think they have anything to do with the serious problems now facing us. The awful post-truth collapse of democracy we are facing is not driven by theologians and believers: Trump and Rupert Murdoch don't believe in God, they believe in the power of the Big Lie . By ignoring truth and science in your desire to score a point in an irrelevant side-show, you're discrediting the fact-based opposition to this. Fake physics is not going to solve the problem of Fake news, it's going to make it worse.

11. **Palmer**
January 2, 2018

Peter, Happy New Year to you. I don't believe you addressed anything I said but just keep singing from the same old hymm sheet. So I'm afraid I will have to end the

discussion of the multiverse here. But if you think Trump and Murdoch can take power without their army of religious believers you are quite mistaken. Just look at Craig and many other influential Christians endorsement of Trump. Perhaps some data on how the faithful voted might help. 80% of white evangelicals voted for Trump whereas 70% of "none's" voted for Clinton. So it does not look like your claim that post truth is not driven by believers is supported by the data.
http://www.pewforum.org/2016/07/13/evangelicals-rally-to-trump-religious-nones-back-clinton/

12. **Peter Woit**
January 2, 2018

Palmer,

White believers voted (like most categories of white people) for Trump. African-American believers voted (like all categories of African-Americans, except the crazy ones) heavily for Clinton. Neither of these facts is relevant to the issue here of whether it's worth discrediting science with untrue claims about the multiverse.

Sorry all, that's it for the political discussion.

13. **pete best**
January 3, 2018

I thought the idea of the multiverse came from the notion of inflation and the inflaton field that is potentially endless so how can you say that inflation is no relevant to the conversation?

I had never heard that standard Guth inflation always had the same physics (perhaps different initial conditions) and it needs string theory in order to have 10^500 possible multiverses thus negating the need for the anthropic principle. I did a search around this but didn't find anyone say this was indeed the case? Can you demonstrate this is indeed what inflation (standard or new inflation) states please ?

14. **Peter Woit**
January 3, 2018

pete best,
There are an infinity of "inflation" theories, I don't know what the "standard one" is. The ones typically used involve a single inflaton field, with a simple potential, it is these that claims are being made to supposedly have CMB evidence for. A single inflaton field with a simple potential is not going to give you a multiverse with the wide array of physics you need.

Various and Sundry

A few things that may be of interest:

- Survey articles prepared for the 2018 ICM proceedings are starting to appear on the arXiv, and Peter Scholze (who will be getting a Fields Medal in Rio) has put his on his web-site. His title is p-adic Geometry, and it gives an overview of the ground-breaking work he has been doing over the last few years. The last section tells us that

  > Currently, the author is trying to understand to what extent it might be true that the "universal" cohomology theory is given by a shtuka relative to Spec **Z**. It seems that this is a very fruitful philosophy.

  For some background about that section, I'd recommend his talk at the 2015 Clay Math conference.

- The New Yorker has a very detailed and interesting profile of Jim Simons and what he is up to with the Flatiron Institute he is now funding here in New York. This new Institute is costing him \$80 million a year, characterized as "a lark" for someone with his assets. David Spergel is running the Center for Computational Astrophysics there, and doing a lot of hiring. When I wrote here about his characterization of multiverse research, his final comment about being able to speak freely because he had tenure left me wondering "wait, what about grants, jobs, etc.?". From the New Yorker article, I realized that while having tenure may give you some ability to speak freely, having a guy with \$18.5 billion willing to write large checks for you gives you a lot more…
- I've just finished teaching a course this semester which concentrated on the formalism for describing geometry in terms of connections and curvature. From the point of view of physicists, this formalism should be of interest because it applies equally well to gauge theory and general relativity. I'd been starting to think again about what light this formalism might shed on how to think about these two subjects together, when last night I noticed a wonderful new article on the arXiv, Gravity and Unification: A review by Krasnov and Percacci.

  This article is an extremely lucid and comprehensive survey of the sort of thing I was thinking about, which can be re-expressed as the question of trying to find, at the classical level, a formalism uniting the vector potentials/field strengths of the SM and the different possible fields used to describe geometry in GR. Some of this has a very long history, going back to the things Einstein was trying in his later years. There have been many different ideas that people have tried since then, and the survey article does a great job of both explaining these ideas, as well as indicating why they haven't worked out.

  A couple of the general ideas that have always fascinated me make an appearance in the article. One of these is that of what mathematicians call a "Cartan connection", the idea that you should think of a geometry as locally looking like a quotient space G/H of two Lie groups. A version of this is known to physicists as the MacDowell-Mansouri formulation, which gets a detailed treatment in the article. Another is the idea of using the fact that the complexified orthogonal group in 4 dimensions breaks up into two pieces, sometimes thought of at the Lie algebra level as self-dual vs. anti-self-dual pieces under the Hodge star operation. A version of this idea is known as the Plebanski formulation, and this decomposition is behind the story of Ashtekar variables. These variable have played a crucial role in modern treatments of GR by Hamiltonian methods, as well as the quantization program of loop quantum gravity.

  The focus of the article is on Lagrangian and classical field theory methods for studying these ideas. There's relatively little about the Hamiltonian story, and also relatively little about the geometry of spinors, two topics that I suspect might provide additional needed insights. For anyone interested in thinking about non-string theory-based ideas about unification of the SM and gravity, there's a wealth of ideas, references and history here to think about. Perhaps future progress on unification will come from some new breakthrough in this field that shows how to get around the problems identified clearly in this article.

- For surveys of recent work on quantization of gravity and discussion by experts, a good place to look is videos of talks at a recent conference held at the IHES. Videos available here include my fellow Princeton student Costas Bachas surveying the approach growing out of string theory in Holographic Dualities and Quantum Gravity, Carlo Rovelli the opposition in Current Quantum Gravity Theories, Experimental Evidence, Philosophical Implications, and an even-handed overview from Steven Carlip with Why We Need Quantum Gravity and Why We Don't Have It. Also well-worth watching, both for the talk and the discussion, is Alain Connes on Why Four Dimensions and the Standard Model Coupled to Gravity.

Finally, for fans of Lenny Susskind's introductory level books on theoretical physics, Andre Cabannes writes to tell me that the most recent volume (which I wrote about here) is being translated by him into French, to appear next year. He also has notes from the lectures on General Relativity, Cosmology, and Statistical Mechanics, for which no book form has yet appeared.

Update: For a detailed account of the event at NYU mentioned here, see this from Jerry Alper.

5. **Peter Woit**
December 12, 2017

Please, unless you actually know who is getting a Fields medal and want to tell us, let's leave that speculation game for another time.

6. **John Baez**
December 12, 2017

Derek Wise wrote a great thesis on Cartan geometry and various formulations of gravity, including the MacDowell-Mansouri formulation – but also the more familiar Palatini formulation, where the SO(3,1) connection and the cotetrad field, which is locally an R^4-valued 1-form, fit together to form a Poincare group connection. What's nice is that Derek explains it all very geometrically. His paper MacDowell-Mansouri gravity and Cartan geometry is probably the easiest place to start. One doesn't need to understand Cartan geometry ahead of time: he explains it nicely using a picture of a hamster rolling in a hamster ball.

7. **Peter Woit**
December 12, 2017

Thanks for reminding me of that John. That paper is a wonderfully clear explanation of Cartan geometry and how to formulate GR using it.

8. **tulpoeid**
December 13, 2017

On the update: Alper's article is a detailed account of how, uninvited, he tries to get closer to the speakers (before the discussion) and two members of the audience, just to show off and obtain some personal advice. And in addition presenting them rather unfavorably for not showing him the warmth he was expecting. I don't know if he'll report on the event itself, but the time spent on this article doesn't tell anyone anything about it (except maybe how great he believes Nima is, yes, unrelated to the event). The first paragraphs about today's students in high profile universities is rather interesting though.

9. **Chris Oakley**
December 13, 2017

I read Alper's piece and am pleased, though not surprised, to discover that Hossenfelder is not obviously susceptible to flattery. Speaking from experience, being a thorn in the side of academia is much easier, not to say effective, if you retain a foothold in it, so let us just hope that she finds a way to do that.

10. **Bill**
December 13, 2017

Reading Jerry Alper's piece, I could not help thinking that the reason Peter had so much trouble remembering him was because during their three-hour interview Peter's mind was too focused on keeping the conversation on topic to remember the interviewer.

11. **Peter Woit**
December 13, 2017

tulpoeid,
I think you're being unfair to Alper. This was an event aimed at the public, so he was certainly invited, and having the audience interact with the speakers was part of the goal there (the audience was not that large). He's a fan of the speakers, it was a quite appropriate place for him to meet them and have a conversation. While (just like in the piece he wrote about talking to me a while ago) his writing style is very personal and largely about himself and how he experiences things, it is pretty much factually accurate. Yes, I didn't immediately recognize him (he did prompt me quickly, probably I would have remembered who he was in a few moments, although I've gotten very bad at recalling names). Yes, the quote from me about Sabine was accurate. I was there for part of his conversation with her, and what he writes is consistent with what I remember.

12. **Derek Wise**
December 13, 2017

Peter,
Thanks! My paper on MacDowell-Mansouri gravity seems to have helped a lot of people understand Cartan geometry and its relationship to gravity, and that makes me really happy!
Since you mentioned the Ashtekar approach in the original post here, I'll point out that Steffen Gielen and I worked out the precise sense in which the real Ashtekar-Barbero formulation is a theory of evolving spatial Cartan connections, starting with our paper Spontaneously broken Lorentz symmetry for Hamiltonian gravity, and then with some of the geometric ideas explained further in Geometrodynamics and Lorentz symmetry.
This of course is not quite the same thing as the Plebanski-type symmetry breaking you mentioned. I've never worked out the precise sense in which the Plebanski formulation is a case of Cartan geometry (is it?!), but I think the above papers (and other work with Steffen Gielen) give the "right" way to understand real Ashtekar variables geometrically.
-Derek

13. **tulpoeid**
December 13, 2017

Maybe I exaggerated my feeling, triggered by the negative-in-disguise portrayal of those who didn't respond according to his expectation. ("Uninvited" was about the repeated attempts at professional cordiality.)

14. **Urs Schreiber**
December 13, 2017

It may be helpful to notice that, in different terminology, Cartan geometry is fairly familiar to many physicsists, who may call it "first-order formulation of gravity" or similar and regularly use it when discussing gravity coupled to fermions.

An excellent but widely underappreciated (forgotten?) textbook all based on this perspective is "Supergravity and Superstrings – A Geometric Perspective".

The authors don't use the words "Cartan geometry", but anyone who knows the subject will immdiately recognize that this is precisely their "geometric perspective" (working locally, of course).

While the aim of this textbook is to go further to super Cartan geometry and then to higher Cartan geometry, the entirely of part one (in volume one) is about standard gravity in terms of Cartan geometry.

15. **Thomas Larsson**
December 14, 2017

    So Cartan geometry is basically the same thing as the vielbein formalism? Then even I would be able to understand.

16. **Urs Schreiber**
December 14, 2017

    Yes. For some reason where in maths texts the term "Cartan geometry" became established, physics texts stick to Cartan's original terminology (Cartan 22) and speak of the "Cartan moving frame method".

    Of course mathematicians have developed the theory with more generality and precision, a seminal textbook is Cap-Slovák 09.

    Another terminology issue to be aware of is that many physicists who do say "Cartan geometry" are concerned with an independent issue, namely the question whether encoding the field of gravity in a "Cartan connection" = "vielbein + spin connection" instead of in a metric tensor (which is what Cartan geometry itself is about, and which is well known and uncontroversial) suggests ways to rewrite the Einstein-Hilbert Lagrangian in ways (e.g. Palatini-Cartan-Holst form) that are then often subject to much speculation about a deeper nature of gravity.

    In view of this it is remarkable that, while the on-shell equivalence of the Einstein-Hilbert action to the Palatini-Cartan-Holst action was long known, the equivalence of the two Lagrangian field theories on the level of phase spaces was established only this year, by Cattaneo-Schiavina 17.

17. **Peter Woit**
December 14, 2017

    Derek and Urs,
    Thanks for the references!

    Thomas Larsson,
    I'd say you have a Cartan geometry when you have a Cartan connection. You can do this generally for a pair H,G of Lie groups, H a subgroup of G, identifying the tangent space of your manifold with Lie G/Lie H. The case of GR is G=Poincare, H=Lorentz. In this case the spin connection and vielbein together are the components of the Cartan connection, with the curvature of this connection having components the usual curvature of the spin connection, and the torsion.

18. **Derek Wise**
December 14, 2017

    Urs, I disagree — Cartan geometry is not just the same things as the method of moving frames. Frames are an important *ingredient* in Cartan geometry, and in certain cases (reductive geometries) the Cartan connection can be split into a coframe field and a connection for the stabilizer group. This special case explains the geometry behind first order formulations of gravity. But, Cartan geometry is much more general (and frankly much more "geometric") than the usual physics understanding of first order gravity. It's about generalizing the whole of Klein's Erlangen Program to the differential setting. It's also about solving the "equivalence problem" relating "raw" geometry (defined in terms of, say, smoothly varying structures on tangent spaces) to Cartan connections with special choice of groups and conditions on curvature. Sharpe's book has some great examples of this, for example, relating conformal geometry to Cartan connections based on either Weyl or Möbius models.

19. **Urs Schreiber**
December 14, 2017

    Derek, careful with suggesting that theoretical physicists don't understand these phenomena only because they use different words than you do. This attitude will backfire.

    If you look at the first part of "Supergravity and Superstrings – A geometric perspective" that i keep recommending, you'll see that it is exactly the geometric perspective of globalizing Klein's geometry that drives the development of their concepts.

    Of course they don't say the *words* "Klein geometry" or "Erlanger program" (we have to distinguish between names and the mathematical reality that they refer to) but they start by considering the homogenous coset spaces that are the Klein geometry hallmark and then find their crucial technique by globalizing these. In their re-invention of Cartan geometry this way, they came up with interesting ways of thinking about these structures: For instance they say "soft group manifold" for the differential form structure which globalizes Maurer-Cartan forms on Kleinian cosets to Cartan geometries. The terminology didn't catch on, but it reflects precisely the understanding that Cartan geometry is a "softening" of Kleinian geometry

    Also, these authors are well aware that this is more general than just the case of Minkowski = Poincaré/Lorentz: In that textbook they discuss also the dS and AdS case, and, crucially, they use all this only as the stepping stone to do super-Cartan geometry, which comes about from considering cosets of the super-Poincaré and super-(anti)de Sitter groups.

    This perspective keeps being developed to great generality by physicists: In approaches to make U-duality geometric one considers Cartan geometry over ever larger cosets, culminating in something like Cartan geometry modeled on E11 modulo its maximal compact sub-group (or sub-thing).

    So once you allow for the fact that not every physicists who studies Cartan geometry uses the same language as you do, you'll find that the Cartan geometry physicists have been and are studying is extremely general and powerful. It serves to pay attention to that.

    (Not the least, Cartan geometry is pretty much the only way to do supergravity — noticing that the only way to define local model super-spacetimes is as coset of supergroups — and that this is what physicists are doing has been particularly highlighted by John Lott 01.)

    While conformal Cartan geometry is not discussed in this particular textbook, they do discuss this in their published articles. (But I won't point to the arXiv now, not to distract you from opening their fantastic textbook!)

20. **Derek Wise**
December 14, 2017

    Urs,
    I certainly don't intend to suggest that physicists don't understand something because they don't phrase it in the language of mathematicians, or vice-versa. And I agree that there's a lot of great work in the physics literature related to Cartan geometry, including the D'Auria-Fré formulation, a bunch of work on first order gravity, and the tractor calculus literature, to name a few. But, when you answer the question "So Cartan geometry is basically the same thing as the vielbein formalism?" with "Yes" I have to disagree. That's just a small piece of Cartan geometry.
    Derek

21. **Jon A**
December 19, 2017

Towards the beginning of the paper of Cattaneo and Schiavina (CS) referenced by Urs's page on first order formulations of gravity, they write that they hope to reproduce for the Palatini-Holst (PH) action the success they'd had with the Einstein-Hilbert (EH) action. CS proved in 2015 the EH action gave a (Batalin Vilkovisk) BV theory which, on manifolds with boundary, moreover gave a proper (add Fradkin) BV-BFV theory, in the sense of Cattaneo, Mnev, and Reshetikhin (CMR). Given a solution of the corresponding master equation, this would give a quantization of gravity.

In Schiavina's thesis, he proves the Palatini-Holst action's minimal BV theory doesn't allow a CMR-BV-BFV theory – the kernel of the pre-boundary two form isn't of uniform rank changes as you move around the space of fields. Worse still, when you impose the Half-shell constraint (without which the connection is underconstrained), the pre-boundary two form isn't presymplectic. So this equivalence of on-shell phase spaces *doesn't seem* to extend to their derived locii (similarly for Pleibanski- while MacDowell Mansouri doesn't seem to have this problem).

Their more recent paper suggests either perturbing the action by a boundary to overcome this problem or considering boundary preserving variations. They explore the latter and obtain something again inequivalent to Einstein-Hilbert.

When CS first began publishing their work two years ago, I thought this stuff would become a hot topic in QG. Whenever I'd run into Michele on campus, I didn't get the sense other physics people cared about it. Good to see this work making its way into the collective consciousness.

Latest on abc

December 16, 2017
Categories: abc Conjecture, Favorite Old Posts

I've seen reports today (see here and here) that indicate that Mochizui's IUT papers, which are supposed to contain a proof of the abc conjecture, have been accepted by the journal Publications of the RIMS. Some of the sources for this are in Japanese (e.g. this and this) and Google Translate has its limitations, so perhaps Japanese speaking readers can let us know if this is a misunderstanding.

If this is true, I think we'll be seeing something historically unparalleled in mathematics: a claim by a well-respected journal that they have vetted the proof of an extremely well-known conjecture, while most experts in the field who have looked into this have been unable to understand the proof. For background on this story, see my last long blog posting about this (and an earlier one here).

What follows is my very much non-expert understanding of what the current situation of this proof is. It seems likely that there will soon be more stories in the press, and I hope we'll be hearing from those who best understand the mathematics.

The papers at issue are *Inter-universal Teichmuller Theory I, II, III, IV*, available in preprint form since September 2012 (I blogged about them first here). Evidently they were submitted to the journal around that time, and it has taken over 5 years to referee them. During this 5 year period Mochizuki has logged the changes he has made to the papers here. Mochizuki has written survey articles here and here, and Go Yamashita has written up his own version of the proof, a 400 page document that is available here.

My understanding is that the crucial result needed for abc is the inequality in Corollary 3.12 of IUT III, which is a corollary of Theorem 3.11, the statement of which covers five and a half pages. The proof of Theorem 3.11 essentially just says "The various assertions of Theorem 3.11 follow immediately from the definitions and the references quoted in the statements of these assertions". In Yamashita's version, this is Theorem 13.12, listed as the "main theorem" of IUT. There its statement takes 6 pages and the proof, in toto, is "Theorem follows from the definitions." Anyone trying to understand Mochizuki's proof thus needs to make their way through either 350 pages of Yamashita's version, or IUT I, IUT II and the first 125 pages of IUT III (a total of nearly 500 pages). In addition, Yamashita explains that the IUT papers are mostly "trivial", what they do is interpret and combine results from two preparatory papers (this one from 2008, and this one from 2015, last of a three part series.):

> in summary, it seems to the author that, if one ignores the delicate considerations that occur in the course of interpreting and combining the main results of the preparatory papers, together with the ideas and insights that underlie the theory of these preparatory papers, then, in some sense, the only nontrivial mathematical ingredient in inter-universal Teichmueller theory is the classical result , which was already known in the last century!

Looking at these documents, the daunting task facing experts trying to understand and check this proof is quite clear. I don't know of any other sources where details are written down (there are two survey articles in Japanese by Yuichiro Hoshi available here).

As far as I know, the current situation of understanding of the proof has not changed significantly since last year, with this seminar in Nottingham the only event bringing people together for talks on the subject. A small number of those close to Mochizuki claim to understand the proof, but they have had little success in explaining their understanding to others. The usual mechanisms by which understanding of new ideas in mathematics gets transmitted to others seem to have failed completely in this case.

The news that the papers have gone through a confidential refereeing process I think does nothing at all to change this situation (and the fact that it is being published in a journal whose editor-in-chief is Mochizuki himself doesn't help). Until there are either mathematicians who both understand the proof and are able to explain it to others, or a more accessible written version of the proof, I don't think this proof will be accepted by the larger math community. Those designing rules for the Millennium prizes (abc could easily have been chosen as on the prize list) faced this question of what it takes to be sure a proof is correct. You can read their rules here. A journal publication just starts the process. The next step is a waiting period, such that the proof must "have general acceptance in the mathematics community two years after" publication. Only then does a prize committee take up the question. Unfortunately I think we're still a long ways from meeting the "general acceptance" criterion in this case.

One problem with following this story for most of us is the extent to which relevant information is sometimes only available in Japanese. For instance, it appears that Mochizuki has been maintaining a diary/blog in Japanese, available here. Perhaps those who read the language can help inform the rest of us about this Japanese-only material. As usual, comments from those well-informed about the topic are welcome, comments from those who want to discuss/argue about issues they're not well-informed about are discouraged.

Update: Frank Calegari has a long blog post about this here, which I think reflects accurately the point of view of most experts (some of whom chime in at his comment section).

New Scientist has a story here. There's still a lack of clarity about the status of the paper, whether it is "accepted" or "expected to be accepted", see the exchange here.

Update: It occurred to me that I hadn't linked here to the best source for anyone trying to appreciate why experts are having trouble understanding this material, Brian Conrad's 2015 report on the Oxford IUT workshop.

Update: Curiouser and curiouser. Davide Castelvecchi of Nature writes here in a comment:

> Got an email from the journal PRIMS : "The papers of Prof. Motizuki on inter-universal Teichmuller theory have not yet been accepted in a journal, and so we are sorry but RIMS have no comment on it."

Update: Peter Scholze has posted a comment on Frank Calegari's blog, agreeing that the Mochizuki papers do not yet provide a proof of abc. In addition, he identifies a particular point in the proof of Conjecture 3.12 of IUT III where he is "entirely unable to follow the logic", despite having asked other experts about it. Others have told him either that they don't understand this either, or if they do claim to understand it, have been unable to explain it/unwilling to acknowledge that more explanation is necessary. Interestingly, he notes that he has no problem with the many proofs listed as "follows trivially from the definitions" since the needed arguments are trivial. It is in the proof of Corollary 3.12, which is non-trivial and supposedly given in detail, that he identifies a potential problem.

Update: Ivan Fesenko has posted on Facebook an email to Peter Scholze complaining about his criticism of the Mochizuki proof. I suppose this makes clear why the refereeing process for dealing with evaluating a paper and its arguments is usually a confidential one.

Comments

1. **Michael Barany**
   December 16, 2017

   I'll be fascinated to follow the technical and other discussions I'm sure this development will provoke. For my part, an observation about peer review in mathematics, which is now an active topic of both historical and sociological research.
   One often refers in evaluating math papers to three criteria associated with GH Hardy: is it (a) true, (b) new, and (c) interesting? The key point here is that *none* of

these is a binary yes/no question for most mathematical papers. There are always degrees of novelty and interest to a paper, and in most cases it is impossible to absolutely verify every claim of a paper. So an editor (and yes it would look better if the editor-in-chief were not the author) must always make a judgement call weighing those three factors (among other considerations): is it "true enough," "new enough," and "interesting enough." So I wouldn't find it unreasonable for an editor to say, under the circumstances, that the work's novelty and (especially) interest make tolerable a weaker consensus about validity to justify publication. Now, it's another question whether struggling to communicate the proof so far should count against the "interesting" criterion, but it's hard to say the proof hasn't generated a lot of interest!

2. **Peter Woit**
December 16, 2017

Michael Barany,
There's no question this is "new" and no question a proof of abc would be interesting. So, this is all about the "true" question: is this a proof or not? Math journals are not supposed to be publishing papers that are not "true", even if new and interesting. Checking a proof of an important result is a critical role of the math refereeing process.

The real problem here though is that there is an important criterion you haven't mentioned, quality of exposition: is the paper "well-written"? No matter how new, true and interesting a paper is, if it's too badly written the journal should return it to the author and tell them they have to rewrite and do better. There's a good argument that the IUT papers are not readable and checkable by experts in the usual way, so should have been rejected on those grounds.

All, I don't want to moderate a general discussion of the refereeing system. Comments should be relevant to this story of the IUT papers.

3. **mahmoud**
December 17, 2017

Could someone knowledgable comment on the effectiveness of Mochizuki's (purported) proof? Brian Conrad posted a detailed comment to an earlier post here explaining that Mochizuki needed a reduction step involving Belyi maps that made the implied constant non-effective, after that comment was made however Vesselin Dimitrov posted a paper on arXiv claiming to replace this reduction with a constructive one. Has Mochizuki commented on this? Is he now claiming to have an effective estimate on the constant (and hence effective bounds for the Mordell conjecture)?

4. **Robin Whitty**
December 17, 2017

Edward Frenkel thinks the possible conflict of interest worrying enough that he deleted his tweet @edfrenkel saying the publication was a 'big deal'

5. **Stephen**
December 17, 2017

"Nottingham the only event bringing people together for talks on the subject"

There was an additional conference in Kyoto which supposedly went a little better..

https://www.maths.nottingham.ac.uk/personal/ibf/files/kyoto.iut.html

6. **Peter Woit**
December 17, 2017

Stephen,
I was referring to "since last year". The Kyoto meeting was July 2016 and I wrote about the situation then here
http://www.math.columbia.edu/~woit/wordpress/?p=8663
As far as I can tell, little has changed since then. There was a meeting in Vermont Fall 2016, but for whatever reason over the last year there has been very little in the way of attempts to bring people together to discuss IUT.

7. **anon**
December 17, 2017

From old pages found on archive.org it appears that S. Mochizuki became the editor-in-chief of PRIMS some time between March and May 2012. So most likely he was the editor-in-chief already when the paper was submitted.

If it is indeed true that the papers are going to be published in PRIMS, I think there needs to be some sort of explanation about how the refereeing process was handled.

8. **Tom**
December 17, 2017

I'm a philosopher, not a mathematician, so I am unable to assess M.'s work on its merits. (Although it sounds like none of you can, either.) But I have thought a bit about how this story has developed over the last few years, and I worry that it is more consonant with a hoax than a mathematical discovery of the first rank.

Consider: (1) All the new jargon in the proof; (2) the inability of top scholars to even understand the proof's strategy; (3) the convoluted ways in which M.'s papers refer to each other and to themselves; (4) M.'s unwillingness to explain his work; and (5) the many "meta" comments in the papers (about, e.g., people who examined the proof and found it compelling).

And now (6): We get what the community has long desired–submission of the work for peer review. But of the dozens of respectable journals which M. could have chosen to undertake this task, he chose the one that is HOUSED IN HIS OWN RESEARCH CENTER. Indeed, M. is the journal's EDITOR-IN-CHIEF. This is, of course, unacceptable even in pedestrian circumstances–which these most certainly are not.

I am confident that the truth of the matter will, in time, come out. It may be that M.'s genius is so profound, and so sui generis, that the conventions that apply to everyone else (Tao, Villani, et al.) do not to him. I mean that seriously. I am only suggesting, here, that there are reasonable worries.

9. **ET**
December 17, 2017

This could become very interesting in terms of the sociology of mathematics. What if, purportedly using Mochizuki's work, other well known results/conjectures are re-proved/proved in a manner that is understood? This will still not be an acceptable proof to (most) of the mathematical community but it would raise eyebrows. Take it up one more notch- what if, again purportedly using Mochizucki's methods from his abc work, new conjectures/results are created that can proved or re-proved using other well accepted techniques? There is a possibility that a path to understanding Mochizucki's techniques could be interpreted through its mathematical application.

10. **Warren D. Smith**

December 17, 2017

Re "new," "interesting" and "true" it is possible to have the "true" part decided by an automated proof-verifier system such as MIZAR, removing all doubt, and providing a far higher standard of truth and believability that has occurred over the vast majority of all prior history of mathematics. (Well, you could still worry that the proof-verifier software, or hardware, is buggy, but I nevertheless claim any proof passing MIZAR is probably more rigorous and more valid than essentially anything in all prior mathematical history.) That is the good news. The bad news is, Mochizuki would have to codify his work in the MIZAR language (or other proof-description language, several are available) which is probably an immensely long and hard task. Normally "formal proofs" are somewhere between 5 and 30 times longer than papers giving "informal proofs." It used to be 30 but over time these systems have acquired giant libraries of already-proved lemmas, and by using them your proof usually can be shortened. So if Mochizuki's stuff can be proved informally in 500 pages then the formal proof would be expected to be 2500 to 15000 pages.

One of the very few people who has ever been willing to work that hard has been Thomas Hales, who proved the "Kepler conjecture" that the densest packing of equal balls in 3-space, was the FCC packing (and various co-equally dense ones), and eventually did so "formally."

Formal proofs tend to be great at demonstrating correctness, but horrible at conveying understanding to other humans. In Hales' case the ideas behind his proof are capable of being understood by other humans, and have been, but the full details require very large computations no unaided human could perform. Mochizuki's proof presumably/supposedly is nicer than Hales' in the sense that everything is doable by an unaided human.

11. **Peter Woit**
December 17, 2017

Tom,
I think the "hoax" scenario is highly implausible. To on purpose create a hoax of this kind that would resist experts attempts to see their way through it would be arguably even more difficult than coming up with a plausible proof the author believes. All indications are that there's a well-thought out strategy of a proof here, based on ideas that Mochizuki has been developing, with some success, for a long time. The problem is not that he doesn't explain the strategy of the proof, it is more that it is so complex and uses such unfamiliar ideas that others have great trouble understanding it in the deep sort of way that is needed to be able to convince oneself that the logic is air-tight. I'm sure Mochizuki is convinced he has an air-tight argument, the problem is that other experts need to be convinced, and that isn't happening. Part of the problem here is that some of the usual ways these things get resolved haven't happened due to Mochizuki's unwillingness to travel. For instance, a more usual scenario would be that someone claiming such a proof would accept one or more invitations to speak at a home institution of other experts, then give a series of lectures there where such experts could interact with him, go through the proof at whatever pace was necessary for them to follow it.

As for publishing this in the journal he is editor in chief of, presumably that was done using whatever their standard mechanism is for editors to publish in their own journal, removing themselves from the refereeing process. Not a great idea in this case though, especially since arguably whoever the editor was should have been telling the author the papers needed to be significantly rewritten before they could be checked. Without knowing the details of the refereeing process though, it's hard to know whether it really was problematic.

12. **Peter Woit**
December 17, 2017

ET,

A large part of the problem here is that the methods used to supposedly prove abc have not found other applications. Normally one would expect a new set of methods like this to find several different applications. The most straightforward way to see there is a problem with a theorem is by looking at the things it implies, and finding one known to be not true by other methods. This bypasses the need to check every detail of the argument, you then know that somewhere one such detail is wrong.

13. **Peter Woit**
December 17, 2017

Warren D. Smith,

I suspect the effort needed to rewrite this proof in a machine checkable form is many times larger than what it would take to rewrite it in a form experts can more conventionally check (which would be much more useful anyway).

14. **David Roberts**
December 17, 2017

I think the referees' names should be made public, else, if they are not willing to stand personally and publicly by the acceptance of the papers for publication, they shouldn't be accepted. I feel this is a stronger position that standing up at a conference and saying "I've spent 700 hours studying IUT and I think it's ok". At least two of Wiles' referee's are known, as one of them is on public record as saying how they found the initial mistakes in the proof of FLT.

15. **Tom**
December 17, 2017

Peter,

You say, "Without knowing the details of the refereeing process though, it's hard to know whether it really was problematic." I do not agree.

Let us consider the best-case scenario: M. "received" the paper. He then sent it to two top mathematicians (Lurie, Okounkov). They reviewed the 1,000 pp. (or whatever), and judged everything to be sound. They reported that to M. with their highest recommendation for publication. There's STILL a problem! Why? Reviewers don't accept papers–editors do. And you can't be objective about your own work.

In contrast, suppose we find out that Go Yamashita was one of the referees. Now we have a problem. Unless the rules are different in math, this work can never be published in another peer reviewed journal. For that reason, and because it is impenetrable, it's never going to receive outside scrutiny.

Why is it being handled like this? The whole situation makes no sense. In circumstances like this, it is important to consider the incentives that people face, and to ask whether there are simple explanations.

16. **BCnrd**
December 17, 2017

Tom:

There are standard protocols in place for an editor to be entirely removed from the evaluation process of a paper in which there is a conflict of interest (e.g., the submission doesn't go to that person, and the final decision can be made by some designated set of editors not including the one with the conflict of interest). The editor-in-chief need not have any more or less significant role in the decision process than other editors; their position may be purely for bureaucratic rather than scientific purposes.

I am an editor at a journal for which the editor-in-chief does not get involved in the scientific evaluation or the acceptance process at all; their role is to handle other aspects of the journal's mission. So though it does indeed not look so good, in principle that doesn't mean it must taint the process. However, you do raise the very apt point that the handling editor(s) bear just as much if not more responsibility than the referee(s) for the acceptance of the papers (and in particular for not forcing the author to carry out a substantial rewriting of the work to improve the clarity for experts in arithmetic geometry).

David Roberts:

Your suggestion wouldn't address the core issue that the writing style of the papers (which remains essentially the same as 5 years ago) does not communicate key ideas and insights in a sufficiently understandable manner to the wider community of arithmetic geometry experts. Having referees attest to their confidence in the correctness in a public manner in their role as referees won't help since no explanations of ideas are thereby conveyed. So abandoning the important principle of confidential refereeing would not accomplish anything in this case.

What I wrote just over 2 years ago in paragraphs 5 through 8 of section 6 of my notes on the Oxford workshop at https://mathbabe.org/2015/12/15/notes-on-the-oxford-iut-workshop-by-brian-conrad/ seems as apt today as it did back then.

17. **Perry Metzger**
December 17, 2017

Re: formal verification:

The formalization of the Feit-Thompson Odd Order Theorem in Coq took about six years, though a lot of that was R&D into how to formalize a proof that complicated, something that hadn't been done before.

I would vaguely guess that a formalization in Coq of Mochizui's work by people who understood it and had a reasonable background in formal verification might take a comparable period — the proof is significantly longer, but proof engineering (and that's a real thing) is much better than it was when Gonthier began the Feit-Thompson effort. (This is, of course, only a guess, one only finds out by trying.)

(Note that Mizar is quite old, I don't think I would even attempt to use a system for this that wasn't, like Coq, based in some sort of modern type theory. Coq and Isabelle/HOL are probably the only realistic choices I'd say, though perhaps Lean might be mature enough at this point, I haven't tried using it for anything real.)

18. **David Roberts**
December 17, 2017

BCnrd I would hope that the added profile of the referees' responsibility in asserting correctness would make them extra careful in their assessment. If the referee reports were also public, so we do not have to rely on M's cryptic comments of the form "Corrected slightly erroneous phrasing at the beginning of the second sentence of the statement of Corollary 2.4, (i)" as posted to his website (along such banalities as "Corrected a misprint ("(from above)" —> "[from above]") in Step (x) of the proof of Corollary 3.12″), then we would have a better idea of how they purportedly analysed and "understood" the proof.

I do not think anonymity of referees such a sacred cow that in the case of what could be a result of immense import there is openness in the process. It would give people a mud-map of how others worked through the material if the documents were not secret, and give some idea how to proceed. If the referees are in fact people who have already gone on record as stating they think the theorem is correct, and said people are in M's orbit, then that also gives people an idea of how much to trust the process.

On a different note, I saw recently some updated comments released on M's website that introduced some terminology for something that was an existing concept (a certain topological group being second-countable was given some opaque adjective, like being "Galois", and then every single peculiar object that relied on this was decorated with the adjective). In principle one could go through the background papers are remove all the cruft or just rename objects to something less "creative". Some kind of dependency graph as the Stacks project has for the various theorems/definitions would illustrate what is really needed, and what is not. Crowd-sourcing efforts like these I feel would be more productive than wringing one's hands and saying "it's impenetrable".

19. **BCnrd**
December 17, 2017

David Roberts:

Based on 5 years of experience of talking with very many top professional number theorists, I can say with extremely high confidence that the referees have to be among those in M's orbit: there is nobody else out there who has been willing to say even off the record that they are confident the proof is complete. Indeed, even some of the speakers at the Oxford IUT workshop who have put a lot of effort into the papers remain uncertain if the proof is complete, particularly confused about the crucial 3.12 in IUT3. So although I can understand the perspective from which you hold out hope that identifying the referees may lead to a clarification about the mathematics, I am sorry to say that I am very confident that it will not help at all in the end.

The unusual terminology for existing notions is a distraction, but if that were the primary difficulty then this unusual saga would have been resolved long ago. I'm doubtful that dependency graphs or crowd-sourcing are going to help either. Maybe it's a reflection of my Luddite personality, but I've never understood the purpose of dependency graphs for learning or measuring the complexity of a serious piece of mathematics: the way to learn is to sit down and read and follow back the references to earlier results until one is done (this is how I read EGA, for example: begin at the interesting stuff and go backwards), and to evaluate difficulty one should simply know the ideas and proofs. For example, when I look at dependency graphs in the Stacks Project for results I know well, I find them to be quite irrelevant to measuring difficulty. (To be honest, I don't understand at all what real purpose those are meant to serve in terms of understanding mathematical ideas. I'd love to be enlightened about that.) Likewise, I don't see how crowd-sourcing can be expected to reveal ideas in a high-level paper on arithmetic geometry when experts at the level of Faltings are completely mystified. It is a much harder task than DeepBlue or alphaGo defeating the world master. 🙂

Frank Calegari's blog post from this evening does an excellent job of summarizing the current view of many professional number theorists:

https://galoisrepresentations.wordpress.com/2017/12/17/the-abc-conjecture-has-still-not-been-proved/

20. **Matthew Emerton**
December 17, 2017

Regarding the question of the paper being accepted: In my view, it adds essentially no new information (regarding their correctness) to learn that the papers have been refereed and accepted. Because if the refereeing process was meaningful, then it was undertaken by experts who are known to the number theory community. (I don't mean that the identity of the referees is known; just that the referees had to have come from a known group of experts. There is no outside group of referees who can adjudicate the situation separate from the various experts who have already tried to come to grips with the papers.) And in this case, the number theory community essentially knows where every expert stands on this matter. Most regard the situation as ambiguous at best, and are not confident in the correctness of the papers. Some experts do claim that the papers are correct, and that they understand the mathematics — but they have not been able to explain the papers, or their understanding, to a wider audience of experts, and so this wider audience remains unconvinced. It seems almost a necessary conclusion that the referees came from this second group of experts, given that they did certify the correctness of the papers, and so there is no reason to give their views any more credence just because they are now being expressed a second time in the guise of the opinions of the anonymous referees.

The bottom line: no expert who claims to understand the arguments has succeeded in explaining them to any of the (very many) experts who remain mystified. This situation hasn't changed just because some of the former experts have now weighed in wearing the hat of an anonymous referee.

21. **Lucifer**
December 17, 2017

In this comment I would like to make three somewhat perhaps bizarre observations on the matter at hand. The first is that I think the publication of these papers doesn't matter. The second is that all the fallout from the Mochizuki ABC situation has already happened. The third is that it was unavoidable that these papers would be published.

The publication of these papers doesn't matter as we will just continue exactly as we have with other published papers that contain errors and/or have incomplete proofs. We will continue to try and prove the ABC conjecture exactly as we were doing before the publication of these papers. The results of these papers will not be used more than they already are; in fact I would think, because of the bruhaha involved, there is much less chance of referees overlooking a reference to these papers than there is of referees overlooking a reference to one the (small but nonzero number) of completely erroneous papers in the literature. It is harder still to catch the use of an erroneous lemma in an otherwise completely correct math paper, especially if the authors are famous.

The fallout has already happened, since if we could use the ideas and methods in these papers to successfully prove something as important as ABC, then number theorists and arithmetic algebraic geometers would already have figured out to use it to prove more. In fact, you'd have many people working on refining the method, reformulating it, and improving the precise bounds found by M. Especially recently we have seen that a breakthrough very quickly leads to a much improved exposition as well as much improved bounds. Two examples are: (1) "bounded gaps between primes" proved by Yitang Zhang which led to a very succesful polymath project, and (2) "bounds for cap sets" by Croot-Lev-Pach which led to a paper by Ellenberg-Gijswijt and then via Tao to slice rank, etc, etc. The stereotypical lone math researcher working in an attic still exists, but I would say more and more of the advancement of highly technical fields in mathematics (such as arithmetic algebraic geometry) relies on having larger groups of mathematicians distilling, refining, combining, and adding pieces to construct a larger whole.

It was unavoidable that these papers should be published. In 2012 M convinced himself he had proven the ABC conjecture (as predicted by M several years earlier), after working very hard and long (starting around 2000 or 2002). Of course getting the papers published was then the next logical step. Not getting the papers published would be a public humiliation. I think the outcome we have now is strange but we can deal with it easily and it is best for M. My hope for the future is many more papers of M such as his amazing papers on the Grothendieck conjecture.

22. **Davide Castelvecchi**
December 18, 2017

A colleague of mine who reads Japanese tells me that the article does not explicitly say that the papers have been accepted, only that they are "forecast"（見通し）to be accepted.

23. **Stephane Hubl**
December 18, 2017

I am afraid your posts related to Mochizuki's theory contain many incorrect statements.

I do not have time to go through everything. Here are just few examples.

"while most experts in the field who have looked into this have been unable to understand the proof."

Who do you call an "expert"? Someone who knows her/his narrow area of vast arithmetic geometry or number theory? What makes such a person an "expert" in Mochizuki's theory or anabelian geometry?
Have you read Fesenko's interview to the AMS?

I've talked with several experts, they understand the proof and agree it is correct.
How many experts (who at least know anabelian geometry) have you talked with, to make your statement?

"Looking at these documents, the daunting task facing experts trying to understand and check this proof is quite clear."

The task is daunting if you lack enthusiasm. If you lack enthusiasm, it is better to switch to another area.

Do you expect that the most fundamental achievement in modern mathematics will be simplified in the first years of its existence to the extent that everyone can easily read it?

How many people understood Deligne's proof of GRH in positive characteristic (the Weil conjecture) when it was published?
How many people understood Voevodsky's proof when it was published?

I've heard about several PhD students who have already studied Mochizuki's theory in full. I see that several talks at the two international conferences on IUT were given by students.

"the current situation of understanding of the proof has not changed significantly since last year"

What is the source of your information? Have you talked with several experts?

I've heard that the number of experts is now 13-17.

"A small number of those close to Mochizuki claim to understand the proof"

What do you mean by "close"? There are 5 or more experts outside Japan.

What is "a small number" for you and what do you compare it with?

Are you aware that there are already more (maybe, two times more) people who understand Mochizuki's theory than the number of people who understood Deligne's proof of GRH in positive characteristic or Voevodsky's proof of the Bloch-Kato conjecture at the time of their publication?

"but they have had little success in explaining their understanding to others."

Have you talked with those young researchers who have mastered IUT by learning from the other experts? Do you imply that everyone who has understood Mochizuki's theory should stop doing everything else and dedicate all her/his full time to explaining the theory to others?

Have you read the excellent survey by Mochizuki (2016)?
I've heard about 5-6 reviews of parts of IUT being written for the volume of proceeding of the RIMS workshop on IUT.

"The usual mechanisms by which understanding of new ideas in mathematics gets transmitted to others seem to have failed completely in this case.

What is your evidence? How to you measure the failure? Have you at least talked to people who attended the RIMS workshop on IUT?

I am afraid your post demonstrates a lot of disrespect to the truth, to Mochizuki, and to those people who have worked hard to become experts in Mochizuki's theory

not even wrong

24. **b**
December 18, 2017

Mochizui should just go back to working and not focus on what the occidental community thinks about what he's done. The math is there, and if it is useful it will be used. The subject is too interesting, and a young mind somewhere, not burdened by hardness, will eventually take it up and clarify things for those that seem incapable of working outside of their comfort zone. I think he wastes his time now trying to be a google math translator for intractable, inflexible thinkers.

25. **Kevin Buzzard**
December 18, 2017

Re: formal verification. I would like to try and refute a conjecture made by Perry Metzger above. Metzger says

"I would vaguely guess that a formalization in Coq of Mochizui's work by people who understood it and had a reasonable background in formal verification might take a comparable period" [6 years, the approximate time it took to verify Feit-Thompson in Coq].

Unfortunately the two situations are completely incomparable. The reason Feit-Thompson was verifiable in Coq in finite time was that there is a very well-written two book project (Bender-Glauberman, published 1994, and then Petervalvi, published 2000) which gives all details of the Feit-Thompson proof at a level which is understandable by a graduate student in group theory without any "extra training". In other words, the books are undoubtedly _mathematics_. This part is the job of humans, and humans did it well. Humans "pre-formalised" the proof if you like, making it clear how each step could be checked from the axioms of mathematics without any pretence of requiring 300 hours of training.

Because this had already been done, a team of computer scientists and mathematicians could then go on and really formalise the proof in a computer proof verification system. The paper describing the formalisation of Feit-Thompson in Coq explicitly explains this essential prerequisite on its first page.

Humans have not yet finished the pre-formalisation part of Mochizuki's work. The papers contain claims which many members of the number theory regard as being unclear. A team of computer scientists cannot work with a document which contains assertions for which the only way to unravel them is to ask a small group of people who claim to understand the proof, especially if the response is that the computer scientists should just go away and do 300 hours of training. Because the pre-formalisation is not yet finished, the formalisation can not yet begin, and until the pre-formalisation is finished I think it would be very unwise to speculate about the length of a possible future formalisation project.

I speak as someone who has been formalising his first year mathematics undergraduate lectures in Lean this term, and can verify first hand that whilst learning the language of these systems is a barrier to entry, if you fully and properly understand an argument as a mathematician there seems to be no barrier in formalising the argument in Lean other than the simple fact that it can sometimes take quite a long time to convince a computer that something is "obvious".

26. **Matthew Emerton**
December 18, 2017

I don't want to get into an argument in comments, and so I will most likely not follow-up if there are any responses to this comment. That being said, I would like to address some of the assertions and implications in a couple of the comments above.

The reason for this is that there are many people (including e.g. science journalists, and their lay readers) who are interested in the status of ABC, and who are not in a position to independently evaluate it, and so who are relying on the reports and commentary of those closer to the action to help them in forming their own opinions and making their assessments. Because of this, I think it is important to give some indication of how the situation with ABC is different to that with other previous breakthroughs.

I am not old enough to have seen the reception of Weil I and Weil II first hand, but I don't think there can be any comparison with the reception of IUT. As Persiflage discusses in his blog post, very soon after the Grothendieckian revolution in algebraic geometry began, there were many centres of expertise in the theory, all over the world. Deligne's strategy for proving the Weil conjectures incorporated many known methods, and could be explained in those terms: sheaf-theoretic methods building on the classical technique of Lefschetz pencils, combined with other ideas such as tensor-product amplification, and certain methods of estimate familiar from analytic number theory. The proof could be broken down and explained in these terms (and there is a lovely article of Nick Katz that does this). There is no doubt that the proof was immediately accepted by the community at large, and immediately recognized as a breakthrough.

I was a graduate student when Voevodsky's work first appeared, and saw first-hand the process of it being disseminated in seminars at Harvard. Many people, some junior, some senior, attended these seminars. His methods were almost immediately taken up and further developed by other experts, and there were existing frameworks in which they could be explained and understood: they combined and built upon methods from the theory of algebraic cycles, methods from sheaf-theory and homological algebra, and methods from homotopy theory. Experts from these various areas were quickly able to grasp various of the essential aspects of the arguments, and further develop them. (This is the phenomenon that has *not* happened regarding IUT — the methods have not been understood and taken up by a panoply of other researchers.)

The suggestion that the experts who do not understand IUT are not *true* experts, but are instead hidebound and lazy, and should not have their judgement listened to, is not reasonable. It is close to a no true Scotsman fallacy.

To give another example: when the papers of Wiles and Taylor–Wiles appeared announcing the proof of modularity and FLT, they used methods from the arithmetic of modular forms and the deformation theory of Galois representations. The best-known experts on these methods, who had written papers on these precise topics (besides Taylor and Wiles themselves) were perhaps Gross, Hida, Mazur, and Ribet. Faltings was a celebrated expert in arithmetic geometry and neighbouring topics, but had not written papers that were as close in technique and subject matter to the W-TW arguments as these latter named experts. Nevertheless, he was certainly able to read their papers, understand the arguments, and he famously contributed one of the first simplifications to the crucial TW patching argument.

If the situation with IUT were comparable to the situation with previous breakthroughs, there would be plenty of experts outside the immediate orbit of its author, and outside the specific field of anabelian geometry, who would have successfully engaged with the arguments, and could comment with certainty on various aspects of the proof. This is manifestly not the case, and the situation with IUT is manifestly not comparable to the earlier situations with the Weil conjectures, the Milnor conjecture, or modularity/FLT.

27. **BCnrd**
December 18, 2017

Stephane Hubl:

I too have spoken with some experts who are convinced the proof is complete, and I am sure that they are sincere in their conviction. But I have also spoken with a rather larger number of experts in anabelian geometry as well as some participants and speakers at the RIMS workshop on IUT who have all invested tremendous amounts of time in the study of the IUT papers and remain frustrated by the task of extracting essential ideas from the papers in their current form (though in time some of them are making modest progress in parts). In particular, there are very well-informed speakers from multiple IUT workshops who remain puzzled by key steps. This cannot be disregarded.

The bottom line is that there has been a serious breakdown of the usual modes of communication of mathematical ideas. This has nothing to do with the question of whether or not the IUT papers contain a complete proof or at least the crucial ideas which yield such a proof, and what follows is not focused on that, but rather on the unprecedented communication breakdown that is the primary concern of many. (Just to be clear, I think that Mochizuki is a tremendously talented mathematician, with a remarkable work ethic.) Matt Emerton has addressed this well in his comment above, and I'd like to share some of my own thoughts on this (and then I too will probably bow out from further comments here).

Stories of PhD students whose have "studied Mochizuki's theory in full" cannot be taken to mean (in the absence of more specific information) that they have understood much when it comes to the difficulties that have confronted experts in anabelian geometry. We all know plenty of examples of well-intentioned PhD students who delude themselves into thinking they understand a piece of mathematics much better than they really do. V. Dimitrov was quite up front in his own presentation at an IUT workshop that he was treating the details as a black box while seeking to make some refinement to get a better conclusion. His experience doesn't indicate anything about the status of IUT (as I am sure he would be the first to acknowledge). So likewise even if a PhD student makes some new observation about one facet of things, that fact itself has no bearing on the overall concerns that persist. Moreover, the fact of a student — or anyone! — giving a talk at such a workshop says nothing about the person's grasp of the overall theory or the technical details. It makes good copy for a journalist to write about energetic bright young people making great progress while the experts complain about being confused, but such stories have little to do with reality.

What is making this situation so different from that of other big advances used by many mathematicians who haven't understood the technical details of the proof is that even after many years have passed there still hasn't been the wider grasp of some key new insights and how they plausibly fit together overall to yield a result of the desired type. It is of course a weaker kind of understanding than technical mastery of the entire argument, but is the kind of "reality check" that mathematicians have always used when judging things and it is usually addressed by the Introduction. The reason this has been rather more difficult than is usually the case is likely due to some singular communication aspects (the unconventional writing style and the decision by the creator not to travel widely to give talks about it) that can hopefully be addressed in time as other explanations are created and especially as the ideas within are used to do other things.

The comparison to Deligne's GRH is based on a flawed perception of the situation at that time (and it also not a fair standard anyway, since as Matt Emerton notes that proof was done within a framework that had existed for a decade and had already been worked through in seminars around the world). At the time of Deligne's publication of his proof of GRH in positive characteristic, experts in algebraic geometry from around the world understood the proof right away, certainly far more than at present for IUT. Although some specific details about the proof of the Lefschetz trace formula hadn't yet been published (which apparently delayed Deligne's Fields Medal from 1974 to 1978), those ideas had been disseminated in seminars at a variety of places. And more importantly, the key insights of Deligne's method were rapidly understood and within a few years Deligne had gone much further with his Weil II paper, and progress kept going in those directions (with new applications emerging, etc.).

An ongoing point of frustration, even among many leading experts in anabelian geometry, has been to extract essential new insights from the IUT work, to get a clearer sense of what is making it tick (so to speak). This is of course asking for much less than a complete command of the entire proof. To the extent that doesn't happen and the methods are not used to do other things, the result can be treated as was Hironaka's resolution of singularities. That proof at the time of its publication was fully understood in its details by almost nobody, but (i) the broad outlines of the method were grasped, including key new ideas (such as normal flatness in commutative algebra) that were used to do other things, and (ii) it was written up in an entirely conventional writing style. Together, (i) and (ii) probably explain why the result was quickly accepted as having been proved, even though Hironaka's intricate nested inductive arguments with delicate invariants were too exhausting for most to get through at the time (even defeating energetic brilliant young people such as Deligne). The reliance on resolution of singularities in proofs of other results was tracked similarly to how one tracks reliance on a widely believed conjecture, and in time a small but dedicated group of experts in the details did emerge and gradually streamline and improve the techniques over many years until an understanding was reached that could be more widely disseminated. One can hope that eventually something similar will happen in the present case. In the meantime, I share the sentiment at the end of Lucifer's comment above and I hope that the modes of communication that have broken down in this circumstance can eventually be repaired.

28. **John**
December 18, 2017

Brian, Matt, Kevin, why three of you are not seriously studying IUT? Why did not you attend the Kyoto conference on IUT?

Matt, you are not presenting the history of Voevodsky's proof correctly

Brian, you write, "What is making this situation so different from that of other big advances used by many mathematicians who haven't understood the technical details of the proof is that even after many years have passed there still hasn't been the wider grasp of some key new insights and how they plausibly fit together overall to yield a result of the desired type." – but surely you know many examples of this kind of things, e.g. class field theory was viewed as impenetrable for most number theorists for at least 25 years.

"An ongoing point of frustration, even among many leading experts in anabelian geometry, has been to extract essential new insights from the IUT work, to get a clearer sense of what is making it tick (so to speak)." – who are these "many leading experts"? Do you know if they managed to read the 2016 survey of Mochizuki?

"The bottom line is that there has been a serious breakdown of the usual modes of communication of mathematical ideas." – we live, we learn, we change, we adopt. Number theorists have been tremedously slow in adapting to new things in comparison to almost everyone else. Smart phones did not exist 20 years ago, but various number theorists still think about mathematics as they live 20 years ago. Adopt. Learn. Improve.

29. **Daniel Moskovich**
December 18, 2017

His blog contains personal thoughts and philosophy as opposed to mathematics. I don't think it is informative about the contents of his papers.

He claims that the world needs walls, and hearts that can see through walls. Without walls, it is a Tower of Babel or Russel's Paradox. He feels he needs a wall of privacy between him and many things, including English speakers and the English language. The wall in his Inter-Universal Teichmuller Theory is the Teichmuller symmetry, and the heart that sees through it is the Etale symmetry.

30. **Art**
December 18, 2017

From the Internet Encyclopedia of Philosophy:

No True Scotsman

This error is a kind of Ad Hoc Rescue of one's generalization in which the reasoner re-characterizes the situation solely in order to escape refutation of the generalization.

Example:

Smith: All Scotsmen are loyal and brave.

Jones: But McDougal over there is a Scotsman, and he was arrested by his commanding officer for running from the enemy.

Smith: Well, if that's right, it just shows that McDougal wasn't a TRUE Scotsman.

31. **Daniel**
December 18, 2017

I see many non-mathematician posting a comment here. For those who do not understand mathematical comments posted here, informal Japanese intro to IUT is now available for free at http://live.nicovideo.jp/watch/lv303564022#7:26:33
It is done by Kato @Tokyo Institute of Technology. He states his talk is accessible to high school students. No translation available.

32. **Dale**
December 18, 2017

Yamashita's corresponding theorem is 13.12, not 3.12.

33. **Peter Woit**
December 18, 2017

Dale,

Thanks for pointing that out, fixed.

34. **Anon, bemused**
December 18, 2017

To make a different comparison, for the people who aren't number theorists.

The most spectacular advances in arithmetic geometry since Grothendieck/Deligne are being made *now*, by Scholze (building on foundational work of Fontaine, in collaboration or conversation with many — Fargue, Bhatt, Kedlaya-Liu, …)

In particular, as just one example, we now have a road map for local Langlands (it is geometric Langlands on the 'curve' built out of the period rings for p-adic Hodge theory).

The new techniques that make this possible are explainable at every level, from that of high school student (a bit vaguely, but this is a comment not a blog post: we are able to treat the prime p like a variable x, by also considering all possible p^n'th roots of p), to the professional mathematician (say, the definition of the v-topology, and how passing to the perfection kills Ext groups).

This is all new to all of us, and learning seminars — on Scholze's papers, and on the background — are happening at almost every institution on the planet.

They are difficult papers. It is a joy to read them — the ideas sing, the implications are staggering, and Scholze also writes really well.

Nothing like this has happened with Mochizuki's papers. Not a single new idea has made it out to the rest of us, nor even old ideas (with the one exception of BConrad's rephrasing in one of the blog posts after the Oxford conference).

This is sad for those of us who havent the time to invest in reading his proof — we all *want* his proof to be both correct and new — and annoying as hell for the ones who have tried reading his proof.

35. **David Roberts**
December 18, 2017

[let me just say beforehand that I certainly give place to the expertise of the number theorists here on the status of the proof]

My thoughts about referees should be viewed as more sociological in nature: either we are pleasantly surprised that someone outside the inner circle has apparently understood the work, and we can ask for an explanation in ordinary language of what they think is happening, or all the world knows a handful of junior colleagues at the same university refereed the paper. Experts suspecting who the referees are doesn't make it clear what is going on. I expect it is closer to the latter option…

Regarding dependency graphs etc, I would like to draw a comparison between "just read back through all the references" in this case and another: that of FLT and the perennial question (now settled *in print* by McLarty) of whether the proof used universes. One expert here said several times on MO that they aren't used, because he has read back through all the references from Wiles to EGA. Is it left to the rest of us to take him on faith, or duplicate that effort? Or better, record somehow exactly which bits of thousands of pages of mathematics are or aren't actually used in a given proof. To the case at hand, apparently the full theory of Frobenioids is not used in the IUT papers. Being able to know what to skip from the prerequisite papers would be a head start for someone trying to figure out what is going on. And I would like to know what on earth happened, whether even any of the prerequisite papers are good for something other than IUT. I would ask M's inner circle what problems Frobenioids, for example, are able to solve that one can't do in ordinary Arakelov geometry.

Or, since the number theorists are floating about here, up to which point are people confident in what is going on in M's work? Is the reduction of Szpiro to the special case sound? Is all the stuff with the étale theta function legit? As a category theorist there is simultaneously a huge amount of naïvety in the IUT papers (isomorphism classes of functors? Totally unused constructions with Grothendieck universes? Why??) and interesting results (equivalences of categories of certain topological groups and of arithmetic objects), but I can't tell if these are being used arithmetically in any way beyond "I can reconstruct stuff from data. Tadaa!"

36. **observer**

December 18, 2017

I think that some “amateur mathematicians” here are being misled into a false sense of understanding of how mathematics research works, and what is actually going on in this particular saga. As someone who has been in a position to observe arithmetic geometry research rather closely over the past few years, but who is also blissfully free from the title of “arithmetic geometry expert”, I think I can be a little more blunt.

This is not an issue of mathematicians being too lazy, or too attached to traditional methods of dissemination and communication, or Mochizuki’s proof being too difficult. The community has seen many spectacular and difficult breakthroughs over the past few decades, all of which were accompanied by various signs of legitimacy. One such sign is that the paper’s introduction should be able to summarize a strategy which is both new and at least plausible. Furthermore, as one reads the paper one should have the feeling of building up contentful observations. And those purporting to understand the solution should be able to give talks and answer questions in a way that seems to convey knowledge.

It should be mentioned that Mochizuki’s earlier work was brilliant and difficult, and was absorbed by the usual process of mathematical dissemination. Unfortunately, the paper presently in question fails to exhibit these signs of legitimacy. It introduces an incredible amount of jargon, which is explained in terms of more jargon. The talks “explaining” the paper continue this trend of seemingly empty verbiage. It is unprecedented (for legitimate work) that after dozens hours of talks, and hundreds of “survey” pages, not a single meaningful idea has been absorbed by the wider community of experts. Although people are too tactful to publicly state this, the situation has led to a strong impression that the reason why nothing is being communicated is that there is no real content to communicate.

37. **Bobito**
December 19, 2017

Because there are nonmathematicians, physicists, amateurs and the like reading this blog, it is perhaps worth pointing out that posters like Brian Conrad and Matthew Emerton are very good mathematicians with a lot of specific and relevant technical expertise and who generally speak/write with a lot of care. While arguments based on appeals to authority are anathema to the scientific/mathematical spirit, they are all that is available to the ignorant, and for the ignorant the question is to properly pick the authorities. For me at least, I give a lot of credit to what those two write because when they write about things I do understand, my judgment is that they write interesting things and communicate them well. So I take their opinions on the Mochizuki situation seriously.

38. **atreat**
December 19, 2017

New discoveries in science and mathematics are usually made by standing on the shoulders of giants. By building on what came before and adding a new piece or idea that opens up new vistas to explore. Surely, Mochizuki is similar. His ideas must have started with a kernel of an idea clearly relating to known work. He must have took that first step into the unknown from known territory. Why can he not explain how his thinking evolved from that first step and trace back to the known ideas?

39. **A reader**
December 20, 2017

Thank you all for this very interesting conversation. A viewpoint somewhat relevant to it might be “On proof and progress in mathematics” (http://www.ams.org/journals/bull/1994-30-02/S0273-0979-1994-00502-6/S0273-0979-1994-00502-6.pdf or https://arxiv.org/abs/math/9404236), by William Thurston (Peter Woit had posted a link to it a few years ago).

40. **Davide Castelvecchi**
December 20, 2017

Got an email from the journal PRIMS: “The papers of Prof. Motizuki on inter-universal Teichmuller theory have not yet been accepted in a journal, and so we are sorry but RIMS have no comment on it.”
This seems to implicitly admit that the papers _are_ under review at PRIMS. Otherwise how would the journal feel like it can comment on the status of papers under review somewhere else? Oh, but the editor-in-chief of PRIMS is Mochizuki himself, so perhaps he is making the journal speak for him?

41. **David Roberts**
December 22, 2017

Given PS’ comment and BCnrd’s corroboration, I thank them for being open about this, and retract my previous bluster and confidence. It’s a pity it took this long for the specific sticking point to become public, though.

42. **Matt Grayson**
December 22, 2017

I was very fortunate to take Algebraic Geometry from Hironaka. He presented resolution of singularities, but I completely failed to understand it. He saved my life, however with this comment: ” You are an undergrad. Undergrads know nothing! As a grad student, you will learn one thing – your thesis. Then, as a Professor, you will start to learn Mathematics.”

I can not thank him enough for that perspective.

43. **BCnrd**
December 22, 2017

David Roberts:

Although the concern about the proof of Corollary 3.12 in IUT3 has been known to quite a few number theorists for some time, and in particular had to be known to all near to IUT (e.g., some speakers at IUT workshops are very well aware of this and have been trying to sort it out), there didn’t seem to be a compelling mathematical reason to make this public before now (say by mentioning it somewhere on the Internet). The reason is that the referee process should be permitted to run its course without undue public pressure.

In particular, if the referees had identified this matter as something needing clarification and if it had then been addressed (prior to acceptance) then there would have been no purpose in having made a public statement about the fact that such a non-trivial concern had arisen. (Indeed, the identification of gaps/errors and their correction during the referee process is entirely standard, so it would not be a reasonable policy that such concerns are announced in public when they are found prior to acceptance.) The assumption of many number theorists was that the referees had to be going very carefully through the papers, so they must have highlighted this known point of concern, and hence in due time before acceptance it would somehow be clarified.

But then there emerged the recent (ultimately incorrect) news that the papers were accepted, yet there had been no change in that proof which adequately addresses the concern (there have been some minor changes in the writing in the proof, but not relevant to this issue). That situation, together with the fact that more than 5 years have passed since the original release of the papers, exhausted the patience of many number theorists; the time had arrived to make this concern more widely known. What seems a pity to me is not that it took until now to make this long-standing concern more public (ideally it would have been clarified N years ago and then would never need to have been discussed publicly at all), but rather that after so much time it still has not been adequately addressed even though so many more trivial changes have been made in IUT3.

44. **David Roberts**
December 22, 2017

BCnrd,

Given the speed at which errors were identified on MathOverflow then rectified, imagine if the "mysterious proof" had been publicly identified and all eyes could have been focussed on that for the past n years. Has anybody told Mochizuki directly that 3.12 needs serious attention and that it's not for lack of understanding the previous "trivial" sections? If I was in a position to do so (eg being a number theorist of good standing) I would have done so already.

45. **BCnrd**
December 22, 2017

David Roberts:

I prefer not to get involved in further discussion on the points you are raising; I have said all that I wish to say on these matters in my previous comments here and on Frank Calegari's blog.

46. **TS**
December 23, 2017

Just in case it might help, although probably experts have looked at that too, there has been two review papers in Japanese by Hoshi, and the second one http://www.kurims.kyoto-u.ac.jp/~yuichiro/intro_iut_continued.pdf touches a little bit upon that 3.12 issue.

Namely, at the end of page 92, just before the paragraph 26, it says (thanks to google translate) that "due to the existence of the compatible isomorphism $^{\dagger 0}\mathfrak{R}_{Frob}\xrightarrow{\sim} .^{\ddagger 0}\mathfrak{R}_{Frob}$ the log-volume of the target object $^{\dagger 0}\Theta$ cannot help but be less than $\text{vol}(^{\ddagger 0}\underline{\underline{\Theta}})$, hence the inequality …"

47. **Trent**
December 23, 2017

I'm sure people have extensively tried convincing Mochizuki to do this, but… mentioning anyways since the situation is so perplexing:

Fesenko says: "his theory is so vast that to explain his work, ordinary visits and lectures are not enough. For instance, prior to such lectures, the audience should already have studied the prerequisites, i.e. those 1,000 pages. It simply does not make sense to come to give a one hour or even ten hours of talks on IUT–people won't understand much, I am afraid."

I can understand thinking that eg a world tour of 2hr lectures is useless, but… 10hrs is useless? really?

and even if one accepts that 10hrs is insufficient, 2hr lectures 2x per week for 1.5 months = 24hrs of lectures. I don't care how complex IUT is, I can't imagine 24hrs of lectures at a major research center not having a positive impact on the dissemination of IUT (especially if it is video recorded). 1.5 months isn't that long to be abroad either, especially if it is all spent in one place rather than constantly going through the annoyance of shuttling around the world.

I have absolutely no idea why such a 1.5 month long lecture series (video recorded or not) hasn't occurred.

(The good news is that maybe with the public attention drawn to Corollary 3.12 the mathematical community will be able to confirm/deny the proof without such a lecture series ….. hopefully.)

48. **David Roberts**
December 23, 2017

BCnrd,

fair enough :-). Thanks for all your input both here and there.

49. **sdf**
December 23, 2017

David Roberts makes a good point in one way or another: it would have reflected much more positively on the mathematical community at large considering the media circus all about this work, if we had something to hold up publicly and say "yes well these manuscripts are all good and well, but part XYZ doesn't make sense and must be addressed by the author". Articles like "mathematicians tormented by proof" may have been prevented etc. (although I suppose one shouldn't underestimate mass-media's ability to misunderstand/misrepresent research-level mathematics)

50. **mJ**
December 23, 2017

The answer to that point is Remark 3.12.2 (ii) of newest version of IUT-III

51. **Dale**
December 23, 2017

As I understand it, Corollary 3.12 in IUT 3 ("main inequality") is central to the whole proof of the abc conjecture. Previous sections of IUT (totalling hundreds of pages) just set up all the definitions and trivial proofs needed to prove Corollary 3.12, and when the corollary is proven abc conjecture is pretty trivial to prove based on that corollary. So what is needed to Mochizui to explain more in detail how one arrives in to the "main inequality".

Is this correct understanding?

52. **BCnrd**
December 23, 2017

mJ:

Thank you for your comment. It came to my attention this morning from someone else via email that Remark 3.12.2 has been very much expanded since earlier versions (I don't know when that change occurred), and that this Remark (not just its part (ii)) should address some aspects of how 3.12 follows from 3.11. The wider awareness about this due to the discussion on Frank Calegari's blog and this one has helped in this direction. I immediately brought this to the attention of several other people who have looked a lot into the IUT papers; hopefully it will clarify things. But the coming days are a time of travel and vacation for many people, so don't hold your breath. 🙂

53. **Peter Woit**
December 23, 2017

All,
This blog entry isn't the place for trying to resolve the mathematical questions raised about the proof. I'm completely incompetent to moderate such a discussion and the set of people interested in participating in this on a blog may have zero intersection with the small set of people competent to engage productively in it. Mathoverflow is a site more set up for this sort of thing, it's an interesting question whether it would work over there.

For settling mathematical issues like this one, there really are very few people in the world with the necessary expertise and talent, capable of telling what claims are unproblematic, identifying where possible problems lie. What is supposed to happen is discussion between the author and this small group of experts, until they understand the proof and the problems they find are resolved. This has failed to happen in this case, for a complicated set of reasons, and anyone who feels like it can try and blame participants X, Y, and Z for not doing more. I think the point Brian Conrad is trying to make is that the math community puts the main responsibility in a case like this on the refereeing process: it is the job of editors to pick referees up to the task (an extremely difficult and important one in this case), and it is the job of those referees to do everything they can to ensure proofs are solid and written in an understandable way. For good reasons this process is conventionally done confidentially. Unfortunately, in this case there is evidence of a failed refereeing process (claims the papers have been refereed, while an expert is pointing to problems that have not been addressed, and many experts have trouble with readability of the papers), and confidentiality makes it impossible for other than a small number of people to know what went wrong.

Addendum: I just saw the latest comment indicating that maybe the comment from "mJ" is highly relevant, and possibly it is blog discussions that will end up having a role in moving this process forward. If so, that's a very unusual way (in comparison to private discussions between experts, the author, and referees) for mathematics to get done.

54. **Wyman**
December 23, 2017

Ivan Fesenko has replied to Peter Scholze. It's, uh, interesting.
https://www.facebook.com/ivan.fesenko.37/posts/1128469910617882

55. **anon101**
January 11, 2018

Recently mentioned by @math_jin on twitter is a series of talks at the end of this month at the Southern University of Science and Technology in Shenzhen http://math.sustc.edu.cn/event/10808.html to be given by Fucheng Tan (who apparently works at RIMS http://www.kurims.kyoto-u.ac.jp/en/list/tan.html)

56. **Merle Aucoin**
January 14, 2018

I am no mathematician but active scientific PI and I follow this case since Castelvecchis first Nature article in utter fascination. Please forgive me to express my uneducated 5c.

I feel the situation is slowly approaching a state were expert statements get more and more explicit. In both directions and notably with some quite renowned critics. Lets suppose IUTT I-IV are complete and correct and prove abc. Then already now there is the question: Will Mochizuki ever/in our life times get full credits for his discovery? I fear due to the growing critics(!) it will not be possible anymore. I think the case just transgressed a point of no return for the maths community.

57. **Peter Woit**
January 14, 2018

Merle Aucoin,

I think your perception of "growing criticism" misses what is going on here. What experts are now saying publicly is not different than what they have been saying privately for a long time now. What changed things was the news (the accuracy of which is still unclear) that the journal of Mochizuki's institution, of which he is editor in chief, was about to publish the IUT proof, claiming it as properly refereed and a correct proof. This news made experts who felt that the proof had not been understood and checked to their satisfaction feel that they needed to say something in public, even though this is, for good reason, not the kind of discussion usually held publicly.

Mochizuki is a well-respected mathematician, and skepticism about this proof is not something personal. It's just a fact that the usual way in which understanding of a proof transmits from an author to the rest of the math community has not happened here, and experts are just making clear that fact. There is a lot of attention now being paid to what has gone wrong, including more focus on a specific part of the proof that experts haven't been able to follow. If this gets clarified and experts start to understand better the proof and be able to check that it works, Mochizuki will certainly get credit for proving abc.

58. **Merle Aucoin**
January 15, 2018

Dear Peter, I see. Thank you for clarifying my misperceptions. I like also to draw your attention to the Wikipedia article on Shinichi Mochizuki, it seems there have been substantial changes and additions since the end of last year. In my eyes most likely from a very close proximity of SM if not from himself. Especially the section on IUTT seems notable, since it contains an attempt to explain the gist of it to even laymen:
https://en.wikipedia.org/wiki/Shinichi_Mochizuki .

This Week’s Hype: The Best Explanation for Everything in the Universe

December 22, 2017
Categories: This Week's Hype

Today The Atlantic has, via Quanta Magazine, some unadulterated, pure, grade A hype for the holidays: String Theory: The Best Explanation for Everything in the Universe. In a time when the credibility of science is under attack, does anyone else see a problem with telling the public that the “Best Explanation for Everything in the Universe” that science has is a “theory” for which we have no definition or equations, no experimental evidence, and no likelihood of ever getting any?

Comments

1. **Mitchell Porter**
   December 22, 2017

   Meanwhile, if anyone wants a glimpse of the current status of theory and prediction in string theory, they might want to examine two papers which came out this week:

   https://arxiv.org/abs/1712.06623 … which presents an equation (page 3) for the fivebrane of M-theory

   https://arxiv.org/abs/1712.06894 … which exhibits “a full non-supersymmetric metastable SM-like 4D string model” (page 17)

2. **Peter Woit**
   December 22, 2017

   Mitchell Porter,

   I suppose they could do that, in which case (after a lot of work trying to understand some very complex constructions) they would see that the current status of “M-theory” is just as I have described it.

3. **Ian Lamm**
   December 23, 2017

   Having read that article, I couldn’t help but get a sense of faint – or not so faint – incredulity.

4. **Cédric Bardot**
   December 23, 2017

   To quote and paraphrase Mikaël Atiyah, String Theory is a “rich mathematical story” about the exploration or geometry with tools incepted by theoretical physicists.
   As far as a new paradigm beyond quantum fields, strings and branes have neither helped very much to better understand the detected standard model Higgs and its connection with higher energy or neutrino physics nor provided a helpful dynamical principle to explain the dark sector of the concordance cosmological model. Connes in a recent IHES video praised a famous string theorist (Veneziano) to stay sceptics about all conjectures and speculations but science sociology in France and the USA may be different just as science economies and policies are I guess.
   Of course Connes (and his physicists and cosmologist coworkers) defends his own view on the geometry-physics interaction offering an equation, a dynamical principle and a new model of spacetime expecting particle and astro-physics will probe the quanta of 4d spacetime that are waiting for the young guy or woman who will make the step further to a Matrix Model…

5. **Urs Schreiber**
   December 23, 2017

   Perturbative string theory is perfectly well defined mathematically and has equations. What does not “have equations” is non-perturbative string theory, due to not being constructed yet. Notice that the same is true for non-perturbative QFT, away from toy examples.

6. **Peter Woit**
   December 23, 2017

   Urs,
   You continually post this same absurd crank comment here that QFT and string theory have the same status. It’s a waste of time to try and respond to someone who wants to continually mislead people by insisting that black and white are the same because they’re both shades of gray.

7. **Urs Schreiber**
   December 23, 2017

   This is about a technical fact which may be discussed exhaustively in a matter-of-fact way:

   Given a 2d SCFT of central charge 15 there is the formal power series of n-point functions of this SCFT integrated over the moduli spaces of super-Riemann surfaces. Perturbative string theory is by definition the S-matrix theory obtained by interpreting this power series as a perturbative scattering matrix.

   This may or may not be identifiable with fundamental scattering processes observed in nature, but it’s well-formed as a definition of a perturbative S-matrix theory.

   In fact perturbative QFT has a directly analogous formulation, where the Feynman perturbation series is equivalently rewritten as a formal power series of n-point functions of a 1d field theory on graphs. This insights is called the worldline formalism of pQFT.

8. **Peter Woit**
   December 23, 2017

   Urs,
   This posting is about non-perturbative string theory which is supposed to explain everything about the real world, we know that perturbative string theory explains nothing about the real world.

9. **martibal**
   December 23, 2017

Cédric, could you give the link to this IHES talk ?

10. **Brian White**
December 23, 2017

Peter,

I'd wouldn't expect Natalie Wolchover to hype string theory, and, having read the article, I don't think that she actually did. The title The Atlantic used was hype, certainly, but I doubt very much she had any control over that. The original Quanta title was "Why is M-Theory the Leading Candidate for Theory of Everything?", which, unlike The Atlantic's title, is consistent with the text. That is, it's an account of how string theory came to occupy its current position, not a triumphalist narrative.

Writing about the circumstances that led Stalin to power doesn't in itself imply that you're glad Stalin came to power, and in fact Wolchover is quite careful not to endorse string theory. To quote: "This basic sequence of events has led most experts to consider M-theory the leading TOE candidate, even as its exact definition in a universe like ours remains unknown. Whether the theory is correct is an altogether separate question."

Maybe that's what you meant by blaming "The Atlantic, via Quanta Magazine" for the hype. In any case, agreed, the effect of the article is bizarre. When Wolchover says that there's no empirical evidence for string theory, it's plainly intended as a serious objection. But The Atlantic's slapping on a title like "String Theory: The Best Explanation for Everything in the Universe" implies the objection doesn't matter.

11. **Peter Woit**
December 23, 2017

Brian White,
I suspect this piece was an outgrowth of Wolchover's doing an extensive interview with Witten, and the "experts consider M-theory to be the leading…." story line reflects accurately Witten's point of view. It's one I disagreed with and wrote a book arguing against a long time ago, and I think my side of that argument has held up very well, with nothing positive happening for the other side since (the landscape?), and all the claims about "predictions" for the LHC turning out to be wrong.

I think that in cases like this, where journalists like Wolchover accurately report the point of view of a field's most prominent and distinguished scientists, the hype problem generated is the fault of those scientists, not of the journalists involved. The problems with this article are exactly the same ones that have been in such articles for 30 years now: proponents of string theory try to make their case by going right up to the edge of untruth in a discussion of highly technical issues, journalists try and accurately report what they say, generating a misleading text, headline writers then turn this into outrageous hype. You never hear complaints though from the original scientists, the failure here for them is not a bug but a feature.

In the case of this article I did write in to say something about the problems with the original article in its comment section. Yes, the ridiculous headline in the Atlantic surely was not Wolchover's doing, but there's a long history of exactly this kind of thing happening with headlines of articles like this for a long time, that it would happen here again shouldn't have been even slightly surprising.

12. **JonW**
December 23, 2017

Peter, that doesn't seem a very fair characterisation of the article. It seems to be more about how difficult it is to construct a theory of everything, and why it is that despite not making any predictions that have been (or could ever be) borne out, M-Theory at least makes it out of the gate in a way that other attempts at Theories of Everything don't. The article is very straightforward about the theory's shortcomings.

13. **Peter Woit**
December 23, 2017

JonW,
I don't think I was unfair to the article, which repeats misleading claims about string/M-theory, e.g.:

"M-theory looks like each of the string theories in different physical contexts but does not itself have limits on its regime of validity—a major requirement for the theory of everything."

and

"string theory's status as the only known consistent theory counts as evidence that the theory is correct."

Despite some caveats and careful wording, the text gives the impression that it's describing a consistent viable TOE, when no such thing actually exists. It's not surprising that the Atlantic headline writer read it this way and wrote the headline accordingly.

14. **John Baez**
December 23, 2017

The version of the article that I see now, following [Peter's link](), doesn't have the title Peter said it did. It's not titled "String Theory: The Best Explanation for Everything in the Universe". It's simply "The Best Explanation for Everything in the Universe." Did they change the title?

The picture above the title has a big fat "M" in the middle, and the article says:

> This basic sequence of events has led most experts to consider M-theory the leading TOE candidate, even as its exact definition in a universe like ours remains unknown. Whether the theory is correct is an altogether separate question. The strings it posits—as well as extra, curled-up spatial dimensions that these strings supposedly wiggle around in—are 10 million billion times smaller than experiments like the Large Hadron Collider can resolve. And some macroscopic signatures of the theory that might have been seen, such as cosmic strings and supersymmetry, have not shown up.

So, Wolchover is saying that "most experts" consider M-theory a "leading candidate" for a theory of everything—while not claiming the theory is correct, and admitting the lack of experimental evidence for it, and even noting that its exact definition "in a universe like ours" remains unknown.

The last caveat, which sounds odd at first, harks back to the previous paragraph in which she wrote:

> AdS/CFT gives a complete definition of M-theory for the special case of AdS space-time geometries, which are infused with negative energy that makes them bend in a different way than our universe does.

So, she's pointing out that AdS/CFT doesn't apply to our universe.

In short, this does not seem like outrageous hype to me. Could the article have changed since Peter saw it? Or does he just have a different attitude than I do? (The latter is quite possible: an article I wrote for *Scientific American* also featured in his *This Week's Hype*.)

15. **Cédric Bardot**
December 24, 2017

    @martibal

    "Why Four Dimensions and the Standard Model Coupled to Gravity".(https://m.youtube.com/watch?v=qVqqftQ92kA Peter had already mentioned it in a former post) The last 30 minutes are a rare occasion to watch Connes discussing with physicists (and philosophers) on some of the last results obtained using his spectral paradigm.

16. **Peter Woit**
December 24, 2017

    John Baez.
"String Theory: The Best Explanation for Everything in the Universe – The Atlantic" is the html title of the page, it appears for instance in the tab for the page in my browser.

    The text title and subtitle are
"The Best Explanation for Everything in the Universe

    String theory is considered the leading "theory of everything," but there's still no empirical evidence for it."

    and I think they make very clear the current version of the 30-plus year old string theory hype problem. For many years the hype problem was stories like this
http://www.nytimes.com/2000/04/04/science/physicists-finally-find-a-way-to-test-superstring-theory.html
from the New York Times, which told us that string theory was finally making testable predictions and was about to be tested (at the LHC, by LIGO seeing cosmic strings, etc.). Now that string theory has failed all these tests, the current string theory hype is that this doesn't matter: as the headline says, string theory is the best explanation for everything, even though there's no observational evidence for it (left unsaid is that there are no prospects for such evidence, the theory is permanently immune from confrontation with experiment). Don't you see a huge problem with telling the public this?

    The headline and sub-title is all most people will read, but it's true that the text contains caveats. Some of these caveats are however misleading. What is not made clear is the reason for no experimental evidence: there is no viable theory. Much is made of "consistency" of the theory, but this is misleading: consistency of what? Also a standard misleading phraseology is the caveat about the definition of the theory: "its exact definition in a universe like ours remains unknown". The problem with M-theory is not that it's an approximation, the problem is that it's not a theory. It doesn't make approximate predictions, it makes no predictions.

    Finally, the "most experts consider M-theory the leading TOE candidate" really should be rephrased in a less misleading manner as "most experts think M-theory sucks as a TOE, but that alternatives also suck, and many feel maybe M-theory sucks less".

