There was a short presentation on E Witten on CNN recently. And no, it's not the one that's really on Jim Simons. Seiberg, Nappi and Kaku were interviewed and asked what they think of Witten. Witten's son was also interviewed. I think it was nice.

Kaku, slide 45:

The Unfinished Theory

= String theory has a new Picture: strings and membranes.
= String theory lacks a physical principle, like the equivalence principle.
= The full symmetry and mathematics of string theory are also unknown.
= String theory has been moving backwards, since it was accidentally discovered in 1968.

I am not sure how these observations lead one to the conclusion that String theory is a good thing to work on. Could someone please explain?

Strings 2005

July 10, 2005
Categories: Strings 2XXX

Strings 2005, the latest in a series of yearly huge string theory conferences, will be taking place this week in Toronto. This series began in 1997 in Amsterdam, and in recent years has attracted 445 participants to Cambridge in 2002, 392 to Kyoto in 2003 and 477 to Paris last year. So far there are about 415 people already signed up, so it looks like this year's conference should be similar in size to ones of the last few years.

I expect that some string theory bloggers wil be reporting from the conference. In particular Jacques Distler will be there, chairing a session that should include two of the loonier talks of the conference (Kachru and Douglas on the landscape), and presumably we'll be hearing from him. Last year there were several people reading "Not Even Wrong" on their laptops using the wireless connection in the lecture hall in Paris, this year I hope anyone there who doesn't have his or her own weblog will let us know what is going on by posting comments here.

The conference will end next Saturday with a public lecture by Lenny Susskind. His talk has the same title as his forthcoming book on the landscape pseudo-science. The theme of the public lectures is listed as: "If String Theory's the Answer, What's the Question?"

Update: Slides from the conference have already started to appear, including Ooguri's survey talk on topological string theory, one of the few subjects in string theory which seems to still be alive. Ooguri makes a valiant effort to try to answer the question "If topological string theory is an answer, what is the question?" He does answer the question "If string theory is an answer, what is the question?", but the answer is disappointing: "What is string theory?"

Jacques Distler is blogging from the conference. In his coverage of this morning he ignores the topological string theory stuff and describes Eva Silverstein's talk. She seems to me to be getting into Bogdanov territory with an obscure mechanism that somehow is supposed to say something about the initial singularity of space-time. Jacques says he doesn't really understand this, and I'm in agreement with him there.

And my logs are starting to show some connections from user37-*.wireless.utoronto.ca. Hi guys! Come on, there are at least nine of you reading this from the lecture hall, so at least one of you can tell us what is going on. String theorists seem to prefer Macs, so far the wireless connections are coming from 6 different Macs and 3 different Windows machines.

Comments

   July 13, 2005

   Thank you everyone for your valuable comments. Thanks to Peter for pointing out that I need to look at QFT and the standard model further and "anonymous" for taking time to find the links of the CDT papers.

   Originally, I had an inclination to look at string theory as I was told that string theory is the only way to explain nature. When I asked what if its wrong, the string theorist I talked to explained that the contribution that it had made in mathematics is already so incredible that even if the whole thing turns out to be wrong its contribution would not go as a waste.(not a very satisfactory answer).I dont consider that I have reached the stage where I can declare to myself what is right and wrong. But I dont want to be a string theory fanatic (for that matter any theory) and hopefully be able to look at all the things with proper guidance.

   July 13, 2005

   Hi FineStructure,

   I'm also trying to tackle this material on my own (even if it takes ten years). That is impressive you were able to do Polchinksi and Zwiebach. I took one look at Polchinksi and realized there were about six other subjects I had to learn first.

   I wish you luck on your studies.
   Mike

3.
   July 13, 2005

   You write:"Jacques Distler … describes Eva Silverstein's talk.
   She seems to me to be getting into Bogdanov territory.."

   I wonder…have the Bogdanovs ever dared to give a
   talk about their 'scientific work' with experts as audience?
   At a conference?

4. **D R Lunsford**
   July 12, 2005

   "All I want to find is the truth" said a youngster. Yes, we were all like that. Sooner or later you've got to develop some ability to think for yourself.

   July 12, 2005

   dan: *will you be blogging loop 05?*
   friendly question, encouraging of you to ask!
   October is too far away to say for sure.
   Probably not, but hopefully someone will be.

6. **dan**
   July 12, 2005

thanks for the discussion “at”.

sounds very promising.
will you be blogging loop 05?

7. **Urs Schreiber**
July 12, 2005

By way of another shameless self promotion let me just mention that two news correspondents of the String Coffee Table are currently liveblogging at least some of the Streetfest.

8. **Matthew**
July 12, 2005

By way of shameless self promotion let me just mention that I intend to liveblog at least some of lattice 2005 (the Plenary sessions), starting July 24th.

9.
July 12, 2005

dan:*do you think, given its good semiclassical limit, there will be an exodus from LQG and spin foams to CDT? (i.e smolin thiemann markopoulou?)*

I will tell you what I think. You may look at the same bunch of researchers and see quite a different picture. In my view, (non-string) Quantum Gravity is a single research community and divsions within that are fairly fluid. Loll has written LQG papers, both Smolin and Markopoulou have written CDT papers. The spin foam sum over histories approach has some resemblance to the CDT path integral.

the people who do (nonperturbative background independent) Quantum Gravity are allied by having similar concerns and familiarity with each others’ methods—you might think of the different methods represented at the Loops 05 conference as a menu or as a repertory, and anyone who wants to do nonperturbative quantum gravity can choose from that menu of tactics.

Probably this year Loll’s new results will attract a lot of attention and the others will see if they can get similar results (with causal sets technique or spin foam) or if they can adapt CDT to what they do, or they will move over and try CDT approach proper.

Loll is just beginning to do black holes with CDT, and there are others who seem further along with that. Loll is also just beginning to include controlled topological variation in the path integral (so that it sums over topologies instead of just over the geometries of a fixed topology). People who use other methodology will want to know about that.

Collectively the (non-string) Quantum Gravity community is in a period of rapid growth, each year more people and more papers. I presume that will continue. I cant predict much about the demographic shifts WITHIN that community because people change back and forth and may even work several lines.

10. **dan**
July 11, 2005

hello “at”

i read the links on loll’s CDT, and i see a claim is made it has a good semiclassical limit (unlike LQG, spin foam, etc)

while i understand LQG is based on asketar’s new variables quantized version of GR, it’s not clear to me how CDT starts and how it quantizes GR, what sort of predictions it makes at high energies/planck scale etc it seems clear to me it is unrelated to LQG.

do you think, given its good semiclassical limit, there will be an exodus from LQG and spin foams to CDT? (i.e smolin thiemann markapolou?)

can you enlighten me?

11.
July 11, 2005

dan: *I am curious as to whether anyone thinks the Loop 2005 conference will show progress and/or results,..*

Personally, I think it will show progress and results and can point you to papers that have appeared since the last conference (which was May 2004) which I consider significant.

But first notice that the Loops 05 website does not define the conference as confined to LQG but rather says:
“the annual international meeting on **non-perturbative/background independent** quantum gravity takes place from 10-14 October 2005 …”

http://loops05.aei.mpg.de/
And notice the topics listed on the homepage, where it says:

“The topics of this conference will include:

Background Independent Algebraic QFT
Causal Sets
Dynamical Triangulations
Loop Quantum Gravity
Non-perturbative Path Integrals
String Theory”

As it happens, both Laurent Freidel (a paper of whose Peter mentioned here earlier this year) and Renate Loll are invited speakers and members of the organizing committee. Loll is associated with research in CDT (causal dynamical triangulations) which is a nonperturbative path-integral approach to QG.

If you want a sampling of recent progress and results bearing on the Loops 05 conference, just go to arxiv and look up the papers of Loll and of Freidel which appeared since May 2004. Then you can form your own estimate of the significance of the work.

12. **dan**
July 11, 2005

I am curious as to whether anyone thinks the Loop 2005 conference will show progress and/or results, esp in comparison to String 2005, both from what has happened before, and in comparison to one another.

13. **Peter Woit**
July 11, 2005

QFT is in some sense a very large subject, being used in condensed matter physics as well as high energy physics, as well as mathematics. So it might be too broad a topic for a conference.

But there's also an attitude among particle theorists that QFT is a completely understood subject, and that the only people who still think about it are those that are just not smart enough to do string theory, which is the real cutting edge stuff.

14. **mortain**
July 11, 2005

I can tell you what will be going on at Strings 2005 without even being there, Peter: same old, same old.

Why should it be otherwise? The expected, wonderful breakthroughs in string theory have been failing to materialize since the event began in 1997. When the time comes, perhaps comparing the content of Strings 2007 and Strings 1997 may demonstrate what actual useful 'progress' string theory has made in the preceding period.

I've wondered for some time why there never was a large annual conference on QFT (named, perhaps, 'QFT'). Is it because QFT is considered a dormant, completely understood topic in theoretical HEP? Is a large portion of the theoretical HEP community implicitly promoting this erroneous opinion?

15. **Tony Smith**
July 11, 2005

John Baez has written a useful web page entitled How to Learn Mathematics and Physics at http://math.ucr.edu/home/baez/books.html

A nice book (based on Sidney Coleman's Harvard lectures and Robert Brandenberger's official homework solution sets) is Quantum Field Theory for Mathematicians, Cambridge University Press, Cambridge, 1999, by Robin Ticciati. John Baez describes it as "… Quantum field theory – so even mathematicians can understand it …". However, be aware that an Amazon review says that the book has misprints, so be warned and take care reading it (of course, any book should be read carefully because of the possibility of misprints).

An older book that I like is Quantum Mechanics and the Particles of Nature: an Outline for Mathematicians, Cambridge University Press, Cambridge, 1986, by Anthony Sudbery, but it is hard to find (Amazon says that it is not available now). As John Baez says, it is "… Not just for mathematicians! …".

Tony Smith

16.
July 11, 2005

To anyone who shows up at Strings2005 with a laptop: yes, please post comments. Put "connectivity" to a good use.

17. **Alejandro Rivero**
July 10, 2005

what should I do before I go too far

My personal experience, I went first far into another branch, non commutative geometry, and now I have found myself looking at traditional QFT, the standard model, model building and all that. (Somewhere in the middle I read the Green-Swartz-Witten, but it did not convince me).

QFT books do not always provide a decent instint in model building, nor on HEP scattering, but they are always a better startpoint that strings or other mathematically minded setup. After managing them, you can confidently venture into more theoretical enterprises. I hope to retake NCG, but by now I have understood how different is the third generation from the two first ones, or how naive is to blindly hope a single higgs doublet. Nor to speak of surprising mass regularities, or the lack of some a priori expected energy scales (eg why the muon and the tau live at well known hadronic energy scales, the muon so near of the pion?), or the Nambu "alpha" principle to hierarchise masses… a lot of things you only learn by playing with the data, and man, I just wished to be more fluent on standard QFT when juggling these balls.

18. **Peter**
July 10, 2005

If you're an undergraduate, after you have a solid background in quantum mechanics, EM, classical mechanics, general relativity and thermodynamics, you should start trying to seriously study quantum field theory (using books like Peskin and Schroeder, Zee, Weinberg, Ramond, others), and the details of the standard model. Really understanding QFT and the standard model is more than enough for even the most ambitious of undergraduates. You should also learn some modern geometry and topology.

It's kind of absurd to be studying string theory if you don't already have a solid understanding of quantum field theory, and that's a very non-trivial project which can take a few years.

19.
July 10, 2005

Fine, I said I'd get some links, on the off chance you wanted to check out some CDT papers
here's the entire CDT output for the past 12 months, it is only 8 papers
http://arxiv.org/find/grp_physics/1/OR+OR+abs:+AND+triangulations+AND+Lorentzian+dynamical+abs:+AND+triangulations+AND+causal+dynamical+ti:+AND+gravit

and you can actually narrow it down to those co-authored by R. Loll

http://arxiv.org/find/gr-qc/1/au:+Loll_R/0/1/0/all/0/1

and of those, the most recent summary of results is
http://arxiv.org/abs/hep-th/0505154

20.

July 10, 2005

Fine asks *However well if string theory is not the answer what should I do before I go too far and become not willing to see anything else*.

no authoritative answer, but my personal response would be you should check out the picture of quantum spacetime coming out of CDT (causal dynamical triangulations, one of the quantum gravity alternatives to string)

there are only a small number of papers to read, most of which appeared in the past year and a half.

I will get some links. It is a path integral "sum over spacetime geometries" approach where they have both analytical and computer spacetime simulation results.
There is evidence that their spacetime agrees with classical GR in the large, and with prevalent semiclassical "quantum cosmology" near the cosmological singularity. And also that their spacetime is highly unclassical at small scale. (may be fractal-like or topologically complicated at very small scales — probably not describable as a differentiable manifold)

So at least it is different. and immediately accessible.

the "question", I suggest, is how should quantum spacetime be represented mathematically? because only once there is a satisfactory spacetime foundation can particles/fields be reconstructed on that basis.

21. **FineStructure137**
July 10, 2005

If String Theory's the Answer, What's the Question? I am an undergraduate and I have already put in lot of energy and time trying to understand string theory from Polchinki book and Zwiebach book to a lesser extent. Also, I check most conferences in String Theory. Recently,I have been following Peter's blog (for a month now)I have been skeptic of string theory for a while. All I want is to find the truth. I guess ultimately I have to find the answer to this question for myself. However well if string theory is not the answer what should I do before I go too far and become not willing to see anything else.

22. **Alejandro Rivero**
July 10, 2005

About the Landscape, I was thinking… if instead the anthropic principle, we use the humbler "Standard Model at Low Energy Limit" principle, how large is the remaining landscape? Still infinite dimensional? Finite? Null?

23. **Chris Oakley**
July 10, 2005

If String Theory's the Answer, What's the Question?

Suggestion:

"How does a bright, sceptical young scientist turn into a raving, pseudo-religious moron?"

Bad Craziness

July 13, 2005
Categories: Uncategorized

I'd been wondering why Lubos Motl seemed rather subdued in recent months, now one of his recent postings makes some reasons for this clear. Evidently since April he's been the victim of someone who has been sending him grotesque anonymous death threats. Luckily the person responsible for this has now been identified by the police. In the comment section of the next entry in his blog, Eva Silverstein tells of also being the victim of similar threats, and again the police had to be called in.

Lubos's participation in the controversy over the president of Harvard's remarks about women in the sciences seems to have earned him both warnings from senior colleagues (I guess this is what his "leashing" was about), as well as harassment by some other anonymous figure. There's no excuse for people trying to hide behind anonymity to engage in personal attacks. While Lubos is not known to completely refrain from personal attacks himself, at least he has always put his name to them.

In his latest posting he discusses in detail Silverstein and McGreevy's claims that one can understand something about the initial singularity of the big bang in terms of tachyon condensation in string theory. Like Jacques Distler, he says that he doesn't understand these claims, which to me seem to be a lot more coherent, but not of a significantly different nature than those of the Bogdanovs.

Comments

1. **Alejandro Rivero**
   July 14, 2005

   I still hope Witten will come around, start thinking about something else, and lead the field in a more promising direction.

   The talks in the last year have been more of a general review of HEP than specific stringy work, so perhaps he is already starting thinking about something else.

   I can not see yet the slides of his talk.

2. **Peter Woit**
   July 13, 2005

   I don't think I'm bullying Lubos, and actually have never personally attacked him in the ways he has attacked me. I even agree with him about a lot of things, for instance I think we see eye-to-eye about the landscape. At least when he's talking about string theory he knows what he is talking about, which is not true of lots of other people.

   I do have the deepest admiration for Witten. He's extremely talented, works very hard, is a nice guy, has helped me in the past, and has accomplished truly amazing things. Some of the high points of my intellectual life have been reading his papers or listening to his talks. I happen to think that his deep belief in string theory is a mistake, just as Einstein was mistaken in his ideas about unification. Unlike Einstein, I still hope Witten will come around, start thinking about something else, and lead the field in a more promising direction.

3.
   July 13, 2005

   Peter, why don't you stop beating around the bush and take on Witten, instead of bullying Bad Boy Motl?

   He's the ring leader of the string circus yet Peter Voit has nothing but the deepest admiration for him.

Panel Discussion in Toronto

July 13, 2005

Comments

1.
   July 17, 2005

   Steve mentioned this link to Sakurai's blog
   http://makotosakurai.blogspot.com/2005/07/2nd-day-of-strings-2005.html

   and then you added it, in an update, to the main post.

   But we never followed up, it seems. Sakurai actually does give some sense of things:

   —quote from Sakurai blog—
   OK. Again from the panel discussion. "Why is string theory worth trying even today?" (It was phrased in a different way.) Some said "it is mathematically beautiful but phenomenologically poor" and some said "it is the only known consistent theory of gravity" (how do you prove its consistency?). My viewpoint is not equal to them. What do you think?
   —endquote—

   If anyone has any ideas it might be nice to post them at his blog. So far he has only one very brief reply. It is interesting that he appears to paraphrase the real question being asked by everybody (not what will be the next revolution but)
   "Why is string theory worth trying even today?"