17. **Frank**
December 24, 2017

    I for one, when I read the Quanta article first, thought maybe someone paid or scared Natalie (who has really good and well known credibility for physics writing), to defend String Theory against all physicists who think it failed 🙂

18. **Anonymous**
December 24, 2017

    I usually prefer not to comment on string theory, so this is a brief exception. Natalie Wolchover (who received some Science Communication Awards, for example the 2017 American Institute of Physics Science Communication Award for Articles, https://www.quantamagazine.org/authors/natalie/ and https://www.aip.org/aip/awards/science-communication/science-communication-award-articles/natalie-wolchover) and Quanta Magazine have both an often well deserved high reputation. In my (albeit anonymous) opinion, and with all the due and well deserved respect for her (previous) news articles and reports, Wolchover's latest article in Quanta Magazine is way below the standard such a high reputation demands. Seriously? After decades of controversy about string theory, Wolchover, as a journalist, should be very much aware of, all she manages is to quote some comments (with all due respect) from a Caltech theoretical physicist (one). Is it enough? I do not think so, if that high reputation is well deserved, both Wolchover's and that of Quanta Magazine. So, please, both, Wolchover and Quanta Magazine, do better next time. Or else, please do not report on string theory and quantum gravity, if you can't do that honestly.

19. **Peter Woit**
December 24, 2017

    Frank,
Unfortunately, as far as I know the business of writing about theoretical physics includes very few opportunities to collect payoffs. To understand that article, note that Wolchover here
https://twitter.com/nattyover/status/943877616217575424
refers to "my interview with Edward Witten, a conversation that felt a bit like talking to God about the secrets of the universe".

    Witten is a genius and an intellectually imposing figure, the article reflects his point of view. There's a good case to be made that he's our best theorist since Einstein, but it's worth remembering that Einstein spent the last part of his life working at the IAS on a TOE that didn't work out. I doubt there were many journalists in the 1950s who managed to get an interview with Einstein, then went down to Princeton to ask him: "Professor Einstein, isn't it true that the TOE you have been working on for the past thirty years has been a complete failure, how do you feel about that?

20. **Philip Gibbs**
December 24, 2017

    The article only claims it is the "best" theory of everything, not a "good" one. The word "best" could even be read as ironic. M-theory's shortcomings are mentioned, e.g. the lack of empirical evidence is in the sub-title. Can anyone name a better theory of everything? What empirical evidence is there for any form of quantum gravity?

    We have seen hype before but I don't see any here. The nearest it comes is "One philosopher has even argued that string theory's status as the only known consistent theory counts as evidence that the theory is correct." This is so loaded with caveats and other devices to weaken its impact that it verges on sarcasm. The positive things the article does say about its mathematical nature seem very balanced to me.

21. **Peter Woit**
December 24, 2017

    Philip Gibbs,

I think I'll read your comment as ironic and sarcastic itself, thus agreeing with you.

22. **Art**
December 24, 2017

Why is The Atlantic publishing a Quanta article (as opposed to Quanta publishing it itself, or Wolchover writing directly for the Atlantic)? Is she under exclusive contract to Quanta? Enquiring minds want to know.

23. **Peter Woit**
December 24, 2017

Art,
From Quanta's website:

"Quanta has partnered with major media outlets such as Wired and The Atlantic to help expand their science coverage. Syndication of Quanta articles has enabled these and several other popular publications — in English, German, Japanese, Spanish and other languages — to provide their readers with excellent coverage of math and science, free from paywalls. Quanta's nonprofit-foundation-funded business model enables it to offer its content widely, at no cost, with only public service in mind."

Part of the deal seems to be that the major media outlets get to put a more exciting clickbaity title on the articles.

24. **Philip Gibbs**
December 24, 2017

Peter,
If I said that string theory must be correct because it is the only known consistent theory, that would be absurd. If I said that string theory's status as the only known consistent theory counts as evidence that the theory is correct, that would be highly debatable and controversial. If I say that one philosopher argued that, then I am merely making the unremarkable observation that a philosopher has said something open to debate. If I say that one philosopher has even argued that … , I am expressing incredulity that a philosopher has said something controversial. Surely that has to be sarcasm? Merry Xmas.

25. **Visitor**
December 24, 2017

Philip Gibbs,
Most people don't read as carefully as you seem to think. They are not looking for sarcasm, irony, nuance, subtlety. They expect a straightforward report about the subject under discussion. And, as far as I'm concerned, rightfully so. An article that needs to be carefully parsed and "deconstructed" to have its message grasped, is more of a word game than an informative explanation or report; i.e. it is a poor article.

26. **NoGo**
December 24, 2017

As a complete non-expert in the relevant things, I take issue only with the following words from the article:
"This basic sequence of events has led most experts to consider M-theory the leading TOE candidate…"
Is it really so? And most experts… on what? String theory? Particle physics? Physics in general?
As a Wikipedia page would say, "quotation needed".

27. **IMHO**
December 24, 2017

Visitor,

Bravo! If we read with great care, parsing every word and phase like scientists are trained to do, we find a technically correct article whose nuanced meanings are arguably uncontroversial.

However, I think we can all agree that the average Atlantic consumer sees a questionable headline that sets a narrative and creates a priori assumptions that aren't necessarily accurate… But this is par for the course for today's click-bait driven media, should we be surprised?

At the end of the day, this double-entendre of an article, while factually accurate when read by many experts, is also misleading to the general public and suggests to a lay reader that M-Theory is well accepted, widely supported, and well on its way to becoming the final theory of everything… And I don't think that's completely true.

This is analogous to reading a tax bill that favors corporations, but then claiming that a title like the Middle Class Jobs Act in no way obfuscates things or influences opinion since a precise technical reading is all that's required to glean the intended message.

28. **Paolo Bertozzini**
December 25, 2017

The official Facebook post of Quanta Magazine linking to the original article is textually as follows:

"Edward Witten's M-theory, which combines all known versions of string theory, is widely seen as the leading candidate for the "theory of everything" because of its demonstrated mathematical consistency in reconciling gravity and quantum mechanics."

Note the stress on "mathematical consistency" … of "M-theory" in reconciling QM and gravity. The author of the article might not be directly responsible for the form of post … but the delibarate intent of "propaganda" is quite clear to me.

29. **Philip Gibbs**
December 26, 2017

Paolo Bertozzini, The only things I find objectionable in that quote are the use to the tired phrase "Theory of Everything" and the sole attribution of M-theory to Witten. It was the culmination of the work of string theorists such as Hull, Townsend and Duff, with Witten being one of the last to concede the important of membranes. Of course, once he accepted it his contributions were phenomenal.

Until someone finds a way to perform quantum gravity experiments with positive results that can tell us something new about quantum gravity, mathematical consistency is all we have, and it is a powerful tool. This is true for any potential theory of quantum gravity. It is a generic problem, not something specific to M-theory. The term "leading candidate" is relative. What alternative can be said to be better? Its shortcomings are clearly mentioned: lack of empirical data, lack of equations,questions unanswered, it might not be correct. The claim in the article is that it is still the leading candidate despite this and that this is nevertheless quite significant. These things do require a very careful reading of the article to tease out its "nuanced" meanings, as someone put it. They are clearly laid out in unambiguous terms. There is no hype or propaganda here.

Sorry if this is getting repetitive.

30. **Peter Woit**
December 26, 2017

Philip Gibbs,
You're just completely ignoring what Paolo Bertozinni wrote. His objection was specifically to the claim of
"demonstrated mathematical consistency in reconciling gravity and quantum mechanics."
for M-theory.

If, as you acknowledge, you have no equations for M-theory, there is no way you can have "demonstrated mathematical consistency" of the theory. All you can have is "conjectured mathematical consistency", which is something very different. Claims of "mathematical consistency" are actually referring to calculations (e.g. in flat 10d spacetime) which are physically inconsistent with the real world. The article is completely misleading because it essentially says that M-theory is a theory of the real world with "demonstrated mathematical consistency". This is an untruth, accurately characterized by Bertozinni as "propaganda".

31. **Philip Gibbs**
December 26, 2017

Peter, I think you are interpreting the words "mathematical consistency" in a much stronger sense than intended in the article. When it talks of "demonstrations of mathematical consistency" it meas that there are some calculations combining quantum theory and gravity that give consistent answers in a non-trivial way. It does not mean that M-theory has been proven to be a fully consistent mathematical theory for quantum gravity. Such strong statements of consistency cannot even be made for QCD.

The article is full of caveats including the fact that its exact definition is unknown. The statements about consistency have to be taken in the context of that information. Without the complete equations you obviously can't have a complete proof of consistency for the calculation of all quantities, in which case that can't be what they mean. When knowledge is incomplete, a consistent theory is one that is not inconsistent based on what is known.

I think given the shortness of the article it does a good job of covering both the positive and negative aspects of the theory in an honest, complete and balanced way. I don't see any signs of propaganda.

32. **Peter Woit**
December 26, 2017

Philip Gibbs,
No one is asking for a "proof", or an "exact theory", an approximate theory understood at the level of QFT would be fine.

"Propaganda" is a good way to characterize claims to have a theory with demonstrated consistency, reconciling gravity and QM, when all you have is some not inconsistent calculations that have nothing to do with the real world. Running this under the title "String Theory: The Best Explanation for Everything in the Universe" takes it from propaganda to outrageous propaganda.

33. **Tim**
December 27, 2017

Just as another datapoint showing that things have gotten completely out of hand, there is currently a display in terminal D of the Philadelphia International Airport entitled "Supersymmetry in Nature" (I'm not kidding, I wish I were). Nothing in the description says anything about why the term supersymmetry is used.

So anyone who has been busy searching for supersymmetry at the LHC … you're just in the wrong place. It's been hiding out at PHL, terminal D, gate 9-11.

I'm sure String Theory can explain why it's there.

34. **Peter Woit**
December 27, 2017

Tim,
Thanks for the news. Looks like this is the explanation

http://www.phl.org/Arts/Pages/Current/AndreaMarquis.aspx

35. **Kea**
December 28, 2017

Tim, I have regularly heard non science people on the street discussing how exciting String Theory is, ever since the big news from the LHC. Nobody seems to have heard about the Standard Model.

36. **Henry McFly**
December 29, 2017

1) no definition or equations
2) no experimental evidence
3) no likelihood of ever getting one

Peter, your statements #1 and #2 are true for string theory, and they were simultaneouly true more than once in the history of particle physics for things other than string theory. I am not sure where you have proved statement #3 for string theory though. That would certainly end this whole discussion.

It's been 22 years since Witten's M-theory unification and 20 years since Maldacena's AdS/CFT correspondence. I think you would also agree that these were pretty big steps which justified pursuing string theory even without any empirical evidence. Now, I am wondering at what point after AdS/CFT do you think string theory became non science? 5 years, or 10 years after AdS/CFT? You started your blog back in 2004, so I guess it was 7 years after AdS/CFT. That sounds like a really short time for someone to be sure that a particular theory is not correct.

37. **Peter Woit**
December 29, 2017

Henry McFly,

The M-theory conjecture does nothing to help with the problems of string theory unification, all it does is open up many more possible ways to produce models. AdS/CFT has nothing at all to do with the problem of string theory unification. You can try and argue that string/M-theory should purely be evaluated as an untestable theory of quantum gravity, and, as with this article, take your stand on "our untestable undefined theory of quantum gravity sucks less than the LQG people's". Up to everyone to evaluate for themselves the pros and cons of this argument, personally I think it's a complete waste of time.

My criticism was aimed at claims made for M-theory as a unification of the SM and gravity. I wouldn't argue that it's non-science, I'd argue that it's bad science. Back in 1984-5 there were good reasons to try out the string theory unification idea, but the problems with it quickly became apparent, as people tried to come up with predictive models. We're now thirty years on from the point it started to become clear this wasn't a predictive unification scheme. I don't think you can point to any analog in scientific history for, after 30 years of failure of an idea, press stories about it being "the best explanation".

As for prospects of testability of string theory unification, with the failure to find "predicted" SUSY or extra dimensions at the LHC, there are now no plausible proposals at all for how to get experimental evidence, and that's what's behind the ridiculous argument being made in this article.

38. **Sandia**
December 29, 2017

Without getting into the String Theory arguments, this article was pretty thin by Quanta Standards, short and nothing really new in it. I suspect it was a piece generated mainly to be distributed in The Atlantic as part of some content requirement agreement. In any case, I think the best way to describe String Theory is that it is a collection of theories of how Planck scale strings might behave, if they existed. The best way to describe M Theory is that it is a theory about what theories of strings have in common. That probably says what needs to be said.

39. **Marshall Eubanks**
December 31, 2017

RE: "It's been … 20 years since Maldacena's AdS/CFT correspondence. I think you would also agree that these were pretty big steps which justified pursuing string theory even without any empirical evidence."

As it happens, there is empirical evidence on this point. It shows that we do not live in an AdS universe, so, no, I at least would not agree to anything of the sort.

Various News

January 9, 2018
Categories: Uncategorized

Now back from vacation in a much warmer location than New York. Some things I noticed while away:

- I see that Paris has a bid to host the 2022 ICM. Everyone should strongly support this, one can't have too many excuses for a trip to that city.
- I'm pleased to see that Sabine Hossenfelder will now be a columnist for Quanta magazine. She's starting off with a piece on asymptotic safety. Also recommended is her new arXiv preprint on fine-tuning and naturalness.
- There's an Indian interview with Nati Seiberg, much of which consists of defending string theory research against the accusation of being a science with no scientific evidence. It's more or less the usual defense that, despite failure as a theory of unification, string theory research has led to other progress in fields such as condensed matter, astrophysics, cosmology and pure mathematics. One problem with this is that it's very unclear now what "string theory research" really is these days, other than a sociological term. About the failure to find SUSY as predicted, he says:

  > One idea is that we will find SUSY particles at the Large Hadron Collider (LHC) but this hasn't happened yet. So given that it hasn't, I think the odds that it would happen in the near future are very small. It's not a likely scenario. If you had asked me 10 or 20 years ago, I would have thought it was quite reasonable that they would find it. But they haven't and that idea did not prove to be right. But people who worked on it should not be penalised for it because they just laid out possibilities and things that experimentalists would like to have.

  I don't think the issue is whether to "penalize" people for working on SUSY, but rather just to acknowledge that the failure to find SUSY at the LHC has important scientific implications, providing significant evidence against heavily promoted speculative ideas about supersymmetric extensions of the SM and superstring unification.

- To keep up on the latest hot trends in particle theory, and sometimes find an excuse for a trip down to Princeton, I periodically take a look at the IAS High Energy Theory Seminar listings (available here). I was surprised to see that this week they've invited Steve Hsu to give a talk about something having nothing to do with HEP theory. His topic is "Genomic Prediction of Complex Traits", a topic motivated by his long-standing interest in finding genetic determinants of intelligence.

  I heard from Hsu back in 2011, when he wrote to ask me if I would publicize this study, which he wrote about here. Hsu was looking for volunteers of "high cognitive ability" (he thought most theoretical physicists would qualify), who would get "free genotyping and tools to explore their genomes". You can read some more debate about this here. A few years back he wrote an essay for Nautilus about how genetic engineering will one day create the smartest humans who have ever lived.

  Until a year or so ago I used to follow Hsu's blog, finally stopped after getting sick of reading his defences of Trump and Steve Bannon. Besides the interest in race determining intelligence (see for instance here), Hsu has what seems to me a disturbing interest in the politics of racial resentment, from the white/East Asian side, which shows up in his fondness for Trump/Bannon. This also shows up in his involvement in a campaign to get Harvard to stop its current affirmative action policies and admit more students of East Asian descent.

  No, I'm not going to allow any arguments over this topic in the comments section. Such arguments immediately descend to an extreme level of stupidity, whatever the IQ of those involved.

Update: I just noticed that Steve Hsu has a blog post about this here, which surely is a better place to discuss what he's up to.

Update: The Economist has an excellent piece about the problems of HEP physics and status of some non-collider experiments looking for BSM physics.

Update: See here for part two of Jerry Alper's report from the event discussed here.

Update: Perhaps the audience at Friday's IAS HEP theory seminar can ask the speaker whether his methods for analyzing people's genetics can be used to tell whether they come from a "shithole country" or not.

Comments

1. **ronab**
   January 9, 2018

   "But people who worked on it should not be penalised for it …"

   However, people who didn't find SUSY and related SM extensions convincing and therefore chose not to work on them were often penalized by not getting jobs. Seems now that a little penalization running the other way would actually be very reasonable.

2. **steve hsu**
   January 9, 2018

   Hi Peter,

   I hope you will come out for the talk on Friday. This area of computational genomics is advancing very fast and although it is not exactly physics it is understandable for most physicists and (at least in my opinion) quite interesting. Re: genomics of intelligence, the effort we started way back in 2010/11 was aimed at finding just a few genetic loci associated with intelligence. The state of the art has progressed significantly since then, with ~1k variants now identified at genome-wide statistical significance. We are on the verge of building crude predictors for adult cognitive ability based on genotype. Predictors already exist for other complex phenotypes like height.

   Re: Trump and Bannon, I've mostly described myself as a centrist Democrat (Bill Clinton and Obama voter, etc.), but I really think Trump (for all his faults) is not getting a fair shake in the mainstream media, on college campuses, etc. It's understandable if we disagree about politics — this is a particularly polarized time in the US.

   Re: Harvard admissions, there is a fair amount of evidence that Harvard and other elite universities are discriminating against Asian-Americans, as with Jews in the early part of the last century. I think that greater transparency (which Harvard has resisted) would help resolve whether discrimination is actually taking place. There are civil lawsuits as well as investigations by the DOJ in progress that will shed significant light on this topic.

3. **Chris**
   January 9, 2018

   Found this interesting statement from Sabine Hossenfelder's blog:

http://backreaction.blogspot.co.at/2018/01/sometimes-i-believe-in-string-theory.html

4. **Peter Woit**
   January 9, 2018

   Hi Steve,
   Yes, about Trump/Bannon I think we're just going to have to disagree. And I'm afraid your enthusiasm for predicting adult "cognitive ability" based on genotype just strikes me as creepy and dangerous. Sorry though, none of this is anything I want to encourage discussion of here (and I just noticed you have a blog entry about the talk, so can host discussion there).

5. **Tim**
   January 9, 2018

   One thing I don't hear much about is string theory's failure as a theory of QCD. I realize no one talks about it now because we have QCD, but it seems to me that we have not one, but TWO data points of string theory failing to be the next big thing.

   I'm sure the subject is complex (and interesting!). What can we learn from the failures and why do they keep happening? The older ones are interesting because despite being potentially less relevant, they might be better understood …

6. **Robert A. Wilson**
   January 10, 2018

   The competing bid for the ICM2022 is from St Petersburg, definitely one of the most beautiful cities in Europe. I for one would much prefer a good excuse to re-visit St Petersburg, over a good excuse to re-visit Paris.

7. **John**
   January 11, 2018

   The economist has a real nice article where you are quoted in it along with Sabine.

Adventures in Fine Hall

January 14, 2018
Categories: Uncategorized

Every so often I get a copy of Princeton's alumni publication in the mail, which I mostly ignore. The latest one however had an entertaining article about the Princeton mathematics department during the 1930s, entitled Adventures in Fine Hall. Various physicists (often misidentified as mathematicians) also make an appearance.

The article is based on an oral history project from the 1980s (Princeton Library website here, archive.org site here). It includes many stories I'd never heard before, including one about Hermann Weyl:

> When attendance at his lectures shrank to three, Weyl threatened to end the course if it shrank further. One day when the third student got sick, the other two students "went out and got one of the janitorial staff to come and sit in the room, so there would be three people in the room and Weyl would give his lecture."

Not quite the same, but this reminds me a bit of a story a Columbia colleague likes to tell about one of Claude Chevalley's calculus classes here at Columbia during the 1950s. Supposedly (accuracy of story not guaranteed) students got together to complain to the chair that they couldn't follow Chevalley's lectures. After someone was dispatched to attend a lecture, and reported back that it was not surprising the students weren't following, a deal was made with the students. Someone else would be found to give them lectures in parallel with Chevalley's, at a different time, as long as they agreed to keep going to Chevalley's lectures. Things are different now, hard to get students to go to one set of calculus lectures, much less two…

For more Princeton math and physics history, the Institute for Advanced Study has its own oral history project (started by Frank Wilczek's wife, Betsy Devine), website here. I don't know if any of those materials are available without going down to Princeton. The IAS has an extensive archive, with a lot of material available online (see for instance here). Poking around I noticed for instance Hermann Weyl's Faculty file (here, here, here and here) and a memo Weyl prepared in 1945 evaluating various physicists and mathematicians as possible hires.

For those interested in IAS history, the archive describes a history of the years 1930-50 there which was commissioned, but not published since Oppenheimer felt it "portrayed the Institute in a less than flattering light." A copy of this document is however now available from the IAS here and here.

   January 16, 2018

   Did Weyl write about Siegel in a separate memo? I was just reading by chance the MathOverflow question https://mathoverflow.net/questions/111519/why-might-andr%C3%A9-weil-have-named-carl-ludwig-siegel-the-greatest-mathematician-of

3. **Kea**
   January 16, 2018

   I imagine the IAS was a very peaceful place to work in those days, since it was still quiet and pleasant when I was there in the 1990s. Was it much smaller?

4. **Peter Woit**
   January 16, 2018

   liuyao,
   It looks to me as if they were planning on offering a position to Siegel, that this list was a "comparison" list, the kind of thing hiring committees put together to justify why the person they have agreed on is the best available.

   Kea,
   Yes, I think in the 3os and 4os the IAS was a much smaller place, even more peaceful than now.

5. **Douglas Natelson**
   January 17, 2018

   Reading that memo, Pauli is used as a comparison benchmark but is apparently out of consideration. Bohr is listed, despite being described as unobtainable. So, had they already asked Pauli and he'd declined? Anyone know the story there?

6. **Peter Woit**
   January 17, 2018

   Douglas Natelson,
   I think Pauli was already at the IAS at this time (he was there 1940-6).

7. **Douglas Natelson**
   January 17, 2018

   Ahh. That'd do it. I didn't remember he'd been there despite reading the recent biography, and I was too lazy to check. Thanks.

8. **Scott Aaronson**
   January 17, 2018

   Weyl's memo is an eye-popping document—possibly the most distinguished group of people in the history of the world, ever to have been straightforwardly ranked and evaluated as potential hires.

9. **David Derbes**
   January 18, 2018

   My friend Bob Jantzen, a relativist at Villanova, spent untold hours turning the typed pages of the Oral History of Mathematics at Princeton in the 1930's into HTML. He did this for free, having been a graduate student of Abe Taub's at Berkeley. If you bump into him at a GR conference, and you like the web site (and how can you not??), you should buy him a glass of a good Italian wine.

10. **Robert T Jantzen**
    January 21, 2018

    As an undergraduate at Princeton in physics (thanks, David!) who took a lot of extra math, I never knew any of this interesting history. Ironically today's math dept at Princeton seems to have no interest in why it became a powerhouse of American mathematics, you will find no link to its history or this website on the department website. Not even the university itself could find a place in its archives to retain the website it held for more than a decade surrounding the original oral history project, a website that I created to give context to that project, through many articles which filled in the details before and after the project. It is filed in web archives so that I cannot update it I am guessing, since I have still not made contact with the chief archivist Dan Linke who has always been very cooperative and who apparently saved the website from oblivion when a reorganization of the university archives orphaned it. He must have posted it in these web archives. Perhaps someone can explain how that site works? I was originally motivated by the fact that only a few paper copies of this oral history project existed unknown to most of the academic community, and the time at Y2K was ripe to transfer it to the internet, which I did as a public service. I emailed the author of the recent PAW article but got no response. I will try again.

The Quantum Spy

January 17, 2018
Categories: Book Reviews

I don't often read spy thrillers, but just finished one, The Quantum Spy, by David Ignatius. Ignatius is a well-known journalist at the Washington Post, specializing in international affairs and the intelligence community (and known to some as The Mainstream Media's Chief Apologist for CIA Crimes). While the book is fiction, it's also clearly closely based on reality. Sometimes writing this sort of "fiction" allows an author to provide their take on aspects of current events that confidentiality prevents them from writing about as "non-fiction". Another example of this kind of writing is that of the now deceased French writer Gérard de Villiers, who wrote a large number of spy novels informed by his connections in the intelligence community. Unlike the often pornographic de Villiers, Ignatius treats the love-making of CIA spies with beautiful Mata-Haris discreetly.

The topic of *The Quantum Spy* is Chinese spying on American research in quantum computing. This is very much in the news these days: after finishing the book I picked up today's paper to read about the arrest of a Chinese-American ex-CIA agent on charges of being a mole spying for the Chinese (a central theme of the Ignatius novel is the divided loyalties of a Chinese-American CIA agent). In the same issue of the paper is a Tom Friedman opinion piece about quantum computing breakthroughs and how "China, the N.S.A., IBM, Intel and Google are now all racing — full of sweat — to build usable quantum systems" that will revolutionize our lives.

I am no expert on quantum computing, but I do have quite a bit of experience with recognizing hype, and the Friedman piece appears to be well-loaded with it. In contrast, at least in describing the the state of technology, the novel does a pretty good job of sticking to reality. Ignatius clearly spent quite a bit of time talking to those very knowledgeable about this. One part of his story is about a company closely based on D-Wave, and he explains that the technology they have is different than the true quantum computer concept that is being pursued by others. Majorana fermions and topologically protected states make an appearance in another part of the story. One character's reading material to orient himself is Scott Aaronson's *Quantum Computing Since Democritus*.

The novel portrays the US and Chinese governments as highly concerned and competitive about quantum computing technology and its security implications. I'd always naively assumed that classified research on quantum computing was carried on just by groups within the NSA or other security agencies, but Ignatius tells a different story. According to him, what happens is that groups performing unclassified government-funded quantum computing research in the open can find themselves forced to "go dark", with their work going forward classified and no longer publicly accessible. His plot revolves around Chinese efforts to get information about such research. I have no idea whether this is complete fantasy or based in the reality of the situation.

In the novel and in real life, there are some analogies between the quantum computing story and the role nuclear physics played in the cold war between the US and Russia. Nuclear and particle physics arguably benefited a great deal for many years from governments worried about trying to get an edge in weapons technology, and to some extent the physics of quantum computing is starting to take on that same role, with (at least in the novel) the Chinese now playing the Russian role.

Just as particle physics likely got a lot of funding and public attention because of nuclear weapons, some parts of physics are now well-funded and high profile because of their connection to quantum computers. In fundamental theoretical physics, the hot topic is the idea that the old dream of replacing space and time with something more "quantum" is going to be realized as "it from qubit", somehow using ideas from quantum computation to get an emergent quantum theory of gravitation. All my attempts to try and understand how this is supposed to work have left me rather mystified. Last week there was a Simons Foundation-funded school in Bariloche about this, with both 't Hooft and Maldacena lecturing on "Black holes and Quantum Information". Perhaps these lectures will be informative and made available. This summer the IAS will host a school on From Qubits to Spacetime, maybe I'll try again then to figure out what is going on by looking at its materials.

   January 17, 2018

   So was it a good spy story?

2. **Peter Woit**
   January 17, 2018

   Douglas Natelson,
   I'm the wrong person to ask, the few spy stories I've read have been because of an interest in some non-spy thriller aspect of the story. The spy thriller aspect of this one didn't seem particularly compelling, but what do I know.

   I do go see movies of this kind, and if you wanted to feature physicists in a thriller movie, I think you could make a decent one from this book.

3. **Yatima**
   January 17, 2018

   According to him, what happens is that groups performing unclassified government-funded quantum computing research in the open can find themselves forced to "go dark", with their work going forward classified and no longer publicly accessible.

   Just look for engineering teams (because all of this sounds far more a problem of engineering than theoretical physics) who publish a few very interesting papers then stop publishing. Look for teams in companies that have a good, solid engineering research tradition like IBM, not teams at crazed gluehead outfits like Google. A room full Chinese information retrievers would be able to list the names of Persons Of Interest by the evening.

6. **Dave Miller**
   January 18, 2018

   The edX online consortium has just started a class by Peter Shor (whom I have seen here occasionally) and his colleague Isaac Chuang, both of MIT, on quantum computation, for anyone interested in pursuing this further.

   Both Shor and Chuang are excellent lecturers; Shor is a major figure in the field. An undergrad physics major should be able to follow the course.

   My own take is that “decoherence,” an interest that Peter Woit and I share, is the killer. The proposed solution is quantum error correction, which the course covers.

   It’s hard for me to see how quantum error-correction can overcome the extremely severe problems due to decoherence, but maybe by the end of the course I will become a believer!

7. **Tim**
   January 18, 2018

   Based on some familiarity with what’s going on in quantum computing, I believe the spying would more likely be the other way around. I believe the Chinese are currently outspending everyone else in this area.

   Canada appears to be more actively pursuing this than the US is.

8. **Art**
   January 18, 2018

   Re “arguably”: What’s the counter-argument? I didn’t realize there was disagreement about the cold war/physics symbiosis.

    I see there is an interview with Ignatius on the sci-fi podcast Geek’s Guide to the Galaxy, episode 291.

Beyond Falsifiability

January 17, 2018
Categories: Favorite Old Posts, Multiverse Mania

Sean Carroll has a new paper out defending the Multiverse and attacking the naive Popperazi, entitled Beyond Falsifiability: Normal Science in a Multiverse. He also has a Beyond Falsifiability blog post here.

Much of the problem with the paper and blog post is that Carroll is arguing against a straw man, while ignoring the serious arguments about the problems with multiverse research. The only explanation of the views he is arguing against is the following passage:

> a number of highly respected scientists have objected strongly to the idea, in large part due to a conviction that what happens outside the universe we can possibly observe simply shouldn't matter . The job of science, in this view, is to account for what we observe, not to speculate about what we don't. There is a real worry that the multiverse represents imagination allowed to roam unfettered from empirical observation, unable to be tested by conventional means. In its strongest from, the objection argues that the very idea of an unobservable multiverse shouldn't count as science at all, often appealing to Karl Popper's dictum that a theory should be falsifiable to be considered scientific.

The problem here is that none of those references contain anything like the naive argument that if we can't observe something, it "simply shouldn't matter", or one should not speculate about it, or it "shouldn't count as science at all." His reference 7 is to this piece by George Ellis at Inference, which has nothing like such arguments, and no invocation of falsifiability or Popper. Carroll goes on to refer approvingly to a response to Ellis by Daniel Harlow published as a letter to Inference, but ignores Ellis's response, which includes:

> The process of science—exploring cosmology options, including the possible existence or not of a multiverse—is indeed what should happen. The scientific result is that there is no unique observable output predicted in multiverse proposals. This is because, as is often stated by proponents, anything that can happen does happen in most multiverses. Having reached this point, one has to step back and consider the scientific status of claims for their existence. The process of science must include this evaluation as well.

Ellis here is making the central argument that Carroll refuses to acknowledge: the problem with the multiverse is that it's an empty idea, predicting nothing. It is functioning not as what we would like from science, a testable explanation, but as an untestable excuse for not being able to predict anything. In defense of empty multiverse theorizing, Carroll wants to downplay the role of any conventional testability criterion in our understanding of what is science and what isn't. He writes:

> The best reason for classifying the multiverse as a straightforwardly scientific theory is that we don't have any choice. This is the case for any hypothesis that satisfies two criteria:
>
> - It might be true.
> - Whether or not it is true affects how we understand what we observe.

This seems to me an even more problematic and unworkable way of defining science than naive falsifiability. This whole formulation is extremely unclear, but it sounds to me as if various hypotheses about supreme beings and how they operate would by this criterion qualify as science.

Carroll also ignores the arguments made in my letter in the same issue (discussed here), which were specifically aimed at the claims for multiverse science that he is trying to make. According to him, multiverse theory is perfectly conventional science which just happens to be hard to evaluate:

> That, in a nutshell, is the biggest challenge posed by the prospect of the multiverse. It is not that the theory is unscientific, or that it is impossible to evaluate it. It's that evaluating it is *hard*.

The main point I was trying to make in the piece Carroll ignores is that the evaluation problem is not just "hard", but actually impossible, and if one looks into the reason for this, one finds that it's because his term "the theory" has no fixed reference. What "theory" is he talking about? One sort of "theory" he discusses are eternal inflation models of a multiverse in which you will have bubble collisions. Some such models predict observable effects in the CMB. Those are perfectly scientific and easy to evaluate, just wrong (since we see no such thing). Other such models predict no observable effect, those are untestable. "Hardness" has nothing to do with it, the fact that there is some narrow range of models where tests are in principle possible but hard to do is true but irrelevant.

The other actual theory Carroll refers to is the string theory landscape, and there the problem is not that evaluating the theory is "hard", but that you have no theory. As for bubble collisions, you have plenty of conjectural models (i.e. "string vacua") which are perfectly well-defined and scientific, but disagree with experiment so are easily evaluated as wrong. While many other conjectural models are very complex and thus technically "hard" to study, that's not the real problem, and acquiring infinitely powerful computational technique would not help. The real problem is that you don't have a theory: "M-theory" is a word but not an actual theory. The problem is not that it's "hard" to figure out what the measure on the space of string vacua is, but that you don't even know what the space is on which you're looking for a measure. This is not a "hard" question, it's simply a question for which you don't have a theory which gives an answer.

I do hope someday Carroll and other multiverse fans will some day get around to addressing the real arguments being made, perhaps then this subject could move forward from the sorry state it seems to be stuck in.

Update: Philosopher of science Massimo Pigliucci has a very good discussion of this debate at his blog. Sabine Hossenfelder has a piece at 13.7 on Scientific Theory and the Multiverse Madness.

Update: Coel Hellier has a blog posting here taking Carroll's side of the debate.

Update: Yet another new argument for multiverse mania as usual science on the arXiv, this time from Mario Livio and Martin Rees. The same problems with the Carroll article recur here, including the usual refusal to acknowledge that serious counter-arguments exist. They give no references at all to anyone disagreeing with them, instead just knock down the usual straw man, those unknown scientists who think that theorists should only discuss directly observable quantities:

> We have already discussed the first main objection — the sentiment that envisaging causally disconnected, unobservable universes is in conflict with the traditional "scientific method." We have emphasized that modern physics already contains many unobservable domains (e.g., free quarks, interiors of black holes, galaxies beyond the particle horizon). If we had a theory that applied to the ultra-early universe, but gained credibility because it explained, for instance, some features of the microphysical world (the strength of the fundamental forces, the masses of neutrinos, and so forth) we should take seriously its predictions about 'our' Big Bang and the possibility of others.
>
> We are far from having such a theory, but the huge advances already made should give us optimism about new insights in the next few decades.

Livio and Rees do here get to the main point: we don't have a viable scientific theory of a multiverse that would provide an anthropic explanation of the laws of physics. The causes for optimism that they list are the usual ones involving inflationary models that give essentially the same physics in other universes, not the different physics they need for anthropics. There is one exception, a mention of how:

> accelerator experiments can (in principle) generate conditions in which a number of metastable vacuum solutions are possible, thereby testing the premises of the landscape scenario.

They give no reference for this claim and I think it can accurately be described as utter nonsense. It's also (in principle) possible that accelerator experiments will generate conditions in which an angel will pop out of the interaction region bearing the laws of physics written on gold tablets. But utterly implausible speculation with no evidence at all backing it is not science.

The authors note that:

> an anthropic explanation can be refuted, if the actual parameter values are far more 'special" than anthropic constraints require.

The problem with this is that you don't have a theory that gives you a measure on parameter values, so you don't know what is 'special' and what isn't. As I keep pointing out, the fundamental problem here is even more basic that not having a probability measure on possible universes: we have no viable theory of what the space of possible universes is, much less any idea of how to calculate a measure on it. And no, we are not seeing any progress towards finding such a theory, quite the opposite over the past decades.

Truly depressing is that even the best of our journalists see this kind of article, written by two multiverse enthusiasts and giving no references or serious arguments for the other side, as "even-handed".

Update: Two new excellent pieces explaining the problems with the multiverse. Ethan Siegel in particular explains the usually ignored problem that the kind of inflation we have any evidence for doesn't give you different laws of physics, and ends with

> The Multiverse is real, but provides the answer to absolutely nothing.

Sabine Hossenfelder explains four of the arguments generally given for why the Multiverse is science, answering them each in turn, with conclusions:

> **1. It's falsifiable!**
> …
> So don't get fooled by this argument, it's just wrong.
>
> **2. Ok, so it's not falsifiable, but it's sound logic!**
> …
> So don't buy it. Just because they can calculate something doesn't mean they describe nature.
>
> **3. Ok, then. So it's neither falsifiable nor sound logic, but it's still business as usual.**
> …
> So to the extent that it's science as usual you don't need the multiverse.
>
> **4. So what? We'll do it anyway.**
> …
> so you are allowed to believe in it. And that's all fine by me. Believe whatever you want, but don't confuse it with science.

Comments

1. **Azadi**
   January 17, 2018

   Excellent post and analysis, as ever Peter.

   I recall reading an article once by Carroll, where he posited the small value of the cosmological constant as the paradigmatic example of how the "inflationary-string landscape multiverse" model was the only one that could account for the data.

   He stated:

   "…Consider the multiverse. It is often invoked as a potential solution to some of the fine-tuning problems of contemporary cosmology. For example, we believe there is a small but nonzero vacuum energy inherent in empty space itself…The problem for theorists is not that vacuum energy is hard to explain; it's that the predicted value is enormously larger than what we observe. If the universe we see around us is the only one there is, the vacuum energy is a unique constant of nature, and we are faced with the problem of explaining it. If, on the other hand, we live in a multiverse, the vacuum energy could be completely different in different regions, and an explanation suggests itself immediately…"

   To me, this is a very weak argument.

   The logic seems to be: the value of the cosmological constant can't be calculated working from first principles. This indicates there may not be a "natural" mechanism to account for why it takes the value that it does. Likewise, quantum physics provides formulas for calculating what the Higgs mass should be, and the Higgs should be very, very heavy. Only its value is actually light with cancellations down to a very fine degree of precision. "Naturalness" is thus probably out as a solution.

   An "unnatural" explanation for the Higgs mass or cosmological constant is then sought, invoking "anthropic" reasoning. Perhaps the Higgs mass or the lambda value isn't fixed precisely by any underlying theory, but can assume a wide range of values in different regions of the universe – that is, in different bubble universes in a multiverse.

   We live in the life-permitting one, because we're here – a selection effect.

   But for the multiverse to work, you need string theory (which in turn needs SUSY, for most variants of it, I think) or eternal inflation…and you've covered the problems with both of those.

   So in the end, according to Carroll, the "multiverse" is true…just because there's allegedly no other show in town, even though nature – courtesy of the LHC – seems to be telling us otherwise about SUSY/string theory, which is a prerequisite for the landscape.

   BTW am I right in thinking that, on its own, cosmic inflation might result in bubble universes if it is "eternal" (rather than chaotic, which doesn't lead to a multiverse) but those universes or "patches" would all have the same constants without the existence of a string landscape provided by M-Theory (or, rather, M-not-so-Theory)?

   It looks like a house of cards.

2. **Jim Given**

January 17, 2018

Yes, and invoking Popper's "falsifiability" as a criterion for a scientific theory is itself a straw man; product of an overly naive model of how science is done. (If the people you cite want to invoke the philosophy of science, they should discuss a modern, i.e., post 1930's, philosophy of science, such as e.g. Imre Lakatos' formulation of a progressive research program. Wikipedia explains:

"A Lakatosian research programme[16] is based on a hard core of theoretical assumptions that cannot be abandoned or altered without abandoning the programme altogether. More modest and specific theories that are formulated in order to explain evidence that threatens the 'hard core' are termed auxiliary hypotheses. Auxiliary hypotheses are considered expendable by the adherents of the research programme—they may be altered or abandoned as empirical discoveries require in order to 'protect' the 'hard core'. Whereas Popper was generally read as hostile toward such ad hoc theoretical amendments, Lakatos argued that they can be progressive, i.e. productive, when they enhance the programme's explanatory and/or predictive power, and that they are at least permissible until some better system of theories is devised and the research programme is replaced entirely. The difference between a progressive and a degenerative research programme lies, for Lakatos, in whether the recent changes to its auxiliary hypotheses have achieved this greater explanatory/predictive power or whether they have been made simply out of the necessity of offering some response in the face of new and troublesome evidence. A degenerative research programme indicates that a new and more progressive system of theories should be sought to replace the currently prevailing one, but until such a system of theories can be conceived of and agreed upon, abandonment of the current one would only further weaken our explanatory power and was therefore unacceptable for Lakatos. Lakatos's primary example of a research programme that had been successful in its time and then progressively replaced is that founded by Isaac Newton, with his three laws of motion forming the 'hard core'."

In these terms, string theory is a (chronically) degenerative research program. This is an argument that scientists should decide not to devote their efforts to this theory. Lakatos, though, recognized that senior scientists who have devoted many years to such a program will continue to pursue it until they retire. As you have often pointed out abandoning this program would not at all diminish science's explanatory power.

3. **Peter Woit**
   January 17, 2018

   Azadi,
   Yes, you accurately describe the CC argument, which raises a host of other issues (anthropics, naturalness). There are claims that this is "evidence for string theory", basically because you think can produce string vacua with any CC and you assume flat probability distribution. So, "string theory" is playing the same role here as "we have no idea what the CC physics is". I don't believe you can get non-trivial evidence for a theory this way.

   Yes about eternal inflation models based on a single inflaton field. They don't give you the CC argument you want, for that you need the string landscape, and typically think of it as having hundreds of inflaton fields.

   Jim Given,

   Yes, Carroll makes a big deal of claiming that he, unlike other physicists with their naive Popperism, has a serious understanding of modern philosophy of science. For him this doesn't seem to include the progressive/degenerative research program distinction, likely because string theory provides a textbook example of the degenerative case.

4. **Rod Deyo**
   January 17, 2018

   Since Galileo and Newton, there are precious few cases, if any, where philosophy has been a helpful approach to progress in the quantitative experimental sciences. But there have been many examples in the past where it fostered sterile debates over what turned out to be irrelevant philosophical concepts, semantics, and personal beliefs. A recent novel feature in such debates is adding modern Bayesian mysticism to give personal beliefs the illusion of quantitative reasoning.

5. **Bernhard**
   January 18, 2018

   What a confusing article… it is really troubling to see a scientific hypothesis being debated and defended on the grounds of assigning "a prior probability that the theory is true" … It is an impossible evaluation for an extraordinary claim like the multiverse.

   He also states that "it is very hard on the basis of indirect evidence alone to send those credences so close to 0 or 1" for which I don't know which "indirect evidence" he is talking about. Indirect evidence would of course be evidence.

   He finishes with the obvious point that "There really might be a multiverse out there, whether we like it or not ", which is true as far as it goes, although I think he should have added that "there really might be NO multiverse out there" and there is currently no way to know one way or the other (and the reason why the whole discussion is completely empty).

   Depressing!

6. **Peter Woit**
   January 18, 2018

   Rod Deyo,
   Polchinski provided a reductio ad absurdum argument against the Bayesianism business in a paper for the same proceedings as the Carroll one. He calculated a Bayesian probability of "over 99.7%" for string theory, and 94% for the multiverse.

7. **Kyle MacDonald**
   January 18, 2018

   One valuable point in Carroll's blog post, which I didn't know, is how to hear Dawid's phrase "non-empirical theory confirmation". I quote Carroll:

   "It sounds like Dawid is saying that we can confirm theories (in the sense of demonstrating that they are true) without using any empirical data, but he's not saying that at all. Philosophers use "confirmation" in a much weaker sense than that of ordinary language, to refer to any considerations that could increase our credence in a theory. Of course there are some non-empirical ways that our credence in a theory could change; we could suddenly realize that it explains more than we expected, for example. But we can't simply declare a theory to be "correct" on such grounds, nor was Dawid suggesting that we could."

   My guess is that Carroll is still inappropriately cool with untestable theories, and that Dawid is even further gone. However, Carroll's explanation of how Dawid uses the word "confirmation" has made me update away from dismissing them.

8. **Peter Woit**
   January 18, 2018

Kyle MacDonald,

I don’t really want to start a discussion here of Dawid’s work, which I’ve written about extensively, see for instance
http://www.math.columbia.edu/~woit/wordpress/?p=5880
http://www.math.columbia.edu/~woit/wordpress/?p=7005

Carroll’s treatment of criticism of Dawid is a bit like the way he treats those critical of the multiverse: he again ignores their arguments and sets up a straw man to knock down. While those who haven’t read Dawid might be critical because of a misunderstanding over use of the word “confirmation”, many (actually, I think most…) who have read Dawid are critical for serious reasons that Carroll doesn’t address.

9. **TCSF**
January 19, 2018

Bayesianism is not meant to enshrine subjective opinion (to give it a falsely elevated status by quantification). Rather, the Bayesian view recognizes that subjectivity exists, but provides a model for how the beliefs of rational agents should be updated and should converge, as more information becomes available. (I felt a need to add this small comment, but realize a general discussion of the topic might not belong on this forum.)

10. **Jim Holt**
January 19, 2018

Peter, your notion of confirmation is simply too narrow. Since “The multiverse exists” is logically equivalent to “All nonexistent things are non-multiverses,” the existence of the multiverse is confirmed by unicorns, leprechauns, square circles…

11. **pan**
January 21, 2018

Hi Peter,
Apart from the lack of scientific validity or usefulness for the multiverse, one thing that i find disappointing as a non scientist is the intellectual banality of it all, and especially the way it is presented by its supporters. Compared to the radicalism of the ideas within early 20th century physics, the multiverse feels more like cheap sci-fi. A radical idea could be useful in shifting discourse even if it has little scientific merit, but the multiverse doesn’t seem to be anything other than a plot twist to hastily wrap up 20th century physics now that the studio ran out of ideas.

12. **tulpoeid**
January 21, 2018

To the best of my understanding, such arguments run along the lines of Thomas Kuhn’s view of scientific progress (the best candidate theory at any given moment is endorsed by the community, even if it doesn’t fit all facts, and progress is made by building upon it and adjusting as necessary). Only that imho Kuhn described what usually happens, not what _should_ happen. In any case certain individuals should stop calling everyone who simply appeals to logic a Popperazzi. But then again, speaking personally I don’t care, strings and multiverse are unscientific under any definition one picks.

“Scientific validity”, “usefulness” … unfortunately there’s a lot more at stake here. Inflation, string, parallel universes and multiverse fans enjoy repeating how this is the next step in Copernicus’ path, rejoicing in rediscovering ways to keep the human race humble. Only that not being the centre of the universe is totally different from declaring the universe unreachable, and if you bring something so radical on the table then the burden of proof falls on you. (Yes, it’s very similar to the burden of proof for unseen creatures falling on those who believe in them.)

Also, Copernicus’ theory happened to explain previously inexplicable facts in an unambiguous way.

13. **Belmonte**
January 22, 2018

Karl Popper is considered a sort of fallibilist, contrary to popular belief he didn’t hold that non-scientific claims are meaningless, such unfalsifiable claims can often serve important roles in both scientific and philosophical contexts, even if we are incapable of ascertaining their truth or falsity. He maintained that while the particular unfalsified theory we have adopted might be true, we could never know this to be the case.

This fallibilism invites to stick the weak version of Popper’s falsificationist criterion in the sense that falsification provides a methodological distinction based on the role that observation and evidence play in scientific practice. Then, the aim of the partial refutation/improvement of a theory isn’t to highlight its inaccuracy but to point out their faint points, that also means to improve the theory. Einstein’s theory of gravity partially refuted Newton’s theory and therefore improved it. Popper thought that the scientific theory that passed the experimental test is submitted to future refutation and/or improvement. Thus, the term falsifiability is synonymous to testability.

Like Gödel’s theorems of incompleteness, that don’t prevent the creative work of the mathematicians, Popper’s fallibilism doesn’t hinder the imagination of theoretical physicists. Lashing out against the popperazi in order to defend a theoretical position is an approach that has little to do with Popper’s fallibilism.

14. **Paolo Bertozzini**
January 22, 2018

Dear Peter,
I am always amazed at the quite unsophisticated level of discussion of foundations of the scientific method by practicing scientists … probably due to the fact that they (scientists) often, or exclusively, become interested in such issues only when they can become “useful” for certain otherwise undefendable/weak ideological biases and claims … or simply when they do not have any other resources for their arguments 😉
The actual critic to Popper’s “falsificationism” and “demarcation theory” of science has a quite long and respectable history that is systematically ignored by the protagonist of current debates. I have been a very close follower of Paul Feyerabend epistemological anarchism position since I was 14 years old and studied these elementary things in high school (yes, it was usually normal to have some readings on epistemology at the beginning of high school) … and all this noise against “Popperism” looks very much like the rediscovery of the hot water for any student that had a chance to read and study the works of Lakatos, Khun, Feyerabend, etc. The problems with “abduction” and foundations of science by inductive methods have even older roots in Hume. The problematic status of falsifiability of theories/models with free parameters has been repeatedly discussed even in jokes (“with four parameters I can fit an elephant, and with five I can make him wiggle his trunk” – E.Fermi, J.von Neumann, F.Dyson, etc.).
The role of “crucial experimental validations/falsifications” has been repeatedly questioned by P.Feyerabend; similarly the usage of fundamental theoretical principles has been criticized, as for instance in the case of “general covariance” by E.Kretschmann’s argument (variants of this argument can be adapted to show that essentially any “sufficiently complicated theory can be made to satisfy certain abstract requirements and/or empirical observations”).
The fundamental issue here (in my understanding) is not the “multiverse”: theoretical physics in one way or another has always been dealing with the existence of “multiverses”: in the most naive sense, theories do not necessarily specify a unique “history” of the physical system under study; such a system can actually be in many different “states” each of them corresponding to different evolutions (in some cases they do even specify a unique selection criterion for dynamical laws) and the operational specification of the “exact state of the system” might be out of reach even in principle. The quite beautiful popularization book “Farewell to Reality” by Jim

Baggott is one of the rare cases where an attempt is made to identify some of the principles and assumptions "usually" hiding beyond scientific practice: very often a "realist reductionist trinitarian" point of view (Ratzinger's Trinity) manifested in a) the assumption of the existence of some fundamental "ontological truth", b) the belief that such truth influences "empirical reality" and c) a faith in the ability of scientists (humans or otherwise) to "obtain reliable information" on such truth from empirical testing of nature. Such principles are usually complemented by equally essential use of criteria like "Occam's razor" ("simple" theories that "compactify information" are preferred) and the related "Copernicanican symmetry principle" (that is actually one of the strongest motivations for the introduction of multiverses).
The real issue here, I repeat, is that some theoretical physicists are exceptionally becoming interested in epistemology because they cannot find other reasonable ways to defend and justify the support received by some theories, currently undergoing "degenerative involution processes" … theories that they a-priori consider as "truth".
The invocation of "Bayesian abduction" as a substitute for Popper's falsificationism here does not seem to be an improvement, since the specification of "priors Bayesian probabilities" is influenced by "arbitrary sociological" input, that in this case just means that the current "most established" (?) hypothesis and conjectures will decide the output ("The role of priors is crucial" – S.Carroll pg.8).
The general epistemological position of S.Carroll (and somehow His deep religious view of "Science" – "Poetic Naturalism" – and the consequent need to find an new absolute methodological criterion for separating "True Science" from "Non-Science") is quite clear in his recent book "The Big Picture" (but also in some of His technical writings on the "ontological role", against "epistemic role" of the wave-function in QM).
You already discussed in some details some of the underlying problems of such philosophical point of view in a previous post, if I remember correctly.
The panorama of epistemology is way more complex today … and I would personally suggest to those that are not comfortable enough with strong "anti-realist" proposals (P.Feyerabend) to give a closer look at positions like "structural realism" 🙂

15. **bks**
January 22, 2018

https://platofootnote.wordpress.com/2018/01/22/peter-woit-vs-sean-carroll-string-theory-the-multiverse-and-popperazism/

16. **Peter Orland**
January 22, 2018

Judging from the comments above, there is prevalent notion held by both pro-multiverse and anti-multiverse partisans that the the validity of these ideas has something to do with the philosophy of science.

I think the multiverse is nonsense on its face. There is no mathematics in it, and it can't be used to calculate anything. And, although I'm not proud to say it, my knowledge of Popper's work is rock-bottom zero.

17. **Chris Kennedy**
January 23, 2018

To be a true scientist, I think it is certainly helpful if one has the ability to "calculate" but that ability must be accompanied by a certain level of reasoning skills.
When it comes to why one would study "the multiverse" in the first place, I think Thomas Reid, founder of the Scottish school of Common Sense put it best: "If there are certain principles, as I think there are, which the constitution of our nature leads us to believe, and which we are under a necessity to take for granted in the common concerns of life, without being able to give a reason for them — these are what we call the principles of common sense; and what is manifestly contrary to them, is what we call absurd."

18. **Peter Woit**
January 23, 2018

Peter Orland/Chris Kennedy,

I agree that there's a very strong common sense argument here. What's mystifying though is that otherwise very smart and sensible people take this seriously. Why is this? What can be done about it?

For a good example I just noticed this on Twitter

https://twitter.com/preskill/status/955830388584148993

Preskill is an eminently sensible theorist, but even he seems unable/unwilling to recognize the obvious common sense point (which Hossenfelder is making) that the fact that the string landscape/eternal inflation theory predicts nothing at all about anything means that it is not a conventional scientific puzzle but just an excuse for a failed research program. Yes, theorists who use this excuse generally couple their use of it with "dismay", but they still hang on to the excuse as a lifeline.

19. **Lee Smolin**
January 23, 2018

Dear Peter,

In the interest of moving the field forward, let me offer a few comments which I hope everyone can agree with.

-No one, not even Popper, proposes that theories are falsifiable up and down by single experiments. After absorbing Lakatos, Feyerabend and Kuhn, we can agree that what we evaluate are, first of all, research programs and second, competing theories within research programs.

-It is more precise to talk about the falsifiability, not of theories, but of predictions, which may be consequences of one or more theories.

-There are cases where the asymmetry implied by falsifiability holds, and cases where it doesn't. But in all contexts, science proceeds by the testing of testible predictions by experiment.

-Within a fixed research program, theories that imply falsifiable, or at least testible, predictions are generally to be preferred to theories that make no predictions. One reason is that they will, when they succeed, provide tighter and more insightful explanations.

-Research programs that generate theories that imply falsifiable predictions are generally to be preferred to research programs that generate none.

-Some theories involving stochastic evolution of a population on a landscape do generate falsifiable prediction. An example is modern population biology. Indeed, having made a great many falsifiable predictions, which were confirmed, this is now considered established science.

-These predictions were possible because one can deduce features common to all fit individuals, which are then the basis of falsifiable predictions.

-Therefor, it is not impossible that a cosmological theory might be constructed to emulate the success of population biology, and involve stochastic evolution of a population on a landscape, in a way that likewise leads to falsifiable predictions.

-Unfortunately, the multiverse of eternal inflation is not of this type. It fails to imply falsifiable predictions because our universe must be considered a highly atypical member of the ensemble, so there are no common features our universe shares with the typical case, which could provide testible predictions. Instead, there are members of the ensemble consistent with wide ranges of possible values of parameters of effective field theory. (One possible exception is the prediction to have a very small negative curvature, but this is not testible, at least so far).

-One can construct cosmological models which do posit that our universe is a typical member of the ensemble its postulates generate, which do imply falsifiable predictions. An example is cosmological natural selection.

Thanks,

Lee

20. **tulpoeid**
January 24, 2018

“What can be done about it?”

More voices are needed.

It’s not easy, because like in many other instances of destructive human behaviour, those who are fed by it have a lot more motivation to devote energy to it. But the crisis is real and can harm science in very long term.

More voices are needed to tell the public (and, because we’ve reached that point, undergrads) that the big words they hear about have amounted to exactly nothing. And probably more courage to stop treating select colleagues as people who can just go on doing their job like it doesn’t matter.

21. **Peter Woit**
January 24, 2018

Thanks Lee,

I’m becoming more and more convinced that it’s a waste of time to engage in abstract argumentation about this issue, decoupled from discussion of any specific theory/model. I’ll leave it to you to do this for cosmological natural selection models, these are not what the currently vocal multiverse proponents have in mind. What they are arguing for are:

1. eternal inflation models based on single inflaton fields, which they never mention are models that don’t give them what they want: the variety of possible universes needed for anthropics.
2. string landscape models, for which they have no viable theory that can say what the landscape is, much less calculate anything relevant about it.

The bottom line here is that these people are, in a highly misleading way, trying to sell a pseudo-scientific story to the public and their colleagues. This is pseudo-science simply because there is no theory there, nor even a plausible hope of finding one.

By the way, there’s yet more of this that just came out

https://arxiv.org/abs/1801.06944

I’ve appended commentary about this to the blog entry.

22. **Scott**
January 24, 2018

I don’t want to be seen as biased, but is it fair to say that it is mostly theorists that are multiverse proponents? How many experimentalists and observationalists buy into the multiverse? Seems an experimentalist would be highly skeptical, I am, if there is no reasonable way to test it.

23. **Peter Woit**
January 24, 2018

Scott,
Yes, it’s mostly theorists who are the problem here. But, sometimes experimentalists (especially in observational cosmology) do buy into the mania, generally just because it functions well as something to get the public interested in their work. As a random example, look at the last part of this Tedx talk
https://www.youtube.com/watch?v=T22s4jCZ4Ho
Saying that you’re going to find evidence for a multiverse is a lot more exciting than saying you’re looking at dust, no?

A problem here is that experimentalists, knowing less about the details of the speculative models involved, are sometimes less able to distinguish between what Carroll claims is going on here (a serious scientific model that is hard to test) and what really is going on (no viable model).

24. **Chris W.**
January 24, 2018

Scott,
I would think that experimentalists and observationalists would be generally be agnostic, at least publicly, as in: “When you have a suggestion and some guidance for a genuine test that we might conceivably carry out, we’re happy to hear it. Until then, we have plenty of other work to do.”

Of course, after some decades, considerable skepticism about (and loss of interest in) the likelihood of a genuine test ever being proposed can be expected. After all, the *raison d’être* of experiment and observation is the testing of ideas that actually admit tests.

25. **Thomas Schaefer**
January 24, 2018

What on earth is “Consolidation of Fine Tuning”?

According to google, a Templeton funded project at Oxford, http://finetune.physics.ox.ac.uk/

26. **Bernhard**
January 25, 2018

” The causes for optimism that they list are the usual ones involving inflationary models that give essentially the same physics in other universes, not the different physics they need for anthropics.”

Peter

I saw this also in the comment section in your discussion with Coel Hellier. Is it correct to say such models are simple implying that whatever lies beyond the horizon of our universe is probably a region (another universe or whatever the name) where the physical laws remain the ones we know? In other words, isn’t this just the same as saying the universe is infinite but simply calling this a multiverse just to include the region we actually know? It would be helpful if such models would actually not call this a multiverse.

27. **Natalie Wolchover**
January 25, 2018

Hi Peter,
I think the Livio-Rees essay deserves more credit. I appreciated that the essay avoids the usual diatribes about the purpose or rules of science, about which no one will ever agree, and dives head first into the actual issues. Why “evenhanded”? They don’t assert that properties like the value of Λ are fine-tuned, rather that they might be, and they clearly articulate the immense (OK, some would say insurmountable) challenges involved in figuring out whether these properties really are fine-tuned. For instance, this paragraph:

“We are currently far from having any theory that determines the values of Λ or Q or the dark matter density (and we know even less about the relative likelihood of various combinations of these constants or how they might be correlated). Still less do we have a cosmological model that can put a ‘measure’ on the probability density of various combinations. But if we did, we would then have another way of testing — and in principle refuting — whether the ‘fine tuning’ was due to anthropic selection. We could do this by examining whether we live in a ‘typical’ part of the anthropically allowed multiverse, or whether the tuning was even more ‘special’ than anthropic constraints required.”

I know you don’t disagree with any of that, since it’s accurate; I imagine you just don’t like the sense of optimism conveyed by “But if we did, we would then have…” I don’t feel particularly optimistic myself about the future prospects, but whether one does or doesn’t, there’s still a crisis.

Best wishes,
Natalie

28. **Peter Woit**
January 25, 2018

Hi Natalie,

I understand your point that Livio/Rees are careful to say “this is all speculative” and that’s why you think of them as “even-handed”. But whether this is speculative is not really the question (few would describe it as not-speculative, as something with significant evidence). The question is whether it’s legitimate science at all, and they write in their abstract:
“Although the concept of a multiverse is still speculative, we argue that attempts to determine whether it exists constitute a genuinely scientific endeavor.”
coming down strongly on one side of that debate. My comments here were specifically addressed at their argument for this, which I think doesn’t hold up at all, for reasons I explain.

29. **Peter Woit**
January 25, 2018

Bernhard,
There is in principle a distinction between points causally disconnected from us because they’re just too far away, and those causally disconnected because they’re in a different “bubble”. For better or worse, the first kind of points are usually said to be in our universe, the second kind in a different one.

The crucial distinction here is a different one: if you are talking about more than one universe, do your other universes have a sufficient variety of laws of physics to allow for an anthropic explanation of our laws? Refusing to make that distinction, claiming evidence for models of a multiverse with no such variety of laws as evidence for an anthropic multiverse is absolutely standard behavior now from multiverse advocates (with Livio/Rees just another example).

30. **Lee Smolin**
January 25, 2018

Dear Natalie,

I appreciate your point, and I also am glad to see you are joining us who have been saying there is a crisis for some time.

But I would like to point out that there is a theory that “…determines the values of Λ or Q”, by putting “…a ‘measure’ on the probability density of various combinations.”

This theory is cosmological natural selection and, as was discussed in the 1992 paper, and the 1997 book, CNS gives a non anthropic explanation for the values of Lambda and Q. The result is that the anthropic principle is not needed to explain this fine tuning. This works because we live in a typical member of the ensemble, as was discussed in my comment above.

Thanks,

Lee

31. **Peter Woit**
January 25, 2018

I’ve added to the posting links to excellent new discussion of this from Ethan Siegel and Sabine Hossenfelder that have just appeared.

32. **Alan**
January 26, 2018

So what’s Sabine’s solution? Anybody’s solution? 1. No multiverse, 2. I read on her blog Sabine doesn’t like the idea reality is a computer simulation (who does?), 3. Some still believe in a complete consistent theory explaining all reality with equations that can be written on a tee shirt (good luck with that), 4. Then there’s possibly a creator.

The link above to fine tuning is interesting … http://finetune.physics.ox.ac.uk/

Isn't this last the way forward as it's exploring fine tuning tentatively without assuming what any final theory will be? It looks like a heck of a project.

33. **Peter Woit**
January 26, 2018

Alan,
Why does Sabine or anyone other scientist have to provide a solution? Part of science is knowing when you don't know something. The situation here is that we don't know whether there's a multiverse with different physical laws since we have no viable testable theory/model. When science can't provide the answer to a problem, you're welcome to advertise your evidence-free speculation, attribute the answer to God/simulation overlords, or deal with the problem in any other way you feel like. You just can't claim that doing this is doing normal science (as Carroll/Livio/Rees are claiming).

34. **Alan**
January 26, 2018

Peter, I'm not frustrated at anyone at all in particular (honest), it's just that once you rule out a multiverse to explain our particular universe with life in it, I think one has to look at this fine tuning issue very carefully. Maybe investigations need to be then carried out beyond what is called "normal science". Does anybody else think like this?

35. **Peter Woit**
January 26, 2018

Alan,
Not one is ruling out multiverse explanations, they're just noting that we have no evidence for such explanations or any plausible way of getting any. Sure, plenty of people react to this situation by wanting to go beyond "normal science" and pursue for instance metaphysics instead of physics. No reason they shouldn't, but they shouldn't be misleading people by claiming that they're doing the usual sort of science when they're not.

36. **Mitchell Porter**
January 27, 2018

I see people saying "there's a crisis, what can we do about it". I think that's nonsense. The real situation is that there are some things we know about nature, other things we don't; and the human race has more ideas and more data than ever before, about the things we don't yet understand. Not only is there every reason for optimism, there's no shortage of concrete things to work on. It's not like we're lost in space with no clue what to do.

37. **Peter Woit**
January 27, 2018

Mitchell Porter,
I think we don't have much in the way of good ideas (lots of bad ones) about certain fundamental issues in physics, but don't think this is a "crisis". The people heavily invested in SUSY/GUTs/string theory unification do have a "crisis" on their hands as their ideas have clearly failed and the bottom is falling out of their investment. Some of them are attempting to prop up their investment by creating a crisis for physics in general, by trying to change the definition of what successful science is in order to avoid acknowledging failure.

38. **Jim Akerlund**
January 29, 2018

Peter,
This is off topic but does https://arxiv.org/abs/1801.08160 imply the first shovel full of dirt on the coffin that is string theory, and will the string theorists see it as such?

Quick Links

January 27, 2018
Categories: Uncategorized

Various things that may be of interest, ordered from abstract math to concrete physics:

- Jacob Lurie is teaching a course this semester on Categorical Logic. Way back when I was a student at Harvard this is the kind of thing I would have found very exciting, much less convinced of that now.
- Talks from a workshop earlier this month on representation theory are available here.
- The Harvard Gazette has an article about a project to develop a "pictorial mathematical language" first proposed by Arthur Jaffe. The project has a website here. It is being funded by an offshoot of the Templeton Foundation I didn't know about, the Templeton Religion Trust, with one of their grants, TRT0080: "Concerning the Mathematical Nature of the Universe", described as "exploring whether or not the universe admits of a consistent description, or more generally, whether our universe be described by mathematics?". They're advertising a postdoc position here.
- Adam Marsh has a wonderful book on *Mathematics for Physics*, especially from the geometrical point of view, with lots of detailed illustrations. It's available from World Scientific here, or as a website here (there are also articles on the arXiv, here and here).
- There's a new Leinweber Center for Theoretical Physics at the University of Michigan, funded by an $8 million grant from the Leinweber Foundation. Inaugural talk was Arkani-Hamed on The Future of Fundamental Physics.
- Each year recently there has been a Physics of the Universe Summit, described by some as involving "one of those glitterati Hollywood banquets". Some years ago, the glitterati evidently were interested in particle physics, recently instead it is quantum computing and AI (see last year and this year). At this year's glitterati banquet, a kidnapping of Kip Thorne occurred.
- Alex Dragt has a book about Lie methods, with applications to Accelerator physics. If you're looking for detailed very explicit information about symplectic transformations, there is a wealth of such material in this book.
- I'm hearing a rumor (via an anonymous comment here) that HyperKamiokande has been denied funding. Can anyone confirm or deny?

Comments

1. **Chiara**
   January 28, 2018

   The Hyperkamiokande website http://www.hyperk.org/ even has a movie on the project. Will it be able to measure neutrino masses?

   If the project really focuses on testing GUT only, its proponents did themselves a bad favor, now that GUTs seem to contradict experiments. But if Hyperkamiokande could measure neutrino masses, it would be a different thing. That might be the last topic of particle physics about which we know very little. Neutrino masses are often given as 1 eV +/- 1 eV which is really a unsatisfactory state of affairs.

2. **Chiara**
   January 28, 2018

   Update: The other English website of Hyperkamiokande is much more specific on its aims: http://www.hyper-k.org/en/physics.html

   The results would give Japanese physics a huge boost, and put them at the forefront of the particle physics world. Let us hope that the rumors are wrong!

3. **Kiril**
   January 28, 2018

   It would be a big news if HK will not be financed, but I would not know how to interpret it in the grand-scheme of future fundamental research. Such a decision will boost even more Fermilab's plans for DUNE, which will be the only "definitive" neutrino experiment on the market. The ILC is also in bad shape in Japan and I was indeed surprised by their will to go ahead with ILC and HK at the same time..
   Let's wait some informed comment. Meanwhile I'll try to ask to some HK colleagues.

4. **tulpoeid**
   January 28, 2018

   Remember that the T2KK experiment is also being planned, with some redundancy to HK.

5. **Paolo Bertozzini**
   January 28, 2018

   Quoted: "Jacob Lurie is teaching a course this semester on Categorical Logic. Way back when I was a student at Harvard this is the kind of thing I would have found very exciting, much less convinced of that now."

   It would be very interesting to know what are Your doubts, reservations or objections to this topic and the reasons for the change of interest. From what I can see from the web-page, it is essentially a course on "topos theory".

6. **Peter Woit**
   January 29, 2018

   Paolo,
   As a student I was fascinated by trying to learn about more and more abstract mathematical constructs of greater and greater generality, later realized the danger with this is that you end up saying less and less about more and more, in the limit saying nothing about everything.

   Lurie is a great mathematician, I'm curious to see what he does with this material.

7. **Philippe Mermod**
   January 29, 2018

   The truth about HyperK is that the budget for 2018 was postponed, which will delay the project with respect to its original schedule. The same thing happened in the past with SuperK/T2K, it seems to be the way it works in Japan.

8. **Anonymous**
   January 29, 2018

   By the way, who is Adam Marsh?

9. **Neel Krishnaswami**
   January 30, 2018

   Most of categorical logic is no more abstract than the material in a typical undergraduate algebra course (indeed, most of the proofs are easier). It's just that this material is not on the usual undergrad main sequence, due to the sociological/historical accident that mathematicians tend to know very little formal logic (a self-perpetuating accident, for obvious reasons).

   It's a lovely subject, because it is just barely abstract enough to support numerous examples, a fact which is enormously useful to workaday computer scientists like me.

10. **Paolo Bertozzini**
    January 31, 2018

    Dear Peter,
    thanks for the reply.
    I do understand Your point (generalizations often treat more "objects" at the price of "forgetting" some of their structure), but I am not sure that the process of mathematical abstraction consists in just this step. Allow me to make a short comparison between two examples of abstraction: 1) "monoids" generalize "groups" (forgetting the existence of inverses) exactly as You say. In this case the generalization is blind to the "extra structure" available in the more specific case. 2) every group is canonically a "groupoid with only one object" and "groupoids" are a vast generalization of "groups". In this case, what happens is that the *extra structure* necessary to define a groupoid "trivializes" (and becomes essentially invisible) in the case of the more special case of usual groups.
    This example is not only academical: in physics people usually *define* "symmetry" as a group (hence if something is not a group, it is not a symmetry), still groupoids (and more generally categories) capture some significant aspects of the intuitive idea of symmetry. Of course "what we are able to fish … depends on the kind of net that we are allowed to use to fish" and there is the clear danger of saying that "something" is not a fish because it is too small (or too big) to be captured in a specific net 🙂
    Best Regards (and thanks for the always stimulating comments and links).

15 Years of Multiverse Mania

January 29, 2018
Categories: Multiverse Mania

Today is the 15th anniversary of the event that kicked off the Multiverse Mania that continues to this day, recently taking the form of a concerted attack on conventional notions of science. 2018 has seen an acceleration of this attack, with the latest example appearing this weekend.

On January 29, 2003, Kachru, Kallosh, Linde and Trivedi submitted a paper to the arXiv that outlined a construction of a supposed model of a metastable string theory state that had all moduli fixed. Ever since the first explosion of interest in string theory unification in 1984-5, it had been clear that a big problem with using string theory to get anything that looks like known physics was the so-called "moduli problem". If you try and use 10d superstring theory to describe our universe, you need to somehow hide six of the dimensions, and the best way to do that seemed to be to argue that superstring theory implied one could do this by compactifying on an unobservably small approximately Calabi-Yau manifold. Such manifolds however come in families labeled by "moduli" parameters, which can be thought of as describing the size and shape of the Calabi-Yau. These moduli will show up as zero mass fields generating new long-range forces unless some dynamical mechanism could be found to fix their values. It was this that KKLT claimed to have found. I won't even try to describe the complex KKLT proposal, which was aptly described by Lenny Susskind as a "Rube Goldberg mechanism".

What string theorists had been hoping for was a moduli stabilization mechanism that would pick out specific moduli field values, getting rid of the unwanted dozens of new long-range forces and providing a way to make physical predictions. While the KKLT mechanism got rid of the unwanted forces, it had been observed three years earlier by Bousso and Polchinski, working with just parts of the Rube Goldberg mechanism, that this sort of thing led to not one specific value of the moduli fields, but an exponentially large number of possibilities. They had noted that this could allow an anthropic solution to the cosmological constant problem, and the KKLT fixing of all the moduli provided a model that accomplished this (without the long range forces).

KKLT did not mention anthropics and the multiverse, but less than a month later Lenny Susskind published The Anthropic Landscape of String Theory, a call to arms for anthropics and a founding document of Multiverse Mania. He immediately went to work on writing a book-length version of string theory multiverse propaganda aimed at the public, The Cosmic Landscape, which was published in 2005. Less than a month after Susskind's manifesto, Michael Douglas published a statistical analysis of supposed string/M-theory vacua, and at some point the estimated number 10^{500} of vacua started appearing based on this sort of calculation.

I didn't notice KKLT when it appeared, but did notice the Susskind arXiv article. I had just finished writing the first version of my book, and remember that my reaction to the Susskind article was roughly "Wow, if people like Susskind are arguing in effect that you can't predict anything with string theory, that's going to pull the plug on the subject." The book took a while to find a publisher, and by the time it was published I had tacked on a chapter about the multiverse problem. I started this blog in March 2004, and recently looked back at some of the earliest postings, noticing that a huge amount of time was spent arguing with people about KKLT and its implications for the predictivity of string theory. It seemed clear to me from looking at the calculations people were doing that this kind of thing could not ever lead to a prediction of anything. I won't go over those arguments, but claim that my point of view has held up well (no prediction of anything has ever emerged from such calculations, for reasons that are obvious if you start looking at them).

Back in 2003-4 I never would have believed that the subject would end up in the state it finds itself in now. With the LHC results removing the last remaining hope for observational evidence relevant to string theory unification, what we've been seeing the last few years has been a concerted campaign to avoid admitting failure by the destructive tactic of trying to change the usual conception of testable science. Two examples of this from last week were discussed here, and today there's a third effort along the same lines, Quantum Multiverses, by Hartle. Unlike the others, this one includes material on the interpretation of quantum mechanics one may or may not agree with, but of no relevance to the fundamental problem of not having a predictive theory that can be tested.

I'm wasting far too much time discussing the obvious problems with articles like this, to no perceptible effect. Hartle like the others completely ignores the actual arguments against his position (he lists some references. describing them as "known to the author (but not necessarily read carefully by the author)"). In a section on "A FAQ for discussion" we find arguments that include

- The cosmological multiverse is falsifiable, because maybe you'll falsify quantum mechanics.
- The cosmological multiverse is testable: "by experiment if a very large spacetime volume could be prepared with an initial quantum state from which galaxies, stars, life etc would emerge over billions of years." Not surprisingly, no indication is given of how we will produce such a state or any theory that would describe what would happen if we did.
- The theory of evolution is just like the theory of the cosmological multiverse.

Both the absurdity and the danger of this last argument are all too clear.

By the way, for a while earlier this year the arXiv started allowing trackbacks again to this blog, but then this stopped again. The origin of the ban seems to have been in the story described here and my early criticism of the string theory multiverse. I have no idea what their current justification for the ban is.

Update: A good place to look for information about the current state of string landscape calculations is at the website for this workshop. The idea that the problems of this subject can be solved by "modern techniques in data science" seems to me absurd, but for a different point of view, look at the slides of Michael Douglas. For something more sensible, try the talk by Frederik Denef, which describes some of the fundamental intractable problems:

- You don't have a complete theory, with only some non-perturbative corrections known, no systematic understanding of these.
- Dine-Seiberg Problem: When corrections can be computed, they are not important, and when they are important, they cannot be computed.
- Measure Problem: Whenever a landscape measure is strongly predictive, it is wrong, and when it's not, we don't know if it's right.
- Tractability Problem: Whenever a low energy property is selective enough to single out a few vacua, finding these vacua is intractable.

Denef does make some very interesting comments about where modern techniques in data science might actually be useful: dealing not with the landscape of string vacua, but with the huge landscape of string theory papers (e.g. the 15,000 papers that refer to the Maldacena paper). He argues:

> For obvious reasons, besides time constraints, incentives to write papers are much stronger for research scientists than to read them. So printed stacks pile up unread, PDFs remain ambitiously open until we reboot our laptops, recursive reference-backtracking gets sidetracked by the deluge of micro-distractions puncturing our days. This, plus the sheer volume of disorganized pages of important results, leads to loss of access to crucial knowledge, to repeated duplication of efforts, and to many other
> inefficiencies. Worst of all, it becomes increasingly harder for young brilliant minds to stand on the shoulders of giants, and thus to make revolutionary new discoveries. It seems inevitable that we will have to outsource the tedious task of parsing the literature, in search for relevant results, insights, questions and inspiration, to the Machines.

Update: There's an interesting article at Quanta magazine about "Big Bounce" models of the Big Bang, competitors to inflationary models. Paul Steinhardt gives his take on the multiverse: "hogwash."

Hi Peter,

I'm just a simple undergrad, but I just wanted to mention that I appreciate your blog very much. I know a few others who'd agree with me when I say that it's because of you that:

* we learned of folks like Sabine Hossenfelder (who also maintains an awesome blog);

* sighed in relief when we realized that we're not the only ones who found it difficult to read popsci books like the "The Universe in a Nutshell";

* or found awesome books through your reviews (e.g. "Summing It Up"!).

Reading about your spat with Polchinski makes me appreciate your efforts more, because I don't think I quite imagined that you'd be suffering personal attacks because of your commentary (even after you apologize for mistakes on your end!)…

You're a good teacher. Keep writing!

3. **Pascal**
January 30, 2018

A question on the 10^500 vacuaa and the resulting lack of predictive power: why don't people just focus on the (presumably smaller?) corner of this landscape that is consistent with the standard model? Has such a "corner" even been found?

4. **Peter Woit**
January 30, 2018

comdotcom,
Seiberg's defense of string theory at least does not include the multiverse nonsense. I do wish though that sensible theorists like him would publicly address this issue. This attack on science is flourishing because of their silence.

5. **Peter Woit**
January 30, 2018

ilovecats,
Thanks!
The weird thing about the Polchinski story is that it's not really personal (we've never met, he knows nothing much about me). It is just an ideological campaign, with the arXiv trackback business an effort on the part of him and others to suppress disagreement with their ideology. Another aspect of this is what you see in the recent "multiverse is science" articles I've been writing about: refusal to even read the arguments of those who disagree with you, trying to pretend they don't exist. At least Polchinski admits I exist (he was the only well-known string theorist to write a review of my book and Lee Smolin's).

6. **Peter Woit**
January 30, 2018

Pascal,
Among the problems:
1. The "vacua" being studied are only an infinitesimal fraction of possibilities (these days the count of possibilities looked at is not 10^{500} but 10^{272000} and surely there are many more).
2. You can't reliably calculate things for any of these "vacua", i.e. you can't identify which are consistent with the correct value of the electron mass because you can't reliably calculate the electron mass in any of them.

So, you are only looking at some irrelevant corner of the full space of possibilities, and have no way of finding the corner of that corner that corresponds to known physics.

7. **John Fredsted**
January 30, 2018

@Woit: Thanks for that update on the number of vacua: 10^27.000, and counting! A whopping factor of 10^26.500 greater than the previous stupendous estimate of 10^500. Could you perhaps point me to a reference where that new estimate appears?

8. **Peter Woit**
January 30, 2018

John Fredsted,

I don't have time to track down the exact reference for this calculation. It's mentioned here
https://web.northeastern.edu/het/string_data/about/
and I've added some comments about that workshop, which is a good source for the current state of string landscape calculations.

9. **new**
January 30, 2018

Peter, can you clarify some issues on KKLT

Do string cosmologists claim the universe originally started out with 10 flat dimensions of space and 1 dimension of time, then as a result of KKLT, 3 remain large, and 6 curled up as a result of the presence of anti-D3 branes and D-brane instantons or gaugino condensation as outlined in the KKLT paper? What is the origin of highly warped IIB compactifications with nontrivial NS and RR three-form fluxes?

is there a naturalistic mechanism that gives rise to KKLT mechanism, and does this have observational evidence or experimental support? What are the origins of anti-D3 branes and how did they come to be wrapped around the extra 6 dimensions? How did these 6 dimensions acquire D-brane instantons or gaugino condensation?

has science established the existence of any anti-D3 branes, D-brane instantons or gaugino condensation or highly warped IIB compactifications with nontrivial NS and RR three-form fluxes observed either in nature or in experiments as described in the KKLT paper?

10. **A**
January 30, 2018

Pascal, even if one could compute the string vacua, another problem is that the SM is described by about 150 measured digits. So, presumably, among 10^500 vacua, there are 10^350 vacua which look like the SM, just by chance.

11. **Jan Dybicz**
January 30, 2018

Peter, the link you provided has the exponent at 272,000, not 27,000.

12. **Peter Woit**
January 30, 2018

new,
KKLT is purely a construction of a metastable ground state with stabilized moduli. There's no theory of initial conditions, no evidence (or even complete theory) of the various elements that make up the KKLT Rube Goldberg machine. This is why the main activity of string landscapeologists is just counting these things.

13. **Peter Woit**
January 30, 2018

Jan Dybicz,
Thanks, fixed! Easy to make that kind of mistake by a factor of $10^{271,173}$.

14. **Balazs Vagvolgyi**
January 30, 2018

On Michael Douglas' slides, he claims about string theory that:

"… it is not hard to find solutions … for which the effective 4d physics at low energies is the Standard Model coupled to gravity …"
"… Only a minority of [the large number of solutions] lead to the Standard Model field content, and those which do lead to a range of values for the cosmological constant, the particle masses and the other fundamental constants …"

This implies that it's so easy to find suitable solutions, that string theorists already have a bunch of compactifications (solutions), that provide SM+GR, except for the values of the fundamental constants. So now we only have to find just the right compactification for our set of constants.

Is this correct?

15. **Peter Woit**
January 30, 2018

Balazs Vagvolgyi,
What Douglas doesn't explain when he says these constructions "lead to a range of values for …" is that you can't actually reliably or accurately compute any of these values. All you have is arguments that there is no known reason they can't be the SM ones. Note that Denef is Douglas's long-time collaborator on these calculations, and his description of two aspects of the issue is "When corrections can be computed, they are not important, and when they are important, they cannot be computed." and "Whenever a low energy property is selective enough to single out a few vacua, finding these vacua is intractable."

So, the situation is that, after you specify some discrete data like the number of generations, you still have an exponentially large number of possibilities, with no way of determining which agree with the SM. There is no way of getting any sort of prediction of anything out of this. Claims made early on (and debated on my blog and others) that maybe some kind of prediction could be made have failed completely.

16. **Anonyrat**
January 30, 2018

a. Seems like a metaphor modernization replacing 'needle in a haystack' by 'vacuum state in a landscape' is appropriate.

b. Mining a pile of documents (not of string theory documents) is a proposed project at where I am. IBM Watson is the suggested tool.

17. **David Levitt**
January 30, 2018

Peter,
I have been following your forum almost from the beginning. Your statement that "…my point of view has held up well" is understated. It is clear now that you were right and your vocal and, sometimes, vicious critics were wrong. This forum provides an incredibly valuable means for the non-specialist physicist to evaluate these HEP theories. You provide unlimited opportunities for other specialists to rebut your arguments – and when they can't, or don't, it is very strong evidence that you are right. I grew up in the 60's reading Scientific American in awe of the brilliant physicists and their wonderful new discoveries. And now, you have shouted out that the current batch of HEP geniuses have no clothes. After a long career as a biophysicist I have developed a more jaded view of these researchers. Although they are obviously highly skilled technicians, this does not imply that they understand or care about the large picture implications of their research. I have two questions that are a little off subject. 1) Why do you think this is a recent HEP problem? Is it just the result of the lack of progress in the field, or has the character of the people attracted to the subject changed from the halcyon days of my youth. If the former, then it would imply that my youthful heroes had the same weaknesses as the current theorists and they were just lucky that there were some new experimental results that needed explaining. 2) Now that you have been essentially proven correct, what sort of response do you get from your colleagues at meetings, especially your former critics? Are they willing to admit their error?

18. **Nonsense**

January 30, 2018

”dealing not with the landscape of string vacua, but with the huge landscape of string theory papers (e.g. the 15,000 papers that refer to the Maldacena paper)”

Google Scholars indicates 16,188 citations for that paper.

19. **Peter Woit**
January 30, 2018

David Levitt,
1) I don’t think earlier generations of theorists were any different. They had the huge advantage of continual new hints and checks on their conjectures from experiment. What we’ve seen over the last 30 years or so is what can go wrong when that is removed.
2)Despite what you might think from blogosphere discusssion, I’ve always gotten along well with string theorists I know, and our views are more similar than you might think, with the main difference just our evaluation of exactly how bad the prospects for string unification are. Over the years many have told me they read my blog and agree with much of what I have to say. Most string theorists don’t believe the landscape stuff is worthwhile, and have voted with their feet and are working on things unrelated to string unification.

No, I have yet to meet a theorist willing to say they were wrong (about string theory or almost anything…). The ones most unhappy with my criticisms have uniformly dealt with this by trying to ignore me as best they can, and continue to do so.

20. **F. G.**
January 30, 2018

So? When do you think we can expect the first papers on the ‘string publication landscape’ ?

21. **Louis Wilbur**
January 30, 2018

Peter, is it really the case that the KKLT 2003 paper achieved such stabilization? As I understand it, that paper is for type IIB string theory and the more recent paper 1709.03554 suggests, if I have read it correctly, that even meta-stability is not possible. I am not an expert in this area so perhaps I have misread it but I would definitely like your take on these papers since they all seem to suggest serious problems with stabilization.

Supersymmetry Breaking by Fluxes
https://arxiv.org/abs/1709.03554

No inflation in type IIA strings on rigid CY spaces
https://arxiv.org/abs/1703.08993

On classical de Sitter and Minkowski solutions with intersecting branes
https://arxiv.org/abs/1710.08886

The Swampland Conjecture and F-term Axion Monodromy Inflation
https://arxiv.org/abs/1703.05776

Also, it seems that there are various no go theorems for positive vacuum energy in string theory. My understanding is that this has the potential to falsify string theory since dark energy is known to be positive. If it is not possible to have anything like cosmic inflation in string theory then string theorists need to move away from the inflationary paradigm to, say, string gas cosmology and then try to deal with dark energy in a completely different way. The below papers seem to say that there are serious problems with positive vacuum energy in string theory and they are definitely relevant to your blog.

Refining the boundaries of the classical de Sitter landscape, Nogo theorems

Revisiting constraints on uplifts to de Sitter vacua
http://arxiv.org/abs/1607.01139

Constraints on Dbar Uplifts
https://arxiv.org/abs/1605.06456

Loop corrections to the antibrane potential
https://arxiv.org/abs/1602.05959

A no-go theorem for monodromy inflation
https://arxiv.org/abs/1510.02005

Constraining de Sitter Space in String Theory
https://arxiv.org/abs/1504.00056

If the very early universe did have a strong but short lived vacuum energy then it has to be the case that it is just as mysterious as dark energy. In other words, very little is known about it except that it has negative pressure, positive energy, and a few other things. But it is a big leap from that to other universes. If there are other universes then the only way to have no measure problem is for the number of such universes to be finite and each universe itself is finite in terms of all of its parameters. One problem with an infinite number of universes is well known by mathematicians since the the time of Cantor: one can pair up the universes to each other in any way one wants and therefore get any measure that one wants. Questions like what percent of the universes contain life are just as meaningless as asking what percent of the positive integers are odd. The percentage can be anything one wants depending upon how the universes or positive integers are bijected with one another. Thank you for the interesting post.

22. **Mitchell Porter**
January 31, 2018

Peter Woit said

“you can’t identify which are consistent with the correct value of the electron mass because you can’t reliably calculate the electron mass in any of them”

A paper yesterday offers a glimpse of what remains to be done, in order to calculate such quantities:

http://arxiv.org/abs/1801.09645

In the standard model and also in string theory, masses of elementary fermions come from yukawa couplings to the Higgs field. The introduction to this paper tells us that in string theory, there are three steps to calculating the yukawa coupling, and that the authors report progress with the second step.

23. **S**
January 31, 2018

Surely one difference between theorists now and fifty years ago is the speed with which they rush to the popular press? Few theorists did that with a new, half-baked theory back then (or am I wrong?). They might have had more experimental evidence, but that would have provided *more* justification for rushing out books, not less, and yet they rarely did so it seems.

24. **simplicio**
January 31, 2018

@S
There's a fair amount of pretty speculative science in old newspapers and magazine articles. I don't think the public appetite for these sort of thing, or Science's willingness to provide it has really changed in the last five decades. The difference is that the absence of new results means the *same* speculative ideas can basically linger for years, never being proven or disproven, making them seem less like speculative ideas and more like well supported science.

25. **Peter Woit**
January 31, 2018

Louis Wilber,
There has always been debate about whether the KKLT Rube Goldberg machine really works or not. But this really doesn't matter, the conclusion that there is no scientific theory of a multiverse is the same either way. Either the theory is radically inconsistent with observation (unstabilized moduli) or completely empty and consistent with anything (KKLT-stabilized moduli).

Mitchell Porter,
The technical problem (lack of explicit Calabi-Yau metric) they are discussing goes back to the beginnings of the subject, and they seem to me to make little progress in dealing with it. In any case this technical problem is not at all the main problem. Note that they just ignore the moduli stabilization problem completely. They don't even get to the point of introducing the pieces of the KKLT machine.

S,
A counter-example is the story of Schrödinger in 1947. Quoting a random source about this
(https://www.salon.com/2015/04/18/albert_is_an_old_fool_einstein_vs_schrodinger_in_battle_of_the_nobel_laureates/)
"The leading announcer was the Irish Press, from which the international community learned about Schrödinger's challenge. Schrödinger had sent them an extensive press release describing his new "theory of everything," immodestly placing his own work in the context of the achievements of the Greek sage Democritus (the coiner of the term "atom"), the Roman poet Lucretius, the French philosopher Descartes, Spinoza, and Einstein himself. "It is not a very becoming thing for a scientist to advertise his own discoveries," Schrödinger told them. "But since the Press wishes it, I submit to them."

Scientists are often misguidedly in love with their own dubious ideas, and there always have been ones willing to go to the press and get public attention. The media environment now is different and much more extensive, but I think the main difference is the lack of real progress being made, so fake claims of progress dominate because they have no competition.

26. **The Observer**
January 31, 2018

Bravo Peter for a bravura performance over the years. I cannot help wonder whether you would be a professor by now had you not taken your stance against the established "way forward" and stuck to it.

27. **Peter Woit**
January 31, 2018

The Observer,
Thanks, but I should make it clear that I haven't suffered professionally because of this in any way, and am very much content with my current academic position and employer.

Muon g-2 Anomaly Gone?

February 1, 2018
Categories: Uncategorized

I just learned some interesting news from Tommaso Dorigo's blog. Go there for more details, but the news is the claim in these three papers that, accounting for GR effects on the precision measurement of the muon anomalous magnetic moment, the three sigma difference between experiment and theory goes away.

This sort of calculation needs to be checked by other experts in the field, and provides an excellent example of where you want good peer review. Presumably we'll hear fairly soon whether the result holds up (the papers are not long or complicated). If this is right, it's a fantastic example of our understanding of fundamental physics at work, with the muon g-2 experiments measuring something they weren't even looking for, a subtle effect of general relativity.

Also interesting will be the implications for the ongoing experiment at Fermilab trying to achieve an even more precise g-2 measurement. I'm wondering whether there is any way for them to isolate the GR effect on their measurement.

The significance of this is that (setting aside questions about the neutrino sector), the muon g-2 measurement is the most prominent one I'm aware of where there has been a serious (three sigma) difference between experiment and Standard Model theory. This has often been interpreted as evidence for SUSY extensions of the SM. Projects producing "fits" that "predict" SUSY particles with masses somewhat too high to have been seen yet at the LHC use the g-2 anomaly as input. Tommaso ends by asking what happens to these fits if the g-2 anomaly goes away.

Update: For some recent things to read about the g-2 anomaly, before this latest news, see here and here.

Update: Rumor about a problem with this calculation here.

Update: According to this comment and this one, the g-2 collaboration has identified a problem with the calculation, making the predicted GR effect unobservably small. If the authors agree, presumably we'll soon see a corrected version of the paper(s).

Looking for more information about this, I ran across two blogs I hadn't seen before. String theorist Joe Conlon of Oxford has a blog called Fickle and Freckled. Not much there besides a posting supporting Brexit and denouncing the fact that nearly all of his colleagues disagree with him, which he fears will cost the university money. A second one is string/SUSY phenomenologist Mark Goodsell's Real Self-Energy. Goodsell seems to be a Lubos fan, dealing with the current g-2 story by linking to his discussion and denouncing the authors as "effectively crackpots". He also seems to be unhappy with a certain blogger:

> I regularly read two or three physics blogs, since they report on the latest news (and rumours). Now, one of these blogs is very popular whose ostensible purpose is to persuade people that string theory is a misguided research topic. Obviously, this is something I disagree with. However, it also talks a lot about high-energy physics generally, and being rather well-connected it can be quite informative and useful. However, it pretty much uniformly takes a very pessimistic line about all concrete ideas for new physics. It is difficult to overstate how damaging this has been, in making physicists and scientists in neighbouring fields depressed about the future of high-energy physics, and opposing this trend is one of the reasons I would like to blog …

Goodsell has devoted his career to string and SUSY phenomenology, and seems to feel that this is the "future of high-energy physics", and I'm responsible for making people discouraged about it. Perhaps he should stop advertising Lubos and denouncing crackpots, instead pay attention to the negative results from the LHC and the evidence they provide that his research program is a failure. Blaming his problems on me for pointing them out isn't going to make them go away.

Update: As mentioned in the comments, Matt Visser now has a preprint criticizing the calculation in these articles.

Comments

1. **Bernhard**
   February 1, 2018

   I cannot read Tommaso's article. Somehow it is being redirected to other stuff and I only see the abstract.

2. **Peter Woit**
   February 1, 2018

   Bernhard,
   I've seen that problem before on that website. For me right now it seems to be working properly. Another thing to try would be
   http://www.science20.com/tommaso_dorigo
   then the correct blog posting. If someone sees the problem you mention, perhaps they could report it to the website owner, saying what the page is that they are being incorrectly redirected to.

3. **Bernhard**
   February 1, 2018

   Peter,

   Thanks. I read it now and also (diagonally) read the articles. Whoever peer reviews those articles has a huge responsibility on his hands. It's almost like reading a standard textbook calculation (even if a hard one) that is surprising nobody had such an idea before.

4. **Art**
   February 1, 2018

   Delicious. Llewellyn Thomas must be smiling somewhere. I wonder if the electron magnetic moment could be measured in a storage ring, as opposed to a Penning trap, to see if the same effect arises.

5. **Dale**
   February 1, 2018

   Isn't it a bit suspiciuous that the GR correction happens to cancel the anomaly down to 0.1 sigma difference between the expected vs observed?

6. **Mike R**

February 1, 2018

Hmm, they claim the shift is due to absolute value of gravitational potential. But the gravitational potential GM/R due to the Sun is more than 10 times larger at the radius of Earth's orbit than Earth's own gravitational potential on its surface. Its probably premature to get excited.

7. **Mike R**
February 1, 2018

Also such effect would almost certainly violate the equivalence principle, if one can distinguish space-time curvature from uniform acceleration with a local experiment.

8. **Art**
February 1, 2018

Because the earth is in free fall around the sun, the equivalence principle says the solar gravitational field has no effect on a local terrestrial measurement.

9. **Friedwardt Winterberg**
February 2, 2018

If I understand the paper this could be a tiny effect caused by the likewise tiny GR space-time curvature by the gravitational field of the the earth. We know of course that this tiny space-time curvature is crucial for the working of the GPS. Question: If that is true what's the big deal if the GR space-time curvature of the earth gravitational field leads to other effects?

10. **UltraDoofus**
February 2, 2018

I went through the papers and it seems a tree-level contribution from Earth's gravitational field cancels out from all relevant quantities, except the 'muon magic momentum' term, which is used to calculate g-2. This apparently explains the anomaly.

Personally, I think this result will hold up. The calculations are pretty straightforward. If there is any inconsistency, it'll be found in no time.

I haven't read the original calculation of g-2, but people are usually thorough about these things. So all of this is pretty surprising.

11. **A**
February 2, 2018

According to the papers, the new effect does not depend on the gravitational field, but on the gravitational potential. It would be breakthrough if it could be measured by local g-2 experiments. One could even claim a bigger g-2 anomaly due to the gravitational potential of the sun and of the galaxy. Let's see if they missed some term that cancels the putative effect.

12. **Bernd**
February 2, 2018

A,
I don't want to spoil your excitement, but people have measured gravitational potentials for quite a while using atomic clocks. There are even portable clocks that can measure the gravitational potential of the earth with a resolution of about 70 cm.

13. **Dale**
February 2, 2018

Bernd,
Atomic clock experiments measure only gravitational potential difference between different locations. The effect in muon experiment is claimed to be proportional to the gravitational potential in that location (and not for example proportional to the gravitational potential gradient i.e. local acceleration).

14. **Bill**
February 2, 2018

Does anyone know what Schwarzschild coordinate system Morishima and Futamase are using in Eq.(3) in paper no. 1?

15. **Matt Visser**
February 2, 2018

The claimed resolution of the g-2 anomaly is asserted to depend on the *absolute* gravitational potential on the surface of the Earth.

Insoafar as one believes this claimed result, one is not working in general relativity,
and has explicitly violated Einstein's equivalence principle.

Insoafar as one believes this claimed result, the effect of the Sun exceeds that of the Earth by a factor 15, and worse, the effect of the Galaxy exceeds that of the Earth by a factor 2000.

(Gravitational potentials at the surface of the Earth, as opposed to gradients, behave somewhat unexpectedly: the Galaxy dominates over the Sun, which in turn dominates over the Earth's self gravity.)

On the other hand, insofar as one claims to be working with general relativity, then one should take note of the Einstein equivalence principle, whereby *absolute* gravitational potentials do not matter, and it is only potential differences that show up in laboratory physics.

The fractional corrections due to GR as compared to SR are of order

(Riemann tensor) x (size of laboratory)^2

With a little work this fractional correction turns into

(gravitational potential) x [(size of laboratory) / (radius of Earth)]^2

Overall, either way this proposal for resolving the g-2 anomaly fails:

1) Either you violate general relativity,
but then the effect of the Galaxy dominates and is 2000 times too big.

2) Or you work within general relativity, and then the effect is suppressed
by the overwhelmingly small factor

[(size of laboratory) / (radius of Earth)]^2.

So unfortunately this claimed resolution of the g-2 anomaly is not going to work.

16. **Chiara**
February 3, 2018

The authors claim that the effective muon magnetic moment is related to the one without gravity by μ_eff(muon)≈ (1+3ϕ/c^2) μ(muon), where ϕ is the gravitational potential.

It seems hard to believe
(1) that this formula does not contain potential differences, because potentials can be changed by a constant or by a change of coordinate system;
(2) that this formula doe not contain a term that depends on the orientation of the experiment with respect to the height coordinate z.

17. **Dale**
February 3, 2018

They do "assume that the motion is confined in the horizontal plane and the
magnetic field is applied vertically" (Part III, after Eq 27). But as Matt stated, they confuse the gravitational potential generated by earth with the minuscule gravitational potential difference in the laboratory (or else claim violation of the equivalence principle).

18. **Dale**
February 3, 2018

Apparently the error is more subtle that we speculated. In the very end of the Part III they correctly conclude that "Therefore, the relative magnitude of the contributions of the gravity gradient and the electromagnetic interaction is f∇ϕ / fEM ≃ 1.5 × 10^−15 which shows the gravity gradient contribution is 10^−15 times smaller than the electromagnetic interaction…"

It is the post-Newtonian effects that they conclude wrongly (as the sentence continues "… and is even 10^−5 times smaller than the post-Newtonian effects.")

19. **vmarko**
February 3, 2018

Beautiful! 🙂 Textbook GR, elementary calculation, this could have been an exercise for a graduate student (I might even give it to my students as an exercise). I haven't checked all minuses and factors of 2, but if the details of the calculations in the papers don't contain any mistakes, this represents an amazing lesson in GR for everyone!

As UltraDoofus noted, the kill comes in the equation (40) in 1801.10246, where the velocity of the muon (encoded in γ) is tuned to the "magic" value so that the term proportional to electric field becomes zero. From there, one reads off the value of the anomalous magnetic moment, and equations (44) and (45) compare it to the value of the a.m.m. without the GR correction term. And according to the table 3, this GR correction term has precisely the correct value to account for the 3.6σ discrepancy between experiment and the SM calculation. This is just way too good to be a coincidence. 😀

On the one hand, I do understand why GR has always been a blind spot in the minds of hep-ph and hep-ex folks (and maybe even some hep-th folks as well). But on the other hand, in face of a 3.6σ discrepancy in a high-precision experiment, the fact that nobody even _bothers_to_think_ of checking the GR contribution (while string theorists are on an all-out hunt for supersymmetry contributions) is just unbelievable! This result is a proper slap-in-the-face to all hep-* folks, to go back into the classroom and learn some GR.

Also, a small spoiler — while the first two papers are nice and instructive, one doesn't really *need* to read them, 1801.10246 is quite enough to make the point. 😀

Best, 🙂
Marko

20. **Art**
February 3, 2018

Bill,
The Schwarzschild metric used is defined in Appendix B.

Matt Viser,
The experimental apparatus is at rest with respect to the earth, as analyzed. To include the solar gravitational effect, one would have to include the accelerations with respect to the sun as well (since the earth is in free fall around it). However, there's no need to go to all that trouble, since the two precisely cancel per the equivalence principle. Ditto for the galaxy.

Various,
The analysis explicitly assumes a Schwarzschild geometry, so the corresponding fields are "baked in". Completely analogously, one can express the gravitational blue-shift of such a geometry solely by the potential of the receiving station.

With all that said,
I am not certain of the result. It seems they are suggesting the "magic gamma" was not selected quite correctly. I doubt the exact value was calculated for the experiment, but rather the result of some extremum search. I look forward to more authoritative discussion of this matter.

21. **Dale**
February 3, 2018

vmarko,
Don't you see a problem that they use gravitational potential of the earth ϕ (and not its' derivative)? It is claimed that a constant rescaling of the time and space coordinates could be made so that ϕlab = 0, and there is no Post-Newtonian contribution.

22. **G. S.**
February 3, 2018

Off topic, but it's going around social media that Joe Polchinski passed away yesterday following his battle with cancer. He was 63.

23. **UltraDoofus**
February 3, 2018

marko,

After looking at the papers again, I'm gonna have to curb my enthusiasm. I think they messed up while taking the post-Newtonian approximation.

As others have pointed out, the bare potential (gauge dependent) shouldn't appear in any observables. Only 'g' or its gradients can satisfy the equivalence principle. So the actual gravitational corrections are likely far too small cancel the anomaly.

Art,

1) The apparatus is not in free fall wrt to the Earth's field, which is why the experiment can only detect the local acceleration, 'g', and its gradients.

2) The redshifted/blueshifted frequency is a dot product between two vectors. So it's gauge independent.

3) Their argument about the magic momentum doesn't stand either. Because it's also gauge independent.

24. **Marc**
February 3, 2018

This discussion, while interesting, is completely irrelevant. The response from the g-2 collaboration (from the spokesperson Chris Polly):

Our spokes already replied to the authors since they made a mistake in the final conclusion. While the additional effect in the bxE term they calculate is 2ppm, they then attribute this full term to be the change in g-2. However, they forgot that that additional contribution needs to be weighted by the relative strength of the bxE term which is 1330ppm of the B field. So even if their calculation was correct, the actual contribution is 2ppm*1330ppm=2ppb. That's negligible for the ongoing experiments measuring to ~100ppb precision. And this argument does not even involve any judgement on the validity of the additional term they calculate.

25. **Noah Graham**
February 3, 2018

Matt Visser,
Is it obvious that the factor in (2) suppresses the effect? The muons are relativistic (gamma ~ 30) so SR effects are of order 1, the ratio of the storage ring radius to the earth radius is about 10^-5, and the correction only needs to be a few parts per billion.

26. **Noah Graham**
February 3, 2018

OK, actually more like 10^-6, but still in the ballpark. Also it must depend on the mass density of the earth somehow (if the earth were a neutron star, the effect would be much bigger)?

27. **Peter Woit**
February 3, 2018

G.S.
Yes, I was sorry to see that news. I never met Polchinski and my own indirect interactions with him were rather unfortunate. Rest in Peace.

28. **vmarko**
February 3, 2018

Ok, maybe I should respond to some of the issues people have raised here, just for the sake of clarity.

First, in the Newtonian approximation of GR, it is a quite standard thing to choose the boundary condition $\phi(\infty)=0$ for the potential. The authors have defined $\phi(r)$ in the sentence below equation (4), and it is obvious that they use this boundary condition to set the zero-level of the potential. Given this, the potential itself becomes observable. If anyone is uncomfortable by this, feel free to substitute (throughout the paper) every appearance of $\phi(r)$ by $(\phi(r) – \phi(\infty))$, which is invariant with respect to adding a constant. This doesn't change the result in any way.

Second, the gravitational potentials of the Sun doesn't play a role. In Newton-speak, this is because it is canceled by the corresponding centrifugal potential, coming from the fact that the Earth revolves around the Sun. In Einstein-speak, this is because the Earth follows a free-fall trajectory, and is thus in a locally inertial frame, so according to the equivalence principle it feels no pull from the Sun (and the tidal forces are too small over the size of the apparatus). The same statements hold for the galaxy. Note that the apparatus does *not* freely fall in the gravitational field of the Earth (as opposed to the Sun and the galaxy), but is being "pushed" off its geodesic trajectory upwards by the floor of the lab. This is an electromagnetic effect (spiced up by the Pauli exclusion principle), despite being described by the gravitational potential ϕ, in Newtonian language. This force is real, we all feel it when we stand up, and it has nothing whatsoever to do with any violation of the equivalence principle.

Third, one should distinguish the contribution coming from the potential ϕ and the contribution coming from the gradient of the potential, $\nabla\phi$. These are different, and the latter is much smaller than the former, as explained in Appendix C of the paper. Thus the gradient can be neglected, while the potential itself should not. The authors correctly showed due diligence to discuss this, I see no problem there.

Finally, regarding the response from Chris Polly, the relevant statement in the paper is this: " If the γ was experimentally tuned to minimize the electric field contribution, the quantity a^{mod} might have been measured.". That is to say, the experiment may contain a systematic error, depending on their procedure for tuning the value of γ. I don't know the details of the measurement process(es), but this doesn't seem to have anything to do with the absolute magnitude of the electric field, since the $\beta\times E$ term in (40) multiplies *both* the a.m.m. and the correction, so it cancels out of equation (44). Or maybe I misunderstood what Chris wanted to say. 😉

I hope this clears things up a little.

RIP Joe Polchinski.

HTH, 🙂
Marko

29. **Dale**
February 4, 2018

Marko,
I am grateful that you explained the topic in a such understandable way.

30. **Robert Matthews**
February 4, 2018

Given the claims that the preprint fails to explain the anomaly by orders of magnitude, I'm amazed there isn't some pretty simple dimensional analytic/O(mag) argument that shows this whole idea of GR affecting so subtle a phenomenon in QFT was always a non-starter.

31. **tulpoeid**
February 4, 2018

vmarko,

I don't know about this result, but let me just say that gravitational (and GR) effects are not unknown to accelerator physicists at all. The field has been taking these things into consideration and even I (not an accelerator physicist) happened to be at such a seminar. The rumor says that g-2 is already half way in writing an answer, as is by now kind of evident from comments above.

32. **Julius**
February 4, 2018

In case of the first article, another way to look at this "potential" effect, note that the factor in formula (4) comes from time dilation, and it is known that gravitational time dilation is, to the first order, proportional to differences of potentials. Since here only one location of comparison is explicitly mentioned, i.e. on the Earth's surface, the other location of comparison is naturally set at the infinity, and the constant cancels out. Hence, there is no contradiction in having pure potential. I was surprised that initially people jumped in with such conclusions, especially when this can be check almost on paper, with possible help from Mathematica.
Also, formula (5) contains mistakes. Surely, the overall factor should be gamma, not its inverse, and, I think, terms in brackets should have opposite signs. Seeing such things on page 2, I am not surprised that they may have forgotten a numerical factor.

33. **Blake Stacey**
February 4, 2018

Matt Visser's response to the original postings has appeared on hep-ph/gr-qc: "Post-Newtonian particle physics in curved spacetime" arXiv:1802.00651.

34. **A**
February 5, 2018

Julius, the difference with the potential at infinity will be relevant when some experiment will be done there. Local experiments cannot measure the local gravitational potential. This was also discussed in arXiv:1802.00651 by Matt Visser.

35. **Bernhard**
February 5, 2018

OK, so it seems the odds against the article being correct are now rather low, given the comments from experts, but the unprofessional reactions towards the authors are really sad. They are not crackpots – they wrote a paper that an experimental collaboration felt the need to respond to. However flawed, which I'm in no position to judge, this is all part of doing science. One wants to avoid making public mistakes, but this is not always possible.

36. **vmarko**
February 5, 2018

It appears that I was wrong regarding my comment to the response of Chris Polly. Namely, in experiment, the a.m.m. is not being determined from equation (44) but from equation (8). The authors correctly point out that this is calculated using the skewed value of γ, which appears to be a valid remark given the GR correction term in (40). So I decided to calculate the variation of (8) with respect to γ, taking into account (40), to see what happens when the value of γ is slightly shifted. And indeed, the variation turns out to be proportional to $\beta\times E$ as well, as Chris wrote. So Chris is right that this effect is weighted with the magnitude of the electric field, which is apparently small enough to suppress the GR correction beyond the experimental resolution.

In the end, it appears that the correction term in (45) and in Table 3 is really just a numerical coincidence. 🙁

Best, 🙂
Marko

37. **Julius**
February 5, 2018

A,
time dilation is not a local event. To the first order it depends on the difference of potentials, and the further apart they are measured, the bigger the effect. If one dislikes time at infinity, then by coordinate transformation time can be brought to a finite distance from Earth. In practice this is what we do for experiments on the ground, since we, are sitting in a potential well, together with our atomic clocks. Maybe what is confusing is the usage of the gradient notion, and I use the differential gradient definition, not some macroscopic difference.

38. **Nadir Bizi**
February 5, 2018

In the first paper, they compare Eqs. (4) and (19) to their Minkoswki counterparts to extract the effective magnetic moment of the muon. But this comparison is only valid in the locally inertial frame of the lab. (e.g. Fermi coordinates).

If one assumes that they are using a locally inertial frame in Eq. (3), then the metric has to be Minkowski at the lab, and the potential vanishes there. Eq.(9) is then “trivial”. The first correction from GR will thus come from variations of the potential (i.e. of the metric), as explained by Matt Visser in his short paper.

If on the other hand one uses Schwarzschild coordinates (as they do), then one is not allowed to extract the magnetic moment from Eqs. (4) and (19).

Their calculations seem correct to me, it is their physical interpretation of these calculations that one must be cautious with.

39. **Dimitris Kosmopoulos**
February 5, 2018

Hello Peter,

in all three papers, the Schwarzschild metric is approximated with respect to the small parameter ε = 1/c …

This is not correct.

The expansion parameter is usually dimensionless (such as e.g. the ratio υ/c, or the fine structure constant α).
And the expansion shall be finite when ε = 0. But in their case, it’s infinite!

Anyway, perturbation expansions are not based on dimensional quantities such as c, because with a change of units c can take any value you want – large or small…
Funny, in all three papers, it is stated that they use units where c = 1.
🙂

Usually Φ/c^2 is considered small for approximations of the Schwarzschild metric, but this gives the Newtonian limit.

Has anyone checked if their derivation of the approximate post Newtonian metric is correct?

40. **arxiv etc**
February 6, 2018

Does it occur to anyone that the authors could have contacted the muon g-2 collaboration privately, to discuss their findings? I asked a friend (member of the collaboration) about this and his reply was that expert theorists rapidly identified the error and this formed the basis of the reply by the collaboration.

41. **X**
February 7, 2018

arxiv,

Ideally they should have asked for feedback from experts and the muon collaboration privately before posting the papers. In practice though it is very understandable that they would choose to “shoot first and ask questions later”. Especially since they seem to be young unestablished people and therefore likely to get minimal credit if their work happened to be scooped “by coincidence” (not) by someone prominent while they were doing the private consultations…

(I had an experience of exactly that, although concerning a much smaller result, as I’m sure many others have had too. As a young nobody I found a result of some significance in a specialized subfield of hep theory – although no big deal in the general scheme of things – and thought I better seek feedback and confirmation from experts before posting the paper… Without getting into the details, the upshot was that I ended up sharing credit for it with 2 others, both of whom were more senior, so my paper was always 3rd and last when that work was cited thereafter… One of the others was an eminent senior person who ended up with the bulk of the credit – not so much because he tried to grab it but because the community just felt more comfortable with him having it, i.e. the Matthew effect in action.)

Regarding the current papers, if the result doesn’t hold up (which seems to be the case now) I hope the authors still get credit for boldness, creativity, and giving us something interesting to think about!

42. **Rob**
February 7, 2018

arxiv etc. What was required was feedback from theorists. It would be a little odd that authors should feel they have to go through an experiment to get this. For theory feedback, the arxiv is the most appropriate choice. There is also no guarantee that the expert theorists engaged by the collaboration would have worked as quickly as they did when the papers appeared in the arxiv. A response to the authors’ work may well have been placed on the back-burner for quite a while.

In general, I prefer these issues to play out in the open. I admire the authors for taking a chance. Yes, they were left with egg on their faces; that’s life. I certainly don’t see them as crack pots, as has been alleged (unless someone can come up with more evidence than is provided by this particular issue). At the very least we’ve all learned that GR plays effectively no role (no surprise) in the muon g-2 measurement and we’ve also been reminded that there is a first rate experiment which may resolve one of the big puzzles in particle physics.

43. **arxiv etc**
February 7, 2018

X and Rob,

It is a simple matter of courtesy. The authors explicitly claimed to offer a resolution of the muon g-2 anomaly. It is a simple courtesy to contact the collaboration “We have performed a calculation which we believe resolves the muon g-2 anomaly. We enclose a preprint of our analysis for your comments. We look forward to your reply.”

#1
The collaboration might ignore the authors. Post a preprint with a statement “We have communicated our results to the collaboration, but to date they have not replied.”

#2
Post a preprint and send a copy to the collaboration at the same time. Include a statement “We have sent a copy of our results to the collaboration and will update our post if and when we receive a reply.”

But at a minimum *demonstrate that they made a good faith effort to communicate with the collaboration*.

44. **X**
February 8, 2018

arxiv,
The problem is that a genuinely good faith effort to communicate with the collaboration before posting the papers would require giving them at least 3 days to respond,

and that is enough time to be “coincidentally” scooped.

E.g. in this scenario, in the case that the result happened to be correct:
The collaboration forwards the papers to their theory expert, who spends an hour or two on them and gets very excited – doesn’t see any immediate flaw in the arguments but still needs to check more carefully. He mentions his initial impression and excitement to someone, who mentions it to someone else, and the rumor quickly spreads among a circle of experts.
One of them, person A, hears the rumor and remembers that he had actually thought about calculating the gravitational contribution to the muon anomaly, and vaguely planned to do it at some point (as a fun exercise; he was sure the contribution would be negligible). Well, since he had the idea, and planned to do the calculation, “why should I just sit here now and let that unknown Japanese group get all the glory” he thinks this to himself. “So he puts everything else aside and immediately gets to work…does the calculations and posts the paper within 24 hours.
(Perhaps person A adds a note at the end of his paper saying that while this work was in preparation he heard from person B that a Japanese group had informally circulated a paper on this topic, although having not seen the paper he doesn’t know if their approach and result is the same…)

In my view it would be fine if the authors send an email to the muon collaboration to point out their paper and solicit feedback once they posted the paper. And for all we know they might have actually done this.

45. **arxiv etc**
February 8, 2018

“why should I just sit here now and let that unknown Japanese group get all the glory” he thinks this to himself. “So he puts everything else aside and immediately gets to work…does the calculations and posts the paper within 24 hours.

That’s just sad, that these are modern scientists. When Einstein received Bose’s manuscript he did not say “why should I just sit here now and let that unknown Indian get all the glory”.

It is obvious the authors did not contact the collaboration, or the collaboration would not have worded their reply as they did. It costs the authors nothing to include a statement in their preprint that they had contacted the collaboration. They did not, as the response of the collaboration makes clear.

It is a simple matter of civil behavior.

46. **Peter Woit**
February 8, 2018

All,
I think the question of whether they should have contacted the experiment has now been properly beaten to death. In any case, in retrospect it seems to me the authors made the more general mistake of not consulting a theorist more expert than themselves in the subtleties of GR calculations. Yes, there’s always a danger that if you talk to experts about your ideas they may get stolen, but on the other hand, if you don’t you’re likely to not find out what the problems are with your ideas until it is too late.

47. **Shantanu**
February 9, 2018

X, Peter etc. Futamese is not a junior person. He is one of the best GR theorists in post-Newtonian business. You can check out his past works.

48. **vmarko**
February 9, 2018

Peter,

“mistake of not consulting a theorist more expert than themselves in the subtleties of GR calculations”

They did not make any mistakes with regards to GR, their calculations are textbook-level proper. The only thing they did wrong was to suggest an interpretation of the experiment that turned out to be wrong. And even in doing that they used careful phrasing, like ”If the γ was experimentally tuned to minimize the electric field contribution, the quantity a^{mod} *might have been* measured” (emphasis mine). I cannot think of a more toned-down formulation of that statement (which turned out to be wrong in the end).

BTW, it is not really common practice to include statements like “we contacted the experimental collaboration, but they didn’t reply yet” into a paper or a preprint. I have never seen any such statements in any paper whatsoever.

HTH, 🙂
Marko

49. **Dale**
February 10, 2018

vmarko
Matt Visser’s rebuttal of the Japanese papers is based on the violation of the equivalence principle. The rebuttal is not based on any details of the experimental set-up. Surely if the Japanese disagree with Matt’s conclusions, they will post a reply to the rebuttal.

50. **Wyman**
February 11, 2018

I am having trouble understanding these objections based on the equivalence principle. The authors appear to be working in the Schwarzschild metric, and instead of referring to a quantity named like r_s / r they refer to the equivalent “gravitational potential of the Earth”, which is uniquely defined by identifying it with the term in the metric.

51. **vmarko**
February 11, 2018

Dale,

They will reply if they find his rebuttal worthy of attention. If I were them, I wouldn’t.

Best, 🙂

Marko

52. **cedric bardot**
February 13, 2018

A very brief arxiv paper (https://arxiv.org/abs/1802.04025) from February the 13th may point quite educationally the erroneous tacit assumption made in the first Japanese paper namely taking a coordinate time for a physical one…

“When we are moved … by a thirst for knowledge, then the error, like the pain or the sadness, passes us without ever being lost, and the trace of its passage is a renewed knowledge” (Alexander Grothendieck in “Harvests and Seeds”)

Various and Sundry

February 9, 2018
Categories: Uncategorized

- I recently spent some time looking at old postings on this blog, partly because of writing this blog entry, partly because Gil Kalai got me a copy of his book Gina Says. For a moment I thought this would be a good time to write something about the "String Wars", but then decided that project should wait for another time. I did go quickly through old postings (there are 1660 of them…) and pick out a small subset that might be more worth reading for anyone with time on their hands. A list is available by selecting the category Favorite Old Posts.
- Another category of blog posts that includes many that I spent more time than usual writing is that of Book Reviews, of which there are 93 here (about ten of these were written for publication elsewhere). Among the forthcoming books I'm hoping to write about are Sabine Hossenfelder's Lost in Math, and the fifth volume of Raoul Bott's Collected Works (listed at Target under "test prep and study guides"). Some other forthcoming books are Sean Carroll's Something Deeply Hidden, and a new book by Brian Greene that I know nothing about other than this.
- A debate various places on Twitter about science journalism and accuracy included this from neuroscientist Chris Chambers, who explains that when he looked into this he discovered what I've often seen in physics reporting: the source of hype is more often scientists and their press releases than journalists. https://twitter.com/chrisdc77/status/960304692449435648
- The nLab project has been joined by the even more exciting mLab project (some discussion here).
- This semester MSRI is running a program on enumerative geometry, with two workshops so far, materials here and here. A lot of this subject has been influenced by ideas from physics, in particular from topological quantum field theories. While my Columbia colleague Andrei Okounkov has been on leave this year, he's written two excellent surveys of some recent work, see here (for the ICM) and here. For older surveys from him, see here and here.

Update: I hear of yet another book in progress: Lee Smolin on realist approaches to quantum foundations, tentative title "Beyond the Quantum".

Update: Today (February 12) the Harvard Physics department is hosting a celebration of the centennial of Julian Schwinger.

Update: One of the prize possessions of my youth was a copy of Abramowitz and Stegun, a huge Dover paperback version of their reference tome *Handbook of Mathematical Functions*. Physics Today has a long new article about the twenty-first century version of this, the Digital Library of Mathematical Functions, now a project run by the NIST.

Update: This week there's a workshop on "Naturalness" going on in Aachen. Results from last year's LHC run should start to appear soon, see here.

   February 19, 2018

   Check out this nice talk from Nima Arkani-Hamed, entitled "The Doom of Space Time". He turns into quite the comedian at 1 hour 40 minutes into the talk, citing "violins, chellos, Nova specials." Great explanations about how space-time must be emergent and offers an intro to his own stab at the problem.

7. **Peter Woit**
   February 19, 2018

Timothy,
Thanks, hadn’t seen that before. I confess though that it’s still unclear to me why spacetime “must” be emergent, and what it is supposed to be emerging from. Back in the good old days when people were talking about quantum gravity I could tell exactly what their quantum gravity theory was, nowadays I often have no idea what the actual theory being discussed is.

8. **Peter Woit**
February 20, 2018

I took a longer look at the Arkani-Hamed talk. It’s the usual story he has been telling for about ten years now, that new ways of computing scattering amplitudes in terms of volumes and combinatorics of geometric objects indicate a grand synthesis, in which spacetime and quantum theory will be emergent notions. He just doesn’t yet know what that grand synthesis is. For an insightful comment from him about these kinds of claims, see this posting

http://www.math.columbia.edu/~woit/wordpress/?p=6476

and this quote:
“So, usually I’ll get up when I talk about scattering amplitudes and give a long introduction about how spacetime is doomed, we have to find some way of thinking about quantum field theory without local evolution in space time and maybe even without a Hilbert space and blah-blah-blah. This is all very high-falutin stuff, this is stuff that Lance wouldn’t be get caught dead saying. I think none of these guys would ever say something that sounds so pretentious, but I have to say it, you know I have to say it, because this is the only way I can get up in the morning, and like “I suck again, OK, here we go, I’m doing it because spacetime is doomed, I swear to God, right”.”

9. **Nick Maiorino**
February 27, 2018

Hopefully this falls under the ***Various and Sundry*** category, but the latest results from the CDEX-10 Experiment are in, and there’s still no sign of WIMP’s.

10. **Low Math, Meekly Interacting**
March 1, 2018

And then there’s the recent EDGES report suggesting DM may be considerably lighter than most WIMP models predicted, if not different in other ways. Guess time will tell if this one will go the way BICEP2’s B modes, but reportedly we won’t have to wait too long for other groups to confirm or refute.

11. **Peter Woit**
March 1, 2018

LMMI,
I know little about this field, but seems way premature to be claiming anything about dark matter from this. For a critical take on the observations (much less the speculative theoretical interpretation), see

Applied Group Theory

February 26, 2018
Categories: Uncategorized

I just noticed that Greg Moore has been teaching a wonderful course in recent years with the misleadingly bland title of Applied Group Theory. His choice of the topics he wants to cover given here is an excellent one and a good outline for anyone trying to get themselves a serious education in the modern overlap of math and physics.

The problem with this outline is that it's far too ambitious to cover in a one-semester course, starting just from basics. Moore notes that in 2008 and 2009 versions of the course he only got through roughly half the topics, with students still complaining about the fast pace of the course. In 2013 he only made it through two out 21 topics, but in doing so generated two book-length documents of notes:

- Chapter 1: Abstract Group Theory
- Chapter 2: Linear Algebra User's Manual

These each contain a wealth of valuable material. I do hope he someday writes up the other 19 topics, but if he does it the way he has been going, the length might turn out to be around 4000 pages, so that might take a while. In the meantime, an account of some of them is available here.

In addition, there's also a list of suggested topics for term papers, nearly a hundred of them, each with a description of an interesting issue that has been a topic of significant research, with references for where to start learning about the topic.

   February 28, 2018

   A gold mine!

2. **Matt Foster**
   March 1, 2018

   It's far less "sexy" than group cohomology (these days), but y'all can find a very applied "users manual" to Lie Algebra representation theory as 9 course module pdfs on my webpage,

   http://mf23.web.rice.edu/

   (scroll down to "Lecture notes")

   These are basically a more fleshed-out version of Cahn's excellent 1984 book _Semi-simple Lie Algebras and Their Representations_. My idea was to try to make representation theory accessible to (upper division) undergrads, which means developing the ideas without bringing in applications to quantum field theory. I haven't figured out the best way to distribute these yet.

3. **Rana Singh**
   March 2, 2018

   Since the reading list for Physics 618 mentions books related to history and culture associated with group theory, two additional books are suggested below, both available from Dover Publications. (1) The Theory of Groups & Quantum Mechanics by Weyl. This is a classic and since last published in 1930, provides an insight into a time when a lot was happening in quantum physics. Interestingly, when discussing the Dirac equation, and trying to reconcile theory with observed facts, Weyl writes, "indeed, according to it the mass of a proton should be the same as the mass of an electron". At that point, one recollects that the positron had not been discovered at the time. It was discovered two years later. (2) The Genesis of the Abstract Group Concept by Hans Wussing. This book discusses the history of Group Theory from a purely mathematical perspective and attributes the development of the subject to the theory of algebraic equations (Galois Theory and the solution of the quintic equation), number theory , and geometry.

4. **D R Lunsford**
   March 3, 2018

   Thanks for pointing that out, looks great.

   -drl

5. **Lindsay Berge**
   March 5, 2018

   On the topic of being "far too ambitious to cover in a one-semester course" and "complaining about the fast pace of the course", my PhD supervisor once delivered a Nuclear Theory course with so much content that one his students wrote on the backboard before he came in to the lecture theater "Question: when can a lecturer go faster than light? Answer: when he conveys no information!"
   He laughed and took all the students to the pub but it is not clear whether he slowed down.
   That said, both "Chapters" are fascinating and inspiring.

6. **Thomas Larsson**
   March 6, 2018

   I have heard the same joke about the pace of growth of the Physical Review.

   There is certainly a wealth of material in these notes, and hopefully Moore will find time to cover the other topics as well. I'm curious about chapter 15 "Kac-Moody and affine Lie algebras, and beyond". In particular what he has to say about the "beyond" part.

Rochester Colloquium Talk

March 6, 2018
Categories: Uncategorized

I'm heading up to Rochester this evening, will give a colloquium talk there in the physics department on Wednesday at 3:45. I'll put up a link to the slides after the talk, for now, here's the abstract:

> **Particle theory: a view from a neighboring field**
>
> High energy particle physics faces a challenging future, largely because of the overwhelming success of the Standard Model. The LHC discovery of a Higgs particle with exactly the predicted properties, coupled with the lack of evidence there for "Beyond the Standard Model" physics, has led some to characterize this as a "crisis".
>
> In this talk I'll consider the current situation from a somewhat unusual point of view, that of someone who began his career in physics departments doing particle theory, but then moved to mathematics departments. The field of mathematics has complex and close ties to fundamental physical theory, and the cross-cultural perspective it provides may be of interest.

Update: Apologies for the earlier mistake (I had "Thursday" instead of "Wednesday" above). The slides for the talk are available here.

   March 7, 2018

   Dr. Woit,
   Your blog post says the colloquium talk is on Thursday but the University of Rochester website says Wednesday. Is it over? If so, could you please post a link to the slides?
   Thanks

7. **Peter Woit**
   March 7, 2018

   Talk just finished, sorry about the mistaken day given in the posting. No recording, I have added a link to the slides.

8. **lun**
   March 7, 2018

   What questions did you get?

9. **JimV**
   March 8, 2018

   This may be a semantic issue, but I tend to disagree that Mathematics is a non-empirical science (as stated in the slides). For example:

   The Taniyama-Shimura Conjecture (based on empirical observation of the characteristic numbers of elliptic curves and modular forms) led to Andrew Wiles' proof of Fermat's Last Theorem (as discussed in Simon Singh's "Fermat's Enigma").

   Scott Aaronson on a mathematical breakthrough in complexity theory: "It's yet another example of something I've seen again and again in this business, how there's no substitute for just playing around with a bunch of examples." – http://www.scottaaronson.com/blog/?p=2325

   Greg Chaitin, co-founder of Kolmogorov -Chaitin Information Theory:

"For years I've been arguing that information-theoretic incompleteness results inevitably push us in the direction of a quasi-empirical view of math, one in which math and physics are different, but maybe not as different as most people think. As Vladimir Arnold provocatively puts it, math and physics are the same, except that in math the experiments are a lot cheaper!" http://www.rutherfordjournal.org/article020103.html

10. **Peter Woit**
March 9, 2018

lun,
The questions were mostly about the multiverse business, and the more I had to say there was just more of the usual if you read this blog.

JimV,

I don't want to start a discussion of this here, but while, yes, mathematical advances often proceed by working out examples, finding patterns, conjecturing and then proving general theorems, the activity of working out examples is something quite different than a physics experiment. In one case you're investigating the world of mathematical structures, in the other physical reality.

11. **Lowell Brown**
March 10, 2018

"mathematical ideas originate in empirics. But, once they are conceived, the subject begins to live a peculiar life of its own and is … governed by almost entirely aesthetical motivations. In other words, at a great distance from its empirical source, or after much "abstract" inbreeding, a mathematical subject is in danger of degeneration. Whenever this stage is reached the only remedy seems to me to be the rejuvenating return to the source: the reinjection of more or less directly empirical ideas."

John Von Neumann

12. **Pascal**
March 10, 2018

On slide 9 : "Experimental study of quantum gravity seems out of reach."

Your fellow blogger Sabine Hossenfelder seems to disagree, for instance she writes:

"I am cautiously hopeful that within my lifetime we will succeed in experimentally demonstrating that gravity is quantized"
http://nautil.us/issue/45/power/what-quantum-gravity-needs-is-more-experiments

Any comment on what's the root cause of this disagreement?

13. **Amami**
March 11, 2018

I honnestly have to say that this talk and this way to see the future of fundamental physics are not very optimistic, especially for young people like me.

14. **Peter Woit**
March 11, 2018

Pascal,
I'm no expert on this, but most of the discussions of possible quantum gravity experiments seem to aim at little more than checking that gravity obeys general laws of quantum mechanics (and it's not clear if they can achieve that). What seems to me to be inaccessible is any experimental access to the study of quantum gravity beyond checking that at low energies there is the kind of consistency of gravity and quantum mechanics expected. In simpler terms, it's the questions about quantum gravity at the Planck scale that really mystify theorists, and that I don't see experiments telling us anything about.

15. **Tim May**
March 12, 2018

Amami, about the prospect in particle physics, and about 1973 in particular (reference to Peter's comment about 1973), I happened to be in a place to cook a steak for Feynman in that year. We were hosting him at our college and later in our off-campus apartment. He was very gracious with his time and various jokes and comments.

I asked him straigtht out what he thought the prospects for particle physics were, and what he might suggest people study instead if in fact particle physics are starting to dry out.

He said he did indeed think it was starting to dry out, that most things had basically been figured out (this was slightly before the Standard Model was mostly finalized, but a lot of things were known).

His advice? Computer science or pure mathematics.

I elected not to go to grad school and instead joined Intel Corporation. A lot of fun physics. Not exactly figurring out the nature of spacetime–not many do–but fun and I retired when I was 34. (Kept doing other things, just not on a 9-5 schedule dictated by other things.)

A physics education, even up to just a Bachelors, for those gifted in physics, is actually very useful in a lot of areas of high tech. I was hired by and worked for he guy who went on to become the President, CEO, and Chairman of Intel (Craig Barrett).

(Not so gifted, no. And even those with Ph.D.s who are not gifted, well, I worked with a lot of these types and they were not very successful in my experience.)

Meaning, if you are good at physics, keep at it. As to whether you may figure out the Theory of Everything, not too likely. And it was not too likely in 1973. Or in 1955. It never was.

Things were more easy to do experiments on in earlier times. For obvious reasons. So a Dirac saw his antimatter prediction confirmed a year or two later. And so on. Today, a prediction might take 200 years to test…simple log energy graphs.

If you are really good at math, keep at it as well. A couple of my roommates in college have had long and distinguished careers in math. I think the influence of the physicists in the house may have had an effect, and I strongly suspect the supper with Feynman did.

16. **GoletaBeach**

March 12, 2018

Fun talk, Peter. Surprised how many of the initial slides were essentially an overview of your version of the current state of experimental HEP.

For some of us, the theoretical motivations have always been a minority portion of the motivations for doing particle physics. Given all the experimental slides you included, odd you didn't mention that. Your talk, though, you are of course free to cover whatever you feel is important.

Can't agree with: "Technological barriers are starting to make it impossible to make progress on HEP physics as before." (slide 31). All the technological barriers at the energy frontier are doing is slowly refocusing experimental effort away from that frontier, on to other frontiers.

The energy frontier has of course the most important source of breakthroughs, but it hasn't accounted for a lopsided portion of the breakthroughs in particle physics.

A list… the discovery of the neutron (could have been done in 1919 when Rutherford started to disintegrate nuclei, took until 1932 due to not doing the right experiment); the neutrino (the great Ellis and Wooster experiment); neutron-induced radioactivity and all of its consequences including the bomb, medical isotopes, and nuclear reactors (Fermi and his Nobel); the measurement of the proton magnetic moment (1930's, indicated proton substructure); the pi/mu distinction (Fermi's old group in Rome during WWII); parity violation (the tau-theta puzzle); K0-K0bar mixing (off the frontier); the nu_mu/nu_e distinction (1962 off the frontier); CP violation in K0-K0bar system (off the frontier); the solar neutrino deficit; the J/Psi (the ISR was the energy frontier, missed charm); both the tau and the bottom (again, off the energy frontier, which was then too dirty; better detectors have improved it); the long b-life and B-mixing; atmospheric neutrino mixing; KAMLAND and Daya Bay/RENO narrowing down the neutrino mixing matrix.

A list so long it gets boring. But I must say: by omitting the rich realm of particle physics discovery that did not occur at the energy frontier (while simultaneously acknowledging the great importance the frontier) you incorrectly, IMO, imply that experimental discovery is over in HEP.

17. **Chris W.**
March 12, 2018

Mathematical "experiments" concern observations of patterns in the outcomes of computations or other formal manipulations, where understanding the laws governing the physical substrate of the manipulations is not the issue. One can do arithmetic computations with pencil and paper (and a scheme for representing numbers and operations on them), a calculator, or a computer. By design, all these tools are facilitating the same manipulations.

In this sense, mathematics is *not* empirical.

18. **Peter Woit**
March 12, 2018

Goleta Beach,
Thanks for the comment. The talk was intentionally provocative with one aim to explain the problem at the energy frontier (the severity of which I don't think is widely appreciated outside of the field). I did give the caveat that there is still hope for other approaches, especially noting that neutrino physics is still poorly understood, but a serious discussion of that would have been another, different talk, one I'd be ill-equipped to give.

On your history, I don't really agree that the charm/tau/bottom discoveries were not "energy frontier". In particular, SPEAR in the mid-seventies I'd describe as an energy frontier machine (since it was at the highest e+/e- energy), just as I'd describe the ILC as an energy frontier machine if it ever gets built. About the neutrino results, yes, that's true that those have generally not been energy frontier results and that will continue to be true.

19. **Pascal**
March 13, 2018

Is there some concensus on what theory should describe the low-energy behavior of quantum gravity (which you agree might be experimentally accessible with some luck and and hard work)?

20. **Peter Woit**
March 13, 2018

Pascal,
Using the standard Einstein-Hilbert Lagrangian for gravity gives a perfectly sensible low-energy effective field theory, and that's generally assumed to be what we would see in the low-energy limit if we could do experiments. The renormalizability problem, from the effective field theory point of view, just shows up at high energies (of order the Planck mass).

21. **GoletaBeach**
March 14, 2018

Hi Peter, perhaps in retrospect SPEAR was an "energy frontier" machine, but at the time two facts made contemporaries view it as off the frontier:
(1)ISR at CERN was at CM energy of 30 GeV, and NAL (now FNAL) was at 20 GeV (see Figure 15 of link below)… both hadron beams
(2)SPEAR's CM energy was at 4.8 GeV, and the J/Psi was down at 3.1 GeV, and the tau-tau threshold was at 3.6 GeV. Richter, in late 1974, resisted going back down to the 3 GeV region to scan… internally it was sometimes said he was the first Nobel prize winner to lobby against the pursuit of the physics he was later awarded for. He acquiesced to a re-scan of the 3.1 GeV region a bit reluctantly, but he did agree. In any case, off the frontier, even SPEAR's frontier.

Now we know all about partons and pdf's and we know that the parton CM energy is well below that of the hadrons, so the ISR and NAL effective energies aren't that different than SPEAR's. But at the time no-one agreed with that view… even Richter in the link below thought the SPEAR data in the summer of 1974 contraindicated the quark/parton model.

At the time (and even now with ILC) e+e- is valued for its cleanliness and precision. ISR missed charm, after all, but could easily, with today's detector technology, have seen charm. Or even with tech of the 1960's and the right idea of pursuing charged leptons while ignoring the hadrons (perhaps). With the advances in hadron-collider detector abilities, it is very hard any more to call e+e- "energy frontier"…. that is, it is hard to imagine LHC missing stuff in the way the ISR did. Not impossible but hard. What the ILC could do… nail down Higgs couplings to great precision, and maybe indicated new physics somewhere "up there" in mass. But neutrino physics has already done that, and other low energy stuff like electric dipole moments are also probing "new physics" at pretty high masses for particles appearing in loops.

The problem will always be: knowing something is in a loop always has ambiguities and degeneracies. Knowing something is in a loop mainly provides support for a new energy frontier machine, and that is what the ILC could do. So could EDMs. I think the natural neutrino "new physics" scale is so high that no imaginable collider could get there, but probably that statement is not air-tight.

Link to summer-1974 Richter talk… http://slac.stanford.edu/pubs/slacpubs/1250/slac-pub-1478.pdf

On the b-quark discovery… really it was high resolution in the FNAL spectrometers, not center-of-mass energy, that made the upsilon discovery. When e+e- started to see the upsilon, it was DORIS and CESR, which were way behind the e+e- energy frontier, which was PETRA and PEP… the latter 2 had 3X the center-of-mass energy of the former.

Some places where the energy frontier was indeed crucial: antiproton discovery, Omega- discovery, W/Z, top quark, Higgs. Crucial stuff, of course.

Presumptuous Blogging

March 12, 2018
Categories: Multiverse Mania

John Horgan at Scientific American today has an interview with Martin Rees in which Rees says:

> It's presumptuous (as some people like Woit and Smolin have done) to deride the way some manifestly brilliant people choose to dedicate their scientific lives.

I generally try and be careful to criticize not people, but the arguments they are making. Rees and others (including a Cambridge University Press referee for *Not Even Wrong*, who basically thought I had good points, but was presumptuous to be making them) often seem offended that I or Lee Smolin are challenging arguments from those smarter than ourselves. It's true that there is a problem with this: bad arguments of the kind I'm criticizing should be challenged by the leading figures in the field, not by me. In particular, many particle theorists smarter and more distinguished than myself are well aware of the problem of multiverse mania, but doing nothing about it, as it destroys the credibility of their field. Among the few personal criticisms of some leading theorists that I have is that they're not doing the job they're paid for here, and I'm not happy wasting my time trying to (presumptuously) do it for them.

On the presumptuous behavior front, here's some more of it:

- Rees's arguments are the usual multiverse propaganda, including the usual red-herring argument defending the multiverse as science:

  > It's sometimes claimed that domains that are in principle unobservable aren't part of science. But not even the most conservative astronomer would take this line. We're in an accelerating universe where distant galaxies will disappear over a horizon, and their far future would never be in principle observable. So it's natural to suppose that there are galaxies that are already beyond the horizon and so forever unobservable. If you're in the middle of the ocean, you'd be surprised if its boundary lay just beyond your horizon. Likewise, astronomers are confident that the volume of space-time within range of our telescopes — what astronomers have traditionally called 'the universe' – is only a tiny fraction of the aftermath of our big bang. We'd expect far more galaxies located unobservably beyond the horizon.

  As usual, Rees gives no evidence for his claim that those skeptical that the multiverse is science are just ignoramuses who don't understand the notion of indirect evidence for a scientific theory.

  Multiverse mania goes on and on, for instance here and here.

- Among the more presumptuous things I've done, there's last week's talk.
- I recently noticed here the analysis that:

  > I "predict" that if by about 2020 the LHC or cosmology do not show any concrete evidence of supersymmetry or superstrings, physicists will attack string theory the way the Huns attacked Rome. Like the Huns, Lee Smolin, Peter Woit, and Roger Penrose have already started encircling string theory, abiding their time, and waiting for the strike. They seem to have read The Rise and Fall of the Roman Empire carefully.

  I've never read Gibbon. If one accepts the analogy though, I think it's conventional wisdom that the String Wars were back in 2006, we didn't wait for 2020. All the evidence I've seen recently is that most string theorists have now given up on the idea that evidence for supersymmetry or string theory will appear at the LHC. Those attempting to defend Rome now are trying to backpedal on their claims from a decade ago. They now argue that finding nothing at the LHC isn't surprising and doesn't matter, but this rear-guard action likely will not be effective.

- More evidence that hopes for LHC-scale SUSY are now pretty much dead can be found by looking at the slides from the recent Aachen workshop on Naturalness, Hierarchy and Fine-Tuning. The debate among theorists has now moved on to trying to figure out what conclusion to draw from the failure of widely-promoted claims about "fine-tuning". One motivation for such claims was that in string theory-based models the CC and Higgs potential are supposedly calculable, with expected results from dimensional analysis that are exponentially large (Planck scale) compared to observations. On this front, an obvious conclusion to draw is just that these models (which are complicated and predict nothing else anyway) are wrong.
- I suppose it really is presumptuous to make a snarky comment about a talk by someone clearly more hard-working and smarter than I am. In any case, I just noticed that slides for Nima Arkani-Hamed's talk *Three Cheers for Shut Up and Calculate!* are now available here. I had written about this here without knowing what the talk had been about, based on the historical origin of the "Shut Up and Calculate!" slogan (and thus assuming the measurement problem would be a main topic). From the slides, Arkani-Hamed's talk wasn't at all about the measurement problem, but largely about quantum gravity, with many slides of speculative claims about new emergent versions of space-time and quantum mechanics (backed by one slide about calculating amplitudes as volumes). I'm quite sympathetic to what he has to say about the importance of prioritizing well-defined calculations over meaningless verbiage, but it seemed to me that in this talk he wasn't really taking his own advice. I can't help wondering who it is that Arkani-Hamed thinks should "Shut up" about vague ideas about quantum gravity and stick to well-defined calculations.

Update: For more presumption, see the latest at Backreaction.

Update: Lee Smolin has been edited out of the list of the presumptuous in the Rees interview, but I'm rather proud to be presumptuous, so I'm still there, and a link has been added to this blog posting.

Comments

1. **paddy**
   March 12, 2018

   Peter:
   If anyone knows "presumptuousness" 'tis the likes of Martin Rees. [Pardon the ad hominem and delete as you see fit.]

2. **Peter Orland**
   March 12, 2018

   Sorry to be officious, Peter, but the title of Gibbon's multivolume monograph (which I attempted, but never finished, back in my youth) is "A History of the Decline and Fall of the Roman Empire". "Rise" is absent from the title.

3. **Preston Burkett**
   March 12, 2018

   This is just so depressing. The vindictiveness string researchers display in their replies to standard empirical questioning is telling. It seems like they have this grab bag of talking points & fallacious arguments that enable them to evade criticism by making their critics look like ignorant naysayers.

By the way, I don't think there's anything quite as presumptuous as saying that you shouldn't question intelligent people because they're smarter than you. That seems to imply infallibility, or at least that smart people are less fallible, & we know that's just not true (there's even data to support it!). There was at least one smart man who said "I know I'm intelligent because I know I know nothing", which to me implies that people who make opposing statements are flattering their own intelligence (as well as advocating explicit elitism).

I'm sorry if this comes off as a rant. I've always loved science & seeing the opportunity for novel ideas squandered like this makes me sad. I hope a team of creative thinkers can break the mold & bring us new theories before too long.

4. **Anindya**
   March 12, 2018

   Regarding Rees' quote about the multiverse, I think he makes a very sensible point in the previous paragraph:
   IF we have a theory that accurately models what happened in the very very early universe and IF that theory predicts a multiverse, THEN we would have to take the multiverse idea seriously.

   I am always surprised that multiverse proponents never emphasize the obvious fact – that no such accurate theory currently exists !
   Somehow, nobody seems to hold them down to this important point.

5. **Patrick Orlando**
   March 12, 2018

   I just finished reading Nima's slides, very good, he really has a way of getting to the heart of the subject. I only have a B.S. in Physics from Columbia but I learned a lot from his slides. Again Excellent job.

6. **Tim May**
   March 12, 2018

   I've enjoyed Nima Arkani-Hamed's talks for many years now. I especially liked the 5-part Messenger Lectures at Cornell, which I've watched twice now. (And three times for Parts 4 and 5, the more speculative pay-off at the end.)

   I haven't seen much snark nor ad hominem from him. Like Edward Witten, he seems to stay above this.

   I favor that kind of avoidance of trash-talking. I'm skeptical that string theory is a theory of everything, but I think it good that some people like Arkani-Hamed and Witten are working at a high level on this and related ideas. (And pretty clearly Witten has contributed a lot to math, even if the experiments to test string theory have not worked out too well, at least not as of yet….and probably not in any of our lifetimes, as near as I can tell.)

7. **Peter Woit**
   March 12, 2018

   I should make clear that the only one I'm accusing of being snarky here is myself.

8. **katzeee**
   March 13, 2018

   Although one shouldn't take analogies too far, I find it interesting to compare String Theory to the Roman Empire, the single dominating Power in its sphere of influence for a very long time…

9. **Philip**
   March 13, 2018

   Peter, if you had to direct someone to a single, undergrad level, explanation of the weakness of the String Theory concept and the Multiverse what resource would you recommend?

10. **tulpoeid**
    March 13, 2018

    Peter,

    The seemingly increased number of people who try to make it appear as if you are the only person defacing string theory and the like for incomprehensible reasons, only speaks about their anxiety and lack of arguments.

    Or maybe they really leave in their shell, totally blind of the fact that about half of particle physicists (including both flavours) wouldn't give a cent for their toys.

    The problem is of course that devoting our time into defense against fake science will (i) take time from working on the good stuff, (ii) will not buy us any recognition or academic status, (iii) it will most probably do the opposite. So, to an outsider it might appear correct that there are no other opponents, which couldn't be further from the truth. It's just that the rest of us don't manage to gather enough self-sacrificial courage to go through all this on a consistent basis (I'm slightly exaggerating of course, since there are several others on it both in the blogosphere and in their local groups). The problem lies with us though, it's a full-blown battle for the future of physics and by staying out we already pick a side.

11. **Gregor**
    March 13, 2018

    Ress writes "We'd expect far more galaxies located unobservably beyond the horizon." Peter, this is indeed a point that many astrophysicists make. And indeed, it is a misleading or non-scientific statement. Why then is it so widespread?

12. **Chris Oakley**
    March 13, 2018

    You do not need to be a genius to realise that anthropic reasoning is a cop-out. I expect that grant-giving bodies are well aware of the fact and soon this will have a tangible effect. The advantage of Peter continuing the fight rather than, say, me is (i) he has a foot in the academic door and (ii) he writes well. In some of the long online conversations that have involved him I tend to skip the oft-rambling diatribes of his adversaries and read only what he has written himself. Sticking to the point is key.

13. **Peter Woit**
March 13, 2018

Philip,
There's my book, Lee Smolin's, and Jim Baggott's "Farewell to Reality". Also entries on the FAQ page here, and endless blog postings in the "Multiverse Mania" category.

About the multiverse though, perhaps the best advice to anyone is to just pick up any pro-multiverse argument and try and find a well-defined theory and evidence for it (you won't find any). Someone should write a book or article explaining why the multiverse is pseudo-science, but the problem with this is that it would mainly just consist of noting that multiverse advocates have no viable theory or evidence for one.

Relevant here (and also to tulpoeid's comment) is the quote I found here

http://quillette.com/2016/02/15/the-unbearable-asymmetry-of-bullshit/

""The amount of energy necessary to refute bullshit is an order of magnitude bigger than to produce it."

14. **Peter Woit**
March 13, 2018

Gregor,

I don't think it's a non-scientific statement. We have a well-defined, tested model that implies existence of objects we can't observe. It is scientifically reasonable to say that we have indirect evidence for such objects. The problem with the same argument in the multiverse case is that we don't have a sensible model with any evidence for it.

15. **Michael**
March 13, 2018

Dear Peter

Do you conduct research in particle physics/cosmology? If not what areas do you work in? While I have a certain sympathy (though rarely total agreement) for a lot of what you say here, I find it somewhat depressing and uninspiring to constantly read criticisms without any positive contributions offered. As they say, its easy to criticise.

I would love to read about some of your research, in addition to your concerns regarding the direction of post 70s theoretical high energy physics. A nice example is Scott Aaronsons blog, where he strikes a fantastic balance between discussions of technical research issues, and more controversial opinion pieces.

16. **Shantanu**
March 13, 2018

Peter, have you or others asked string theorists " what happened to predictions made pre-LHC era that detection of supersymmetry will vindicate string theory?"
If not, I suggest all of you do this the next time you attend a talk on string theory

17. **Peter Woit**
March 13, 2018

Shantanu,
The answer they will give to this question is clear: low energy SUSY was always a "prediction" in the sense of a possibility, not a sure thing, and, in general, our use of the term "prediction" isn't quite the standard one…

18. **Peter Woit**
March 13, 2018

Michael,
This is off-topic and adding to my time wasting problem by discussing it more here doesn't really help, but a few comments:

Most of my time is spent not on this, but on working these days on a project that I started writing about long ago here:
http://www.math.columbia.edu/~woit/brstdirac.pdf
I hope to have a vastly expanded and improved version of that later this year, and will do some blogging about it then, but it's clear that for something like this, what's needed is a well-written paper, not blog entries. No, I don't do research in cosmology, and don't actually blog about it that much other than to try and help cosmologists from having their field overrun by pseudo-science.

Today though I'm spending much of my time going to talks in this workshop

http://www.math.columbia.edu/department/probability/CFT18/CFT18.html

hope to write more about this in another blog entry.

I'd love to be as productive as Scott Aaronson, but that is never going to happen.

19. **Philip**
March 13, 2018

Thanks very much Peter, apologies for not looking a bit harder re FAQ etc.

20. **Douglas Natelson**
March 13, 2018

Well, Horgan declared that science is done, so he should also be well calibrated about presumptuous statements. Snark aside, it is just sad that someone with Rees' standing would imply that it's somehow wrong or inappropriate for people who aren't leading high energy theorists to be critical.

21. **Dave Miller**
March 13, 2018

Peter,

Section 9.2 of your BRST paper mentions, without comment, possible connections to the Atiyah-Singer Index Theorem. I assume this section will be expanded in the future? Do you have any ideas that will help make the proof of the Index Theorem more transparent?

It has always seemed to me that there must be a more geometrically transparent explanation of why the Index Theorem is true (i.e., without appealing to homotopies of Fredholm operators and all that).

Anyway, if you do have any insights into the Index Theorem, I hope you will write them up (and mention it here in the blog).

Dave

22. **ilovecats**
March 13, 2018

I am confused. During the peer review process, ideas are criticized by anonymous reviewers. If the author is unable to respond to the criticisms, then can the author argue back with the defense that there is no proof that the reviewer(s) (being anonymous) is(are) at least as manifestly brilliant and dedicated (old) as the author?

23. **Marshall Eubanks**
March 13, 2018

The Huns never attacked Rome. The Alaric and the Visigoths sacked Rome in August, 410 AD, and the Vandals sacked Rome in June, 455, but the Huns (in the West) never got South of the Alps.

(Peter Heather's "The Fall of the Roman Empire…" is an excellent source for this complicated period in history.)

24. **Peter Woit**
March 14, 2018

Dave Miller,
That's a problem that has always fascinated me, but I don't have anything really new to say about it. The most insightful proof of the index theorem I know of is the one inspired by Witten and supersymmetric quantum mechanics. There's a sense in which this is a TQFT, with a BRST operator (which is just the Dirac operator), so this story fits well into the story I'm trying to explain in that paper.

25. **Dave Miller**
March 14, 2018

Well, Peter, if you can just go into all the gory details on what you just summarized here (or point to a place where someone else does that), that would help.

I know of course about the Witten supersymmetric proof, but I've never been clear as to how it really works or even if it is really, properly speaking, a proof.

I have gone through the classic embedding, cobordism, and heat kernel proofs, and, while of course I did not find any errors, I was reduced to just seeing if each line followed from the previous lines: i.e., the proofs did not really click for me. I get the impression that there are an awful lot of people in the same situation.

It seems to me there must be some approach to the Index Theorem of the sort all of us physicists take to Stokes' theorem and the divergence theorem: for both of those theorems, we draw the obvious diagrams and point out that the contributions from all the internal lines (for Stokes' theorem) or internal surfaces (for the divergence theorem) are counted twice with opposite signs and therefore cancel. It is then "obvious" that those theorems are true, and a rigorous proof is just doing all of this much more carefully.

Maybe the supersymmetric approach is the equivalent way to approach the Index Theorem, but I have yet to find some place where that is explained at a physicist's level.

Thanks.

Dave

26. **Rollo Burgess**
March 16, 2018

Roger Penrose is just as critical of String Theory etc. He's not dismissed as being presumptuous, presumably because he's a grandee/bigwig. So I guess he's tacitly dismissed as being past it…

27. **DrDave**
March 18, 2018

I think it is a fair point that there is some sort of implied hierarchy about aiming only at PW and LS…I see now that LS is mysteriously redacted (with no changelog that I can see).
"I think it's important that some people should continue to tackle this "Everest problem" – to seek a testable theory from many perspectives.. It's presumptuous (as some people like Peter Woit have done) to deride the way some manifestly brilliant people choose to dedicate their scientific lives. [See Woit's response to this comment.] "
This redaction creates this decidedly weird sentence "some people like Peter Woit…"
It's nice that the link to this blog is inserted, but this doesn't seem to me to be acceptable journalistic practice. Is it a quote? Is the whole thing edited with bits removed to change the meaning?
As far as criticism (let's all stay away from the term "derision" which is singularly inappropriate), few statements are as flatly critical as Glashow's comment in The Elegant Universe series. I watched this again after many years and was struck by the clarity of Sheldon's comments, I wish they had included more–if you haven't seen it the link is here:
https://www.youtube.com/watch?v=ESrHsoV4AAY&feature=youtu.be&t=16m30s

28. **Marion Delgado**
March 18, 2018

When I first read this blog, I was fresh out of physics undergrad and grad math that included math physics. I went to a lot of science presentations then, including some that involved string/brane/M theory and brought friends to them. I also watched many more presentations online. Over the course of time I pretty much started skipping anything that was too string theory-based, and some of the credit for that has to go to Peter Woit and Lee Smolin. I have to add, however, that some of it goes to Michio Kaku and Lubos Motl.

Recent Developments in Constructive Field Theory

March 13, 2018
Categories: Uncategorized

This week there's a mini-workshop here at Columbia organized by the probabilists, on Recent Developments in Constructive Field Theory. I'll be attending some of the talks, will write more here if I can come up with something constructive to say.

Update: One of the talks today was Sourav Chatterjee on Yang-Mills for Probabilists, explaining what Yang-Mills and lattice gauge theory are, along the lines of this preprint. The discussion brought back memories of my grad school days and early research, but I fear didn't give much cause for optimism that there will be much progress anytime soon on a rigorous understanding of 4d Yang-Mills theory.

Update: Today Scott Sheffield gave a talk on *Gauge theory and the three barriers*. He started with the initial motivation of finding a continuum theory of random surfaces giving an alternative representation of gauge theory in 4d (this goes back to Polyakov and others around 1980). There's not much progress on this, but the question has inspired a wealth of results involving in some sense random surfaces. For some details of all of this, one place to look is the website of Sheffield's recent graduate course.

Comments

1. **Bill**
   March 14, 2018

   Peter, what makes you say "I fear [it] didn't give much cause for optimism…"

   Isn't translating and explaining the problems clearly to mathematicians a good thing?

2. **Peter Woit**
   March 14, 2018

   Bill,
   Definitely a good thing. I just meant that, from the discussion amongst experts in the field, things haven't advanced that much since my grad student days and it seems that we're still very far from a solid understanding of basic issues about pure Yang-Mills in 4d.

3. **Abdelmalek Abdesselam**
   March 20, 2018

   Dear Peter,
   Thank you for advertising our little workshop. But, man, that was a bit harsh: "but I fear didn't give much cause for optimism that there will be much progress anytime soon on a rigorous understanding of 4d Yang-Mills theory". If this was a workshop on number theory, it would be like saying "but I fear didn't give much cause for optimism that there will be much progress anytime soon on a rigorous understanding of the Riemann Hypothesis".
   Anyway, I thought the meeting was quite exciting with lots of interesting new results and prospects for more in the near future.

4. **Peter Woit**
   March 20, 2018

   Abdelmalek Abdesselam,
   Sorry if that came across as harsh, your analogy with the Riemann hypothesis is appropriate.

   In the end, what struck me from the talks that I attended was the way the Yang-Mills question has inspired a range of new mathematics, answering other questions although not the Yang-Mills one. Maybe someday this activity will develop new ideas that will ultimately provide the needed new insight into Yang-Mills.

   Also worth pointing out is that to a large extent it seems that physicists have given up on the Yang-Mills problem (even on finding a useful heuristic calculational method, much less something rigorous). That mathematicians are willing to keep studying this and trying to find something new is encouraging.

Stephen Hawking 1942-2018

March 14, 2018
Categories: Obituaries

Front-page on every news source today is the sad report that Stephen Hawking died yesterday at the age of 76. For the best description of his scientific accomplishments, I recommend the obituary in the Guardian written by his sometime collaborator Roger Penrose.

I was going to write a little bit about one time I heard Hawking speak (or rather, his student interpret for us his speech), which was at the IAS back in the early 1980s. I just noticed though that evidently John Baez was at the same talk (he was an undergrad, I was a grad student), and describes it well here.

At the time I remember that many thought that quantum gravity would be understood within a few years, and that Hawking would not be able to live longer than another year or two, given the nature of the disease he was suffering from. It's wonderful that the second of these turned out to be so wrong.

While Hawking was already a star in the physics community back then, his celebrity with the wider public came later. Of all the scientists who over the years have achieved some degree of celebrity, I can't think of another one who so much both deserved and enjoyed the public attention.

Update: There are dozens of articles appearing discussing Hawking's life and work. One you may not have seen which I enjoyed is from Nathan Myhrvold.

Update: Another piece by someone who worked with Hawking, Marika Taylor. It includes some discussion of his views on M-theory.

Update: Hawking has inspired some new theorizing from Niall Ferguson.

Comments

1. **Shantanu**
   March 14, 2018

   Peter, do you know of Hawking's views on string theory, string wars, his impact on particle physics etc and whether he was aware of your book.

2. **Peter Woit**
   March 14, 2018

   Shantanu,

   I have no idea how much, given his condition, Hawking was able to stay informed about topics other than what was relevant to what he was working on (which would have been hard enough). So, no idea how much he knew about string theory and its wars, or particle physics. In later years his name appears as the author or co-author of dozens of books and I've always wondered how much he could have been involved in some of them.

   One I really disliked, The Grand Design, I wrote about here
   http://www.math.columbia.edu/~woit/wordpress/?p=3141
   Much of it was the usual M-theory/multiverse propaganda and Hawking seems to have liked the use of this as a counter-argument to theological arguments from design. I have no idea to what degree Hawking was a well-informed enthusiast for the dubious science described in the book, or whether he might have been enlisted without knowing much about it.

3. **Azadi**
   March 14, 2018

   I was very sad to read about his passing in the news.

   What an inspirational person and a rare intellect to boot.

   He will leave a lasting legacy, I'm sure.

   I must say though, the Guardian newspaper's "editorial" epitaph to him over here in the UK left a somewhat bitter aftertaste in my mouth,

   https://www.theguardian.com/commentisfree/2018/mar/14/the-guardian-view-on-stephen-hawking-the-mind-of-god

   "The death of a brilliant and complex scientist will mean we are all poorer because his mind will no longer roam the multiverses

   From his wheelchair, Hawking's mind roamed the multiverses."

   Roam the multiverses?

   A lifetime of extensive contributions to scientific theory and the media still homes in on "multiverses".

4. **Peter Woit**
   March 14, 2018

   Azadi,
   Unfortunately, as mentioned above, and see for instance here
   https://www.math.columbia.edu/~woit/wordpress/?p=347
   the Guardian's epitaph was appropriate, since Hawking was a multiverse enthusiast, and as much involved in publicity for multiverse mania as anybody.

5. **Dave Miller**
   March 14, 2018

   I attended a talk Hawking gave at Caltech, one of his first presentations in the States on his work on black-hole evaporation, in the early '70s: I've kept the handout of the draft of the paper given out to the audience (I pulled it out recently and found I still do not completely understand it).

   During the '75-76 academic year, I had the chance to meet Hawking when I was taking GR from Kip Thorne; Kip arranged for us students to attend a seminar with a dozen or so participants that Hawking gave: I had enough sense to keep my mouth shut and just listen.

I’m pleased to see that the media coverage I’ve seen so far is trying to avoid the usual “equal to Newton/Einstein” hype and instead focusing on the fact that Hawking was a truly brilliant physicist who showed extraordinary courage in dealing with a horrible disease.

Courage is admirable, and the fact that the public rightly focuses on Hawking’s extraordinary courage says something good about the public.

While it is sad that he is gone, the fact that he survived so long and achieved so much is truly uplifting.

6. **Justin**
March 14, 2018

The official account is that Hawking died after 12:00 am March 14. Your article posted on the 14th reading that he died yesterday. It is interesting that Hawking was born 300 years to the day after the death of Galileo and died on Albert Einstein’s birthday which was also coincidentally Pi day.

7. **Peter Woit**
March 14, 2018

Justin,
I saw the announcement before I went to sleep last night, a bit after midnight New York time, so his death must have happened yesterday (Tuesday) New York time. The Reuters news wire story
https://www.reuters.com/article/us-people-hawking/stephen-hawking-dies-at-the-age-of-76-press-association-idUSKCN1GQ0CX
was at about midnight here, (4 am UK time) and says Tuesday, but perhaps they are using New York time. I guess Hawking died very early in the day on the 14th, and someone got the news out immediately.

8. **"i'd teach you but i'd have to charge"**
March 18, 2018

Hi Peter, did you see this?

“Thomas Hertog, a physics professor who co-authored the paper with Hawking, said the paper aimed “to transform the idea of a multiverse into a testable scientific framework.””

http://www.businessinsider.com/stephen-hawking-paper-from-just-before-he-died-could-find-new-universe-2018-3

9. **G. S.**
March 18, 2018

Peter,

Thank you for posting the link to the Hawking obituary written by Roger Penrose. It was an honest assessment of Hawking, the man, and his contributions to physics and society.

G.S.

10. **Peter Woit**
March 18, 2018

I wrote about Hawking-Hertog here
http://www.math.columbia.edu/~woit/wordpress/?p=347
It is based on the string landscape, has all the problems of that approach (especially, no real theory), and so hasn’t predicted anything and can’t ever predict anything.

11. **Anonyrat**
March 19, 2018

Via a Bee tweet:
https://www.telegraph.co.uk/science/2018/03/18/stephen-hawking-leaves-behind-breathtaking-final-multiverse/?WT.mc_id=tmg_share_tw
Stephen Hawking’s ‘breathtaking’ final multiverse theory completed two weeks before he died

Quote: “Currently being reviewed by a leading scientific journal, the paper, named A Smooth Exit from Eternal Inflation, may turn out to be Hawking’s most important scientific legacy.”

Probably refers to this:
https://arxiv.org/abs/1707.07702

12. **Peter Woit**
March 19, 2018

Anonyrat,

“A final theory explaining how mankind might detect parallel universes was completed by Stephen Hawking shortly before he died, it has emerged.”

It’s really depressing to see that people intent on dishonestly pushing multiverse hype would exploit Hawking’s death to engage in more of this. There’s nothing in that paper that solves the problem of finding a predictive multiverse theory, much less predicting anything based upon it.

13. **Mike Hall**
March 20, 2018

Bee has just blogged about Hawking-Hertog.

Her title ‘Hawking’s “Final Theory” is not groundbreaking’. Much more sensible than the mainstream media reports (as one would expect).

Abel Prize to Langlands

March 20, 2018
Categories: Langlands

The 2018 Abel Prize has been awarded to Robert Langlands, an excellent choice. The so-called “Langlands program” has been a huge influence on modern mathematics, providing deep insight into the structure of number theory while linking together disparate fields of mathematics, as well as quantum field theories and physics.

The Abel Prize site provides a wealth of information about Langlands and his work. Davide Castelvecchi at Nature appropriately describes the Langlands program as a “grand unified theory of mathematics” (Edward Frenkel’s Love and Math popularized this description).

Many blog posts here have discussed the Langlands program and ideas that have developed out of it. For a good example of how wide the impact of these ideas has been, this week the Perimeter Institute will be hosting a conference discussing the latest work on the geometric version of the Langlands program, as well as connections to gauge theory and conformal field theory.

For the original work of Langlands himself, besides the material at the Abel site, the AMS Bulletin has recently published a long article by Julia Mueller. For the original sources and a wealth of other material written by Langlands himself, see the IAS site that collects his writings.

Comments

1. **Peter Shor**
   March 20, 2018

   Wonderful! I assume this breaks the long-standing tradition of rewarding mathematicians for theorems but not for conjectures (which can sometimes be much more important).

2. **Peter Woit**
   March 20, 2018

   Peter Shor,

   Langlands did prove some special cases of his conjectures (e.g. Jacquet-Langlands, Langlands-Tunnell, local Langlands at **R** and **C** for GL(n)), and his work was much, much more than just formulating conjectures, containing all sorts of important detailed results. It is interesting to speculate what the math community would think of someone who only formulated conjectures of this importance, but never proved anything.