   If Sakurai's paraphrase reflects the sense of the discussion and the responses he heard people give were generally as weak as he suggests then it is not surprising that Florian Gmeiner wrote to Distler's blog complaining of depression.

2. **Peter**
   July 15, 2005

   Sen's slides do seem to have disappeared. There were about half a dozen of them, and they didn't say very much, actually.

3. **Peter**
   July 15, 2005

   Hi Anonymous Graduate Student,

   I didn't mean to imply that all graduate students are impressionable, I'm well aware that some aren't. Only for the impressionable ones would Jacques's hyping of the prospects for string theory be educational malpractice.

   Actually I'm more and more noticing the last few years that a larger and larger fraction of graduate students are well aware that there's a problem in the field, no matter what people like Jacques are telling them. I hope that by reading what I have to say, what Jacques has to say, what Lubos has to say, etc., that students will have enough information to make up their own minds about what is going on.

4.
   July 15, 2005

   Must say that a virtual blackout of reporting on the panel discussion leaves the field open for people to invent their own scenarios, like for example

   MODERATOR'S OPENING REMARKS

   Steven Shenker (moderator of "The Next Superstring Revolution"):

   "Ladies and gentlemen, I think everyone realizes that if we don't want to start looking silly, we have to decide what we're going to say about all these vacua…"

5.
   July 15, 2005

   Peter you say
   Update:It looks like Ashoke Sen's slides from the panel discussion are on-line.

   but I couldnt find anything from the panel discussion there, what i found related to a talk on extremal BH scheduled for later in the week.

   was there something from the panel discussion posted there earlier?

6. **Anonymous**
   July 15, 2005

   "Saying things like this to impressionable graduate students is really educational malpractice."

   Why the assumption that graduate students are impressionable? I'm pretty damn opinionated and also well-informed, if I do say so myself, as are many other grad students I know.

   — An anonymous grad student

7. **Peter Woit**
   July 14, 2005

   Hi Quantum,

Quite a while ago I wrote a short piece about this:

http://www.arxiv.org/abs/physics/0102051

Physics Today refused to publish it, ultimately American Scientist did.

Don't believe everything you read about the beauty of string theory….

8. **quantum**
July 14, 2005

Is there any basic book or article or post that would list the reasons why you anti-string theory partisans are so sure of yourself? I want to learn. I thought that string theory is so beautiful it must be right! I'm a layman tho.

I've pimped your site over at my blog quantuum.blogspot.com

9.
July 13, 2005

dan:
some thoughts
1- paradigm shift from LQG to LOLL's CDT
2- implementation of LOLL's CDT into LQG
3- CDT reproduces many results expected of a QG such as black hole entropy

Dan I am a great fan of Loll and the CDT approach she and co-workers have developed and my comments may be responsible for what you said here, so I must apologize for somehow giving the wrong impression.

Loll is just beginning to work on Black Hole. She does not have black hole entropy formula. Look at her recent paper with Dittrich. Other QG people (e.g. LQG) are farther along on that.
Loll approach is comparatively new and has catching up to do.

it is too extreme, or maybe premature, to speak of a "paradigm shift". I think some notion of quantum spacetime is gradually emerging as people work on these various methods like LQG and CDT. It all contributes to the same understanding. I am frankly delighted with Loll CDT recent papers and results but it is too early to say that one approach to nonperturbative QG will "win the race" and beat the others.

I probably suggested the idea of "implementation of CDT into LQG" and it is my fault for having such an awkward notion. I do believe that there will be some kind of assimilation of methods. But I cannot picture how that will work out! I think some of the other people are going to have to match CDT results or else (as you mentioned earlier) start using Loll's methods. I am confused as to how this will actually happen and I am afraid that I may have communicated my confusion.

It is pretty clearly too early to try to look ahead to this October.
My bad, for doing this. I cant resist saying however that I think it is an exciting time in QG largely because of the past year's results in CDT and the organizers of the October conference have shown this by how they organized it. Last year it was a "Loop and Spin Foams" conference and Renate Loll just happened to be there and gave one paper. this year the outlines seem to have changed significantly. I will try to post something about this when the full Programme is posted (they say something this month but it could be longer)

10. **dan**
July 13, 2005

"No I don't think that something new and exciting will happen at one of these conferences."
Hello Peter,
I am curious as to whether you think (or expect) the same for Loop 2005.

some thoughts
1- paradigm shift from LQG to LOLL's CDT
2- implementation of LOLL's CDT into LQG
3- CDT reproduces many results expected of a QG such as black hole entropy

11. **Peter Woit**
July 13, 2005

Hi Gadfly,

Thanks for that link. The discussion over there was triggered by the cover story of the latest Discover magazine. I just went out and got a copy and will post some comments later.

12. **Peter Woit**
July 13, 2005

To whoever is anonymously posting uninformed attacks on my motivations:

I'll delete any more nonsense of this kind that you submit, but for your information let me just explain that, for various reasons including a clever choice of parents, I'm in excellent financial shape. I don't need either government money or anyone else's mil, and could live comfortably without working at this or any other job if I felt like it.

This financial freedom means that I can afford to piss off people if necessary, and I feel it gives me some responsibility to say things that other people think but are too afraid to say because of fear of repercussions. Witten's role in this whole story is a central one, and I say exactly what I think about it.

13.
July 13, 2005

Quantoken,

Actually there is a simple explanation why Peter is obsessed with the string landscape loons on the fringes instead of hammering away at their leader, Witten, which is that he shares a common goal with those same loons.

Its all in anticipation of the end of public financing for certain science activities that will be deemed nice intellectual pursuits but of dubious practical relevance.

There has been such a massive wealth redistribution and a shrinking middle class will no longer be able to provide the funds.

So its all about getting the attention of the rich aging kooks largely ignorant of science looking for some deep meaning in life before they croak.

Thats why Peter runs a Mockracy to generate as many page hits as possible. Just like the string landscape fruitcakes, its all about finding a Templeton with a mill burning a hole in his pocket.

14. **gadfly**
July 13, 2005

Apparently some economists are concerned about the state of string theory. they fear that is getting worse than their "dimal science"

http://economistsview.typepad.com/economistsview/2005/07/string_theory_h.html

15. **Quantoken**
July 13, 2005

Peter:

The point is any one who is more likely to stand up in those panel discussion and criticize things will most likely NOT attend such conferences. At least not some one who has some minimum self-respect. You would stand up and criticize things, I think, but you will NOT go to such conference in the first place.

The CNN news is still relevant. Medical research is certainly a different dissipline. But the scientific dishonesty discloser is NOT limited to just medical research, but is rather widespread in virtually all other scitific research areas. If scientists in a certain theoretical research area is bold enough to go to TV and announce to audience of the whole world that their theory "explains every thing" while in fact they have not explained a single thing in nature, do you think they have been more honest than the medical researchers?

Scientists are as human as any one and given chances they can all likely be **dishonest** if it serves some personal benefits, whether they are medical researchers or researchers in other fields.

Quantoken

16. **ksh95**
July 13, 2005

Hmmm, no conference participants want to talk about the panel discussion. I don't understand this. Perhaps some one could explain to me why string theorist's opinions about string theory are deemed top secret.

17. **Peter Woit**
July 13, 2005

Hi Steve,

Thanks for pointing out that link, I'll add it to the posting.

18. **Aaron**
July 13, 2005

I'm not going to put words in Jacques's mouth. You can, for example, see his comments about the paper.

I think I'll also follow Jacques's lead, for now at least, in not talking about the panel. I'm sure you'll find out somehow, anyways.

19. **hack**
July 13, 2005

I couldn't help but think of string theorists when I read this article.

20. **Peter Woit**
July 13, 2005

Hi Quantoken,

No I don't think that something new and exciting will happen at one of these conferences. What amazes me though is how the whole subject gets crazier and crazier all the time. I admit to being fascinated by seeing supposedly smart people behave like this and can't believe that no one ever stands up at one of these panel discussions and acknowledges how bad things have gotten. I think this is a truly bizarre and amazing time in the history of science and can't wait to see what happens next. Right now it's kind of like watching lemmings, hard to believe what one is seeing.

And no, bad medical research is a different story, off this topic.

21. **Peter Woit**
July 13, 2005

Hi Aaron,

I'm not surprised by the vote. For the last year or two every string theorist that I've talked to about this has had nothing but scathing things to say about the whole landscape business, many quite unprintable. What I find weird is that despite this, the landscape has become such a popular thing for people to work on. Even people who profess to not believe in it feel compelled to work on things related to it. For instance, which alternative did your colleague Jacques raise his hand for? We know what his latest paper was about.

Still curious about the panel discussion….

22. **Quantoken**
July 13, 2005

Peter:

It’s curious to note even you clearly belong to the anti-string camp, every time there is a string sort of conference going on some where, you showed a great interest and stick your neck out long to find out and you openly beg for insider information about “what’s going on” in those conferences.

You have been inconsistent, Peter. Are you so interested in those meetings because you **worried that they may make some some surprise announcements** of some great news that they made some great discovery and explained everything in nature by SST? Do you really believe there will be something interesting at all?

To me, string theory has clearly failed to demonstrate that it has anything to do with nature at all. And that is unlikely to change any time soon. So **it is un-interesting, and it is boring**. And I would not be interested in any related string research activities, until they can announce something that seem to be relevant. So I really don’t know where Peter gets so enthusiatic in the stuff.

Might as well discuss [this CNN news](), which I think is actually interesting, and shows why sciece fraud is widespread in today’s research community.

July 13, 2005

lubos asked the same question on his blog awhile back.

among the suggestions lubos himself offered……..

LQG!

would you believe it?

Is String Theory About to Snap?

July 13, 2005
Categories: Uncategorized

The August issue of Discover magazine is out, with a cover story entitled "Is String Theory About to Snap?". The editors of the magazine describe how they recently became aware of the controversy over string theory when they organized a celebration of Einstein in Aspen last summer. They quote Lawrence Krauss as telling them "String theory may be in a worse position now regarding being testable than it has been at any time in the past 20 years." To get a response to this, they asked Michio Kaku to write something for them. They refer to him as a "cofounder of string theory", which I suspect some people might object to. Presumably they meant to repeat what is in their profile of him, which calls him a "cofounder of string field theory."

Kaku's article is entitled Testing String Theory, and is a thoroughly intellectually dishonest piece of writing, designed to mislead anyone without expertise in what is at issue here. He succeeded in misleading whoever wrote the blurb for the article which goes: "No experiment has ever allowed us to test whether any of the assumptions of string theory are true. That is about to change." No it's not. None of the experiments Kaku mentions will "allow us to test whether any of the assumptions of string theory are true".

As I've explained in detail on other occasions, the simple fact of the matter is that string theory does not make any predictions, unless one adopts a definition of the word "prediction" different than that conventional among scientists. A scientific prediction is one that tells you specifically what the results of a given experiment will be. If the results of the experiment come out differently, the theory is wrong. String theory can't do this, since it is not a well-defined theory, but rather a research program that some people hope will one day lead to a well-defined theory capable of making predictions.

At places in the article Kaku qualifies his claims of "predictions", for instance saying near the beginning of the article that certain experiments "could provide significant evidence that would support string theory" (note all the qualifiers in this phrase: "could", "significant evidence", "support") but that "the rub is that all the new evidence, no matter how compelling, will still provide only indirect proof." He soon abandons his qualified language and starts talking about the following topics:

1. Gravitational waves: He says of gravitational waves created in the Big Bang: "String theory predicts the frequencies of such waves", and that this prediction will be tested by LISA. I don't know specifically what he has in mind here, but I know of no way to use string theory to make a specific prediction of the spectrum of gravitational waves that LISA will see. The only things he mentions are inflation and epkyrotic scenarios, the first of which has nothing to do with string theory, the second very little.

2. The LHC: Kaku discusses the possibility that superpartners exist, but does note that you don't need string theory to have these. He also discusses possible Tev-scale particle physics effects of extra dimensions, without mentioning that string theory makes no predictions at all about what these extra dimensions are like, or even what their size is. There is absolutely no reason other than wishful thinking to expect extra dimensions in string theory of a size invisible until now, but visible at LHC energies.

3. Laboratory tests of the inverse-square law: Kaku claims: "according to string theory, at small scales like a millimeter, gravity might hop across higher dimensions and perhaps into other, parallel universes". This is a load of nonsense. String theory predicts no such thing. It may be consistent with this, purely because it is consistent with anything. He does go on to say "Perhaps the additional dimensions would show up only on smaller scales — string theory is still somewhat vague about this prediction." "Somewhat vague"??? As far as I know string theory makes no prediction about this at all, except that most string theorists expect effects to show up below 10^{-33}cm, not 10^{-1}cm.

4. Dark matter searches: according to Kaku "Once particles of dark matter are identified in the laboratory, their properties can be analyzed and compared with the predictions of string theory." Only problem is string theory makes no such predictions. He's talking about neutralinos, but in string theory the neutralino mass could be absolutely anything. After discussing these string theory"predictions" about dark matter, he goes on to speculate that maybe there is no dark matter anyway, just "huge clumps of shadow matter in a parallel universe, causing our galaxies to form in mirror-image locations", then admits that such an idea is incapable of ever being experimentally tested.

After going through all this, he saves the real kicker for the end: "Some theorists, myself among them, believe that the final verdict on string theory will not come from experiments at all". So he doesn't even believe in any of the nonsense he has been spouting. He admits that "The principal reason predictions of string theory are not well-defined is that the theory is not finished." So the earlier talk of "predictions" is now no longer operative. He goes on to invoke the pipe dream that someday someone will come up with a finished version of string theory that will predict precisely the standard model, neglecting to mention that there's not the slightest evidence that this is a realistic possibility. On the contrary, all the evidence now points to the conclusion that, if string theory makes sense at all, it has an infinity of different vacuum states, and is probably a radically non-predictive theory. Impressive that Kaku could write a whole article about the prospects of string theory, and somehow neglect to mention the huge and very relevant controversy surrounding the idea of the landscape. Do you think he hasn't heard about it?

   July 19, 2005

   Alejandro wrote: "Hmm, anonymous, could it be said that a fat graviton is something as a colored gluon, and then asymptotic freedom strikes? Or is it another mechanism?"

   I don't think there's *any* concrete model, really. From the Sundrum papers it seems one really wants to realize the graviton as an extended object on the scale of 20 microns, while the photon and other known particles remain pointlike. Needless to say, this is a strange picture that doesn't look like any known field or string theory.

   I have wondered about the asymptotic freedom idea you suggest, but I don't know how it could be realized.

   I think whoever first comes up with a good field theoretic or string theoretic framework in which a fat graviton seems plausible will have made major progress.

2. **Torbjorn Larsson**
   July 18, 2005

   Alejandro, thank you, I enjoyed the info.

   It seems like I have one or two years to read it all thoroughly. 🙂 It's a pity if they want to sit on their results until they themselves can verify with differing experiments. Hopefully the other groups work faster…

3. **ks**
   July 18, 2005

   @Anonymous

   Are you shure that string theory is NOT a kind of (nevertheless constrained) meta-language of physics that is able to include/express anything? What is blurred at least to an outsider of string theory like me is the relationship between expressivity as a language and it's own constraints and assumptions. As an analogy: in software development we distinguish between frameworks and applications. A framewok by itself is vacuos (it can be useless or clumsy but it never maps an application domain in a falsifiable way). It just defines how applications can be customized with few effort to run under the constraints of the framework. The applications ('theories') are performing the real stuff. In this sense 'string theory' may be a kind of doubling of theoretical physics within physics, creating a framework for particular theories to work with.

4. **Alejandro Rivero**
   July 17, 2005

   Torbjorn, the information is identical to a rumour started in Lubos blog one month ago, if you read it slowly.

   http://motls.blogspot.com/2005/06/deviations-from-newtons-law-seen.html

5. **Torbjorn Larsson**
   July 17, 2005

   I'm sorry about the confusement; I was reading too fast, I guess.

   The summary article was from April and with full references, so it didn't contain the information you were privileged to have.

   Thanks for the info, it looks interesting!

6. **Alejandro Rivero**
   July 17, 2005

   Hmm, anonymous, could it be said that a fat graviton is something as a colored gluon, and then asymptotic freedom strikes? Or is it another mechanism?

7. **Anonymous**
   July 15, 2005

   Torbjorn, your repeated posts confuse me, but I'm sure what I said was right, so let me elaborate:

   — Down to 100 microns, the tests show no deviation.
   — Below 100 microns, they do begin to see some deviation. So far this is unpublished, and might go away. If it does not, it poses a serious problem for string theory. The reason is that string theory can easily explain gravity getting *stronger* at short distances (due to more dimensions being accessible), but not getting *weaker*. It doesn't immediately invalidate the theory, but no one seems to have any model of how string theory could account for this.
   — The fat graviton, to be related to the cosmological constant, implies gravity will be modified below some scale that cannot be much larger than 20 microns. In other words, if the tests find no deviation below about 20 microns, the fat graviton is ruled out. But if the current deviation is confirmed, it's provides a compelling reason to think about the fat graviton.