3. **(((anon)))**
   March 20, 2018

   The conjectures were built on some serious theorems – classification of irreducible representations of real groups (standing on Harish-Chandra), meromorphic continuation of Eisenstein series, etc etc ….

   But yes, re-contextualising Satake’s isomorphism, that was more influential than either of the above.

   And he deserves the prize for his prose style alone.

4. **Chris Woodward**
   March 20, 2018

   I enjoyed Lafforgue’s geometrically-oriented survey of recent work
   https://arxiv.org/pdf/1803.03791.pdf

5. **Low Math, Meekly Interacting**
   March 21, 2018

   For those of us who need some help, Kevin Hartnett provides a brief but nice bit of exposition in Quanta.

   https://www.quantamagazine.org/robert-langlands-mathematical-visionary-wins-the-abel-prize-20180320/

6. **Davide Castelvecchi**
   March 21, 2018

   I second Peter Shor’s comment! I am old enough to remember a joke that went around math departments in the 1990s that with Bill Thurston you could now get a Fields Medal just for conjecturing something — and that with Edward Witten you didn’t even need your conjecture to be clearly stated. Although that was of course a bit unfair in both cases 🙂

This Week’s Hype

March 20, 2018
Categories: This Week's Hype

Many thanks to Sabine Hossenfelder for her efforts to debunk the attempt to use Hawking’s death as a platform for multiverse hype. See her [posting at Backreaction]() for a good explanation of what is going on here.

To summarize the problem, there are loads of news stories out there telling the public that [Stephen Hawking’s ‘breathtaking’ final multiverse theory completed two weeks before he died](), [Stephen Hawking’s Final Paper Proposes Way to Detect the ‘Multiverse’](), etc., etc. Cosmologist Carlos Frenk and theorist Thomas Hertog seem to be among those encouraging this nonsense.

This is all based on [this recent paper by Hawking and Hertog](), which contains nothing like a way to “detect the ‘Multiverse'”. It’s a toy model of bubble universe formation, one the authors admit they can’t even solve:

> However, the setup we have considered does not allow us to describe the transition from the quantum realm of eternal inflation to a universe in the semiclassical gravity domain. This is because our duals are defined in the UV and live at future infinity. It therefore remains an open question whether the conjectured smoothness of global constant density surfaces impacts the eternity of eternal inflation. To answer this will require a significant extension of holographic cosmology to more realistic cosmologies

Their calculations inspire them to state: “… we conjecture that eternal inflation produces universes that are relatively regular on the largest scales”, but this is just an extremely vague conjecture without much backing it. Using it to get press stories published claiming to have found a way to “detect the ‘Multiverse'” is just absurd, and it’s sad to see Hawking’s passing memorialized with a cloud of ridiculous hype.

Update: Another detailed explanation of what is going on here, from [Ethan Siegel](). His summary:

> There are no observable consequences; there is nothing to measure; there is nothing to test. There’s no prediction about the end of the Universe, and there are no robust conclusions we can draw about its beginning. There are tremendous limitations to the implications of this work, and there are few compelling reasons to believe that their toy model has relevance for our physical Universe. It is a seed of an idea that itself is controversial, based off of an also-controversial foundation, and this is a very small step in its development. Furthermore, all of what they do is based on the Hartle-Hawking no-boundary conjecture, which is still not generally accepted as true. The authors go so far as to admit, in the discussion of this paper, that even within their toy model, they have not shown that there is a non-Multiverse-inducing exit to eternal inflation:
>
> “It therefore remains an open question whether the conjectured smoothness of global constant density surfaces impacts the eternity of eternal inflation.”

Comments

1. **Robert Gauthier**
   March 20, 2018

   Right up there with claims by certain religious groups that Hawking, an avowed atheist, had a death-bed conversion to Christianity.

2. **atreat**
   March 21, 2018

   I think this one should win the theoretical physics equivalent of the Razzie Awards for the years best (most shameless) hype.

3. **Low Math, Meekly Interacting**
   March 21, 2018

   I’ve lost all trust in sound (or text) bites culled from interviews without seeing the full transcript, so I’m not sure what to conclude about Hertog. It’s common to see mountains made of molehills, but can’t remember so much popsci press about literally nothing in quite a while. Powerful is the dead celebrity.

   I would have figured a claim that the multiverse is perhaps less profligate and more prosaic than some models suggest could fuel plenty of Mania without the added layer of fabrication. Apparently that’s not enough for the necrophiles out there.

4. **Anonymous**
   March 21, 2018

   “Right up there with claims by certain religious groups that Hawking, an avowed atheist, had a death-bed conversion to Christianity.”

   I would argue that Hertog’s claims are worse than the death-bed conversion stories. First of all, nobody takes those deathbed conversion stories seriously. They don’t undermine who the person portrayed themselves as being. Hawking’s earlier works used a lot of language that indicated he was open to some kind of deism or pantheism (see A Brief History of Time). Later on, he disavowed himself of any religious belief or agnosticism and claimed that his physics research completely ruled out the possibility of a belief in God. So he was an atheist. He knew he was, we knew he was.

   This paper, however, is crap and it undermines people’s confidence in the scientific enterprise. Nobody really cares if you believe in God. Some physicists do, some physicists don’t, and many simply just don’t care one way or the other. This bizarre, and bogus, multiverse claims subject the scientific discipline to ridicule. It’s worse than bad science fiction, because we are at a crossroads in society where there is a real risk that people will stop believing in science.

5. **Peter Woit**
   March 21, 2018

   LMMI,
   From the press stories, hard to tell what Hertog’s role in this is. But Hossenfelder’s posting has an extensive quote from him (not sure of source, email to her?) which explicitly makes the sort of claims that led to the bogus headlines.

6. **Blake Stacey**
   March 21, 2018

It’s rather weird how a paper whose abstract says “the exit from eternal inflation does not produce an infinite fractal-like multiverse” becomes a *whoooo multiverse!* story. Sure, they’re arguing for a multiverse of their own flavor (“a much more limited set of possible universes”), but from a distance, it looks like a bucket of cold water on the idea that an extravagance of bubble universes is the natural and inevitable conclusion from orthodox cosmology. The headline could just as well have been, “In final paper, Hawking cuts multiverse down to size”.

What is Real?

March 22, 2018
Categories: Book Reviews, Quantum Mechanics

There's a new popular book out this week about the interpretation of quantum mechanics, Adam Becker's *What is Real?: The Unfinished Quest for the Meaning of Quantum Physics*. Ever since my high school days, the topic of quantum mechanics and what it really means has been a source of deep fascination to me, and usually I'm a sucker for any book such as this one. It's well-written and contains some stories I had never encountered before in the wealth of other things I've read over the years.

Unfortunately though, the author has decided to take a point of view on this topic that I think is quite problematic. To get an idea of the problem, here's some of the promotional text for the book (yes, I know that this kind of text sometimes is exaggerated for effect):

> A mishmash of solipsism and poor reasoning, Copenhagen claims that questions about the fundamental nature of reality are meaningless. Albert Einstein and others were skeptical of Copenhagen when it was first developed. But buoyed by political expediency, personal attacks, and the research priorities of the military industrial complex, the Copenhagen interpretation has enjoyed undue acceptance for nearly a century.

The text then goes to describe Bohm, Everett and Bell as the "quantum rebels" trying to fight the good cause against Copenhagen.

Part of the problem with this good vs. evil story is that, as the book itself explains, it's not at all clear what the "Copenhagen interpretation" actually is, other than a generic name for the point of view the generation of theorists such as Bohr, Heisenberg, Pauli, Wigner and von Neumann developed as they struggled to reconcile quantum and classical mechanics. They weren't solipsists with poor reasoning skills, but trying to come to terms with the extremely non-trivial and difficult problem of how the classical physics formalism we use to describe observations emerges out of the more fundamental quantum mechanical formalism. They found a workable set of rules to describe what the theory implied for results of measurements (collapse of the state vector with probabilities given by the Born rule), and these rules are in every textbook. That there is a "measurement problem" is something that most everyone was aware of, with Schrodinger's cat example making it clear. Typically, for the good reason that it's complicated and they have other topics they need to cover, textbooks don't go into this in any depth (other than often telling about the cat).

As usual these days, the alternative to Copenhagen being proposed is a simplistic version of Everett's "Many Worlds": the answer to the measurement problem is that the multiverse did it. The idea that one would also like the measurement apparatus to be described by quantum mechanics is taken to be a radical and daring insight. The Copenhagen papering over of the measurement problem by "collapse occurs, but we don't know how" is replaced by "the wavefunction of the universe splits, but we don't know how". Becker pretty much ignores the problems with this "explanation", other than mentioning that one needs to explain the resulting probability measure.

String theory, inflation and the cosmological multiverse are then brought in as supporting Many Worlds (e.g. that probability measure problem is just like the measure problem of multiverse cosmology). There's the usual straw man argument that those unhappy with the multiverse explanation are just ignorant Popperazzi, unaware of the subtleties of the falsifiability criterion:

> Ultimately, arguments against a multiverse purportedly based on falsifiability are really arguments based on ignorance and taste: some physicists are unaware of the history and philosophy of their own field and find multiverse theories unpalatable. But that does not mean that multiverse theories are unscientific.

For a much better version of the same story and much more serious popular treatment of the measurement problem, I recommend a relatively short book that is now over 20 years old, David Lindley's *Where does the Weirdness Go?*. Lindley's explanation of Copenhagen vs. Many Worlds is short and to the point:

> The problem with Copenhagen is that it leaves measurement unexplained; how does a measurement select one outcome from many? Everett's proposal keeps all outcomes alive, but this simply substitutes one problem for another: how does a measurement split apart parallel outcomes that were previously in intimate contact? In neither case is the physical mechanism of measurement accounted for; both employ sleight of hand at the crucial moment.

Lindley ends with a discussion of the importance of the notion of decoherence (pioneered by Dieter Zeh) for understanding how classical behavior emerges from quantum mechanics. For a more recent serious take on the issues involved, I'd recommend reading something by Wojciech Zurek, for instance this article, a version of which was published in Physics Today. Trying to figure out what "interpretation" Zurek subscribes to, I notice that he refers to an "existential interpretation" in some of his papers. I don't really know what that means. Unlike most discussions of "interpretations", Zurek seems to be getting at the real physical issues involved, so I think I'll adopt his (whatever it means) as my chosen "interpretation".

Update: For another take on much the same subject, out in the UK now is Philip Ball's *Beyond Weird*. The US version will be out in the fall, and I think I'll wait until then to take a look. In the meantime, Natalie Wolchover has a review at Nature.

Update: There's a new review of What is Real? at Nature.

Update: Jim Holt points out that David Albert has a review of the Becker book in the latest New York Review of Books. I just read a print copy last night, presumably it should appear online soon here .

Update: Some comments from Adam Becker, the author of the book.

> I won't try to rebut everything Peter has said about my book—there are some things we simply disagree about—but I would like to clear up two statements he makes about the book that are possibly misleading:
>
> Peter says that I claim the answer to the measurement problem is that "the multiverse did it." But I don't advocate for the many-worlds interpretation in my book. I merely lay it out as one of the reasonable available options for interpreting quantum mechanics (and I discuss some of its flaws as well). I do spend a fair bit of time talking about it, but that's largely because my book takes a historical approach to the subject, and many-worlds has played a particularly important role in the history of quantum foundations. But there are other interpretations that have played similarly important roles, such as pilot-wave theory, and I spend a lot of time talking about those interpretations too. I am not a partisan of any particular interpretation of quantum mechanics.
>
> Second, I don't think it's quite fair to say that I paint Bohr as a villain. I mention several times in my book that Bohr was rather unclear in his writing, and that sussing out his true views is dicey. But what matters more that Bohr's actual views is what later generations of physicists generally took his views to be, and the way Bohr's work was uncritically invoked as a response to reasonable questions about the foundations of quantum mechanics. It's true that this subtlety is lost in the jacket flap copy, but that's publishing for you.
>
> Also, for what it's worth, I do like talking about reality as it relates to quantum mechanics. But I suppose that's hardly surprising, given that I just wrote a book on quantum foundations titled "What Is Real?". I'd be happy to discuss all of this further over email if anyone is interested (though I'm pretty busy at the moment and it might take me some time to respond).

Comments

1. **Carl Zetie**
March 22, 2018

My 13 year old son has been reading some of the introductory texts on QM and his reaction on discovering Everett was to ask me, "So Everett's Many Worlds has the same problem as the Copenhagen interpretation, plus an enormous number of additional universes that are not detectable. How is that better?".

Good kid, but I'm going to need to find him a math tutor soon because he is overtaking my undergrad education.

2. **Jim Baggott**
March 23, 2018

Give me a little more time. I hope to be able to set the record straight in a book to be published probably in 2020. You can read the preamble here: http://www.jimbaggott.com/articles/a-game-of-theories/

3. **Mateus Araújo**
March 23, 2018

Dear Prof. Woit,

I don't understand what you mean by "the wavefunction of the universe splits, but we don't know how". We know exactly how; this is the whole point of Many-Worlds: it is just normal Hamiltonian evolution. What do you think is lacking?

4. **Ben Jones**
March 23, 2018

It's fine to say that 'in either interpretation, we don't know what happens at the moment of measurement'. But I disagree that this leaves MW and Copenhagen on an equal footing. Doesn't Copenhagen posit an additional _mechanism_, that of 'collapse', whereas Everett's view wouldn't?
And are there not additional problems with Copenhagen, such as the 'selection' of a single branch is the only non-deterministic element of the whole system?
@Carl the non-detectability of the 'other universes' follows naturally from how we understand QM to work, it doesn't count as a piece of evidence against it if we wouldn't _expect_ to be able to detect them. An unreasonable swish of Occam's Razor.

5. **David Brown**
March 23, 2018

"Popperazzi" (play on Italian "paparazzi") is the preferred spelling.
https://www.philosophersmag.com/index.php/footnotes-to-plato/77-string-theory-vs-the-popperazzi "String Theory vs the Popperazzi" by Massimo Pigliucci, 2015

6. **Peter Woit**
March 23, 2018

David Brown,
Thanks. Fixed.

Mateus Araujo,
Just saying "the Schrodinger equation does it" doesn't solve the measurement problem (for instance, the preferred basis problem). All you're doing is saying that, you don't know how, but the Schrodinger equation is going to somehow give precisely the same implications for physics as the collapse postulate.

Ben Jones,
Copenhagen says collapse happens in a measurement, it's silent on what the theory of collapse is (adding specific new physics to explain collapse is not Copenhagen but something else).

7. **hdz**
March 23, 2018

Peter, I do not intend to enter the details of your discussion, since I have got tired about it. (If somebody should be interested, he/she may look at my website http://www.zeh-hd.de – especially the first two papers under "Quantum Theory".) However, as a historical remark let me point out that in my understanding, von Neumann and Wigner were never part of the Copenhagen interpretation – rather they objected to it more to less openly (starting in Como). When Wigner used the term "orthodox interpretation", he exclusively meant von Neumann's book (including the collapse as a physical process – not just a "normal" increase of information), and I am told that he complained that, as a consequence, he was never invited to Copenhagen. Bohr always disagreed with any attempt to analyze the measurement problem in physical terms.
Essentially, I agree with Mateus Aroujo and and Ben Jones
Regards, Dieter

8. **Jim Baggott**
March 23, 2018

This kind of discussion can get hopelessly confused very quickly. To my knowledge, the 'collapse of the wavefunction' was never part of the Copenhagen interpretation, which is based on some kind of unexplained 'separation' between the quantum and classical realms, or what John Bell would refer to as the 'shifty split'. I believe the notion of a 'collapse' was introduced as a 'projection postulate' by von Neumann in his book Mathematical Foundations of Quantum Mechanics, first published in German in 1932 (in my English translation the projection postulate – a statistical, discontinuous process in contrast to the continuous, unitary evolution of the wavefunction – appears on p. 357). Influenced, I believe, by Leo Szilard, von Neumann speculates that the collapse might be triggered by the intervention of a (human) consciousness – what he refers to on p. 421 as the observer's 'abstract ego'.

All this really shouldn't detract from the main point. The formalism is the formalism and we know it works (and we know furthermore that it doesn't accommodate local or crypto non-local hidden variables). The formalism is, for now, empirically unassailable. All *interpretations* of the formalism are then exercises in metaphysics, based on different preconceptions of how we think reality could or should be, such as deterministic ('God does not play dice'). Of course, the aim of such speculations is to open up the possibility that we might learn something new, and I believe extensions which seek to make the 'collapse' physical, through spacetime curvature and/or decoherence, are well motivated.

But until such time as one interpretation or extension can be demonstrated to be better than the other through empirical evidence, the debate (in my opinion) is a philosophical one. I'm just disappointed (and rather frustrated) by the apparent rise of a new breed of Many Worlds Taliban who claim – quite without any scientific justification – that the MWI is the only way and the one true faith.

9. **Mateus Araújo**

March 23, 2018

Peter Woit,

There are dozens of papers explaining how you can model the measurement process in unitary quantum mechanics via entanglement and decoherence; Zeh's and Żurek's, among them. It's not as if anybody is saying "the Schrödinger equation did it" without explaining how.

And the measurement problem is usually defined as the incompatibility between collapse and unitary evolution. So even just saying "the Schrödinger equation did it" does solve the problem, on this level. Of course, one must also explain emergence of classicality, permanence of records, probability, etc., but this is not the measurement problem.

10. **Peter Woit**
March 23, 2018

hdz,

Thanks Dieter.

I should point out that Dieter Zeh is one of the major subjects of the book. He's perhaps the best example of the story Becker wants to fit everything into: a "quantum rebel" who made significant advances in our understanding of foundations and the measurement problem, advances which were not initially recognized due to an entrenched "Copenhagen" ideology that denigrated any such work. Partly due to his work, I think for many decades now mindless Copenhagen ideology has not been such a problem (but we're well on our way to mindless Many Worlds ideology being a major problem).

As he notes and the book describes, there's controversy over who was on the Copenhagen bus, partly because it was never clear exactly what the Copenhagen Interpretation was, and partly because many people took somewhat different points of view at different times.

11. **Peter Woit**
March 23, 2018

Mateus Araújo,
To me the (non-trivial) measurement problem is exactly the "emergence of classicality, permanence of records, probability, etc.," problems you list, with entanglement and decoherence some of the insights needed to solve them. If you define the measurement problem as you do, then the solution you give by having quantum mechanics apply to the macroscopic world is a trivial one which most everyone expected anyway.

12. **Mateus Araújo**
March 23, 2018

Peter Woit,

I'm claiming that this is not "my" definition of the measurement problem, but rather *the* standard definition. See for example Maudlin's "Three measurement problems", a canonical reference on the subject.

Of course, the solution *is* trivial; you merely need to give up collapse, or introduce hidden variables, or introduce physical collapse. The problem is that most people don't want to do any of these, hence they are stuck with the measurement problem.

Look, I agree wholeheartedly with you that the interesting problems are those I listed; I'm just insisting on narrow definitions and standard terminology, otherwise it becomes impossible to talk to each other.

13. **Peter Woit**
March 23, 2018

Mateus Araújo,

This whole subject is full of endless and heated arguments over problems that are meaningless and/or lacking in substance. Your definition of "the measurement problem" seems to me to insist on sticking to the substance-free aspect of a substantive problem, thus encouraging substance-free-discussion. What's the correct term to refer to the substantive problem?

By the way, on the meaningless side, Becker's book has a lot about "What is Real?" and claims that the problem with Copenhagen is that it denies the reality of the microscopic world, a discussion I thought it best to just ignore.

14. **Mateus Araújo**
March 23, 2018

Peter Woit,

Indeed it is! And I think a great many heated and meaningless arguments happen because the parties are talking about different things =)

But I don't know which problem you refer to as "the substantive problem". Do you have in mind a collective name for the three I listed? I don't think there exists a standard name for this set, except maybe as "problems of the Many-Worlds interpretation". They are different problems, that are usually studied separately, and referred to by their individual names.

15. **Peter Woit**
March 23, 2018

Mateus Araújo,
I guess I always thought "what happens to the cat?" was the substantive measurement problem, so I'm looking for a name for that.

16. **Blake Stacey**
March 23, 2018

Asher Peres once wrote that there are at least as many Copenhagen Interpretations as people who use the term, probably more. Among other problems, saying "*the* Copenhagen Interpretation" glosses over substantial differences between Heisenberg and Bohr.

> The idea that one would also like the measurement apparatus to be described by quantum mechanics is taken to be a radical and daring insight.

Despite this issue being discussed by Pauli, von Neumann, ….

17. **Mateus Araújo**
March 23, 2018

    Peter Woit,

    You want unitarity to hold, so that atoms are described by quantum mechanics, and you want collapse to happen, so that the cat is definitely dead, but you can't have both: the measurement problem!

    And the solution is again trivial, threefold. Give up on collapse: there are worlds with live cats and worlds with dead cats. Introduce hidden variables: the cat was always dead, you just didn't know it. Introduce physical collapse: the superposition collapsed on the level of the geiger counter, so that the cat was always dead.

    Maybe the measurement problem is like the problem of having your cake and eating it too. You know it's impossible, but you really really want to!

18. **Jim Baggott**
March 23, 2018

    I think we can agree that this is all a lot of fun. I've been studying these problems for more than 25 years, and I can discern relatively little progress in this time. But I've come to believe that it is helpful to distinguish between 'reality' (however you want to think about it) and the reality or otherwise of the *representation* we use to describe it.

    We can likely all agree that the moon is there when nobody looks, and even that invisible entities like electrons really do exist independently of observation ('if you can spray them then they are real', as philosopher Ian Hacking once declared). But this doesn't necessarily mean that the concepts we use in our representation of this reality should be taken literally as real, physical things. If we choose to agree that the wavefunction isn't real (as Carlo Rovelli argues in his relational interpretation), then the QM formalism is simply an algorithm for coding what we know about a physical system so that can make successful predictions. All the mystery then goes away – there is no problem of non-locality, no collapse of the wavefunction, and no 'spooky' action at a distance.

    I don't particularly like this interpretation, as it is obviously instrumentalist and can't answer our burning questions about how nature actually does that. But it does help to convince me that this endless debate over interpretation is really a philosophical debate, driven by everybody's very different views on what 'reality' ought to be like. And, as such, we're unlikely to see a resolution anytime soon…

19. **Peter Woit**
March 23, 2018

    Jim,
    I'd rather do almost anything with my time than try and moderate a discussion of what is "real" and what isn't.

    Any further discussion of ontology will be ruthlessly suppressed.

20. **Per Östborn**
March 23, 2018

    Trying to stick to physical issues, I have always wanted to see proponents of the many worlds interpretation derive the spectrum of the hydrogen atom from some clearly defined postulates (or solve some other basic physical problem). Until then it is not clear to me what the theory actually is saying. If anyone can refer to such a calculation I would be glad. Clearly it is not enough to postulate the unitary evolution of the Schrödinger equation, but I have never been able to pinpoint the other postulates of the many worlds interpretation.

21. **George Herold**
March 23, 2018

    Thanks for the nice post and discussion. I'm an experimentalist, who is more comfortable with opamps than operators. I have perhaps a naive question; Do any of these books discuss the DeBroglie-Bohm (Pilot wave) theory? Since all these interpretations are just a matter of taste, I find this hidden variable type theory easiest to swallow. In a double slit, the particle 'knows' about both slits, but still goes through (only) one of them. Is there any reason not to be happy with this picture?

22. **Peter Woit**
March 23, 2018

    Per Östborn,
    The calculation in Many Worlds is exactly the same textbook calculation as in Copenhagen. It's the same Schrodinger equation and you solve for its energy eigenvalues the same way. That is the problem: there's no difference from the standard QM textbook.

    The Many Worlds people might claim as an advantage over Copenhagen that you can imagine doing much harder calculations about how a Hydrogen atom interacts with its environment during a measurement process, giving insight into the question of why we see energy eigenstates and the Born rule. My point of view would be that Copenhagen never said you shouldn't do exactly those calculations if you wanted to better understand what was happening during a measurement, it was just a rule for when you couldn't do such calculations.

23. **Peter Woit**
March 23, 2018

    George Herold,

    Becker's book has a long and detailed section about the story of Bohm and Bohmian mechanics which you might find of interest. Personally I don't find Bohmian mechanics compelling, both for reasons Becker mentions and for others having to with the much greater mathematical simplicity of the conventional formalism when applied to our best fundamental theories.

    Sorry, but I really don't want to carry on more discussion here of Bohmian mechanics. I realize a lot of people are interested in it, but I'm not at all interested, so such a discussion should be conducted elsewhere.

24. **Lee Smolin**
March 23, 2018

    Dear Peter and all,

Can I suggest a basic distinction between different approaches to quantum foundations?

The first class hypothesizes that the standard quantum mechanics is incomplete as a physical theory, because it fails to give a complete description of individual phenomena. If so, the theory requires a completion, that is a theory which incorporates additional degrees of freedom, and/or additional dynamics. Pilot wave theory and physical collapse models are examples of these.

The second class of approaches take it as given that the theory is complete, so the foundational puzzles are to be addressed by modifying how we interpret the equations of the theory.

People engaged in the first class of approaches are trying to solve a very different kind of research problem than those in the second class. I would submit that both are worth pursuing, but that progress in physics will eventually depend on the success of the first kind of approach.

25. **Peter Woit**
March 23, 2018

Thanks Lee,
That's a very useful distinction. The Becker book contains a lot of material about such attempts to complete quantum mechanics with new physics that would entail a different resolution of the measurement problem. I didn't discuss these here, largely because I'm much less optimistic than you that the search for this kind of completion will be fruitful.

26. **Per Östborn**
March 23, 2018

Dear Peter,
It is not clear to me, but my impression is that MWI proponents claim that some of the standard postulates of QM can be removed (or replaced by other ones). Then their calculations from first principles must be different from the textbook ones, since they are forbidden to use the removed postulates, of course.

As you write, they seem to want to gain insight into why we see energy eigenvalues and why we should use the Born rule. This suggests that they argue that these features of QM can be derived from a smaller or different set of postulates than the standard one.

27. **Peter Woit**
March 23, 2018

Per Östborn,

I'm no expert and don't want to get into the details of exactly what "Many Worlds" is, I think there are many versions. One aspect of it though is yes, the idea that you can derive the relation to classical observables and the Born rule, not postulate them. There's active research and debate on the extent to which you really can do this. I just want to point out that you naturally ask exactly the same questions in Copenhagen, whenever you decide you want to analyze in more detail what's happening during a measurement. It's exactly the same equation and physics.

28. **Edward**
March 23, 2018

I think the most interesting Copenhagen/anti-Copenhagen split was between Heisenberg, Bohr, and others on the one hand and Einstein, Schrodinger, and to some extent de Broglie on the other. There was a generational split and Heisenberg's views may have prevailed because the older physicists died off.

29. **Narad**
March 23, 2018

> Any further discussion of ontology will be ruthlessly suppressed.

I think I'm going to have to have that printed on a T-shirt.

30. **Chris W.**
March 23, 2018

I think it would be fair to say that the acceptance of the Copenhagen interpretation, or what various people took it to be, was substantially a function of the high regard in which Bohr and Heisenberg were held as pioneers in the development of quantum mechanics, combined with a strong desire to just "get on with it"—find a way to state problems and do calculations that most people felt they understood well enough to do research and make sensible progress.

Later, when a great deal of research had been done and generally accepted progress had been made, it's understandable that the "yes, but…" questions about quantum theory would be resurgent, especially with the conundrums of quantum gravity looming in the background, along with the growing exploration of quantum phenomena at mesoscopic scales.

To my mind the current situation is reminiscent in some ways of Mach's objections to the conventional understanding of Newtonian dynamics at a time (the mid- to late 19th century) when such concerns had little apparent significance for most working scientists. All this appeared in a different light with the advent of special and general relativity.

31. **Mateus Araújo**
March 24, 2018

Peter Woit,

I think this is pretty much correct; one can also simply postulate the Born rule in Many-Worlds, as done in single-world theories, but it feels a bit wrong, as one should also explain what probabilities are. Hence the interest in deriving the Born rule in Many-Worlds, as this should shed some light on the issue. One can, though, adapt these derivations also to single-world quantum mechanics, as done by Saunders here.

I don't think, however, that the derivations we have are completely satisfactory, and I'm personally trying to improve on them.

32. **Peter Shor**
March 24, 2018

David Mermin, who didn't particularly like the Copenhagen interpretation, found himself driven to use it when he was teaching quantum mechanics to computer scientists who didn't know much about physics. (See his article *Copenhagen Computation*.)

Bohr, at Copenhagen, similarly was teaching quantum mechanics to physicists who didn't know much about quantum mechanics. So maybe this explained why he gravitated towards the Copenhagen interpretation.

And then maybe Bohr came up with all this weird extraneous philosophy to try to convince himself that what he was teaching them actually made some sense.

33. **Paddy**
March 24, 2018

Jim Baggott (or anyone else for that matter):

You attribute "collapse" or reduction of the wavepacket to von Neumann (1932). A clear statement (albiet much shorter) is in Dirac's Principles, Sect 10. Unfortunately our University Library foolishly left the first edition (1930) on the open shelves, and it has long since vanished, so I've only traced this statement back to the 2nd ed… My question to anyone who can lay hands on a copy is, is this bit in the original edition, or did Dirac add it after reading von Neumann?

As I probably learned from one of Jim's books, the "reduction" of the wavepacket
is Heisenberg's terminology, from the uncertainty principle paper, so von Neumann or Dirac were in any case just sharpening up Heisenberg's insight.

34. **Tim Maudlin**
March 24, 2018

It is a bit hard to know how to comment on a discussion of a book called "What is Real?" when it has been asserted that

"I'd rather do almost anything with my time than try and moderate a discussion of what is "real" and what isn't.

Any further discussion of ontology will be ruthlessly suppressed."

The question "What is real?" just is the question "What exists?" which is in turn just the question "What is the true physical ontology?" which is identical to the question "Which physical theory is true?". Peter Woit begins by writing "Ever since my high school days, the topic of quantum mechanics and what it really means has been a source of deep fascination to me…". But that just is the question: What might the empirical success of the quantum formalism imply about what is real? or What exists? or What is the ontology of the world? To say you are interested in understanding the implications of quantum mechanics for physical reality but then ruthlessly suppress discussions of ontology is either to be flatly self-contradictory or to misunderstand the meaning of "ontology" or of "real". That is also reflected in the quite explicit rejection of any discussion of two of the three possible solutions to the Measurement Problem: pilot wave theories and objective collapse theories.

Has Foundations made real progress since Copenhagen? Absolutely! We have two key theorems: Bell's theorem and the PBR theorem. The first tells us that non-locality is here to stay, so Einstein's main complaint about the "standard" account—namely its spooky action-at-a-distance—cannot be avoided. Anyone who thinks that they have a way around it is mistaken. That lesson has not yet been learned, even though Bell's result is half a century old. PBR proves that the wavefunction assigned to a system reflects some real physical aspect of the individual system: two systems assigned different wavefunctions are physically different. So if Carlo Rovelli or the QBists or Rob Spekkens thinks that the wavefunction isn't real, in the sense that it does not reflect some real physical feature of an individual system, then PBR has proven them wrong. Bell and PBR lay waste to many approaches to understanding quantum theory, including Copenhagen and QBism. Jim Baggot suggests that we can "choose to agree" that the wavefunction isn't real and somehow thereby eliminate non-locality and spooky action at a distance. No you can't, for reasons given by both Bell and PBR. A theorem is a theorem, and we are not free to ignore it.

The choices are: additional (non-hidden!) variables (e.g. Bohm); objective collapses (e.g. GRW); Many Worlds (e.g. Everett). That's it. Anything else has been ruled out by the empirical success of the quantum predictions. And this is no more a "philosophical" debate than any other dispute in physics is. It is a debate about what the correct physical understanding of the world is. Only once these real advances in our understanding have been generally acknowledged will we be in a position to make further progress.

35. **Peter Woit**
March 24, 2018

Tim Maudlin,

Your comment has some similarities to Lee Smolin's, wanting to focus on the "real" question of whether QM is all there is (his "second class", your "Everett" choice) or new physics is needed (his "first class", your Bohm or GRW). While there's a lot in Becker's book about the history of "new physics" proposals, and you and Smolin are quite right that this is a true fundamental question, more significant than empty discussions of "interpretations" corresponding to identical physics, the problem here is that I'm just not interested. As with any proposals for "new physics", people make their own evaluations based on different experiences, and it's a good thing that others who see things differently think more about such proposals.

This is a case where no such new physics proposals come with any experimental evidence in their favor, so personal criteria of what is worth spending time on are all one has. My own criteria for paying attention to speculative proposals weight heavily the mathematical structures involved. The proposals I've seen for supplementing QM invoke mathematical structures that to me seem quite a bit more complicated and ugly than the ones of QM, thus my lack of interest. Maybe someday someone will come up with a different proposal that's more appealing. Til then, I'll keep deciding not to spend more time thinking about such things.

36. **hdz**
March 24, 2018

I do not always agree with Tim Maudlin, but in this case I do almost completely. Clearly, the philosophical debate about reality is worthless for physicists, but physicists usually (and tacitly) understand it in the sense of a conceptually consistent description of "Nature" (of what we observe with our senses). So it is certainly not compatible with complementarity. Of course, everybody is free to propose new concepts and theories, but I have decided to wait until such author presents some empirical success (what else can I do?). Mathematical structures have to be formally consistent, Peter, but that is no sufficient argument for their application to the empirical world. (Just consider Tegmark's unreasonable Level IV of multiverses.) This is not only an argument against Sting Theory! (I have written a comment against Strings (or M-theory) in German long before "Not even wrong" appeared; it can be found on my website under "Deutsche Texte".)

So my conclusion from Tim's three choices are that the first two ones are well possible (though not more), but we have to wait for empirical support. Then only Everett remains (until being falsified) as yet as a global unitary theory. Let me add that the concept of decoherence, which has clearly been experimentally confirmed, was derived from an extension of unitarity to the environment, while Everett is its further extension to the observer. So why is it "unmotivated" or incomplete? In my opinion there are no arguments but only emotions against Everett! So please take some time to study my website!

March 24, 2018

Thanks Peter for pointing that the MWI is basically an inversion of the standard one, an evidence rarely mentioned. So the 'real' problem remains untouched: what are probabilities? Actually, surprisingly few physicists seem to be aware of the existence of Bertand's pardox, something which has disturbing implications. The stance 'it doesn't matter what probabilities are as long as we know how to calculate them' or saying 'there is an axiomatic for them' are just ways to avoid the question. Does something physical collapse or is it our ignorance that ends in a measurement? It is rather obvious that a meaningful distinction between a description and its referent (to avoid saying 'reality') can become badly twisted when it is not clear what is not known.

Peter Shor,

You wrote:

> David Mermin, who didn't particularly like the Copenhagen interpretation, found himself driven to use it when he was teaching quantum mechanics to computer scientists who didn't know much about physics.

Does *anyone* ever teach Intro QM without implicitly using the Copenhagen interpretation?

Or, to put it the other way around, does anyone teach Intro QM using MWI or the Bohm model?

To connect with your own work, it does seem to me that MWI is the "natural" way to think about quantum computing. Not that I think MWI is true: I think it has two fatal flaws — the "preferred basis" problem that Peter Woit has mentioned and the probability-measure problem.

Do you yourself see any affinity between MWI and quantum computing?

Dave Miller

March 25, 2018

To me, the more interesting question is not about whether theory is complete, but… what experiment will displace or extend QFT as the underpinning of all microscopic theory? David Mermin sometimes pointed out that the fact we still use QFT with no new constants of nature was a failing of experimental high energy physics. I tend to agree with him, but still… increasing energy is still an enormously attractive route to finding real chinks in QFT. Also, delayed choice types of measurements are attractive. Unattractive to me… characterizing experiment as a servant of whatever trend is popular in the theory community… strings, multiverses, etc.

42. **Jim Baggott**
March 26, 2018

Paddy,
It's certainly true that the idea that a quantum system 'jumps' into some eigenstate as the result of an observation or measurement is implicit in the early history of quantum mechanics, arguably as far back as Bohr's 1913 atomic theory. Despite statements by Heisenberg and Dirac implying such 'jumps' as part of the measurement process, the reason we know this as 'von Neumann's theory of measurement' is because he was the first to put it forward as an axiom of the theory, the collapse or projection being a statistical 'process of the first kind' vs. the unitary evolution of the wavefunction as a causal 'process of the second kind'. I tend to trust Max Jammer on this – see his 'Philosophy of Quantum Mechanics', p. 474. Incidentally, von Neumann treated the apparatus as a quantum system, so departed from the Copenhagen interpretation's 'shifty split' between quantum/classical domains.

Peter,
I sense the discussion of your review of Adam Becker's book is now pretty well exhausted, but if you will allow I'd like to make a couple of final observations. I fully understand why you like to keep the discussion focused on what you consider to be meaningful questions – as posed here by Lee Smolin and to an extent by Tim Maudlin. I don't want to make this seem too black-and-white but, generally, if you don't think the wavefunction is 'real' then you're likely to be satisfied that quantum mechanics is complete (Copenhagen, Rovelli, consistent histories, QBism). But if you prefer to think that the wavefunction is physically real (Einstein, Schrodinger, Bell, Leggett) then obviously something is missing – quantum mechanics is incomplete and the task is to find ways to reinterpret or extend the theory to explain away the mystery, and hopefully deepen our understanding of nature at the same time. Although the MWI in principle adds nothing to the QM formalism, I'd argue that it 'completes' QM by adding an infinite or near-infinite number of parallel universes. But all this comes back to a judgement about the ontological status of the wavefunction and hence a choice of philosophical position.

I don't think any kind of 'new mathematics' will help to resolve these questions. In fact, my studies of the historical development of QM suggest instead a triumph of physical intuition over mathematical rigour and consistency, which is why von Neumann felt the need to step in and fix things in 1932. My money is therefore on new physics, as and when this might become available, perhaps as part of the search for evidence to support a quantum theory of gravity.

Can I leave you with a last thought? In the famous experiments of Alain Aspect and his colleagues in the early 80s, they prepared an entangled two-photon state using cascade emission from excited Ca atoms. We write this as a linear superposition of left and right circularly polarised photons, based on our experience with this kind of system. The apparatus then measures correlations between horizontally and vertically polarised photon pairs, detected within a short time window. So we *re-write the wavefunction in terms of the measurement eigenstates*, and we use the modulus-squares of the projection amplitudes to tell us what to expect. Now I can't look at this procedure without getting a very bad feeling that all we're really doing here is mathematically *coding* our knowledge in a way that gives us correct predictions (which we then confirm through experience). I really don't like it, but I confess I'm very worried.

43. **Peter Woit**
March 26, 2018

Jim,
My semi-joking threat to suppress ontology is due to the fact that I seriously don't know what you or others mean when they say something is/is not "real", or "physically real". I have the same problem with Lee Smolin when he writes about time being "real/not real". Hanging one's treatment of a complex issue on this highly ambiguous four-letter word seems to me to just obscure issues (I started to write "real issues"…).

About MWI, I'm on board with the "everything evolves according to Schrodinger's eq." part, not so much with the "add an infinite number of parallel universes" part.

While I think new deep mathematical ideas may inspire progress on unification, in the case of the measurement problem, the argument from mathematical depth and beauty goes the other way. The basic QM formalism already is based on very deep and powerful mathematics. Here my problem is with things like Bohmian mechanics and dynamical collapse models which deface this beauty by adding ugly complexity not forced by experiment. The measurement problem to me is essentially the problem of understanding how the effective classical theory emerges from the fundamental quantum formalism. Mathematics may or may not be helpful here, I don't know. The confusions I see in most discussions of QM interpretations aren't ones that mathematics will resolve, they need to be resolved by careful examination of the physics one is discussing.

Some people seem to expect that the new physics needed to get quantum gravity will resolve the measurement problem, but I don't see it. The measurement problem is there when you do a very low energy experiment, whereas the quantum gravity problem is about not understanding Planck-scale physics. I just don't see how the quantization of gravitational degrees of freedom has anything at all to do with the measurement problem.

About the photon experiments. I don't think the mysterious thing is the "re-write the wavefunction in terms of the measurement eigenstates" part, that is very simple and completely understood. The mystery is the "The apparatus then measures correlations between horizontally and vertically polarised photon pairs" part, where a macroscopic apparatus described in classical terms is coming into play.

44. **Lee Smolin**
March 26, 2018

Dear Peter,

I agree the statement "Time is real" is misleading and I regret using it. The more precise claim is that "time is fundamental" in the sense that there is no deeper formulation of the laws of physics that does not involve the evolution of the present state or configuration, by the continual creation of novel events out of present events. ie at no level is time emergent from a timeless formulation of fundamental physics. Were the Wheeler-deWitt equation correct this would not be the case.

I view my papers on the real ensemble formulation and relational hidden variables to be modest attempts to develop and explore new hypotheses to complete quantum mechanics.

To answer Peter, these are inspired by developments in quantum gravity, particularly the hypotheses that if time is not emergent, space may be emergent from a network of dynamically evolving relationships, as it is in several approaches to quantum gravity such as spin foam models, causal dynamical triangulations and causal set models.

But if space is emergent, so is locality and hence so must be non-locality. Hence we may aim to show the origin of Bell-non-locality from disorderings of locality which follows from the emergent nature of locality.

This may be a way to realize the idea, which is currently popular, but was first stated by Penrose in his papers on spin networks, that the geometry of space and quantum entanglement may have a common origin.

45. **Jim Baggott**
March 26, 2018

Peter,
I honestly think you've answered your own question. You say "I don't think the mysterious thing is the re-write the wavefunction in terms of the measurement eigenstates part – that is very simple and completely understood". So what is it that exists? A quantum state made of circularly polarised states? A quantum state made of linearly polarised states? Or both, but involving a process that gets from one to the other that doesn't appear anywhere in the formalism except as a postulate, based on a mechanism we can't fathom? Or are we just using these 'states' as a convenient way of connecting one physical situation with another?

46. **Blake Stacey**
March 26, 2018

I noticed an item in the latest quant-ph update that may be of interest to the folks participating here: [a critical evaluation of Wallace's attempt to get meaningful probabilities out of (neo-)Everettian QM](#).

47. **Peter Woit**
March 26, 2018

Jim,
The question "what exists?" is just as ill-defined as "what is real?". The fundamental issue here is that I think I understand completely what a "quantum state" is (any one of the mathematically isomorphic descriptions), but I don't understand completely what a "physical situation" is (it may involve some system under study, some macroscopic apparatus, my consciousness, and how they are interacting). Everett tells me that a "physical situation" is also just a quantum state, and I'm willing to believe him since I don't have evidence against this, but that doesn't change my lack of full understanding of the "physical situation" I'm somehow part of.

48. **Reader**
March 26, 2018

Another interesting article on the history of MWI by the same author here:
https://blogs.scientificamerican.com/observations/the-difficult-birth-of-the-many-worlds-interpretation-of-quantum-mechanics/

49. **Doug McDonld**
March 26, 2018

You write 'The mystery is the "The apparatus then measures correlations between horizontally and vertically polarised photon pairs" part, where a macroscopic apparatus described in classical terms is coming into play.'

I fully agree with you in this. The problem is, explaining "how" this happens. I don't mean in a philosophical sense, I mean describing it using, somehow, just plain quantum mechanics of increasingly complicated sets of interactions that end up in a macroscopic apparatus that everybody agrees is classical. This is doable. Its where the payoff is eventually going to come. The hard part is explaining it.

By increasingly complicated, I mean in terms of say measuring the energy of

a high energy photon slamming into an LHC calorimeter in terms of a cascade
of events. Each even is small in quantum energy terms, collectively they add up to the answer, including both quantum uncertainty and statistical uncertainty. Its not called a calorimeter for nothing … that says its classical.

Normally on blogs like this one my viewpoint usually gets moderated out.

50. **Laurence Lurio**
March 26, 2018

When you are stuck in a philosophical morass, the solution, if one exists, is likely to come from experiment. There is a growing experimental community working on building quantum computers who are worrying about wave function collapse as a very practical matter. It will be interesting to see which interpretation that community gravitates to.

51. **Jim Baggott**
March 27, 2018

Peter,
Try this. Imagine a modern-day equivalent of Ptolemy's model for the orbital motions of the planets based on very large numbers of epicycles. We develop a computer programme to calculate planetary orbits with a very high accuracy. We all agree that the planets are 'real' (they continue to exist when nobody's looking at them through a telescope) and that the physical situation we are describing (planets moving with certain speeds in certain directions across the night sky) is 'real'. But I don't think anyone would consider the epicycles themselves to be 'real', in the sense that they represent real physical forces or processes that somehow govern or determine these motions.

We would say that the epicycles are a convenient way of *representing* the planetary motions, but they shouldn't be taken literally as aspects of the real physics. Likewise, some theorists have questioned the status of the wavefunction in QM. They don't necessarily deny that there is 'real physics' going on, but they argue that the wavefunctions are like epicycles – they are a convenient way of summarising what we know and calculating probabilities, but they shouldn't be taken literally as representing the real physical states of quantum systems.

52. **Yatima**
March 27, 2018

Let's wait for the [Quantum Computers to fail in interesting fashion.]

That is a testable, well, not prediction. But outlook.

I was actually astonished to see experiments on evidence of superposition on [large molecules] come back positive: *"We observe high-contrast quantum fringe patterns with molecules exceeding a mass of 10 000 amu and 810 atoms in a single particle."*. Does the universe know what a human cognitive apparatus labels a "single body"? Why doesn't it superpose the single body into a mismash different "single bodies"?

53. **Peter Woit**
March 27, 2018

Jim,
I understand there's a complex issue of the relationship of reality and our models of it, but it's exactly this deep philosophical issue that I don't want to enter into discussions of, because I don't see that it sheds any light on the non-trivial measurement problem (the relation of quantum and classical). It may very well shed light on some of the debates between interpretations that have gone on over the years, but ones that I've long ago lost interest in.

54. **Low Math, Meekly Interacting**
March 27, 2018

Hope this isn't OT and/or too basic to merit inclusion in the discussion. Apologies if so.

What's the consensus on probability in MWI? As others have mentioned above, it doesn't appear that everyone agrees it's a matter that's been satisfactorily resolved. To the extent that I understand the pro arguments, I'm not especially satisfied either. The whole notion of somehow equating the "illusion" of probability with frequency seems like slight-of-hand. World mangling doesn't seem to help much. It's not clear to me how these supposed solutions do anything but leave us with exactly the same questions about quantum dice we might have with other interpretations. The notion that all these branches are somehow extant also seems to necessitate something like an anthropic principle to explain the fact that I have never experienced bizarre phenomena that are highly unlikely but not excluded. I don't need a multiverse to explain why I don't get "heads" ten thousand times in a row with a fair coin, do I? To me that's not just an aesthetic problem, it's a problem with legitimately excess baggage.

55. **Peter Woit**
March 27, 2018

LMMI and others,

I confess that I have a more basic confusion here. I don't see why the explanation for probability entering the picture isn't just the usual one: we only have probabilistic information about the state of the measurement apparatus. This seems too obvious to be any sort of explanation, I'd love to hear why from someone who has thought about this more than I have (which is not much…).

56. **Mateus Araújo**
March 27, 2018

Low Math, Meekly Interacting,

It's hard to say what the general consensus is, I haven't run any polls. But I can tell you my opinion.

One thing that Many-Worlds explain better about the quantum dice is why the outcome is in principle unpredictable: there is nothing to predict, as all outcomes happen. This ties in well with the Deutsch-Wallace theorem: since all outcomes happen, you should be indifferent about them, which leads to uniform probabilities to states with equal coefficients. Throw in some unitary invariance, and you have the Born rule. So I think the Many-Worlds explanation for subjective probabilities is pretty satisfactory.

What is not satisfactory, and is probably the source of your unease, is the explanation for objective probabilities, as it is simply lacking. This is not a point against Many-Worlds, as there is no explanation for objective probabilities in single-world quantum mechanics either. Why don't you get "heads" ten thousand times in a row with a fair coin? Because the probability is small? Because the mod-squared amplitude is small?

I think, however, that it can be explained, most easily in a toy many-worlds theory where worlds can be counted. Consider that after each throw of the coin exactly one world is created with “heads”, and one world is created with “tails”. Then after 10,000 throws there will be 2^10,000 worlds, and in only one of them you see 10,000 heads in a row. In general, the relative frequencies measured in this toy theory will be close to the objective probability of 1/2 in most worlds.

57. **Daniel Tung**
March 27, 2018

Mateus,

“there is nothing to predict, as all outcomes happen”
But an observer can try to predict whether she will see this or that outcome, right? Because to any observer, she only sees one outcome. Only to a God’s eye point of view do all the outcomes occur. Observers don’t have this viewpoint.

Moreover, what forbids the classical world to adopt a kind of MWI when dealing with uncertainties? If so, we do not need to explain why anything happen anymore, just accept that everything happened and we happened to be in a world where THESE things happened.

Since in the MWI we dragged the observer into the interaction, we can go further and ask why the observer made this measurement choice and not others. We don’t have to stopped at the Outcome MWI. We can have a much bigger world – the Choice MWI, by saying that in fact all the incompatible measurement choices are made, but in different worlds. The problem of probability measure will become more intractable, and the entire situation becomes more absurd.

58. **Tim Maudlin**
March 28, 2018

Peter,

The term “real” is not deep and obscure, it is empty and reduplicative. Similarly with “actual” and “true” and “exists”. Thus: “I have a dog”, “I have a real dog”, “I have a real, actual dog”, “I have a real actual dog that exists” and “It is true that I have a real, actual dog that actually exists in reality. Truly I do.” all say exactly the same thing. And the question of physical existence or physical ontology is a matter of physics, not philosophy.

Here is a simple question of physical ontology. When we first learn electromagnetism, we are taught to use two mathematical vector fields the E field and the B field, to represent the physical electro-magnetic situation. And we are also taught to use the scalar and vector potentials to represent the physical situation. But we are warned that the scalar and vector potentials are not “real”, in the sense that mathematical representations that differ in the values of A and phi can represent the very same physical situation if a gauge transformation carries {A, phi} into {A’, phi’}. In short, there are mathematical degrees of freedom in the mathematical representation that do not correspond to physical degrees of freedom in the physical situation. And when the Aharonov-Bohm effect was discovered, this classical understanding was no longer tenable. How exactly to understand what the physical degrees of freedom might be is a question of physics, and not philosophy. One can ask that question using questions like “Are the scalar and vector potentials physically real?” meaning “Are the physical degrees of freedom isomorphic to the mathematical degrees of freedom in the mathematical representation that uses A and phi?”.

Now you may not be interested in this question. You can take the instrumentalist attitude that no matter how that question is answered, if you know how to use the formalism to make predictions that is all you care about. No one can stop you from adopting such an instrumentalist attitude. But those of us who care deeply about this question do not do so as “philosophers”, whatever that might mean. We do so as physicists, interested in the nature and structure of the physical world. The question “Are the scalar and vector potentials physically real or merely mathematical conveniences?” is slightly poorly phrased, but it is posing these very physical questions.

59. **Joking**
March 28, 2018

But Tim, how exactly are you deciding whether it is E&B or A&phi that are, or represent, the “true physical degrees of freedom”? A priori, any of these is just a mathematical object, namely a scalar or vector field in 3-dimensional space. And you have to derive empirical consequences for a priori real objects, such as ultimately dogs, in order to decide which of these mathematical objects is useful or necessary for the description of reality, and before assigning them reality themselves. Without the Lorentz force and Newton’s laws, the reality of the electro-magnetic field is an empty statement. Similarly, without the Schrödinger equation and the laws of quantum mechanics, the reality of the (integrated) vector potential just has no content whatever.

I agree that the question of physical ontology is not a philosophical one. But what physics teaches is that physical reality is hierarchical, interdependent, and not all the same. The quantum mechanical wave function is not real in the same sense as a dog, for example, though the distinction is not peculiar to quantum mechanics as your E&M example illustrates. What Bohr reminded everyone is that the beginning and end of the discussion of physical reality are experimental setups and experimental outcomes described in plain language. By that token, many worlds or Bohmian position variables have physical reality only to the extent that they have empirical consequences (but do they?).

It also needs to be said that in the discussion of physical ontology, “exists” frequently appears in the sense of the mathematical quantifier, which has to be carefully distinguished from the notion of physical reality (which is also different from the mathematical notion of reality). I hope you agree that at least this distinction applies.

60. **Peter Woit**
March 28, 2018

Tim Maudlin/Joking,

Sorry, but I really will start ruthlessly suppressing discussion of ontology now. Debates about “is the vector potential real?” have nothing to do with the QM measurement problem (and, if you ask me, trivialize and obscure actual important issues, but that’s a topic for another day…)

61. **Davide Castelvecchi**
March 28, 2018

Philip Ball’s book has a great discussion of the tricky issues that plague the many worlds hypothesis (he is not a fan)

62. **Peter Woit**
March 28, 2018

Thanks Davide,

I may (or may not…) wait until it comes out in the US to take a look at the Ball book. In the meantime, for some idea of his criticisms of MWI, there are other things he has written, for example

https://aeon.co/essays/is-the-many-worlds-hypothesis-just-a-fantasy

63. **Jim Holt**
March 28, 2018

The Columbia physicist/philosopher David Z Albert will have a long and pungent review of Becker's "What Is Real?" in the next issue of the New York Review of Books. The review will be online at nybooks.com tomorrow at noon. (Spoiler alert: Oppenheimer does not come off well.)

64. **Stephane**
March 29, 2018

Hi Peter,
is the book by N.P. Landsman – Foundations of Quantum Theory – From Classical Concepts to Operator Algebras (2017) on your list of read books about Quantum Physics?
http://www.springer.com/gp/book/9783319517766

I'd be happy to hear your thoughts about it.

65. **Peter Woit**
March 29, 2018

Stephane,
Thanks for pointing that out, I hadn't seen it before and haven't had a chance to look at it closely. Landsman has thought very carefully and done a lot of work on the question of how classical physics emerges from quantum physics. One thing I can recommend is this article
https://arxiv.org/abs/quant-ph/0506082

From what I remember, Landsman clearly lays out the issues, I think comes down on the side of "there is still something going on here that we don't understand" (I may be misrepresenting him).

66. **Art**
March 29, 2018

Albert's NYRB article is more his own re-telling of the history than a book review, imho. (If only Bohm, Everett, and Bohr could have taken some walks together!) But it gives me an opportunity: this novice was quite taken with Albert's observation (echoed by Coleman in "Quantum Mechanics in Your Face") that, after a measurement fork in the quantum mechanical garden paths, all observers see a definite result (but not necessarily the same result), with nary a superposition in sight. Is this result significant, trivial, or somewhere in between?

67. **Peter Woit**
March 29, 2018

Art,
This is the heart of the measurement problem of quantum mechanics, and to my mind very much significant, with the difficult question that of providing a compelling explanation of how this happens.

68. **Chris W.**
March 30, 2018

By the way, I had somehow missed the fact that Gerard 't Hooft has published with Springer a book-length exposition of his heterodox approach to the foundations of quantum mechanics.

69. **Dave Miller**
March 30, 2018

Daniel Tung wrote:

Yes, Daniel, that is indeed how it is supposed to work. You describe this as the situation becoming "more absurd." Well, perhaps. But lots of people found special relativity absurd, and it seems to be true.

To be sure, this multiple infinity of universes does raise some questions about Occam's razor, but the MWI proponents say the ideas are simple even if the MWI multiverse itself is not so simple.

The real problems are the ones that Peter Woit and I have mentioned, the "preferred-basis" problem as to why the universe "splits" along certain directions in Hilbert space and not in other directions, and the "probability-measure" problem as to how the multiple universes lead to Born's rule.

From the beginning, various MWI proponents have claimed that MWI automatically produces Born's rule, then other MWI proponents admit there are problems, then still others claim they have some new way of getting Born's rule, and so it goes. I have been watching this process for nearly fifty years now, and I fear it reminds me a bit more of theology than physics (not that theology can't be amusing!).

By the way, superficially there is a simple solution: you just announce that the probability measure on the space of possible universes just *is* the Born rule. Of course, then you are not *deriving* the Born rule but just assuming it, just as we do in textbook QM.

Furthermore, as physicists, we want the Born rule to be true in some frequentist interpretation, not just as an abstract measure. How do you do that? Well, often MWI proponents have spoken as if there are a large but finite number of universes in the MWI multiverse, and the probability measure is just a relative count of the number of universes in which one or another outcome occurs.

But that just does not work: You actually need an infinite number of universes, not a finite number, so naïve counting does not work. Also, the universes are not actually separate and discrete (that, after all, is the whole point of MWI: to be able to deal with quantum interference).

So, as far as I can see, the end result of decades of work and rather heated debate is that you just have to throw in Born's rule with a frequentist meaning as an extra assumption in MWI, which largely defeats the point of MWI in the first place.

If you want to dig into this further, David Deutsch is an intense proponent of MWI who has been aware of the two basic technical problems and who, at least on occasion, thinks he has found solutions. Deutsch has done some interesting work connecting MWI to quantum computing and even to time travel and travel to parallel universes (he somehow got Phys. Rev. to publish the latter work!). My own feeling is that if Deutsch, who is indeed very bright, can't get this bird to fly, and I don't think he can, then no one can.

But, I am sure, many MWI proponents will have a different take: there is no final agreement in matters of theology!

Dave

70. **Mark Hillery**
March 31, 2018

From the review in the New York Review of Books by David Albert:

"It wasn't until sometime in the 1980s that a small and embattled community of physicists, mathematicians, and philosophers, who had learned of the the theory [Bohmian mechanics] from Bell, began to take an active interest in what Bohm had done. His theory is now regarded as one of the two or three most important achievements in the history of our understanding of quantum mechanics."

Regarded by whom? As an antidote to this, I highly recommend the following posting by Reinhard Werner, a first-rate mathematical physicist, who has made numerous contributions to quantum information, for those of you who do not know him: https://tjoresearchnotes.wordpress.com/2013/05/13/guest-post-on-bohmian-mechanics-by-reinhard-f-werner/

71. **Peter Woit**
April 2, 2018

Mark Hillery,
Thanks for the comment and link. The fondness of philosophers (and a few physicists) for Bohmian mechanics has always mystified me.

72. **Peter Woit**
April 5, 2018

Note that I've added some comments by the author, Adam Becker, to the posting above.

73. **Tim Maudlin**
April 18, 2018

Mark Hillery: Regarded by who? Regarded by the people who actually work on foundations of physics and foundations of quantum theory in particular. A group to which Werner most certainly does not belong. Nor, obviously, does Peter Woit. You can start with Bell's "On the Impossible Pilot Wave", since Bell was the leading figure in foundations in the latter half of the 20th century. (If you disagree with the assessment, I would be extremely curious who else you think deserves that honor.)

74. **Curious Mayhem**
April 18, 2018

Lindley's book is excellent. It's been clear for some time that Zurek and others' work on decoherence is the way forward on this question.

The invocation of strings and multiverses for the many-worlds idea is hilarious — many-worlds dates from the 1950s, about 30 years before the rise of string theory as we know it now and 40+ years before the "landscape." This is like string theory "predicting" Kaluza-Klein, inflation, gauge theory, general covariance, and what-not, long after those made their appearance. What claptrap.

Cophenhagen and its interpretation have roots long before the military-industrial complex. They didn't know how to fully resolve the problem, although von Neumann isolated it in the measurement operation. Most physicists then didn't care, and don't care now, about the ultimate nature of reality implied by QM. They just know they can calculate with it and get amazing results. "Shut up and calculate."

Various News

March 28, 2018
Categories: Uncategorized

- Reader Chris W. pointed me to this story about what Cédric Villani, aka the Lady Gaga of French mathematics, has been up to. I see that the report of the "Mission Villani" is now available (in French or English) and it's front page news at le Monde. There's also an AI for Humanity website now up, and plans for all sorts of events tomorrow (video here) involving Villani and French president Macron.

  For insight into what this means, you'll need an AI expert. I'm curious to hear if there's anything really surprising in the report.

- Neil Turok and collaborators have a new proposal for how to understand the Big Bang, with the headline version "The universe before the bang and the universe after the bang may be viewed as a universe/anti-universe pair, created from nothing." There's a short summary here, a longer paper with details here.

  The papers make various claims of predictions, I'm curious to hear from cosmologists what they think of these. Much of the papers does look like fairly straightforward QFT calculations, which I'll try to look at more carefully when I find time.

- The LHC is now in a machine checkout phase, ready for resurrection around Easter Sunday, with the start of beam commissioning for the 2018 run.

Update: A wealth of analyses of physics papers is available at this website and this preprint.

   March 28, 2018

   I had noticed Turok's and collaborators paper. I do HEP, not cosmology. However I have a question/comment. What is the CKM phase in the "anti-universe"?

   There is something I am confused about — In the anti-universe if the physicists there take their time "t" as positive, like we do, and call their atoms to be made of "particles" like we do, and write their Standard Model Lagrangian for sub-TeV scale particle physics, will they end up with exactly the same Lagrangian we have, with the same CP violating phase in the CKM matrix? I think from the way the introductory passages in the paper have been written, they would.

   Then isn't this just a duplication of the universe (rather than an anti-universe)? Or is it that their Lagrangian would have \delta_CKM reversed in sign. In which case their particle physics would be very different and the following statement they make would pbly not be true "In other words, the density of particles of species j with momentum p and helicity h at time t after the bang equals the density of the corresponding anti-particle species with momentum p and helicity –h at time –t before the bang."

   Looks to me that these are two universes duplicated rather than a universe-antiuniverse pair but I could be totally wrong.

   March 29, 2018

   "For insight into what this means, you'll need an AI expert." I was trained as an AI expert, although I've rarely worked as one. That said, assuming that you're referring to https://www.aiforhumanity.fr/pdfs/MissionVillani_Report_ENG-VF.pdf , I don't think knowing much about AI is required; it's a policy document, with a lot of wishlist items.

   I find their description of "exposed" jobs (jobs that may be replaced – pages 83-84) interesting. As someone who works primarily in medical robotics, I think that they are missing the costs and benefits in their analysis. As an example, both waitstaff in restaurants and chemists in blood labs have been highly automatable for well over a decade. The former is rarely done, whereas the later is ubiquitous. The reason is that automation of the former doesn't save a lot of money – and has significant costs (space, maintenance, less social interaction between the customers and the restaurant, etc), whereas automation of the later saves large amounts of money and space.

3. **Tim**
   March 29, 2018

   It's not two positive universes, although it appears that way to people who are limited to each universe. It's a subtle and interesting point about the paper.

   The paper, if I understand it correctly, makes the point that in order to understand the Big Bang, you need to use a consistent set of characterizations (metric, wavefunctions, etc) that handle BOTH the universe and the anti-universe, and not just the late time situation, where the "other" universe can be ignored. In particular, this involves a particular choice of the CPT invariant vacuum, which is halfway between the asymptotic vacua of the universe and antiverse. All of the CPT things are actually reversed in the antiverse, including which direction time flows, what is a particle and what is an antiparticle, CP violation, etc. But the universe + antiverse is CPT invariant. This only matters when considering the Big Bang, but the consequences for both universes are huge, including eliminating the need for inflation and predicting that there is an undetectable (except by gravity) background of stable right handed neutrinos that could explain dark matter.

   People who actually understand this stuff can correct me, but it seemed like a very interesting paper to me when I read it.

4. **GreatDoofus**
   March 30, 2018

   Anon & Tim,

   I think the term 'anti-universe' is misleading. The analysis is still at the level of QFT on a classical spacetime background. What they're doing is 'enhancing' symmetry of the FRW metric (which is already invariant under parity, spatial rotations and translations) by making it invariant under reversals of the conformal time. To do this you just need to extend the geometry of the universe backwards, past the Big Bang.

   The extra symmetry simplifies the structure of QFTs and imposes some new constraints on neutrinos and dark matter. Also, it can explain the origin of scalar perturbations without the need for inflation.

   You'll need to ask a cosmologist for more details, but, I think testing this model should be straightforward.

5. **ay**

March 30, 2018

The predictions seem rather weak to me. What can we do with a non-interacting neutrino with such a high mass? There are some restrictions on neutrino properties that, if verified, would not really single-out the theory. That's not to say I have any reason to think it's wrong. Just that deriving revolutionary new theories with a liklihood of testability seems difficult these days.

6. **Narad**
   March 31, 2018

   > I don't think knowing much about AI is required; it's a policy document, with a lot of wishlist items.

   I'm with Fred P; I only did two years on a Ph.D. with one of Roger Schank's recent grads (yes, case-based reasoning basically gave the world irritating voice-based phone trees at the end of the day), but two standouts were that the authors didn't have enough AI to hand to use hyphenation and the line "[d]efining artificial intelligence is no easy matter" (re Schank, see [his entry] for the 2014 Edge ideas-to-be-retired question).

   How "explaining machine-learning algorithms has become a very urgent matter" is also a head-scratcher. It seems about as urgent as explaining how to interpret oscilloscope results for test points on 1970s color TVs was. The table that Fred P pointed out also seems to posit Rosie the Robot.

7. **Pascal**
   April 2, 2018

   > How "explaining machine-learning algorithms has become a very urgent matter"

   Well, assume for instance that a computer has decided that someone must undergo a certain medical treatment. It would be nice to be able to explain this decision to the patient or to (human) doctors! But many modern AI algorithms cannot explain in a human-comprehensible way how they reached a given decision. That's because the "learning" often takes place by tuning a large number of parameters of a complex model (think "deep learning) on big data sets. Et voilà! We hope (and sometimes can prove) that because the model fits the training data, it will also perform well on future unseen examples.

   The "old AI" of the 1970's of the "expert system" type followed a more explicit rule-based approach, and was probably better at giving explanations. But it was outperformed by more recent statistical approaches. I suppose Villani would like to have the best of both worlds.

8. **srp**
   April 2, 2018

   Pascal is correct; DARPA, for example, has projects explicitly aimed at trying to make intelligible the predictions of these regression equations (that's what they really are, high-dimensional non-parametric regressions extrapolating from training data). Another unpleasant discovery has been the remarkable vulnerability of these data-mined regressions to various types of spoofing, with an arms race taking place over the last few months between the spoofers and those trying to make the systems more robust.

9. **Tim**
   April 2, 2018

   So there is a flaw in Pascal's comment.

   Is there a need to explain the decision to a human, or simply a need to verify that it is right?

   Remember, checking that an answer is right is usually far easier than finding the answer (P != NP !!).

   For safety issues like medical diagnoses, you actually only need to verify that the answer is right. You do *not* have to actually understand how it was found.

10. **srp**
    April 2, 2018

    I haven't had a chance to go over this yet, but the abstract is promising and the authors are very sharp:
    http://www.nber.org/papers/w24449

11. **Narad**
    April 3, 2018

    > DARPA, for example, has projects explicitly aimed at trying to make intelligible the predictions of these regression equations (that's what they really are, high-dimensional non-parametric regressions extrapolating from training data)

    Could you please give me a pointer? We had one fellow in the lab (who actually got the lone Ph.D.) who was working on CBR for, IIRC, targeted radiotherapy applications.

    April 3, 2018

    Here's a quote:

    "The U.S. military is pouring billions into projects that will use machine learning to pilot vehicles and aircraft, identify targets, and help analysts sift through huge piles of intelligence data. Here more than anywhere else, even more than in medicine, there is little room for algorithmic mystery, and the Department of Defense has identified explainability as a key stumbling block.

    David Gunning, a program manager at the Defense Advanced Research Projects Agency, is overseeing the aptly named Explainable Artificial Intelligence program. A silver-haired veteran of the agency who previously oversaw the DARPA project that eventually led to the creation of Siri, Gunning says automation is creeping into countless areas of the military. Intelligence analysts are testing machine learning as a way of identifying patterns in vast amounts of surveillance data. Many autonomous ground vehicles and aircraft are being developed and tested. But soldiers probably won't feel comfortable in a robotic tank that doesn't explain itself to them, and analysts will be reluctant to act on information without some reasoning. "It's often the nature of these machine-learning systems that they produce a lot of false alarms, so an intel analyst really needs extra help to understand why a recommendation was made," Gunning says.

    This March, DARPA chose 13 projects from academia and industry for funding under Gunning's program. Some of them could build on work led by Carlos Guestrin, a professor at the University of Washington. He and his colleagues have developed a way for machine-learning systems to provide a rationale for their outputs. Essentially, under this method a computer automatically finds a few examples from a data set and serves them up in a short explanation. A system designed to classify an e-mail message as coming from a terrorist, for example, might use many millions of messages in its training and decision-making. But using the Washington team's approach, it could highlight certain keywords found in a message. Guestrin's group has also devised ways for image recognition systems to hint at their reasoning by highlighting the parts of an image that were most significant."

April 4, 2018

Another Shank disciple here: I have an all-but-thesis from him from the mid-1980s.

Re: srp's link. The gestalt in AI in the '70s was that linear descent search in large spaces could, in principle, only find local minima, so the idea that big data and "machine learning" are going to solve all mankind's problems seems unlikely in the extreme. A joke (if memory serves, in a Newell and/or Simon AI book at the time) illustrating this had a picture of a robot climbing a tree, pointing to the sky, and screaming "I'm getting closer to the moon". IMHO, this describes the current state of AI way too well.

From Princeton to Prison

April 2, 2018
Categories: Uncategorized

One of my graduate school classmates today sent around a link to a story about someone many of us remembered, Dragoljub Cetkovic. I somehow missed it last year when it appeared, it's by Paul Halpern and entitled [From Princeton to Prison: The 'Boy Genius' Who Was Recruited by John Wheeler and Sentenced by Trump's Sister](). As the story explains, Drago Cetkovic was a precocious young physicist, who John Wheeler brought to Princeton in 1974 (Barry Simon says it was actually Remo Ruffini, Wheeler's postdoc, who had recruited him). Drago was studying quantum field theory, but wasn't much interested in doing things like passing exams or working as a Research Assistant (the usual assignment for first-year grad students). This led to trouble and him getting kicked out of the graduate program.

By the time I arrived in Princeton, Drago was a mysterious fixture around the department, often to be found in the library. I recall a couple times asking him about what he was working on, receiving a dense and, to me, utterly incomprehensible explanation. There were rumors that he was somehow being supported on some grant or money from the IAS, but I have no idea how he made ends meet (Simon says he at times was sleeping on John Milnor's floor). I left Princeton in 1984, and things evidently went downhill for him after that. As explained in the Halpern piece, as well as in [this story from the time](), in 1987 Drago for some reason left a cyanide-laced tea bag in a Princeton grocery store, and called in some sort of threat. He ended up being sentenced to five years in prison, I don't know what happened to him after that.

Some of the stories about him refer to his supposedly threatening Barry Simon's life (Simon was the faculty member in charge of graduate students who had to ask him to leave the program). I had heard this story, and one day when I was talking to Drago, asked him something like:

"Hey, I heard you threatened Barry Simon's life, and that's why he left Princeton to go to Caltech. Is that true?"

His answer:

"No, that is not true. And, if it were true, Caltech would not be far enough!"

I do wonder what happened to him, hope that he sooner or later ended up in a new and much better phase of life.

Update: My memory of those days is rather faulty, it quite likely was Nathan Myrhvold who asked him about Barry Simon. Nathan also recalls that he was working on spinor geometry. Maybe now I'd understand what he was trying to explain to me back then.

   April 4, 2018

   I think the only boy genius that Wheeler brought to Princeton and who then went on to make something of himself is Demetrios Christodoulou.

6. **william e emba**
   April 15, 2018

   I remember Drago, and I had some interesting conversations with him. I left Princeton in 1980, sometimes ran into him when I visited campus afterwards over the next five years. I was shocked beyond belief, utterly freaked, when I realized that an article I was reading in the *Weekly World News* was about his arrest for the cyanide lacing. I had thought Alexander Abian was more their speed.

Raoul Bott: Collected Papers, volume 5

April 4, 2018
Categories: Book Reviews

I noticed today that the final volume of Raoul Bott's collected papers, which Loring Tu has been working on editing for quite a while, has finally appeared. The Springer webpage for the book is here, and its content is available at institutions with a Springer subscription here here. Many of the articles within can be accessed by other means, for example Tu's article about Bott's life and work is available here (updated version here) and the collection of articles by others about him is here.

After Bott's death in 2005 I wrote a blog post here, and won't repeat what's there. Much of the material in this last volume is related to mathematics that grew out of Witten's work on Chern-Simons theory. Unlike earlier volumes, which are devoted mostly to Bott's important research papers (almost all of which are well-worth reading!), here many of the articles are of an expository nature, written for various lectures that Bott gave. The volume also includes various incidental material, such as speeches written for various events. Reading these gives a good idea of the wonderful human being that he was, it's great to have them finally collected and available.

Comments

1. **Eric Weinstein**
   April 10, 2018

   Thanks for this Peter.

   Any idea if there might be a curated collection of links to lectures given by Raoul which are available on line? I went looking a while back and was disappointed at how little I could find.

2. **Peter Woit**
   April 11, 2018

   Eric,
   Would be great if someone could do that. I haven't looked much, but unfortunately I think Bott's lecturing years were coming to an end about the time everyone started recording lectures to put on Youtube. Quite a shame, since his lectures were always a wonderful experience.

Are We In the Swampland?

April 5, 2018
Categories: Swampland

Way back in 2005, soon after the emergence of the "String Landscape" and the ensuing debate over whether this made string theory untestable pseudo-science, Cumrun Vafa in response started writing about the "Swampland". In contrast to the "Landscape" of effective field theories that are low energy limits of string theory, the "Swampland" is the space of effective field theories that are not low energy limits of string theory. One motivation here is to be able to claim that string theory is predictive, since if you can show a theory is in the Swampland, then string theory predicts that theory doesn't describe our world.

I wrote a couple blog postings about this back then, see here and here. The situation was rather comical, with Jacques Distler unintentionally making clear one problem with the whole idea. He was enthusiastic about it, and gave as one example the suggestion that one and two generation versions of the Standard Model were effective theories that could not be derived from string theory, but Volcker Braun immediately wrote in to tell him about such a derivation. At this time I started having my problems with the arXiv (and its moderator, Distler) about trackbacks, but that's another story.

I haven't paid much attention to the Swampland business since then, but noticed last night a new preprint with the title *What if string theory has no de Sitter vacua?*. The authors summarize their argument:

> From this analysis we conclude that string theory has not made much progress on the problem of the cosmological constant during the last 15 years. There is a general agreement that the presence of dark energy should be an important clue to new physics. So far, string theory has not been up to the challenge. Or to be more precise, string theorists have not been up to the challenge.
>
> The well-motivated introduction of the anthropic principle and the multiverse, was a big relief. The mathematical standards were lowered, and unconstrained model building could set in exploring a wild and free landscape of infinite possibilities. But beyond this suggestive connection between a possible multiverse and the rich mathematical structures of string theory not much solid results have been achieved. We reviewed some fraction of the mounting evidence that most, if not all of this landscape, is a swampland and we refer to for similar lines of thought. We believe it makes more sense to listen to what string theory is trying to tell us, then to try to get out of the theory what one would like to have. In recent years, especially with the program of the Swampland , there is luckily a growing community that embraces this idea. Perhaps this program really already made its first prediction: no measurable tensor modes in the CMB.
>
> From what we have seen so far, we believe that the most sensible attitude is to accept there are no dS vacua at all because string theory conspires against dS vacua.

The suggestion here is basically that effective field theories on a deSitter background are in the Swampland, so can't be derived from string theory. Since we seem to live in a deSitter space, the obvious conclusion to draw from this is that string theory is falsified: it can't be the fundamental theory we are looking for. The authors discuss various unconvincing ways to try and avoid this conclusion.

By the way, the authors make the usual flawed argument that "the string theory landscape is just like the Standard Model":

> This kind of criticism is, however, misguided . One might compare with quantum field theory, where there is an infinity of fully consistent theories. Experiments are needed to pick the right one, and parameters must be fitted. When this is done the theory still has enormous predictive power, and no one would claim that the Standard Model is useless. One could argue in a similar way concerning the string landscape.

They also claim:

> Paradoxically the critics of string theory and the proponents of the string landscape all agree on one thing: the landscape exists and we more or less know its properties.

At least this string theory critic has never agreed on this. I don't believe "string theory" is a well-defined enough framework to answer the question of what all its ground states might be, or to properly characterize them. If you accept conjectures about the theory put forward by the landscapeologists, all evidence is now that the set of ground states they identify is so large as to make predictions impossible. The argument against string theory is that there are two possibilities here: either the theory is too poorly understood to tell us what its ground states are, or it does tell us something, and there are too many ground states to make useful predictions. Either possibility leads to the same conclusion that this is a failed idea.

It is rarely acknowledged just how serious the problem of a lack of a definition of "string theory" really is. To get some idea of how bad this problem is, one can consult one of the main references in this paper, a survey of the Landscape and the Swampland, based on Vafa's 2017 TASI lectures (this paper also discusses the idea that deSitter is not in the Swampland). Claims are often made that AdS/CFT resolves the problem of defining a non-perturbative string theory of quantum gravity, but in the paper one finds:

> We can now ask the question if using this AdS/CFT correspondence gives a non-perturbative definition of string theory. The motivation for this is that we can give a non-perturbative definition of SYM theory, for example by lattice regularization, whereas the holographic quantum gravity dual theory in AdS has no complete definition. The fact that the CFT side, i.e. the non-perturbative definition of SYM, gives in principle, a non-perturbative definition of the AdS side, is of course true. But this may be not very useful for deeper questions of quantum gravity. In fact the regime that the gravity side is weakly coupled is big corresponds to when the SYM is strongly coupled. In fact 't Hooft was trying to use string theory as a solution to the gauge theory question at strong coupling and not the other way around!…
>
> we find ourself back at the beginning: we want to know fundamentally, what is quantum gravity? It should describe the quantum fluctuations of the metric. From a brief analysis of the standard Einstein-Hilbert action, we see that fluctuations of the metric at the Planck scale should become very violent, leading to potential changes in the topology of the spacetime . This leads naturally to the idea that quantum gravity should be equivalent to summing over all spacetime topologies and geometries:
> $$Z_{QG} \sim \sum_{\text{top. and geo.}} e^{-S}$$
> In general we have no idea about what description will lead to the correct sum over geometries and topologies. We only do know that there should be some mechanism that washes out the Planck scale fluctuations to produce a smooth space at lower energies. It seems that this description must come from some new fundamental principle, rather than from some duality such as mirror symmetry or AdS/CFT. This lack of knowledge of describing the gravity side quantum mechanically is "the missing corner" in our understanding of string theory.

In both this survey and the new paper, the tactic of trying to remove the Landscape to restore the predictivity of string theory hits up against the obvious problem: you're left with no theory at all (the equation above, with an undefined sum and an undefined action, is the essence of no theory).

Comments

1. **Jack Morava**
   April 5, 2018

Perhaps it's relevant that it's not known whether or not there is a countable number of smooth structures on the four-sphere?

2. **Peter Woit**
   April 5, 2018

   Jack,
   I think the notation "sum over all topological and geometric structures" speaks for itself. As a good rule of thumb, whenever people in this field talk about having a "measure problem", if you look into it you'll find that they don't even know what the space is on which they are looking for a measure. The space of "all topologies and geometries" is a good example.

3. **Marc Nardmann**
   April 5, 2018

   @Jack Morava: If by "countable" you mean "having cardinality at most aleph_0", then it *is* known that the set of diffeomorphism classes of smooth structures on the 4-sphere is countable. Even the union, over all compact 4-manifolds M, of the sets Sm(M) of diffeomorphism classes of smooth structures on M is countable.

   In the "sum over all topological and geometric structures" context, one should also consider *noncompact* 4-manifolds M, and on those Sm(M) has usually (conjecturally: always) the cardinality of the continuum. Therefore compact 4-manifolds would probably be irrelevant, because the set of geometric structures (whatever that means precisely) on them should be expected to have measure 0 within the space of all topological and geometric structures. Of course one needs a precise definition of the space and of the measure to verify this expectation.

   The set Sm(M) can be uncountable only for (noncompact) manifolds of dimension 4. Some people have suggested that this explains why our universe is 4-dimensional: the set of universes of other dimensions should be expected to have measure 0 within the space of all universes. Again, it all depends on the chosen space and measure. (Probably M-theorists would prefer anyway to explain why our universe is 11-dimensional?)

4. **Peter Woit**
   April 5, 2018

   Sorry topologists, but that's enough about this issue, which has nothing to do with the topic of the posting.

5. **Søren Bro Thygesen**
   April 6, 2018

   So this is the basis for your problems with trackbacks? I find that incredibly childish on Distler's part. I'm aware that smart people often have eccentric behaviour but man..

6. **Peter Woit**
   April 6, 2018

   Søren Bro Thygesen,
   To be accurate, I have no idea at all (despite signficant effort to find out) why trackbacks to my blog are now banned, or exactly what Distler's role in this is.

7. **Shantanu**
   April 6, 2018

   Peter: have any journalists written about this paper or interviewed others?

8. **Peter Woit**
   April 6, 2018

   Shantanu,

   Not that I know of. Seems unlikely that any would. Claims about string theory and the landscape/multiverse make a very appealing story (physicists have this far-out cool idea that explains everything!). The new claims aren't such an appealing story, and the "swampland" designation isn't very good marketing. No one wants to write or read stories like "you know that cool stuff you read about last year? Best to just forget about it, probably doesn't work". In addition, when asked "what replaces the landscape/multiverse", I think all those who want to get rid of the landscape have is the old xkcd cartoon

   https://xkcd.com/171/

9. **new**
   April 6, 2018

   Peter can you comment on this

   " Perhaps this program really already made its first prediction: no measurable tensor modes in the CMB."

   if the above is a genuine prediction of string theory, what are the implications to string theory if they find measurable tensor modes in the CMB?

10. **Peter Woit**
    April 6, 2018

    new,
    There's no such thing as a "genuine prediction of string theory", for tensor modes or for anything else.

11. **Cobi**
    April 8, 2018

    One should mention that after writing down the qualitative "sum over spacetimes" formula, Vafa et al. review an explicit realization in the context of topological string theory.

12. **clayton**
    April 8, 2018

    Sav Sethi at Chicago has been making similar claims in seminars for quite a while now; this has been on the arXiv since last fall in 1709.03554, which Danielsson and Van

Riet cite. I think that these issues are well known in the string theory community, but it doesn't affect the day-to-day activity, which is no longer driven primarily by reproducing the Standard Model at low energy. Whether that is evidence of failure or (a good kind of) resilience seems to be a question of taste.

13. **Peter Woit**
April 8, 2018

Cobi,
Yes, a sum over some Calabi-Yau three-folds is discussed, but this isn't a theory of quantum gravity. The xkcd cartoon applies.

Clayton,
"no longer driven primarily by reproducing the Standard Model at low energy" is a pretty weasel-worded way of saying "not driven at all by getting particle physics at any energy". Also seems to be synonymous with "have given up on getting a theory that can be connected to the real world".

If you read all the way through Sethi, at some point you finally come to a mention of what the real problem is: there is no well-defined theory capable of giving unambiguous answers to the questions being asked. More specifically, Sethi writes:

"To answer this question, we require a framework for computing quantum corrections. String theory should be that framework but we immediately face an obstacle. String theory requires an on-shell solution. There is no currently understood method of computing quantum corrections off-shell, and this is closely tied to the fact that observables in string theory are always correlation functions of vertex operators, which are only defined in an on-shell background."

14. **Petite Kabylie**
April 9, 2018

Peter,

I do not quite agree with your argument this time:
"…either the theory is too poorly understood to tell us what its ground states are, or it does tell us something, and there are too many ground states to make useful predictions. Either possibility leads to the same conclusion that this is a failed idea."

I am ok with the second possibility, but not with the first. If a theory is poorly understood it just means more work (and more time) is needed to get the idea off the ground rather than a right away dismissal.

15. **DrDave**
April 9, 2018

PW (2005): "I've heard from someone associated with the arXiv that it's not their intention to allow trackbacks to my postings to be censored and that part of the problem has been both difficulties they've been having with new software…."
Curious what this person would say now.

16. **Peter Woit**
April 9, 2018

Petite Kabylie,
I was using "poorly understood" as a polite way of saying there is no theory (i.e. no non-perturbative version of M-theory for which the ground states are well-defined, and not in conflict with experiment).

It is fine to take the attitude that if one doesn't have a viable theory, that just means one needs to put more time and work into finding one. In evaluating this question, in this case one should keep in mind that people have been trying unsuccessfully to solve this problem for over thirty years, and that most of the experts in the field who have worked on this have given up long ago and are doing other things (I know of no promising ideas for a viable definition of M-theory, and thus virtually no one working on this).

17. **Curious Mayhem**
April 18, 2018

The emptiness of that Z ~ SUM(topo,geo) exp(-S) — where we have no idea what the sum, its measure, or the action is — reminds me of Pauli's reaction to Heisenberg's proposal for a unified theory, with "just some details to fill in":

"This is to show the world that I can paint like Titian. [A big drawing of an empty rectangle] Only technical details are missing."

(Apparently from a 1958 letter to George Gamow, in reaction to Werner Heisenberg's claim to a journalist that Pauli and Heisenberg had found a unified field theory. Quoted in Michio Kaku's Hyperspace, p. 137 (1995).)

18. **Peter Woit**
April 18, 2018

Curious Mayhem,

Story also told in my book, didn't realize Kaku also had it.

19. **Moyses**
April 26, 2018

dS from 10d, but not à la KKLT: https://journals.aps.org/prd/abstract/10.1103/PhysRevD.97.046010

20. **Urs Schreiber**
April 27, 2018

Moyses, that article by Moritz, Retolaza, and Westphal appeared as preprint already in 07/17, and its claim is discussed in the above article by Danielsson-vanRiet:

> We now highlight 3 problems with the IIB constructions that have been pointed out in the recent literature: […] 2) issues with anti-brane backreaction on the 4D moduli, which was found recently by Moritz, Retolaza, and Westphal [131]

21. **Moyses**
April 27, 2018

Urs Schreiber, I understand that such problems are part of the perturbative approach to IIB strings. Somehow, they are analogous to perturbative IR divergencies in QCD that can be cured by the lattice. For instance, a nonperturbative approach as IKKT shows different behavior at latter times: doi:10.1007/JHEP10(2012)147

Math News

April 12, 2018
Categories: Uncategorized

Various mathematics-related news:

- The Perimeter Institute has been moving towards an increased engagement with mathematics and mathematicians in recent years. Matilde Marcolli and Ben Webster are now joining them as Associate Faculty.
- Quanta magazine has an excellent article by Kevin Hartnett on the state of efforts by mathematicians to understand mirror symmetry.
- My colleague Dorian Goldfeld has become editor of the Journal of Number Theory, succeeding David Goss, who passed away last year. He tells me that the journal will sponsor a biennial conference, first one next year, announcement here. There will also every two years be a David Goss prize awarded to a young researcher in number theory.
- The latest Notices has an interesting and extensive article about Claire Voisin.
- John Baez has an ongoing online course on Applied Category Theory.
- Mathematician/musician Tom Lehrer is 90 this month, and there's a story about him at Nature. For an example of his music, listen to Lobachevsky.
- I'd missed the news that Roger Howe now has a tenure-track position at Texas A & M. Good luck to him on getting tenure! Howe duality is very much worth knowing about, here's an expository treatment.

Update: This Friday and Saturday there will be a meeting in Cambridge on the topic of Ethics in Mathematics. Supposedly talks will be livestreamed on Youtube (perhaps here ?).

Comments

1. **LMR**
   April 13, 2018

   It's interesting to see how Marcolli's career has evolved over the years: I didn't know that she's taken an interest in computational linguistics since 2014. Her essay, "A drifter of Dadaist persuasion", available from her Caltech website and to appear (as indicated there) in an AMS publication, is a fascinating read.

2. **David Roberts**
   April 13, 2018

   > Howe is an elected member of the National Academy of Sciences and the American Academy of Arts and Sciences. He has more than 40 years of service in the fields of mathematics and mathematics education and has received numerous honors for spearheading national education initiatives and ultimately expanding the frontiers of mathematics…

   and he's just gotten a tenure-*track* job? What hope do the rest of us have?? 🙂

3. **Thomas Larsson**
   April 13, 2018

   David, I got the impression that Peter was being ironic. I cannot think of a reason why somebody past 70 would want to get tenured, except perhaps ego. Surely universities can fire tenured professors once they reach mandatory retirement age (67?) if they want to.

4. **Peter Woit**
   April 13, 2018

   Thomas Larsson,

   I was being ironic, and I think David Roberts was too. Either the article was misusing terminology, or it might even have been technically correct (some institutions have a policy that even a senior hire doesn't officially get tenure until after their first year, or something like that).

   In the US, there is no mandatory retirement age and tenured faculty can stay on as long as they want, which can sometimes create problems.

5. **Chris Oakley**
   April 16, 2018

   I feel the need to point out that, irrespective of any mathematical credentials, Tom Lehrer is, in my humble and miserable opinion, the author of the funniest songs ever written. His music does not seem to date, either. Anyone who has not yet discovered him has a treat in store.

6. **Michael Gogins**
   April 16, 2018

   Peter, about Mathilde Marcolli, what is she talking about with respect to cruelty and exclusion in the mathematical community? Is she being a bit paranoid, or are people rejecting her work for bad reasons? It's puzzling to me because from where I sit, as a non-scientist, she seems to have had a lot of success. I read her essay with great interest.

7. **Peter Woit**
   April 16, 2018

   The essay being referred to is here
   http://www.its.caltech.edu/~matilde/MarcolliArtMath.pdf

   Michael Gogins,

   I've never met Marcolli, know only a little about her work, which is interesting, but highly idiosyncratic. You'd have to ask her for specifics, but you probably should take into account the context of what you quote (on page 4) which refers to the Surrealist critique of "the violence intrinsic in traditional family and bourgeois society." I suspect her criticisms apply to a lot more than just the math research community.

For some insight into one of her main reasons for going to Perimeter, note that she has a blog:

http://listeningtogolem.blogspot.com/

8. **Jim Given**
April 16, 2018

Peter, by coincide, I am only now reading the very excellent essay by Roger Howe, "On the Role of the Heisenberg Group in Harmonic Analysis," which I'm sure you are familiar with.

9. **Michael Gogins**
April 16, 2018

Thank you for the link to Marcolli's blog. I read the two most recent posts. She is certainly alarmed, and alarming, and the blog does give insight into her paranoid-sounding remarks.

There seems to be a common thread here with Grothendieck's political attitudes…

As for myself, I am certainly very alarmed, but I don't think as much so as Marcolli.

10. **Jim Given**
April 18, 2018

Prof. Marcoli gave a lecture on creativity and mood disorder that may be valuable to many in the research math community:
http://www.its.caltech.edu/~matilde/DarkBrightness.pdf

11. **S**
April 18, 2018

I read Marcolli's essay. I found it interesting, but also quite frustrating. There is a very great deal of talk about the violence and cruelty of the mathematical community and of (most, it seems) mathematicians, but a great lack of detail as to what form this cruelty might take; which certainly would be of enormous interest to those of us who might wish to try to do anything about it. It is quite upsetting that Marcolli has had such painful experiences; but as there is very little content about the form of any of those experiences, there is little I can say except that — it is quite upsetting that she has had such painful experiences.

The exception would be where she discusses the putting away of books, which is quite a specific complaint, and one that I vigorously agree with.

12. **LMR**
April 20, 2018

Michael Gogins,

Marcolli has something in common with Grothendieck's parents, who surely had a profound influence on his worldview.

S,

For what it's worth, the essay corroborates some of the rumblings of disaffection, which I've heard a while ago, that were coming from the field in which she was active.

13. **Jim Given**
April 21, 2018

Some people seem to be genuinely troubled (reasonably so) at Prof. Marcolli's talk of "violence" within the mathematics community. For example her dismissal (from IHES?; from Connes' research group?) is described as "violent" in her blog.

It seems relevant here to note that, while Marcolli's art provides a playing-with, and an ironic commentary upon Modernist art; her commentary is pure Postmodernism, with its recondite code of "marginalization"; "the Other"; "violence" and other standard terms of reference in the Postmodernist discourse. In brief, "violence" need not mean what it would mean in e.g. a police report. In context, one has per se no warrant for any assumption that it does.

14. **LMR**
April 23, 2018

Jim Given,

IHES? Marcolli never had a position there. She was at the MPIM in Bonn. I think she made it very clear in the essay Peter linked to above that it had everything to do with her being ostracised by some in the noncommutative geometry community, about which I had heard of some internal troubles brewing during the time Marcolli made the move to Caltech.

15. **Jack Morava**
April 29, 2018

I only now became aware of this thread, sorry for not writing sooner. I don't know MM well; we've met from time to time and we've corresponded occasionally. She is a major mathematician, a significant original voice, and I have the greatest respect for her and her work. [Cf eg https://arxiv.org/abs/hep-th/0411114 for an example from some years ago.] She deserves to be taken very seriously.

16. **LMR**
May 3, 2018

Jack,

I'm sure everyone here has the greatest respect for Marcolli and her work. I'm certainly in awe at the eclectic nature of the mathematics she's done so far, not to mention her concurrent productivity in her artistic pursuits as well. On the other hand, it's rather heartbreaking – though also insightful – to read in her essays (URLs supplied by Peter above) about the obstacles she's had to overcome, in order to achieve the success she's had.

17. **former mathematician**
May 3, 2018

Tom Lehrer is the source of the ironic phrase "in our copious free time." It is from the patter introducing "It makes a fellow proud to be a soldier."

18. **Jack Morava**
    May 3, 2018

    @ LMR: I agree completely, thanks.

19. **cedric bardot**
    May 7, 2018

    To provide justice or – in a less "Postmodernist" way for Jim Given 😉 – to pay a fair tribute to the mathematical- physics work of Mathilde Marcolli, it could be worth quoting explicitly her partnership with Connes in the exploration and distillation of space-time and the geometric setting of prime numbers, chasing in parallel nothing less than the Rieman hypothesis and quantum gravity. Following the tracks made by the falks who build the standard theory of Yang-Mills-Higgs interactions in the quantum world and walking in the steps of Grothendieck motives, they delivered in common an ambitious and dense book : "Noncommutative Geometry, Quantum Fields and Motives" that must not have been easy to write. This tremendous work should have heightened the unrest created by necessary compromises due to different points of view or conflicting agendas not to mention the meeting of two strong inspirational but not necessary complementary personnalities.

    For instance Connes has never hidden his skepticism about supersymmetry, string theories or loop quantum gravity and wants to keep forging ahead his spectral non-commutative geometry (NCG) project. On the opposite Marcolli has always been willing to build bridges between NCG and the other speculative ideas in theoretical physics. Her last book on "Noncommutative Geometry" is a very nice example of this inclination (the first chapter is free of charge at the Publisher website and is worth reading as a fresh review https://www.worldscientific.com/doi/pdf/10.1142/9789813202856_0001).

    Mathilde Marcolli is definitely a ronin of noncommutative geometry (http://siddhartadevi.blogspot.fr/2009/03/science-frictions-and-ronin.html). Her math will not go away for sure and time will tell if her contributions to physics will find a path to the validation by experimental research. Working in a closer relationship with the Perimeter Institute may definitely help her to convince more physicists – thanks to her past (or future?) work – that the Higgs boson from attospace (and possibly dark matter at cosmological scale!) is (are) spectral noncommutative geometry staring us in the face…

20. **cedric bardot**
    May 7, 2018

    My apology for misquoting the title of Marcolli's last book which is "Noncommutative Cosmology".

Losing the Nobel Prize

April 19, 2018
Categories: Book Reviews

There's a fascinating new book just now appearing in book stores, Losing the Nobel Prize, by astronomer Brian Keating. An excerpt from the book is available at Nautilus, with the title How My Nobel Dream Bit the Dust. Some reviews that are out are here, here, here and here. Sabine Hossenfelder is not too happy with the book (response from Keating here).

Much of the book is an excellent explanation, from the beginning, of a significant part of the current state of cosmology. It does a good job of even-handedly explaining the controversy over the scientific status of inflation and the multiverse, giving Paul Steinhardt's views equal billing with those of multiverse enthusiasts like Guth and Linde. It's written from the point of view not of a theorist, but of an observational astronomer, and thus explains well some of the details of the current state of the technology being used. Much of the book is about the BICEP telescope, operated in the hostile environment of the South Pole.

One of the strongest aspects of the book is that it is also the memoir of a life and a profession, giving a very personal take on what it's like to get interested in astronomy as a kid, then grow up and pursue a career in the field. Keating's book is very much in the tradition of Watson's *The Double Helix*, giving a portrayal of himself and others that doesn't leave out the very human aspects of ambition, competitiveness and jealousy.

Unlike the Watson book, which is about a great scientific achievement, the unusual aspect of Keating's story is that what he was involved in was not a success, but the biggest fiasco in the history of his field. On March 17th, 2014, the New York Times reported on its front page that Space Ripples Reveal Inflation's Smoking Gun, and this same story was reported by most media outlets. This was based on results from the BICEP2 telescope unveiled at a press conference at Harvard (press release First Direct Evidence of Cosmic Inflation). At the press conference, PI John Kovac claimed that the chance the results were a fluke was only one in 10 million.

I wrote several blog postings about the story as it evolved, you can find them here, here, here and here. The BICEP2 result was often portrayed as a definitive experimental vindication of the multiverse, which was one reason I was writing about it. By the later postings, I was covering the story of the collapse of the BICEP2 claims, as it became clear that what they had measured was a signal coming from dust in the galaxy, not from primordial gravitational waves.

Keating's insider account of what happened makes clear that the true story is that the BICEP2 telescope, because of the way it was designed (sensitive to only one part of the sky at one frequency), was never capable of distinguishing primordial gravitational waves from dust. They were in hot competition with the Planck satellite collaboration, which did have the capabilities needed to distinguish the signal they were seeing from dust, and was generally assumed to be the experiment with the best chance of seeing primordial gravitational waves. BICEP2 could have released its data, making clear that it might be primordial gravitational waves or it might be dust, that Planck would need to weigh in to decide. This would have made a splash, but probably not a front-page one, and if the gravitational wave signal was real, Planck would have shared in the glory of identifying it.

Instead of behaving responsibly, the BICEP2 collaboration found arguments to convince themselves that the dust could not be a problem, arguments which included scraping data off a slide of a preliminary Planck result presented at a conference (while, it seems, misunderstanding the significance of the data in that slide). Keating gives a very defensive explanation of how this happened, claiming that he was well aware of the danger that the signal was just dust. About Planck, he writes

> We desperately tried to work with the Planck team, while being careful not to tip them off as to what we'd found… The Planck team wouldn't cooperate.

which I guess really means "we desperately tried to rip them off, but they weren't that dumb." While he had these concerns, in the end he decided to agree (as did the whole collaboration) with the tactic of writing a paper claiming dust wasn't a problem and going public with an aggressive and heavily promoted discovery claim.

The cost/reward computation they were engaged in when they decided to go public with a problematic claim involved two possibilities:

- Planck data would show the dust was not a problem. If this was the case, BICEP2 would be the people who found the primordial gravitational waves, Planck the losers who measured some boring dust.
- Planck data would show that the signal was dust. This would be embarrassing, but, this is America, and all publicity is good publicity, right?

As far as I can tell, the BICEP2 scientists haven't suffered much professionally from the fiasco. When David Spergel talked here at Columbia about the subject, he noted that this hadn't stopped the PI, John Kovac, from getting tenure at Harvard. In the book, Keating mentions some "embarrassment and guilt", but no negative professional consequences, instead explaining how a few months later Jim Simons came to him to offer to fund a next generation observational program (the Simons Observatory, of which he is now Director) to be built in Chile. The Nobel Foundation in 2015 was contacting him to request him to nominate candidates for 2016. Keating does write that he thinks the BICEP2 story shows that scientists should be given some formal training in ethical norms, but at the same time he makes clear that violating such norms sometimes provides significant rewards, with few penalties.

A major theme of the book is Keating's obsession with the possibility of winning a Nobel Prize as well as long discussions of what's wrong with the way Nobel Prizes are awarded and what he feels should be done about this. On some of these issues I agree with him. In particular, the Higgs discovery story makes clear the problem with awarding prizes only to individuals, not collaborations. You end up with a prize not for the most important experimental discoveries in physics, but for the most important discoveries made by experimental groups with a small enough list of high profile leaders.

Sabine Hossenfelder's review was quite hostile about Keating's complaints concerning how the Nobel Prize is operated, for reasons I didn't understand until I read the book. It's very hard to have much sympathy for Keating's recounting of his many Nobel-related jealousies and resentments. In particular, even if there had been no dust, he was never really in the running for a piece of the BICEP2 prize nomination since he had been pushed out of a leadership role due to his involvement with a competing experiment. He still seems bitter about this and gives the impression that this is at the root of his complaints about the Nobel. One suspects that if there had been no dust and he had been given more prominence in BICEP2, after his trip to Stockholm he'd instead have written a book describing the Nobel Prize as the most well-designed and enlightened thing in the world. Instead of owning up to mistakes and writing a post-mortem about lessons learned and what to do about them, Keating's choice to instead write a book blaming the Nobel Prize committee is a peculiar one.

Update: Keating has a Losing the Nobel Prize website, dedicated to promoting reform of the Nobel Prize along the lines suggested in his book.

Update: Not content with using notoriety achieved through incompetent and unethical scientific behavior to launch a bizarre and incoherent campaign against the Nobel Prize, Keating is taking to right-wing media outlets to attack the atheism of his fellow scientists, see here and here. I'm afraid that on the multiverse issue he has the stronger argument: multiverse proponents are making a huge mistake using that to go to war with religion.

Comments

1. **DrDave**
   April 19, 2018

   I wonder how many in the print and online media printed a full retraction.

2. **lun**
April 19, 2018

It is interesting to compare BICEP2 to OPERA, from the experimental angle.
OPERA made a highly non-trivial error, which took months of expertise to understand properly. Their release was relatively cautious (inasmutch as it is possible with such a claim), yet when the error was found the collaboration really suffered (the spokesman had to resign). BICEP2… well, the blogpost above says everything that need to be said.
Why such a difference?

3. **Richard Easther**
April 20, 2018

With regard to BICEP2 and OPERA, part of what gets overlooked in some of this is that BICEP2 had done lovely work — they had great data at far higher sensitivity than any previous polarisation experiment, if I am recalling things correctly; the analysis was flawed but the data was good.

Conversely everything OPERA announced evaporated and even the hint of a claim to have found superluminal particles is a far larger deal than detecting a primordial B-mode 🙂 Not really making a judgement as to whether either outcome was fair, my own sense was that the OPERA announcement did attempt to have a dollar each way on the outcome; it was a bit too much "I'm not saying aliens" for my taste, but there are big differences and well as parallels between the two cases.

4. **tulpoeid**
April 20, 2018

So, this is a fascinating book not for the reasons its author thinks it is.

The professional benefits that BICEP2 collaborators have received, from the spokespersons down to the last student, and the impossibility of having them retracted is phenomenally annoying. If Keating is complaining about how a single prize determines research (ehm… does it really?) then he'd better complain about tycoons determining research by handing out money to people from failed experiments. But who am I to judge a heavily promoted academic.

(PS: OPERA's claim was a crazy one by current standards, and their release was not cautious, like, at all.)

5. **Another Anon**
April 20, 2018

I remember OPERA were much more cautious about their claim, raising serious doubts and asking for other groups to check their results. I remember wondering at the time why it had such a destructive effect on their team when the loose cable was found (note: a loose cable is an unfortunate accident, but making a decision to scrape data off a slide and go the max publicity route with press releases and doorstep videos is not an accident).

Truth is, sorry to say, I think they had a ton more scientific integrity than the BICEP team, hence the difference in their methods of presenting their results. I found this: "Some OPERA team members thought the whole episode had besmirched the collaboration's reputation", hence the resignations even though it was an accident, whereas I remember the BICEP team carrying on as if nothing bad had happened, indeed, treating it as an opportunity to push for funding for a bigger telescope. Plus an opportunity for Andrei Linde to change his story and say that B-modes were not important for inflation after all.

6. **Peter Woit**
April 20, 2018

DrDave,
My impression is that some media outlets later put out stories like "questions raised about BICEP2 results", placed much less prominently than the initial stories. PRL referees saved the BICEP2 people from themselves by getting them to remove the worst of their mistakes. If the referees had quickly let the paper through, likely the paper would have had to have been formally retracted.

lun,
I did some searching around for examples of any apology from the BICEP2 people or negative effects on any of their careers, could find nothing. A quite remarkable fact is that Kovac's Wikipedia entry still has the following as description of his career:

"He is the principal investigator of the BICEP2 telescope, which is part of the BICEP and Keck Array series of experiments.[3][4][5] Measurements announced on 17 March 2014 from the BICEP2 telescope give support to the idea of cosmic inflation, by reporting the first evidence for a primordial B-Mode pattern in the polarization of the CMB.[6][7][8] If confirmed, this measurement provides a direct image of primordial gravitational waves and the quantization of gravity."

Looking around for statements from Kovac post-fiasco, I couldn't find anything from him acknowledging that BICEP2 had done anything wrong, see for instance
https://www.ozy.com/provocateurs/john-kovac-found-the-holy-grail-of-cosmology-and-then-didnt/39632

7. **Peter Woit**
April 20, 2018

Thanks to XOR'easter for fixing somewhat the Kovac Wikipedia page.

8. **Tony Verow MD**
April 20, 2018

This is a fascinating blog post. I am certainly no expert on astrophysics so I can't weigh in on the minutiae. I do wonder though if it would have been possible for the BICEP2 folks to have a third party review their work and it's extraordinary claims before submitting it formally to the peer review process. I get the sense from the blog post that they were far too deep into their scientific process to be throughly objective about drawing conclusions. Not being critical, just wondering if an aloof reviewer might have helped shepherd the conclusions a bit more. Perhaps this was not a realistic thing to do secondary to time and publishing pressure…..not to mention Nobel aspirations!!

9. **Peter Woit**
April 21, 2018

Tony Verow,
Keating doesn't really address at all the question of why the dust estimates BICEP2 used were so wrong. Part of the story is surely that they wanted to believe low dust estimates.
Since their experiment was inherently incapable of distinguishing dust, likely they themselves had little expertise in the dust issue. They should have been getting outside help on this, but perhaps the people with this expertise pretty much all were associated with competing experiments like Planck that could do dust measurements. BICEP2

did not want the competition to get wind of their result, out of fear that they would get scooped, so they weren't about to consult outsiders.

10. **Tim May**
April 22, 2018

My recollection of the BICEP2 thing is perhaps different from others. I remember the repercussions of the episode more clearly than the initial announcement.

I'm thinking of seeing some videos of "random knocks on the door" of people in Palo Alto (Linde and his wife) which were clearly staged (they both appeared at the door) and then the denounment (sp?) a few weeks later that the results were not what they had initially been thought to be.

My recollection was that science worked.

I think the retraction worked better than expected, in other words.

11. **Peter Woit**
April 22, 2018

Tim May,
The video you are thinking of is here:
https://www.youtube.com/watch?v=ZlfIVEy_YOA
It was put on YouTube by the Stanford press office, has over 3 million views. It is still there with original text claiming discovery, has not been updated with the news this was just dust. The same is true of the linked Stanford web page with story for the public and the press (no retraction there). This page links to the Bicep/Keck collaboration web page. Nothing on their web page anywhere acknowledging that their original claims were a mistake.

Yes, science worked, but with no help from the BICEP2 people. Their attitude seems to have been (and continue to be) that there is nothing wrong with making highly publicized and hyped discovery claims that turn out to be bogus, because other people will clean up your mess if you are wrong (and, it's all the Nobel committee's fault for making you do this…).

12. **ay**
April 22, 2018

This is the first time I have watched the video. It was squirm-inducing. I also thought that it was impolite to refer to Linde as "the founding father of inflation".

13. **S**
April 23, 2018

I've always felt a little bad for Linde, though. I have my issues with various of his behaviors, but it does appear to me (unlike Tim May) that, in this instance, he was genuinely surprised, and on video, and that he actually tried a little bit to be cautious ("Let us hope it is not a trick,") and still to some degree got laughed at in public through actions entirely of others.

14. **Another Anon**
April 23, 2018

It's always best to simply present your result in the literarature, not to push it too hard, let momentum build over time as it's importance is understood. There's nothing worse than some scientists endlessly trying to sell their result, which they are convinced is so important. We're not salesmen, we're scientists. We've got class.

15. **Low Math, Meekly Interacting**
April 23, 2018

I'm with Tim May. Exhorting one and all to meet the highest ethical standards is a worthy cause that I won't debate. But the practical reality has always been, and likely will always be, that if an incentive structure exists that rewards bad behavior, then there will be bad behavior. Science often works well when human competitiveness (which is also part of the bad incentive structure) can be harnessed as a kind of innate immunity…so long as there is an objective standard by which the results of competitors can be judged. To the extent we continue to value accurate accounting of natural phenomena over some alternative, scientific inaccuracy is something humanity can cope with.

Of course, it helps a lot when the natural phenomena in question can be observed. Lose observable reality, in the conventional sense, and you lose science, as far as I'm concerned. Here, fortunately, science really did work. It doesn't have to be pretty.

16. **Peter Woit**
April 23, 2018

LMMI,

My problem really isn't with the ethical issues of how scientists compete with one another to do science (although, when caught very publicly doing something unethical, it would be nice if the people involved would at least say they were sorry…). The unusual part of this story was the full-court press by scientists and their institution's press offices to promote a bad scientific result and get it on the front page of the New York Times, coupled with a seeming complete lack of concern once it became clear that what was being promoted was an epic fail. For instance, I don't think there's any conceivable excuse for the BICEP2 people and the Stanford press office not taking down that YouTube video, or at least editing the associated text to explain what happened.

17. **srp**
April 23, 2018

Perhaps this thread will move the Stanford press office to clean things up.

18. **S**
April 24, 2018

Perhaps taking it down could be construed as somehow covering their tracks? I think editing the text seems like the best solution.

19. **piscator**
April 24, 2018

This isn't complicated. If you submit a paper to a high-profile journal, get it accepted, put out a snazzy press release to accompany the publication of the paper, and then it all ends up falling apart because the results evaporate, *THAT* is how science works – and such a route is still filled with large egos and dreams of glory.

If you announce the result via a press conference *BEFORE* having the paper accepted in a journal then *you have to be correct* and there are no excuses for error. There can't be any pleading afterwards that this is the scientific process in normal operation, because it's not.

This whole episode was an embarrassment and it should have had measurable negative effects on the careers of those involved. It didn't.

20. **Peter Woit**
April 24, 2018

srp,
I don't think the problem is the press office, it's the BICEP2 scientists. Looking through all their various current webpages about their work, it's nearly impossible to find anything that explains their heavily publicized results were wrong. The closest thing I could find was this:
https://kipac.stanford.edu/research/projects/bicepkeck-array
which tells us
"BICEP2 detected this B-mode polarization in its three year data set with a strong significance. Interpreting this as primordial gravitational waves, this places a constraint on the tensor to scalar ratio at r=0.20+0.07/-0.06. This is strong evidence for cosmic inflation, as well as the first direct image of gravitational waves, and direct empirical evidence of quantized gravity. However, the joint analysis with Planck satellite data followed and showed that the galactic dust seems to contribute much of this B-mode polarization measured by BICEP2. "
No admission there was any problem with what they did in March 2014, and "seems to contribute much" is highly misleading.

21. **Shantanu**
April 24, 2018

Does anybody know when Planck, SPTpol and ACTpol are coming out with their own results for r?

22. **Low Math, Meekly Interacting**
April 24, 2018

To be clear: I pretty much agree with everything said. There's no excuse.

Maybe my expectations have hit rock bottom, but I'm encouraged that we aren't in a branch of the multiverse where BICEP2's results are being touted as proof thereof, or anything else of interest beyond cosmic dust backgrounds. There was a better experiment, a joint analysis, and no one need consider the question of primordial B-mode polarization in the BICEP2 data set ever again.

The fact that "science worked" is still a remarkable thing, I guess. Given that Keating and his ilk really are out there, it's something to be thankful for, at least a little.

23. **A.J.**
April 24, 2018

I am reminded of a story I once heard about Leo Kadanoff. Apparently, on the day Ken Wilson was awarded the Nobel prize, Kadanoff showed up in the department wearing a three-piece suit. When asked why he was wearing such a thing, he laughed and replied, "Well, it's not every day you don't win a Nobel Prize."

24. **william e emba**
April 24, 2018

The fiasco was partly bad luck. The Planck-scraped data were preliminary results regarding dust levels, based on an area of the sky far from where BICEP2 was looking. There were no criticisms until more preliminary Planck information revealed that other areas had somewhat higher dust levels, generating warning flags to the BICEP2 extrapolation. Ultimately, the dust levels where they were looking turned out to appear at the same magnitude of the purported B-modes.

However, it is just as premature to state that BICEP2 actually observed dust as it had been to claim they observed B-modes. It is currently unknown what the BICEP2 data represents, as they only measured one frequency. BICEP3 is measuring several frequencies, and combined with the BICEP2 data, they should be able to tease out the difference between B-modes and dust.

As for ethics, that's one big minefield. I neither agree nor disagree with the ethical criticisms of the BICEP2 collaboration. There are those that claim that all data, all preliminary deductions, and so on, ought to be shared promptly with the scientific community, instead of hoarded to maximize the original researchers' return on investment, as is commonly done. From that point of view, the Planck collaboration was in the wrong.

25. **milkshake**
April 25, 2018

That radio talk is pretty disturbing – he is hinting that scientific bias and groupthink of his colleagues in cosmology are actually rooted in their leftist politics and their godlessness. Then he explains how the Nobel committee is so non-transparent and possibly also unethical, and unwilling to listen. He goes on and on how Nobel is essential to the right functioning of science, and how he was elbowed out from the BICEP collaboration by his fame-thirsty colleagues who wanted maybe the Nobel for themselves… And I don't understand what Torah has to do with anything in his field unless he wants to win Templeton instead.

26. **Chris Oakley**
April 25, 2018

Kadanoff's statement seems to be missing "… when you expected to" at the end – I expect every day of my life to be a day that I do not win a Nobel Prize, and yet rarely wear a three-piece suit.

I cannot speak for other fields, but definitely feel that exaggerated regard for this particular trophy is part of the problem in high-energy physics. Following the 1979 Glashow, Salam, Weinberg award HEP theorists seem to have wasted inordinate amounts of time building models as Nobel Prize lottery tickets instead addressing the real underlying problems of quantum field theory.

27. **Peter Woit**
April 25, 2018

william e emba,
According to Spergel and others, the problem with the BICEP2 use of the Planck preliminary data was not that it was preliminary, but that they ignored the notation "not CIB subtracted" on the slide. If they had taken that into account, they would have found that it implied their result could easily be just dust. This wasn't bad luck, it was incompetence.

What BICEP2 was trying to do with Planck was get access to their unpublished data that they needed, without them finding out that they had interesting unpublished data. You can make the argument that all experiments should share unpublished data, but that's exactly what BICEP2 was trying to avoid (what they ended up with, a shared analysis with Planck). Yes they were unlucky, in the sense that they didn't get away with this.

The attempt to argue that maybe BICEP2 was right is nonsense. They claimed observation of r=.02, not sure what current limits are, but they're below r=.01.

28. **Peter Woit**
April 25, 2018

milkshake,

That is disturbing. Watching things in this field go from bad to worse, ending up with multiverse mania, I've always thought something like "at least it can't get worse than that". This makes clear there is something worse possible: multiverse pseudo-science becoming part of our culture's sad descent into tribalism and culture wars.

29. **Cobi**
April 25, 2018

"I'm afraid that on the multiverse issue he has the stronger argument: multiverse proponents are making a huge mistake using that to go to war with religion."
Are "multiverse proponents" really doing this? From the video you linked it seems more like Keating is the one building a fake dichotomy between the multiverse and god.

30. **Peter Woit**
April 25, 2018

Cobi,
For one of many examples, see for instance
https://www.preposterousuniverse.com/writings/dtung/

31. **GoletaBeach**
April 25, 2018

Humans will be human. Nobel Prizes are a sociological phenomenon… not a scientific one. Science doesn't need them, but they do motivate some humans to discovery, and motivate other humans to jealousy.

Humans, not science, decide funding priorities.

Was it Benjamin Graham, a stock analyst, who said… in the short turn, the stock market is a popularity contest, and in the long run, a weighing machine? In the short run publicity and politics do decide science funding and priorities, in the long run, science *should*. And, I might add, in the long run, we are all dead.

Short run decisions will always be error-prone. It is up to all of us to focus on the science in the long run, and get better results. And seems to me in the B-modes, science did win in the end. I can forgive and overlook all the wrong BICEP hype… it is part of the short-term transient of human error.

I think Keating and BICEP also warrant a fair amount of forgiveness, and it doesn't really bother me that Kovac has tenure.

Fermi's Nobel Prize was partially for the discovery of the new elements Hesperium and Ausonium, which were flat wrong. Ida Noddack even pointed out the flaw in Fermi's arguments, prior to the Nobel Prize. Science lost in the short term then.

But Fermi's techniques of neutron bombardment still were a stunning advance in science. BICEP also got the ball down the field.

Keating ain't my favorite guy. As the old saying goes, though, sometimes it takes a pig to find a truffle. But, as truffle hunters know, the pig usually eats it, which is why dogs are used by truffle hunters. Yup, we experimental scientists are just pigs and dogs.

But in the long run, with concerted effort, a few truffles can be found, not eaten, and actually discerned and appreciated by everbody. I hope.

32. **Stephan**
April 27, 2018

GoletaBeach says: "Humans will be human."

Well, then, when hyping their BICEP2 results in a scientific journal and in the scientific press and in science departments, the Kovac et al. should have stated that they arrived at the results not as scientists, but as humans. They should have warned the unsuspecting public.

33. **Jim Given**
April 28, 2018

Perusal of the "educational" channels on TV, e.g. AHC, will show the multiverse frequently being used as part of the large pagan web being spun by those channels. In brief, multiverse beliefs are used to legitimize and "scientize" Heaven, the Hereafter, alternate realities, etc. This web of contrarian belief, typified by the vast mythology of the Ancient Aliens series, is a continuation of the New Age writings of the 1970's. Historians will note that all of this is a recurrence of the Spiritualism of the early Twentieth Century. But like a previous commentor, I see little warrant for blaming the multiverse proponents for such exploitation.

April 30, 2018

Stephan said: "Well, then, when hyping their BICEP2 results in a scientific journal and in the scientific press and in science departments, the Kovac et al. should have stated that they arrived at the results not as scientists, but as humans. They should have warned the unsuspecting public."

I'm not aware of a single scientific result that was arrived at by anybody other than a human. Therefore, I don't think there was any need for the BICEP2 folks to make a distinction. We all know they are merely error-prone humans. We all know science is done exclusively by error-prone humans. I tend toward forgiveness for the errors. Stephan, if you don't want to forgive, that is fine, your choice.

37. **Peter Woit**
April 30, 2018

S,
Gross, like many string theorists, has a long history of arguing that "spacetime is doomed", that string theory will lead to some new fundamental theory in which spacetime is not fundamental, but an emergent concept. I think he'd readily admit though that there never has been a convincing specific implementation of this idea. These days people are trying to get spacetime as emergent using entanglement/holography ideas, I'd be curious to hear his take on those.

As usual, I'm less interested in speculation about quantum gravity than in speculation about particle physics. I may be in Princeton on Thursday, and go to Gross's second talk, see here
https://phy.princeton.edu/events/hamilton-colloquium-series-david-gross-kavli-institute-theoretical-physics-uc-santa-barbara
If I do, I'll try and write about it here, and if anyone goes to the first talk and wants to report here, that would be an excellent place to do so.

38. **Jonas Nyman**
May 3, 2018

Most criticism of the Nobel prize is just based on simple misunderstandings. No, the Nobel Foundation would never ever send letters to anyone asking them to nominate. The Nobel Committees (one for each prize) do that, and they send out thousands of such letters, so getting one doesn't imply anything… Finally, the Nobel prizes are awarded according to a set of rules and criteria. The most important are the ones specified in the will of Alfred Nobel. These obviously cannot be changed! The will forbids awarding groups or institutions, the peace prize being an exception. In fact, according to the wording of the will, it is not the people that are being awarded, it is the discoveries. When the Nobel committees decide on the prizes, they first decide which discovery shall be awarded, and only then do they decide on the individual(s). Besides the will itself, there is an agreement between the executor of the will and the Nobel family, which clarifies some things that the will does not make any recommendations on. For instance, it was agreed that a prize can be split between two or three individuals, and it sets out rules for who are eligible to nominate.
The purpose of the Nobel prize is to honor the last will and testament of Alfred Nobel. It makes no sense for random people to have opinions about how he wrote it.

39. **Jim**
May 6, 2018

I remember the URSI meeting in Boulder in I think January 2012, when I counted at least 9 different experiments all trying to measure B-mode polarization in some form, through different means. I thought (and still think) this was an absurd allocation of resources, but then I don't get to make such calls.

The two big considerations were what l (basically angular frequencies) you'd be sensitive to (Planck and BICEP were complimentary in this regard), with what colors, and how well you could eliminate the foreground dust. One experiment's goal, and it may have been BICEP/Keck Array, was to just measure the B modes first. If they could, then they could figure it out later if the signal was from dust or not. If you couldn't, you put an upper limit on what was there to be detected. I don't think anyone in that room thought it really would have even been detected within two years. I left my somewhat related field permanently shortly thereafter

I was very surprised by the early 2014 announcement. Having known and worked nearby a lot of the members, though not Keating, I thought there was no way they would make such a claim without thorough rejection of the dust hypothesis. Everyone I knew thought the B-mode signal from dust would dominate any cosmic signal. So I thought they must have very strong evidence, but, having left the field already, I really couldn't investigate. I must say, the unraveling did not surprise my intuitions, but it did surprise me that the people who made the claims had done so with such disregard for prudence and caution.

I think a lot of this had to do with 9 separate, or largely separate, groups all doing the same thing. How in the world is having so much funding going into these areas a good thing? Everyone just picked up on the hot topic of the day and raced into it. Any idea how to fix that?

Physics News

April 30, 2018
Categories: Uncategorized

Various physics-related news:

- The LHC is back in business doing physics, with intensity ramp-up for the 2018 run ongoing. Today the machine is colliding 1551 bunches of protons, ultimate goal is to get to 2556 bunches. They are at least a week ahead of the planned schedule, which would have only reached 1200 bunches next week.
- There's a conference going on at the KITP this week, discussing the latest state of dark matter theory and experiment. By the way, see here for how prominent theorists communicate these days instead of using email…
- At the Atlantic and Knowable Magazine, Tom Siegfried provides yet more multiverse coverage. Seems that he's at work on a multiverse book.
- At the Edge, Sabine Hossenfelder has an on-target analysis of the situation in fundamental theoretical physics. The problems she points to are ones that motivated books by Lee Smolin and myself back in 2006. Things haven't improved since then and I hope she'll have better luck generating concern for these issues than we did.
- At Alta, Jennifer Ouellette has a fascinating account of the maneuverings for credit among the many observers of the neutron star merger last year. It sounds like some of those involved are suffering from the same disease as Brian Keating: not reality-based conviction that they're in the running for a Nobel Prize.
- Director Claire Denis is now at work on a sci-fi movie entitled High Life that sounds more promising than the last black hole movie. She's getting scientific advice from Aurelien Barrau and comments:

> If there are theories about me, I'd rather not know. Astrophysics – now that's fascinating. String theory, worm holes, the expanding universe, the Big Bang versus the Big Bounce – those are the kind of theories that make you feel like living and understanding the mystery of the world. Film theory is just a pain in the ass.

Update: One more. David Gross will be back in Princeton this week, giving talks on gravity and particle physics. I may head down Thursday to revisit scenes of my youth.

Update: I just watched some of the KITP dark matter "debates", see here. Highly recommended if you want to hear informative exchanges between experts on the subject, see especially the Dan Hooper talk (and the MOND/dark matter debate here).

Update: For machine learning experts who want to try their hand at an HEP data analysis problem, a Kaggle competition to build a track reconstruction algorithm opened yesterday. For details, see here and here.

Update: Gross's Princeton talk on the "Future of Particle Physics" was not much different than this one from a couple years ago (with the enthusiasm for supersymmetry deleted). I was thinking of writing something about this, comparing it to similar talks from way back when (see for instance here). Probably better though to wait for a better opportunity to write something substantive about where the path followed by Gross and others over the years has ended up.

Update: Video of the David Gross Princeton talk on the Future of Particle Physics is available here.

Comments

1. **Dave Miller**
   May 1, 2018

   Peter,

   Bee Hossenfelder's analysis of the sociology of physics, to which you linked, is one of the clearest explanations I've seen: I urge everyone to read it.

   Incidentally, much of what Bee writes was anticipated by Szilard in his little satire, "The Mark Gable Foundation," published in his *The Voice of the Dolphins and Other Stories*, which is also well worth reading.

2. **Azadi**
   May 2, 2018

   Peter,

   I was wondering if you had seen today's latest news item about the late Professor Hawking's final paper, in which he apparently disclaims the string-landscape multiverse (i.e. with the different laws of physics applying in the pocket universes, courtesy of M-Theory) in favour of Tegmark's "level 1" multiverse (an extension of our own, all having the same physical laws and physical constants).

   I haven't read the original text, so I am basing this upon the media accounts.

   The reports, somewhat irritatingly, appear to be exaggerating the significance of this: as if Hawking, in this paper, was making a ground-breaking assertion that significantly moved the field on, in terms of explaining the so-called fine-tuning problems without recourse to a mere probabilistic, selection effect that has no predictive power.

   But I'm glad, at least, that Hawking's last piece of research appears to have taken a stab at the string-theory-multiverse mania.

   See:

   https://www.theguardian.com/science/2018/may/02/stephen-hawkings-final-theory-sheds-light-on-the-multiverse

   "…Reality may be made up of multiple universes, but each one may not be so different to our own, according to Stephen Hawking's final theory of the cosmos.

   The work, completed only weeks before the physicist's death in March, paints a simpler picture of the past 13.8 billion years than many previous theories have proposed.

   Published on Wednesday in the Journal of High Energy Physics, the new work is the result of a long collaboration with Thomas Hertog, a Belgian physicist at the Catholic University of Leuven. "We sat on this one for a very long time," Hertog said. "I do believe he was really fond of it."…

In the latest work, Hawking and Hertog challenge that view. Instead of space being filled with pocket universes where radically different laws of physics apply, these alternate universes may not actually vary that much from one another…

“In the old theory there were all sorts of universes: some were empty, others were full of matter, some expanded too fast, others were too short-lived. There was huge variation,” said Hertog. “The mystery was why do we live in this special universe where everything is nicely balanced in order for complexity and life to emerge?”

“This paper takes one step towards explaining that mysterious fine tuning,” Hertog added. “It reduces the multiverse down to a more manageable set of universes which all look alike. Stephen would say that, theoretically, it’s almost like the universe had to be like this. It gives us hope that we can arrive at a fully predictive framework of cosmology.”…”

3. **Fred P**
   May 2, 2018

   “For machine learning experts who want to try their hand at an HEP data analysis problem…” – This limit shocked me:
   “The software … should run on a i686 processor with 2GB (tbc) of memory.” source: https://sites.google.com/site/trackmlparticle/

   The i686 is a more than 22-year old processor (evidence: https://en.wikipedia.org/w/index.php?title=P6_(microarchitecture)&oldid=837000310) in a field where the main recent improvements rely heavily on much more modern hardware to take large problems and get results in reasonable timespans. Here’s a somewhat dated summary if you’re interested: https://blog.algorithmia.com/hardware-for-machine-learning/

   I am unclear that they will get useful results from this competition. Either the environment they’ll need will be radically different from the one they’re testing in, thus skewing any results to ones that may be sub-optimal for their purposes, and/or they’ll have to run using toy datasets that may have dubious applicability to the problems they are interested in.

4. **Peter Woit**
   May 2, 2018

   Azadi/Doolittle,
   I was trying to ignore this, finally gave in (see the latest posting).

5. **Carlos**
   May 4, 2018

   Dave,
   Thank you for mentioning Szilard’s nice piece (from 1948!). It’s one of the best science satires I’ve read in a long time, and it should definitely be more widely known. It makes us really wonder how far back has science started to become sick. “Off your teeth!”

6. **fg**
   May 4, 2018

   to Fred P: my guess regarding this constraint is that this software would be run as part of very high level triggers, very close to the detectors themselves, where only radiation hardened electronics can survive. And the best way for electronics to be robust against radiation is to have rather big transistors (much larger than the current state of the art in miniaturization).

7. **Anon**
   May 4, 2018

   fg: I don’t know the reason for i686 condition but the higher level triggers of the LHC experiments are on the surface, so radiation is not the reason. The experiments update their computing every year or two with several thousand of the latest computers, and are either using already or developing GPU systems for the future.

8. **fg**
   May 5, 2018

   Anon,
   My bad… I meant low level triggers. Having tracking information in these early triggers would open up new ways of selecting some rare events.

9. **Jan Dybicz**
   May 7, 2018

   Peter,

   Is there a video of David Gross’s two Princeton talks available?

10. **Peter Woit**
    May 7, 2018

    Jan Dybicz,
    Not that I know of. At the talk I attended, there was video being recorded, don’t know where/when it might appear publicly.

This Week's (Stale) Hype

May 2, 2018
Categories: Fake Physics, Multiverse Mania

The usual hype machine is at work this week, with the usual mechanism:

- University press offices and grant agencies put out irresponsible hype about the work of one their faculty or grantees. In this case, it's Taming the multiverse: Stephen Hawking's final theory about the big bang from Cambridge, and Stephen Hawking's last paper, co-authored with ERC grantee Thomas Hertog, proposes a new cosmological theory, in which universe is less complex and finite from the European Research Council.
- This gets distributed via services that either just reprint such press releases (phys.org or EurekAlert! in this case), or rewrite with added hype (Stephen Hawking's Final Theory About Our Universe Has Just Been Published, And It Will Melt Your Brain).
- Journalists then write stories based on these press releases, which appear all over the place (see here, here, here, here, here and here for example). At this point, whatever was in the original press releases that tried to add caveats or stick to reality gets abandoned, and a completely misleading headline gets slapped on at a final level of the hype machine.

Normally I try to defend the journalists involved, feeling that the most irresponsible behavior is coming from the scientists themselves. In this case, Hertog has a lot to answer for, but it's not Hawking's fault since he's dead. Any semi-competent journalist should have realized that this is not news: the same stories had already been written and published a month ago, and then conclusively debunked in many places (see here, here and here for instance).

This is rather depressing, making one feel that there's no way to fight this kind of bad science, in the face of determined efforts to promote fake physics to the public. It's one thing for journalists to be misled by a new variant on an old debunked story, but that they're getting misled again by exactly the same story is a new development.

Update: More hype from Hertog, this time from Scientific American, which tells us that his work is based on

> string theory, one of the most dominant emerging paradigms in 21st-century physics.

Hertog is asked about the undeniable fact that his work predicts nothing:

> **How do you counter critics of string theory, who argue it cannot be tested?**
>
> I don't agree with this statement; it is not my intuition that string theory can't be tested. We may already have observations based on studies of the universe's large-scale structure and evolution that are telling us something about the nature of quantum gravity. Of course, further theoretical work will be needed to arrive at a mathematically rigorous, fully predictive framework for cosmology.
>
> **So, your paper's key predictions depend on the reality and nature of inflation. Will that be testable?**
>
> There are the obvious observables, yes. Just as it amplified tiny quantum fluctuations in the early universe, inflation should have amplified gravitational waves in the early universe, too. Gravitational waves are ripples in spacetime, first predicted by Einstein, that were finally observed just a few years ago—but the ones we have observed come from black holes and other stellar remnants in neighboring galaxies, not from the primordial universe. These amplified gravitational waves would leave their imprint on the polarization of the cosmic microwave background. Astronomers are actively trying to detect this polarization pattern.
>
> **So you are optimistic they will succeed?**
>
> Well, our theory certainly predicts that primordial gravitational waves should be there at some level.

As Sabine Hossenfelder points out, saying "at some level", without even an order of magnitude estimate, is not a prediction at all. In addition, this non-prediction is exactly the same non-prediction of the theory (eternal inflation) that Hertog is claiming his work challenges.

Comments

1. **David Appell**
   May 2, 2018

   Unfortunately many science journalists let press releases led them around by the nose. They're about all they pay attention to.

2. **Anthony Moose**
   May 2, 2018

   "This is rather depressing, making one feel that there's no way to fight this kind of bad science, in the face of determined efforts to promote fake physics to the public."

   On the plus side, most members of the public are so scientifically illiterate, and so disinterested in science journalism in general, that this will hardly have any effect on their understanding of physics, or lack thereof.

   The people who do know enough to get in trouble are probably either already enamored with multiverse hype, or know enough to be skeptical of headlines and articles like these.

   I could definitely see why it's frustrating, though. It's probably not unlike trying to fist-fight the Pacific Ocean.

3. **Hal Porter**
   May 3, 2018

   I'm a former science journalist (among other topics, though never focused on theoretical physics–how,about indoor air pollution?), now 70 y.o. I agree with Appell; I understand Moose's despair/cynicism but follow that path and one ends falling into any number of social abysses. There would simply be no hope other than some farcically improbable intellectual autarchy. The project of universal education, in the broadest sense, must be followed if one is to avoid another dark age, a la Dick, etc. It seems to me this blog has congruent aims.

   About the journalists, call up the sources! Research! Reporting! Don't call up or otherwise contact scientist just to get two views to create a he said, she said dialogue, but try to understand, as much as possible (especially in theoretical physics) what the author of the whole study is trying to say. Even I could understand 2/3 of the papers out of Fermilab delimiting the mass of the Higgs boson–if such existed–back, what, 7-8 years ago. With that awareness, some 4-5 hours of genuine research (over several days, you’ve got to actually think/absorb) one could produce a modest, 300-500 word story on the subject, crudely addressing method, means, and the meaning of results ruling out at that point. But you’ve got to do the thinking, the research, and talk to people (who may not always be right)! What intellectual laziness–or cowarice or greed–does laziness is.

Woit’s objections here are very fair; I used to blame the college PR Depts. more, but the research scientists have a duty to anti-hype these releases; though in fairness may be under a lot of pressure and dealing naively in areas where they they have no training. Furthermore, in publishing contexts, the writer DOES NOT WRITE THE HEADLINE (my horror stories abound).

Of course these issues nowadays quickly conjoin with anti-science anti-global warming political/financial agrandizement memes. The good fight against the barbarians risks losing sight of the need for intellectual and ethical rigor on our side also.
Sorry for the extended rant.

4. **Thomas**
   May 3, 2018

   This is exactly what happened today here in Germany. Every big and every wanna be news magazine brings a front story about this new “bahnbrechende” theroy from Hawkins. The funny thing is that the name Thomas Hertog is never ever mentioned. This is a déjà vu because it all happened shortly after his death. The same papers the same news all over again … 🙁

5. **Gram Nasi**
   May 3, 2018

   Try what? It’s “try to defend” not “try and defend”.

6. **Peter Woit**
   May 4, 2018

   Gram Nasi,
   Fixed.

7. **Jim Holt**
   May 4, 2018

   @ Gram Nasi
   “Try and defend” is a perfectly literate use of the rhetorical trope called hendiadys. Peter did not deserve your censure.

8. **Kevin**
   May 4, 2018

   An exception: today, the Bavarian radio programme BR2 summarized the paper as follows: one more speculation in an existing huge number of speculations; experimental check with gravitational waves not correct; nobody dares, for reasons of piety, to voice public disagreement; but almost complete private disagreement within the research community.

9. **David Appell**
   May 4, 2018

   Anthony Moose says:
   On the plus side, most members of the public are so scientifically illiterate, and so disinterested in science journalism in general, that this will hardly have any effect on their understanding of physics, or lack thereof.

   Huh? In the US, the situation is the exact opposite of this.

10. **lun**
    May 8, 2018

    In related news, Italians are celebrating the 50th anniversary of string theory today.
    Is this a midlife crisis situation? :-/

US HEP Budget News

May 14, 2018
Categories: Uncategorized

There's a HEPAP meeting today, with news about the US HEP budget situation, presentations here. Since the 2016 election physicists have been worried about how the Republican Congress and Trump administration will treat scientific research in general and physics research in particular. For instance, I see that FQXI has just announced the winners of its latest essay contest, with the second place essay by Alyssa Ney (on "The Politics of Fundamentality") claiming that "it is easy to point to trends in allocation of research funding away from basic research in the sciences", noting:

> Another indication of the present threat to physics funding is U.S. President Donald Trump's 2018 proposed budget. This includes a decrease of 18.4% to the Department of Energy's high energy physics program and a cut of 19.1% to nuclear physics. The budget slashes funding of basic science at the National Science Foundation (NSF) by 13%. http://www.sciencemag.org/news/2017/05/what-s-trump-s-2018-budget-request-science

The actual enacted budget numbers for DOE HEP physics are:
FY2015 \$766 million
FY2016 \$795 million
FY2017 \$825 million
FY2018 \$908 million

It's true that the Trump administration produced a FY2018 budget calling for a cut to \$627.7 million for DOE HEP, but that was no more to be taken seriously than anything else Trump says, and the Republican Congress instead passed a huge (10.1%) increase, to \$908 million. For FY2019 the Trump administration is calling for a DOE HEP budget cut to \$770 million (15.2% cut), but, again, no one should be taking that seriously. It's still early in the budget process, but the House subcommittee dealing with the FY2019 DOE budget has responded to the request for a cut of 13.9% to DOE Office of Science by instead passing a 5.4% increase (it's not yet known what the HEP part of that will be). For latest budget numbers, see here.

Over at the NSF, numbers for the Physics directorate for FY2017 are not yet available, but the enacted budget numbers for the NSF as a whole are:

FY2015 \$7,344 million
FY2016 \$7,494 million
FY2017 \$7,472 million
FY2018 \$7,767 million

The Trump administration requested a cut of 11% to NSF for FY2018, instead got a 3.9% increase. They are requesting a 3.8% cut for FY2019, the House subcommittee dealing with this instead has passed a 5.2% increase (to \$8,175 billion).

It should be uncontroversial to point out that the US budget process has been seriously broken for a while. FY 2018 started on Oct. 1, 2017. DOE HEP only recently got the \$908 million number for its budget and now is scrambling as it is "faced with a year's worth of funding actions in around 4 months". They've been spending their time preparing details of the Trump administration fantasy of how to cut 13.9% out of the FY2019 budget, instead of making rational plans for the future about how to spend the actual budget numbers they will get (OK, maybe they're dealing with reality in secret…).

In order to avoid any misunderstanding about what I think about the current situation, my take on it is:

- Until the 2016 election, US scientific research spending was relatively flat, due to the Obama administration's attempt to reduce deficit spending and respond to Republican outrage at the budget deficit and demands for reductions in non-defense federal spending. We're now starting to see large increases in research spending, as it becomes clear that whatever the current Republican party cares about, it's not the deficit or the level of federal spending.
- Physicists outraged at the Trump administration proposed research cuts need to realize that this, like everything else, is just theater, and understand that the current Republican party has just as little interest in cutting physics research as it ever had in reducing the deficit. Take a look at reality and stop complaining about your research funding. Fueled by huge increases in inequality in US society, truly awful things are happening in this country, but they're not happening to you, quite the opposite. Stop whining about your science not getting enough respect and funding, and instead try and figure out what can be done to restore a healthy democracy and a more equal society.

Informed comments about HEP funding welcome, those who want to rant about politics are not. Sorry, it's my blog, so I get to explain my point of view, even though I don't want to engage here with the diseased post-truth reality TV show politics today's Republican party has grotesquely exploited to come to power.

Comments

1. **Casey Leedom**
   May 15, 2018

   Just curious: do you know how to break down those budget numbers into specific sub-fields of HEP? And are there any sub-field trends which are interesting?

2. **Peter Woit**
   May 15, 2018

   Casey Leedom,

   See for instance slides 6 and 13 of this presentation:
   https://science.energy.gov/~/media/hep/hepap/pdf/201804/GCrawford_20180514_DOE_HEP_Budget_Planning_and_Execution.pdf

   In recent years HEP theory had seen significant cuts, those are dramatically reversed in the new FY2018 budget with an increase of nearly 30% for theory and computation.

3. **Anonymous**
   May 15, 2018

   Slide 17 of that presentation that shows that "theory" as previously conceived is not actually seeing an increase. In fact, it still receives a (small) cut this year, and a dramatic one under the FY19 request. There is also language there that emphasizes neutrino physics theory.

   The increase comes entirely in the form of the new category of "Quantum Information Science." We'll have to see what research programs are funded under that initiative as it is new.

I was not at HEPAP, so don't know what words went with the slide, so take this with a grain of salt.

4. **Peter Woit**
May 15, 2018

Anonymous,

Thanks for pointing that out. The "Quantum Information Science" description includes "foundational concepts relating particle physics and QIS", so presumably includes research previously funded from the theory account on the hot topic of getting spacetime out of quantum information science, as in the upcoming IAS summer school: https://pitp.ias.edu/
A massive new funding stream available for this helps explain to me some of its popularity, which otherwise has always seemed to me kind of mystifying.

5. **David Roberts**
May 15, 2018

Mildly tangential, but can one extract numbers for mathematics funding? Asking for a friend…

6. **Peter Woit**
May 15, 2018

David Roberts,
As far as I can tell, numbers for the FY2018 NSF budget by directorate are not yet available. It is known that the overall NSF budget for research is up 5%. I don't know of any reason math research should be disfavored compared to other topics, so a roughly 5% increase seems like a good guess.

7. **Blake Stacey**
May 16, 2018

In re the new "hot topic of getting spacetime out of quantum information science", I'm vaguely concerned that I haven't seen substantial push-back against it. Ideas that receive no challenges don't become good ideas. The only critique I've noticed in print is the comment by Giddings (arXiv:1803.04973 and references therein) that defining entanglement presumes a decomposition into subsystems, which means you have to postulate a spacetime or maybe some kind of proto-spacetime structure first, before you can try to build a spacetime out of entanglement.

At conferences, I've chatted about the "build spacetime from entanglement" notion with quantum-information people who weren't blown away by the idea, but that's just pub talk.

So, I too am a bit mystified by the appeal, but "follow the money" might turn out to be good advice….

8. **Peter Woit**
May 16, 2018

Blake Stacey,
My own general problem is that the toy models being studied look interesting and I can see why people do this (with funding just one reason), but I haven't seen a plausible conjecture about an underlying theory that would give emergent spacetime and look like the real world.

This is off-topic, will return to it some day in a more suitable context.

9. **Nielson**
May 17, 2018

For some context, according the Bureau of Labor Stats in 2016 there were 19900 physicists and astronomers in the USA. This is obviously a larger pool than those that split the 700+ million dollars for merely high energy physics, but even if we divvy it up as such, it still comes to 35000 dollars each (as an overestimate), roughly the amount of income tax you'd pay on the typical 100-120K salary.
Comparatively, the entire US government spending (including all kinds of entitlement programs which were paid into at one point) is about 4 trillion, divided over say 325 million people, so an average of around 12000 dollars.

10. **Bernhard**
May 18, 2018

The 5% increase for the DOE is real, I saw it first at:

http://www.sciencemag.org/news/2018/03/science-department-energy-gets-hefty-raise-final-2018-budget

The only negative side that I know of for a fact is that both the DOE and the NSF are disfavoring strongly small research groups to operate and favoring only the larger ones. Lone faculty investigators seeking for small grants to keep theirs groups alive are a thing of the past.

Further, the NSF has some weird criteria on which topics are eligible or not for funding, instead of having a broader view and let scientific competence be the ultimate judge.

(And of course, nothing of this is can be blamed on the government.)

11. **Marc**
May 18, 2018

It is always disturbing when someone says "I know for a fact…" and then says something that is false. "Lone faculty investigators seeking for small grants to keep their groups alive are a thing of the past".

If you go to NSF fastlane's award search, and look at all proposals funded by the HE/Cosmo Theory program (Dienes as program officer) that started in the 2016-17 fiscal year, you will find 27 proposals (along with a few conferences) funded. 20 of them are lone faculty investigators.

12. **Peter Woit**
May 18, 2018

Marc,
It may be relevant that Bernhard is an experimentalist.

13. **Dan Mittleman**
May 19, 2018

Many US researchers (anecdotally, the majority) in condensed matter physics and photonics, including both experimentalists and theorists, rely heavily on single-PI NSF grants for funding their groups. This may not be true in HEP, but HEP is not the only thing that qualifies as physics.

14. **Bernhard**
May 20, 2018

Marc/Dan,

It's good to know that what I have said cannot be applied as a general aspect of research funding of US HEP.

My experience with US HEP funding is, as Peter pointed out, as an experimentalist. I have not, admittedly, investigated this deeply – but I have witnessed all groups with lone investigators with lone faculty members in my experiment to have their funding cut. I have discussed this with several colleagues and it's not really much of a secret.

About NSF, again, this is an experimentalist perspective – they fund only certain physics and detector activities/not all and that is irrespective of competence. It's not a healthy state of things if you ask me.

If things are brighter for theory and condensed matter I'm really glad.

15. **Douglas Natelson**
May 20, 2018

To build on Dan's comment, a tension within NSF condensed matter, and more broadly the DIvision of Materials Research and big swaths of the engineering directorate, is trying to balance single investigator awards and center grants. If anything, the number of PIs supported through center grants has been falling in an attempt to avoid cannibalizing the single investigator awards further. More on topic, I've learned quite a bit recently about collaborations in astro and astro-particle (incl dark matter detection), and what has really surprised me is the heterogeneity in funding models.

This and That

May 21, 2018
Categories: Langlands, Uncategorized

I've been trying to find time to write about some books I've been reading. Maybe later this week. In the meantime, some things that may be of interest:

- This week in Norway there will be various events in celebration of the 2018 Abel Prize awarded to Langlands (see here). If you want to find out the latest ideas from Langlands about geometry and the Langlands program, you better be able to read Russian, so you can read this.

  Langlands will give a lecture on Wednesday, on the geometric theory, followed by lectures from Jim Arthur and Edward Frenkel (streamed here). One would think that this would be a good opportunity for non-Russian readers to find out what Langlands is up to, but it wouldn't surprise me if Langlands lectures in Norwegian…

  This fall the University of Minnesota will host an Abel conference, dedicated to Langlands and his work.

- Last week the IHES hosted a conference in honor of Roger Godement. Videos of the talks are now available here. The stories of how his political engagement played out in the context of his professional life were something I had never heard about. For instance, I had missed the "Postface" (French version, English version) to one of his textbooks on analysis.
- The Stacks Project has a new website, some discussion of the changes is here.
- It's the 50th anniversary of the Veneziano model and thus the birth of string theory, so various celebrations are going on this year, including this recent one. From the history as given in the talks there, no one would know that this is an idea that didn't work out (twice, actually…).
- There's a very interesting interview with John Preskill at ycombinator.
- A correspondent pointed me to the following, from a review by Alan Lightman of Carlo Rovelli's latest, in the New York Times book review. Lightman disagrees with Rovelli on the low entropy problem of cosmology, suggesting instead that the multiverse is the answer:

  > One possibility, entertained by a number of leading physicists, is that there are lots of universes, the so-called multiverse, with very different properties and initial conditions. Some of those universes may have started in conditions of maximum disorder, with nothing driving change, no distinction between future and past, where atom-size pottery shards gather themselves up to form atom-size teapots as often as the reverse. But some of these universes would have been created, by accident, with relatively high order. We live in such a universe because otherwise we wouldn't be here to discuss the matter. The theory of "quantum gravity," which is still not fully formulated, describes such a continuous creation of universes with random properties and initial conditions.

  Maybe I've missed something amidst the other multiverse mania, but the only person I've ever heard use "the multiverse did it" to explain this entropy problem is Sean Carroll, and it always seemed to me that he had never had any success in getting anyone to take that seriously.

Update: Glad to hear from the comment section that Carlo Rovelli "not appreciate at all the current infatuation with the idea of a multi-universe." Unfortunately the multiverse publicity machine rolls on, with the usual nonsense, see here. I don't agree with Sabine Hossenfelder that the problem is "over-reliance on mathematics". What's going wrong here is bad physics and bad science, nothing to do with mathematics.

Update: I'm glad to hear from Glenn Starkman that the Standard Model is also getting a 50th anniversary celebration soon (June 1-4), see here. Many of the talks look quite interesting, and there will be a livestream here.

Update:The Abel lectures are now online here.

Comments

1. **Pierre**
   May 22, 2018

   The Preskill interview is great–particularly his discussion of the "geometry of entanglement."

2. **atreat**
   May 22, 2018

   To be clear, it is Alan Lightman – not Rovelli – who postulates a multiverse with that quote! Just reading your blog snippet I thought it was Rovelli who was talking about a multiverse, but after reading the article it is clear that Lightman is the one doing so and not Rovelli.

   I haven't read Rovelli's book so maybe it has something about the multiverse in it, but I would hesitate to ascribe any sentiments to him just based on this review. It looks like the reviewer injected his own multiverse nonsense into it.

3. **Peter Woit**
   May 22, 2018

   atreat,
   Thanks, that was unclear as written. I've rewritten to clarify. The quoted material was Lightman's disagreeing with Rovelli and suggesting the alternative explanation that "the multiverse did it".

4. **atreat**
   May 22, 2018

   This – https://arxiv.org/abs/1505.01125 – seems to be Rovelli's account of entropy and it is very much akin to his Relational QM in that he believes these problems are largely a matter of assuming the universe permits an objective privileged perspective.

   The paper mentions Carroll's inflationary multiverse explanation and offers an alternative. So I think it safe to say that Rovelli does not believe any multiverse explanation is necessary.

5. **Carlo Rovelli**
   May 22, 2018

   Just to set the record straight and avoid possible confusion, since the post mentions me and multi-universe: I myself do not appreciate at all the current infatuation with the idea of a multi-universe. I see no compelling evidence for "other universes".

Carlo Rovelli

6. **David Roberts**
   May 22, 2018

   The Stacks Project people, or at least those behind Gerby, the spin-off general-purpose technology for massively hyperlinked and tagged large mathematical documents, are apparel tly working with Lurie on something called Keradon, for his works
   http://www.math.harvard.edu/~lurie/Kerodon/main.html

   No details yet, but Lurie crowdsourced a professional logo https://www.crowdspring.com/logo-design/logographic-for-front-page-of-mathematics-website-2896944/entries/

7. **John Baez**
   May 23, 2018

   Someone from the Scientific American interviewed me about the 50th anniversary of string theory and also the crackpot index, seeming especially interested in the last item:

   > 50 points for claiming you have a revolutionary theory but giving no concrete testable predictions.

   I had to repeatedly emphasize that I don't think string theory is inherently "crackpot". I said that the fascinating thing about string theory is how much it's done for mathematics while providing nothing so far in the way of concrete testable predictions. I'm curious about how much if any of this makes it into the article.

8. **Tuyen**
   May 23, 2018

   I attended Langlands talk in Oslo. Here is part of my notes from the lecture:

   There are 4 different parts in Langlands program: Arithmetic (original one) from 19th century, Finite fields (still arithmetic): Weil zeta functions, Geometric theory: due to Russian schools – some aspects problematic (Langlands doubts about this theory), Physical implication (springs out from the Geometric theory): Langlands is not convinced that there is any application (he wants his name to be removed from this part of the program).

   Langlands was happy that the example he worked out in his paper showed that there is no physical relation, it is a completely mathematical theory (the Geometric Langlands program)!

   Yang-Mills comes in the paper by Atiyah-Bott, but to Langlands that is just calculus of variation, no physics involved.

   An interesting quote from him: "As far as I know, all of mathematics goes from the number 1. "

9. **UpDownUp**
   May 24, 2018

   Hertog thinks his and Hawking's ideas will be testable:

   https://www.scientificamerican.com/article/a-conversation-with-thomas-hertog-one-of-stephen-hawkings-final-collaborators/

10. **TG**
    May 24, 2018

    A nice, and accessible even to a non-specialist, review of the mutual contribution of string theory to physics and mathematics was published by Natalie Paquette in Inference Magazine (no multiverse is mentioned):

    http://inference-review.com/article/a-view-from-the-bridge

11. **Peter Woit**
    May 24, 2018

    UpDownUp,
    I just wrote a little bit about this as an update to the earlier posting on this topic, see

    http://www.math.columbia.edu/~woit/wordpress/?p=10260

    I think Hertog's attempt to claim these ideas are testable via CMB measurements is really outrageously misleading.

    TG,

    Thanks. I saw that when it first appeared, it is quite good. Intended to mention it here, but it looks like I somehow missed doing that.

12. **LMR**
    May 25, 2018

    TG,

    That's indeed a very nice survey on TFTs, Donaldson theory, mirror symmetry and monstrous moonshine. Thank you.

    Peter,

    It seems opportune to mention this very curious Quanta article on mirror symmetry:

    https://www.quantamagazine.org/three-decades-later-mystery-numbers-explained-20180503/

    Quanta's Kevin Hartnett seems to be very interested in mirror symmetry lately, as it's the second article he's written on the topic in as many months:

    https://www.quantamagazine.org/mathematicians-explore-mirror-link-between-two-geometric-worlds-20180409/

What’s interesting about the “mystery numbers” article is that it appears to be announcing a forthcoming paper from a massive collaboration – involving Columbia’s Abouzaid, as well as Ganatra, Iritani and Sheridan – that would use tropical geometry to give an explanation for why multiple zeta values turn up in mirror symmetry.

It all sounds like terribly exciting mathematics, if everything works out.

13. **KC**
May 28, 2018

Langlands needs substantial editorial help for that Russian document. I kept having to stop while trying to read it because of errors all over the place. I showed it to a native speaker, who couldn’t stand looking at more than a couple of paragraphs. I don’t think he should have publicly posted a document in poorly written Russian, particular one that long. Anyone who can read it will be discouraged by so many distracting mistakes.

14. **Bernhard**
May 28, 2018

The 50 years SM Symposium looks very, very interesting! I really envy whoever is able to attend it in person. Also, happy to see Weinberg is joining. If I’m not mistaken he’s the one who actually coined the name.

But too bad Higgs is not among the speakers.

15. **David Roberts**
May 28, 2018

It would be nice to get the ideas summarised, at the very least, in English. Langlands pretty much said in his acceptance speech that this paper would be his last substantial piece of work, so we can’t expect too much further along these lines from him.

16. **NoGo**
May 28, 2018

I tried to read this article by Langlands…
I cannot comment on the mathematics of it, as most of it is above my head, but as a native Russian speaker, I wish he had someone to go over his article and fix it.
His written Russian is not very good, to put it politely… pretty much every sentence has at least one grammatical error, often more… Most of the time I could still understand it, although often enough I had to pause to figure out what the sentence was supposed to mean, and some I could not parse at all.
I did not make it past the Introduction…

When Einstein Walked With Gödel

May 28, 2018
Categories: Book Reviews

Jim Holt has a new book out, a collection of essays entitled When Einstein Walked with Gödel. I wrote enthusiastically about his last book (Why Does the World Exist?) here and, if you have any interest at all in the overlap of mathematics, science and philosophy, I recommend this one just as highly. Holt is pretty much a unique example of someone able to regularly write about topics in this area in a manner that is both enlightening and entertaining.

This is a book of essays written on different topics for different venues, of too great a variety to try and itemize here. Most of them have some sort of connection to mathematics and philosophy, typically centering on one idea or one, often historical, figure. Holt loves to write about the most abstract of ideas (the subtitle of the book is "Excursions to the Edge of Thought"), but in the context of the particular very human qualities of the thinkers responsible for them. For example, an essay about von Neumann and his role in the building of an early computer at the IAS includes this description:

> His passion for America's open frontiers extended to a taste for large, fast cars; he bought a new Cadillac every year (whether he had wrecked the last one or not) and loved speeding across the country on Route 66. He dressed like a banker, gave lavish cocktail parties, and slept only three or four hours a night. Along with his prodigious intellect went (according to Klári) an "almost primitive lack of ability to handle his emotions."

In a short essay discussing the thorny "demarcation problem" of how to distinguish science from non-science, Holt describes briefly the ideas of Paul Feyerabend (epistemological anarchism) and Imre Lakatos (progressive versus degenerating research programs). At the same time, he includes the story of their arguments over these ideas in the context of their personal friendship:

> These friendly antagonists exchanged abundant letters on the matter, with a good deal of ribaldry–some of it of a sort that no longer evokes an easy smile. "I am very tired because my liver is acting up which is a pity, for my desire to lay the broads here (and there are some fine specimens walking around on campus) is considerably reduced," Feyerabend wrote from Berkeley. The affection between them is much in evidence…
>
> Philosophically, however, there is no detectable convergence in their positions over their years of correspondence. That is not surprising, really, given how vexed the demarcation problem is.

One of the essays included here is a slightly edited and updated version of a review of my book and Lee Smolin's written back in 2006 for the New Yorker (my blog post about it is here). Of the many reviews of these books at that time, Holt's seems to me the most accurate and insightful take on the two books and the issues they were trying to address.

For a very well-executed review of the new book at the New York Times, see here. Jerry Alper has an interview and discussion of the book here.

Bonus micro-review: Another book I just finished reading is Errol Morris's The Ashtray, which is also about philosophy and science. Morris, one of my favorite filmmakers, started out a career as a Ph.D. student of Thomas Kuhn's, and that did not go well. For more about the book, see reviews here and here. I'll just comment that Kuhn seems to have done the world a favor by kicking Morris out of the Ph.D. program and changing his career path to one where he could make the wonderful films he is responsible for.

1. **Low Math, Meekly Interacting**
   May 29, 2018

   Perhaps this darker aspect of von Neumann's personality got in the way of him being a celebrity like Einstein (or maybe John Nash is a better comparator). Everything I've read about him would seem to make him a contender for most intellectually gifted person alive when he was, if not of all time. One could hardly invent such a character: a polymath with near miraculous grasp of almost anything he apprehended, as fond of wearing expensive suits to any occasion as he was of partying, dirty jokes and driving like a maniac. The "mad genius" is a harmful stereotype, so I'm actually grateful, but I do wonder how Hollywood passed on him (ridiculous amalgams like Dr. Strangelove notwithstanding)

Feynman at 100

May 29, 2018
Categories: Uncategorized

The past month has seen quite a few events and articles celebrating the 100th anniversary of Richard Feynman's birth (see for example here, here, here and here). Feynman was one of the great figures of twentieth century physics, with a big intellectual influence on me and on many generations of particle theorists. In particular, his development of the path integral formulation of quantum mechanics and the Feynman diagram method for calculating and understanding what quantum field theories are telling us are at the center of how we have learned to think about fundamental physics and apply it to the real world.

When I first started studying physics, in the seventies, Feynman was a major figure to physicists, but not that well-known outside the subject. After the 1985 appearance of the book of anecdotes "Surely You're Joking, Mr. Feynman!" and his 1986 role in the report on the Challenger disaster (followed by more anecdotes in the 1988 "What Do You Care What Other People Think?") Feynman became a huge public figure. The Physics section of any book store that carried science books would often have nearly a whole shelf of books by and about him, with the only competition the shelf of books about Einstein (the Hawking shelf didn't get going until a bit later).

I avidly read the Feynman anecdote books when they came out and was suitably entertained, but I also found them a bit disturbing. Too many of the anecdotes seemed to revolve around Feynman showing how much smarter he was than someone else. I hadn't thought much about this, but was interested to read historian of science Melinda Baldwin's piece Feynman the Joker this month at Physics Today. It ends with:

> But Feynman's charm and brilliance were only one side of his personality. His writings, and the accounts of those who knew him, reveal a man whose faith in his own brilliance could veer into self-absorption and the mistreatment of others, particularly those whom Feynman didn't consider his equals. Even people who admired Feynman's intellectual gifts could become exasperated with his antics, and some important professional and personal relationships went off the rails when that happened. Feynman's legacy reminds us that it's important to have fun with physics—but to make sure those around us are having fun too.

I think this is an overly harsh take on Feynman, but do think that his later career suffered from the sort of self-absorption Baldwin points to. She links to an interview with Gell-Mann, which includes:

> **One of your best-known interactions was with Richard Feynman at Caltech. What was that like?**
> We had offices essentially next door to each other for 33 years. I was very, very enthusiastic about Feynman when I arrived at Caltech. He was much taken with me, and I thought he was terrific. I got a huge kick out of working with him. He was funny, amusing, brilliant.
>
> **What about the stories that you two had big problems with each other?**
> Oh, we argued all the time. When we were very friendly, we argued. And then later, when I was less enthusiastic about him, we argued also. At one point he was doing some pretty good work—not terribly deep, but it was very important—on the structure of protons and neutrons. In that work he referred to quarks, antiquarks, and gluons, of which they were made, but he didn't call them quarks, antiquarks, and gluons. He called them "partons," which is a half-Latin, half-Greek, stupid word. Partons. He said he didn't care what they were, so he made up a name for them. But that's what they were: quarks, antiquarks, and gluons, and he could have said that. And then people realized that they were quarks, and so then you had the "quark-parton" model. We finally constructed a theory—I didn't do it by myself; it was the result of several of us put together. We constructed the right theory, called Quantum Chromodynamics, which I named. And Feynman didn't believe it.
>
> **He didn't believe that the theory was correct?**
> No. He had some other cuckoo scheme based on his partons. Finally after a couple of years he gave up because he was very bright and realized after a while that we were correct. But he resisted it, and I didn't understand why he had to be that way. Partons…

Looking at Feynman's career, his great accomplishments were in the years 1947-58, and it's somewhat surprising that he didn't make major contributions (besides the partons…) to the development of the Standard Model in the years from 1958-73. One contributing factor may have been his insistence on "What I cannot create I do not understand." John Preskill recounts in a recent talk:

> Feynman often told students to disregard what others had done, to work things out for oneself. Not everyone thought that was good advice. One who disagreed was Sidney Coleman, a Caltech grad student in the late 50s and early 60s. Coleman says: "Had Feynman not been as smart as he was, I think he would have been too original for his own good. There was always an element of showboating in his character. He was like the guy that climbs Mt. Blanc barefoot just to show it could be done. A lot of things he did were to show, you didn't have to do it that way, you can do it this other way. And the other way, in fact, was not as good as the first way, but it showed he was different. … I'm sure Dick thought of that as a virtue, as noble. I don't think it's so. I think it's kidding yourself. Those other guys are not all a collection of yo-yos. Sometimes it would be better to take the recent machinery they have built and not try to rebuild it, like reinventing the wheel. … Dick could get away with a lot because he was so goddamn smart. He really could climb Mont Blanc barefoot."

A related aspect of Feynman's working method was a sizable amount of hostility to any abstract mathematics. In his talk at the Caltech Feynman 100 event, Lenny Susskind makes a great point of this, seeing Feynman's insistence on physical intuition rather than mathematics as a key to his strength. For some problems though, as Sidney Coleman realized, refusing the mathematician's toolbox may just make it impossible to do what you need to do.

A peculiar aspect of the Caltech scientific symposium was that the two talks on particle physics (by David Gross and Hirosi Ooguri) spent a great deal of time promoting something that Feynman detested. While Gross described a major legacy of Feynman as "a healthy disrespect for authority" and "a total aversion to BS", those characteristics led Feynman to have a very negative view of string theory, up until his death. He was known to remark that "string theorists don't make predictions, they make excuses", and in a 1987 interview stated:

> Now I know that other old men have been very foolish in saying things like this, and, therefore, I would be very foolish to say this is nonsense. I am going to be very foolish, because I do feel strongly that this is nonsense! I can't help it, even though I know the danger in such a point of view. So perhaps I could entertain future historians by saying I think all this superstring stuff is crazy and is in the wrong direction.
> **What is it you don't like about it?**
> I don't like that they're not calculating anything. I don't like that they don't check their ideas. I don't like that for anything that disagrees with an experiment, they cook up an explanation – a fix-up to say "Well, it still might be true". For example, the theory requires ten dimensions. Well, maybe there's a way of wrapping up six of the dimensions. Yes, that's possible mathematically, but why not seven? When they write their equation, the equation should decide how many of these things get wrapped up, not the desire to agree with experiment. In other words, there's no reason whatsoever in superstring theory that it isn't eight of the ten dimensions that get wrapped up and that the result is only two dimensions, which would be completely in disagreement with experience. So the fact that it might disagree with experience is very tenuous, it doesn't produce anything; it has to be excused most of the time. It doesn't look right.

Asked at the end of his talk what he thought Feynman would say about string theory today, Ooguri responded with an argument that string theory had made a lot of progress since Feynman's time, was much better understood, and was the only known consistent way to do things. He said he was very curious to know what Feynman would say, but I think it's extremely clear what that would be: he thought it was BS back in 1987, and thirty years of lack of any progress towards making any predictions has shown that he was right back then.

I'm still an admirer of Feynman's work and career (and sorry that I never got a chance to meet him), but at the same time think it's a good idea to acknowledge that he, like any scientist, had his limitations. Adopting his hostility to abstract math and trying to climb Mont Blanc barefoot is likely a bad lesson to draw from his career. On the other hand, a really good lesson to learn from Feynman would be the importance of recognizing when theorists have nothing but excuses and are engaging in BS. There's no question at all about what Feynman would have thought of the current mania for the string theory multiverse.

1. **Joao Leao**
   May 29, 2018

   Peter,

   I also grew up admiring Feynman and still do. Unlike you I had a chance to meet him and talk a bit with him and I wasn't disappointed though he was not the stupendous lecturer that most people still make him out to be (that was Julian Schwinger!!). He was tentative and messy but he was charming and quite unique in the way he captured your attention. I take a bit of issue with what you say about the interviews that became, "You must be joking,…". The anecdotes have a common thread which is his pleasure in mystifying other people by leading them to believe he was much smarter than he really was! There is a different way to interpret the whole of these episodes as suggesting that people are a lot more gullible than you may think and ready to make him smarter than he was. I believe that is the source of the charm and the popular success of that book. The following ones show much more of his humane side specially the story about the death of his first wife which was later turned into a movie.

   As for Gell-Mann's qualms I would say his ego is pretty comparable to Feynman's in magnitude from what I could gather since I also met him a few times. I would not care for whatever option each of them held about the other or whether "quark" is any more refined than "parton" just because it was picked from Finnegan's Wake rather than Dollywood!