8. **Torbjorn Larsson**
   July 15, 2005

   I have a bad day; Anonymous said the reverse, and it fat gravitons aren't ruled out.

9. **Torbjorn Larsson**
   July 15, 2005

   Oops, sorry; they seem also to have ruled out the fat graviton as Anonymous said.

10. **Torbjorn Larsson**
    July 15, 2005

    "I think it's worth noting that tests of the inverse-square law stand to actually *invalidate* string theory,…"

    I'm no expert but I don't think they invalidate ST; it has as usually covered all bases. According to http://physicsweb.org/articles/world/18/4/6/1 the inverse-square law is fine to small scales. What they started to rule out is some, but not all, brane-world scenarios.

11.
    July 15, 2005

    dan mentions
    http://motls.blogspot.com/2004/12/ny-times-20-years-of-strings.html

    which is Lubos blog about the Overbye NYT article. There was a Notevenwrong blog too about the same article, if I remember right.
    It was an interesting article partly because of the anecdotes, and gems of triumphant rhetoric. I dont happen to have a subscription to the NYT so I used these alternative links

    http://www.iht.com/articles/2004/12/07/news/string.html

    http://pmbryant.typepad.com/b_and_b/2004/12/string_theory_d.html

    the second has a part of the original Overbye article that the first omits, namely the exchange between Brian Greene and Steve Shenker at the conclusion, about "If it's wrong, don't you want to know?"

    dan also quotes A. Garrett Lisi from earlier this thread, the comparison with microsoft, posted at July 14, 2005 01:05 PM.
    I would like a direct link to that. Has Garrett published that comparison somewhere else? it is too apt to lose. I don't like having to hunt for it by scrolling down though the comments.

    A propos overblown rhetoric, there is Overbye's final paragraph:

    String theory's biggest triumph is still its first one, unifying Einstein's lordly gravity, which curves the cosmos, and the quantum pinball game of chance, which lives inside it.

“Whatever else it is or is not,” Harvey said in Aspen, “string theory is a theory of quantum gravity that gives sensible answers.”

should be an anthology of grandiose string pronouncements. It would make entertaining reading now, and more so in a few years, I suspect.

12. July 15, 2005

    I’ve always had the impression that string theorists roll their eyes upward at Kaku’s attempts to exaggerate his role in the development of string theory, but are loathe to diss him in public in fear of negative publicity for the field.

13. **dan**
    July 15, 2005

    Does Lubos Motl work for Microsoft?

    http://motls.blogspot.com/2004/12/ny-times-20-years-of-strings.html

    “The article also includes an appropriate portion of a text about loop quantum gravity – a few percent. The most relevant recent discovery in loop quantum gravity was done, according to the article, by Vafa, Neitzke, Gukov, and Dijkgraaf, and Cumrun explains that if loop quantum gravity is correct, it must be a part of string theory. I am sure that our loop quantum gravity colleagues will agree wholeheartedly. ;-)”

    as a response to

    “I see string theory as the microsoft of physics — all marketing, with technological “development” coming only from the principle of “embrace and extend” leveraged to succeed via its monopoly. If I use this model to speculate as to the future, I don’t think string theory will have a spectacular crash, as some might hope and as it certainly deserves. Rather, some non-string researcher, or research group, will make some real progress and the string theory mob will embrace it and claim it as their own. The resulting fun will depend on how adamantly the successful “confounders of string theory” protest that their stuff has nothing to do with strings — but my pessimistic view would be that this voice would be lost amid the torrent of stringy activity and papers tied to their work. Time will tell.”

14. **Anonymous**
    July 15, 2005

    I think it’s worth noting that tests of the inverse-square law stand to actually *invalidate* string theory, or at least force one to consider very different scenarios than the conventional ones, in the very near future. Eotwash apparently sees a weakening of gravity at around 20 microns, where Raman Sundrum predicted one would see this if a “fat graviton” explains the cosmological constant. This is exciting stuff, and I hope they are able to confirm the tentative evidence of a signal.

15. **Quantoken**
    July 15, 2005

    Kyle said:

    “In fact, I’ll go a step further. There are high school REU students out there who hold greater claim to having advanced physics than Kaku has in the past twenty years. If only they were doing work on things that sound suitably star-treky, then maybe they could join him in such grand publications as Discover.”

    Actually I will make the observation that any random walking soul on the streets would have a **perfectly legitimate claim** that he/she has advanced physics in the past year than what Kaku did in the past 20 years.

    Because even if the random soul has not worked in physics, he/she has very likely paid taxes and thus provided support by the public funding to support physics researches. So that’s a positive contribution. Whereas Mr. Kaku, if he had achieved nothing, he would have wasted 20 years worth of research funding and thus contributed negatively to science.

    But it’s even worse. By going to TVs and publish popular readings that utterly lie about and mislead the public about scientific facts and realities, Kaku not only wasted tax payer money, he also contributed negatively to the progress of real science.

    Quantoken

16. **Ben**
    July 15, 2005

    I’m no expert, but it boggles my mind that someone who has published the highly technical books that Kaku has, by major technical publishers (Springer, Oxford), could be incompetent, which seems to be the implication here. On the other hand, that seems to be the implication about all of string theory. I am not saying you are right or wrong, since as I said I don’t know. But something really weird is going on.

17. **A Scott Crawford**
    July 15, 2005

    How much did the LIGO facility down south cost? $600 million or something? And now we eagerly await a signal that’ll EITHER be a wrinkle in gravity, OR a car backfiring on a not so nearby highway! Just as Einstein predicted!

    Just to play the devil’s advocate… the LISA system is going to adjust the position of it’s three SV’s using the coronasphere model. This assumes there is ALWAYS solar weather, or varying degrees of both proton and photon density interacting in a particular volume of “euclidian” space (at one AU), &etc. (CQ Magazine has monthly solar weather charts for the curious)

    The first observation is that solar weather is, in practical terms, aether. One might almost want to look at chromatic aberrations, or (echm) other signal characteristics (like spherical aberrations or x) to see if an interferometer inside a spaceship can allow one to determine lots of stuff without looking out the windows. That’d be pretty cool, as it’d be nice to zoom up past ‘c’.

    The second observation is that the LISA SV’s beams aren’t traveling through a shielded vacuum or a stable magnetic fiield. The SV’s will tell us a lot of things about Sol. But how one distinguishes between a space jiggle due to cloud of charged dust from the sun and one due to a cosmic wave of gravity is beyond me.

    The last observation is actually a question. Is the scientific principle commonly referred to as Ockhams Razor, dead, or alive? If the former, what’s replaced it? If the latter, how well does String Theory (xyz) hold up if the Razor is applied?

18. **ks**

July 15, 2005

It is at least the mass audience who is willing to spend money into an enterprise without any practical use (former generations may have believed in new high energy wappon systems as a side-product of accelerator research). It will be sold as a part of “culture” starting with greek intellectuals speculating about the arch? and ends up with string theorists doing the same thing collaboratively with more advanced mathematical tools. Maybe Kaku has understood better than the mainstream mathematical physicist that whatever theory will be finally accepted by the community it will end up in physics-actors like him and books about timetravel, wormholes and parallel universes i.e. pop-culture that justifies the luxury of HEP research. Therefore Kaku goes well beyond John Horgans claim that scientists practice ‘ironic science’ but deny this circumstance.

19. **Andy Dabydeen**
July 15, 2005

I think Kaku is pop-scientist, that is what offends a great deal of his critics. Regardless of his position, lack thereof, and the liberties he’s taken, what he has managed to do is communicate to a mass audience — which is not such a bad thing — even if some say he’s delving into the realm of science fiction.

20. **D R Lunsford**
July 15, 2005

Kaku’s QFT book is not bad. In fact it’s very conservative, which is what you really want in a textbook. Of course there is no single tome that will do, since the theory is broken to begin with.

Peter’s comment perplexes me. As I understood it, string theory emerged from an attempt to explain nuclear forces and in particular resonances, in the sense of literally banding together nucleons and using Hooke’s law (!). So how could Kaku have been an evangelist before there was anything to get really worked up about?

-drl

21. **Kyle**
July 14, 2005

Why would that irk you? It doesn’t take much to pass up someone standing still. Spend a couple of years helping out in a good lab and you’ll have done more to increase the scope of physics’ predictive power than some others have in decades of mathematical meanderings.

In fact, I’ll go a step further. There are high school REU students out there who hold greater claim to having advanced physics than Kaku has in the past twenty years. If only they were doing work on things that sound suitably star-treky, then maybe they could join him in such grand publications as Discover.

22. **ksh95**
July 14, 2005

Hack said
I seriously doubt it! What kind of demented instructor would choose Kaku as a primary text for a QFT course? Aside from Kaku himself, of course.

Agreed. I think it’s a horrible introductory text. The quality of Kaku’s book, however, was not the point of my post.

I just get irked by goofy statements like, “…I contributed more than Kaku when I was an undergrad…”.

23. **hack**
July 14, 2005

“Respect your elders young grasshopper. One day you may be taught QFT from Kaku’s books.”

I seriously doubt it! What kind of demented instructor would choose Kaku as a primary text for a QFT course? Aside from Kaku himself, of course.

24. **Peter Woit**
July 14, 2005

Hi Garrett,

I think you’re being unfair to Microsoft, their product actually works. But I think you’re right that what will happen in the future is that anything new and successful will be dubbed a “version of string theory”. In his Discover article, Kaku refers to all sorts of different things as “versions of string theory”.

25. **garrett**
July 14, 2005

I see string theory as the microsoft of physics — all marketing, with technological “development” coming only from the principle of “embrace and extend” leveraged to succeed via its monopoly. 26. **Anonymous**
July 14, 2005

A few years back I was at a conference where Kaku was a guest of honour. I was looking forward to meeting the guy and managed to pull strings to join him for dinner. He was not the person I expected. He was one of those annoying scientistic scientists – one of those who thinks that if it’s been published in a paper it must be “absolutely and scientifically proved”, even, surprisingly, from the ‘softer’ sciences like biology. He’d quote stuff on a wide variety of topics as if he were some kind of oracle with perfect knowledge of The Truth. Anyway, the next day he gave his talk. It was more of the same with him laying down The Law as to what was and wasn’t physically possible. He stated some ‘fundamental’ limit on computing: maybe it was a limit on switch size, something like that. Anyway, there was a bit of noise coming from the back of the auditorium. It got a bit louder. A bunch of people were conferring. And eventually they said something. This group had already exceeded his so called ‘fundamental’ limit in the lab. They had intended to make no announcement about it yet but after the arrogance of Kaku’s speech they couldn’t contain themselves any longer!

28.
July 14, 2005

I found the statement "cofounder of string field theory" on his web site.

That's very clever, actually. The layman will not notice the difference between "string theory" and "string field theory", so it practically reads "cofounder of string theory". But to the expert, Kaku can always say "Hey, I said string FIELD theory", which is a relatively obscure subject that very few people know or care about its history anyway. Very clever!

29. **Mike Crowley**
July 14, 2005

Peter,

I found this entry very helpful in providing a more realistic context for Kaku's book "Parallel Worlds". The article you described is very similar to the arguments he sets out in this book.

I reviewed the chapter where he discusses testing String Theory. He devotes a lot of space to gravity waves but I'm still unclear how they confirm String Theory; however, he writes "One important goal of LISA is to provide the smoking gun for the inflationary theory… Some, such as Kip Thorne of Cal Tech, believe that LISA may be able to tell whether some version of string theory is correct. As I explain in chapter 7, the inflationary universe theory predicts that gravity waves emerging from the big bang should be quite violent, corresponding to the rapid, exponential expansion of the early universe, accompanied by much smoother gravity waves. LISA should be able to rule out various rival theories of the big bang and make a crucial test of string theory."

At the end of the chapter he writes, "My own view is that verification of string theory might come entirely from pure mathematics, rather than from experiment. Since string theory is supposed to be a theory of everything, it should be a theory of everyday energies as well as cosmic ones. Thus, if we can finally solve the theory completely, we should b able to calculate the properties of ordinary objects, not just exotic ones found in outer space. For example, if string theory can calculate the masses of the proton, neutron, and electron from first principles, this would be an accomplishment of first magnitude."

He then quotes Einstein and concludes the chapter dramatically: "If true, then perhaps M-theory will make possible the final journey for all intelligent life in the universe, the escape from our dying universe trillions upon trillions of years from now to a new home." (After learning what I've learned here, it's no longer possible to read paragraphs like that with a straight face.)

Yesterday morning on a local talk show in Phoenix I heard the anchor praise Kaku, describing him as "one of the fathers of String Theory" and also "like the rock star of theoretical physics–he has a huge following and a web page."

30. **Peter Woit**
July 14, 2005

Kaku was one of the co-developers of string field theory, see his 1974 papers with Kikkawa. Of course there was little interest in this at the time, since a year earlier Gross et. al. had discovered asymptotic freedom and the best people in the field were all doing gauge theory.

31.
July 14, 2005

It's also a fact that there is (almost) no such thing as a (serious) "string field theory", and if there is, then Witten is the founder (probably Warren Siegel should also be mentioned). I recall that Kaku wrote a paper or two on the subject in the 80's (as so many other people), but nothing like a major contribution.

32. **Joe Bolte**
July 14, 2005

I would encourage you to write something similar to what is here as a letter to the editor of Discovery. No matter who owns it, or what its standards are, I think it's important to point out to readers who may not have a sophisticated knowledge of what constitutes science that Mr Kaku is being extremely slippery here.

33. **Kyle**
July 14, 2005

I'm proud to say that by the time I graduated with a B.S., I had contributed more to physics than Kaku has before or since.

I believe this is so because though he has done much work (of what quality?) in mathematics, I have never seen any evidence of Kaku having produced anything in physics at all.

34.
July 14, 2005

Kakuphony!

35. **Alejandro Rivero**
July 14, 2005

I fail to find the updated version of "Comments On String Theory", if it is http://arxiv.org/abs/hep-th/0212247

36.
July 14, 2005

Peter,

For pete's sake, Discover Magazine is a rag owned by Disney which is far below the standards of Scientific American (which itself has been going downhill for the past two decades). Who cares what they have to say pro or con.

Some of your concerns in your post can be put to rest by Witten himself in his paper entitled “COMMENTS ON STRING THEORY” which was updated as of June 2005.

but no you keep chasing after kooks like kaku because you’re runnin a mockracy.

37. **M**
July 14, 2005

Maybe a fine-tuned version of your post would be an appropriate “letter to the editor” of Discover, or even a rebuttal to Kaku’s piece? Or do you think Discover would ignore it, preferring sensation over accuracy along the lines of “We are on the cusp of discovering great things; isn’t that really exciting?”

38. **Quantoken**
July 14, 2005

MICHIO KAKU. I wonder what kind of scientist this guy is and what kind mind he has. These days I can not turn on television without seeing the face of this big mouthed MICHIO KAKU, especially when I watch science related channels.

Does any one know what kind of research he does? A search in ARXIV turned up just 6 of his papers. And **nothing since 1999**. Has he turned himself into a TV actor or SciFi novelist or sort of thing?

Quantoken

39.
July 13, 2005

Kaku, Kaku. What can I say! Where do I begin!

The Landscape in Toronto

July 14, 2005
Categories: Uncategorized

Most of the talks at Strings 2005 about the landscape have now taken place, although there's at least one more this afternoon by Dine. Frederik Denef gave a survey talk entitled Constructions and distributions of string vacua. One amusing thing he does is note that even in toy models with these exponentially large numbers of states, counting the number of states with vacuum energy less than some bound is computationally an NP-hard problem. He describes a wide range of constructions that people have come up with to fix the moduli, concluding that you can "throw enough ingredients together to get sufficiently complicated potential, and this will fix moduli, at least at effective field theory level", but that these constructions are "ugly". He then goes on to survey various results about the statistical distributions of these states, and ends by announcing a workshop in Trieste next spring on "String Vacua and the Landscape."

The talk on Is the number of string theory vacua finite? by Michael Douglas makes Denef's survey of distributions of vacua kind of pointless. The number of such vacua is definitely infinite, which ruins ones ability to get a probability distribution by counting vacua. Douglas hopes that by putting in a cutoff on the diameter and volume of the compactification space, as well as the size of the vacuum energy, he can make the number of vacua finite. He explains this conjecture, for which the evidence is not very compelling.

Even if he gets the finiteness he hopes for after imposing these cutoffs, the problem then is that the distributions of vacua depend strongly on the cutoff and are peaked at the cutoff value. This is what happens in examples that Kachru talked about at the conference. Douglas is reduced to arguing that "it seems a priori plausible that cosmological selection could depend on the volume of the extra dimensions", i.e., that somehow the Big Bang would get rid of the problem that his program is predicting large compactification spaces when he wants small ones. There seems to be no reason for this other than wishful thinking. One thing is clear though now: it makes no sense to spend time computing distributions of these vacua, since this gives a result you don't want. In this game though, it's not like you give up on your research program when it gives results that don't look at all like the real world.

Comments

   July 19, 2005

   Hi jkg,

   The Douglas program is based on the idea that we live in a randomly chosen (by not understood dynamics of the early universe) part of the multiverse, randomly chosen among those in which life is possible. If this is true we would expect to be in vacua corresponding to high probabilities, not low ones (consistent with anthropic principle). Douglas et al hope (hoped?) to use this idea to make some predictions. It is these hopes that have collapsed.

   Susskind has written a whole book about why this is a great idea, you can read it later this year. Personally I always thought this was just nuts.

2. **Torbjorn Larsson**
   July 19, 2005

   I'm not qualified to say much in this except that the difference between Peter and Bob (and me) is split by 'among which String methods can not _yet_ distinguish'.

   The 'not yet' is wide open to be realised as 'soon' to 'never'. I'm not sure how we would be certain of any of these extreme cases.

3. **jkg**
   July 19, 2005

   Hi,

   Sorry for asking naive question, but I do not quite get what could be the relevance of probability distribution of universes in multiverse (if you can calculate it, and I understand that you cannot in the landscape scenario.) Suppose in string theory I you calculate the probability of having our universe to be 99.9% and in another string theory II this probability is 10^{-10}%. So what? Should I say that the second theory is wrong and the first is right? Certainly not! Leibniz said that we live in the best of all possible worlds, which is perhaps right, but why am I to believe the we live in the most probable one (or most improbable, or whatever?)

4. **Peter**
   July 19, 2005

   Robert,

   If you think about it for a minute, you'll see there's an obvious problem with your analogy between QFT and string theory. You can use QFT to make an infinite number of precise experimental predictions, then go out and check them and they work. This is called doing science. Sure, QFTs don't predict absolutely everything, but they come with a precise understanding of what they predict and don't predict. There are lots of QFTs, but one of the simplest ones seems to work perfectly.

   The problems with string theory in general are complex, but the problem with the landscape is very simple: it's not science. The one hope for getting predictions out of it (one for which there was never any evidence, just pure wishful thinking), Douglas's statistical program, has now collapsed, although its practicioners seem to be having trouble clearly admitting this.

   The people investigating the infinite number of vacuum states that make up the landscape can't tell us how they're going to ever get any sort of prediction out of this. What physical quantity are you going to calculate, use to make a prediction such that it can be checked and if it is wrong, you'll admit that the idea is wrong? It's fine if you can't do this calculation yet, but it's not fine if you don't have a plausible program for getting there.

   What string theorists are doing now is launching into an endless investigation of an infinitely complicated structure, with no scientific justification for doing this. The only justification is the idea that string theory must be right, and this is what string theory leads to. This is no longer science, it's a cult.

5. **Bob McNees**
   July 19, 2005

   "that is, there were a whole bunch (one followed by 100 zeros) of quite different versions of nature—with all different basic features and constants—among which String methods could not distinguish!"

This is a bit of a disingenuous comment. I know, it's hard to believe that anyone around here would offer a gross oversimplification of the state of things in string theory, but it seems to have inadvertently happened.

First of all, the notion of "the landscape" has been met with more than a healthy amount of skepticism in the string community. That's not to say that it's entirely wrong, but it's certainly not the universally accepted source of communal shame that Peter makes it out to be. But let's suppose, for the sake of argument, that all of the arguments surrounding the landscape go through, or even that Douglas' speculation about the number of vacua being infinite holds up. Claiming that this dooms string theory requires that we already have a near-complete technical mastery of the subject, so that the notion of large (or infinite) families of vacua becomes an irreparable flaw in the theory.

That's just not true.

Consider the following analogy: write down every field theory you can think of. I'll even spot you four dimensions…go ahead, start writing. How many do you have? Is it a few? A few dozen? 10^100? 10^500? An infinite number? What does this have to do with the landscape, you say? Pretend for a moment that you're ignorant of every mechanism by which you might effectively reduce the number of theories you've just written down, to those which you feel qualify as "realistic". How will we ever describe nature? My lord, with so many theories, how will we ever make progress? Field theory was supposed to unify quantum mechanics and special relativity, but all it has done is land us in this embarassing morass of theories consistent with quantum mechanics and special relativity. Let's all go home…field theory is a bust.

Of course, now I'm the one who's being disingenuous. You know lots of physical principles that narrow down the number of realistic field theories. We've even singled one out as describing most of what we see. But based on your reasoning, why should you even start to narrow down the field? Such a large task, even if it was only made large because you began with an incomplete knowledge of what principles you should apply, is apparently reason to just give up.

The point is, we have no reason to believe that string theory isn't full of selection principles that deal precisely with Peter's (and many string theorists') objections to the landscape. Personally, I'm not sold on the landscape. But I am aware that, left unaddressed, the idea of lots and lots of vacua for string theory might pose a problem for predictability. Do I abandon the field? No. In somewhat novel fashion, I conclude that perhaps I should work on the problem. Quixotic, I know, but I've heard that actually working on a problem usually gets better results than complaining about the problem.

"But one should always have hope."

Yes, one should. String theory is hard. We're working on understanding it. We run into hard problems all the time, and what to make of the landscape is one of them. As discussed earlier in the post, progress on such problems is often made by working on them.

6.
July 18, 2005

Torbjorn, at the time I was talking about, they could not distinguish the right one. I cannot speculate about future String methods and what they will be able or not able to do about the Landscape. You probably remember it was described as a needle in a haystack—or Lubos Motl compared Landscapeology to a drunken man looking for the keys to his house not in the light of a street-lamp but in the middle of the ocean, on the surface. But one should always have hope.

7. **Alejandro Rivero**
July 18, 2005

And, every time I look in there, full of inaccurate information.

Hey, our thread on numerology tries to keep a high standard of 99.9% numerical accuracy and above! Perhaps you mean *nonsensical* or *misleading*. But we are accurate.

8. **Torbjorn Larsson**
July 18, 2005

Thanks for the physicsforums tip.

Since we laymen already lay about, perhaps you can clarify why "…among which String methods could not distinguish" is necessarily true.

The KKLT model is but a very special case of a huge class of more general compactifications. It is made, as I understand it, primarily to have 4 large dimensions and a small positive cosmological constant. (It also entails other good benefits.)

Why do we discount other compactifications and methods to constrain vacua just because this particular case failed?

9. **Aaron Bergman**
July 18, 2005

10.
July 18, 2005

pseudo

did you already try physicsforums.com with your question?
it is more oriented toward layfolk (general reader-type) questions.

the gist of the "Landscape" business is that around January 2003 there was a massive setback in the String research program. Some people at Stanford (Kachru, Kallosh, Linde, Trivedi) came out with a paper showing that String doesnt predict just one version of physics—this is what had been hoped for: a theory that would explain why a lot of the basic constants in physics are what they are.

In fact the KKLT paper showed that String doesnt even narrow it down to just 2 or a dozen or a thousand different versions. KKLT found that the number of possible String "ground states" or "vacuum states" was more like ten-to-the-hundred. that is, there were a whole bunch (one followed by 100 zeros) of quite different versions of nature—with all different basic features and constants—among which String methods could not distinguish!

This became known as the "Landscape" of string versions of physics, or (to put it in a more technical language) the Landscape of String Vacua. (Vacua or vacuums, in this case, just means the possible ground states or basic blank conditions of nature.)

Later researchers (after january 2003) determined that the number was more than ten-to-hundred, it was maybe more like ten-to-500, or maybe infinite. This year infinite seems to be emerging as a favorite estimate.

This development has been interpreted by some as ending String hopes of being a useful scientific theory (able to predict unique outcomes and explain a lot of stuff). One possible response to the existence of the Landscape is to say that String is over and it is time to look for a different theory.

Another possible reaction which some String theorists have shown is to try to "save" the program by abandoning the expectation that a physical theory should be testable by making unique predictions. This has lead to talk about "Anthropic Principle" or as some say, the "Anthropic Lack of Principles".

We heard a lot of talk about that in 2003 and 2004 but the word has fallen out of favor. The idea was that the world is just the way it is and we dont have to explain it, because if it were very different then life wouldnt have evolved and we wouldnt be here talking about it. You wouldnt have Conscious Life-forms Like Us ("anthropic" is just a technicalsounding word for "Like Us" in a very broad sense, here).

Now String theorists seem embarrassed by the word "Anthropic" and they are using the word "Environmental". they sometimes say that some basic key physical constants **don't have to be explained because they just are what they happened to be**.

This is a way of saving String by excusing it from having to predict or explain basic features of nature. It is an abdication from the traditional scientific quest. String theory is all right as long as we decide we dont expect a fundamental theory to predict unique values of the constants of nature. Like, why, on the macroscopic level that we can see, does spacetime have 4 dimensions? Well one answer is let's not try to explain that, it just is. It is **environmental** which here is a code-word for "how it happened to turn out".

Maybe the number 4 dimensions is a bad example and i should be taling about something more technical like the cosmological constant or the fine structure constant, but maybe you get what I'm trying to say without that.

11. **pseudo string fan**
July 18, 2005

Hi guys,

I often meet the following terms in string theory's discussion:landscape and anthropic principle

I think landscape in string theory is quite different from that found in a dictionary. I also can't find the explanation of anthropic in my dictionary. Could someone tell me what they mean in string theory? Thank you in advance.

12. **Alejandro Rivero**
July 16, 2005

What is depressing, is the following slide
http://www.fields.utoronto.ca/audio/05-06/strings/sugimoto/index.html?2;large#slideloc

The author seems to think that his audience is not going to be interested in anything related to experimental input, and he uses a full slide to justify the interest on QCD. Pitier if one thinks that string QCD is the main silver bridge for young graduates to return to reality.

13. **Alejandro Rivero**
July 16, 2005

Not rare, if you have sometime seen these panels, which are rather formal. Panelists either took the opportunity to keep selling his own product, or try to come when an enthusiastic, politically correct, speech to please the public. I think it should be funnier, and more interesting, if some place were left to think aloud, instead of reading aloud.

14.
July 15, 2005

In terms of the physics, the panelists gave their ideas for about an hour. Then there were some comments and ideas from the audience. There was some discussion of the anthropic stuff, but it didn't come close to dominating the two hours. The moderator ended with the vote and that was it.

Thanks for the report, Aaron.

Impressive lineup:

Raphael Bousso (UC Berkeley)
Shamit Kachru (SLAC & Stanford)
Ashok Sen (Harish-Chandra Research Institute)
Juan Maldacena (IAS, Princeton)

Andrew Strominger (Harvard)
Joseph Polchinski (KITP & UC Santa Barbara)
Steve Shenker (Stanford), moderator.
Eva Silverstein (SLAC & Stanford)
Nathan Seiberg (IAS, Princeton)

The organizers' announced purpose of the session was "to explore, in an informal and interactive way, possible directions that may lead to major new progress in our field."

Judging from your account not much worth telling about except a show of hands 4:1 in favor of the cosmological constant being "physical" as opposed to "environomental".

If you remember anything else that struck you as interesting, later on, hope you will share it with us. Thanks again for the reportage.

15. **Torbjorn Larsson**
July 15, 2005

So no ideas worth mentioning and a vote not worth explaining?

16. **Aaron**

July 15, 2005

In terms of the physics, the panelists gave their ideas for about an hour. Then there were some comments and ideas from the audience. There was some discussion of the anthropic stuff, but it didn't come close to dominating the two hours. The moderator ended with the vote and that was it.

17.
July 15, 2005

Aaron:*There's just not all that much to say about it, physicswise*.

In that case, if it's no big deal, then there's no reason not to report your impressions and what you got of the sense of the discussion, is there Aaron? So please report.

18. **Aaron**
July 15, 2005

I'd be careful, if I were you, about ascribing beliefs on the anthropic principle without talking to the actual people. (One of the advantages of a conference like this is that you actually get to do that. I don't feel it's appropriate for me to talk for other people, however, so I'll just leave it there.)

I also wouldn't get too excited over the panel discussion, either. It wasn't some great string theory Waterloo or anything. There's just not all that much to say about it, physicswise.

19.
July 15, 2005

It's hard to know where string theorists are on the Landscape issue collectively (if there is a common viewpoint) because of the failure of anyone to report Tuesday's panel discussion
http://www.math.columbia.edu/~woit/blog/archives/000218.html

In the comments on your blog #218, I remember Aaron did say there was a show of hands at the end of the session:

"I won't say much about what else happened, but at the end, there was a vote of hands on whether the cosmological constant was 'environmental' or 'physical'. The results: 4:1 or so against.
…
Posted by: Aaron at July 13, 2005 03:53 PM"

He doesnt say against what. presumably "environmental" = resorting to Anthropic Principle (approx.) and the showing was "4:1 or so" against appealing to the Anthropic Principle. Hope I am not misconstruing.

Don't know if Aaron actually counted or if he or someone just eyeballed it and said 4:1 because it felt right. Not sure if I am interpreting it right when I think of it as a strawvote that went against Susskind and the (Dine Douglas Denef) consulters of the entrails. Maybe it doesnt matter how the vote went and what the issue really was.

But at least it sounds like the folks Tuesday were concerned about "environmental versus physical" and worried enough that none of them want public notice of what went on in their discussion.

Letter to New York Review of Books

July 14, 2005

   July 17, 2005

   From: http://physicsmathforums.com/showthread.php?t=56

   All Tied Up & Strung Along: Hollywood String Theory Movie!!! Looking For Extras!!!
   FOR IMMEDIATE RELEASE:

   ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

   “As contemporary physics is about money, hype, mythology, and chicks,” Ed Witten explained from his offices at the Princeton Institute for Advanced Study, “The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy.”

   Brian Greene, the famous String Theorist who will be played by David “the truth is out there” Duchovney, explained the plot: “String theory’s muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Thoery faster than the speed of light, and violating the conservation of energy by mining higher dimensions for matter to publish more BS than the big bang itself could account for.”

   “At first I am reluctant to stop, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he’s doing in my soul, and he explains that the answer to that is containined in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour, he can let me in on it. But as soon as he points out that we can make more money in Hollywood than printing more coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler, adding little else, I am converted. I agree to turn my back on String Theory’s hoax and save Jessica Alba.”

   But it’s not that easy, as standing in his way is Michio “king of pop-theory” Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the “ironic” pretense his salary, benefits, and all-expense paid trips depend on. “I have better hair,” Kaku argues as he delivers a flying back-kick, ” I should be String Theory’s front man!!”

   How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, or twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail? We’ll all just have to wait!

Cosmic Variance

July 18, 2005
Categories: Uncategorized

Sean Carroll, of Preposterous Universe, has joined forces with Mark Trodden (of Orange Quark), and new bloggers SLAC particle phenomenologist JoAnne Hewett, USC string/brane theorist Clifford Johnson, and Chicago cosmologist Risa Wechsler. They'll be collaborating on a new weblog entitled Cosmic Variance, and I'm looking forward to following what they do with it.

This may be part of a new trend of consolidation in the physics weblogging industry, following the lead of the String Coffee Table and the massive, multi-national, government-subsidized Quantum Diaries site. Will small, independent, artisanal producers like myself be able to compete with huge combines like Cosmic Variance, with their professional software and expensive ($6.95/month!) web-hosting services? Or will we be driven out of business as our profit margins are squeezed to the vanishing point? Wait a minute, I'm not making a profit at this anyway…

Actually, today I'm in Austin, Texas on personal business. I suppose I should be looking up Jacques to see if he, Lubos and I can organize an even bigger competing organization.

   "Saying things like this to impressionable graduate students is really educational malpractice."

   Yes. You should totally start a blog with Jacques.

3. **Arun**
   July 18, 2005

   As long as you don't compromise your independence…

4. **Matthew**
   July 18, 2005

   I'll second the Peter/Jacques/Lubos blog idea. Reading that would take entirely too much of my time 🙂

5. **Sean**
   July 18, 2005

   Peter, you should definitely team up with Jacques and Lubos. I would certainly read that blog.

6. **Levi**
   July 18, 2005

   You are forgetting the economies of scale in their operation. $6.95/5 = $1.39. You don't stand a chance.

Hawking Paper

July 18, 2005
Categories: Uncategorized

It has been almost exactly a year since Hawking gave a talk in Dublin claiming to have found a resolution of the black hole information paradox. Tonight a preprint giving some details of his argument has appeared.

I'll leave to the quantum gravity experts the evaluation of exactly how convincing Hawking's argument is. It is based on using the Euclidean quantum gravity framework, which Hawking refers to as "the only sane way to do quantum gravity non-perturbatively". I've always been fond of the idea that you have to think about QFTs using a Euclidean signature for the background, so I wouldn't argue with him about this point, but I assume others will.

Comments

1. **Lubo? Motl**
   July 23, 2005

   My comments about the article are available on my blog.