2. **Peter Woit**
   May 29, 2018

   Joao Leao,

   I haven't met Gell-Mann either, but from what I've heard don't doubt that his ego is just as healthy as Feynman's was. He did however have a lot more success with the theory of the strong interactions than Feynman ever did. Part of this may have just been being of a somewhat younger generation, but I think his ability to exploit symmetry arguments involving the non-trivial abstract mathematics of the representation theory of groups like SU(3) was also part of the story (and I think it's possible this is what Coleman had in mind in his comments).

3. **Mateus Araújo**
   May 29, 2018

   When I was younger I had unreserved admiration for Feynman, read a lot of his books, and learned much of what I know from him (in fact there is even a video of my impersonating Feynman on the Internet, which I'm afraid has more views than my papers have readers).

   Unfortunately, one thing that I took unquestioningly from him was his hostility to philosophy, which lasted until I met actual philosophers, and realized that they are far from the empty-headed-talking-about-angels-dancing-on-pinheads stereotype that Feynman propagates: they actually know a LOT, have little tolerance for unrigorous thought, and understand well problems that still confound physicists to this day.

4. **Peter Woit**
   May 29, 2018

   Joao Leao,
   I just noticed that Clifford Johnson seems to have somewhat shared my reaction to the 85 book, see
   http://asymptotia.com/2018/05/11/feynman-centenary/
   "the famous "Surely You're Joking…" book, which even back then in my naivety, I began to recognise as partly a physicist's user manual for how to be a jerk to those around you. (I know I'm in the minority on this point…) "

5. **milkshake**
   May 29, 2018

   The take from these anecdotes is that Feynman loved to draw attention to himself in a sly or subversive way – whenever the setting was pretentious, serious, highbrow, he would try to do something outré.

   He adopted his exaggerated Brooklyn-Italian accent to sound like a street-smart gangsta because he grew up in a working-class neighborhood where being geeky was unfashionable; he was short and bad at sports. The prankster persona was perhaps also his way of impressing other kids.

   The other thing I heard – and I don't know if it's true – is that he was hard to collaborate with because he was too self-absorbed, that for most students it was not ideal to have him as a PhD advisor – the issue being that he was self-taught for good and bad and his style of working was difficult to emulate.

   He was fond of saying that physicists can re-invent the parts of math they need for their work rather than trying to follow the developments in mathematics in general; this was probably fine for him but not the best practical advice. He joked about those other physicists who (unlike him) knew group theory stuff.

6. **Low Math, Meekly Interacting**
   May 29, 2018

   I also have been through some of the erstwhile Feynman worshiper's stages of grief, though I still love re-reading all those books I collected. I'll forever be grateful for "QED: The Strange Theory of Light and Matter", even if it's dated. I still find "There's Plenty of Room at the Bottom" charming, even if it had nothing to do with actual progress in the field of nanotechnology. While an unrefined and halting speaker, his public lectures still always struck me as remarkably dense with instructive content. I liked how he made this point so emphatically:

   "It doesn't matter how beautiful your theory is, it doesn't matter how smart you are. If it doesn't agree with experiment, it's wrong."

   I watched a recording of a lecture he gave, I think at the Esalen Institute. It was a little embarrassing (the attire alone…), but he made a very pithy comment near the end about what was then (mid-80s?) the current state of theoretical particle physics. Something about underestimating theorists' taste for speculation in response to the dwindling supply of new experimental data. While his tone was cheerfully derisive, I wonder if the current state of affairs would leave even him too depressed to comment.

7. **Peter Woit**

May 29, 2018

LMMI,

I think you're referring to this talk
https://www.youtube.com/watch?v=4eRCygdW–c
around the 59 minute point,

8. **Joseph Conlon**
May 29, 2018

The Feynman cult is a funny thing – for writing something similar in spirit in my book (about how Feynman's approach was not the right one for the 1970s developments at the boundary of maths and physics) I get these angry rants from crackpots about how *dare* I say that Feynman was not the greatest genius that ever lived, etc, etc, etc, and in any case I'm just a dumb string theorist who could never appreciate Real Physics.

That said, I don't think the position you adopt here (that, for all his greatness, Feynman's flaws as a scientist and a human should be recognised, but when it comes to his end-of-career judgement on string theory he is infallible) is coherent. If (as is surely true) we should not take Feynman's opinion on topics on the intersection of physics and mathematics as the most acute one, then why should we care what what he thought about string theory?

And while on this topic, the anecdotes in the Feynman books about his visits to strip clubs and the like read odd on first reading and even more so today. Powerful man tells stories about how he got laid; not a genre that has aged well.

9. **Anon123**
May 29, 2018

There's no question that Feynman was smart but I think more than that he was extremely clever and valued that much more than rigorous intelligence. Clever people are smart but cleverness looks at the the world in a different way. I have the impression that Feynman talked about this but I don't have a reference handy. But the difference between intelligence and cleverness has always stuck with me (being somewhat smart but not overly clever). I think a lot of success in physics obviously requires smarts but cleverness is often the key to new insights.

10. **Peter Woit**
May 29, 2018

Joseph Conlon,
I don't think that Feynman's judgment on anything was infallible, just that it's clear what it was (and would still be now) in the case of string theory. Given this, it's rather odd to honor his memory with talks promoting a research program he thought was misguided. It would have been just as odd to honor him by bringing in a bunch of mathematicians to promote, say, the categorical representation theory approach to geometric Langlands as the right way to think about certain quantum field theories.

On his fondness for strip clubs and anecdotes about best strategies for convincing low self-esteem women in bars to come home with him, I don't want to host a discussion of the morality of his sexual behavior here. As far as I know, this didn't involve women he had professional relationships with, and he seems to have been no more a misogynist than the average person of his age.

11. **Low Math, Meekly Interacting**
May 29, 2018

Yes, that's the one. There's another on computers, I think. Also a bit cringeworthy.

On the other hand, a Nobel Laureate in physics, taking the time for an open exchange of ideas with what's likely a pretty woo crowd even by Californian standards. Everyone being reasonably respectful. A remarkable social feat, if nothing else.

12. **Amitabh Lath**
May 29, 2018

I was a grad student in the Friedman-Kendall group at MIT when "The Hunting of the Quark" was published (which Riordan claimed led to the 1990 Nobel Prize for quark discovery). The book has anecdotes from the late 60's about Feynman coming up to SLAC as the deep inelastic scattering experiments were starting to get hints of something hard inside the proton. According to the book, he came to"snoop around" the End Station counting house and would later brilliantly recast Bjorken's "scaling" in pictorial terms (Feynman diagrams). But when I asked them for more Feynman stories I was told that when they all hung out with him he was a pretty typical theorist, this whole "pool shark from Brooklyn" persona came later.

13. **Chris Oakley**
May 30, 2018

I suspect that Feynman was the most brilliant physicist who ever lived. His legacy, although substantial, does not do him justice. He did not seem to have had the patience to follow things through to the bitter end, and this allowed lesser talents, such as Gell Mann, to steal a march on him. It is interesting that Einstein will always be better remembered both by physicists and the general public – a less brilliant man, but with more patience (arguably too much, considering how he wasted his latter research years).
Also, as Gell Mann pointed out, Feynman's ego always got in the way. The Challenger disaster investigation is a nice example of NASA using this to their advantage.

14. **Anon**
May 30, 2018

There's no such thing as 'abstract' math, though there is certainly a cargo cult about abstraction in mathematics. Best to read Feynman's prejudice as directed against the cargo cult, and not abstraction. We mathematicians understand -and judge – even the most spectacular abstractions in concrete and hands on ways, not dissimilar to Feynman's. You can transform any problem into some construction of moduli, some functorial property, recasting it as finding a point in a space that you want to be non-empty, but at the end of the day, the equations need solving.

But the metaphors and language we use to describe how we think differ among individuals – so people may perceive disagreement if they don't understand the mathematical commonality of our agreements.

PS what could be more concrete than SU_3? Matrices!

15. **Urs Schreiber**
May 30, 2018

One might hope that Feynman knew of better reasons to be sceptical of string theory than that alleged issue with the number of spacetime dimensions.

A little reflection reveals the following situation:

In ordinary QFT, spacetime dimension may be any natural number.

In ordinary gravity, if that number D is fixed by hand, then the number of macroscopic dimensions seen in generic solutions is a natural number smaller or equal to D.

Hence to do better than plain QFT on this front, one should want a theory that predicts spacetime dimension D to be a small natural number and equipped with some mechanism to stabilize some large dimensions.

A natural way to achieve this is to invoke spin geometry, due to the sensitivity of spin representation theory to spacetime dimension.

In this vein, for instance Roger Penrose has claimed that the number 4 of spacetime dimensions is naturally explained as being the number of dimensions in which twistors work. But in fact twistors work more generally in spacetime dimensions 3, 4, 6 and, with some modifications, 10. This happen to be the same spacetime dimensions in which the Green-Schwarz superstring exists, and it is for the same mathematical coincidences in both cases (related to the four real normed division algebras).

A small number of small natural numbers of potential spacetime dimensions, around and including 4, such as this one, is not too bad, certainly as compared to the anything-goes of plain QFT.

If one brings not just spin geometry to bear, but in addition asks for geometric realization of conformal fixed points of QFTs, then the available set of dimension is {3,4,5,6}, as it appears in AdS/CFT. Also not too bad, if one is really interested in understanding where spacetime dimension comes from.

16. **Another Anon**
May 30, 2018

Chris Oakley: "I suspect that Feynman was the most brilliant physicist who ever lived."

Why? Because he jointly developed quantum electrodynamics? And, er, that's it.
I think you're confusing charisma and celebrity with achievement.
Dirac the complete opposite. No charisma, but greater achievement. Public doesn't even know about Dirac.

17. **Peter Woit**
May 30, 2018

Urs,
I don't think you'd impress Feynman with that answer to him.

Anon,
"Abstract" may be the wrong word, I was just trying to characterize the limited set of mathematical tools that Feynman was comfortable (and extremely expert at) using. I don't think these included SU(3) matrices.

Chris Oakley/Another Anon,
Sorry, enough of the sterile debate about who was the greatest.

18. **milkshake**
May 30, 2018

Regarding the sterile debate about greatness: A popular magazine OMNI featured Feynman interview prominently on the cover – with the caption "The smartest man in the world"
Someone showed this to Feynman's old mom. Her incredulous reaction was "Who? – our Richie? God help us!"

19. **Amitabh Lath**
May 30, 2018

The charisma question is worth exploring.

Right after the 1990 Nobel Prize was awarded for the quark discovery I was based at SLAC and noted some real concern that the media attention would all go to Feynman, and Bjorken (a SLAC theorist) would be left out. The emerging narrative seemed to be that in the late 60's the experimentalists were baffled by their results and genius Feynman swooped in and explained to them: hey youze guys, them's partons! But it was Bjorken who had done meticulous work with structure functions to figure out what the results were saying.

There is a real issue here that Bjorken's current algebra is dry and mathematical and Feynman's diagram of an electron zipping past a proton exchanging a photon is much more intuitive. The physics community in the late 60's was enamored of S-Matrix theory and the idea of a composite nucleon was not getting traction. Having Feynman on board probably did help sell the results.

Of course Bjorken himself still remains consummately above the fray belying the caricature of theorists battling over recognition.

20. **Amitabh Lath**
May 30, 2018

About Gell-Mann and Feynman's quark vs. parton fued: to the experimental community it was more than a linguistic joke. Although Gell-Mann came up with the quark theory he (allegedly) considered them mathematical constructs only and pushed back against the idea of them being actual pointlike things inside protons. Feynman of course had no such reservations about the physical existence of partons.

Gell-Mann stuck to his guns basically until the November revolution in 1974. There are anecdotes of Gell-Mann chiding Feynman about his "put ons" and the idea of objects with fractional charge.

This might seem an esoteric philosophical question but to young experimentalists at the time it determined who was invited to give plenary talks at major conferences etc. Having someone of Feynman's stature helped a lot, since the Stanford/SLAC people were not prominent enough at that time.

21. **Joao Leao**
May 30, 2018

Peter,

I also think you are being unfair with Feynman's contributions to Strong Interaction physics. Parton Phenomenology became quite important to the understanding of Deep Inelastic Scattering experiments at SLAC in the mid seventies and — pace whatever bile Gell-Mann holds — Feynman gave a remarkable set of lectures on QCD at Les Houches in 76 or 77 and in the 80s he made a lone brave effort to find a general solution to the theory in low dimension.

He also made notable contributions beyond Particle Physics namely superfluids, the polaron and plasmon theory, etc… In the late nineties he was seminal in developing the early conceptions of Nanotechnology ("Lots of Room at the Bottom") and Quantum Computation with his Mosquito Island Conference intervention and his work on Quantum Logic Gates. He spend a summer here in Cambridge working with Ed Fredkin and Danny Hillis on the original concept of the Connection Machine. That was actually when I had the chance of meeting him and found him quite an engaging and quite delightful person not the showman or jerk of legend.

22. **GoletaBeach**
May 30, 2018

What I remember is that in 1960's, particle theory had veered off into the analytic S-matrix and a whole denial that relativistic field theory in the perturbative limit was relevant at all… a movement led by Geoff Chew, David Gross' PhD advisor. Feynman was part of the counterculture at that time… he still believed in the applicability of perturbation theory. But he recognized that the strong interaction needed some additional physics insight, and so he started from scratch with partons. He thought BJ was way too enamored with fancy math.

There was an awful lot of doubt that quarks where physical back then… we thought they were just an accounting scheme. The phase shift to their reality arrived when the neutrino scattering experiments (one led by Barry Barish) got data that laid right on top of the SLAC DIS data, where the extrapolation needed the assumption that quarks were real.

David Gross and others were smart enough to circle back into perturbative field theory; BJ bugged out and became extremely phenomenological and even worked in experiments. Gradually folks with strong math ability discovered deep field theoretic connections, and it always looked to me like they made there way back to a better, deeper version of Geoff Chew. Always seemed to me that Feynman, starting in the 1970's, just didn't want to do that, and explored other stuff.

Very few great innovators are *not* egotistical. Is there a single physics Nobel Laureate without a double-extra-huge ego? Maybe Charles Townes. Maybe Carl Anderson. It is the old…. "sometimes it takes a pig to find a truffle" deal. And the pig usually eats the truffle, unlike the rest of us dogs, who turn the truffle over to our masters.

23. **CWJ**
May 30, 2018

" Is there a single physics Nobel Laureate without a double-extra-huge ego?"

Of the ones I've met, Hans Bethe, Ben Mottelson, and Willy Fowler didn't seem to. Willy could be irascible (of course I met him only toward the end), but Bethe and Mottelson were gracious and kind to a young physicist still wet behind the ear.

Murray Gell-Mann and Sheldon Glashow, on the other hand, lived *exactly* up to the stereotype.

David Thouless was somewhere in between. He probably had an ego, but he didn't openly make it about himself. Nonetheless, he could certainly make students (and colleagues, even ones who had pretty healthy egos themselves) wither and feel small and irrelevant.

24. **Tim May**
May 30, 2018

I cooked a steak for Feynman in 1973 in Isla Vista, the hippie area next to UCSB. We sat around for several hours. A great time.

At one point I expressed some doubts about where particle physics was going. Feynman said that were he going forward he would tend to go into computer science. I did. I joined a small company named Intel the following year.

And as the saying goes, "And that made all the difference in the world."

Feynman was a great guy.

–Tim May

25. **liuyao**
May 30, 2018

By chance I was watching some of the YouTube videos of Gell-Mann (Web of Stories interviews), and it is easy to get too negative an impression of their relationship. I'm glad that Peter had taken to include Gell-Mann's "enthusiasm" towards Feynman. (Keep these in mind if you want to read an old Atlantic piece on their rivalry: https://www.theatlantic.com/magazine/archive/2000/07/the-jaguar-and-the-fox/378264/)

That Feynman in his later life got overconfident with his way of doing physics is not uncommon among great physicists. Einstein was most famous in that regard, and Dirac also, to some degree (with his Large Number Hypothesis).

26. **Amitabh Lath**
May 30, 2018

>Is there a single physics Nobel Laureate without a double-extra-huge ego?

I can point to two.
My thesis advisor Henry Kendall and his colleague Jerry Friedman (1990 Nobel Prize in physics, shared with Dick Taylor of SLAC).

Kendall kept teaching undergraduate atomic physics (the dreaded "junior lab") after 1990. This has to be one of the most time consuming thankless teaching assignments ever, and he was great at it. Friedman is one of the kindest men I have ever met, and remained so after the prize. He became dept. chair and totally revamped undergraduate teaching which had been fairly Victorian until then.

27. **Petite Kabylie**
May 30, 2018

I watched many times Feynman's Messenger Lectures on youtube and each time I am amazed how he manages to be that funny and yet explain physics with such depth. By reading Feynman's biography though I learned that he himself admits that his lectures fade compared to Schwinger's. I have searched the web in vain for Schwinger's

video lectures. Can anyone please provide a link, if any, to Schwinger's video lectures so that I could compare with Feynman's impeccable style?
Thank you!

28. **Marshall Eubanks**
May 30, 2018

I used to regularly attend John Schwartz and Murray Gell-Mann's supergravity seminars in the mid-1980's at CalTech; Feynman was always there.

What I remember was Feynman being upset in the lack of any possibility of experimental confirmation of the new ideas of string theory and supergravity. I can still remember him getting in an argument with Gell-Mann and saying vehemently "but there's nothing to measure!" That to me seems much more on point than uncertainty on how many dimensions get compactified.

29. **Michael Weiss**
May 30, 2018

>Is there a single physics Nobel Laureate without a double-extra-huge ego?

My undergraduate adviser Ed Purcell–such a gracious, kind and generous person. For those who may think that Ed was "only" an experimentalist, his group led to way to the non-relativistic QM theory of NMR relaxation.

Ed once told me that he and his remarkable then-younger colleagues (N. Bloembergen [also a Nobel laureate], R. Pound [who may have just missed sharing the NP with Taylor and Hulse] , Torrey [a scientific statesman]) had the opportunity to develop the theory "only because the really smart physicists had overlooked the problem."

By this turn of phrase, it was evident that Ed did not include himself in this category –even if his physical intuition was second to none. This profound intuition is so beautifully evident in his elementary E&M text in the Berkeley series.

Ed told me the following Feynman story: he once declined to give a prestigious seminar at Harvard in order to meet high-school students in Cambridge. But I could not tell whether thought this was admirable or droll showmanship of some sort.

BTW John Preskill was Ed's TA in 1976 (I think) when he taught an introductory QM course ("Physics 143"). John once had a blog post on this experience.

30. **Doug McDonald**
May 30, 2018

I know well no Physics Nobel winners, but I worked for a Chemistry one, and the post-doc that worked with us both also won one, (but … we did scattering measurements). I was a colleague with a winner in Medicine. All three were very nice people and delights to work with or talk to. None were great lecturers.

Then there was the guy across the street named Schwinger. I sat in on his 1st year
grad quantum mechanics class (non-relativistic, no field theory). I saw what people here say about his lectures. They were beautiful and well organized. And indeed, listening one could imagine that one could have, back in the day, thought up all of QM onesself, just from experiment. But after an hour back across the street thinking, it all,
always, fell apart. By "all" I mean his logical progression from something that, listening, seemed obvious, to where he was going. There were gaps in the argument. Much later I studied real relativistic field theory. Now I, vaguely after all these decades, realize that he had thought things through from relativistic/field theory bases and cooked up hand-wavy explanations that made sense. I should have asked the real physics students if they felt the same. But they were inspiring lectures.

I never heard Feynman, but his online lectures are hand-wavy enough as-is that I never feel that hour later letdown.

31. **Patrick Orlando**
May 30, 2018

Partons
A Feynman story. I entered Columbia in Sept. 1967 as a Physics major. One day on the bulletin board outside the physics office on the 8th floor was a notice that He was coming to talk about parton theory. Of course I went, it was in one of the two stadium size lecture halls on the 3rd floor. I brought a friend of mine who was from Brooklyn as I was. We had to seat up in the higher rows as the room was almost full. Feynman talked and wrote on the blackboards, pulling down all three of them to fill with equations that to me at the time where incomprehensible. At the end of the lecture when the questions began from the Full Professors in the front, some also Nobel laureates, one said "but there's more to it than that ! " And Feynman said in his heavy Brooklyn accent, (like mine) "yes there's the Numerator ! " And everyone laughed.

32. **Douglas Natelson**
May 30, 2018

Joao Leao: Feynman died in 1988. He did not have anything to do with seminal developments of nano in the 90s, and his "Plenty of Room at the Bottom" lecture was in 1959.

33. **Richard Séguin**
May 31, 2018

This amusing story about Feynman recently appeared in the UW-Madison alumni magazine.

https://onwisconsin.uwalumni.com/features/2-who-got-away/

He was once hired by UW-Madison, but immediately took leave for Los Alamos to work on the war effort.

"In June 1945, an impatient Mark Ingraham, dean of the College of Letters & Science, sent Feynman a letter demanding that he return to campus and start teaching classes."

"Years later, Feynman finally returned to Madison. 'It's great to be back,' he told the crowd, 'at the only university that had the good sense to fire me.'"

34. **Shantanu**
May 31, 2018

Peter, something underappreciated is Feynmann's contribution to GR and also showing using an ingenuous thought experiment that gravitational waves carry energy.

35. **Shantanu**
May 31, 2018

Very few great innovators are *not* egotistical. Is there a single physics Nobel Laureate without a double-extra-huge ego? Maybe Charles Townes. Maybe Carl Anderson. It is the old…. "sometimes it takes a pig to find a truffle" deal. And the pig usually eats the truffle, unlike the rest of us dogs, who turn the truffle over to our masters.

I can give one counter-example : Joe Taylor. Extremely nice and modest. He also travels by long distance trains. In fact when we met at a conference one participant didn't even know he had a nobel prize and asked if the train fare was costly 🙂

36. **Marshall Eubanks**
May 31, 2018

Douglas Natelson – I saw Feynman give an updated version of the "Plenty of Room at the Bottom" lecture at JPL (in the von Karman auditorium) in the mid-1980s. I believe he was also thinking about massively parallelized computers at the time (JPL and Caltech were both working on hypercube computers then), but I have no idea what came of that.

37. **Bryan Draughn**
May 31, 2018

I'm just an avid reader. Physics grabbed my attention at a very young age but I have a very hard time with mathematics. I get it, but I get lost in it.
Feynman's "Surely You're Joking Mr Feynman!" Changed the way that I thought about everything because Feynman demonstrated in the book that you CAN change the way you think about everything…and probably should.
I can't help but mention a strong hunch about him from what I've gathered throughout the years regarding his personality.
He warns strongly how one can think oneself into a corner , or worse, overlook a pivotal detail and way down the line that detail can undermine even the most colossal body of work.
My point is, I can imagine the man being constantly aware of the dangers that an advanced mind could potentially bring down on someone. Himself and others alike.
I always get that sense of caution when I watch one of his interviews or lectures.
If he had an ego that was out of proportion, I would be surprised if he wasn't well aware of the danger in that.

38. **Amitabh Lath**
May 31, 2018

Feynman's contribution in the deep inelastic scattering seems to be in just looking at the data and ignoring everyone else's ideas.

As GoletaBeach admits above, the theorists working on the quark model thought of them as accounting gimmicks. I suppose the idea of asymptotic freedom eventually helped things progress?

As for the SLAC/MIT DIS experimentalists (and theorists like BJ) it was nuclear physics, a continuation of the work done at the Cambridge electron accelerator (which had exploded). The jargon is full of terms like structure functions and form factors. Particle physics was something done at Berkeley, and then at the newly built national lab in Batavia IL.

In my mind Feynman's genius was in ignoring these artificial experimental and theoretical boundaries, as well as the prejudices of the smart set.

39. **Anonyrat**
May 31, 2018

Feynman's students who did not continue in physics say that Feynman's great teaching was on being happy.

40. **CWJ**
May 31, 2018

I often cite this quote from Feynmann:

"The first principle is that you must not fool yourself — and you are the easiest person to fool."

41. **Bill_K**
May 31, 2018

Here's an exchange between Feynman and Gell-Mann that happened in a Caltech seminar.
Feynman was at the front board making some miscellaneous remark about "Bosey-Einstein statistics." Gell-Mann in the audience interrupted him with a smirk and a glance around the room, "It's Bose. BOSE! Anything else is an affectation!"
You can decide for yourself what this says about anyone's egos…

42. **Douglas Natelson**
May 31, 2018

Let me add my thesis adviser, Doug Osheroff, and his co-laureates Bob Richardson and Dave Lee, to the list of physics Nobel winners without enormous egos – all very nice, friendly people. Horst Stormer, too. Steve Chu doesn't suffer fools, but he's also very good about what he does and doesn't know, a trait absent in many people with fewer credentials and awards. Bob Laughlin deliberately cultivates a larger-than-life persona – hard to judge how much of that is real ego. The bottom line: Physicists are people, with the whole variety of personality types. Getting to meet and interact with these interesting people is a feature of a career in the field. Success as measured by the Nobel prize doesn't have to correlate with being an egomaniac. (Peter, if this is too off-topic, go ahead and delete it.)

43. **Low Math, Meekly Interacting**
May 31, 2018

I've greatly enjoyed watching interviews with Freeman Dyson, recounting his role in the development of QED and related interactions with Feynman and other major figures of that era. Dyson was kinder to Schwinger than Gell-Mann, but given his withering assessments of IAS leadership at that time, it's clear Dyson is not someone who is necessarily easy to impress. It's also clear he held Feynman in total awe.

Pointless arguments about IQ aside, I'm inclined to take Dyson seriously.

44. **GoletaBeach**
May 31, 2018

Nice to read all of the positive comments about Physics Nobelists. I guess I don't see ego as necessarily unpleasant… perhaps Feynman is a good example of a compelling personality but still, somehow he made himself the center of it all. My one interview in his office didn't really let me measure that directly.

If Tim May reads this… hope he does… the current undergrad group in Physics at UCSB would love it if you exchanged any info about Feynman in Isla Vista with them… these days the group is UDIP at physics.ucsb.edu… the used to by the Society of Physics Students… at the moment they call themselves Undergraduate Diversity in Physics. They are quite active and fun, and any photos of Feynman in IV would be treasured by them.

45. **Ethan**
May 31, 2018

Thanks for posting this Peter.

I have been thinking about Feynman a lot lately. In fact it's only accidentally -by watching one of the numerous interviews he gave in the 1970s and 1980s- that I realized that this year is the year we celebrate his 100th birthday.

The good thing about him is that there is a lot of video material on him available in youtube. To me these Feynman videos are a window into the thinking of the kind of genius we don't see anymore. He regularly comes in the top 10 on surveys like this http://www.caltech.edu/news/physics-world-poll-names-richard-feynman-one-10-greatest-physicists-all-time-368 . I wish we had more videos from other great intellectual figures of the XX-the century like Claude Shannon, John Von Newuman and the others mentioned in the preceding link who lived in the XX-th century.

I mean no offense to those who currently work in the forefront of physics but I do believe at the same time that the "publish or perish" frenzy is a killer. Would Richard Feynman stand a chance in today's academia? It's very hard to predict but I somehow think he wouldn't. With all the confusion about some who are say that falsifiability is a thing of the past, I find this critique of cargo cult science refreshing: https://www.youtube.com/watch?v=tWr39Q9vBgo . I think he would be probably appalled as to how far we have gone as a scientific community in this nonsense.

46. **Tim May**
May 31, 2018

GoletaBeach, I'll be very brief here.

I sent a short message to their address recapping what I said here, with a few more details. It didn't bounce.

I can't circulate the several snapshots I have somewhere, as I wasn't the photographer and people have gotten sensitive about formal release permissions. I lost touch with the guy who took the snapshots a long time ago.

47. **Naturally Inconsistent**
June 1, 2018

Pardon my two simple points. First the shorter one.
In reply to Urs, when they first built QFT, they did not try to predict the number of dimensions. They simply used it as an ingredient, and be done with it. The point is that you cannot claim to "predict number of dimensions" and then have to manually set the compactification simultaneously, and expect to be respected. Either you say you literally don't know, and just work with that assumption, or you explain it without fudge factors.

About partons, I was taught that Feynman was deliberately trying to separate phenomenology from theory. Which, typically for new theories, that is a smart thing to do. That is, partons are "these are what have been observed in experiments, that are basically going to be there no matter which theory you later wish to fit", and quarks and gluons have as main job to try to fit/explain what Feynman was quantifying with partons. Philosophically, the separation of the map and the territory, is a great move, one that led us to wonderful things like tensors.

I am in no way denying that Feynman was egoistical, wanting to show off his intelligence, and bad to women. (Though I certainly needed someone to point these facts out to me.) I am just saying that the quark v.s. parton issue, is really not an issue at all.

48. **tulpoeid**
June 2, 2018

I liked this balanced attitude towards Feynman quite a bit, you don't come across this every day.

As about "Surely you're joking", and living outside USA, all these years I've been having the impression that the consensus is that a big portion of the book is made up. Therefore I'm somewhat surprised to find out that many people don't view it to be so.

49. **Blake Stacey**
June 2, 2018

According to Sidney Coleman, "Bose" was pronounced "boʊʃ", i.e., with a long *o* and a *sh*-sound at the end. This was somewhere early on in the QFT lecture videos that Harvard put online several years ago, but I forget exactly where.

50. **David Brown**
June 4, 2018

@Marshall Eubanks: You misspelled John Schwarz's name:
https://en.wikipedia.org/wiki/John_Henry_Schwarz

51. **Joao Leao**
June 4, 2018

Douglas Natelson: I meant late eighties in my comment. Sorry about that. Feynman "updated" his classical lecture in one he gave at JPL in 1983 later transcribed and published under the title "Infinitesimal Machinery". http://www.oz.nthu.edu.tw/~d9511818/Infinitesimal%20Machinery.pdf

52. **GoletaBeach**
June 6, 2018

Word got back to me from their lab professor today that your one image was received, Tim May. You elated a whole lot of young physics majors, thank you kindly for that!

53. **anon**
June 7, 2018

I would like to know when Sidney Coleman spoke that way. Indeed, he did great things in his best years, but in the late ones, gosh. The paper "High-energy tests of

Lorentz invariance” in my view is a shameful one – any particle has its own limiting velocity – and caused a lot of confusion.

Moreover, Gell-Mann defence of “right words” sounds funny to me: “partons” is OK and “aces” is OK too, as the model works.

By contrast, Feynman’s words of his last years include those for “future historians”.

54. **Peter Woit**
June 8, 2018

anon,
The Coleman quote is from 1992 or earlier, see more of it at
https://www.nytimes.com/1992/09/20/magazine/part-showman-all-genius.html
This is from long before the paper you don’t like and Coleman’s later health problems.

I suspect Coleman’s take on Feynman is quite insightful. He got to observe him from up close, and one of Coleman’s best qualities was his irreverence. He did not suffer from the hero-worship that afflicts many who have written about Feynman.

55. **Angelos**
June 13, 2018

Linguistically, ‘parton’ is no worse a hybrid than ‘neutron’, to say nothing of ‘gluon’. And it has the advantage of suggesting its meaning — unlike ‘quark’, which is purely conventional.

There Are No Laws of Physics. There's Only the Landscape.

June 4, 2018
Categories: Multiverse Mania

At Quanta magazine, IAS director and string theorist Robbert Dijkgraaf has signed up to the multiverse mania bandwagon with an article announcing [There are no laws of physics. There's only the landscape](). Dijkgraaf's version of the string landscape ideology is:

> The current point of view can be seen as the polar opposite of Einstein's dream of a unique cosmos. Modern physicists embrace the vast space of possibilities and try to understand its overarching logic and interconnectedness. From gold diggers they have turned into geographers and geologists, mapping the landscape in detail and studying the forces that have shaped it.
>
> The game changer that led to this switch of perspective has been string theory. At this moment it is the only viable candidate for a theory of nature able to describe all particles and forces, including gravity, while obeying the strict logical rules of quantum mechanics and relativity. The good news is that string theory has no free parameters. It has no dials that can be turned. It doesn't make sense to ask which string theory describes our universe, because there is only one. The absence of any additional features leads to a radical consequence. All numbers in nature should be determined by physics itself. They are no "constants of nature," only variables that are fixed by equations (perhaps intractably complicated ones).

While giving the usual 1995 justification for the "M-theory" conjecture of a unique string theory, Dijkgraaf neglects to mention that, 23 years later, no one has a viable proposal for what this unique theory might be. He mentions none of the problems of moduli stabilization, or that the theorists "mapping the landscape in detail" don't actually know what equations govern this supposed landscape and thus have hit a dead-end, unable to predict anything about anything.

The problem is that what Dijkgraaf is writing about is the situation of [Theorists Without a Theory](), trying to turn this failure into success by arguing that it is a radical new discovery, the discovery that "There are no laws of physics". He ends with

> A more dramatic conclusion is that all traditional descriptions of fundamental physics have to be thrown out. Particles, fields, forces, symmetries — they are all just artifacts of a simple existence at the outposts in this vast landscape of impenetrable complexity. Thinking of physics in terms of elementary building blocks appears to be wrong, or at least of limited reach. Perhaps there is a radical new framework uniting the fundamental laws of nature that disregards all the familiar concepts. The mathematical intricacies and consistencies of string theory are a strong motivation for this dramatic point of view. But we have to be honest. Very few current ideas about what replaces particles and fields are "crazy enough to be true," to quote Niels Bohr. Like Alice and Bob, physics is ready to throw out the old recipes and embrace a modern fusion cuisine.

The argument seems to be that we need to throw out our highly successful quantum field theories, replacing them with a "radical new framework" describing "impenetrable complexity". But what is this "radical new framework"? As best I can tell, what's now popular at the IAS is the "it from qubit" idea that is the topic of [this summer's PITP program](). It seems that Witten has taken up the study of quantum information theory, with a new [expository preprint just out](). I'll look forward to seeing what the PITP lecturers present, but so far I haven't seen the slightest indication that this "radical new framework" can get off the ground as a fundamental unified theory.

Comments

1. **Greg Weiss**
   June 4, 2018

   I seem to remember string theorists brushing off claims that their theory is unfalsifiable, saying something akin to 'all you have to do to prove that String Theory is incorrect is to prove that Quantum Field Theory is incorrect.' I guess even that is no longer the case.

2. **Sabine**
   June 4, 2018

   It is not correct that string theory is "the only viable candidate for a theory of nature able to describe all particles and forces, including gravity, while obeying the strict logical rules of quantum mechanics and relativity." [Asymptotically Safe Gravity does this too](), and if you ask me, ASG is much more viable than string theory since it doesn't require a negative cosmological constant or extra dimensions or supersymmetry. And of course others have approaches which they claim can do it too.

   I am pretty sure that Dijkgraaf knows this statement is wrong, and it's really hard for me to read his piece as anything more than a desperate attempt at marketing.

   (Since some people have recently asked me, no, I do not work on ASG.)

3. **Kir**
   June 5, 2018

   No guys I give up with physics if this is the mainstream idea of where our field is going. This is just babbling about something. It is like saying that the world stands on elephants on a turtle without proof. This guy has no equations, no theory, no vacuum of string theory that resembles the standard model, to coherent string theory with a positive comsmological constant, and blathers about all this. Simply incredible. Also science is entering the era of post-truth. Truth is what most of the people accepts or talk about or like, not the result of the scientific inquiry. I'm frightened that an IAS director talks like this.

4. **Reader297**
   June 5, 2018

   Just as an historical aside, I'll note that Dijkgraaf is incorrect in referring in his article to "the famous particle-wave duality discovered by Heisenberg." Heisenberg didn't "discover" wave-particle duality. Planck and Einstein (among others) had long ago supplied physical arguments that light had a particle-like nature, and de Broglie famously suggested in 1924 that electrons and other particles of matter had a dual wave-like nature. Heisenberg hadn't burst onto the scene by that point. His big breakthrough was with matrix mechanics the following year, which was a decidedly non-wave-like approach to quantum theory.

5. **Urs Schreiber**
   June 5, 2018

   > […] the "M-theory" conjecture of a unique string theory, […] 23 years later, no one has a viable proposal for what this unique theory might be.

   At StringMath17 ([here]()) I had reported on an approach to unravelling M-theory via super homotopy theory. I think it is fair to say that this looks promising, recent progress is surveyed [here]().

6. **Rollo Burgess**
June 5, 2018

The logical flow of this article reminds me somewhat of books about the Holy Grail, Egyptian pyramids being built by aliens, etc. Possibilities are vaguely introduced, then subsequently assumed and embellished: for example para. 5 begins 'if our world is but one among many…' then para. 6 starts 'the game changer that led to this switch of perspective…' as though the new perspective was a done deal not a wild speculation.

There is also a pseudo-humility (we must accept that we cannot produce fundamental theories like the old ones) concealing an actual arrogance – i.e. there is little acknowledgment that perhaps the reason why we haven't done it yet is because we are stuck, because it is hard, because a lot of focus is being invested in what Imre Lakotos would have called a 'degenerating research programme', etc. rather than because actually reality is fundamentally different to what we previously believed and we have reached the end of physics as traditionally conceived.

If this was a debate in literary theory it would be quite funny, but in physics it is sad and worrying, particularly as post-truth nonsense abounds in other areas with real and obvious real-world consequences.

7. **Douglas Natelson**
June 5, 2018

I had expected better of *Quanta*. They've been reasonably good in the past at not publishing extraordinarily speculative stuff as if it's the be-all and end-all, and they're usually careful not to imply that high energy physics is the only branch of the discipline. Apparently not so now.

8. **Low Math, Meekly Interacting**
June 5, 2018

I know it probably isn't, but I really, REALLY hope that sterile neutrino finding is valid. Because, my God, such smart people desperately need something better to be working on than this.

9. **Bud Rapanault**
June 5, 2018

This isn't so much post-truth as it is post-empiricism. And since empiricism is the sine qua non of science it is also post-science. "Impenetrable complexity" would seem the post-modern harbinger of a new dark age, one wherein the very purpose of science, to understand the nature of physical reality, is seen as a quaint anachronism.

10. **Low Math, Meekly Interacting**
June 5, 2018

Douglas,

I had the exact same impression of an earlier Dijkgraaf contribution: This is not up to Quanta standards. My suspicion at the time was maybe he was too busy to finish the article properly. Peter's (probably more accurate) assessment was being an expert can make it very hard to write effectively for non-experts. Sometimes you need a really good science journalist to do the subject justice for lay audiences. Doubtless there's a little of that problem involved.

But, again in agreement with you, the trouble runs much deeper. I want to know what this work tells us about OUR corner of the landscape. Because that's the part human beings can do something remotely resembling what I like to think of as "science", i.e. some day, some how, speculations make contact with empiracle observations. Otherwise, not only is the work perplexing, it's profoundly BORING. I want to know what dark matter is. I want to know if there was an inflationary epoch or not. I want to know if gravity must be modified. Etc. By telling us about "everything" we are supposed to accept that it's OK to learn precisely nothing specific about the universe we inhabit, nothing illuminating in any remotely constrained way about any of the highly observable mysteries we know exist. New experimental data can't come fast enough.

11. **atreat**
June 5, 2018

Douglas, how can we expect better of Quanta magazine when this guy is the Director at IAS? Seriously, how can a magazine be expected to check this guy when his fellow scientists do not? This is embarrassing for the entire scientific community…

12. **Peter Woit**
June 5, 2018

Douglas Natelson,
I don't think Quanta would have published this if it were by a science journalist, it does come off as uncritical propaganda for dubious speculation. The most disturbing thing about it is that it's not written by a lazy journalist, but by Robbert Dijkgraaf, one of the most respected and prominent figures in theoretical physics. Dijkgraaf has been one of the most influential scientists in the Netherlands and now is director of the IAS. In these roles he will have a great deal to say about the future of the field. At one point multiverse mania was concentrated on the West coast, with the IAS not following this. That seems to now have definitively changed.

13. **CWJ**
June 5, 2018

Kir,
Keep in mind, this isn't the totality of physics. For perspective, high energy particle theory is only about 1% of the NSF physics budget, and only about half of that is spent on extremal ideas like this.

LMMI,
Unfortunately, it seems the MiniBOONE results, while congruent with LSND, are still just as confusing. Just saw a talk which explained it well. There are two elements to any neutrino oscillations–the mass difference, which gives the oscillation length, and the mixing matrix elements, which gives the oscillation amplitude. While the oscillation length from MiniBOONE/LSND suggest a 4th (sterile) neutrino, the mixing matrix elements needed are so large they should have been seen in other experiments. So it seems the simplest explanation, a 4th sterile neutrino, is still problematic. Apparently a third experiment, MicroBOONE, is in the works…

14. **Amitabh Lath**
June 5, 2018

Interesting how institutions get captured by a given theory. When I was a postdoc, the Fermilab theory group was all into Technicolor. Michigan and Gordy Kane were all SUSY, all the time. And now the IAS seems to be into Landscape. I heard tales that Berkeley in the "Tao of Physics" era was the same way with whatever theory of hadrons they were peddling at the time.

I wouldn't worry about it too much. Dark Matter and Dark Energy are still need to be explained, and the hierarchy problem isn't going away anytime soon.

15. **NoGo**
June 5, 2018

Aside from the content of the article (which people much more competent than I commented on), I've noticed that in form it was dumbed-down much more than I would expect in a Quanta article. All this baby talk about Chinese and Italian food, which as far as I can tell explains nothing, would not look out of place in mainstream media, if not Reader's Digest, but not in Quanta…

On this background statements like "string theory has no free parameters" and "It doesn't make sense to ask which string theory describes our universe, because there is only one" are especially puzzling. I wonder what he meant by this (if anything). My best effort in understanding the food analogy is that it tries to indicate that something like "all variants of string theory predict the same physical effects", but since he himself implies that string theory does not predict any specific physical effects, I remain puzzled…

16. **Phogos**
June 5, 2018

I'm actually rather encouraged about field moving toward it/qbit stuff. I think the chances of it leading to a TOE any time soon are pretty slim, but papers such as Witten's expository one are rigorous, interesting to read, and connect with other disciplines. So as a taxpayer I'm getting some value from them. That was most assuredly not the case for 99% of what the field has produced over the past decade or two.

17. **Marko**
June 6, 2018

"It seems that Witten has taken up the study of quantum information theory"

It's where the most funding is going to be available in the next 10-20 years. EU has provided a 20bn eur budget to fund quantum information science in that period, while China has a couple of orders of magnitude more than that — they already have a satellite in orbit, sending Bell pairs across continents and providing for quantum-crypto secure phone calls between China and Austria…

One would be stupid not to get string theory into the mix for a piece of the pie, regardless of any actual or potential "radical new framework" stuff. People who give the money won't recognize any lack of content anyway.

But I'm completely baffled that Witten actually wrote a 30+ page recap of stuff that is readily available in textbooks, and written by actual experts on quantum information theory. What is he trying to achieve with that?

Best, 🙂
Marko

18. **Peter Woit**
June 6, 2018

Marko,
Witten is lecturing at the PITP school this summer, I assume this document was prepared for that purpose. Also, best way to learn a subject is to write about it…
He also recently wrote this other expository article:
https://arxiv.org/abs/1803.04993
I doubt that funding has much to do with his getting interested in this, he's someone whose research will get funded if he wants, whatever he is doing.

Dijkgraaf on the other hand has for many years not been doing much research, his main activity now is fund-raising. I think his writings for the public should be seen in that light: he would like to get people to believe that all is well with HEP theory, so that they can be more readily convinced to fund it.

Heinz-Dieter Zeh 1932-2018

June 6, 2018
Categories: Obituaries

I was sorry to learn today of the death on April 15th of H. Dieter Zeh, one of the major figures responsible for improving our understanding of the physics involved in the measurement problem and related interpretational issues in quantum mechanics. For an excellent account of the story of Zeh's work and its early reception, see Adam Becker's recent book What is Real?. For a very good article about Zeh (in German), see here.

Zeh is the physicist most responsible for first identifying and studying the crucial role of decoherence in the measurement problem. As Becker explains, he encountered a quite hostile reaction to his early work from defenders of Copenhagen orthodoxy. He finally managed to get his paper On the Interpretation of Measurement in Quantum Theory published in 1970, and then started to explore what came to be known later by the term "decoherence". In later years he wrote many articles explaining these ideas, for one that includes some historical context, see here. Zeh maintained a website with links to his writings, at www.decoherence.de or www.zeh-hd.de, which seems to be down at the moment, hopefully only a temporary situation (a recent Wayback Machine capture is here).

I was pleased that every so often Zeh contributed insightful comments here, most recently just three weeks before his death. Here's a list of the ones I found in a quick search:

- February 22, 2012
- February 22, 2012
- April 26, 2012
- August 17, 2014
- March 23, 2018
- March 24, 2018

During the past few years I also had some email exchanges with Zeh. For details of his latest thinking about issues like the multiverse, he pointed me to this paper, which he every so often updated. A few months ago I was quite sorry to realize (when someone told me that Zeh lived in Heidelberg) that I had missed an opportunity to try to meet him in person when I was there a couple years ago. I'm even sorrier about this now that such a meeting will no longer be possible.

Update: Claus Kiefer has written an obituary here. Zeh's website will remain available here.

Comments

1. **Another Anon**
   June 6, 2018

   Very sad news.
   Surely he was deserving of the Nobel Prize for proposing decoherence which, as he said in that last comment on your site, has now been clearly "experimentally confirmed".

Back at Work

June 7, 2018
Categories: Uncategorized

Now back from a week away, mostly spent in Cambridge. Among the accumulated items of interest:

- Inference has a review of my book, Woit's Way, by Andrew Jordan. I like the way it starts out:

  > *Quantum Theory, Groups and Representations* is based on a series of lectures that he gave at Columbia University.
  >
  > And it is excellent.

  The review gives a very good explanation of what's in the book, what level it's at, and what I'm trying to accomplish. Besides getting all this right, he also gets right some of the things that could have been done better (I did the indexing and I'm kind of lazy, it should have at least twice as many entries).

  A reminder: the book is available either in my version at my website, or from Springer here.

  By the way, when I was in Cambridge I spent a couple days at the conference in honor of Bert Kostant, who was a major figure in the study of the relation of representation theory and quantization. Among the talks there, David Vogan gave a survey talk on Quantization, the orbit method, and unitary representations. He explains clearly the fundamental relationship between representation theory and quantum theory that is central to my book. Roughly the first half of the talk corresponds to topics discussed in the book. I decided to not write about the topic of the second half of Vogan's lecture, the representation theory of reductive groups and the orbit method, since that would take the book in a different direction, one currently of more interest to mathematicians than physicists (and Vogan has already done a better job of writing about this topic than I ever could).

- Also in the new issue of Inference are several pieces commissioned as responses to Natalie Paquette's wonderful survey article A View from the Bridge about topological QFT and influences running from physics to mathematics. These pieces include takes on the relation of math and physics from Édouard Brezin, John Iliopoulos, Hirosi Ooguri and Martin Krieger, as well as a rather odd one from string theorist Xi Yin.

  Yin's piece is entitled An Ode to Ugly Physics, and he argues that:

  > the deepest and most far-reaching ideas of physics are not the most elegant or beautiful, but the ideas that are confusing, not rigorous, improperly formulated, or, in fact, utterly incomprehensible to mathematicians.

  One problem is that many of the examples he gives of "ugly" physical ideas (for instance, spontaneous symmetry breaking) are ones that I think most mathematicians would describe as rather beautiful. He's right that some of the examples he gives (e.g. complex string theory calculations) are ones that mathematicians wouldn't find that beautiful, but often these are calculations that have been unsuccessful in their goal of making contact with reality. Yin ends with:

  > I believe that part of the job of a theoretical physicist is to make the lives of mathematicians miserable. There are, incidentally, few things I can think of that could make a mathematician more miserable than reading Leonard Susskind's papers.

  This includes a footnote to this recent paper by Susskind, and he's right that this is not one mathematicians would think highly of. For good reason though, with Yin's implication that this is an important idea in theoretical physics something I find rather dubious (but then again, some would say I'm a mathematician…).

  Truly bizarre is Yin's response to the fact that string theory has failed to make any connection to observable physical reality:

  > I couldn't help but notice a striking parallel with the way mathematics became detached from physics during the nineteenth century and, in particular, the outrage that accompanied Cantor's transfinite set theory and Hilbert's non-constructive proofs. Was the kind of mathematics that could never be exhibited with real objects actual mathematics, or was it theology? With the benefit of hindsight, we now know that the mathematics flourished like never before during the twentieth century. One can only hope the same thing happens with string theory in the decades to come.

  So, having no connection to experiment and observation is not a bug, but a feature, exhibiting a radical new advance in how to do physics? This takes the "post-empirical" thing even further than I've seen anywhere else.

  Finally, also in the same issue of Inference is the final part of a series of articles by Sheldon Glashow, this one dealing with the Standard Model. Glashow ends the essay with some comments on string theory, quoting someone I have to agree with.

- On the neutrino front, there's a new result out from MiniBooNE that has gotten a lot of attention. As usual, good sources for clear explanations and informed evaluations are Tommaso Dorigo and The Mad Hatter.

  For much more of the latest results on neutrinos, Neutrino 2018 is happening this week in Heidelberg, slides of presentation appearing here.

- The Perimeter Insitute earlier this year hosted a workshop on geometric Langlands and QFT, talks available here. Dan Falk has an article about this subject here. He also has a piece about Why some scientists say physics has gone off the rails, partly based on Sabine Hossenfelder's new book, which I'll write about here very soon.
- Michael Harris at his book's blog tells the story of how he was commissioned by New Scientist to write something about Peter Scholze's ideas. His draft ended up not getting used, luckily for us he includes it in the blog posting. New Scientist did however end up publishing a story about this, under the headline The Theorem of Everything (non-paywalled version here).
- The Simons Foundation has just put out its 2017 annual report. To get some idea of their increasingly large influence on mathematics and physics research, here are some numbers:

  Assets, end 2017: \$3.298 billion
  2017 income: \$646 million
  2017 expenses: \$409 million
  2017 grants: \$273 million

  Mathematics and physical sciences receive 31.77% of the grant money. To get a sense of the scale of this, one could compare the fraction of expenses corresponding to math and physical sciences (31.77% x \$409 million= $130 million) to the FY 2017 NSF budget numbers

  Mathematical sciences: \$234 million
  Physics: \$281 million
  Astronomical sciences: \$252 million

In the areas of math, physics and astronomy where the Simons Foundation is concentrating its resources, I suspect that the amounts they're spending are getting up to the NSF level.

Update: For a take on the Copenhagen interpretation that I very much agree with, see Philip Ball's Myths of Copenhagen.

Comments

   June 8, 2018

   Any hope of finding the videos for Kostant conference's talks online?

2. **Peter Woit**
   June 8, 2018

   Carlos,

   I see that videos of the talks have just been posted, available via the conference website:
   https://math.mit.edu/conferences/kostant/

3. **Carlos**
   June 8, 2018

   That's great Peter. Thank you!

4. **Peter Erwin**
   June 9, 2018

   If you're going to apply "31.77%" to the entire budget of the Simons Foundation (including things like "depreciation and amortization" and "taxes"), then it makes more sense to compare it with the total "Mathematical and Physical Sciences" part of the FY2017 NSF budget, which is \$1.349 billion. That figure doesn't include whatever part of the \$200 million "Major Research Equipment & Facilities Construction" goes to mathematical and physical sciences (e.g., about \$90 million for telescope construction), so it's an underestimate.

   Funding at a level roughly 10% of that which NSF provides is pretty damn impressive, but not quite "getting up to the NSF level" yet. (And this of course doesn't include the funding that NASA and DoE provide.)

5. **Steven Patenaude**
   June 13, 2018

   I'd call Andrew Jordan's review high praise. If I were the audience for your book, I'd snatch it up in a heartbeat.

Lost in Math

June 7, 2018
Categories: Book Reviews

Sabine Hossenfelder's new book Lost in Math should be starting to appear in bookstores around now. It's very good and you should get a copy. I hope that the book will receive a lot of attention, but suspect that much of this will focus on an oversimplified version of the book's argument, ignoring some of the more interesting material that she has put together.

Hossenfelder's main concern is the difficult current state of theoretical fundamental physics, sometimes referred to as a "crisis" or "nightmare scenario". She is writing at what is likely to be a decisive moment for the subject: the negative LHC results for popular speculative models are now in. What effect will these have on those who have devoted decades to studying such models?

Back in 2006 Lee Smolin and I published books concerned about where fundamental physics was heading, and five years ago Jim Baggott's Farewell to Reality appeared with another take on these issues. Hossenfelder's is the first book on this topic to appear since the LHC results showing a vanilla Standard Model Higgs and no evidence of supersymmetry or other speculative BSM physics. The remarkable thing she has done is to address this in a characteristically direct manner: go talk to those responsible and ask them what they have to say for themselves.

Four of the people that Hossenfelder interviews would be on any short list of the most influential figures in theoretical particle physics, both responsible for where we are now by their past actions, and looked to by others for a vision of where the field is going next. They are Nima Arkani-Hamed, Steven Weinberg, Frank Wilczek, and Joe Polchinski.

Arkani-Hamed is introduced with:

> He's won loads of awards, including the inaugural 2012 Breakthrough Prize for "original approaches to outstanding problems in particle physics." The problems are still outstanding. So is Nima.

and here's an extract from the interview

> "Has the LHC changed your perspective on naturalness?" I ask.
>
> "It's interesting–there is this popular narrative now that theorists before the LHC were totally sure that susy will show up, but now there's a big blow. I think that the people who are professional model builders, the people I consider to be the best people in the field, they were worried already after LEP… The good people, they were not at all sure susy would show up at the LHC. And nothing has changed qualitatively since 2000. Some loopholes have been closed, but nothing has changed qualitatively…"

As with many of the interviews, Hossenfelder intersperses her own internal response to what she's hearing:

> But not one of those "best people" spoke up and called bullshit on the widely circulated story that the LHC had a good chance of seeing supersymmetry or dark matter particles.

She doesn't mention, but surely is aware, that many prominent theorists pre-LHC had made public bets that the LHC would find SUSY, and that those wagering this way included Arkani-Hamed himself. For accounts of the 2016 Copenhagen event where the bet was paid off, see here and here. You can read there what Arkani-Hamed had to say then about losing the bet, and the quote:

> "I think Winston Churchill said that in victory you should be magnanimous," Damgaard said after Arkani-Hamed's talk. "I know also he said that in defeat you should be defiant. And that's certainly Nima."

In the interview with Hossenfelder, Arkani-Hamed goes on to say:

> The people who were sure it would be there are now positive it's not there. There are people now who speak out about being depressed or worried or scared. It drives me nuts. It's ludicrously narcissistic. Who the fuck cares about you and your little life?

There's a lot more in the interview and you should get the book and read the whole thing. Hossenfelder does a wonderful job of portraying both Arkani-Hamed's serious arguments and his aggressive "Damn the torpedoes" self-confident attitude. This is not someone who is going to admit that, whatever bet he lost, some failure has occurred that indicates this is a time for reflection on mistakes made and reevaluation of the path forward.

Hossenfelder travels to Austin, Texas to talk to Steven Weinberg, who it appears may not realize she is a physicist, just has been told he is supposed to talk to a "writer". She notes that:

> Weinberg doesn't talk with you, they told me, he talks *at* you. Now I know what they mean. And let me tell you, he talks like a book, almost print-ready.

I won't try and reproduce much of her conversation with Weinberg, the multiverse is a main topic (she thinks it's an empty idea, Weinberg is willing to go along with it). About where particle theory is headed, Weinberg says:

> I don't know how much elementary particle physics can improve over what we have now. I just don't know. I think it's important to try and continue to do experiments, to continue to build large facilities… But where it will end up I don't know. I hope it doesn't just stop where it is now. Because I don't find this entirely satisfying…
>
> I don't take seriously any negative conclusion that the fact that the LHC hasn't seen anything beyond the standard model shows that there isn't anything that will solve the naturalness problem… Supersymmetry hasn't been ruled out because it's too vague about what it predicts.

Her next interviewee is Frank Wilczek, who she finds in Tempe, Arizona. His take on string theory unification is rather negative:

> … it's not clear what the theory is. It's kind of miasma of ideas that hasn't yet taken shape, and it's too early to say whether it's simple or not–or even if it's right or not. Right now it definitely doesn't appear simple.

Asked about the argument that string theory could reproduce gravity, Wilczek responds:

> If your standards are low enough, yes. But I don't think we should compromise on this idea of post-empirical physics. I think that's appalling, really appalling… If there was any bit of experimental evidence that was decisive and in favor of the theory, you wouldn't be hearing these arguments. You wouldn't. Nobody would care. It's just a fallback. It's giving up and declaring victory. I don't like that at all.

Wilczek is still unwilling to give up on SUSY and the idea of a SUSY GUT, with his main argument the coupling constant unification calculation he did with Dimopoulos and Raby back in 1981:

> “They haven’t found susy partners, though,” I say. “Is this something that worries you?”
>
> “I am starting to get worried, yes. I never thought it would be easy. There have been bounds from and proton decay for a long time, and this indicated that a lot of the superpartners have to be heavy. But we have another good shot with the energy upgrade. Hope springs eternal… I would definitely not believe in supersymmetry if it wasn’t for the unification of gauge couplings, which I find very impressive. I can’t believe that’s a coincidence.”

~~It’s not mentioned in this book~~ , but Wilczek has already paid off one bet about SUSY (with Garrett Lisi) and likely will have to pay off another next year. I don’t know if by “energy upgrade” he’s thinking of the HE-LHC, or the 100 km much bigger proposed ring, but in any case those won’t happen before at least 2040. No matter what happens, I don’t think Wilczek will ever change his mind about the SUSY-GUT paradigm he has found attractive since the 1980s.

In January 2016 Hossenfelder traveled to Santa Barbara to talk to Joe Polchinski, who was already sick with the brain cancer that ultimately would take his life two years later. Unlike Wilczek, Polchinski was a fan of string theory and of evaluating it by “post-empirical” criteria. He at one point published a “Bayesian” calculation arguing that string theory is correct with probability “over 3 sigma” (i.e. over 99.7%). Asked about prospects for a unified theory, Polchinski says:

> I think string theory is incomplete. It needs new ideas… But string theory has been so successful that the people who are going to make progress are the people who will be building on this idea.

Arkani-Hamed, Weinberg, Wilczek and Polchinski reflect a range of points of view about the current situation and what it means. Unfortunately it seems to me that they share an unwillingness to face up to failure, and this doesn’t bode well for the future of particle theory, with “more of the same” the agenda that is being set.

Besides these four interviews, the book also contains accounts of meeting and discussions with quite a few other physicists, all well worth reading, and often written with a sly humor. The description of visiting Garrett Lisi on Maui is not to be missed, and he has a lot of sensible things to say (“For a surf bum, he’s surprisingly intellectual” the author writes). He tells the story of how Jacques Distler and others threatened (unsuccessfully) to organize a boycott of Scientific American if it published an article by him. In addition to the interviews there’s a great deal of valuable discussion of the problems with the way research is organized and the reward structures scientists operate under (for instance, publicly admitting failure is definitely on the “not encouraged” list).

So far I’ve ignored the main framing device that Hossenfelder uses throughout the book, that of her questioning the idea of “beauty” as a motivation for evaluating ideas about physics. This is not because I disagree all that much with what she writes, but instead that I fear a complex set of issues is likely to get over-simplified, and this over-simplified version of the book’s argument is all that much of the public is ever going to hear about it. Hossenfelder explains that the concept of “beauty” she is challenging is a specific set of ideas about “symmetry, unification and naturalness” that she sees as dominating physics research. I agree that there’s a problem with this specific set of ideas and how they have been used, but I’d keep them separate and don’t see putting them together as “beauty” to be helpful. At various points she makes it clear that her worry is that we are getting stuck due to outdated notions of “beauty”, while still believing that successful new ideas will come with a new form of “beauty”.

The book ends with

> We know that the laws of nature we presently have are incomplete. To complete them, we have to understand the quantum behavior of space and time, overhauling either gravity or quantum physics, or maybe both. An the answer to this will without doubt raise new questions…
>
> …There’s much work to do. The next breakthrough in physics will occur in this century.
>
> It will be beautiful.

Update: Science magazine has a review. For some reason they seem to have decided it was a good idea to have the book reviewed by a postdoc doing exactly the sort of work the book is most critical of. The review starts off by quoting nasty anonymous criticism of Hossenfelder from someone the reviewer knows on Facebook. Ugh.

Update: I’ve written a similar but somewhat different version of this review for MAA Reviews, one aimed more at mathematicians.

Update: More reviews here and here, as well as a posting from Hossenfelder where she explains her current professional situation in the context of deciding to write the book.

Update: I’m glad to see that Science has edited the review there to remove the use of an unattributed quote.

June 8, 2018

The "demand for alternatives" style of riposte comes up so frequently I think it deserves its own blog. Not so much a refutation of the "only game in town" assertion, which is really a separate issue. I'm thinking more of this highly prevalent notion that, assuming there really is only one game in town, one is therefore compelled to play it or shut up. In fact, the original joke is only funny because the players know the game is rigged. It doesn't seem to occur to them to just stop playing and find some other way to occupy their time. A rather sad explanation might be that they're compulsive gamblers, and simply can't help themselves.

Why doesn't it occur to people that it's quite enough to point out the game is rigged? Why is it incumbent on him or her doing this service to also have another game at the ready, or refrain from comment? Of course it would be preferable if an alternative could be proffered immediately, but that's not the point. It's the responsibility of the player of the rigged game to act on that knowledge rationally, i.e. stop being cheated, maybe take a break and at least think about your next occupation if you've got nothing better to do. Why is it someone else's job to figure all that out for you? Apparently many folks feel that it very much is the critic's job, which is truly strange.

7. **Amitabh Lath**
June 8, 2018

Oh come on! LHC has not found evidence of new physics *in the easy to look for signatures*: lepton or jet resonances, large missing momenta, multiple leptons, etc.

There are so many ways we could be missing the new physics signals. It could be decaying to many jets (the multi-jet background is millibarns, and we don't understand jet production even to leading order, so it is tough picking out a new physics signal at femptobarn production cross section). It could be long lived. It could be very low mass (LHC detectors can be blind for low mass signal, but we are figuring out clever new techniques). It could be a high mass thing decaying via lots of intermediate states, shooting off very soft pions at each step. There are so many hard to find places that new physics could be hiding, and we have just started. LHC data taking started less than a decade ago.

(of course, when I say "easy to look for" I mean doable, but with LOTS of hard work)

8. **Daniel Tung**
June 8, 2018

A multiverse believer probably should not think that our universe has beautiful laws, simply because universes with ugly laws obviously outnumber universes with simple, beautiful laws.

9. **Avals**
June 8, 2018

Once I met Sabine Hossenfelder at a conference in Warsaw. I was standing in front of the conference schedule, and she dropped by and pointed out to me her own talk in the schedule, and said that that was the talk I absolutely have to go see. I thought it was pretty strange and narcissistic. I didn't go to listen to her talk. Nor will I go read this book.

10. **Peter Woit**
June 8, 2018

Amitabh Lath,

I think the reference to negative LHC results "for popular speculative models" is pretty accurate, specifically I had in mind technicolor, SUSY, extra dimension models. In, for example, minimal SUSY with 100+ extra parameters, it's not completely clear what "generic" means but the possibilities you list seem to me to correspond to arguably "non-generic" cases. The full parameter space will never get covered and minimal SUSY will never get completely ruled out, but it becomes less and less plausible that the superpartners are hiding in exactly the regions hard to access experimentally.

To be clear, while it's accurate to say that the LHC has so far seen no non-SM physics, that certainly doesn't mean it's not going to, there's a very long ways to go and many places to look. To the extent early searches have been focused on looking for specific signatures of implausible SUSY and extra-dimensional models, as those searches get done and people move on to look for other things, arguably the chance of success will go up…

11. **Peter Woit**
June 8, 2018

Avals,
I met Sabine in person for the first time a few months ago, and she did not strike me as unusually narcissistic, but did strike me as unusually direct. At your conference in Warsaw likely all the other speakers standing around also thought that you should be going to their talk, but unlike her they didn't directly tell you this.

I'm curious to see what the reaction to her book will be, as compared to what happened back in 2006 with my book and Lee Smolin's. Smolin and I certainly both thought our ideas were important and people should pay attention to them, but I think we both lack Sabine's directness, which may be useful to her in getting attention for her ideas.

12. **Art**
June 8, 2018

Michael Harris' "Mathematics Without Apologies" made the point that mathematicians and physicists are some of the last people to still use beauty as a criterion for their efforts, artists having long ago abandoned that standard. I recall being quite struck by that.

13. **Supernaut**
June 8, 2018

" The review starts off by quoting nasty anonymous criticism of Hossenfelder from someone the reviewer knows on Facebook. Ugh."

I'm starting to get the impression that Science mag is losing respectability a bit.

"Raising these issues 20 years ago was useful and needed courage. Now it's useless."

Not at all; as Peter points out, this book comes out post-LHC results. Sounds interesting and I'm hoping to get it. Thanks for the review.

14. **Amitabh Lath**
June 8, 2018

Peter, first please call me Amit.

Basically any beyond-SM stuff that shows up (at LHC or in some underground tank) has a mass scale, some effective coupling to the SM, and possibly quantum numbers like charge, flavor, color, lepton number. A complete top-down model like SUSY is one way to generate these but frankly simple ad-hoc models that map out the space of possible new physics signatures are more helpful right now.

So even if the parameter space for (some minimal version of) SUSY is more or less covered, that hardly means that the parameter space for all possible new physics signatures allowed by field theory is eliminated.

15. **Sabine**
June 9, 2018

Avals,

I can't recall neither you nor the conference, but clearly we don't share the same sense of humor.

16. **AS**
June 9, 2018

20 years ago many influential theorists did not want to see what was going to happen, so it was useful and "dangerous" to point out the problem. It was as useful as alerting about a possible subprime mortgage bubble. After that both bubbles bursted, it's now useless to write a book about "idiots who lost their house". What was overpriced is now underpriced: there are potentially interesting ideas which are not being explored because they belong to fields that presently have an excessively bad reputation among young theorists.

17. **Thomas**
June 9, 2018

"For some reason they seem to have decided it was a good idea to have the book reviewed by a postdoc doing exactly the sort of work the book is most critical of. "

Why do you need to specify she is a postdoc ? How is this relevant ? Why not say "a researcher" ?

18. **ranjeet**
June 9, 2018

Dear @Luca, what AS was saying (most probably) that, raising these issues 20 yeas back would have been fruitful and would have directed the physics to the meaningful trajectory but now it has gone to irreversible and unfortunate distance…. so that it is now useless even to talk about it. But, it is never too late…. for a good thing or correction.

19. **Anonyrat**
June 9, 2018

^^^ After the bubbles burst, it is worth understanding what happened to keep it from recurring.

20. **Amitabh Lath**
June 9, 2018

Peter, you said:
>as those searches get done and people move on to look for other things, arguably the chance of success will go up…

Both ATLAS and CMS already have large groups looking at non-SUSY signatures for new physics.

Both experiments have set up multiple physics groups that concentrate on a specific type of signature and build up analysis expertise. Both have an "Exotics" group that is separate from the SUSY group, and searches for things like microscopic black holes, long-lived signatures, quark substructure, multi-jet resonances, particles with both lepton and baryon number, 4th generation particles, Majorana neutrinos…

If you are under the impression that somehow experimental physics is in the thrall of SUSY and only when it is completely wiped out (ha!) will our imaginations be freed, you are mistaken.

PS: If you have any clever ideas for possible beyond-SM stuff that you feel is being ignored (SUSY or not), feel free to share. Of course your ATLAS colleagues at Columbia might like to get a first crack at it 🙂

21. **Frank Wilhoit**
June 9, 2018

We begin to see more and more questions paraphrasing "has physics gone off the rails?" In other words, has the *science* gone off the rails? But this is backwards.

Dr. Hossenfelder's book shows that the political environment of the field has gone *completely* off the rails, as shown by the fact that people who have real ability and real accomplishments are quoted spouting utter, patent nonsense.

When this happens, to any field, the substantive efforts must follow the politics off the rails. (If this is not obvious, I do *not* refer to the internal party politics of any nation or even to the corresponding meta-politics; I refer to the ideological premises that constrain the public discourse within a field of inquiry.)

22. **Peter Woit**
June 9, 2018

Amit,

I was just trying to come up with some reason for optimism… Was not trying to imply that the LHC experiments are currently overly devoted to looking for SUSY. Actually, over the past year or so I've been struck by how little activity there is on that front (i.e. few new SUSY limits based on 2017 data).

The problem of who to share my promising new idea about an LHC testable improvement of the Standard Model with has not yet come up…

23. **Peter Woit**
June 9, 2018

Thomas,
The level of experience in the field of the reviewer is relevant. I still think it is an odd decision of Science to commission of a review of a book like this from someone only one year past their Ph.D. (and, as far as I can tell, no experience writing book reviews).

24. **Tanner**
June 9, 2018

Enjoyed your informative review of Sabine's book. Gave me a sense of the book. It's unfortunate that the review published in Science was more focused on snark than being informative.

25. **tulpoeid**
June 9, 2018

Allow me some replies to three comments:

@Thomas, in addition, a postdoc is not tenured yet so highly dependent on their seniors' views of them.

@Amitabh, the point is that all predicted (either minimal or reasonable) parameter space by the theories criticized here has been excluded. This is very different context than the general searches at LHC experiments. Also, during the first years of LHC running, the physics groups had to make very real-world decisions on which analyses get priority (in computing and human time).

@AS, right now we are in the middle of the "bubble bursting" but it shows no sign of slowing down. For instance, multiverse has started taking over public science writing during the last year.

26. **Mike Klymkowsky**
June 9, 2018

There are disciplinary issues here as well. Biologists quickly learn that "brilliance" alone is not sufficient to understand the complexity of (history-dependent) biological systems.

Physicists, particularly of the theoretical-type, appear to believe that everything can be deduced from first principles or hypothetic, unobservable constructs – that brilliance is everything (together, perhaps, with an excessive self-confidence even in the face of serious miscalculation).

see Bernstein, R. (2015). "Belief that some fields require 'brilliance' may keep women out." Science. http://www.sciencemag.org/news/2015/01/belief-some-fields-require-brilliance-may-keep-women-out

27. **Dempsey**
June 9, 2018

I've heard Wilczek stress the coupling constant unification/SUSY calculation several times. As a rank outsider, I've always been impressed with this, but then you read that maybe it's not so special after all. I have no way of evaluating this. On the one hand, Wilczek is obviously in the first rank, and you can't ignore his opinions. On the other hand, the coupling constant unification is his baby, and maybe he seriously overstates its importance. Wish I knew.

28. **Anonyrat**
June 10, 2018

Dempsey : from Bee, 2007
http://backreaction.blogspot.com/2007/12/running-coupling-constants.html
Read the comments too.

29. **Thomas Larsson**
June 10, 2018

Dempsey, you may want to have a look at what Wilczek wrote in his [Future Summary]() from 2001:

"5.5. Produce the New Particles!
Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, there must be several accessible to the LHC."

Now that the results from the LHC are in, it is clear that at least low-energy SUSY is plain wrong.

30. **David Orrell**
June 10, 2018

The idea that "science is being led astray by aesthetics" (as I put it) was the thesis of my 2012 book Truth or Beauty: Science and the Quest for Order (Yale UP). Glad to see that some physicists are coming round to the same idea!

31. **Peter Woit**
June 10, 2018

Dempsey,
I looked into this when writing "Not Even Wrong" and wrote about it there. At the time, one recent source was this
https://arxiv.org/abs/hep-ph/0202185
which states:
"The supersymmetric gauge coupling unification misses by about 10%. More precisely, the experimental value of the strong coupling is about 10-15% lower than the value computed by running down theoretically from the point were the SU(2) and U(1) couplings meet."

I haven't looked for more recent versions of this calculation. From what I remember, one part of the story is that the two-loop calculations make agreement worse, people often refer to the better agreement at one-loop. Also, how you numerically categorize the accuracy of this calculation depends on how you formulate things (I think it looks better if you fix observed couplings and compare extrapolated couplings at the GUT scale).

There are also two generic problems with this kind of calculation, indicating one shouldn't take any particular numbers too seriously:

1. The result depends on what you choose as your scale of SUSY breaking, as well as other details of the many coupling in the SUSY model.
2. These calculations inherently assume a "desert", that there is no physics affecting the coupling constant running, in between the TeV scale and the GUT scale. I think most theorists have always felt this is an implausible assumption.

All in all, this has always struck me as a rather weak argument, and I suspect Wilczek's fondness for it has something to do with his involvement at its birth.

32. **Anonyrat**
June 10, 2018

A more recent SUSY unification++ calculation: nothing much changes, I think. https://softsusy.hepforge.org/doc/threeLoop.pdf

33. **Oss Ickle**
June 10, 2018

Avals,

I'm a professional comedy writer, and an avid reader of Sabine's writings (e.g., her blog, her comments to others' blogs). I can't wait to read her book.

She's absolutely hilarious, and when I read your comment about what she said, I laughed out loud (for the most recent time) at her wit, self-awareness, irony.

Perhaps there's a language barrier, perhaps you are humorless (or "differently humored"). Dunno.

34. **Amitabh Lath**
June 10, 2018

I don't know why everyone is so concerned what the Very Intelligent People are thinking about the multiverse or the landscape or whatever. I'm not up on my history of science but wasn't a similar group declaring physics over with in the late 19th century? This is what happens when theory runs ahead of experiment.

We need the 21st century versions of the Michelson–Morley and Rutherford results. And I am hopeful on that front. I can only speak to my small corner but the work going on in detector design, data analysis, triggers, etc is stunning. Truly bleeding edge. There are techniques being developed for microsecond trigger decisions that rival full offline analyses from a couple of decades ago. If it's there we'll find it. It won't be "here's SUSY" or "here's the techni-pions" or whatever. It will start out as an excess that won't go away, and build. Theorists (the good ones anyway) will jump on it and all this metaphysical talk will be forgotten like that 19th century end-of-physics talk.

35. **John Baez**
June 11, 2018

I wish people would stop using "physicists" or "theoretical physicists" to mean "high-energy particle physics theorists" when issuing condemnations such as Mike Klymkowsky's above:

> Physicists, particularly of the theoretical-type, appear to believe that everything can be deduced from first principles or hypothetic, unobservable constructs….

or more importantly because it's being read by more non-experts, [Dan Falk's article about Sabine's book](#):

> "All of the theoretical work that's been done since the 1970s has not produced a single successful prediction," says Neil Turok, director of the Perimeter Institute for Theoretical Physics in Waterloo, Canada. "That's a very shocking state of affairs."
>
> This doesn't mean physicists aren't busy; the journals are publishing more research than ever. But Turok says all that research isn't doing much to advance our understanding of the universe — at least not the way physicists did in the last century.

There's a lot of top-notch theoretical physics going on today in many fields – condensed matter physics, fluid dynamics, biophysics, astrophysics, etc. Experts will realize that the above complaints are really complaints about *one specific branch* of theoretical physics. But ordinary people may not realize this. They may actually believe it when people say theoretical physics is going down the tubes! I think anyone who really cares about physics should avoid spreading this wrong impression.

36. **John Baez**
June 11, 2018

Well, I said "high-energy particle physics theorists"… but maybe what people are really complaining about is "theoretical physicists seeking new fundamental laws", or something like that. I just want people to be specific about their complaints, not to tar lots of innocent victims with the same brush.

37. **Douglas Natelson**
June 11, 2018

Thank you, John. Bear in mind that often it's not just journalists, but the high energy theorists themselves who use all of "physics" as shorthand for their piece of it. It would be great to break them of that habit.

38. **Joelson F. Silva**
June 11, 2018

John Baez,

Finally someone pointed to this issue here. Many times physicists (high energy theoretical physicists, more especifically) use the term theoretical physics as synonyms for high energy theoretical
physics, and this is a huge mistake. For exemple, in my research area (condensed matter physics)
We living a great moment, hot topics , for example, topological phases of matter, exotic excitations, high temperature superconductors, transport in
mesoscopic systems (non-equilibrium dynamics), open systems, low-dimension physics and the Fermi liquid breakdown, strongly correlated electrons, etc. All topics above using complex theoretical techniques and bring up important new results in theoretical and mathematical physics every day (and more important,
for us physicists, with experimental results). Then, I believe that high energy physcists must be more carefull with the term "theoretical physics" .

39. **John Baez**

June 11, 2018

Yes, Douglas, it's the physicists themselves who should take the lead, by explaining that there's a lot more to theoretical physics than the quest for a "theory of everything"… and the rest of physics is doing just fine. Theorists focused on this quest may not want to admit this, but in the long it's in their own best interest.

40. **Anthony**
June 12, 2018

Nature Magazine also has a review out.
https://www.nature.com/articles/d41586-018-05374-9

41. **Low Math, Meekly Interacting**
June 12, 2018

I rather like Siegel's unequivocal focus in his review, a point he's made again and again: beauty may or may not be a reliable guide, but it must be acknowledged that the beautiful ideas in question have simply failed. No mealy-mouthed excuses about the unexcluded regions of whatever parameter space, or undue acknowledgement of those counter-arguments. They have already proven to be wanting. When evidence falsifies, it's false. When evidence is unobtainable, it's folly. Period. Evidence is the only truly reliable guide, period. Seek it elsewhere, and only where there's some hope in finding it. It's worth shouting from the rooftops. Cognitive biases and fashion and sociology are all worth mention, but should be painfully obvious culprits in human affairs. How anyone could claim to be free of them is hard to fathom. That they do is still unsurprising. Trust empirical evidence, reproduced, and nothing else. I believe that is not only the key to the survival of all science, but of our species as well.

42. **Peter Woit**
June 12, 2018

LMMI,
My problem with this is that I don't think it's so simple, in particular I don't think it's a simple failure of "beauty". For instance, in the case of SUSY, there's a good argument that the super-extension of the Poincare group is a "beautiful" idea, but this idea immediately runs into the problem that you need to break the symmetry (explicitly or spontaneously) and what you get is very unbeautiful (eg. over 100 extra parameters to describe the possibilities). So, to me, what the LHC was testing (SUSY extension of the SM, softly broken at the TeV scale) was not a beautiful idea but an ugly one. A believer in beauty to my mind would have said that SUSY was already disqualified at the beginning, once one realized it had to be badly broken, and there was no beautiful way to do that. I think what Hossenfelder is pointing to as flawed is not actually arguments from "beauty", but arguments that start with a symmetry principle which has to be badly broken to agree with reality.

As for the "just trust experiment" idea, the problem we have is often a lack of any relevant experiments. That some small part of the theory community has gone off into ridiculous claims about "post-empirical" theory is a bit of a red herring. Few theorists really take that bizarre move seriously. The "post-empiricists" are doing great damage to the public perception of the subject, but the more significant issue is the large number of theorists working on the same failed ideas, hoping they can somehow extract something empirically testable out of these ideas. We've seen over the years that all you get by pushing "empirically testable" is moving people in the direction of studying ugly complex models that somehow might be testable, even though they are highly implausible and explain nothing. We might actually be better off with people giving up for now on testability and trying to find a new beautiful idea (i.e. new forms of symmetry). I think Hossenfelder in the end agrees that a successful new breakthrough will produce a new form of "beauty". To me it's thus not unreasonable to try and find that, independent of experiment if you have to. But you have to be really honest with yourself about when ideas don't work and are unbeautiful, and the sociological reasons why people can't or won't do that are a big problem (one that Hossenfelder has written a lot about).

43. **Anon**
June 12, 2018

hi peter — just got hold of the book and began reading it. the beginning was interesting and then after that it is quite confusing. Have to read it more carefully. The interviews with scientists are interesting.

I dont really get what the issue with beauty is, that Sabine is trying to convey. If some beauty driven theories are falsified that is part of the scientific process — to come up with falsifiable theories. Is it the time we are taking to abandon them? Whats happening currently is not very beautiful — to try and come up with theories that may have consequences for LHC even if they have problematic things like very small couplings for parameters you'd think are order 1 on grounds of beauty. The other thing that is currently being done that is not beautiful is to try and save theories like SUSY — which solved the hierarchy problem and could be falsified from that point of view. Like Nima wanting a 100 TeV collider to make sure that the hierarchy problem is not resolved even at that scale (or if it is then to discover the new particles/physics) — that collider would probe theories not as beautiful as the solutions LHC probed.

Anyway I think the biggest miss in the book is the neutrino masses and mixings which is the new thing that has happened experimentally — neutrino physics was anticipated considering symmetries such as B-L and parity.

Have had the book only for an hour or so. Will read more.

44. **Low Math, Meekly Interacting**
June 13, 2018

I truly hope you are right, Peter, and I would be extremely happy to be wrong. My admittedly rank-amateur outlook is one of pessimism without some breakthrough experimental guidance. I'm not all that convinced people should keep hammering away at the current data set while the elders hope that some day a young genius theorist, free of the shackles of these failed ideas, will save HEP theory from itself and bring enlightenment. I'd put the odds on that as roughly equal to the odds that SUSY will be confirmed by the 100 km collider. I.e., while it could happen, I see zero reason to expect it.

45. **Peter Woit**
June 13, 2018

LMMI,
The problem is that if you insist people wait for experimental guidance to try and make progress, you're basically arguing that theorists should abandon research on these questions. There is some sign that's already happening, as HEP theorists give up and try to rebrand themselves as condensed matter or quantum information theorists. Unfortunately their "giving up" often is taking the form of "we have discovered that the multiverse did it, so these questions are hopeless", discouraging anyone else from working on the questions that they failed at.

Personally it seems to me that there are huge unexplored areas at the intersection of QFT and mathematics. Some HEP theorists have moved from failed ideas to trying to work on fundamentals of QFT (without experimental guidance) and that's great. My one problem with Hossenfelder's book is that I fear her argument will be read as discouraging this, that it's "searching for beauty", so hopeless, whereas her real argument is with a narrow failed set of ideas, not "beauty" in general.

46. **Urs Schreiber**
June 13, 2018

whereas her real argument is with a narrow failed set of ideas, not “beauty” in general.

Nor maths, for that matter. Rules-of-thumb, such as “naturalness”, witness a dearth of rigorous arguments, not an abundance.

“The alternative to naturalness, often neglected as an alternative, is having a theory.” (Kane 17, p. 33, p. 57)

47. **Low Math, Meekly Interacting**
June 13, 2018

I find the fight over the “demarcation problem” to be tedious and don’t have much of an opinion myself, but could the situation for theorists interested in exploring the intersection of maths and subjects like QFT be improved simply by moving to a different department? It might be pure semantics, but if one chooses to call it a form of “applied mathematics” one can avoid a certain amount of philosophical angst, I suppose. It might also be a healthy development for HEP theory, if people in that bucket are perceived as going too far off the reservation (as opposed to just refusing to give up on failed predictions as such practice is more conventionally understood).

This truly is more of a question than a proposal, as I’m not really qualified to have an opinion.

48. **Peter Woit**
June 13, 2018

Urs,
I agree that the problem is caused by people who don’t have a theory, but Kane has no credibility since he is a perfect example of what you don’t want. Yes, he has a theory, lots of theories, one for every possible experimental result…

LMMI,
I don’t think the “demarcation problem” has to do with the boundary between mathematics and physics, it’s about the boundary between testable and untestable statements about the physical world, which is something different.

The problem here is people refusing to give up failed ideas, and thus flirting with non-science, not that they have moved into mathematics. While many physicists would love to get rid of this problem by dumping it on a math department, the math departments are not going to go along with this. There is a very healthy overlap between math and physics, but it’s something very different.