2. **D R Lunsford**
   July 22, 2005

   I say, so what? The Clifford algebra of spacetime is *not* H(2), because in the non-relativisitic limit the Dirac theory has to reduce to the Pauli 2-spinor theory. The H(2) theory would lead to Majorana fermions, and these are not seen. Dirac spinors are *not* quaternionic.

   -drl

3. **Tony Smith**
   July 20, 2005

   Peter Woit discusses "… Euclidean signature and with Minkowski signature, especially when there are spinors …", saying
   "… Mathematically the simplest way of saying what you have to do is to formulate the theory in Euclidean space and analytically continue. …".

   Danny Ross Lunsford then commented: "… Yes, but this introduces yet another complex structure that requires interpretation. …".

   John Baez at http://math.ucr.edu/home/baez/symplectic.html made an observation that may be relevant:
   "… Fermions are quaternionic …".

   Therefore, if you want fermions/spinors in your (1+3)-dim spacetime, you want quaternionic structure.
   Since you want fermions/spinors, look at the relevant Clifford algebras, which for (1+3)-dim spacetime can have signature either -+++ or +—.
   Although their spin groups are isomorphic to each other (and to SL(2,C)), the entire Clifford algebras are distinct, one being M(4,R), the 4x4 real matrices, and the other being M(2,Q), the 2x2 quaternionic matrices.

   If you follow John Baez and go to the quaternionic M(2,Q), you see that the vector spacetime is not a real 4-dim Minkowski space as to which you must add a complex structure to get analytic continuation,
   but
   is in fact a 1-dim quaternionic space which has its own built-in machinery for analytic continuation.

   Therefore, if you follow John Baez's observation to its logical conclusion, you get the benefits of Peter Woit's analytic continuation without the introduction of Danny Ross Lunsford's extraneous ad-hoc complex structure.

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

4. **D R Lunsford**
   July 20, 2005

   Peter,

   Yes, but this introduces yet another complex structure that requires interpretation. The existing complex structures (e.g. electromagnetic duality, Dirac algebra and spinors, 2-spinors..) have tight geometric interpretations, much as the "circular points at infinity", the solution to R^2=0, characterize Euclidean space. In fact if there is going to be any interpretation of this analytic continuation it will amount to mutating the light cone, which characterizes propagation, with the circular points at infinity, which charactize distance.

   -drl

5. **Peter Woit**
   July 19, 2005

   I'm certainly not sure what is the exact relation between QFTs in curved spaces with Euclidean signature and with Minkowski signature, especially when there are spinors, but something interesting is going on. Even in flat space, free field QFT, if you try and directly formulate it in Minkowski space you run into trouble (the propagator is given by an integration contour that goes through poles) and you have to do something. Mathematically the simplest way of saying what you have to do is to formulate the theory in Euclidean space and analytically continue.

6. **D R Lunsford**
   July 19, 2005

   Peter – it doesn't bother you pretending that the signature of spacetime is definite?

   -drl

7.

July 19, 2005

I think that Hawking, as well as Penrose, are upset that Hollywood has overlooked them in their latest venture.

Has anything Hawking predicted been experimentally verified?

Has anything Penrose predicted been experimentally verified?

Tied Up & Strung Out: Hollywood String Theory Movie!!! Looking For Extras!!!
FOR IMMEDIATE RELEASE:

ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

“As contemporary physics is about money, hype, mythology, and chicks,” Ed Witten explained from his offices at the Princeton Institute for Advanced Study, “The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy.”

Brian Greene, the famous String Theorist who will be played by David “the truth is out there” Duchovney, explained the plot: “String theory’s muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone.”

Greene continues: “At first my character is reluctant to stop theorizing, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he’s doing in my soul, and he explains that the answer is containined in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. But as soon as he points out that we can make more money in Hollywood than printing more coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler, I am converted. I agree to turn my back on String Theory’s hoax and save Jessica Alba.”

But it’s not that easy, as standing in Greene’s way is Michio “king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this” Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the “ironic” pretense his salary, benefits, and all-expense paid trips depend on. “I have better hair!” Kaku argues as he delivers a flying back-kick, “There can be ony ONE! I WILL be String Theory’s front man!!”

But Greene fights back, “Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket) It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!! And what the #&#%&$ does M stand for in M theory???”

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We’ll all just have to wait!

But in the meantime, how do you think it will play out?

MDT’s postulate: THE FOURTH DIMENSION IS EXPANDING AT A RATE OF C RELATIVE TO THE THREE SPATIAL DIMENSIONS IN QUANTIZED UNITS OF THE PLANCK LENGTH, GIVING RISE TO TIME AND ALL QUANTUM MECHANICAL AND RELATIVISTIC PHENOMENA.

Two Cheers for String Theory

July 21, 2005
Categories: Uncategorized

Over at the new Cosmic Variance blog, Sean Carroll has posted a defense of string theory against what he sees as disdain, resentment and disparaging remarks from other physicists, a defense he entitles Two Cheers for String Theory. I've written a couple of comments over there, and maybe this will lead to an interesting discussion. But I'll be traveling a lot of the time during the next week and a half, so my ability to participate in such a discussion, here or over there, may sometimes be limited. We'll see what happens….

Comments

   July 29, 2005

   Wolfgang,

   I am not talking about conventional anomalies proportional to the third Casimir, which indeed are inconsistent – the anomalous algebra does not possess any unitary lowest-weight reps. If you introduce the observer's trajectory and quantize it together with the fields, there are also new anomalies proportional to the second Casimir. This is necessary to do canonical quantization in a manifestly covariant way, see hep-th/0501043.

   It should be possible to describe these new anomalies also in the conventional, non-covariant Hamiltonian formalism, although I have not thought so much about it. The YM gauge algebra can be cast in the form

   [J^a(m_0,m_i),J^b(n_0,n_i)]
   = f^abc J^c(m_0+n_0,m_i+n_i)
   + k \delta^ab m_0 \delta(m_0+n_0)\delta(m_i+n_i),

   where four-momentum m = (m_0,m_i) has been split into temporal and spatial components. The extension can be expressed covariantly, but this form is suitable to make my point. Note that this is a 4D generalization of the affine algebra, and it is easy to show that it is indeed a Lie algebra.

   The spatial subalgebra, generated by J^a(0,m_i), is anomaly free. This means that you can construct the Hilbert space as usual, and mod out spatial gauges. However, a rarely observed fact is that the temporal gauges are implemented as time-dependent canonical transformations. If the extension is non-zero, you will run into serious trouble with this.

   This does not happen for the free Maxwell field, because the adjoint rep of U(1) is trivial. But it does happen in interacting theories, where the second Casimir k != 0. I do not understand this in detail, because I have only quantized interacting theories in a formal sense, but it must be related to renormalization.

   Anyway, the second-Casimir extension is simply there, and it always arises when you build lowest-energy reps of the gauge algebra, see math-ph/9810003.

   I have been reading this review of string theory, very complete including susy, D=26, D=10 etc…
   J. Scherk An introduction to…
   http://prola.aps.org/abstract/RMP/v47/i1/p123_1?

   Now I think about, they missed the opportunity to stab the muon as a susy partner of the pion.

3. **WL**
   July 28, 2005

   Hi Thomas,

   I did not say nor imply that anomalous local gauge theories would be consistent, rather that you'd be warmly invited to try to prove this 😉

   In fact, it is standard knowledge that it is not possible; unitarity will be lost (and renormalizabilty: the anomalous graphs scale not in the way the non-anomalous ones do, and there is no renormalization scheme where you could cancel the divergences of both types of graphs simultaneously).

   If nature is any guidance: the spectrum of the standard model is supposed to be anomaly free, and this had in the past led to the prediction that given the tau lepton there should be a bottom quark (and similarly a top quark given the tau neutrino). This prediction has been experimentally verified later, and one may view this as a spectacular triumph where theory made a prediction based on consistency, ahead of experimental data.

   Summa summarum, I don't see why one would insist on abandonding gauge invariance and giving up consistency for no good reasons.

   As for gravity, things may be more subtle and it looks indeed that background (in-)dependence may have something deep to do with anomalies. In topological strings there is a beautiful story relating certain anomalies to an apparent background dependence, and this could be a prototype for something more general; there are some recent, extremely interesting papers on that. However, the involved "holomorphic" anomalies are not crucial for the consistency of the theory, so there is no parallel to local gauge symmetry; rather, it is more the other way around, namely the holomorphic anomalies arise _because_ one insists on a consistent geometric interpretation of the theory.

4. **Thomas Larsson**
   July 27, 2005

   Wolfgang,

   I thought we agreed that gauge anomalies cannot in general be dismissed on the grounds of unitarity violation – the subcritical free string. The chiral Schwinger model in 2D is another example, at least according to Roman Jackiw. As for 4D gravity, here is what I have and have not done.

   I don't see how to use path integrals, so I prefer a version of canonical quantization which is more directly connected to representation theory. But any correct quantization method should do.

   Moreover, I don't know how to prove unitarity, because I don't know what the invariant inner product is. But I do know that every non-trivial, unitary rep of the diffeomorphism algebra must be anomalous (in 1D, c=0 implies h=0), and I know how construct anomalous reps. So at least I satisfy a necessary condition.

   The problem, both for path integrals and unitarity, is this: In order to avoid infinities, I must first expand all fields in a Taylor series around the trajectory q(t), and truncate at some finite order p. This gives me a classical, non-linear realization on finitely many fields of a single variable, which is exactly when the normal-ordering prescription works. Without this step, normal ordering gives infinities and diffeomorphisms do not act in a meaningful way.

   Thus everything is expressed in terms of Taylor data instead of field data. Classically, this is nothing, but I don't see how to make sense of a path integral over Taylor data. And although one can readily write down inner products, I haven't found an invariant one. Another problem is that truncation to order p is a regularization, which must be removed at the end. Infinities resurface in this limit, and can only be cancelled with a clever choice of field content.

   I don't claim to have quantized gravity. However, I have quantized (on a linear space rather than a Hilbert space) a regularized form of gravity, while maintaining manifest diffeomorphism covariance, constructed the relevant anomalies, and derived conditions when the regularization can be removed. I think that that is a rather significant achievement, in particular since there is no abundance of good new ideas around.

   July 26, 2005

   Thanks Quantoken,

   I contacted with Eotvos group and are waiting for reply.

   I cannot "rebate" your arguments now, since that i discover this posible weakness of Newtonian potential today.

   However, let me say that like in some well-known LED models (e.g. mm-scale string extradimensions), perhaps the reduction of dimensionality could be undetected with usual non-gravitational thecniques being real.

6. **WL**
   July 26, 2005

   Thomas,

   the issue of background independence in QG is a subtle one and I prefer not to get drawn into this. But as far as local gauge anomalies are concerned, I wouldn't see how an anomalous theory would make sense from a path integral point of view. And I would expect important basic properties like unitary getting violated – so in order to be convincing, why don't you cook up a proof that anomalous gauge theories are unitary, that would help your case !

   Juan said:
   "Basically the idea is as follow if recent sugestion of experimental verification of weakenes of Newton force to short scales is correct. This would be a final knock to String M theory."

   Not to defend the string M theory, but it should be clear that the "recent experimental verification" of weaker gravity force at shorter distance is very weak in credibility, and does not say anything either way. Further, it has **nothing to do with reduction of dimentionality, even if the reduction of force is credible and verifiable. Clearly the distance scale at which the allerged force reduction happens is well above atomic scale, and we have plenty of solid evidence that at atomic scale everything is just as 4-D as the macroscopic scale. Should dimentions start to reduce, which could be possible, it should start at a much much smaller scale.**

8. **Juan R.**
   July 26, 2005

   Recent post in cosmic variance

   Basically the idea is as follow if recent sugestion of experimental verification of weakenes of Newton force to short scales is correct. This would be a final knock to String M theory.

   Ignoring possible dependence on relative velocity, one obtains strong effective gravitational interaction to shorter distances, I take like good the rule 1/r^(2+d) for d extra dimensions (some recent RS brane model introduces Yukawa like exponential correction from extra 5th dimension), we can observe that smooth behavior is obtained formally with

   d 0 imply formally elimination of divergencies on (1/r^2) force strengh since (1/r^2) ?-> (1/r^0) at short scales without appeal to an arbitrary (by hand) add cut-off.

Are not these exciting news?

9. **Thomas Larsson**
July 26, 2005

Wolfgang,

Although people know that subcritical strings are fine, they still seem to believe that gauge anomalies are inconsistent, and that gauge symmetries are redundancies of the description. Lubos has repeated that phrase for five years. Moreover, in a discussion a long time ago, Jacques Distler implied that there is a fundamental difference between conformal gauge symmetries, relevant in string theory, and conformal global symmetries, relevant to 2D critical phenomena. Why would he do that if he realized that gauge symmetries can become global upon quantization?

So one thing I want to do is to eliminate the widespread myth that all gauge anomalies are inconsistent and must be cancelled.

This issue comes up in the context of diffeomorphism symmetry in QG. It was always obvious to me that the diffeomorphism group will acquire anomalies in 4D QG, which is pretty obvious since already 2D QG has gauge anomalies. (The anomaly can be traded between the Weyl and diff sectors, but it can not be removed.) With this is mind, I generalized the Virasoro algebra to higher dimensions (in particular 4D), and worked out its Fock representations. Fortunately, the same problem was simultaneously addressed by mathematicians Rao and Moody (of Kac-Moody fame), which helped me overcome the crucial obstacles.

In case you think that there are no pure gravitational anomalies in 4D, it is only true if you quantize the fields alone. A crucial insight is that one must also explicitly specify where observation takes place, and quantize the observer's trajectory together with the fields. This is mandatory because the relevant Virasoro-like cocycles are functionals of this trajectory.

One can view the controversy between ST and LQG in the light of this result. The key lesson of GR is background independence, and the key lesson of QM is that it is QM, in the Fock sense. However, Lee Smolin has informed me that a rigorous theorem rules out anomaly-free Fock quantization of background-independent theories, and I see no reason to doubt that assertion, partly because I have proven similar (but very non-rigorous) theorems myself. Locally, this leaves three possibilities:

1. QG is not background independent. A lot of people would dislike this possibility, because it would violate the spirit of GR, but it is a logical possibility.

2. One should not quantize in the Fock sense, but only in the weaker LQG sense. A lot of people would certainly dislike this, especially the part of the unbounded harmonic oscillator spectrum.

3. The diffeomorphism symmetry is anomalous. This neither violates the spirit of QM nor GR, it is known to happen in 2D, and much of the math is now here. However, the anti-gauge-anomaly myth prevents this idea from being taken seriously.

10. **WL**
July 26, 2005

Thomas,

that strings with c less than 26 are fine and make sense is known since a long time, there are hundreds of papers (I guessimate) on this issue called non-critical strings. This includes the well-investigated c=1 model, etc. What is what you want to convey – that professional physicists wouldn't know about this ?

As for desinformation, it is one of the unfortunate virtues the internet has brought to us, namely that laymen can just go ahead and spread nonsense, and other laymen are sadly influenced by this as they have no way to distinguish crap from serious science. This is what I meant when I was referring Q's statements, in relation to someone expressing appreciation for them.

11. **Thomas Larsson**
July 26, 2005

Wolfgang,

The most notorious desinformation spreaders are those highly educated people who claim that a gauge symmetry necessarily is a redundancy of the description, despite the fact that 2D gravity coupled to D &lt 26 scalar fields is neither inconsistent nor anomaly free. It has taken me a long time to reeducate Lubos, but now I think that he finally understands this point.

It is not surprising that quantizing 4D gravity fails if you don't know about the relevant diff anomalies.

12. **WL**
July 26, 2005

"Quantoken,

Thank you for the explanation; much appreciated. That would be a bitter disappointment if the LHC were not to get up and running.
"

Indeed. Fortunately I see many thousands of highly educated people around here working hard to make sure it will work. They know what they are doing, in contrast to those notorious desinformation spreaders who have not the faintest clue of what they talk about and who would still live in caves if all of mankind would think like them.

Mike Crowley said

Please forgive my ignorance, but I was recently watching a lecture for non-scientists on particle physics that seemed to suggest that the discovery of super-partners for the elementary particles might be a validation of string theory, and that this is something potentially achievable at labs like CERN and FERMILAB. Is this a misunderstanding?

Well, personally i suspect that supersimmetry will be not observed (as already suceeded in the past).

Supersimetry is not a prediction of String theory. It is a requirement put by hand for admending tachionic behavior (experimentally unobserved). The observation of supersimmetry will be not a verification of ST.

Moreover, ST predicts exact supersimmetry and if observed in a future experiment we will observe only high-energy supersimetry behavior, but still low-energy non supersimetric one. ST **fails** to provide a mechanism for the observed low energy behavior and, therefore, is incorrect.

14. **Michael**
July 25, 2005

Hi Peter,

“you can’t reliably calculate anything at generic values of the moduli and couplings”

That’s what I said when I wrote that it’s hard to compute things in the middle of moduli space absent a more unified definition of string/M-theory. But it’s not so terribly discomforting as you claim. Certain points in moduli space can be shown to have low-energy limits which are exoctic things like E_8 gauge theory or massless “gauge strings”. We have no idea how to right down an effective Lagrangian in such cases. On the other hand, in the string theory, many things remain computable in principle. If string theory is worth nothing because it can’t give better answers to these questions yet, then QFT is even worse off. We would have never even known that we *should* be able to make sense of things like E_8 gauge theory. Understanding this means realizing that it would be more than amazing if we had been able to understand all of the moduli space from the out start.

But we’re getting there…

15. **Mike Crowley**
July 25, 2005

Quantoken,

Thank you for the explanation; much appreciated. That would be a bitter disappointment if the LHC were not to get up and running. I remember how disappointing it was when the Superconducting SuperCollider project was canned–it would probably be operational by now.

16. **Peter**
July 25, 2005

Michael,

No, you don’t have a “good non-perturbative formulation” and you can’t reliably calculate anything at generic values of the moduli and couplings. If you look at the discussion over at cosmicvariance you’ll see the professional string theorists admitting this. You’ll also note that they and Sean agree with my intial point that you found so ignorant. As Sean points out, one way of seeing that non-perturbative string theory may have amplitudes that look like field theory ones, not stringy ones, is just to look at the 11d supergravity corner of the conjectured moduli space for M-theory.

I’m kind of charmed at the idea that I’m bullying the likes of Jacques Distler, Lubos Motl, or other serious string theorists. But you should know a lot about bullying,since you seem to think the way to deal with someone who makes serious arguments that threaten your beliefs is not to answer them but to personally insult and attack the person making the arguments.

17. **SocialRetardTeenager**
July 24, 2005

Peter,

The suspenders holding up my pants broke and I had to use a *string* to tie them back up.

18. **Quantoken**
July 24, 2005

Microly said: “….a theorist saying that the worst thing that could happen in particle physics at higher energies would be to discovery “only” the Higgs.”

That’s because the Higgs particle is the only missing piece of the standard model that has yet to be confirmed by experiments. People wants to go beyond the standard model so they need some clue by finding something that the standard model failed to predict. If Higgs and only Higgs is found, then the picture of standard model is complete but they still can not move beyond it, so that’s the worst of possible outcomes.

The problem is nobody said anything specific about how these supposed super partners look like. Certainly that’s true for Higgs particle or Higgs particles as well. If you can’t tell specific details you can’t really say you have predicted something. They know absolutely nothing about the allerged new particles they expect to discover, except for the names. So you bet they have prepared a bunch of printed labels so anything that jump out of LHC will be automatically assigned a label and be claimed as something they predicted beforehand.

I predict that the most likely outcome of LHC is it be killed before producing anything useful, either because
1.it run far over budget, or because
2. they fail to achieve the design specifics, or
3. everything work as expected but still no new discoveries except for maybe a couple of high energy resonance states of known particles.

Quantoken

19. **Mike Crowley**
July 24, 2005

One other quick question: I remember reading a quote from a theorist saying that the worst thing that could happen in particle physics at higher energies would be to discovery “only” the Higgs. Is this related to the super-partner search? This comment bewildered me, because I came away from these lectures thinking that the discovey of the Higgs would be an important triumph.

20. **Mike Crowley**
July 24, 2005

I really appreciate this discussion that has been going on across several blogs, and appreciate also entries like this that take into account that laypersons are interested in this difficult topic as well.

Please forgive my ignorance, but I was recently watching a lecture for non-scientists on particle physics that seemed to suggest that the discovery of super-partners for the elementary particles might be a validation of string theory, and that this is something potentially achievable at labs like CERN and FERMILAB. Is this a misunderstanding?

Thanks!

21. **Juan R.**
July 24, 2005

Lubos has written a reply to Sean article in his own [blog].

Curiously, he agrees with me on that the article is outdated and shows very wrong ideas about real status of string theory. As said in several occasions, research ST is not the same that layman version of ST.

My several years claim of that string theory is a theory without strings and the name is maintained by marketing purposes are supported by Lubos now.

22. **Quantoken**
July 24, 2005

Michael below:

Do you realize that your response below had NOT disputed a single point Peter raised. If any thing you enhanced Peter's arguments where ever you can. You seem to be pretty weak in logical skills and must look quite dumb if been spotted walking on the street.

I especially like this:

Peter said to Michael:
"You seem very proud of knowing what is in the first chapter of Polchinski, but **do you know anything else about physics**."

I would have removed the unnecessary word "else" above. Michael may have wasted decades training himself in being able to recite the whole book of Polchinski in reverse order without a mistake, but he surely had NOT picked up any idea what is science and what physics is all about. Physics is all about being able to explain and predict observables. Not a single thing in Polchinski book, or any other super string theory stuff has proven itself relevant to anything in nature.

You may continue to wish that there will be more super string revolutions to come. But over 2 decades of research so far yields absolutely nothing that is valuable, and can be summed up in one word "failure". In light of that, any wish that the situation could change in the near future, can only be described as wishful wishes.

I think some one must have got to be incredibly stupid to be so willing to plunge his/her intelligent lifetime into such a hopeless pursuit, like dropping a stone into water, knowing full well how fruitless this could be. While people pursuing some other un-explored ideas may probably be gambling for success, SSTers can only be described as suicidal.

People like Edward Witten must have an IQ far exceeding Einstein. But I view them as Einstein's wasted because they are pursuing the wrong path. As I said already if the nature is not co-operating and is not 10-D, then not even god can create a 10-D theory to describe a none 10-D universe, unless it's either a wrong or an useless theory.

Michael, thousands of much more qualified researchers before you have wasted a collective one thousand intelligent lifetimes without figuring out something useful. What makes you think you are any different from them, in terms of luck? Or you consider this whole enterprise as just a job to earn livelihood? Then there are much easier ways to do it.

Quantoken

23.
July 23, 2005

Some analogy:

String = WMD
String Theory = War in Iraq
String Theorists = NeoCon

24. **Torbjorn Larsson**
July 23, 2005

Michaels:

"What I dislike is pretenders."

I understand the general feeling. This time you didn't drag in bystanders into that sentiment by falsehood.

Thomas:
"I don't think that neither you nor Michael grasped the discussion over at Lubos' blog."

It is correct that I do not grasp the technical part. What I meant was probably correct was when Michael accused you of bringing up a seemingly detail as "the most important lesson of string theory" as trying to seem important.

Now you have explained your inspiration in a much different light. I am sorry if I hurt your feelings.

Nigel:
"Torbjorn ? please realise it is personal when the rejection is made because I am not contributing to mainstream string speculation."

I sincerely does not understand your thinking. If you had contributed 'to mainstream' you had not been rejected, you say so yourself. There is absolutely nothing personal (about you as a person) in that.

Maybe you mean that you take it personally? As per above reasoning you should not.

25. **Juan R.**
July 23, 2005

I add my reply to Sean here

Dear Sean, the problem with current unpleasant status of string theory into the community was built by own string theory community. Let me first remember to you some basic points ?the list, of course, is not exhaustive?, which will help to you to rewrite your ?cheers?.

– String theory did born like a failure to explain strong force and since it has been always a complete failure. Nothing predicted and all past claims shown to be false. String theory is a theory without laws or postulates because they are modified with time. Please, let me remember to you the history of dimensions: 4D -> 5D -> 26D -> 10D -> 11D -> 12D (some people is working in more than a time dimension) -> 4D (Segal has claimed that we may find a 4D version for solving compactification problems), etc. The claim of string theory is ?open? is, of course, a complete nonsense when claim is properly interpreted on both epistemological and ontological terms.

– It is well known that string theorists have manipulated public opinion about string theory. In fact, no popular string theory writer has still convincingly explained to public that string theory failed like a TOE since is being substituted by still unknown M-theory. The popular dissemination of string theory to non-experts violates the most basic ethic guidelines.

– The arrogant attitude of many string theorists is also very well known. Please talk with some critics of them like Peter Woit or Glashow and learn the true sense of the word ?pressure?.

– String theory is a mathematical goulash and a dishonest copy of formalisms developed by others. For example, after of decades of very wrong claims about the supposed TOE, now string theorist recognized that were wrong since usual quantization of string was not exact. Now they are launching the TFD version of string theory BUT TFD was previously developed outside of string theory. Again, non-string theorists were correct and ?smart? string theorists (e.g. Witen Greene, Vafa, Schwartz, etc.) completely wrong. In fact, none string theorist did contributions to TFD. Even some string theorist has recently recognized that string theorists usually copy the work of others and after ?rename? it like string theory.

– All past claims by string theorists were shown to be false, absolute all! In fact, the popular idea of that pointilike particles would be substituted by one-dimensional strings has been superseded by recent M(atrix) formulation by Banks and others, which is basically a quantum mechanics of pointlike particles (D0-branes). People again are ignorant of that, since that, like openly admitted by some theorists, the old name ?string theory? is maintained by marketing purposes.

– It is also well knonw and denunciated in several occasions that string theorists have ignored other approaches to quantum gravity. It is very hard for a loop theorist to hear in a popular talk ?given by a string theorist? that string theory is the only approach to quantum gravity. The only game into the city!

– It is also well known that young researches were forced to research into string theory because financial support of other theories was stopped in departments, funding agencies, and others due to aggressive string marketing activities. Many young physicists begin a PhD on string theory, discovered that string theory was a waste of time (real string theory is not the same that popularised version of string theory), and leaved the field. Some of them feel…

– Let me take a simple example from chemistry. According to ?ignorant? and very arrogant people like Ed Witten, string theory is a promising TOE and reduces all of others sciences, e.g. chemistry. A moment, chemists know that is false, the reduction of chemistry to physics is a myth, as brilliantly explained in innumerable papers in Foundations of chemistry and others journals. Interestingly, 30 years ago some chemists were working in advanced formalisms for explaining behaviour that cannot be studied with usual methods. If you compare the very advanced theoretical work developed in the 60 and 70s with corresponding string theory status you found that string theory was wrong like a TOE even a joke. String theorists, arrogant as they are, ignored all of that and claimed that all of chemistry was an application of string theory. String theory was so advanced that no one other theory could provide to us an explanation of nature more profound, they said. Of course, chemists smiled, like they smile in the 20th century, when physicists (including Nobel laureates like Stark) attempt to convince to them that chemical bond was modelled by classical electrodynamics and that Lewis bond theory was, in simple words, nonsense. Now in the last part of 90, some string theorist discover that all past claims were wrong and are developing a new version of string theory called non-critical one. It is interesting that all past quantum methods and basic stuff is abandoned whereas work developed in the 60s by chemist Ilya Prigogine (see for example his Nobel lecture) used for a radical generalization of old string theory. But the ideas used NOW in string theory were developed in the 60s by other people! Prigogine and others were correct, string theorists again wrong. Interestingly, the ideas of the 60s have been updated in the 90s by the Prigogine and co-workers. Therefore, the current ?radical? generalization of string theory by string theorists is, again, an outdated theory. This is real status of string theory; an authentic revolution if one read that masterful piece of marketing called the Elegant Universe (by Brian Greene) and focused to laymen, but claimed to be ?very conservative? and outdated in the recent conference Quantum future by expertises that know stuff. Said I again once more? The first step for any serious theorists is to read previously published literature and then develop a better theory, but crackpots are specialist in ignoring the scientific method. If string theorists continue to develop a really outdated theory at one hand and arrogantly claim that are doing (they believe that in their infinite ignorance) the most important, the most powerful, the most fundamental theory at the other, then they would feel comfortable with the mocking of their colleagues. If Brian Greene, offensively claim in his talks that we may quantize everything, and Dyson convincingly reply him saying that Greene is providing no solid arguments in his belief, the problem is not with Dyson, the problem is with Brian Greene, that would first study serious stuff before doing irrelevant claims surrounded by a halo of pomposity.

– Etc.

Sincerely, I believe that non-string theories have been very generous with string theory community. String theorist would please to us our kindly attitude.

Once ?refreshed? your memory, let me now comment some of your points.

The idea of that string theory is the most promising way to reconcile gravity and quantum mechanics, is one of well-established myths of literature. In an absolute sense, loop quantum gravity is so ?successful? like the strings but in a relative sense (successes / total number of researchers), the loop approach has been around 10 times more satisfactory. Please, let me remember to you again that string theory has been substituted by M-theory.

It is false that ?string theory? is based in one-dimensional loops. In fact, you appear to unknown the current joke on Internet that say that ?string theory is now a theory without strings?. Yes, you obtain a remarkably rich structure, but just at mathematical level.

It is false that string theory predicts or explains gravity (this is another myth). ?To predict? a massless spin-two particle is not the same that quantum gravity. In fact, causality is defined on a flat fixed metric with graviton modes arising in the perturbation, which violate GR basic idea of that full causality is defined in the full metric. This has been the main criticism of general relativists and loop theoreticians during decades. Now, string theorists are recognizing that great mistake (in the past they claimed that one would not take GR ?too seriously?) and are unsatisfactorily searching for a background independent version of the old (outdated) string theory.

?In string theory, you just say the word ?strings,? and gravity leaps out at you whether you like it or not.? This is not true, in fact one use previous ideas from GR, like to leave ?freedom? to the metric into the string action. Somewhat like we need know previously that universe looks 4D and then introduce an arbitrary (that is by hand) compactification 10D -> 4D x 6D.
?At this point it?s a little unclear what the fundamental building blocks of string theory are? It is clear that string is NOT the fundamental entity into the non-perturbative regime.

?One often hears that string theory simply makes no predictions, but that?s clearly false. If you scatter two particles together, string theory unambiguously predicts that the cross-section should look stringy, not like that of fundamental point particles.?

Humm, even ignoring that prediction really mean, this is another myth. Let me simply quote to D. Friedan:
?Even if some particular macroscopic background spacetime is chosen arbitrarily, by hand or by ?initial conditions,? string theory still fails to be realistic at large distance. The large distance limit of string theory consists of the perturbative scattering amplitudes of the low energy string modes, which are particle-like. But the particle masses are exactly zero, and the low energy scattering amplitudes are exactly supersymmetric. String theory fails to provide any mechanism to generate the very small nonzero masses that are observed in nature, or to remove the exact spacetime supersymmetry, which is not observed in nature. More broadly, string theory is incapable of

generating the variety of large characteristic spacetime distances seen in the real world. At best, for each macroscopic background spacetime in the manifold of possibilities, string theory gives large distance scattering amplitudes that form a caricature of the scattering amplitudes of the standard model of particle physics.?
The problem, of course, is not the popular statement of the difficulties for testing Planck-scale physics as you incorrectly argue; the problem is that nobody has obtained the successful standard model from string theory. A first step of any new theory is obtain that is already known before predict any new (including Planck-scale physics). So string theory is not compatible with available experimental data. ?it?s just that we are as yet unable to test them.? As explained above, this is wrong.

?Recently there has arisen another sense in which string theory purportedly makes no predictions, associated with the ?landscape? of possible string vacuum states.?

?Well, too bad. It would have been great to make such predictions, but the inability to do so doesn?t render string theory non-scientific.?

No comment!

?? and possesses a mathematical beauty that is so compelling that the theory simply must be correct.?

The world is as it is, no that we like we want that it was. Mathematical beauty is a guide newer a justification. Moreover, string theory is rather ugly, at least for me. About his supposed ?beauty?, sceptics suggest that string theorists try to colourfully camouflage the well-known theory's flaws, like "a 50-year-old woman wearing way too much lipstick?.

?These kinds of arguments just don?t carry that much weight with the non-converted.?

Yes, I believe that ?converted? is the correct word to use here. String community looks like a sect or, in the words of one of its most famous members, ?a kind of a church?. It is not science.

?it?s the most promising way we know to quantize gravity. If there were multiple very successful ways to quantize gravity, it would be important to distinguish between them experimentally; but so long as the number of successful models is less than or equal to one, it makes perfect sense to make every effort to understand that model.?

This marvellous piece of promotion just emphasize the myth of string theory is the only game in the city. Please read literature in semi phenomenological approaches to quantum gravity and recent advances in other theories like LQG and predictions for the future LHC.

Yes, the comparison between Microsoft and Apple Linux is correct!! Microsoft is a layman-oriented business, whereas Apple or Linux are more specific but more serious. Moreover, it is well knonw that windows OS is a copy of graphical Apple OS and certain kernel properties of Linux/Unix. The success of Windows is in marketing and layman orientation, somewhat like string theory. It is interesting remark that when Microsoft presented the revolution of the trash icon, graphical copy and paste, multitasks, and others features in his first versions of windows, all of that was already known for decades for Mac users. Remember the famous Windows blue display. Yes, your comparison is really good!!

?It didn?t have to work out that the entropy of a black hole calculated from semiclassical gravity ala Hawking would be equal to the entropy of a corresponding gas of strings and branes, but it is.?

Another myth!! Loop quantum gravity obtains the entropy of Schwarzschild black holes. In ?string? (really brane) theory, one traditionally has worked with BPS and idealized models of black holes. Strictly speaking, the ?traditional? results in string theory do not concern, precisely, black holes, as they are found in a limit in which the gravitational constant is turned off. But they concern systems with the same quantum numbers as certain black holes. There is a kind of analogy instead of an identity with GR black holes.