49. **Urs Schreiber**
June 13, 2018

The broad properties of the G2-MSSM which G. Kane is highlighting, such as the crucial “slightly split” susy, are not controversial (there was also some informed discussion of this on your blog a while back here). Kane et al. discuss the latest exclusion of parameter ranges in arXiv:1803.04394, this is not anything goes.

But even if the G2-MSSM is experimentally excluded tomorrow, a good point remains: This is a top-down model embedded in a coherent ambient theory, and with properties argued from by systematic analysis of the theory instead of by rules-of-thumb, avoiding the folklore fallacies that are being criticized here.

Of course the precise numbers extracted depend on assumptions, or else we are living in a Douglas Adams novel. It’s easy to make fun of this from the sidelines, but it remains a truism that the job of model builders is to tune the assumptions admitted by their models to fit the data.

Kane’s book is really good, sober and to the point. He has a great quote in there along the lines of better risking to make a fool of oneself than not trying the worthwhile. That’s the attitude that the community could use more of.

50. **Peter Woit**
June 13, 2018

Urs,
Your love for SUSY hype is getting off-topic, I’ll just point out that “really good, sober and to the point” is an extremely inaccurate description of Kane’s books about SUSY, for reasons that are laid out here:
https://www.math.columbia.edu/~woit/wordpress/?p=5793

To bring the discussion back to the topic of the book, Kane does appear in it. Hossenfelder describes the scene at the 2015 Munich conference, where Gross and other string theorists interrupted Kane’s talk, making it clear they did not think his “predictions” followed from string theory, but thought that he was using “additional hand-selected assumptions in order to reproduce what we already know about the standard model”. When she asked Kane about what he would do if his prediction of a run 2 gluino didn’t work out, he said that he would “wonder what one could change in the model”, gave no indication he would under any circumstances give up on string theory. This (and the book edits I documented) are not the way science is supposed to work.

In the Arkani-Hamed interview, he makes very clear that Kane does not count as what he considers one of the “good people” in the subject.

51. **Anindya**
June 13, 2018

John Baez,

In a sense, the use of “theoretical physicists” in these articles is on track because in the layperson’s eye, theoretical physics IS associated with “The Quest for the Theory of Everything”. Maybe we have Stephen Hawking to thank for that.

An analogy might be how “investment bankers” have been broadly implicated in the great financial crash of 2008.
But actually the big bulk of that was specifically traders in credit derivatives of various sorts. Those doing mergers and acquisitions – which is a huge part of investment banking – were not really part of this.

52. **Anindya**
June 13, 2018

And just an addendum – I also think “particle physics” is a misleading term because it makes it seem like these people are trying to find new particles.
Whereas in reality, these are all attempts to find the fundamental laws of nature.

Maybe “fundamental physics” ? Or would that raise the hackles of all the “non fundamental” physicists? 🙂

53. **Another Anon**
June 14, 2018

“Maybe “fundamental physics” ? Or would that raise the hackles of all the “non fundamental” physicists”

Yes, I also think “fundamental physics” is the correct term.
Also, I’m never sure why people use human-centred “high-energy physics” instead of “particle physics”, which seems the better term. You’re only calling it “high energy” because you’re low-energy – it’s not high energy to a quark.

54. **TS**
June 14, 2018

While haggling about correct terms, let me point out that theoretical particle physics is progressing by leaps and bounds, and it’s incorporating maths in novel ways all the time. It’s just not the kind of fundamental physics that tries to find new theories that’s making these steps, it’s the kind that takes existing theories and applies them to actual experiments. Calculating differential cross-section for multi-body final states beyond leading order has become more or less routine with automated tools available, two-loop calculations are becoming more and more common, and are rapidly becoming a routine thing for two-body final states, hadronization is studied quantitatively etc.

It’s perhaps not the way we expected our knowledge would progress and not the way we expected particle physics and mathematics to cotinue their interplay, but these are significant advances.

55. **F. G.**
June 14, 2018

Anindya, Another Anon

How about “foundational physics” ? Or “foundations of physics”, the term actually used by Sabine Hossenfelder to describe her day job in a recent interview published at Edge :

” The field that I mostly work in is the foundations of physics, which is, roughly speaking, composed of cosmology, the foundations of quantum mechanics, high-energy particle physics, and quantum gravity.”

https://www.edge.org/conversation/sabine_hossenfelder-looking-in-the-wrong-places

56. **OT**
June 15, 2018

OT: http://www.fields.utoronto.ca/video-archive/event/2388

57. **Peter Woit**
June 15, 2018

F.G.,
“Foundations” isn’t so good, since it often means work on quantum mechanics, which, whatever its problems, they’re different than the ones cause by overly speculative and experimentally inaccessible work. Chad Orzel writes about this here

https://www.forbes.com/sites/chadorzel/2018/06/14/the-difference-between-particle-physics-and-quantum-foundations

I do try and properly attribute the problem to “HEP theory” or “fundamental physics”, but there is no good word that accurately picks out the part of the subject in trouble, and whatever phrase one picks, it’s likely to be too long for many headline writers.

58. **DrDave**
June 16, 2018

Science magazine did it more or less the right way. They removed the quote, and then they put a note in saying they removed the note. There’s other problems with the review, but it is worth noting that many of our larger newspapers do not adhere to basic editorial standards. It’s quite common nowadays to rewrite an article with a changelog. At least someone higher up the foodchain said, hey, this is not OK and fixed it.

59. **Lars**
June 24, 2018

A slightly different perspective from Nobel laureate Murray Gell-Mann

https://www.ted.com/talks/murray_gell_mann_on_beauty_and_truth_in_physics

60. **Geoffrey Dixon**
July 1, 2018

Perhaps the reason our theoretical pyramid is unstable is that it’s been built upside down. No amount of nth order QFT applied to ideas resting on too small a foundation will succeed – and if it does, then Nature is an ass. Mathematics contains enormously generative, and beautiful, structures that resonate perfectly with the universe we actually observe.

I look forward to reading Sabine’s book. It will eventually sit on my shelf next to Peter’s and Smolin’s books. Then I’ll go rewatch the Red Sox job offer scene in the film Moneyball, and stop thinking about things that will not change in my lifetime.

The Multiverse Falsified

June 19, 2018
Categories: Multiverse Mania

The July 1 issue of the Monthly Notices of the Royal Astronomy Society includes an article evaluating the standard multiverse prediction of the cosmological constant, with result:

> The predicted (median) value is 50–60 times larger than the observed value. The probability of observing a value as small as our cosmological constant Λ_0 is ~2 per cent.

If your theory only makes one prediction, and that prediction is off by a factor of 50, that's the end of it for your theory. I'm very glad that this has now been sorted out, the multiverse hypothesis has been falsified, and theorists who have been working on this can move on to more fruitful topics.

Update: As David Appell realized, the last sentence here was sarcasm (or maybe black humor). Those promoting the multiverse are doing Fake Physics™, not Physics. This is ideology, not science, and there is no chance that they will stop referring to the "successful multiverse prediction of the CC", no matter what analysis shows a seriously incorrect prediction.

As Blake Stacey points out, this paper was on the arXiv back in January (see here), and has just been ignored by multiverse proponents. Part of doing Fake Physics™ is ignoring any information that contradicts what you want to believe. Another commenter points to this 2014 argument from Sesh Nadathur, which similarly as far as I know has just been ignored.

After appearing on the arXiv in January, this latest work was promoted by press release from Durham University back in May, which led to lots of media stories (e.g. here). For some reason, the press release didn't really explain that this work falsifies the usual claim that the value of the CC is evidence of a multiverse. Instead, the work was promoted as showing that the multiverse is "more hospitable to life" than thought, which sounds good I guess, but seems like a bizarre way to explain the significance of this work.

For various sensible explanations of what is really going on here, see Jim Baggott, Philip Ball, and Sabine Hossenfelder. I've often repeated my own version of how to see there's a problem with trying to explain the CC this way. There is no actual multiverse theory, so proponents assume a "flat measure over the anthropically allowed region" and then calculate. This is exactly the same input as my theory of the CC, which is that I have no idea what is going on, so any value is equally likely. The bottom line from the latest work on this is that, even if for some reason you believe you can get a sensible "prediction" this way, the prediction comes out wrong.

Comments

1. **David Appell**
   June 19, 2018

   I'm guessing your last sentence is sarcasm.

2. **Blake Stacey**
   June 19, 2018

   The arXiv version is arXiv:1801.08781 [astro-ph.CO].

3. **Anon**
   June 19, 2018

   Hi Peter

   Do you know if the situation has gotten worse for the multiverse since this 2014 blog post that also appears to have similar arguments like you quoted:
   http://blankonthemap.blogspot.com/2014/02/does-multiverse-explain-cosmological.html

4. **Daniel**
   June 20, 2018

   There's a new article at Aeon which I think you might be interested:
   https://aeon.co/essays/has-the-quest-for-top-down-unification-of-physics-stalled

5. **Mitchell Porter**
   June 20, 2018

   It remains true that Weinberg did successfully predict the size of dark energy, to within an order of magnitude, in his paper "The cosmological constant problem". It's there at the top of page 8: "we would expect a vacuum energy density rho_V ~ (10-100) rho_M0". (The actual rho_darkenergy is something like 14 times rho_baryon.)

   You can take the position that he was right just by accident, and that the size of dark energy is determined by something else, or determined by nothing at all. Of course that's possible.

   But it also remains very possible that he was basically right! The subsequent literature on the anthropic prediction of the cosmological constant just reruns his argument in a variety of concrete scenarios. This paper tells us how the argument fares, for a particular cosmological model, under a variety of auxiliary assumptions. Sometimes it works and sometimes it doesn't.

   If I was an anthropic theorist, the conclusion I would draw from this paper, is that I should go back and study closely the details of Weinberg's original argument, because it worked perfectly when he did it, the first time around.

6. **Anonyrat**
   June 20, 2018

   Mitchell Porter:

   The Sesh Nadatur comment referenced above is that the Weinberg argument doesn't work with the current earliest time of galaxy formation, i.e., current observations — the maximum redshift at which a galaxy has been found. It is not just that Weinberg's argument fails with the current cosmological model, it is that he got lucky with what the state of observational knowledge was when he wrote that paper.

7. **Peter Woit**
June 20, 2018

Mitchell Porter,
I'll leave this to the experts, but my impression was that the claim of the new paper is that Weinberg's calculation is wrong (doesn't agree with what we now know). In any case, the two possibilities seem to be:

1. Weinberg's calculation was wrong. Multiverse proponents will just ignore this and continue to tell people to believe in a multiverse because of Weinberg's "successful" calculation.

2. Weinberg's "prediction" was fine, but you can get pretty much any "prediction" you want by changing your uncheckable assumptions about how the multiverse works. Again, calling this sort of "prediction" a success would be misleading.

8. **Peter Woit**
June 20, 2018

Daniel,

That is interesting, will likely soon discuss it in a posting.

9. **Lee Smolin**
June 20, 2018

Dear Peter,

I've been making this point in books and reviews for many years. (For example hep-th/0407213). A further point is that if you expand the list of constants to be determined by Weinberg's anthropic argument, from just the CC to the CC and Q, which measures the size of the primordial density fluctuations, the discrepancy between the predicted most likely value and the observed values grows to many orders of magnitude (See Figure 2 of astro-ph/0401424.)

Thanks,

Lee

10. **Peter Woit**
June 20, 2018

Thanks for pointing that out Lee. Yes, that's another serious problem with the oft-repeated "Weinberg's successful prediction" claim.

11. **Low Math, Meekly Interacting**
June 21, 2018

The undead quality of the "Weinberg predicted the CC" argument ranks very high on the list of habits of multiverse proponents that puzzle me. As it was apparently quite rigorously dispatched years ago, what gives? It's not like SUSY, where an excess of flexibility makes falsification impossible. The multiverse itself has much the same virtue for those who wish to move the goalposts forever. So why bother with a very narrowly-focused prediction that HAS been falsified? Has Weinberg himself ever said anything publicly about the current state of his prediction?

12. **Peter Woit**
June 21, 2018

LMMI,
To his credit, I don't think Weinberg himself really does this, and his comments on the multiverse always seem to be of the order of "maybe yes, maybe no", not ever "my successful prediction shows it's true". For many others, especially multiverse ideologues, being able to invoke Weinberg's name and the words "successful prediction" is just irresistible and there is nothing that will ever get them to give this up.

13. **Uncommon Sense**
June 21, 2018

Does any of this relate directly or analogously to Everettesque/ Many-Worlds QM?

14. **Peter Woit**
June 21, 2018

Uncommon Sense,
No, not in the slightest. They are two completely different things.

15. **Blake Stacey**
June 23, 2018

Just to update the argument from 2014:

The highest-redshift galaxy so far observed, as best I can tell from the literature (it's been [a long time] since I worked in astrophysics) is at $z = 11.1$. See [Oesch *et al.* (2016)]. Following Weinberg's argument, this gives a bound on the vacuum energy density of about 5800 times the present cosmic mass density. This is three orders of magnitude larger than the observed value, a ratio well into the regime where Weinberg himself says the cosmological constant would be "so small that even the anthropic principle could not explain its smallness".

Knockin' On Heaven's Door

June 21, 2018
Categories: Uncategorized

I've been thinking about what to write about this essay by Ben Allanach, which gives his take on the current state of HEP theory. Allanach is a specialist on the phenomenology of SUSY models, but here he announces that he's basically giving up on these models:

> The trouble is that it's not clear when to give up on supersymmetry. True, as more data arrives from the LHC with no sign of superpartners, the heavier they would have to be if they existed, and the less they solve the problem. But there's no obvious point at which one says 'ah well, that's it – now supersymmetry is dead'. Everyone has their own biased point in time at which they stop believing, at least enough to stop working on it. The LHC is still going and there's still plenty of effort going into the search for superpartners, but many of my colleagues have moved on to new research topics. For the first 20 years of my scientific career, I cut my teeth on figuring out ways to detect the presence of superpartners in LHC data. Now I've all but dropped it as a research topic.

While most HEP physicists still try and end their talks with some sort of optimistic expression of hope that things will change soon, I was struck by a recent talk by John Iliopoulos, which was more somber and more realistic:

> No coherent picture emerges
>
> We were expecting new physics to be around the corner…..
> But we see no corner
>
> The easy answer: We need more data
>
> Two problems: (i) We do not know what kind of data
> (ii) They will not come for quite a long time
>
> A rather frustrating problem!

and he ends with

> The Future of Particle Physics will undoubtedly be bright, but
>
> I will not learn the answer

While thinking about this I happened to look at an old posting of mine, a review of Lisa Randall's Knocking on Heaven's Door written back in 2011. There I wrote

> One odd thing about the book is the title, which for Randall carries a positive meaning that she acknowledges doesn't correspond to the very dark one of the Bob Dylan song from the soundtrack of the Sam Peckinpah film. It's a beautiful song, but one not about finding truth, but about getting shot in the gut and facing death, hopefully not relevant to particle physics in the LHC era:
>
> *Mama, put my guns in the ground*
> *I can't shoot them anymore.*
> *That long black cloud is comin' down*
> *I feel like I'm knockin' on heaven's door.*

It does seem like much of the last 40 years of HEP theory is now "knockin' on heaven's door", deeply wounded by negative results from the LHC. What this means for the future is still up in the air: what story about what has happened will become the conventional wisdom?

   June 22, 2018

   Peter,
   it occurs to me that all this "woe be upon us for LHC keeps confirming the Standard Model" is mostly prevalent among theorists of a certain age.

   We have occasional LHC-lunches where experimentalists and theorists get together (consider yourself invited if in the Garden State!). The last one was a few days ago and I was struck by the excitement among the young theory grad students and postdocs about the upcoming High-Luminosity LHC run. They were going on about clever new techniques to find hidden new physics, proposing new detectors for long-lived dark photons deep in the LHC tunnels, etc etc.

   The attitude was "nature is being coy, now it gets interesting". What a contrast from the essay by Allanach.

3. **Moyses**
   June 22, 2018

   Sterile neutrinos, g-muon (4 sigma) and B-mesons anomalies, no-MOND (i.e. "absence of a fundamental acceleration", 10 sigma)…
   Surely You're Joking, Mr. Woit 😉

4. **Roger**
   June 22, 2018

   Moyses

Regarding anomalies associated with sterile neutrinos, g-2 muon + B-mesons, the community maintains a healthy scepticism. The number of sigma of a deviation is irrelevant if there is an underestimated or overlooked uncertainty. At any given time over the past few decades one could have done as you've done and suggest new physics on the horizon due to the anomalies of the day – leptoquarks at HERA in 1997 was my favourite. Its difficult to see that the situation today is qualitatively different.

5. **Peter Woit**
June 22, 2018

Amit,

I'm glad to hear that the part of HEP theory directly interacting with the experiments is healthy. The part that I think has been mortally wounded is the part that has had the assumption that the path to further unification will be based on a SUSY extension of the SM. This isn't a bad thing in and of itself, depends on what emerges from the wreckage (Dijkgraaf's recent "There are no laws of physics" piece unfortunately shows that something worse is possible).

6. **Amitabh Lath**
June 22, 2018

Peter, the part of HEP close to experiment is the actual heart of HEP. These people are never as loud or visible as those who become media darlings peddling mysticism be it "landscape/multiverse" or in a previous era "The Tao of Physics".

7. **John Dixon**
June 23, 2018

Ben Allanach and many others have been using the ideas of the MSSM, with some very sophisticated computer programs, to see if there is evidence for SUSY at the LHC. But I claim that the MSSM is quite flawed. The MSSM is explained on the Particle Data Group website, for example. The idea is that there is an invisible undetectable sector that breaks susy. Then that communicates to the visible sector somehow, also in an unknown way. The practical consequence is that we break susy explicitly with many parameters. I would argue that this is not a theory at all. It is certainly not susy.
It is more like the emperor's new clothes. If the MSSM turned out to be right, that would be horrible. What does susy really predict, if anything? I would say that nobody knows. Spontaneous breaking of SUSY does not work in a simple way, or even in a complicated way. Does it really predict superpartners, if it is done correctly? To know that, we need a new way to interpret SUSY. What the experiments, and Ben Allanach's work, and the work of many others, prove, is that the MSSM is not right. But it is not at all clear that the MSSM is the right way to do SUSY. Lets hope it is not, because it is very ugly and non-predictive, whereas SUSY is a simple consequence of quantum mechanics and relativity.

8. **Peter Woit**
June 23, 2018

John Dixon,

I should make it clear that when I'm referring to problems with SUSY here, it is to the standard SUSY extension of the SM (the MSSM) and more complicated variants. As you note, such theories have always been problematic, since you need to break SUSY and this introduces a great deal of ugliness, extra parameters and lack of predictivity. This was well-known (I wrote about it in my book) and has always been a good reason to not believe in the MSSM. The interesting news here is that a theorist like Allanach, who has devoted much of his career to these things despite these problems, has finally given up.

There are lots of other possible "supersymmetries" (I don't believe though that "SUSY is a simple consequence of quantum mechanics and relativity"), but that's another topic, not relevant to what Allanach is writing about.

9. **John Dixon**
June 23, 2018

Hi Peter. Thanks for your prompt reply. I see that we agree about the mssm. What I meant was that susy is the square root of a translation in quantum field theory. I am not talking about other supersymmetries, whatever they are. The general impression is that spontaneous breaking of susy is the only game for Susy. That is not so. We can do susy without expecting superpartners by transforming the superpartners to sources in the supergravity master equation. My point is that those ideas might conceivably bring Ben Allanach back to Susy because the experimental consequences could be very different.

10. **Urs Schreiber**
June 24, 2018

> susy is the square root of a translation in quantum field theory

There is a noteworthy subtlety with this statement, if it is meant as a mathematical motivation for supersymmetry: Not all super-Lie algebra extensions of the Poincaré Lie algebra are standard susy super Lie algebras — a counter-example is described here.

Hence, to mathematically motivate standard susy super Lie algebras among all "square roots of translations", one needs to invoke another principle.

Here is one: Start with the superpoint, regarded as an abelian super Lie algebra. Then iteratively a) double the fermionic part and b) pass to the maximal invariant central super Lie algebra extension; and repeat.

This process turns out to discover the correct supersymmetry super Lie algebras, avoiding the spurious ones above. Interestingly, it singles out more: It discovers the susy super Lie algebras precisely in dimensions 2+1, 3+1, 5+1, 9+1 and 10+1. See the theorem here.

11. **paddy**
June 24, 2018

Nothing substantial to add other than
(A) waiting for LMMI's questions/comments and PW's answer far better than my typical "huh?"
(B) Urs Screiber's comments are self serving. Or maybe I just do not understand him?

12. **Peter Woit**
June 24, 2018

paddy,
Urs's comment are all right, they just, as often, ignore the main point. There's a huge amount one can say about what happens when you decide to extend the Poincare algebra to some bigger superalgebra. In many of these extensions you have odd generators that when squared give usual translation generators of Poincare.

The fundamental problem occurs when these new generators commute with the energy-momentum generators. If the new generators act trivially on the vacuum, then particle states get taken to particle states with the same energy-momentum relation, i.e. same mass. These "superpartners" will have opposite statistics, but problem is we know of no same mass fermion-boson pairs. So, to avoid this, you have to assume the new generator acts non-trivially on the vacuum, i.e. that the supersymmetry it generates is spontaneously broken. This is where you get into trouble: while there are lots of ways of devising spontaneously broken models, they all tend to either not look like the real world, or require introducing lots of new parameters, then choosing them so as to make the superpartners invisible.

While proponents like to go on about how beautiful this new symmetry is, and how wonderful it is that it relates bosons and fermions, the basic problem is simple: the supersymmetry doesn't relate any bosons and fermions we know about. Put differently, restricting to the state space of known particles, the supersymmetry acts trivially. This may be a beautiful new algebra, but as far as known physics is concerned, it is the trivial algebra.

13. **Amitabh Lath**
June 25, 2018

Okay so SUSY didn't pan out. As people have pointed out, it is only minimal SUSY, made even more minimal by experimentalists who scan in just two or three parameters (yeah, guilty). But fine, maybe nature doesn't do SUSY.

This is no reason to run away from the LHC. Not only is it the only game in town (modulo neutrinos) for the next 20 years, but it has only collected about 2% of its total data haul.

To do a systematic search for deviations from Standard Model we still need guidance from theorists about what new physics signatures could look like. We also need to understand the SM much better than we do now.

Theorists, we need you! Now more than ever.

14. **Low Math, Meekly Interacting**
June 25, 2018

Hi, Amitabh,

If I understand correctly, the question of whether or not nature does SUSY is one that shall remain open forever, since it cannot be disproven. What has been all-but-disproven is the notion that SUSY makes the mass of the Higgs "natural". So while the LHC has only begun to collect data, that first 2% has had an oversized impact. Furthermore, there doesn't appear to be a (known) compelling reason to expect new physics is lurking in the remaining 98% to be collected. The one principle widely touted as a good reason to build the LHC (beyond finding the Higgs) has been demolished. At what scale should experimentalists expect new physics? What guiding principle will take the place of (and hopefully prove more reliable than) "naturalness"?

Experimentalists, I rather think theorists are in most dire need of your contributions at this time. Given the past 40 years, what more reliable guidance would you expect for where to look than "wherever you can"?

15. **Peter Woit**
June 25, 2018

LMMI,
There are different sorts of HEP theorists, many of whom are not of much use to LHC experimentalists, only able to offer rather obvious advice (e.g. "measure everything you can about the Higgs, would be great if you could measure Higgs self-interactions…"). Those expert on certain kinds of specific BSM extensions (e.g. SUSY models) that haven't been found and now look implausible are going to have to retool to try and find some more useful role to play. I think that's what Allanach is trying to do.

I take Allanach's essay as saying that he wants to concentrate on looking at possible experimental anomalies, then using theory to characterize the possible things that could be causing such an anomaly, consistent with all known negative results. One can then play a useful role for experimentalists by telling them things like: "a particle X could explain that B-meson anomaly, and if that's the cause you should also see something unexpected in this other channel". This is definitely useful, but how well it's going to work depends on what anomalies one has to work with. A much harder thing to do is to start with no anomalies and ask "what are the possible consistent SM extensions that would produce something visible at the LHC", indicating where to look for anomalies. Many people have been trying to do this for a long time, coming up with something new here is very hard.

Then again, there are also lots of theorists still needed to understand exactly what the SM predicts in various cases, so that experimental results can be accurately compared with the SM to look for anomalies.

16. **Amitabh Lath**
June 25, 2018

LMMI, as Peter points out there are many flavors of HEP theorists, some of whom work with experimentalists. We need more.

Yes, we are in an era where experiment is going to drive theory, but theory drives experiment. UA1, UA2 at the SPS were built for W and Z discovery. Electroweak theory played a key role in detector design, and electron and muon identification progressed because theory said that was how to bag these vector bosons. CDF and D0 at the Tevatron were optimized for the top search, and a whole lot of R&D went to make the radiation-hard silicon vertex detectors because theory said tagging the b-quark in top decay was critical. The LHC detectors have superb photon resolution because higgs theory said the diphoton decay, although rare, was among the cleanest.

Right now the mix of technologies that will go into the HL-LHC detectors is being decided. Necessary compromises are being made about hardware, bandwidth, physics reach.
And for the first time in many decades we do not have one single driving vision for new physics search. A theorist with a compelling new model (even if half baked) could make all the difference at this moment.

17. **GoletaBeach**
June 27, 2018

A little surprised to read by Allanach:

"Instead, many of us have switched from the old top-down style of working to a more humble, bottom-up approach."

"Old, top-down style"? Just about every significant particle physics discovery has arisen from the bottom-up approach… from Ellis and Wooster discovering the neutrino at least through to the bottom quark discovery by Lederman at all at FNAL. That finally infinitesimal "top down" extrapolations predicted the W, Z, Higgs, and top quark is a small crust on top of a deep core of bottoms-up work.

Actually SUSY was all the rage after UA1 "discovered it" in the 1980's. There is a whole book about that discovery, and its disproof… "Nobel Dreams" by Gary Taubes. Looking for SUSY and not finding it has been around a lot longer than Allanach.

When to give up? Everyone knew in the 1990's that SUSY's lowest WIMP-nucleon cross section was about 10^(-55) cm^2, yet people get worried now if nothing is seen at 10^(-48) cm^2.

This Week's Hype

June 27, 2018
Categories: Fake Physics, Multiverse Mania, Strings 2XXX, Swampland

New Scientist today has a feature article headlined

> **How to think about… The multiverse**
>
> The idea of an infinite multitude of universes is forced on us by physics.

It starts off quoting Sean Carroll:

> "One of the most common misconceptions is that the multiverse is a hypothesis," says Sean Carroll at the California Institute of Technology in Pasadena. In fact, it is forced upon us."It is a prediction of theories we have good reason to think are correct."

The problem with this claim is that it's simply not true. There is no model that "we have good reason to think correct" that predicts a multiverse of universes with different physics (i.e. fundamental constants). I've written about this many times, see for instance Theorists Without a Theory. In case you were thinking of interpreting Carroll's claim in some other way, the article goes on to invoke Alexander Vilenkin:

> "The so-called constants of nature, like the mass of the electron or Newton's gravitational constant, will have different values in different bubbles,"

To be fair to New Scientist, I haven't read beyond the headline and first few paragraphs of this article, since the rest is behind a paywall. Maybe the later part of the article (which most people can't read) explains what is wrong with the Carroll and Vilenkin claims.

For the latest on the models supposed to give us different physics in different parts of the multiverse, you might want to take a look at this new paper on the arXiv, and Cumrun Vafa's talk about it this week at Strings 2018. The paper and talk conjecture that the supposed metastable dS solutions of the string landscape don't really exist (they are in the "swampland" of things that aren't solutions of string theory). If this is true and you want to save string theory, as Vafa explains, you need to invoke different sorts of supposed solutions to string theory, with the CC replaced by a "quintessence" mechanism.

At the end of the talk (1:01), Eva Silverstein tries to explain what is wrong with Vafa's arguments. He responds "I'm not saying you're wrong, you might be right, this might be also be right". This shows clearly the fundamental problem of the subject: there is no well-defined theory here, just a bunch of conjectures about what one might be, with no way to tell whether Vafa or Silverstein is right, and no way to extract well-defined predictions from the mass of possible conjectures.

Update: Thanks to those who sent me a copy of the full New Scientist article. It's short, and the part behind the paywall is even worse than the part publicly available, just adding to the confusion by invoking "many-worlds", with more from Sean Carroll. Our doppelgangers doing exciting stuff in other universes make an appearance, although Carroll expresses a lack of interest in what they're up to.

Update: The Strings 2018 talks and videos are available here or at this Youtube channel, and 4 gravitons has a blog posting. As usual with Strings 20XX conferences, very little about actual string theory there. For an overview of the state of the field, you might want to watch this video of the 50 years of string theory session, moderated by David Gross. Dan Harlow was the only speaker raising the elephant in the room question: "is string theory still a useful candidate as a theory of HEP physics?" (and also asked whether they should finally rename the conference series). Gross read off submitted questions for the panel, most of which were asking about the elephant in the room. The panelists each found a different way of avoiding dealing with the question. Other questions asked about the hot "is there a dS string vacuum?" issue, responses were "maybe yes, maybe no", with no indication of any way to resolve this.

Comments

1. **Jim Baggott**
   June 27, 2018

   I give an alternative view in a post earlier this week to Prospect magazine's science blog. https://www.prospectmagazine.co.uk/science-and-technology/the-problem-with-multiverse-theories-theyre-just-not-science
   What I really don't understand is what theorists like Sean Carroll think they're gaining by holding these views.

2. **Peter Woit**
   June 27, 2018

   Thanks Jim,

   I think it's very clear what Carroll is gaining here: he has written a whole book (From Eternity to Here) claiming to explain a problem about time via different physics in different universes. Most people think this is not science, so he needs to convince them that it is science, that the multiverse is "forced on us by science".

   What harder to understand is why he never responds to arguments explaining the problems with this, just ignores them, only responding to straw man arguments. Even harder to understand is why journalists put his claims front and center, ignoring the problems with them. As I said, I haven't seen the rest of this piece, but typically pieces like this are almost entirely quotes from multiverse proponents, with little if anything from people pointing out the problems.

3. **Another Anon**
   June 27, 2018

   "One of the most common misconceptions is that the multiverse is a hypothesis," says Sean Carroll

   Well, I can actually agree with Sean Carroll for once! As the start of the Wikipedia page on "Hypothesis" says: "For a hypothesis to be a scientific hypothesis, the scientific method requires that one can test it."

   So, I'm totally in agreement with Sean Carroll – it fails the criteria for a hypothesis. Dunno what you'd call it, really. An "idea"? A "bit of fun"? Don't care, really.

4. **Armin**
   June 27, 2018

   "What [is] harder to understand is why he never responds to arguments explaining the problems with this, just ignores them, only responding to straw man arguments."

Isn't cognitive bias the obvious explanation?

If we already believe something to be true, we tend to evaluate new input, including critical questions, in terms of how it confirms our beliefs, and if we believe it not to be true, we look for ways the new input helps us avoid having to believe it.

I think this can give rise to situations in which people talk past each other.

5. **Peter Woit**
June 27, 2018

Armin,
What is odd here is not that "cognitive bias" is a factor, but that well-known arguments are completely ignored. This is not the way academia is supposed to work (you aren't supposed to get to ignore arguments you don't like) and it's not the way journalism is supposed to work (journalists are supposed to be aware of and present arguments of both sides).

6. **David Roberts**
June 28, 2018

I find it curious the Agrawal-Obied-Steinhardt-Vafa paper you link to starts with three "naturality" assumptions, there called Criterion 1, Criterion 2 and an unlabelled definition, that certain quantities (Delta, c, and alpha, resp.) are all ~O(1). Also, the paper doesn't exactly shout it from the rooftops that certain things that have been held to be true about string theory just don't seem to work. My conception of how sciences work is that if you make a real advance that seems to turn all accepted wisdom/best working current theory on its head, then it's seen as a big thing, you make a lot of noise, and (sadly) put out a press release trumpeting how everything we knew was wrong, and we have a much better idea now…

7. **SteveB**
June 28, 2018

I subscribe to New Scientist and the whole mutliverse article is only a few paragraphs long. It is one of 13 articles in the issue that start with "How to think about …" Besides MV there is "Time", "Genes", "Consciousness", "Particles".

The MV article brings up eternal inflation, string theory as our "best stab at a ToE" and "Then there is the quantum multiverse, predicted by the "many worlds" interpretation of quantum theory"

No contrary opinions are given…

8. **Peter Woit**
June 28, 2018

David Roberts,

The problem is that the new "swampland" paper doesn't show that well-advertised claims about string theory don't work, it just says "maybe they don't", without a lot of justification. Not enough for a press release…

SteveB,
Thanks. Some people did send me a copy, I added some comments to the posting.

9. **David Roberts**
June 28, 2018

@Peter,

if they aren't saying that kind of thing, then maybe they should be. Urs Schreiber is now highlighting that there are serious problems turning up up for the KKLT approach, see eg the quotes in comments on [this G+ post](), taken from Danielsson-Van Riet, arXiv:1804.01120. Here's a sample:

> p. 26: "It is not unthinkable that dS space is simply a space that cannot exist quantum mechanically. […] This has been claimed before in several papers that study QFT in curved space [161–168] and if those papers are correct, then doing a proper string computation should reveal that dS vacua cannot exist."
>
> p. 30: "We therefore think that the most natural assumption, at this point in time, is that string theory conspires against the existence of dS space."

Note the citations of work in pure QFT, which is surely the kind of thing that should make anyone sit up and take notice, regardless on one's position on string theory (I have no skin in the game: ST is just interesting mathematics to me).

10. **Peter Woit**
June 28, 2018

David Roberts,

The problem with this whole subject is that basically what people are doing is arguing about whether or not solutions exist to a set of unknown equations, based on a very complex web of guesses and information about limits of these equations. You then end up with the kind of thing you quote, arguments invoking "not unthinkable" and "the most natural assumption". All that's clear here is that the technical issues are very complex and murky. My best guess from all I've seen is that there's no reason to believe there is a well-defined problem here, all evidence is with Vafa's "maybe you're right, maybe I'm right".

I also don't think it matters who is right: either infinitely complicated metastable dS string vacua exist, making string theory useless for predictions, or they don't, and you don't have solutions to work with, which is equally useless.

I've wasted far too much time following these discussion for nearly 15 years, see
https://www.math.columbia.edu/~woit/wordpress/?p=9968
and put up with a lot of personal insults from string theorists who take the attitude that my refusal to go farther down this rabbit hole proves that I'm not competent and shouldn't be listened to. For some recent examples, see for instance
http://www.math.columbia.edu/~woit/wordpress/?p=7432&cpage=1#comment-216526

This illustrates well what has always been a major problem with string theory research: the constructions are so complex and ill-understood that they provide lots of intricate and challenging technical problems to work on. People get deeply involved in this and a whole field of research is generated, with practitioners tending to take the attitude that anyone dismissing work on these constructions should not be listened to because of their lack of expertise.

We’re now 30-some years and tens of thousands of papers down the road from the first attempts to construct a “string vacuum” that looked like the real world. You don’t need to be an expert in all the intricacies of every attempted construction to notice that the output of all this activity is no explanation of anything about the real world, just a bunch of excuses for not being able to get such a thing.

11. **Peter Woit**
June 28, 2018

After writing that last comment, took a look at tonight’s new hep-th papers on the arXiv. At least two of them are about the “are there dS solutions” question. This is now officially the latest fad of a faddish subject.

12. **Anonyrat**
June 29, 2018

Lifted from the comments on your blog, April 15, 2004

serenus zeitblom says:
April 15, 2004 at 4:07 am
Peter, you should look at http://arxiv.org/abs/hep-th/0404075
It’s clear that the claim that string
theory can produce “anything” just isn’t
true. In particular, it is very far from
clear that it can produce a deSitter
background. The KKLT proposal essentially
suggested that you could get dS out of string
theory if you were willing to tolerate extremely
contrived models involving known gadgets such
as fluxes. Now it seems likely that even
this is not true.

13. **Urs Schreiber**
June 29, 2018

Or in the words of Danielsson-VanRiet 18 p. 4:

> Paradoxically the critics of string theory and the proponents of the string landscape all agree on one thing: the landscape exists and we more or less know its properties. But what if they are wrong?

14. **Peter Woit**
June 29, 2018

Urs,
I remember reading that and noticing that it’s completely untrue. This critic of string theory has never agreed that “the landscape exists and we more or less know its properties.” I have no idea whether the unknown equations of string theory have the claimed metastable dS solutions, suspect it’s not even a well-defined question. What I’ve always argued is that it doesn’t matter: whether you have too many solutions or none, you can’t say anything about the real world.

15. **Peter Woit**
June 29, 2018

Anonyrat,
Yes, nothing ever changes on this issue, as for many others about string theory.

All,
I added some links and comment re: the Strings 2018 conference that just ended.

16. **Robert Karl Stonjek**
June 30, 2018

We’ve started a discussion on this topic at my ‘Cosmology and Astrophysics News’ Facebook group (that’s GROUP, not PAGE :). I’m taking the same case as the author of this page, others are not…

All welcome to join in, oh and I post Cosmo-astro news every day as do some others…never a dull moment 😀

July 2, 2018

Just wondering that you wonder about Sean Carroll, et al.

We’re living now with alternative facts – so alternative science is the logical result.

Strings 2018 Panel Discussion

June 30, 2018
Categories: Strings 2XXX, Swampland

A [panel discussion at the Strings 2018 conference](#) ended by addressing audience questions, and this seemed to me to give some insight into where string theory is now. I noticed that the Youtube video comes with an auto-generated transcript, so decided it was worth the time to clean that up a bit and post it here.

David Gross: The plurality of questions had to do with the connections of string theory to real-world experiment. Some of these were raised by the panelists already. Let me just give you a sense of those questions, and see if you would like to briefly address them:

> How long can string theory survive without experimental verification? At what point does it become mathematics?
>
> Can string theory survive as a theory of the physical world if de Sitter space can't be accommodated and supersymmetry ruled out?
>
> In the next fifty years do you expect any physically relevant result (i.e. worthy of a Nobel Prize) to come out of string theory?
>
> Has string theory given up on particle physics?
>
> When and where do you foresee a real confirmation of string theory in particle physics or cosmology (other than the existence of gravitons)?
>
> In what area of physics do you expect the first observation of string theory?
>
> Do you think string theory is closer to phenomenology than 50 years ago?
>
> What could be a prediction of stringy models that can be verified in the lab and it cannot be an effective field theory model that gives you the same prediction?
>
> How much of the string community has given up on the goal of connecting string theory to the standard model and observational cosmology?
>
> Susy isn't observed, what should we do? Is it okay to believe that string theory is still the theory of everything?

David Gross: So, this is symptomatic of this community. I imagine the younger members of the community perhaps a bit worrisome.

Eva Silverstein: My answer is yes. (laughter) To the very last question you posed.

Juan Maldacena: I think the main virtue of string theory is to be a consistent theory of quantum gravity and maybe we shouldn't be… I mean of course it would be wonderful to have a comparison to experiment but it's a complicated theory and it might take many years until we understand how to compare it to experiment. I think an important thing is to understand the theory, understand basic things like the singularity because it might be that we'll understand that experimental connection by understanding the Big Bang singularity and some predictions from there, or something in this direction.

John Schwarz: One of those questions had to do with "is string theory just mathematics?" I've heard this question many times and I find it puzzling that someone would consider mathematics to be a pejorative term. Where would physics be without it?

David Gross: I don't think that was the question. The question was "if string theory without experimental verification goes on and on is it indistinguishable". There was nothing pejorative.

John Schwarz: I'm sure the person in this audience who raised that question didn't mean it that way but I've heard it used by others in that way.

Dan Harlow: I just want to give a sociological data point so I mean I won't repeat what I said in my talk but it's a true fact that you know every every month or two I am contacted by an experimentalist. Usually this or that atomic physics experimentalist who is looking for things to do in their lab and somehow thinks that talking to me will help. I'm not sure if it will or not, but I think that there's this fantasy that you find on the blogs that string theory is something that exists independent of the rest of physics and I think really nothing could be further from the truth. I mean I feel we're really part of physics I talk to physicists all the time and not just string theorists. (laughter)

David Gross: There were a few other versions of this question that perhaps reflected the anxiety of some of you here, which had to do with funding and and having to defend yourselves in your academic departments and universities and that I think is a real issue. I think Daniel addressed that but let me give you some other points of advice to defend string theory or what we call the activities of this crowd, with respect the funding agencies or department chairmen. String theory was attacked bitterly in the eighties for being not even science and but now it's truly impossible to make that argument. It is continuously connected to the standard model after all through our dualities and the standard model is certainly part of nature and verified experimentally. So string theory and field theory are not distinguishable and certainly not the standard model. String theory has given us many insights into the standard model, condensed matter theory, information theory, mathematics etc. It is easy to defend it intellectually, aside from the fact that it's addressing these deep conceptual problems of unifying quantum gravity with the other interactions, or just understanding gravity. So you should feel no shame in defending this field and arguing for both funding and positions.

Gabriele Veneziano: One mistake we made in the early days of the atomic theory was to think that the hadrons were elementary and to which we had to find a string idea. One of the big assumptions of the new 80s interpretation is that the particles we consider elementary today are indeed so. Maybe the fact that we so far failed to find a model is that we try to find a string theory for the wrong thing.

David Gross: There are also many questions about de Sitter space:

> The existence of dS solutions appears to be controversial. What are the technical obstacles to resolving that controversy?
>
> Is de Sitter space in the swampland? Can we get de Sitter in string theory? If yes why haven't we succeeded? If no, why not?

David Gross: Igor (sorry Igor) asked an even broader question:

> Is there a stable non-supersymmetric compactification of superstring theory whose existence has been established using known controlled approximations? Should have Poincaré or dS or AdS symmetry corresponding to the two or more non-compact dimensions?

David Gross: This is an interesting topic where there's clearly controversy. I've been unable to find a strong statement on the negative side. Juan has offered to defend it or at least he has been put forward to defend the existence of dS solutions.

Juan Maldacena: There are constructions that I think are reasonable, there are scenarios for how the solutions should work. They involve complexity in an essential way in the sense that you have to invoke complexity to find this fine-tuning that was talking about, and they are reasonable so if you're going to say that they don't exist you also should argue with comparably strong arguments. Also no one guarantees us that the physical theory will have very simple solutions, so if you want to solve for the oxygen atom you can decide whether it will exist or not. Even in QCD if you try to decide what's the last stable nucleus you will not beable to predict it probably from pure theory.

I'll say one more thing, but this is more speculative. So our understanding of the vacuum in string theory many times relies on having an asymptotically simple situation: asymptotically flat space, asymptotically AdS, and if we ask "where does AdS arises from?" then "Oh well it's a brane embedded in a bigger space and so on". So we have this kind of "turtles upon turtles upon turtles" picture of the theory, so everything is defined by a bigger simpler asymptotic space. But where did this asymptotic space come from? de Sitter is different, de Sitter is a bit like a sphere, so it has no edge or anything and we need to think now "We're theorists, how to describe that?" So maybe we'll understand another framework where we understand the fact that it has no boundary is more crucial and essential and we'll see that those equations might have a different nature than the types of equations we think about.

David Gross: That's a defense of KKLT. Trivedi isn't here, I was going to ask him to defend it. There are many people who are confused as to whether this is a crisis for string theory or not, and Hiroshi volunteered to give some criticism of these compactifications.

Hirosi Ooguri: I was asked to say something about it probably because I posted a paper with Cumrun earlier this week about this which Cumrun talked about. So, the last 20 years or so, especially after dark energy was identified, there have been enormous attempts to construct de Sitter space and other accelerated universes, with various degrees of rigor, and this is really a very important part of string theory research. So, many of the things we do is to look at a set of these constructions and try to deduce lessons from these data. This is like experimental science where we are given a set of this data and then try to understand it. But of course depending on how much rigor you ask, how much sort of control you would like, the set of data you look at can be different. Just like experimenters look at the different sigmas and then select reliable data. I should say in the case of string theory it's particularly difficult because string theory doesn't have parameters so all the low-energy parameters are the vacuum expectation value of some field. So if you successfully stabilize all the scalar fields then by definition these are numbers and not controlled. This is in contrast to the case of say, QED, where we have the fine structure constant which you can dial in a given theory, in our world a given number you can dial, so we can trust it, so the situation seems to be different. When the KKLT compactification first appeared I was hoping that maybe since there are so many ends around the flux that you can actually find a series of models where you have control over that, which we have not seen. I think this is difficult and so you can draw different lessons from this and I think it's very important to sort of develop tools to make more sort of finer predictions out of this existing situation.

Comments

1. **Dave Miller**
   June 30, 2018

   A specific question: Dave Gross stated, String theory has given us many insights into the standard model, condensed matter theory, information theory, mathematics etc."

   I happen to have a longstanding professional interest in information theory: this is an important and well-established (and very useful) area of mathematics and electrical engineering (I myself am co-inventor on some patents that involve applications of information theory).

   Does anyone know what Gross meant when he referred to "information theory" in the context of string theory?

   This is not a snarky question: I would genuinely like to know.

2. **Peter Woit**
   June 30, 2018

   Dave Miller,
   You should pay attention to the context of those quotes. Gross is explaining a propagandistic line of argument based on AdS/CFT (it relates QFT to string theory, so any application of QFT is an application of string theory!) fit to use with your department chair or NSF program officer.

   For the actual science he is referring to, over the next couple weeks look for lectures at the IAS, see here:
   https://pitp.ias.edu/

   My guess is that those lectures might contain some interesting applications of QFT to quantum information theory, with string theory playing no role at all.

3. **Hirosi Ooguri**
   June 30, 2018

   As the person who is quoted at the end of this transcript, I would like to clarify that, when I said at the end of my remarks that it is important to develop tools, I had in mind theoretical tools to understand non-supersymmetric physics, both in quantum field theory and string theory. In this regard, I am very encouraged by progress in non-supersymmetric quantum field theory, with highly nontrivial extensions of what we had learned about dualities in supersymmetric cases. I highly recommend the review talk by Francesco Benini followed by the plenary talks by Nathan Seiberg and Zohar Komargodski, captured in the Youtube video here: https://www.youtube.com/watch?v=x3gzgqtpZWc&t=1710s

4. **Sabine**
   July 1, 2018

   It's interesting that the narrative that string theory would be useful to calculate properties of the quark gluon plasma has entirely disappeared.

5. **Anton**
   July 1, 2018

   Peter,

   it seems that none of the questions asked at he beginning were answered. Is that by mistake or by design?

6. **MBN**
   July 1, 2018

   I find the second part of the first question strange? Lack of experimental/observational confirmation isn't what makes it mathematics. In my opinion string theory needs a lot more before it can be called mathematics.

7. **Peter Hickman**
   July 1, 2018

   The status of string theory (ST) can be summed as per slide at 14:10

‘To conclude, Lets wish to ST 50 more years of prosperity and to produce by 2068 a string theoretic standard model’

At 13:32, ‘still a challenge to reproduce a “low energy” viable model of elementary particles and their interactions’

ST as the best candidate for a BSM or explanation for the SM is not evident at all.

8. **Dave Miller**
July 1, 2018

Well, Peter, hope springs eternal: I had genuinely hoped that there was some connection to information theory!

I’ll be interested to see if there is indeed a connection as you suggest between QFT and quantum information theory (as a physicist who has worked with classical information theory, I have an obvious interest here). Offhand, I do not see how there can be such a connection: the work I have seen in quantum information theory relies on very basic quantum theory — basically the bra-ket notation, superposition, tensor products based on two-state systems, and the Born rule, and not much else.

But, I hope to be happily surprised with a real connection to QFT. If you see anything come up on the subject, I hope you’ll mention it in a post.

Thanks.

Dave

9. **a**
July 1, 2018

The problem is masturbation, not mathematics. When propaganda was at the top, young researches had to skip physics to jump on string theory and be hired, and the field degenerated in mathematics not relevant for understanding physics. If now there are good physicists trying to understand if strings can give non-supersymmetric compactifications, I would be interested in knowing their results.

10. **Peter Woit**
July 1, 2018

Anton,
I think the unwillingness to publicly answer those questions speaks volumes, and has a lot to do with the context Gross brings up: admitting failure would carry a serious cost.
It would be very interesting to hear what the speakers honestly think about those questions. My guess is that it’s something along the lines of “our current understanding of what string theory is can’t give the hoped for unification of the SM and quantum gravity. Maybe some new ideas coming out of string theory research will someday change this, who knows.”

11. **Mark**
July 1, 2018

@Dave Miller: String theory (AdS/CFT) provides examples of chaotic quantum systems, where many hugely complicated-looking things are calculable (using string theory methods). In quantum information physics delocalization of quantum information under time evolution is an interesting question, and stringy methods have led to a lot of progress there, maybe culminating in:
https://arxiv.org/abs/1503.01409
If you look at who’s citing this paper (or close relatives), among many others, you’ll find the very established quantum information theorists Kitaev (https://arxiv.org/abs/1710.03363), Brandao (https://arxiv.org/abs/1705.07597), Qi (http://arxiv.org/abs/arXiv:1511.04021), and Hayden (http://arxiv.org/abs/arXiv:1602.06271).

12. **tulpoeid**
July 1, 2018

“It is continuously connected to the standard model after all through our dualities and the standard model is certainly part of nature and verified experimentally.”

To paraphrase Borges, Let this person’s funding be cut now, even if my own is too.

13. **Peter Woit**
July 1, 2018

tulpoeid,
I’ve heard Gross make this statement before, always found it bizarre. Unless I’ve missed something, there is no known string theory dual to the SM and the claim that the SM is “continuously connected to string theory through dualities” is at best misleading in the extreme. I suppose the SM and string theory can both be embedded in “the space of all theories”, and continuously connected therein.

Gross’s response to the questions from the audience does make things very clear: this is not about a level-headed evaluation of the science, it’s about protecting grant money and positions. I hadn’t heard the “string theory contributes to quantum information theory” claim before, but I think we’re going to be hearing it a lot more from now on. Quantum information theory is the hot topic for grant funding and thus for university administrators, so claiming to be part of that field is the most promising way to get continued funding.

14. **Sebastian Thaler**
July 1, 2018

David Gross: “String theory was attacked bitterly in the eighties for being not even science … but now it’s truly impossible to make that argument.” Heh.

15. **Peter Woit**
July 1, 2018

Sebastian Thaler,

I think Gross was referring to this, from 1986
https://arxiv.org/abs/physics/9403001
by Ginsparg and Glashow. It was in some ways remarkably prescient:
“Contemplation of superstrings may evolve into an activity as remote from conventional particle physics as particle physics is from chemistry”
where you could replace “chemistry” by “quantum information theory”.

In other ways though, they had no clue, since they thought there was no way this could go on in a physics department, that such research would have
“to be conducted at schools of divinity by future equivalents of medieval theologians”

Also unfortunately all too prescient is the next sentence:
“For the first time since the Dark Ages, we can see how our noble search may end, with faith replacing science once again.”

16. **Mark M**
July 3, 2018

Sabine (and Peter),

While it seems the formal string theory crowd has largely moved on from applications related to the quark gluon plasma, some physicists working on string-inspired approaches (AdS/CFT) to understanding hot and dense QCD are taking it very serious, having their own workshop this week: http://igfae.usc.es/~holoquark2018/

17. **Richard Gaylord**
July 10, 2018

hi:

do you know how the transcript was generated. can this be done with any you tube video? it is VERY useful since some of us fall asleep during lectures and you can read a transcript at one’s own pace and you can go back and forth .between different sections.

18. **Peter Woit**
July 10, 2018

Richard Gaylord,

Clicking on the “three dots” below and to the right of a youtube video generally brings up a transcript. No idea how these are generated, must be automated speech recognition of some kind.

Various Links

July 5, 2018
Categories: Uncategorized

A random assortment of possibly interesting links:

- New videos from the IHES include new interviews, and talks from the recent Ofer Gabber conference. If you want to know more about prisms than what you can get from the video here, I hear rumors that Bhargav Bhatt will be our Eilenberg lecturer this fall at Columbia.
- Another talk at the Gabber conference was the latest on local (quantum) geometric Langlands from Gaitsgory. Also on this topic, there's a July 4 preprint from Arakawa and Frenkel (advertised here).
- John Horgan has an interview with Jim Holt, headlined Why Does Jim Holt Exist?. For reviews of Holt's two most recent books, see here and here.
- For two interesting blog posts from HEP experimenters about news from their field, see Jonathan Link at SciAm on neutrinos, and Tommaso Dorigo on the Higgs self-coupling. Dorigo's posting is the more technical one, explaining a new CMS result bounding the Higgs self-coupling.

  The LHC experiments still seem to be a long ways away from actually measuring the Higgs self-coupling, but may be able to do so in future higher-luminosity stages of the LHC program. The Higgs remains the least understood part of the SM, responsible for most of the undetermined parameters of the theory. Any measurement of its self-interactions is an important goal.

  While it often seems that experimental results relevant to going beyond the Standard Model are inaccessible due to the necessity of higher energies, these two blog posts point to important open questions about the SM that are hard to study not because of fundamental limits on collision energies, but because of small event rates and high backgrounds.

- The question recently came up here (see this posting) of how good the SUSY GUT coupling constant unification prediction is. At a recent summer school lecture, Ben Allanach says the prediction is off by 5 sigma, i.e. that if you try and predict the strong coupling at the Z mass this way, you get 0.129 +/- 0.002, whereas the measured value is 0.119 +/- 0.002. Someone should tell Frank Wilczek…

Update: For more on the dS vacua issue, see this blog posting by Ulf Danielsson. Danielsson refers to criticism of the landscape at my blog, but ignores the point I've often made that string theory is in just as much trouble if the advertised dS vacua don't exist, since then it has no known way to connect to the real world and its positive CC. Somehow he sees this as a virtue, that "These are exciting times", which I find mystifying.

He also claims that, all is well, since:

> By studying the mathematics of the theory we will find out what it predicts, and by comparing with observations we will learn whether it has anything to do with reality.

But the underlying problem here is that the mathematics of the theory is unknown. Read the responses above from two experts to the question of why this issue has not been conclusively determined. Neither of them present any possibility of a conclusive determination. For both of them, this is about weighing the plausibility of various conjectures about possible solutions to unknown conjectural equations. At this point I seriously doubt it is possible for this to be resolved one way or the other.

Update: ICHEP 2018 is winding up, talks available here. There was one plenary summary talk on "Formal Theory Developments", by Tadashi Takayanagi. It begins by promoting string theory, then goes on to address the problem of how it relates to fundamental physics with:

> However, please do not ask me questions like:
> How to derive Standard Model from string theory?
> Why do we live in 4 dimensions?
> How to realize de-Sitter spacetimes in a well-reliable way?
>
> String theory is still too infant to give complete answers to them.

The "complete" is intentionally misleading, since string theory now gives no answers at all to these questions. While celebrating the 50th anniversary of string this year, it seems that "string theory is too new an idea to evaluate" is the standard answer to anyone who points out its failures.

Comments

1. **Anony**
   July 5, 2018

   You're misreading the slides. Those numbers are for non-susy GUTs.

2. **Deane**
   July 5, 2018

   I like the face Ofer made when the Langlands Program is mentioned, as well as what he says about Gaitsgory.

3. **Peter Woit**
   July 5, 2018

   Anony,
   No I'm not, you are. Interesting that the current SUSY error in gauge unification is of a size that you mistake for the non-SUSY error.

   The numbers I gave are from page 40, which explicitly says "in the MSSM". If you look at the plot on page 58 you see the 5 sigma size problem, and that the numbers were generated by the SOFTSUSY package, described here https://softsusy.hepforge.org/
   From the plot the calculation uses benchmark point 40.2.5, from this paper
   https://arxiv.org/abs/1109.3859
   The numbers for this benchmark point look around current SUSY limits.

   It looks like anyone who wants to can run the software and generate their own numbers. I'm somewhat curious whether how sensitive the numbers are to assumed superpartner masses. Has the way the LHC has pushed up superpartner mass bounds also pushed up the error in the SUSY gauge unification prediction?

4. **Sabine**
July 6, 2018

I'm pretty sure that Wilczek knows this (the problem in general, maybe not the exact numbers) because he points out in the interview that's in my book that gauge coupling unification gets worse the higher the susy breaking scale has to be. And we've meanwhile passed the point where it's not working well any more.

Of course the running might be more difficult, so that it still all fits, see eg this paper. So if you want to believe, you can still believe.

Also, you could simply shrug it off because GUT and SUSY are two separate things, so who says that a supersymmetric extension of the standard model actually must have a gauge coupling unification in one point?

5. **James Wells**
July 6, 2018

The current LHC limits on supersymmetry in no way have the slightest impact on the attractiveness or viability of gauge coupling unification in a supersymmetric context.

All the talk of 5sigma error is decidedly irrelevant, unless you speak of a very special approach called "precision unification", where the high-scale corrections are assumed to be very small for some non-generic reason. Zero GUT threshold corrections is not expected if you have a real GUT gauge group in field theory, as high-scale threshold corrections from required high-mass rep remnants are formally of the same order in QFT as the weak scale corrections.

The whole question is how big do you expect those corrections to be. In SUSY they are, and continue to be, surprisingly tiny corrections required for unification. (Perhaps too small even if you like lots of GUT reps.) In SM, the corrections are huge, but not altogether impossible if there are lots of high dimension GUT states hanging around.

Lack of superpartners at LHC is not qualitatively changing the discussion of gauge coupling unification by experts. The reason is that the dependences are logarithmic rather than, say, quadratic (as in "finetuning" discussions, which have qualitatively changed). One order of magnitude change in mass limits is not much to a logarithm.

A rather complete discussion can be found at https://arxiv.org/abs/1502.01362
where Sebastian Ellis and I put susy and non-susy gauge coupling unification expectations in context, and tried to give a visual picture of the issues.

6. **Peter Woit**
July 6, 2018

James Wells,
Thanks! Perhaps you should be the one to tell Wilczek about this. In Sabine's book he tells her that "the changes of unification start getting worse when susy partners haven't shown up around 2 TeV", giving this as an argument for why the LHC might still see superpartners, just beyond current bounds.

There's a long history of these gauge unification calculations being sold as a strong argument for SUSY, rarely making clear the weaknesses of such an argument.

7. **Chethan Krishnan**
July 7, 2018

Dear James Wells,

"The current LHC limits on supersymmetry in no way have the slightest impact on the attractiveness or viability of gauge coupling unification in a supersymmetric context."

Is the following a fair summary?

Non-SUSY GUTs need high threshold corrections for unification to happen, while SUSY GUTs were generally expected to need only tiny threshold corrections. This is generally presented as a good thing, for reasons which are not very clear to me.

(Of course, if I am not mistaken, Allanach's slide 40 now says even SUSY requires bigger threshold corrections, possibly in light of more precise measurements of low scale couplings).

You seem to be saying that the smallness of the threshold correction is more or less an arbitrary benchmark for the attractiveness of a GUT.

If that is the case, according to you, shouldn't the SM be as good or bad as the MSSM as a candidate for unification? In fact, from your paper that you linked, it looks like one has to (at least for some choices of GUT group) compensate for the threshold corrections s in supersymmetric theories, potentially making them less attractive than SM?

On a general note-

Do you know a reason why people (like Wilczek, or your refs[1-7]) seem to be implying that small threshold corrections in MSSM is a good thing? (Please correct me if I am wrong.)

8. **Urs Schreiber**
July 7, 2018

From [Ellis-Wells 17, p. 23-25]:

> We have discussed how gauge coupling unification generally only improves in a supersymmetric theory, even at very high scales, with respect to the SM.

And before:

> Thus, even the Standard Model up to the high scale is compatible with gauge coupling unification from this perspective, although the corrections becomes quite large in that case, and one has to ask whether nature would rather have large corrections at the GUT scale for a SM GUT or very small corrections for a low-scale SUSY GUT.
>
> […] the introduction of supersymmetry both reduces the needed threshold corrections at the high-scale and increases the GUT scale […]. This latter element is helpful since one generally requires that the GUT scale be above about 10^{15} GeV so that the X,Y GUT gauge bosons do not induce too large dimension-six operators that cause the proton to decay faster than current limits allow.
>
> Thus, exact gauge coupling unification is viable for intermediate values of supersymmetry breaking, which are also compatible with the Higgs boson mass constraint.

> […]
> One important experimental prediction of minimal supersymmetry, even for superpartners at very high scales, is the existence of a relatively light Higgs boson. This has been seen by the LHC. We have shown in this paper that even arbitrary high scales of super-partners allow the light Higgs boson, due to the required matching of the SM effective theory Higgs self-interaction coupling to gauge couplings in the supersymmetric theory.

9. **paddy**
   July 7, 2018

   A question from someone not hep-th since mid 70s. I have seen 3 things used to support SUSY over the years since: (1) naturalness (2) gauge coupling unification at gut scale and (3) providing dark matter WIMP candidates. Are these pillars not crumbling one by one?

10. **Anon**
    July 8, 2018

    In GUTS and SUSY GUTS there is also tuning/finetuning needed now to get the fermion masses (including light neutrino masses) and mixing right. It would be interesting to have a table of tuning needed for popular SU(5), flipped SU(5) and SO(10) models from fermion mass and unification of couplings point of view. This is apart from usual finetuning needed for gauge hierarchy problem.

    Paddy — naturalness was the main reason to expect SUSY at weak scale. Now it is clear that the MSSM needs to be fine tuned to least a 1% level for the gauge hierarchy problem. And so that pillar has crumbled. A 100 TeV collider could potentially probe finetuning to 0.01% level.

    GUTs and WIMPs were more secondary reasons (though very remarkable reasons), and there is no evidence for them either. But there is no evidence for non-SUSY GUTs or WIMPS or for dark matter particle (other than due to gravitational effects) either.

11. **GoletaBeach**
    July 9, 2018

    "…. these two blog posts point to important open questions about the SM that are hard to study not because of fundamental limits on collision energies, but because of small event rates and high backgrounds."

    A significant experimental thrust since, well, "re"-started in the late 1970's with the IMB proton decay effort has been devoted to pushing the envelope on small event rates and backgrounds.

    Naturally there was even earlier work by Reines in South Africa, a group of Indian physicists working at the Kolar Gold fields, a Cornell/U Utah group that worked in mines in the Wasatch, and, most notably, Ray Davis and his group in South Dakota. There was even a low background group in the Manhattan Project, because initial samples of most of the interesting transactinides were at the nanogram level, meaning, decay rates were low.

    In the US, though, the low background effort has struggled… follow-ons to Ray Davis have had a rocky road with the NSF rejecting, and DUNE/Fermilab/DOE finally coming to the rescue; IMB was shut down and effort transferred to Kamioka in Japan, a large 1980's effort was shunted to Gran Sasso in Italy (Macro and later Borexino), and SNO, conceived at UC Irvine, took place in Canada. Daya Bay in China had a huge US contingent as well. And of course at the South Pole the US has supported a grand high-energy neutrino experiment, IceCube.

    I doubt that the science program of any nation on earth has been as internationally-oriented as that of the US in low-background physics. Comparatively, the US-based low background program has grown weaker, and the consequence is much of the expertise at the nitty-gritty of low background experimentation lives in Germany, Italy, Japan, and Canada. At this point, frankly, the US abilities aren't as good.

    I'm not arguing for US nationalism, but when it comes to conceiving and implementing new low background experiments, the US can feel like the old Soviet Union in accelerator-based physics: lots of ideas, but modest ability to execute. Perhaps the US low background program is a bit out of balance, and needs a tuneup.

12. **Amitabh Lath**
    July 9, 2018

    The majority of LHC limits on SUSY assume R-parity conservation (RPC). Models with RPC give you large missing momentum in the detector, which gives CMS and ATLAS great sensitivity.

    SUSY limits for R-parity violating (RPV) signatures are much softer. There is no honking big missing momentum signature to trigger on. So maybe it's R-parity conservation that is in trouble, not all of SUSY?

    Full disclosure: I've worked on searches for RPV SUSY.

13. **Anon**
    July 10, 2018

    Amitabh,

    Generic R-parity violating terms at the TeV scale in MSSM will lead to quick proton decay. So generally RPV SUSY shd be at a much higher scale such as around the GUT scale.

    Only a restricted number of RPV terms that do not lead to proton decay are permitted at TeV/multi TeV scale. Ruling these out is pbly also important from hierarchy problem point of view.

14. **Amitabh Lath**
    July 11, 2018

    Anon: yes proton decay does put limits on RPV but you need both leptonic and baryonic RPV to make the proton decay. Nature could make just one of those non-zero, and make a large number of LHC searches blind to SUSY signal. Also, the limit on proton lifetime is 10^34 yrs so both leptonic and baryonic RPV could be nonzero but small enough to evade that limit.

    Look, my point is that experimentalists put limits on specific models, with many caveats (requirements on leptons, heavy flavors, jets, missing momenta…). This then somehow goes from "they have ruled out some very basic minimal SUSY models" to "ruled out MSSM" which quickly morphs into "killed SUSY".

    We know our blind spots too well to endorse a statement like that. Maybe some mickey-mouse version of SUSY is dead, and maybe SUSY as a source of Dark Matter is in jeopardy, but overall I would say LHC has done a thorough preliminary survey for the easiest signatures and is working on the next level of complexity.

15. **Paul**
July 11, 2018

Peter,

I have to say, I love your blog. You do a great job keeping us informed and up-to-date. I apologize for this off-topic comment. No need to have this posted. I see you've been to Paris many times. I am planning to visit the city and would love to visit sites in Paris that have a physics theme. I believe there's a Marie Curie museum, as well as (I think) a museum dedicated to Becquerel. What other places should I visit that have a physics theme or otherwise have some historical significance to physics?

Also, have you been to other European cities of historical significance to physics? I'm sure there are many, as Europe was at the center of science for so many years. I was thinking Berlin, Germany, and Bern, Switzerland because of Einstein. Geneva, for obvious reasons, but I'm not sure what others.

Again, sorry for the off-topic comment. You can delete the comment, but if you could shoot me a brief email whenever you have time, that would be great!

16. **Low Math, Meekly Interacting**
July 11, 2018

"Killed SUSY" is of course too expansive because it's impossible. That's the problem, right? What's dead is the idea that SUSY solves what was perceived to be a mystery in need of a solution. Now we know the Higgs mass is "unnatural". The "WIMP miracle" looks to be a hoax. There may not be a GUT scale for all anyone really knows, so trumpeting the idea that couplings unify (when squinting at a log-log plot) may be an attractive fantasy. What motivates the effort to falsify SUSY moving forward? As pointed out on this blog many, many times, the fact that there are literally an infinite number of models that have not been ruled out yet is not in itself a reason to go about crossing them off a comprehensive list, one by one. However, some very well promoted ideas have been thoroughly debunked. In fact, the volume hype that has been deflated stretching back literally decades is itself quite staggering. Experimentalists have done a fantastic job, and you deserve far, far more lionization in the popular science press than you're getting. You've hopefully saved a lot of people from further wasting their careers. I wouldn't be so forgiving of those who are still openly tempting people to eschew all reasonable hope of empirical support in their lifetimes.

17. **Peter Woit**
July 11, 2018

Paul,
That's pretty off-topic, except for the fact that next week I'm leaving for a vacation trip that will start with a couple days in Paris (and then head off for the far, far North).

Others may have better suggestions, but as a kid I was fascinated by the Palais de la Decouverte science museum. As an adult, an interesting museum more devoted to engineering than science is the Musée des Arts et Métiers, with a Foucault pendulum there and at the Pantheon
https://en.wikipedia.org/wiki/Conservatoire_national_des_arts_et_m%C3%A9tiers

The small Curie museum is part of a university complex worth visiting. I vaguely remember something about Becquerel's old lab in or next to the Jardin des Plantes.

Sorry, but never been to Bern, and during the couple short visits I've made to Berlin, there were all sorts of things to see that seemed of more interest than tracking down what's left of where Einstein would have been.

18. **Peter Woit**
July 11, 2018

LMMI,
I think the best motivation for continued SUSY searches is just that they provide well-studied examples of things to look for that are not already ruled out. Up to experimentalists to use their judgment for whether these searches are worth the effort, or other ideas are more promising. Would be great if theorists could provide better ideas of what is promising, that's very difficult right now.

19. **Anon**
July 11, 2018

Thanks Amitabh for your note. I guess like experimentalists' blind spots there are also the theorists' cover ups…. what I mean is if you supersymmetrize the standard model, the most general model that emerges is R parity violating and leads to proton decay. So it is already ruled out in most of the parameter space (unless some couplings are very small which theorists don't like). To save the situation R-parity conservation is introduced and it is not a happy situation as it is an additional symmetry. But miraculously this provides a WIMP dark matter candidate — in other words R-parity conservation can be motivated from Dark matter point of view rather than from saving SUSY from proton decay issues. So theorists are happy. But now experimentalists have ruled out R-parity conserving SUSY at TeV scale. SO now some R-parity violating can be considered, though not all terms together. But we lose the dark matter — so we are really saving SUSY at this point. And that is not really something that is theoretically pretty.

In any case LHC has enough energies to also rule out R-parity violating MSSM as a solution to the hierarchy problem right. I guess that is what you are working on from experimental end and that is much needed to do.

There are some models such as the minimal suppersymmetric left-right model, that automatically conserve R-parity, and where it has been shown that R-parity must be necessarily spontaneously broken with the sneutrino picking up a vev.

20. **CWJ**
July 11, 2018

I just got from Paris and second the Musée des Arts et Métiers. Somehow I missed it on previous visits, I don't know how. The top floor in particular is scientific instruments.

Another lovely museum with scientific instruments is the Museo Galileo in Florence, not far from the Uffizi. Excellent displays. Also includes Galileo's finger in a jar. The rest of him is in the Basilica di Santa Croce across the city.

21. **lun**
July 12, 2018

Regarding the ICHEP2018 talk, the speaker (Takayanagi) claims the Ryu-Takayanagi formula was proven by Lewkowicz and Maldacena in 2013, presumably referring to
https://arxiv.org/abs/1304.4926
Is this really counted as a "proof"? It reads (and is claimed by the authors) as a plausibility argument based on a worked example. Or am I misunderstanding it?

22. **Thomas Van Riet**
July 13, 2018

Dear Peter,

You say " the point I've often made that string theory is in just as much trouble if the advertised dS vacua don't exist, since then it has no known way to connect to the real world and its positive CC"

The point made in Danielsson's blog (& my paper with him and the papers of Vafa and friends) is that this is wrong. Cosmological observations do not necessarily imply a positive cc. The bounds on the equation of state parameter allow the dark energy to be time-dependent. Exactly as it would be for quintessence for instance. Secondly, it could already be at the quantum field theory level that de Sitter isometries (ie the constancy of dark energy) is broken. This has been ongoing work of Polyakov, Mottola, Woodard,…and many more since the eighties even. If that is correct then string theory better not give us dS vacua. [There is even the possibility that departures from the FLRW Ansatz for the universe, ie spatial inhomogeneities, take away the need for dark energy to explain observations. But I have no good understanding of that.]

Secondly, you say " But the underlying problem here is that the mathematics of the theory is unknown " and then a bit later you say criticize people that actually point out that lots of the theory still needs to be developed to know things for sure. My point being, that your criticism seems to lack some consistency. Either way string theory always looses for you. If we have a landscape of dS, then string theory is not even wrong, if we do not have a landscape then string theory is wrong. You complain about not having finished the theory but then you critize those that say "give us more time".

Finally, it could be true that string theory is not sufficiently developed yet to think of phenomenology. However there are corners of the theory where we do understand it and we can study aspects. This is what drives string phenomonologists. Now some of us are claiming that those corners might show signs of a conspiracy against dS space. Which, if correct, is certainly a deep insight.

23. **Lee Smolin**
July 13, 2018

Dear Thomas,

Your point is well taken. But, it seems all of us who are curious about how nature unifies gravity and the quantum nonetheless face a very peculiar situation in which there are several ways to get partway to a quantum theory of gravity. Each has its defining results, which give its enthusiasts reason to work on it. And each has its stubborn obstacles, which justify its critics' skepticism. It seems to me if we want to demand consistency and an objective, scientific attitude, we should all put our cards on the table and answer two questions:

-What negative result would cause me to give up my currently favoured approach?

-What positive result within another, possibly new, approach would motivate me to switch my efforts to developing it?

In addition, I would argue that no matter which of the approaches we currently work on, we should all be able to answer questions like: Name five approaches to quantum gravity,, and describe the key results, strong points and weak points of each.

Thanks,

Lee

24. **Peter Woit**
July 13, 2018

Thomas van Riet,

To elaborate a bit on the "point I've often made" about metastable dS vacua: those pushing that program have a proposal for how they are going to get testable predictions. They will study the space of such vacua (nowadays, using "Big Data" techniques), find a way to put a measure on it, and make statistical predictions. I've often argued that this clearly can't work (with a main reason they don't have a theory well-defined enough to know what the space of vacua is, much less what the measure on it is), but that's their proposal for how they are going to turn string theory into legitimate science that makes testable predictions.

You can conjecture that these dS vacua don't exist, so their program falls apart, but then what is your proposal for how you are going to get testable predictions out of string theory? The most straightforward implication of a conjecture that string theory is inconsistent with a positive CC is that it's inconsistent with our well-tested standard cosmological model, so it's wrong. But, you don't like that implication, so you do what theorists always do when their model fails a test: try to evade this failure by making the model more complicated. Sure, you can add "quintessence" fields, then postulate that for unknown reasons they have exactly the properties needed to evade the (very strong bounds) that usually rule them out. This is the opposite of making a prediction, it's just evading making one.

This kind of thing is exactly what philosophers of science describe as a "degenerating research program", it's the way scientific ideas typically fail. While their idea is failing this way, the usual behavior of those trying to evade the failure is to argue "we just don't understand the implications of our idea well enough, maybe someday we will find some new understanding that will turn failure into success". This is what is going on with the idea of string theory as a unified theory.

I don't believe string theorists have any serious answer to Lee Smolin's "What negative result would cause me to give up my currently favoured approach?" question above. You've shown that "no dS vacua in string theory" is a negative result that won't cause you to give up, instead you move to quintessence fields. There are already very significant negative observational results about quintessence, and the very likely continuing negative such results clearly are going to have no effect on getting string theory researchers to give up on string theory unification.

25. **Urs Schreiber**
July 13, 2018

It's not like outside of string cosmology there'd be no handwaving in cosmological model building.

For instance, according to Buchert et al. 15 (CQG+) there are mistaken assumptions in Green-Wald 11, so that it remains open whether the cosmological constant is an artifact of neglecting backreaction of spatial inhomogeneities in the concordance model (as in Buchert 07).

(Of course Danielsson-VanRiet 18 do mention this as one possibility, p. 27.)

26. **Shantanu**
July 14, 2018

Thomas: Just so that I understand, are you saying if future precision observations are consistent with a cosmological constant, then is string theory ruled out?

27. **Thomas Van Riet**
July 14, 2018

@ Lee Smolin:

Thanks for engaging.

-What negative result would cause me to give up my currently favoured approach?

A reason to give up string theory would be when it simply does not pass internal consistencies. Say it would say something wrong and inconsistent about black hole entropy (for instance the coefficients of the log A contribution to the entropy)

For all theories beyond the standard model we can say that whenever a prediction is not verified by experiment we can give it up as a model of the universe. It does not mean one should give it up as a model (I will still study Ising models although they do not describe real magnets). However as with all theories of physics beyond the standard model, and especially ALL approaches on quantum gravity, it seems direct verification requires energy scales we cannot yet access. Nonetheless there could be effects from the highest energy scales manifesting themselves at low energies. This is why hierarchy puzzles are outstanding. They are a failure of decoupling UV physics from IR physics. So lets see what our favorite UV complete theories of gravity and other forces can say about the cc problem. What already strikes me as amazing is that string theory is a framework where I can, in some corners, compute the vacuum energy (agreed, we are still fighting about the details of the computations. But in some corners we certainly agree). For quantum field theorists, that is a dream that cannot really be met.

-What positive result within another, possibly new, approach would motivate me to switch my efforts to developing it?

If the other approaches provide a framework to address questions in QFT that need UV completion. I gave already as example: computing vacuum energies in certain field theories. I can write a whole essay here and I will no do it (maybe I start blogging myself soon). For instance one of the amazing features of the string theory framework is our ability to understand strongly coupled field theories better, whether through holography or some D-brane picture of the field theories. In any case it is clear that those people that call themselves "string theorists" are typically versatile and willing to look into various directions. A clear manifestation of that is for instance the whole "entanglement&geometry" program. As far as I can tell that program is not really string theory. Perhaps "string theory inspired" a bit.

28. **Thomas Van Riet**
July 14, 2018

@ Shantanu,

Since we have not yet settled the debate about the existence of dS vacua, I cannot tell. Just to be clear: I think the vast majority of string phenomenologists thinks the evidence for dS vacua is there. I do not agree, but at the moment I am part of a minority. I guess we just need to work more…

29. **Lee Smolin**
July 14, 2018

Dear Thomas,

Thanks very much. I am sympathetic to much of what you say. For example, I agree that the recent revival of the idea that space emerges from quantum entanglement is highly promising. But are you aware that this idea was raised by Penrose in the 1960's and that it motivated his invention of spin-networks? Or that it has been explored in a number of loop quantum gravity papers? (If you are interested look at recent papers by Etere Livine or papers by Daniele Oriti et al or myself which derive forms of the Ryu- Takayanagi relation within LQG.) Indeed I would suggest that this growing area offers an opportunity for people exploring diverse approaches to learn about other approaches and, perhaps even appreciate commonalities among them.

I also appreciate your answer to my second question: "If the other approaches provide a framework to address questions in QFT that need UV completion" seems a clear criteria. Let me suggest a few papers from different approaches that might then interest you.

-There is a claim that the asymptotic safety approach to QG forces a uv completion of the standard model, which relates its coupling constants and, in particular, determines the value of the top quark mass: https://arxiv.org/abs/1707.01107.

-Computations in several approaches, including asymptotic safety, causal dynamical triangulation and LQG suggest the uv completion is reached through a dimensional reduction in which the uv limit of correlation functions scale in a reduced spacetime dimension.

Thanks,

Lee

30. **tulpoeid**
July 17, 2018

Paul,

just noting that if you find yourself close to Bern (e.g. Geneva) and you're interested in such tourist attractions, Einsteinhaus is definitely worth a small daytrip.

abc News

July 17, 2018
Categories: abc Conjecture

The last couple months I've heard reports from several people claiming that arithmetic geometers Peter Scholze and Jakob Stix had identified a serious problem with Mochizuki's claimed proof of the abc conjecture. These reports indicated that Scholze and Stix had traveled to Kyoto to discuss this with Mochizuki, and that they were writing a manuscript, to appear sometime this summer. It seemed best then to not publicize this here, better to give Mochizuki, Scholze and Stix the time to sort out the mathematics and wait for them to have something to say publicly.

Today though I saw that Ivan Fesenko has put out a document entitled [Remarks on Aspects of Modern Pioneering Mathematical Research]. It refers in footnote 18 to:

> two recent texts by Sh. Mochizuki, 'Report on discussions, held during the period March 15–20, 2018, concerning inter-universal Teichmüller theory (IUTCH)'and 'Comments on the manuscript by Scholze–Stix concerning inter-universal Teichmüller theory (IUTCH)', July 2018

I haven't seen these two texts, or the Scholze-Stix manuscript. What I have heard about them is that Scholze-Stix identify what they see as a specific, serious flaw in the proof, and that Mochizuki denies that this is a problem or that his manuscript needs to be revised. Presumably, after the two sides try and sort this out amongst themselves, at some point we'll see something publicly available describing the details of their disagreement.

Fesenko's document has a lot of unpleasant things to say about those who have written anything at all skeptical concerning Mochizuki's claimed proof, mostly without naming names. He refers to journalists and "US bloggers" as having produced "ignorant absurd articles and posts", presumably has someone other than me in mind since the information posted here about this I believe has been quite accurate and of reasonably high quality. The one negative reference to identified mathematicians is in the text with footnote 18 pointing to Scholze and Stix, which says:

> Several researchers, who could have become potential learners of IUT and then progressed to become experts, declined invitations to participate in the IUT workshops. Some, affected by negative emotions, broke professional rules of conduct and made public their ignorant and sometimes intolerant opinions. Tellingly, the only questions produced were shallow and misplaced and they were communicated only after several years of requests to do so.

Peter Scholze is by far the most talented arithmetic geometer of his generation, a sure thing to receive a Fields Medal at the ICM in a couple weeks. That his questions about Mochizuki's proof were "shallow" seems highly unlikely, to me at least.

Much of Fesenko's article concerns the question of whether contemporary mathematical research is too narrow and unambitious, devoted to minor improvements and producing lots of publications. This is a serious issue, one though where other fields than arithmetic geometry (e.g. fundamental physics) are in a much worse state. Fesenko tries to make the difficulties mathematicians have had with Mochizuki's claims about his IUT research an exemplar of this problem, but this seems to me misguided. There are quite good reasons for why experts have been skeptical about IUT and the supposed abc proof, reasons which will be conclusively vindicated if Scholze and Stix turn out to be right. Ironically, an excellent example of the kind of fundamental breakthrough that Fesenko is asking for is Scholze's own ground-breaking work over the past few years.

Comments

1. **mJ**
   July 17, 2018

   What a wonderful article! Thanks Woit!

2. **anon**
   July 17, 2018

   Fesenko also confirms that Mochizuki's papers were indeed submitted to PRIMS.

   The whole IUT story has plenty of bizarre features. I find Fesenko's extremely aggressive promotion of the theory very strange. I wonder if Mochizuki himself is happy with it…

3. **David Roberts**
   July 17, 2018

   Thank you, Peter. It was very frustrating to have people winking and nudging each other around the internet when hinting at what you discuss, because they were in the extended personal circles of mathematical celebrities and got to hear it in person.

   Hmm, now I see totallydisconnected deleted their discussion of the rumour…

4. **No wish to be harassed**
   July 17, 2018

   Being criticized by Ivan Fesenko for breaching "professional rules of conduct" is the equivalent of being criticized by Trump for "not telling the truth" – it should be worn as a badge of honor. You do have to admire his political mastery to somehow have wrangled the biggest grant ever awarded to a mathematician in the UK to study "IUT," a theory that at this point resembles nothing more the emperor's new clothes. (Explanatory note: grants in the UK in pure math are decided by non-experts who may not even be pure mathematicians.) I can see plenty of reasons for someone in such a position to act in a manner not entirely aligned with the pursuit of truth. This is not a document to be taken seriously, and anyone with basic knowledge of the people involved will see through it immediately.

5. **Peter Woit**
   July 17, 2018

   NWTBH,
   I see no reason to doubt that Fesenko believes what he says and is motivated not by money, but by enthusiasm for the new mathematics that Mochizuki has produced. It would be a good idea for him to take a more charitable view of the behavior of others who, also out of love of new mathematics, have been doing the best they can to try and understand and check the proof.

6. **T**
   July 18, 2018

As an outsider (physicist/mathematician) who has been watching this story with interest, I have to say I can't completely disagree with these statements by Fesenko:

> "Unusually for mathematics, some mathematicians felt appropriate to publicly criticise IUT and its study without having studied it in any serious way.
> Negative online criticism went always in a very vague form without any single concrete mathematical evidence. Sometimes it was hostile."

Among others, this post comes to mind, which was eventually closed to comments with the note "If you don't agree with me feel free to start your own blog."