26. **Michael**
July 23, 2005

Dear Peter,

"You seem very proud of knowing what is in the first chapter of Polchinski"

It's chapter 6.4, Peter. Get a copy and try to catch up.

"The point I was making that you seem to have trouble following was just that if you don't really know what your theory is, and all you have is a perturbation series which you hope is asymptotic"

What you say is true: the different perturbative formulations are probably only asymptotic series. On the other hand they are dual to one another. OK, that's not a very concise definition, and it's hard to do calculations in the "middle" of moduli space. In the realm of each perturbative formulation a wealth of information on non-perturbative aspects is available (worldsheet instantons etc. pp.). Sure, we are quite anxious to tie this all together and find the underlying fundamental symmetry principle. But until then we have a good non-perturbative definition that consists of these many parts and aspects. Claiming that, absent the final concise definition, nothing can be done is simply false.

I personally think that there is a lot to do. Along the way we'll have to kill off the landscape and pay more attention to certain mathematical details that didn't seem to matter too much up to now. It will be fun and worth every hour of work.

"you don't know what the value of the coupling "

Well, we haven't found the way string theory selects the vacuum we live in. But we are able to consider various backgrounds, some of which are semi-realistic, and we know precisely what the coupling is in all of these cases. Furthermore, remember that there are stringy features common to any and all backgrounds. It's still in Chapter 6.4 of Polchinski…

"you can't reliably compute anything"

Look, Peter, You know it better. In QFT you have to choose a gauge group and fix a variety of parameters by hand before you can compute things. In string theory, at the present level of our understanding, the equivalent procedure is to choose a point or region in moduli space and a background. Once you do that, you can reliably calculate almost anything you want, at least in principle. The great advantage of string theory is that it naturally includes quantum gravity and that there likely is a dynamical mechanism that should eventually tell us what the background and moduli are (at the present age of the universe 😉). QFT has no hope of doing either. That's why we take the stringy extension of it so seriously.

"He's a real poster boy for string theory."

Thanks for the flowers. I wasn't even so kind to you as to deserve this kind of compliment.

"let's first hear your qualifications"

No, thanks, I don't need this silly kind of publicity that you use as a substitute for an academic career.

"Are you the socially retarded teenager you appear to be? Maybe an undergrad?"

No, but I wish I was that young. My social abilities have no bearing on the present discussion, do they? I have already conceded that it is reasonable on your part to consider me an a*hole and, if you want, a nerd.

"My qualifications include a 1985 Ph.D. in particle theory from Princeton, postdocs in physics at Stony Brook and math at Berkeley (MSRI), four years as an assistant professor at Columbia, and currently I'm a non-tenured full-time faculty member at Columbia with the title of Lecturer. I regularly teach graduate courses here, including one in quantum field theory recently."

Congratulations, that's a bunch of nice accomplishments. So why do you act like a chief bully now instead of being proud of yourself?

27. **Thomas Larsson**
July 23, 2005

Torbj?rn,

I don't think that neither you nor Michael grasped the discussion over at Lubos' blog. For five years, I and Lubos have disagreed about the consistency of gauge anomalies. His argument was always "A gauge symmetry is a redundancy of the description, you idiot". With my last post, I think I convinced him that he was wrong, since a counterexample can be found in the most elementary chapter of GSW. Boy, that must have hurt

28. **D R Lunsford**
July 22, 2005

In other words, Peter is a professor who has accountability instead of tenure. I like it.

-drl

29. **Peter**
July 22, 2005

I've been traveling, so internet access is intermittent. I'll probably soon try and delete some of the more off-topic posts. I'll leave the ones from Michael, whoever he is. He's a real poster boy for string theory.

Michael:

You seem very proud of knowing what is in the first chapter of Polchinski, but do you know anything else about physics. The point I was making that you seem to have trouble following was just that if you don't really know what your theory is, and all you have is a perturbation series which you hope is asymptotic to the real, unknown thing, and you don't know what the value of the coupling is, you can't reliably compute anything, and so you shouldn't be claiming to have predictions. Did you follow that? Do you have a counterargument?

Before we hear your counterargument, let's first hear your qualifications. Are you the socially retarded teenager you appear to be? Maybe an undergrad? My qualifications include a 1985 Ph.D. in particle theory from Princeton, postdocs in physics at Stony Brook and math at Berkeley (MSRI), four years as an assistant professor at Columbia, and currently I'm a non-tenured full-time faculty member at Columbia with the title of Lecturer. I regularly teach graduate courses here, including one in quantum field theory recently. OK, what about you?

30. **Levi**
July 22, 2005

Michael,

If you are such a hotshot string theorist, why aren't you over there discussing it with the other big boys and girls?

31. **Michael**
July 22, 2005

Hi Torbjorn,

I think it's great if "laymen" take interest in physics and string theory. I personally welcome everybody to talk and discuss such things no matter what their level of education or background might be.

What I dislike is pretenders. Why would Peter Woit, who's academic career ended in 1989, be in a position to lecture people like Sean Carroll and even Jacques Distler on string theory? This is disingenuous. If he were to ask or to try and understand, that would be great. Instead he is putting out bold claims debating professional physicists. In the process he reveals gaping holes in his knowledge of the subject's very basics. For example, the soft behavior of string scattering amplitudes is covered in any 1st semester grad course on string theory and is explained in detail in Polchinski's 1st volume. Yet Peter Woit essentially bases one of his arguments on the assumption that such behavior does not exist. His comments on perturbative vs non-perturbative physics are seriously confused, too. This is something he ought to know, having received a PhD in theoretical physics in the 80s. You know, there is a huge disparity between what he knows and is capable of, and what he pretends to be.

Please do not think that I do not welcome reasonable thoughts and arguments by everyone — even Peter Woit.

32. **Torbjorn Larsson**
July 22, 2005

Maybe Michael is the same as who attacked Thomas Larsson over at Lubos blog.

That Michael was probably correct; this one is seriously wrong.

Obviously there are non-knowledgeable people who can find interest in the discussion; I am one of them.

We will discuss ST whether or not practicioners take part. If they don't the discussions will be poorly informed.

And to try to supress the discussion is Not Even Wrong; it will lead to resentment and bad-will.

Nigel:
It was not false when they said that ST is the currently accepted theory, and it was not personal. It would be best if you can accept that.

Science is not democratic. It needs a democratic society, but nothing in the process of science itself is using democracy.

33. **Nigel Cook**
July 22, 2005

The Higgs boson explains inertial mass, which by Einstein's equivalence principle is the same as gravitational mass.

34. **Nigel Cook**
July 22, 2005

"Super string theory is even worse than astrology because it does not make any prediction at all. It hasn't even made even an astrology type of ambiguous and bad predictions. "

Quantoken, you have hit the nail on the head. The 'soft stringy' theorists are charlatans, always hoping to one day make a 'prediction'. Other people have to produce results to earn a living.

35. **Quantoken**
July 22, 2005

Michael said:
"How can I insult what does not exist? You are not a string theorist, wake up. Your pathetic obvious mistakes over at cosmicvariance.com are evidence enough. You don't know about the uniquely stringy "soft" behavior of string scattering amplitudes. And you are unable to see that non-perturbative aspects don't matter in the IR. Among many other things, this shows how little you know."

It does NOT matter a bit at all whether Peter has intimate knowledge about super string theory or not. It works the same way that Peter can confidently criticize astrology **without** necessarily knowing any thing about astrology at all. Any one with the least bit grasp of what astrology is can safely criticize astrology as superstition, because it does NOT make good predictions. Super string theory is even worse than astrology because it does not make any prediction at all. It hasn't even made even an astrology type of ambiguous and bad predictions.

So, knowing just that little bit of knowledge of the fact that super string theory has not made a single prediction, is sufficient enough to allow any one to criticize super string theory. I believe Peter knows at least that much of the facts, so he is fully qualified to be a criticizer of SST.

My point is one can waste decades of time to pick up tons of intimate math skills needed to "research" super string theory, but it still does not add you a single ounce of knowledge about the nature, since so far super string theory has proven no relevance to the nature and does not go beyond a mere mind exercise so far.

An obvious thing that I want to point out is no one is smart enough to change natural laws. **If the nature is inheritantly not a 10-D world, there is no way you can correctly describe nature using a 10-D theory**, no matter how smart or how hard you try. It's a dead end.

Quantoken

36. **Nigel**
July 22, 2005

'String theory' doesn't exist, what does exist is speculation. Serious people have better things to do than mudslinging over trivia of no consequence, that predicts nothing, leads nowhere, and cannot be tested. By Popper's definition of science as being merely tested speculations, 'string theory' is not science. What part of this can't the 'string theorists' grasp?

37. **Michael**
July 22, 2005

"Are you honest and realistic enough to know that you're a gutless asshole?"

Yes, I guess I'd feel that way if I were you. And I understand that my blunt ways must be painful for you. Judging by the vulgar expressions you use: very painful, indeed.

"I wonder why you're insulting my competence"

How can I insult what does not exist? You are not a string theorist, wake up. Your pathetic obvious mistakes over at cosmicvariance.com are evidence enough. You don't know about the uniquely stringy "soft" behavior of string scattering amplitudes. And you are unable to see that non-perturbative aspects don't matter in the IR. Among many other things, this shows how little you know.

38. **Levi**
July 22, 2005

Wonderful discussion over there!

39. **Peter**
July 22, 2005

Hi Michael,

Are you honest and realistic enough to know that you're a gutless asshole?

Either you're the 12 year old you appear to be, in which case I wonder why you're insulting my competence, or you're an adult string theorist, in which case you may (or may not) know more about string theory than me, but are definitely a really sad case.

Posting this kind of shit from the protection of anonymity is pathetic. Grow up, whatever age you are.

40. **Michael**
July 22, 2005

Why do you think the discussion might be interesting? You are not exactly knowledgeable in the area. I hope you are honestly and realistic enough to know that.

41. **D R Lunsford**
July 21, 2005

I guess it's postmodern cool to offer a defense of abject idiocy.

[physics, strings] = ih

42. **Carl Brannen**
July 21, 2005

"Two Cheers for String Theory" wasn't exactly a ringing endorsement. It was lukewarm at best.

One of the quotes was: "If true, this puts a damper on the hope that string theory would predict a unique vacuum state, and we could explain (for example) the ratio of the muon mass to the electron mass from first principles."

It turns out that if you square the sum of the square roots of the masses of the electron, muon and tau, you will end up with a mass that is exactly (to exp. error) 1.5x the sum of the masses of those three leptons.

I suggested this as evidence that the standard model was incomplete to an older physicist. His attitude was, "so what?" From his point of view the masses were arbitrary and it really didn't matter if they happened to fall in some sort of pattern.

Funny that he didn't feel the same way about the coincidences that the standard model managed to explain.

Carl

Categories: Uncategorized

Several months ago Erick Weinberg had told me that his recollections of the story of the calculation of the Yang-Mills beta function were different than David Politzer's. Erick actually did independently do the beta function calculation (for the case with scalars). At the time we talked he thought he had gotten the sign right, but the coefficient wrong, but now he has checked it and says the coefficient is right. He has posted his thesis on the arXiv, equation 6.68 is the beta-function. From the comments after this equation, you can see that he was aware that this meant that perturbation theory would break down in the infrared. Like 't Hooft though, who also did this kind of calculation, he wasn't aware of the significance of asymptotic freedom in the ultraviolet for explaining the SLAC deep-inelastic scattering results.

Fabien Besnard has a new blog (in French), which is quite interesting. His latest post is a report from a Paris conference celebrating the Einstein centenary. He's shocked by the comments of string cosmologist Thibault Damour that Popper was wrong, scientific theories don't need to be falsifiable.

The New York Times has an article about the actress Danica McKellar and her work in mathematical physics. She was working with Lincoln Chayes while an undergraduate at UCLA. Lincoln and his then-wife Jennifer (also a mathematical physicist, now at Microsoft Research) were graduate students with me at Princeton. I have many happy memories of them and their impressive leather outfits, and our joint trips down to the punk-rock club City Gardens in Trenton.

Comments

1. **Torbjorn Larsson**
   July 30, 2005

   stevep: That was much clearer and illustrative! I agree that questions of falsifiability should not immediately throw out ad-hocs. And I fully agree that there are other criteria to throw stuff out, as you illustrate nicely.

   Since we are using illustrations I too will take the opportunity to show how falsification can work. I was working in a group where we wanted to set up a model for a particular class of plasma processes to make thin films. This class has an hysteresis effect.

   Earlier models assumed the hysteresis (!), so they could not be falsified. We set up a model from surface mass balances that showed this effect without assuming it. That model was widely accepted because of that (and because it fit nicely without ad hoc parameters). I saw it work, so that is a reason why I feel strongly that falsification can be a tool in the tool box too.

2. **stevep**
   July 29, 2005

   Torbjorn: I can be less vague by talking about stuff I work with. Economic models often start by trying to characterize an individual's or organization's optimization problem. Then they solve for the agent's optimal policy (say, an investment decision) as a function of some exogenous parameters (say, a set of prices and technical features of the input/output relationship).

   There are plenty of potential points of empirical falsification in these situations–we could have the wrong objective function, the wrong exogenous description, or the agent may not optimize but do something else. All of these turn out, in general, to be hard to observe and test. Nevertheless, some of these models are useful and others are not, even when their falsifiability is held constant (say, at a very low level). When they are useful, they help us understand what is likely to be going on in a given problem and give us a start on figuring out what advice to give to someone in such a situation.

   Since you prefer to think about throwing theories out, the bad models have some combination of a) definitions of the agent's choice set and constraints that are hard to map intuitively to real-world problems, b) lots of technical detail that obscures the primary mechanism, c) strong assumptions about functional forms that are hard to characterize intuitively, d) omitted variables that are of equal or greater importance to those included (although abstraction is OK if done consciously and without fooling oneself). There's probably some other stuff, too, but those are the main bad things to look for. Usually, you can trade some of these off against each other, too, i.e. stronger assumptions can cut out extraneous technical detail. But lots of models get weeded out at review (or published but ignored) based on these kinds of considerations.

3. **Torbjorn Larsson**
   July 28, 2005

   stevep: I must be dense (or vacuumheaded 😉 since the details of your argument are vague to me. But it is interesting.

   Problem are that: You seem to discuss philosophy. I prefer to discuss use. You are interested in how to make a theory useful. I try to find out what makes it useless, IMO it is what we discuss and it is much easier to find.

   You discuss predictive formal theories that may have trouble being falsified. But their predictions are tested for falsification by large errors. The objection you make about small errors should go into the 'slippery notion' category.

   Your discuss nonpredictive formal theories, which are logical and mathematical theories and perhaps prototheories. The domains of logic/mathematics are tested then parts of them are used in theories on the real world. Prototheories should eventually be falsifiable.

   You discuss a floor tiling model that I can't agree with. It is the tiling model we are working on, not arithmetic that have been plenty verified earlier. This is exactly the matter of trust and why falsification is good.

   "Sorry to be so long-winded."

   It's OK as long as the ride is interesting.

4. **stevep**
   July 28, 2005

   Torbjorn: Perhaps I can clarify.

   You said: "Information theory is a widely tested theory. It is used and verified in data communications, data compression, and other fields, sometimes directly on channel capacity and error rates. I can't find the reference, but IIRC Shannon did verifications in his first paper. Shannon entropy corresponds closely to thermodynamic entropy which you may see as another field to falsify it in."

I agree that the theory is widely used because it is useful–that was my premise. My point was that these "verifications" are not empirical tests in the Popperian sense, driven by observation. They are all done by the application of formal logic. The conclusions of communication theory follow deductively from the assumptions, with no room for contingent empirical tests. There is no conceivable set of observations of communications systems that could cast doubt on the correctness of communication theory. That's not "slippery," it's the nature of deductive logic. If you think you've empirically falsified the theory, it must be because you inappropriately applied it.

The only "empirical" aspect to Shannon's theory is that his assumptions about the abstract transmitters, channels, and the rest map directly and cleanly onto their real-world counterparts. The correctness of that mapping is intuitively obvious and no one bothers to "test" it–if we found that the infomation counts didn't add up, we'd look for missing bit generators or absorbers, not worry that the theory is in danger of "falsification." The intuitive correctness of that mapping is also why the theory is so useful.

You expressed puzzlement about how logical omniscience (or its lack) relates to falsifiability. My point about logical omniscience is that a theory can make a contribution by clearing up logical inconsistencies in our thinking, even if it has no direct empirical falsifiabiltiy. The proof that there is no greatest prime number is valuable because we don't necessarily grasp it intutively before we see the proof. Yet the theorem is not empirically falsifiable. Contradictions in logic are not empirical tests, because we can postulate any abstract system we like without it having any necessary correspondence to the world we live in.

You say: "I think you allude to Peters 'slippery notion' of falsifiability. This is a indeed problem. One could also say that the theory is falsified and that a new one is needed. If you redefine your categories or their application, I could say that it is a new theory already."