7. **Anon**
   July 18, 2018

   The is a typo in the article name: Remarks on Aspects of Modern Pioneering Mathematical ResEarch

8. **Also don't wish to be harassed**
   July 18, 2018

   "It seemed best then to not publicize this here, better to give Mochizuki, Scholze and Stix the time to sort out the mathematics and wait for them to have something to say publicly."

   And the production of some document by Fesenko was enough to change your mind about this? Seriously?

9. **Peter Woit**
   July 18, 2018

   Anon,
   Thanks fixed.

   ADWTBH,
   The point is that Fesenko has now chosen to publicize the Scholze-Stix story (in the form of an attack on them). Now that this is public I think it's fair game to blog about, and it's actually a good idea to make public a better explanation of what is going on than just what Fesenko has done.

   T,
   What might not be obvious about that blog posting is that Cathy O'Neil is both a number theorist herself, wife of an expert in arithmetic geometry and friend of many other experts in the field. What she wrote was based on detailed inside knowledge of the process leading experts in the subject were going through trying to understand the proof during the first few months it was available, and the problems they were running into. She waited to write this until it had started to become clear to experts how difficult it was going to be to understand and check this proof in conventional ways. In retrospect several years later, her analysis of the problems with the proof was quite on target.

10. **David Roberts**
    July 18, 2018

    @Also don't wish to be harassed:

    well, Fesenko did just out a manuscript due to Scholze-Stix and the existence of a written-up response by Mochizuki. Given the rumours that 'two prominent and very well-regarded mathematicians have isolated a specific and serious error in Mochizuki's proof of the abc conjecture' were already documented online, one might put together the facts independently of Peter writing anything of what he had heard.

11. **ADWTBH**
    July 18, 2018

    Surely this blog post is going to publicize the authorship of the not-yet-publicly-announced [SS] manuscript massively more than footnote 18 on page 6 of Fesenko's document ever would have. Perhaps what you say about it being "fair game" is true by some standard of journalism (though that same standard of journalism might have required asking [SS] for comment — did you?). But with respect to the collegial standard of not publicly broadcasting mathematical work that the authors have not yet announced, this post falls massively short.

12. **Peter Woit**
    July 18, 2018

    ADWTBH,
    Again, I'm not the one who made public the existence of the Scholze-Stix manuscript. Fesenko did this, together with a characterization of it as raising only "shallow and misplaced" questions about the proof. If you're unhappy about this, you should take it up with the person responsible.

13. **Sometime number-theorist**
    July 18, 2018

    I had not read Cathy O'Neil's blog post before, but it is the exact argument of which I was wondering why there weren't more mathematicians making it. To put it in the simplest possible terms: the burden of proof is on Mochizuki — no matter how often he claims he has proven ABC, or no matter the loftiness of the terms in which he expounds the correct manner to become an "expert" in his proof.

    The problem in the dialogue occurs when one party starts making assumptions that the other party does not accept, and predicating their arguments on these assumptions. A consistent failure to recognize the fact that one makes such assumptions, for me is a clear sign of intellectual dishonesty.

    Now the above statement may point to a reason why mathematicians by and large have been loathe to take a harsh stance on Mochizuki (O'Neil apparently excepted). It is not a nice thing to accuse another of intellectual dishonesty. The insult is hurled about far too much, especially on the internet, and it has a tendency to escalate matters.

    Perhaps the thing with accusations of intellectual dishonesty is not so much that they can't be correct, but that they can't be productive. No one can be expected to take such a qualification in good stride. So then the question becomes: what is the honest and correct way to make the same point? Because if you can't call out this kind of trickery for what it is, perhaps out of a fear to be perceived as a troublemaker or a name-caller, then you are not taking responsibility for the integrity of your field.

    I think this is an important question, although I haven't thought about it for long enough to pretend that I have any solid answers. It might even be one of the great questions of our time: from fake news, to fake physics, and now on to fake mathematics.

14. **Peter Woit**
    July 18, 2018

sometime number theorist,

I don't think "intellectual dishonesty" is a good way to characterize the problem with Mochizuki's proof, or a term that Cathy herself used or would use . I have no doubt Mochizuki was and is sincere in his belief that he both has a proof, and has written it down carefully so that others who apply themselves can follow it and check it. It's not an unusual problem though that an author needs to be told to rewrite a manuscript since in its current form others cannot understand it or check it with some reasonable amount of effort.

The new twist to this story is that evidently Scholze long ago had specific criticisms of the proof, and that these never got answered by Mochizuki or addressed by the referees. So at least one expert could follow the proof well enough to identify a possible problem. If you want to look for a past failure in how mathematics is supposed to be done, it seems to me that this is the place to look. It's great though that things are now working as they should, with the mathematical issues getting appropriately discussed and debated by those expert in them.

15. **Sometime number-theorist**
July 18, 2018

@Peter Woit:

I think it is exceedingly hard for both you or me to say whether Mochizuki is convinced whether he has a proof or not. More generally, if you're defining intellectual honesty in terms of the mental contents of the individual in question, you run into the problem of having a subcategory without a feasible criterion for deciding whether an object belongs to it or not. We need to go by what we can observe as much as possible, I would say, even if we don't want to be called behaviorists.

(Consider this question: can an individual delude themselves? If yes, isn't is possible for an individual to think on a conscious level that they have proven something, while being at a deeper level aware that they haven't, or might not have? And isn't an indication of such a state that such an individual reacts aggressively, evasively, or in any kind of obstructing manner, when the point of the integrity of the proof is pressed?)

I really think that mathematicians who are reluctant to call Mochizuki out on intellectual dishonesty should ask themselves the question at what point (or under what circumstances) they *would* be prepared to do so. This has gone on for more than five years now, and the amount of rhetoric from the IUT camp hasn't let up as of yet, and on top of that, substantial amounts of tax-payer money start to get involved as well.

16. **Peter Woit**
July 18, 2018

Sometime number-theorist,
To be fair to Mochizuki, the over-the-top rhetoric generally hasn't been coming from him. It's quite possible we're going to soon see a resolution of this, as experts will see that either Mochizuki has a convincing answer to whatever problems Scholze-Stix are raising or he doesn't. At that point, people may have different takes on how to characterize a possible refusal by Mochizuki to recognize a problem, with "intellectual dishonesty" one of the possibilities.

17. **Sometime number-theorist**
July 18, 2018

@Peter Woit:

Fair enough. But let me just add, I *do* think that the behaviour of Mochizuki's defenders partly reflects on Mochizuki himself. And if people here are posting anonymously out of a fear of harassment, then I think that that is also a signal that something else than a pursuit of truth might be going on here.

18. **Interested**
July 18, 2018

Fesenko's article mentions some recent papers by Mochizuki in the footnotes:

"See two recent texts by Sh. Mochizuki, 'Report on discussions, held during the period March 15–20, 2018, concerning interuniversal
Teichmüller theory (IUTCH)'and 'Comments on the manuscript by Scholze–Stix concerning inter-universal Teichmüller
theory (IUTCH)', July 2018"

However, I am unable to find these anywhere on Mochizuki's website. Does anyone know whether they are available anywhere?

19. **Peter Woit**
July 18, 2018

Interested,

As far as I know, these and the Scholze-Stix manuscript have not been made publicly available, and the intention was that they would not be made public until each side had a chance to fully address the other side's points. I don't know why Fesenko chose to discuss them publicly.

20. **T**
July 19, 2018

Peter,

FWIW, I'm aware (I've been aware) that C. O'Neil used to be a number theorist, and that she knows some experts. My (humble) disappointment stands.

It appears that Mochizuki has been open to correspondence and technical questions about his work all along. It sometimes seemed (from a distance, to an outsider like me) that some of the tension/friction stemmed from Mochizuki's not having visited various institutes in person to explain his theory. This implicit demand (or, again, perhaps my uninformed, outsider feeling of such) was surprising and disappointing to me.

21. **Mateus Araújo**
July 19, 2018

T,

"It sometimes seemed (from a distance, to an outsider like me) that some of the tension/friction stemmed from Mochizuki's not having visited various institutes in person to explain his theory. This implicit demand (or, again, perhaps my uninformed, outsider feeling of such) was surprising and disappointing to me."

I'm a physicist, not a mathematician, so I might be talking from another side of a cultural divide, but the demand that Mochizuki goes around explaining his theory seems entirely natural to me. Putting a paper on the arXiv is not enough, you definitely need to actively defend it, especially if people are interested in it and cannot understand it.

22. **Peter Woit**
    July 19, 2018

    T/Mateus Araujo,
    No one has ever “demanded”, explicitly or implicitly, that Mochizuki travel to their location. Many have, accurately, pointed out that his refusal to travel has made communication with other experts more difficult.

    In any case, this has nothing to do with the latest situation, where, exactly because of the importance of face-to-face communication, Scholze and Stix traveled to Kyoto to talk to him.

23. **Some observer**
    July 19, 2018

    ” I don’t know why Fesenko chose to discuss them publicly.” Since he cites full titles, I assume he got authors permission, and presumably will also have read the work. Now you can ask why Mochizuki has not released the paper and the answer will be similarly generic: He will wait for the Schulze-Stix one. Since it seems that from Mochizukis POV the Schulze-Stix objection is “mostly harmless” it might well be that the whole thing is a ‘non-starter’ and we will find ourselves in a few months at exactly the same state of affairs we had one year ago.

24. **Peter Woit**
    July 19, 2018

    Some observer,
    I’m having trouble seeing why, whatever he thinks of the Scholze-Stix manuscript, Mochizuki would approve of the idea of having it first characterized publicly as “shallow and misplaced”, before it or his response were made available.

Leaving Town

Categories: Uncategorized

About to head out on vacation tonight, back in a couple weeks. On the hot topics in fundamental physics, two items are:

- Concerning the "no dS string vacua" conjecture, a new preprint begins by explaining why the existence or non-existence of such vacua is a question that has not been resolved (and, it seems likely to me, can't be resolved):

  > classical no-go theorems such as indicate that realizing de Sitter vacua in string theory requires quantum and/or stringy ingredients. The fact that corrections to classical 10d low energy supergravity are qualitatively important implies that dS compactifications, in contrast to AdS or Minkowski compactifictions, must live in a regime in which these corrections cannot be made arbitrarily small , hence perturbation theory cannot be made arbitrarily accurate. Moreover the absence of supersymmetry in dS, and perhaps more fundamentally the lack of a complete, nonperturbative formulation of string theory, make it hard to obtain exact results beyond perturbation theory. Thus a completely rigorous, parametrically controlled construction of individual de Sitter vacua in string theory has remained out of reach.

  The paper also explains why if you try and get known physics with a quintessence field rather than a CC, you immediately run into serious problems with coupling to the Standard Model.

- Slides and video of the talks at this year's PiTP summer school on "From Qubits to Spacetime" have started to appear. Once I get back from vacation I'll try and watch some of the talks and hope to figure out how one is supposed to get our spacetime and its physics out of qubits.

Recently people have contacted me suggesting I blog about two physics-related topics likely to lead to vigorous debate. I'd begged off in both cases, since engaging in such a debate or moderating it would be on a short list of things I'd most like to avoid doing. This afternoon though, it struck me that there is an excellent, if cowardly, way to deal with this. I'll mention the two topics briefly here, then shut off comments on the blog and leave town. So, some may find interesting and want to argue elsewhere about:

- One of the PiTP lecturers, Aron Wall, has a blog on physics and theology, called Undivided Looking. Wall's theological views include thinking he has a pretty good idea about how God wants people to behave, in particular he's pretty sure that God doesn't want them having homosexual relations. He wrote extensively about this in a blog entry (now deleted) back in 2015. He'll be soon taking up a faculty position at Cambridge University, and some people are not happy about this, see for example this statement from the Cambridge University Student's Union.
- If you'd like to attend an early universe conference this September, one place you could do so is in the Israeli-occupied West Bank settlement of Ariel, where Ariel University is hosting a workshop on Inflation, Alternatives and Gravitational Waves.

Back now from vacation. On the global warming front, I can report that Northern Norway has gotten rather warm, Svalbard is still pretty cold.

While I was away the big mathematics news was from the ICM. As everyone expected, one of the Fields medalists was Peter Scholze. I was surprised to find a blog post of mine quoted about this in the NY Times, since normally the way this works is that journalists are told who the winners are in advance, and then contact experts in the field (which I'm definitely not one of) for quotes. Some tweets from Davide Castelvecchi at Nature about the unusual embargo rules may provide some explanation:

> The whole situation was surreal from the beginning: the organizers gave reporters advance notice of the winners, but on condition that we would not contact them — even though the winners had already been told long in advance.
>
> They also made no other sources available. In other words, we were supposed to write about these difficult concepts without talking to any experts.
>
> …
>
> Oh and I forgot to say: The email with the names of the winners had no information whatsoever on why they won – in other words, no prize citations.

I suspect one reason for the unusual rules is that the ICM people had decided to concentrate on getting stories out through Quanta magazine, which ran the results here. The stories are very well done, and Quanta magazine is great, but a more usual process involving the rest of the science journalism press would have been a good idea.

One other big piece of news from the ICM was the choice of St. Petersburg over Paris as the site for the 2022 ICM. I was sorry to hear this. Perhaps it's just that I'd rather have an excuse to go to Paris than one to go to St. Petersburg. It does seem to me though that in these worrisome times, when offered the choice between the world's most active opponent of liberal democracy and one of the great remaining healthy liberal democracies, the other choice than the one the IMU made would have been the better one. My understanding is that Russia offered twice as much money, and that many feel that was the deciding factor.

Update: I hadn't realized that the problems with the IMU embargo this year were not new, they were much the same as the problems four years ago with the announcement of the 2014 prizes. See here for discussion of the 2014 story (which, when reading it, I first mistook for a discussion of 2018), and here for a discussion of 2018.

The writer of the new story suggests that "Next time the IMU offers up an embargo agreement, reporters should just refuse" which I'd also semi-jokingly suggested in a comment. Actually, given the history of this, it seems to me that journalists seriously should plan to do this next time, and that sympathetic and well-informed mathematicians should help them find out in advance who the winners are. This would allow journalists to contact experts and do proper reporting, with no reason to wait until the ICM to write their stories.

Update:

- The ICM Youtube channel still doesn't have plenary talks from the ICM posted. Peter Scholze's talk on Period maps in p-adic geometry is available now on a different channel. It's an excellent overview of, not the technology of perfectoid spaces, but some of the results achieved using them.
- The reason there are relatively few comments here about the decision to have the next ICM in Russia is that I've deleted most of them as they come in. Many commenters don't believe Russia is any unusual threat to liberal democracy (or, if it is, that US/European liberal democracy is anything worth saving). Most also disagree with the idea that such a threat should have any effect on what mathematicians do. I agree that in general it's best to keep mathematics and the ICM out of politics. A question to think about though for those who know the history of the 1930s is that of whether there was some point during the rise of Fascism that one would stop thinking it was a good idea to have the ICM in a Fascist capital. We're not yet far along the horrific path of the 1930s, but maybe that just means that all should be thinking about what can be done to keep the world from going down that path again.

  Another frequent comment is "but, by your logic, the US would not be a good place to hold the next ICM!". I fear the answer to that is that yes, Paris would be a much better choice than the US at this point.

Comments

1. **Bill**
   August 6, 2018

   I agree with your St Petersburg vs Paris comment. It seems that the IMU decided some time ago to promote mathematics in countries without a strong mathematical tradition (or a collapsing one), instead of giving an excuse to people like you and me to go on vacation.

2. **Davide Castelvecchi**
   August 6, 2018

   I cannot comment on whether the ICM indeed decided to focus on the Quanta coverage, because I don't know. My multiple emails to the organizers requesting explanations got either evasive responses or no response at all.

   But I don't think there is anything for anyone to be gained by, for instance, making biographical information about the winners available to reporters only after the embargo has expired, as the ICM did. Also, I believe there is nothing to be gained by giving reporters an embargo that expires hours after the announcements have been made via webcast.

   But I suspect that this whole issue is symptomatic of an attitude occasionally seen within the math community. In my professional life as a reporter, I mostly interact with physicists and astronomers, but I also do cover math, and sometimes I do see a difference between the two worlds.

   I feel that some mathematicians see dealing with the press as being subjected to an indignity or an embarrassment; therefore, one should just pretend that the press does not exist (for instance not responding to requests), or perhaps only make exceptions for publications seen as allies. Fifty years ago, that mainly meant Scientific American; now it's Quanta. Note: this is no criticism of either of those publications, for which I have utmost admiration; I have worked at the former and have several friends who work at the latter.

   So, some mathematicians seem to be under the impression that they get to choose who will cover them and their field. But one of the basic facts about a free press in a free world is that the press gets to choose what to cover, not the other way around. This misconception sometimes backfires in a spectacular way: think of Perelman, who thought that somehow you can make a major breakthrough such as solving the Poincaré conjecture and have only experts notice it and discuss it. But the more Perelman sought obscurity, the more morbidly curious people got about him, and the more attention he attracted toward himself — culminating in a New Yorker profile and two biographies.

Fortunately, such extreme cases are rare, and in general, attitudes have been slowly changing. Many mathematicians are very open and helpfully reach out to journalists. And you see more and more mathematicians who are also excellent communicators, and even YouTube sensations (Kelsey Houston-Edwards and Grant Sanderson come to mind, among many others).

3. **Deane**
   August 6, 2018

   Peter, since I posted a public rant on Facebook about how the Times barely managed to run an article about the Fields medalists on the same day they were presented at the ICM, I figure I might as well repost it here:

   My annual (very long) rant: It appears that the IMU is just as bad at PR as the AMS. Until yesterday, they had not provided advance but embargoed notification of the Fields medalists to the right people at the New York Times. It turns out they sent it to the wrong person (someone who writes not about science but about Brazil and who doesn't even work full-time for the Times). So the Times wasn't going to be able to prepare an article to appear as soon as the announcement was made.

   What's the big deal? Well, the Times is mostly in the business of publishing breaking news and, unless it makes a special effort, it's not interested in stale news, which is what the news about the Fields Medalists would be in a few days. We *want* news stories like this to appear in major newspapers like the Times, which means they should be notified as early as possible.

   Luckily, a certain Times science writer told his brother, a mathematician, who in turn texted someone in the IMU leadership, who then finally arranged for the information to be sent to the Times science writer yesterday, which was just enough time to submit an article in time. This is obviously *NOT* the way to do PR for mathematics.

   I looked through the IMU web site and found only pages that discussed how to *submit* news to the IMU and absolutely none about any efforts to disseminate news to the media. That is totally lame. I am fairly certain that all of the other scientific professional societies make an active effort to issue press releases and place stories in the media. Neither the IMU nor the AMS have learned how to do this effectively. It's still luck or pressure by a few people that gets math stories to be reported in the Times.

   I've been complaining about this since 2004, when Chern died. As far as I can tell, the situation has not improved much since then.

   (I do want to say that both John Ball and Ingrid Daubechies, when they were presidents of the IMU *did* notify the Times in advance. Ball even visited the Times newsroom, but that was the year Perelman was awarded the medal. Apparently, this practice has not been properly institutionalized at the IMU and was done this year at best carelessly.)

   I would be grateful, if those of you who are in the leadership of the AMS and IMU to keep pressuring these organizations to institutionalize and professionalize their efforts at media relations. Just having lots of math stories in Quanta is NOT enough. Its readership is too narrow.

4. **Deane**
   August 6, 2018

   Davide,

   The problem is that even the mathematicians who *want* coverage by the press have a poor understanding how the game works and, when things turn out badly, act like it's the press who did something wrong, when in fact the press was just doing its job the way it always does.

   And the professional mathematical societies, such as the AMS and IMU, do not seem to have any capable press relations staff who know how the game works. So they passively put out press releases that they think look interesting and then wonder why nobody pays attention to them.

   When I first realized there was a problem in 2004, I asked Kenneth Chang, who, as you know, is the New York Times science writer who stayed up until 1:20am the night before in order to file the Fields Medal story on time, to compare his interactions with the American Chemical Society, American Physical Society, and the American Mathematical Society. He commented on the first two, but said that he had had no interaction with the AMS at all. I don't think things have improved much since then. That's why I wrote that rant I just reposted here.

5. **Oldster**
   August 7, 2018

   On the ICM conference in St. Petersburg, I can recall memories of working on a project at LANL in the 1970's, and we were encouraged to share data with a fellow project in Novosibirsk. They were ahead of us in that research area anyway, although we also taught them some (preapproved) valuable things as well during a visit to Novosibirsk. And, we hosted another Soviet scientist at LANL for a few days. Such contacts were encouraged both for professional reasons, and for diplomatic reasons as valuable to detente when we still considered the Soviets "foes". Thus to me the discussion now becomes, is holding a conference in St.Petersburg something that might serve a similar useful purpose? And as the Tsar's summer residence and quite close to the rest of Europe, it must have some charm?

6. **anon**
   August 7, 2018

   I agree about political aspects of the ICM host selection, but purely as a vacation destination I find St. Petersburg in August much nicer than Paris in August.

7. **Peter Woit**
   August 7, 2018

   Thanks Davide and Deane,
   Next time around, if the IMU provides the same embargo terms, perhaps publications could consider instead asking around and seeing if they could get the names elsewhere, do proper reporting, and release stories before the ICM…

8. **Davide Castelvecchi**
   August 7, 2018

   Update: Embargo Watch has now covered the issue
   https://embargowatch.wordpress.com/2018/08/07/the-math-prize-embargo-that-didnt-add-up/

9. **Peter Woit**
   August 7, 2018

   Davide,

Thanks! I wasn't aware of the 2014 history of this, reading about it at first I thought I was reading about 2018. Just added an update to the posting with links.

10. **Deane**
    August 7, 2018

    Peter,

    I think your comment is off the mark in two ways. First, reporting on prizes is not investigative reporting, and there's no way the Times is going to rely on unofficial sources for who won. You'll have to clarify what "proper reporting" is. I think you're implicitly assuming that a reporter can tell whether one person is the right person to listen to and another is not. And there's also how much time a science writer has to devote to a breaking news story, even with advance warning. All a writer wants are some good quotes, and frankly I thought Ken managed to do a great job there, getting a couple nice ones from Jordan Ellenberg, especially given the tight deadline he had. Ken had an advantage over Davide, because his brother has introduced him to many mathematicians and he now knows who's likely to give a good quote and who's not. There is also the nontrivial effort to write a few not-too-misleading sentences on why each person got the prize.

    The more important thing is that the math community needs math stories like the Fields Medals to be disseminated a lot more than the Times . I believe that the math community, compared to the other scientific communities, has suffered a lot from its incompetence in media and public relations. The other professional societies have media relations offices who actively try to pitch stories to the media. The AMS does not.

    My personal involvement with this began in 2004 when Chern died. I emailed my brother and told him that the Times *had* to write an obituary. My brother's response was "because you said so, we're doing it". This shocked the hell out of me. It implied that if a mathematician brother of a Times science writer had not insisted on this, the Times would have probably never published one. Note that it is *not* the responsibility of the Times to keep track of deaths of scientists or other science news. It learns of them primarily from official communications from scientific professional societies and universities. So I asked my brother to compare the media relations activities of the American Chemistry Society, American Physical Society, and American Mathematical Society. He commented on the first two, and said, "I've never had any contact with the AMS at all". Things have improved very little since then.

    That 4 obituaries of mathematicians (this for now is the easiest way to place math stories into the Times) appeared last year in the Times was due only to the pressure of a few individual mathematicians (luckily not just me and including at least one Fields medalist). The AMS never sent out anything, and didn't even post the sad news on their own web site for at least a month afterwards (I stopped checking after that).

11. **Peter Woit**
    August 7, 2018

    Deane,

    I should make clear that I wasn't intending in any way to criticize Kenneth Chang's reporting. Considering the restrictions he was working under he did a fine job. The problem is the IMU, and now knowing this is not a new problem, but that they did exactly the same thing in 2014, I think it's up to mathematicians to intervene and make sure this doesn't happen again.

    The problem with the IMU behaving like this is that it is likely to cause journalists to simply not cover the story at all, exacerbating the problems you point out. The way things are going, in the future we'll see excellent articles at Quanta, nothing in the rest of the press. I don't see how that is good for mathematics.

    I'm quite serious that if the IMU doesn't change its policy, mathematicians should consider just going around them to the press, with those who get reliable information about the identity of the winners contacting journalists to let them know. Journalists could then go and cover the story without the embargo restrictions.

    I realize this is not the way such things are normally reported, for very good reasons. In particular, unofficial reports of who the winners are could be wrong, but I think this would quickly become clear once journalists started calling up the supposed winners for comment.

12. **Bill**
    August 7, 2018

    By the way, since no one has mentioned this, Quanta Magazine actually published the article on Alessio Figalli about an hour before the live announcement on Youtube.

13. **August**
    August 7, 2018

    I've heard rumors that Jim Simons provided funding for 15K cheques that Fields medalists received this year, because the IMU ran out of money in their Fields Medal account.

14. **anon**
    August 7, 2018

    A couple of years ago IMU formed an ad-hoc committee to look (among other things) at how the major IMU awards are announced. One option that they considered was the 'Nobel method': announcing the winners in a press conference well before the ICM. I think that would be much better than the current system (the committee recommended keeping the current system).

    With every passing ICM awarding the Fields Medals seems to be turning more and more into something like Breakthrough Prize -type show. I'm starting to agree with critics of the Fields Medal (mathbabe for example) and I wish that IMU de-emphasised the medal a bit.

15. **anon**
    August 7, 2018

    August:

    apparently not Jim Simons. From the IMU webpage:
    "The medals and cash prizes are funded by a trust established by J.C.Fields at the University of Toronto, which has been supplemented periodically, but is still significantly underfunded. The discrepancy in 2018 was made up by the University of Toronto and the Fields Institute."

16. **August**
    August 7, 2018

    Of course, that's what they would say…

17. **Deane**
    August 7, 2018

Quick comment about Quanta supposedly breaking the embargo. What actually happened is that an Italian newspaper broke the embargo and released the news about Figalli. The rule is that once one publication breaks it, then everybody else gets to do it, too. So Quanta published *only* their story on Figalli. It was pretty weird to see a story only about Figalli and not the others. I think the Times also published their article at that point, even though their story was about all 4 medalists.

18. **Deane**
August 7, 2018

Peter,

I agree with you that the IMU (as well as the AMS) have to improve their practices and make it easier for *all* news organizations to publish math stories. So their embargo restrictions and ineptitude during the ICM are harmful.

But I want to repeat that it is NOT the responsibility of the Times to compensate for this, for example, by guessing and calling up people. That's kind of a ridiculous thing to expect a science writer to do.

Since it's all public by now, I can say more specifically what happened. Ken told me, only the day before the ICM opening, about not being able to get a response from the IMU. He did this, I think, mostly out of frustration and told me that I didn't need to do anything. He would just try to write the story afterward the news became public. I still wanted to try. I first looked up who was in the IMU leadership to see who I would feel comfortable contacting. I first texted a member-at-large, who told me that I should contact Ken Ribet instead. I then texted Ribet, who was in Rio and who got the IMU to finally send the names to my brother by around noon. My brother then was able to do the research, finding among other things, your blog post, and talking to various people. It's not always so easy to find people at the last minute like that, but he's good at it. Still, he had to stay up until 1:30am writing the story. That's way beyond the call of duty for a science writer.

I later found out that Ribet himself was on the selection committee and therefore knew who the medalists were. I don't know whether he told my brother directly or got someone else to do so.

19. **Peter Woit**
August 7, 2018

Deane,
Thanks for the further details about what happened. My take on this is that if it weren't for extraordinary efforts by you and your brother, there would have been little or no coverage of this by the Times. Presumably many other publications didn't bother, and that's why if you look around, you find little coverage of this, at least in US media. And there would have been even less if it hadn't been for the medal getting stolen…

Faced with this situation, I'm not suggesting at all that it is up to reporters at the Times or elsewhere to try and figure out who the winners will be. What I'm suggesting is that, if the IMU doesn't change its ways, it's the responsibility of mathematicians to do something about this, specifically, to break confidentiality and get the news to reporters. In every case that I can remember, a few days before the ICM, I know of people who had figured out who the winners were. One would normally avoid leaking this to the press, so as not to interfere with the IMU's plan for how to release the news, but maybe their plans should be interfered with.

20. **Zoviyer**
August 8, 2018

Even more annoying and disappointing that the IMU embargo on the press, and really hard to believe for this age, is the fact that they are not streaming the Plenary lectures. Even the lectures at the congress in Madrid all the way back to 20016 were streamed (and are still available at http://www.icm2006.org/video/). They seem happy to just put some very superficial posts in Instagram (not at odds at all with that platform!).

21. **martibal**
August 8, 2018

With the risk to be old fashioned, why is it so important that Fields medalists have their "story" on the first page of the Times ? I believe that some years ago the Fields Medals had very little echo outside the maths community. Was it is so bad ? In this blog we are complaining posts after posts against the "big show/circus" that high energy theoretical physics has become; if maths tries to resist to this tendency, that might be a good new.

22. **Peter Woit**
August 8, 2018

martibal,
Not sure how important it is, but it seems a good opportunity, once every four years, to get some public attention for high-quality pure mathematics research. Unlike the Breakthrough Prize business, which tries to do this with Hollywood glitz and large checks, the Fields medal is little money, and awarded in the serious context of the ICM conference. I think Peter Scholze explicitly recognized the difference between the two things, by turning down the (junior) Breakthrough Prize award, and accepting the Fields Medal award.

The kinds of stories put together by Quanta about the medalists and their work I think are good things for the public to see. It would be great if the IMU's press people helped more of the press to create such stories, to get wider distribution. One can sensibly argue that the IMU should stick to math research, not engage with promoting it to the public. But, part of what they are trying to do is such promotion, and I don't see an argument for why they should do it, but badly.

23. **Kenneth Chang**
August 9, 2018

The issue of the Quanta favoritism is the same as four years ago, but in every other respect, the resources and help from IMU were _much_ worse this time around.

In 2014, IMU contacted me directly, an email from Ingrid Daubechies, the IMU president. I don't know if she personally wrote it, but someone clearly made the effort to find reporters who were likely to be interested in writing about the Fields. This time, IMU sent an email to foreign@nytimes.com, a catchall mailbox for all sorts of news from all over the world. Not surprisingly, the email never made its way to me.

In 2014, reporters who received the embargoed news release could interview the medalists. (The exception was Maryam Mirzakhani, for understandable health reasons.) This time, reporters were not to contact any of the medalists ahead of the announcement.

In 2014, IMU provided the name of an expert who could talk about each medalist's work. This time, there was no such help.

In 2014, IMU provided a description of the medalist's work. It was highly technical, but at least it was enough for me to at least ask Deane, "What the hell does this mean?" This time, there literally was nothing more than names and the Simons Foundation videos.

I complained to the IMU/ICM people afterward and was told several of the medalists had said they did not wish to speak to the press. I don't remember this ever happening before (Mirzakhani again being the exception). I don't think this is coincidental. It appears that at least some of the medalists feel that the significant time they spent for the Quanta articles and Simons videos fulfilled their obligation to the public.

24. **Thomas**
August 9, 2018

If some of you are ready to put aside the "media coverage problem" for a few minutes, I think an interesting point could be trying to analyze how close some other young mathematicians were to win a Fields medal this year. More precisely, since guessing the future medalists is one of the favorite games of math addicts (see here for instance: https://poll.pollcode.com/44839318_result?v), I've noticed that, except for Peter Scholze, the three other medalists appeared kind of outsiders compared to the most proposed names found on the web. Indeed the names which came out were mainly: Fernando Codá Marques, Ciprian Manolescu, Simon Brendle, Geordie Williamson, or Maryna Viazovska. I agree that Alessio Figalli was sometimes proposed, but not as a big favorite. So I guess we have at least 2 big surprises this year: Caucher Birkar and Akshay Venkatesh.

While I clearly think that's part of the fun to have surprises with the Fields medal results, it would be cool to really discuss the weight of the contributions of the winners in comparison with the one of the "main losers". So we could try to understand the final choice of the IMU for the Fields medalists, and in the same time sharing a bit the word outside the light of the 4 winners…

25. **Deane**
August 9, 2018

Let me clarify that although I've been complaining specifically about coverage of the Fields Medals, my overall larger concern is the coverage of math in general. I want to see more math stories in the New York Times, period. The Fields Medals are just the lowest hanging fruit. Obituaries of mathematicians seem to be the next lowest. I want more.

Mathematicians like to complain about all the fuss about the Fields Medals. In an ideal world, I would, too. But we need whatever publicity we can get, and if, for the moment, it's easy to get coverage of the Fields Medals, I don't see why we should spurn it.

26. **Peter Woit**
August 9, 2018

Thomas,

I was thinking of writing about this in the posting, in the end didn't mainly because of lack of time. An important point for the public to understand is that, while there are some winners like Scholze who would be chosen no matter what, typically many of the Fields Medal winners are very good mathematicians, but not that distinguishable from some other very good mathematicians who don't get chosen, in this case simply because there were only three non-Peter Scholze slots available this year.

I suspect a different committee would have made some different choices, recognizing a different group of very accomplished people. Part of the issue is that there is no sensible single well-ordering of mathematicians by who is "best". Different people's work is very different, and different people will have different judgments about what kind of work they like best. So, while admiring the accomplishments of this group, it's a good idea to keep in mind that there is a significant number of others, unrecognized by the medal, but doing equally good work.

27. **Anni**
August 9, 2018

Reading the write-ups and talking with other mathematicians, I had the impression that: Birkar deserved it, Venkatesh is a good choice but so are the next ten people, Figalli (?).

Another interesting issue is to compare sectional panels and invited speakers. In the section I know best one-third of the speakers are from the area of the committee chair and a number of speakers are collaborators and former students and postdocs of other committee members.

28. **Peter Woit**
August 9, 2018

Anni,

I don't want to encourage everyone to debate here their relative evaluations of the Fields medal winners/non-winners. To see who was on this and on previous Fields medal committees, see
https://www.mathunion.org/imu-awards/fields-medal#on-page-3
The members of this year's committee that I know something about all seem to me likely to have taken the job seriously and done it well. One of them, Terry Tao, has some comments here:
https://terrytao.wordpress.com/2018/08/01/birkar-figalli-scholze-venkatesh/

That said, I still suspect a different group of well-known mathematicians with equally good judgment and taking the job equally seriously, quite likely would have come up with (besides Scholze) some different names.

29. **Davide Castelvecchi**
August 9, 2018

What Ken said sadly confirmed my hunch — that at least some of the winners did not wish to speak to the press.

30. **Peter Shor**
August 10, 2018

My impression from the 1998 ICM was that the press knew the names of the Fields Medal winners well before the public was supposed to and interviewed them (although the names did leak out somehow).

I suppose they may have blamed the press for the leaks, and that this led to the current state of affairs.

31. **Koji Fujiwara**
August 10, 2018

I attended ICM as a speaker. I was thinking about this discussion during the closing ceremony. I understand the frustration of the journalists.

One thing I noticed is that ICM is the International congress of mathematicians, it is not for/on/of Mathematics. It is an event where about 3000 mathematicians get together, about 200 invited talks are given, and 4 young rising stars are chosen and given medals. It is different from, say, Nobel prizes. For example, Nobel prizes of

physics are chosen every year, but only the laureates are there and no other physicists.
During the ICM, I could see lots of efforts are made to reach out to the mathematicians from countries and areas where there is a chance of improvement, say, Africa. IMU is doing good jobs toward mathematicians.

That might explain how IMU have been to journalists. I am not justifying it, but looking for reasons that made the difference. I imagine that the headquarters of IMU possibly does not have a clear idea yet on what they want to do toward the general public.

32. **bixter zavala**
    August 12, 2018

    I find it rather appalling that, judging by the number of comments in this thread, the press issues related to Fields Medal seem to be of (much) greater importance than the decision to host ICM 2022 in Russia. The latter is far from morally neutral. It's basically legitimizing a regime notorious for invading and occupying another country (the annexation of Crimea) as well as other infractions (political prisoners, MH-17 etc.). I would expect the mathematical community to use its conscience and at the very least voice its condemnation.

Theorists with a Swamp, not a Theory

August 13, 2018
Categories: Swampland

In recent weeks string theory has been again getting a lot of press attention, because of claims that new progress is being made in the study of the relation of string theory and the real world, via the study of the "swampland". This is a very old story, and I've often written about it here. I just added a new category, so anyone who wants to can go follow it by clicking on the Swampland category of posts.

Recent press coverage of this includes an article by Clara Moskowitz at Scientific American, entitled String Theory May Create Far Fewer Universes Than Thought. This motivated Avi Loeb to write his own Scientific American piece highlighting the dangers of string theory speculation unmoored to any possible experimental test, which appeared as Theoretical Physics is Pointless without Experimental Tests. Loeb reports:

> There is a funny anecdote related to the content of this commentary. In my concluding remarks at the BHI conference we held at Harvard in May 2018, I recommended boarding a futuristic spacecraft directed at the nearest black hole to experimentally test the validity of string theory near the singularity. Nima Arkani-Hamed commented that he suspects I have an ulterior motive for sending string theorists into a black hole. For the video of this exchange, see
>
> https://www.youtube.com/watch?v=WdFkbsPFQi0

Last week Natalie Wolchover reported on this controversy, with an article that appeared at Quanta magazine as Dark Energy May Be Incompatible With String Theory and at the Atlantic as The Universe as We Understand It May Be Impossible (the Atlantic headline writer misidentifies "we" as "string theorists").

Wolchover accurately explains part of this story as a conflict between string theorists over whether certain solutions (such as the KKLT solution and the rest of the so-called "string theory landscape") to string theory really exist. Vafa argues they may not exist, since the proposed solutions are complicated and "Usually in physics, we have simple examples of general phenomena." In response Eva Silverstein argues:

> They essentially just speculate that those things don't exist, citing very limited and in some cases highly dubious analyses.

On Twitter, Jim Baggott explains the problem

> Let's be clear. This is not a 'test' of string theory. There is no 'evidence' here. This is yet another conjecture that 'might be true', on which there is no consensus in the string theory community.

and in a retweet, Will Kinney accurately notes that

> The landscape is a conjecture. The "swampland" is a conjecture built on a conjecture.

and points to an earlier tweet thread of his about this. Sabine Hossenfelder replies with the comment that

> The landscape itself is already a conjecture build on a conjecture, the latter being strings to begin with. So: conjecture strings, then conjecture the landscape (so you don't have to admit the theory isn't unique), then conjecture the swampland because it's still not working.

The Simons Center summer workshop this year has been devoted to Recent Developments in the Swampland, videos are here (this was also the case in 2006, see here). Next month in Madrid a conference will be devoted to Vistas over the Swampland, and I'm sure many more such gatherings are planned.

Unfortunately I think the fundamental problem here somehow never gets clearly explained: String theorists don't actually have a theory, what they have is an approximation to an unknown theory supposed to be valid in certain limits, and a list of properties they would like the unknown theory to have. If this is all you have, there's no way to distinguish when you're on dry land (a solution to string theory) from when you're in the swamp (a non-solution to string theory). Different string theorists can generate different opinions, conjectures and speculations about whether some location is swamp or dry land, but in the absence of an actual theory, no one can tell who is right and who is wrong. I don't know why Vafa back in 2005 chose "Swampland" as the metaphor for this subject, but it's an unfortunately apt one: string theorists are stuck in a swamp, with no way of getting out since they can't tell what's dry land and what isn't.

Comments

1. **4gravitons**
   August 14, 2018

   I'm not an expert in string compactifications, but for what it's worth I don't think the problem here is that the theory itself is ambiguous. Nonperturbative physics is hard, especially for gravity. Even with a completely well-defined theory (say, 11D supergravity), it's not straightforward to verify that some arbitrarily complicated compactified quantum spacetime is a valid solution to the full theory.

   (Case in point: asymptotic safety is still an open question, and that starts out in 4D.)

   There's a case to be made that if someone doesn't have a good handle on the nonperturbative physics, they shouldn't act like they're doing cosmology with it. But I don't think the problem is just that M theory doesn't have a Lagrangian.

2. **Lars**
   August 14, 2018

   "It's conjectures all the way down"

   Conjecture built on guess
   In turn that's built on hunch
   The latter really rests
   On inference a bunch

3. **Peter Woit**
   August 14, 2018

   4gravitons,

Presumably you agree that there is a problem with a lack definition of non-perturbative string theory. Why are you so sure that this problem isn't relevant to the problem here? I'd recommend reading the introduction to arXiv:1807.06581 (written by people who are experts on this), which explains the underlying problem behind the dense thicket of technicalities which arise here:

> Compactifcations of superstring or M-theory to 4d Minkowski or AdS space are well understood and have led to the idea that string theory gives rise to a gigantic landscape of possible 4d low energy eective theories [2{11]. However, classical no-go theorems such as [12] indicate that realizing de Sitter vacua in string theory requires quantum and/or stringy ingredients. The fact that corrections to classical 10d low energy supergravity are qualitatively important implies that dS compactifcations, in contrast to AdS or Minkowski compactifcations, must live in a regime in which these corrections cannot be made arbitrarily small [13], hence perturbation theory cannot be made arbitrarily accurate. Moreover the absence of supersymmetry in dS, and perhaps more fundamentally the lack of a complete, nonperturbative formulation of string theory, make it hard to obtain exact results beyond perturbation theory. Thus a completely rigorous, parametrically controlled construction of individual de Sitter vacua in string theory has remained out of reach. On the other hand, starting with [6], much progress has been made over the past 15 years in developing models containing all the ingredients needed to produce effective potentials generic enough to support an abundance of dS vacua, barring extraordinary conspiracies that would somehow eliminate all of those.

4. **JGS**
   August 14, 2018

   It's funny that the Atlantic article, which is a reprint of Natalie Wolchover's Quanta piece, says that string "theory permits some 10,500 different solutions: a vast, varied "landscape" of possible universes." Some typo!

5. **4gravitons**
   August 14, 2018

   Peter,

   I agree that the lack of a full non-perturbative definition of the theory is often brought up in this context, it's just not obvious to me that it isn't a red herring, something that gets emphasized because it's a big deep problem that's plausibly related and thus makes for good introduction-padding material. Put another way, I know of very few cases where having a non-perturbative definition alone actually helps answer the kind of question these people are trying to answer, without some extra magic like unbroken supersymmetry. But again, I may just be showing my ignorance here.

6. **Paraphraser**
   August 14, 2018

   Classical no-go theorems indicate that realizing confinement in Yang-Mills theory requires quantum ingredients. The fact that corrections to classical 4d low energy chromodynamics are qualitatively important implies that confinement must live in a regime in which these corrections cannot be made arbitrarily small, hence perturbation theory cannot be made arbitrarily accurate. Moreover the lack of a complete, nonperturbative formulation of Lorentz-invariant Yang-Mills theory make it hard to obtain exact results beyond perturbation theory. Thus a completely rigorous, parametrically controlled construction of hadron states in Yang-Mills theory has remained out of reach.

7. **Peter Woit**
   August 14, 2018

   4gravitons,

   It sounds like you don't actually understand the technical issues here, but somehow are convinced that it's a good idea to suggest that Denef/Henecker/Wrase (who are experts on this) are padding their introduction with misleading red-herring material. Sorry, but this is pretty bizarre behavior.

   I've ended up wasting huge amounts of time the past fifteen years arguing about the KKLT construction with people. Besides a very small number of cases, the people who have wanted to argue about it with me don't seem to actually understand any details of what the issues are. One of the weirder general aspects of the "string theory" story over the years is the way it is so difficult to get a concrete actual definition of things that people are making claims about. What exactly is a "solution to string theory", and why are experts now disagreeing over what is and what isn't such a solution? If you think Denef/Henecker/Wrase are spouting nonsense, can you point to somewhere where someone gives a precise answer to this question that isn't nonsense?

8. **Peter Woit**
   August 14, 2018

   paraphraser,

   As you're undoubtedly well-aware, there is a complete non-perturbative formulation of Yang-Mills theory (lattice gauge theory), expected to be Lorentz-invariant in the continuum limit, with massive amounts of numerical data backing up that expectation. Trying to claim that the state of Yang-Mills theory and that of non-perturbative string theory are the same is just absurd.

9. **4gravitons**
   August 15, 2018

   In retrospect I think I was confusing the naive notion of defining a theory (having the Lagrangian, etc.) with the more sophisticated requirements (having something like lattice gauge theory) that you/Denef/Henecker/Wrase have in mind, so sorry for muddling things. Agreed that in the absence of that kind of definition the criteria for what is and isn't a solution seem quite vague, I've likewise been frustrated by the lack of explicit statements of what these people would count as a sufficiently established solution.

10. **mrp**
    August 15, 2018

    As a non-expert, it is not clear to me from the media coverage whether the conjecture put forth by Vafa and others is a mathematical conjecture or an empirical conjecture. Can anyone clear this up for me?

11. **Peter Woit**
    August 15, 2018

    mrp,
    It's not an empirical conjecture. It is often promoted as a well-defined mathematical conjecture: the solutions of the string theory equations have (or do not have) certain properties.

    The problem is that you don't know what the relevant string theory equations are. So, this is a conjecture about a conjecture:

First conjecture: There is a well-defined theory satisfying a certain list of properties.

Second conjecture: The equations of this unknown theory do or don't have certain specific properties.

The second conjecture is a "mathematical conjecture", but I'm not so sure the first one deserves to be called that.

12. **Anonymous**
August 15, 2018

I would like to point out that the notion of "swampland" is independent of string theory.

The swampland is defined as the collection of low energy effective field theories which include perturbative gravity but does not admit a non-perturbative completion.

Finding criteria to decide if a low energy theory belong to the swampland is
of rather obvious interest.

Conjecturing such criteria on the basis of our current knowledge of string theory and holography is of course a more hazardous enterprise, as we only have a solid non-perturbative understanding of certain supersymmetric, Anti de Sitter backgrounds
but we are interested in non-supersymmetric, possibly de Sitter backgrounds.

Nevertheless, well-posed conjectural criteria are a reasonable subject of inquiry
and once formulated they are independent of the validity of string theory or landscape ideas.

It seems inappropriate to characterize that work as "conjecture built on a conjecture
built on a conjecture".

13. **Peter Woit**
August 15, 2018

Anonymous,
One aspect of the swampiness problem here is that it's often unclear what definition of "swampland" is being used. According to you the definition makes no reference to string theory, according to others it does. For instance, Wikipedia tells us that:

"In physics, the term swampland is used in contrast to the term "landscape" to indicate physical theories or aspects of such theories that could be true if gravity were not an issue but are not compatible with string theory."

I'm using the term in this sense (EFT incompatible with string theory) and pointing out the problem with this definition (you don't know what equations the words "string theory" are referring to). The recent "swampland" controversy has centered around the question of whether string-theory based constructions like KKLT are true metastable string theory ground states, this is a controversy about string theory.

When you instead use the definition "EFT incompatible with non-perturbative quantum gravity", you need to explicitly state your assumptions/conjectures about what properties quantum gravity will have non-perturbatively. Some people believe string theory is the only consistent non-perturbative QG, so, for them, there's no difference in the two definitions. If there's a difference for you, you need to explicitly state your assumptions.

In the case of the current controversy, there's good observational evidence for de Sitter, and no evidence for "quintessence" + lots of reasons to be skeptical about it. So, if you believe Vafa's conjecture and your swampland is the string theory one, you have good evidence against string theory (but, due to swampiness, not evidence string theorists will accept). If you believe Vafa's conjecture and your swampland is the non-perturbative QG one, then you have evidence there is no non-perturbative QG. I'd argue that in this second case you haven't shown there is no non-perturbative QG (since I think there's a consistent theory of the world, including QG), you've just shown that there's a problem with your conjectured properties of non-perturbative QG. An added reason why one wants to be clear exactly what properties are being conjectured.

14. **Moyses**
August 16, 2018

Dear Peter,

as you seems to have former publications in LQCD, I assume that you do not ignore IKKT results derived by similar Monte Carlo methods. Clearly, such matrix approach to ST provides a nonperturbative fully-covariant formulation for IIB ST. Surprisingly enough, not only numerical solutions (but also analytical ones) suggest the same results, i.e.: an expanding (3+1)d Universe dynamically emerges together with a cosmological "constant". Please, check for instance: arXiv:1208.0711 and references therein.
All the best,
M.

On Status of KKLT

August 16, 2018
Categories: Multiverse Mania, Swampland

(Warning, this is just more about the topic of the last posting, which for most people will be a good reason to stop reading now. On the other hand, if you're obsessed with the controversy over string theory, you might find this interesting).

I finally got around to watching some more of the Simons Center Workshop on the Swampland talks, and noticed a remarkable exchange at the end of Thomas Van Riet's talk On Status of KKLT (starting at 1:30). The first commenter (a German, Arthur Hebecker?) starts off saying "I think you are doing something that is very dangerous", with the danger being that KKLT will get thrown out and people will think that it is a "theorem" that string theory has no dS vacua. He is interrupted by Vafa who tells him that "your statement is defamatory, let's calm down". The German goes on to explain to Vafa the significance of the danger he is concerned about:

> Maybe for you in the US it's fine at Harvard, for me it will be a pain because people will turn against me. The little standing that string theory and new physics at all has in Germany will be harmed by a backlash on us that we have been talking nonsense all the time, which is not true.

Van Riet after a while interjects that there is an even worse danger:

> The opposite happened and actually back-reacted very badly. We had the books by Woit and Smolin and it was based on the existence of the multiverse as a correct statement, right? And that's when the criticism of string theory took off, right?

Someone else in the audience (Iosif Bena?) comes in on the Vafa/Van Riet side of the argument, criticizing multiverse mania:

> I think the main problem was that at the beginning people in the KKLT camp, they came up with, "OK string theory has the multiverse, we're not going to do physics anymore, the anthropic principle…" They came up with all these ideas that hurt string theory much much worse, at least in Europe, at least in my part of Europe. And you know, essentially hurt us heavily… Then there were these books by Woit and Smolin that were very popular…

It's remarkable to see publicly acknowledged by string theorists just how damaging to their subject multiverse mania has been, and rather bizarre to see that they attribute the problem to my book and Lee Smolin's. The source of the damage is actually different books, the ones promoting the multiverse, for example this one. A large group of prominent theorists, especially many from the West Coast, including the group at Stanford and the late Joe Polchinski at Santa Barbara, used the existence of the KKLT construction to push very hard a pseudo-scientific excuse for why string theory wasn't working out. I've often point this out, and I do think this has been very damaging to the public perception of string theory. But the underlying problem is the takeover of string theory by multiverse pseudo-science, not that I and Lee Smolin criticized it.

A striking fact about the Stony Brook workshop is that none of the participants were from Stanford, and none of the many prominent figures responsible for promoting KKLT were there. It looks like there is now a dramatic split going on, with Vafa leading the charge to try and fight back against what in recent years has been a seeming dominance of string theory by the pro-multiverse faction. I think such a split is long overdue, that most string theorists for years now have been making a terrible mistake by going along with multiverse pseudo-science. As Hebecker(?) explained though, fighting back publicly at this point carries its own dangers. In particular, many observers will be asking: "for years you told us about the 10^{500} vacua", now you say that maybe there aren't any. Which is it? Why can't you tell? And do you really have a serious alternative for how to connect string theory to the real world?

Vafa tries to not take sides, to portray this as a simple technical question that will yield to further calculations by theorists. Where I disagree with him is that I'm very skeptical that this is a technical question with a well-defined answer. This is not a new controversy: theorists have been arguing about moduli stabilization and this de Sitter/no de Sitter issue for twenty years or so, without coming to any firm conclusions. If you watch the technical talks at the Stony Brook workshop, the degree of technical complexity of the arguments is striking, as is their often rather vague nature. What you don't see is a specific set of equations that everyone agrees on. We'll see what happens in coming months and years, there are likely to be a large number of papers written on this subject. Also to look out for, likely the efforts of Vafa and others to throw doubt on KKLT will not be taken lying down. The West Coast Empire will strike back…

Update: At CNN, Don Lincoln has an article about this, which ends with:

> It's not quite a WWE cage match, but it's going to be fun to watch these theories fight it out.

Update: Tonight the West Coast Empire has struck back, defending here and here their dS vacua against the Swampland attack, and going on the offensive, accusing the conjecture of their attackers as being "ruled out by cosmological observations, at least at the 3 sigma level".

Comments

1. **Sabine**
   August 17, 2018

   (Yes, that's Hebecker.)

2. **Bai**
   August 17, 2018

   As a complete outsider to HEP (I am a condensed matter physicist though), I find appalling that issues like the damage being made to a community (in certain parts of the World..) are openly discussed and considered at Scientific events. It makes it so explicit that some of these fellows (I suspect the vast majority..) give a lot of importance to avoiding their University chairs being shaken, their funding being cut, etc, than seeking the ultimate truth in their research. It is very sad to see the kind of game (hard) Science is becoming, and it all sets a terrible example for future generations…

3. **Peter Woit**
   August 17, 2018

   Bai,
   This exchange was interesting precisely because these issues, while important to people, are virtually never publicly discussed. This is not something that regularly happens. Also note that, in response to Hebecker bringing up the issue, Vafa and the others, while acknowledging the political problem, properly responded that such issues should not be relevant, that what was important was finding the scientific truth of the matter, whatever the political ramifications.

4. **Jesse O.**
   August 17, 2018

"The West Coast Empire will fight back…"

It is wholly irresponsible to come so tantalizingly close to an "Empire Strikes Back" pun.

5. **Peter Woit**
August 17, 2018

Jesse O.,
Irresponsibility fixed.

6. **Joelson F. Silva**
August 17, 2018

In condensed matter theory theoretical physicists have your own "Vietnam War", called high critical temperature superconductors, and for those thet believe in AdS/CFT approach to the problem, this method can "describe" only few properties of the problem as the pseudogap
region and fails to most others real problems in condensed matter, for exemple, universal viscosity prediction for bad metals. However, is not about that I wanna talk here, seens to me that the string theory is the "Vietnam War" for high-energy physicists, but in condensed matter we recognize our "defeat", even P.W. Anderson recognized your mistakes in the first approach to the problem. Many important things came from the High Tc superconductors search, as new numerical techniques, but we don't find the answer to the problem, until today. We don't give up of the High Tc supercondutors, we move on to new approachs and ideas, this was not easy, due the "fights" beetwen the Popes of the area and the intimidation over the new
researchers and your ideas. I think that HEP physicicts must do the same, move on to new ideas outside string theory, in this sense, the Woit work and others are fundamental. The first step to the string theorists is recognize the "defeat" in this "Vietam War".

7. **Lee Smolin**
August 17, 2018

Dear Peter,

I have usually stayed silent in the last 12 years since my The Trouble with Physics was published, but given the remarks you quote, I think its important to remember some key points:

-Leonard Susskind's paper, "The Anthropic Landscape of String Theory (0302219)" was posted in February of 2003. This immediately ignited the controversy over KKLT and the landscape; Susskind's book The Cosmic Landscape, written to bring his polemic to a large public audience was published in December 2005. By the time my book appeared in September 2006, the controversy had been going for 3 and a half years. Several prominent science journalists told me my discussions of the landscape were already old news.

-Indeed, the issue of there being a vast landscape of string theory vacua, and hence a problem of predctability, was widely know back to papers of Strominger and others back to 1987. It was the motivation for my 1992 paper on cosmological natural selection; indeed I introduced the term "landscape" in the context of that work, borrowed from population biology. What was new in 2003 was only that KKLT addressed the issue of whether there are any string vacua for positive cosmological constant.

-Many people criticized my book without reading it, quoting others who also had not read it. Many who did read it commented, publicly or to me, including several string theorists, that the book had been mischaracterized and was not a simple "attack on string theory". Several praised the book for its fair and balanced treatment of the successes and failures of string theory, that was in detail, little different than that given in Brian Greene's book of the same year.

-The subject of the book was very different, it was the role of controversy and disagreement, and how they are resolved, as engines which drive progress in science. String theory was there as a case study.

-Nonetheless, I would claim the critique of string theory's strengths and weaknesses has largely held up over the 12 years since. The successes are still reasons to consider it one of the candidate approaches to QG. The big open problems I elaborated there: the lack of a background independent formulation, the absence of a proof of uv finiteness to all genus, and the problem of testibilty, are all still unresolved. In the time since a great deal of good work has been done on related topics such as AdS/CFT, little of which, however, addresses these key open issues.

-The book advised that string theory be studied as one of several approaches to QG, which have complementary strengths and weaknesses. Each is interesting, none is problem-free. Indeed my previous book Three Roads had suggested a route to unification of string theory with LQG. These remain valid, reasonable views.

-Of course, others will disagree. As TTWP argued, this kind of friendly, respectful, disagreement is necessary for science to progress. Given that, we should all welcome a diverse scientific landscape, especially to leave room for young scientists to discover better theories, for this is how science progresses. That remains the message of the book I wrote.

Thanks,

Lee

8. **Peter Woit**
August 17, 2018

Hi Lee,

Thanks providing some valuable perspective on your book.

As for my book, I can't help but mention that the original version was mostly written in 2002, pre-Susskind/landscape. There is nothing in the version of the manuscript submitted to Cambridge University Press in early 2003 about the landscape/multiverse/anthropics issue (basically because I was unaware of it). If string theorists hadn't managed to stop CUP from publishing that version, mine might have appeared with nothing about this topic in it. The chapter on this topic was added in 2004, in the version that Jonathan Cape later published.

Personally, I think the arguments of both books have held up very well over the years since they were written, much better than those of contemporaneous books enthusiastic about the prospects for string theory, supersymmetry, extra dimensions. But I think string theorists are wrong to attribute their problems to the books. Their problems are with the science, not with the fact that some people pointed out the scientific (and sociological) problems.

9. **Shantanu**
August 18, 2018

Peter, was Strominger at this meeting? IIRC he is not a fan of landscape or anthropics. (see his colloquium at Harvard which you had blogged about) Does he side with Vafa on this issue?

10. **Peter Woit**
August 18, 2018

Shantanu,
No Strominger, and I assume his point of view on this is probably the same as that of most people's, string theorists and non-string theorists: landscape/anthropics is a dead end, and no point in wasting time on arguing about the complex details of whether Rube Goldberg machines like KKLT really work or not.
.

11. **Jeff Berkowitz**
August 18, 2018

Hello Dr. Woit, in your posting you write: "[Various key theorists] … used the existence of the KKLT construction to push very hard a pseudo-scientific excuse for why string theory wasn't working out."

I want to make sure I understand this comment. You are saying that due to the existence of the KKLT paper, the community of theorists–or at least a faction of the community–was able to "fend off" the "dark energy versus aDS" issue for a long time without being "called to account" for the conjectural nature of KKLT. Is this correct?

12. **Peter Woit**
August 19, 2018

Jeff Berkowitz,
No. The significance of the KKLT paper is that their mechanism produces not just one "solution" with positive CC, but an exponentially large number of them. It is this huge number of solutions that has been used as basis of the claims by a group of theorists that string theory implies both an (anthropic) solution to the CC problem, and suggests that what we think of as fundamental constants that should be calculable, instead are environmental. It is this aspect of KKLT that I think motivates Vafa and others to try to find an argument against it, hoping to kill off the "landscape" pseudo-science this way.

13. **Narad**
August 24, 2018

>If string theorists hadn't managed to stop CUP from publishing that version

I seem to have missed this story. Could you elaborate or provide a pointer, please? I was in journals publishing, but we were close with (supporting, actually) the books division at the university press I worked at, and although CUP is much larger organization, acquisitions editors are practically on a quota basis.

Quantum Supremacy

August 26, 2018
Categories: Uncategorized

Hasn't been much that I've heard about worth discussing here recently. Presumably everyone is on vacation. I'll try and gather some things that may be of interest, starting first with the hot topic of "quantum computation". It looks like this will be drawing an increasing amount of attention and resources in the field of physics research. For instance:

- Slides and videos from the summer IAS program From Qubits to Spacetime are available here.
- There will be a graduate seminar at Harvard this fall, blog post about it here.
- In a few weeks Fermilab will host a workshop on Next steps in Quantum Science for HEP.
- Moving through the US Congress is a National Quantum Initiative Act, which would provide over a billion dollars in funding for things related to quantum computation.
- At the NSF MPS (Mathematics and Physical Sciences) they're promoting NSF's Quantum Leap. This is the first of four "Big Ideas" (discussed here) which will influence what gets funded. The other three are multi-messenger astrophysics, big data, and things related to biology.
- Launching this week is The NSF 2026 Idea Machine, which is a competition for suggesting research questions, more "Big Ideas" for the NSF to fund. If you want to enter the competition that opens Friday, I'm guessing that invoking the word "Quantum" will help.

   August 27, 2018

   Also, Scott Aaronson has a new set of notes on quantum information:

   https://www.scottaaronson.com/blog/?p=3943

2. **Onlooker**
   August 27, 2018

   Interesting that Witten seems to have switched fields into quantum computing.

3. **George Herold**
   August 27, 2018

   Thank you for the nice series of links. I'm a hardware guy and found this one useful (from the NSF Big Ideas.)

   https://www.nsf.gov/attachments/245240/public/materials_for_quantum_leap.pdf

   Is it just me, or does this seem like a lot of hype? (Topological insulators as the next transistor?)

4. **Shantanu**
   August 27, 2018

   Maybe I am naive, but can someone tell me how quantum computing provide insights on Physics beyond standard model (or just more insights into standard model) or give clues on what LHC would see?

5. **Peter Woit**
   August 27, 2018

   Shantanu,
   I don't think any of this has any relations to questions about the SM or possible BSM physics. In some sense, the move to this study of new quantum materials and quantum computation marks a giving up on the idea of trying to understand more about the SM.

   There seems to be some hope that this will lead to new ideas about quantum gravity and, especially, how to resolve the black hole information paradox. I haven't had time to look into this carefully, but from what I've seen, the ideas about quantum gravity seem extremely crude, untestable, and explain nothing at all about the relation of quantum gravity to the SM.

6. **Stephen Marney**
   August 27, 2018

   Peter,
   Wouldn't quantum computation allow us to simulate the SM and BSM physics to perhaps get new insights into these models of physics?

7. **Peter Woit**
   August 27, 2018

   Stephen Marney,
   The problem is that most of the mysteries of the SM have to do with what appear to be weakly coupled degrees of freedom, where perturbation theory is a very effective computational tool and I don't see how quantum computers would help. The strongly interacting sector of the theory is one where maybe quantum computers will help, but all evidence is that there the dynamics is known and fixed (SU(3) Yang-Mills).

   For a different perspective, I see that Sabine Hossenfelder has a new piece out in Quanta:
   https://www.quantamagazine.org/the-end-of-theoretical-physics-as-we-know-it-20180827/

   The main reference to the SM there is
   "maybe what we currently think of as fundamental — space and time and the 25 particles that make up the Standard Model of particle physics — is made up of an underlying structure, too. "
   but my problem with this sort of claim is that I've never seen a plausible idea for what this new "underlying structure" is supposed to be.

8. **CWJ**

August 27, 2018

There is an important aspect of testing SM and BSM physics, and that in many cases, for example in dark matter detection, neutrinoless double-beta decay, and neutrino cross sections, and that's one needs the interaction matrix element between particles and nuclei; and to get accurate results one needs to solve the nuclear many-body problem well. I know, I know, you all probably think this is either "long ago solved physics" or "black box physics," but neither is true. (It happens to be my area of research.) The last 15 years have seen tremendous improvement in rigorous calculations of the nuclear many-body problem…but mostly for light nuclei (lighter than oxygen), and many of the interesting targets are heavy (like xenon). So the idea here is to do nuclear many -body calculations on heavy nuclei with quantum computers.

Now, will quantum computers actually be able to outperform classical computers in this regard? And if so, how soon? Well, that's the question.

(And, no, density function theory isn't enough for some of these calculations. And coupled clusters only work well near closed shells.)

9. **Chris Woodward**
   August 29, 2018

   A google search for "quantum computing" gave me as first hit a
   report by Accenture https://www.accenture.com/t20170628T011725Z__w__/us-en/_acnmedia/PDF-54/Accenture-807510-Quantum-Computing-RGB-V02.pdf#zoom=50
   which mentions, as the first possible application in Table 1
   "portfolio selection", which I guess means stock picking. Oh boy.

10. **Mateus Araújo**
    August 31, 2018

    CWJ,

    Simulating complex quantum systems is precisely what quantum computers will be good for. Shor's algorithm gets a lot of attention, for obvious reasons, but there is no fundamental reason why quantum computers should be good at factoring, or why classical computers should be bad at it.

    On the other hand, the idea that any physical system at all can be efficiently simulated by a digital quantum computer is taken seriously by a lot of the community (it is known as the Church-Turing-Deutsch thesis), and I personally would be shocked if a xenon nucleus turned out to be intractable.

11. **CWJ**
    August 31, 2018

    Mateus,
    I agree that quantum computers *ought* to be good for modeling complex quantum systems. But in practice it may be very different.

    Fortunately, a paper on the arXiv just appeared, explaining how to do this for quantum many body systems (atoms, but presumably I can translate it to nuclei). Now I just need to find the time to read it….

    https://arxiv.org/abs/1808.10402

Quick Links

   I've felt for quite a while that the term "predatory journal" is misleading. My suspicion was always that plenty of scientists who published in such journals were doing so with their eyes wide open. Their motivation was obvious; it rhymes with "shmenure committee". But it's very easy for us scientists to cast ourselves in the best possible light, and the terminology reflects that presumption of doe-eyed innocence we grant ourselves.

3. **Cormac McG**
   September 1, 2018

   Hi Peter
   The Hamilton link – excellent! – has compelled me to suggest some other Hamilton related items. I feel no shame in plugging my physicist colleague Iggy McGoverns sonnet sequence on the life of William Rowan Hamilton entitled "A Mystic Dream of Four" – 64 sonnets organised by themes inspired by his life, his physics and maths, as well as his correspondents. I should have suggested you could go to see him when he was reading in New York last November. (His most recent book is "The Eyes of Isaac Newton")

   Also, before the summer a new art installation celebrating Hamilton's theoretical prediction of conical refraction was unveiled in the Physics department in Trinity College Dublin. Commissioned by James Lunney the sculpture details the "diabolical point". See https://www.tcd.ie/news_events/articles/new-art-installation-the-radiant-stranger-is-launched-in-school-of-physics/ In the photo Iggy McGovern is pictured (fourth from left) at the launch as he was reading one of his poems on Hamilton, while Sir Michael Berry (at left) was also speaking. James Lunney (third from left) is familiar with conical refraction as new investigations which he began with high coherence laser light revealed various interesting chiral, polarisation and phase behaviour. Certainly not all of these effects were anticipated by Hamilton, but the singular nature of conical refraction had captured the interest of Michael Berry with a number of later co-publications on the newer experimental observations with James Lunney. But I will not attempt to summarise this subject here.

   Finally, still on the Hamilton theme there is an interesting probably apocryphal anecdote involving a Mercury/Apollo era astronaut visiting Trinity College Dublin in 70s/80s being disinterested throughout their visit until at the last is shown by the arts-educated Provost a bust of Hamilton in the Long Room library, said astronaut suddenly waxes in interest and (perhaps) also uses some choice words about quaternions! This arising as all the astronauts were trained to reflexively compute quaternions as this was embedded in their training. Appears to still be a part of astronaut training?

   Hope that however off topic this was it was somewhat interesting!

   Enjoy Labor Day weekend
   Regards
   Cormac M

Beyond Weird

September 5, 2018
Categories: Book Reviews

Philip Ball's Beyond Weird is the best popular survey I've seen of the contemporary state of discussions about the "interpretation" of quantum mechanics. It appeared earlier this year in a British edition (which I just read a copy of), with the US edition scheduled to come out next month. Since it's already out in Britain, there are several reviews you can take a look at, an insightful one is Natalie Wolchover's at Nature.

The topic of the "weirdness" of quantum mechanics is one receiving a lot of attention these days, with two other books also appearing this year: Adam Becker's *What is Real?* (which I wrote about here), and Anil Ananthaswamy's Through Two Doors at Once. Lack of time as well as not having much of interest to say about the book has kept me from writing about *Through Two Doors at Once*. It's much more focused than the other two, giving close attention to the two-slit experiment and surprising variants of it that have actually been performed in recent years.

Some of what I very much liked about *Beyond Weird* is the way Ball avoids getting into the usual ruts that books on this topic often end up in (with the Becker book one example). He avoids the temptation to follow a historical treatment, something that is almost irresistible given the great story of the history of quantum mechanics. The problem is that the early history of quantum mechanics and the struggles of Bohr, Einstein and Heisenberg to understand what it was saying is a fascinating story, perhaps the most compelling in the history of physics, but it is one that has been well-told many times in many places. Books that cover the later history have found it hard to resist the temptation of revisionism, caricaturing Bohr, Heisenberg and the dominant "Copenhagen interpretation" while making heroes instead of David Bohm, John Bell and Hugh Everett.

Ball has little to say about the personalities involved, but instead seriously engages with the central troublesome issues of the quantum mechanical picture of the world. The Copenhagen interpretation is given a fair treatment, as a warning about the limits one runs up against trying to reconcile the quantum mechanical and classical pictures of reality.

Instead of spending a lot of time in the rut of Bohmian mechanics, Ball dismisses it quickly as

> But it is hard to see where the gain lies… Even Einstein, who was certainly keen to win back objective reality from quantum theory's apparent denial of it, found Bohm's idea 'too cheap."

Dynamical collapse models like GRW also get short shrift:

> It's a bodge, really: the researchers just figured out what kind of mathematical function was needed to do this job, and grafted it on… What's more of a problem is that there is absolutely no evidence that such an effect exists.

As for the "Many-Worlds Interpretation", which in recent years has been promoted in many popular books, Ball devotes a full chapter to it, not because he thinks it solves any problem, but because he thinks it's a misleading and empty idea:

> My own view is that the problems with the MWI are overwhelming – not because they show it must be wrong, but because they render it incoherent. It simply cannot be articulated meaningfully… The MWI is an exuberant attempt to rescue the 'yes/no', albeit at the cost of admitting both of them at once. This results in an inchoate view of macroscopic reality suggests we really can't make our macroscopic instincts the arbiter of the situation…
> Where Copenhagen seems to keep insisting 'no,no and no', the MWI says 'yes, yes and yes'. And in the end, if you say everything is true, you have said nothing.

There's a lot of material about serious efforts to go beyond Copenhagen, by understanding the role that decoherence and the environment play in the emergence of classical phenomena out of the underlying quantum world. This discussion includes a good explanation of the work of Zurek and collaborators on this topic, including the concept of "Quantum Darwinism".

The last part of the book is up to date on what seem to be some currently popular ideas about the foundations of quantum mechanics. One aspect of this goes under the name "Quantum Reconstruction", the attempt to derive the supposedly hodge-podge axioms of quantum theory from some more compelling fundamental ideas, hopefully the kind your grandmother can understand. These ideas are conjectured to somehow have to do with "information" and limits on it. I'm not sympathetic to these, since the axioms seem to me not "hodge-podge", but connected to the deepest unifying ideas of modern mathematics. At the same time, I remain confused about what "information" is supposed to be and how these new foundations are supposed to work. And, as far as I've ever been able to tell, these are not things your grandmother is likely to understand, unless your grandmother is Scott Aaronson…

Comments

1. **Ralph Ballart**
   September 5, 2018

   I'm pleased he discusses Griffith's Consistent Quantum theory which to me is the most satisfying interpretation. I especially like the idea that experiments actually measure what's there prior to the measurement and that wave functions don't actually collapse.
   Griffith's book is available at Amazon or free to download here http://quantum.phys.cmu.edu/CQT/

2. **Dave Miller in Sacramento**
   September 6, 2018

   Peter,

   I agree with you (and Einstein!) that Bohmian mechniacs is "too cheap." But, it should also be mentioned that making Bohmian mechanics consistent with special relativity involves kludges that are unbelievably artificial.

   The interest of Bohmian mechanics lies simply in the fact that it shows that something that von Neumann thought he had proved to be impossible is in fact possible, even if it is not plausible. In short, Bohm widened the possibilities of thought aboout QM, even if his own theory is almost certainly not true (in his later writings, Bohm basically admitted that Bohmian mechnics was more a toy model than a likely candidate for a true theory).

   Bohm's model does seem to have been one of the motivcations behind Bell's work, and Bell seems to have been one of the founts for the work based on entaglement (quantum computing, quantum encryption, etc.) of recent decades.

   On MWI, I think we also should mention that the technical names for the two big problems are "the preferred-basis problem" and the "probability-measure problem": in ordinary English, why does the multi-world universe split into classical separate worlds in just the way it does, and how do you get probabilities out of the theory when in fact the probability that anything (i.e., everything!) happens is always 1.000. The MWI proponents have been wrestling over these problems for decades and never have come to a resolution that satisfies everyone: personally, I doubt they ever will.

There are certainly various hints that QM somehow has something to do with "information," but I have never seen anyone spell out the details.

From all of which I conclude that still no one truly understands quantum mechanics.

Dave

3. **Scott Aaronson**
September 6, 2018

The "derivations" of QM from information-theoretic principles, for example those of Hardy and Chiribella et al., are beautiful and surprising and interesting. They underscore just how little mathematical freedom you have in trying to generalize probability theory the way that QM does. But their wider meaning remains unclear.

Even if I *were* your grandmother, I can attest that I wouldn't find it particularly obvious a-priori that the "pure states" of a theory (meaning, those not nontrivially expressible as probabilistic mixtures of other states) should all be continuously transformable into each other, or that it should be possible to purify any mixed state in an essentially unique way by passing to a larger system. Indeed, these don't strike me as statements that anyone would've even thought to formulate, had they not had the example of QM! I would've treated it as even less obvious that any compound mixed state must be recoverable from the statistics of local measurements on its components. The latter axiom needs to be invoked, in almost all informational derivations, to rule out the restriction of QM to real amplitudes only, and to explain why amplitudes are complex numbers.

If a 19th-century mathematician had wanted to invent QM from first principles, with zero guidance from experiment, it still seems to me that their best bet would've been to ask themselves, "what's the best way to generalize the rules of probability to involve negative and complex numbers?"

In any case, I see the informational derivations as trying to answer a question that's almost orthogonal to the measurement problem that one cares about in interpretation of QM. Instead of asking what kind of "reality" (if any) the mathematical formalism is describing, we're simply asking how one could've guessed, from general principles, that this particular mathematical formalism would be the right one. (I.e., we're asking whether QM has a 'derivation' as compelling as Einstein's 1905 derivation of the Lorentz transformations.)

4. **Urs Schreiber**
September 6, 2018

There is a kind of derivation of principles of quantum physics by following the tao of stable homotopy theory, I discuss that in arXiv:1402.7041. This exhibits quantization as closely akin to the passage to "motives", hence comes with some evidence that it is possible to arrive at this solely from thinking about first principles.

A key idea here is that, in view of the foundational role of homotopy theory, it is naive to assume that rings (as in: numbers) in fundamental physics are necessarily as taught in high-school, such as the rings of real or complex numbers; instead they may be "rings up to coherent homotopy", technically known as "E-infinity ring spectra". The above note considers a god-given concept of path-integral with phases not in the ring C, but in the E-infinity ring KU, and proves that this reproduces geometric quantization at least of compact Poisson manifolds.

5. **zzz**
September 6, 2018

One of your Becker book review updates had a quantum superposition effect on the text.

"collapse of the state vBeyond Weirdector with probabilities given by the Born rule"

6. **tulpoeid**
September 6, 2018

From the description in the first link:

"We now realise that quantum mechanics is less a theory about particles and waves, uncertainty and fuzziness, than a theory about information: about what can be known and how. "

What is that supposed to mean? I'm asking in earnest. Have duality and uncertainty been abandoned recently? I don't know if it refers only to the "last part of the book" but it sounds more generic.

7. **ilovecats**
September 7, 2018

> I'm not sympathetic to these, since the axioms seem to me not "hodge-podge", but connected to the deepest unifying ideas of modern mathematics.

.

Where might one read more about this connection? (I'm a math student, so not too good with the physics)

8. **LMR**
September 7, 2018

Just a quick elaboration of the comment by Urs: the passage to "motives" mentioned there seems to be related to the fact that the category of spans (or correspondences) is a dagger-compact category. It turns out that quantum computation (or the finite parts of quantum mechanics anyway) can be formulated in terms of dagger-compact categories (à la Abramsky-Coecke).

Relevant nLab pages:

https://ncatlab.org/nlab/show/span

https://ncatlab.org/nlab/show/dagger-compact+category

tulpoeid wrote:

"Have duality and uncertainty been abandoned recently? I don't know if it refers only to the 'last part of the book' but it sounds more generic."

Uncertainty hasn't been abandoned, but the book argues that the idea of particle-wave duality may not be as helpful as thinking about quantum mechanics as a theory of information.

9. **Paul Hayes**
September 7, 2018

I think a 19th century mathematician's best bet would've been to "view the algebra of random variables and their expectation values as the foundational concept" in a generalisation of probability theory – as Segal eventually did – so that it could accommodate their invention of QM.

10. **Peter Woit**
September 7, 2018

Scott,

Thanks for the comments! I don't see any particular reason you should be able to "guess" QM from some general principles about how the world is supposed to work, but maybe it is useful to categorize the constraints imposed by various assumptions.

Urs,
To explain that to your grandmother, she would have to be Grothendieck…

zzz,
Thanks, fixed.

ilovecats,
See my book
http://www.math.columbia.edu/~woit/QM/qmbook.pdf

All,
Please resist the temptation to use this comment section to discuss your favorite ideas about QM, and stick to comments of relevance to the Ball book.

I'm resisting temptation to go on about such ideas, but at least I can put them in another posting, which I may do soon…

11. **Peter Morgan**
September 7, 2018

Peter, I try never to forget your injunction to "remember that this is not a general physics discussion board, or a place for people to promote their favorite ideas about fundamental physics", but it's all too easy to forget during the chase that what seems to me like a reasonable response to Scott's comment that 'If a 19th-century mathematician had wanted to invent QM from first principles, with zero guidance from experiment, it still seems to me that their best bet would've been to ask themselves, "what's the best way to generalize the rules of probability to involve negative and complex numbers?"' might not seem so reasonable to you.

I'll repeat the first paragraph of my bad comment: "I went to the trouble of obtaining the English edition because Philip Ball is visiting Yale's YQI this Fall. I also enjoyed it and very much recommend it. That is, I found its sensibilities much more like my own than I've found of most recent popular books."

12. **alex**
September 7, 2018

A small remark related to the last paragraph about the so-called 'quantum reconstruction'. It's not about my favorite approach, but just a historical observation. When I read about these extensions of probability, the first thing I thought was that this was already been done 50 years ago, and pretty convincingly so. In the so-called 'quantum logic' approach, von Neumann, already in the 30s, introduced the non-Boolean space of projectors in a Hilbert space as the 'event space' for quantum probability, which replaces the standard Boolean one of classical probability (realized as the borel algebra of subsets of phase space). Then in the 50s Mackey conjectured that the only possible quantum probability measures on such lattice were the ones given by the standard Born rule via the usual trace and density matrix formula. This conjecture was then proved to be true by Gleason, in a landmark theorem. Mackey also conjectured, on some of von Neumann's old ideas, that the necessity of the lattice of projectors in quantum physics could perhaps be derived as a consequence of imposing some restrictions on an abstract lattice, in particular, orthomodularity. In the 60s, Piron proved that this implied that this abstract lattice is necessarily isomorphic to the lattice of closed subspaces on some generalized Hilbert space. Then, finally, in the 90s, Sóler proved that this generalized Hilbert space can only be real, complex, or quaternionic. Recently, Moretti proved that Poincaré symmetry makes the real case to collapse to the complex one. Thus, in a very venerable line of research which goes back to von Neumann himself, the standard textbook axioms of quantum mechanics have already been reconstructed from a generalization of probability (in particular, the lattice of events is allowed to be non-Boolean, that's why it's called generalized). This is the standard approach and is the one which is discussed in most of the mathematical physics literature. It also leads directly to the Topos reformulation of those axioms. Another reconstruction is the GNS construction in the C*-algebraic approach. So, having all those long established results, which are mathematically rigorous and crystal clear in their assumptions, why do we need another one based on the loose notion of 'information' is something I don't see.

13. **Urs Schreiber**
September 8, 2018

LMR,

absolutely, relation to dagger-structure is discussed in section 4.5.

14. **Michael Rivard**
September 9, 2018

Peter,

Thank you for publicizing Phillip Ball's book and linking to Natalie Wolchover's review of it. I look forward to receiving my copy from Amazon and learning why none of my pets have ended up in a superposition of dead and alive states 😉.

Is Quantum Mechanics a Probabilistic Theory?

September 7, 2018
Categories: Quantum Mechanics

There is a simple question about quantum theory that has been increasingly bothering me. I keep hoping that my reading about interpretational issues will turn up a discussion of this point, but that hasn't happened. I'm hoping someone expert in such issues can provide an answer and/or pointers to places where this question is discussed.

In the last posting I commented that I'm not sympathetic to recent attempts to "reconstruct" the foundations of quantum theory along some sort of probabilistic principles. To explain why, note that I wrote [a long book about quantum mechanics](), one that delved deeply into a range of topics at the fundamentals of the subject. Probability made no appearance at all, other than in comments at the beginning that it appeared when you had to come up with a "measurement theory" and relate elements of the quantum theory to expected measurement results. What happens when you make a "measurement" is clearly an extremely complex topic, involving large numbers of degrees of freedom, the phenomenon of decoherence and interaction with a very complicated environment, as well as the emergence of classical behavior in some particular limits of quantum mechanics. It has always seemed to me that the hard thing to understand is not quantum mechanics, but where classical mechanics comes from (in the sense of how it emerges from a "measurement").

A central question of the interpretation of quantum mechanics is that of "where exactly does probability enter the theory?". The simple question that has been bothering me is that of why one can't just take as answer the same place as in the classical theory: in one's lack of precise knowledge about the initial state. If you do a measurement by bringing in a "measuring apparatus", and taking into account the environment, you don't know exactly what your initial state is, so have to proceed probabilistically.

One event that made me think more seriously about this was watching [Weinberg's talk about QM at the SM at 50 conference](). At the end of this talk Weinberg gets into a long discussion with 't Hooft about this issue, although I think 't Hooft is starting from some unconventional point of view about something underlying QM. Weinberg ends by saying that Tom Banks has made this argument to him, but that he thinks the problem is you need to independently assume the Born rule.

One difficulty here is that you need to precisely define what a "measurement" is, before you can think about "deriving" the Born rule for results of measurements, and I seem to have difficulty finding such a precise definition. What I wonder about is whether it is possible to argue that, given that your result is going to be probabilistic, and given some list of properties a "measurement" should satisfy, can you show that the Born rule is the only possibility?

So, my question for experts is whether they can point to good discussions of this topic. If this is a well-known possibility for "interpreting" QM, what is the name of this interpretation?

Update: I noticed that in 2011 Tom Banks wrote a detailed account of his views on the interpretation of quantum mechanics, [posted at Sean Carroll's blog](), with an interesting discussion in the comment section. This makes somewhat clearer the views Weinberg was referring to. To clarify the question I'm asking, a better version might be: "is the source of probability in quantum mechanics the same as in classical mechanics: uncertainty in the initial state of the measurement apparatus + environment?". I need to read Banks more carefully, together with his discussion with others, to understand if his answer to this would be "yes", which I think is what Weinberg was saying.