No, I was not talking about modifying the theory (although that is an interesting set of issues). I am saying that if you count the tiles on your floor, discover that there are 5 rows and 4 columns but that when you count them you end up with 22 tiles, you are not going to modify your theory of arithmetic. Instead, you are going to postulate that extra tiles pop up when you're not looking, or some other modification of the application situation–not the arithmetic theory that appears to be "falsified."

You say: "These are criteria out of vacuum. Verification of theories can be done without them. c) is actually contrafactual; since you want general theories they tend to be simple instead of consisting of several particular ones. (Due to Occam's razor if you wish.) Instead they may be, and usually are, complicated to use in the particular case."

My head may bear some resemblance to a vacuum, and these criteria are indeed not the result of prolonged analysis. But there is a logic to them. I'm interested in what makes a theory useful.

If a theory is like arithmetic or communication theory or queuing theory–mathematically derived from a set of premises not subject to test–then it can't be useful because it rules out contingent states of the world. Rather, it helps us because we can use it to figure out the non-obvious consequences of our premises. If we're interested in real-world problems, then we need the theory to be clear about how to map the real world into those premises, and ideally it should be easy to figure out the conclusions of those premises.

Your point about Occam's razor is a good one. Simple theories of great generality may be hard to use in specific situations, even though their parsimony increases the chances that they are predictive. Their is thus a tradeoff in theory usefulness between these two considerations. But with theories whose predictivity is not in question, like arithmetic or communication theory, there is no real gain to Occam's razor (unless simplicity makes a theory easier to remember).

Sorry to be so long-winded.

5. **Alejandro Rivero**
July 28, 2005

I am happy with E. Weinberg uploading his old papers. Some moths ago, in his duty as PhysRev editor, he rejected one of my papers, and a couple weeks later I become really disturbed: I discovered that in the rejection he was using an standard template… instead of suggesting pointers to his old work, which could be of some value to improve mine!

What world do we live in, if the bureaucratic roles of seniors researchers block them of guiding the younger ones?

6. **Torbjorn Larsson**
July 27, 2005

stevep:

I have several problems with your commentary.

"One problem with falsification as a criterion is that it rules out something like Shannon's communication theory. Shannon's theory is the foundation of network engineering, but an empirical "test" of it is obviously ridiculous–it follows mathematically from assumptions and definitions about "sources," "channels," "coding," etc."

Information theory is a widely tested theory. It is used and verified in data communications, data compression, and other fields, sometimes directly on channel capacity and error rates. I can't find the reference, but IIRC Shannon did verifications in his first paper. Shannon entropy corresponds closely to thermodynamic entropy which you may see as another field to falsify it in.

"A big reason why they can be useful is because we are not logically omniscient–we do not instantly know all the deducible conclusions of the things we believe."

I fail to see that this means re falsifiability.

"Some of these conclusions may be impossiblity theorems, but they still are not empirically falsifiable."

By observing a contradiction to impossibility.

"Communication theory tells us that certain things are impossible, but they are logically, not contingently, impossible; if you ever saw an event that seemed to violate the theory, you would have to go back and (assuming no errors in data) redefine how you applied the categories of the theory to the phenomena."

I think you allude to Peters 'slippery notion' of falsifiability. This is a indeed problem. One could also say that the theory is falsified and that a new one is needed. If you redefine your categories or their application, I could say that it is a new theory already.

"A theory that is not empircally falsifiable must be judged by how much a) the entities it proposes to reason about are operationally definable, b) it includes the factors important to distinguishing situations, and c) it is easy to use in situations we care about."

These are criteria out of vacuum. Verification of theories can be done without them. c) is actually contrafactual; since you want general theories they tend to be simple instead of consisting of several particular ones. (Due to Occam's razor if you wish.) Instead they may be, and usually are, complicated to use in the particular case.

7. **stevep**
July 27, 2005

One problem with falsification as a criterion is that it rules out something like Shannon's communication theory. Shannon's theory is the foundation of network engineering, but an empirical "test" of it is obviously ridiculous–it follows mathematically from assumptions and definitions about "sources," "channels," "coding," etc. The nature of Shannon's contribution was to draw out the surprising conclusions of mundane assumptions and definitions, not to make bold predicitons about contingent facts. Communication theory establishes the basic logical constraints on signal transmission under different noise regimes, etc. (Warning: I am not an electrical engineer or an expert in communication theory–just an interested bystander.)

Falsifiability is a fine thing when you can get it, but lots of useful intellectual frameworks need not be falsifiable and can still say useful things about the world. A big reason why they can be useful is because we are not logically omniscient–we do not instantly know all the deducible conclusions of the things we believe. Some of these conclusions may be impossiblity theorems, but they still are not empirically falsifiable. Communication theory tells us that certain things are impossible, but they are logically, not contingently, impossible; if you ever saw an event that seemed to violate the theory, you would have to go back and (assuming no errors in data) redefine how you applied the categories of the theory to the phenomena.

A theory that is not empircally falsifiable must be judged by how much a) the entities it proposes to reason about are operationally definable, b) it includes the factors important to distinguishing situations, and c) it is easy to use in situations we care about. There are probably other criteria, too, but I can't think of them right now.

I am not qualified to judge whether string theory is on the road to becoming a good non-falsifiable theory like communication theory (or queuing theory, or accrual accounting), but the discussions I have read so far make me wonder. It doesn't sound like the three criteria listed above are going that well. And certainly most of the people pursuing it have the ambition to be empircially falsifiable, so even if it did turn out the way I've described, they wouldn't be too happy.

8. **Torbjorn Larsson**
July 26, 2005

Thank you Clark, it was educational.

"Merely to suggest that its problems can't just be seen as simple falsification. From my limited knowledge I'd say it has more than enough problems to still be questionable though. Let's just not buy into Popper to attack Superstrings."

However, here I don't agree. If falsification is useful at all, it should be used. Some of the anthropic principles that has been used falls for that requirement IIRC. But here I am quickly going offtopic because I don't know enough about the current subject to take it any longer. I think Lubos Motl says similar things on his blog, though…

9. **Clark Goble**
July 26, 2005

Torbjorn, I think Kuhn ends up being the most problematic of the philosophers, if only because of the problems of "paradigm" as having a stable meaning. (He acknowledges this problem in his later writings, but doesn't completely fix the problem) Still, I think the later neoKantians like I think most take Kuhn to be do recognize the categories that we are presented the world through are in part socially determined. That means that falsification is partially socially determined. Kuhn wouldn't go as far as Feyerabend. But I think all of those people have some points – although one can debate how much of an impact it makes in practice. But I think Kuhn's right in that this is because we have some dominate paradigms (or frameworks if we are to adopt the more positivist approach that I think Quine still favors somewhat)

The problem is that Superstring theory is, as I understand it, attempting to be one of those frameworks. As such, discussions of falsification become rather difficult. Especially when for the phenomena in question there isn't a dominant system it is competing against. instead there are other frameworks with at least as many problems as Superstring theory. Given that fact, I'm not sure how falsification even in practice makes much sense.

One might instead just ask for some novel predictions of something unexpected. Yet thus far they can't offer this.

Please note I'm not suggesting falsification isn't useful, although I think the Popper view of them is hard to buy into. Rather falsification, testability, predictions and much else all work together. It just isn't as simple as Popper presents it unless one of comparing a small theory against a dominant overarching one. Even there I think it can run into problem. (Experimental error, some other phenomena at work, etc.) So I think simplicity issues always enter in.

This isn't to defends superstring. (And I'm not enough of a theorist to be able to) Merely to suggest that its problems can't just be seen as simple falsification. From my limited knowledge I'd say it has more than enough problems to still be questionable though. Let's just not buy into Popper to attack Superstrings.

From:

http://physicsmathforums.com/showthread.php?p=200#post200

The Inmates ($tring Theorist$) Are Running The Asylum

$tring theory has done far more damage to physics than just $tring theory itself.

$tring theory's central postulate is that there is nothing more to be asked, and that all government funding for all of science should thus go to $tring theory.

$tring theory has fostered a class of fundamentally dishonest, hand-waving, conjecturing, posing, preening, vogueing pretenders. Corruption allows them to make more money from lying than seeking the truth, so they have no incentive to do physics. The fashionista class has bled over into other fields–even the experimentalists raising millions upon millions to test $tring theory's hoax–they're in on the con too.

They're all in on the joke, and should you speak out against them, they laugh at you. They call you a crank when you question their ridiculous theories that as someone pointed out here have no laws, nor postulates, nor any predictions that can be tested. When you ask them to draw a cube in dimensions 8-10, they jeer, sneer, and put you on the blacklist so you'll never be a peer. And everyone lives in fear of not being a peer, because peer review is how they further the untrue.

$tring Theory is about one thing–money. Book deals, government grants, TV shows–it's a big-time tax-funded circus. A theory of nothing–an elite insider's club for those smart enough to learn the rules of accepting and living the lie, but to stupid to ever think on their own. The worst have risen to the top. It's not the first time in all of history, and it never lasts long.

I have dated many beautiful, elegant women, but none of them were subsidized by NSF nor the government nor student loans.

11. **Torbjorn Larsson**

July 25, 2005

Gosh, sorry! Of course I mean Clark, not Michael!

12. **Torbjorn Larsson**
July 25, 2005

I am not doing research anymore and foundational questions did not matter much at the time. But I am still curious, so here goes:

'Undermine' seems to be a vague term in english, I found both both 'weaken' and 'destroy'. I would agree with the former but not the later. Which did Michael mean?

Feasible falsifiability seems to be good tool to make us trust theories and debunk much junk or faithbased reasoning. There are a lot of problems as Peter and Michael mentions, but it is still doable.

Kuhn, Lakatos, Feyerabend and Quine critisizes falsifiability. From a very short overview of the later two I get the feeling they are confused philosophers with critiques that does not mean much if one want to use falsifiability.

Kuhn's and Lakatos' criticism are more social and practical, about the problems of not allowing ad hoc hypotheses. Enforcing falsifiability would diminish social influence on theories. And since we can't enforce falsifiability on each and every statement in non-formal theories ad-hocs would survive as long as they are needed.

In short, I agree with Peter and can agree with Michael if he means the weaker version of his statement. Applied to string theory it seems that most or all of the anthropic principles used on several occasions would be immediately out. To the benefit of the theory and lessening of criticism until the whole theory can be verified as more than a new part of QFT, or whatever the conclusion was on Cosmic Variance.

If anyone can explain more on the problems of falsifiability I would certainly appreciate that.

13. **Clark Goble**
July 25, 2005

Alas, I didn't do grad work in superstring theory. (Although I did for a while consider doing work in spinors and clifford algebra which I guess would have led me towards loop theory given my inclinations)

As to whether Quine or Kuhn styled critiques apply. I suppose it would depend. I think both of them would argue that there are competing interpretations that would undermine falsification. That is one community would say things have been falsified while the other hasn't. The problem with string theory is that I don't see that they've even *gotten* that far yet. But I can see why some would suggest this as a problem in the future.

14. **Peter**
July 25, 2005

Clark,

I think the kinds of critique of Popper that I assume you have in mind (Kuhn, Quine?) aren't really relevant in this context. While falsifiability can sometimes be a slippery notion, up until now physicists haven't had any trouble agreeing what it means in this particular case and that it is an important criterion for distinguishing whether a proposed idea about theoretical particle physics is vacuous or not. The only physicists challenging this now are ones whose pet theory is failing the test, and all evidence is that this is just because they don't want to admit failure.

If you can identify how one of the standard problems with falsifiability is relevant to this particular case, that would be interesting.

15. **Clark Goble**
July 25, 2005

Surely critiques of Popper have been around long enough that someone shouldn't be surprised that many reject his overly simplistic views of scientific theory. I don't see why someone would be shocked on this. This has been widely discussed for probably 30 – 40 years.

July 23, 2005

Re: [Peter Woit]I'm certainly not sure what is the exact relation between QFTs in curved spaces with Euclidean signature and with Minkowski signature, especially when there are spinors, but something interesting is going on. Even in flat space, free field QFT, if you try and directly formulate it in Minkowski space you run into trouble (the propagator is given by an integration contour that goes through poles) and you have to do something. Mathematically the simplest way of saying what you have to do is to formulate the theory in Euclidean space and analytically continue.[/Peter Woit]

The short way of describing the interesting thing that is going on is to note that QFT is equivalent to a quantum statistical mechanics for a space-time where time is imaginary (i.e. carries the same signature as the space coordinates) and cyclic. Quantum statistical mechanics is simply classical statistical mechanics for waves (which are not distinguishable) as opposed to particles.

The problem, of course, is that time is not cyclic. However, if you start with a space-like metric (such as would be used as the path length ds along the track of an observer or particle) and promote proper time from being a parameter to a coordinate, you will have a Euclidean space-[proper]time. If you assume that proper time is not classically observed as a coordinate because it is small and cyclic, you will have exactly what you need to establish a quantum statistical mechanics as the theory underlying quantum field theory.

Now all this has VERY IMPORTANT implications on particle theory. As it is currently written elementary particles and fields are specifically designed to avoid any possiblity that a non Lorentz compatible theory will slip through. This is partly due to the success of this technique, and partly due to the fact that Lorentz symmetry has not been experimentally disproved. If the gravitation people begin moving into Euclidean relativity, rather than Einstein's relativity, the particle people will have to eventually follow.

I find it very gratifying that Stephen Hawking is moving into Euclidean gravitation. I find it even more gratifying that the particle physicists gave me a 3 year head start on figuring out what the Dirac equation looks like in a world where Lorentz symmetry is only an accidental:

19.
July 23, 2005

at the end, Fabien Besnard uses an expression I hadn't heard before which I think is a reference to this fable of La Fontaine
http://www.lafontaine.net/lesFables/afficheFable.php?id=122

to let the prey go and chase the shadow
l?cher la proie pour l'ombre

or, as in this story, not the shadow but the reflection in a pond: the image or appearance being taken for the real goal

I wish he would correct his spelling of Karl Popper's name

Seattle Conference

July 26, 2005
Categories: Uncategorized

This week I'm in Seattle, among other things attending a Summer Institute in Algebraic Geometry sponsored by the AMS. This is the latest in a series of large summer conferences on algebraic geometry that have taken place about every ten years. The last one was in Santa Cruz in the mid 90s, the one before that at Bowdoin in the mid 80s. This one is being billed as "the largest algebraic geometry meeting in the history of the world", with about 320 mathematicians here this week, and a total of around 600 planning on showing up for at least part of the three weeks during which the conference is taking place. The full schedule of talks is on-line, and copies of speaker's notes and transparencies should soon be appearing there.

The main topic of the first week is billed as "interactions with physics", but there's actually not a whole lot of that going on here. The organizers originally hoped that Robbert Dijkgraaf would be lecturing this week, but that didn't work out. Kentaro Hori of Toronto is giving a series of three talks on mirror symmetry, and some of his lecture notes are already on-line. Rahul Pandharipande started off the conference with the first in what looks like it will be a very interesting series of lectures on Gromov-Witten invariants. This has now become a huge subfield of algebraic geometry, with many ramifications, some of which have been inspired by physics, and there continues to be active interaction between math and physics around this subject. Many of the talks in the afternoon parallel sessions are also related to this topic.

An unrelated note: Lee Smolin has a rather philosophical, but interesting, new preprint out entitled The case for background independence

Comments

1.
   July 26, 2005

   You mentioned the new Smolin article ("what's wrong with string theory, how to fix it with background independence, and other thoughts" heh heh) http://arxiv.org/hep-th/0507235

   He is probably right and I hope string theorists read and heed this article.

   The new article also provides a survey of the various nonperturbative/backgroundindependent approaches to QG (Loop, CDT, causal sets…) same ones represented at Loops 05 conference. It has thumbnail accounts of various approaches and lots of references. So for some purposes it is a de facto review article (as well as proposing a cure for string theory).

   Here, for instance, is the description of CDT, beginning on page 21,

   —quote from Smolin's paper—

   5.3 Causal dynamical triangulation models

   These are models for quantum gravity, based on a very simple construction[26]-[32]. A quantum spacetime is represented by a combinatorial structure, which consists of a large number N of d dimensional simplexes (triangles for two dimensions, tetrahedra for three etc.) glued together to form a discrete approximation to a spacetime. Each such discrete spacetime is given an amplitude, which is gotten from a discrete approximation to the action for general relativity. Additional conditions are imposed, which guarantee that the resulting structure is the triangulation of some smooth
   manifold (otherwise there is a severe inverse problem.) For simplicity the edge lengths are taken to be all equal to a fundamental scale, which is considered a short distance cutoff. One defines the quantum theory of gravity by a discrete form of the sum over histories path integral, in which one sums over all such discrete quantum spacetimes, each weighed by its amplitude.
   —end quote—

   ===================

   Does anyone have a subscription to "contemporary physics"?

   http://www.ingentaconnect.com/content/tandf/tcph

   I understand that the May-June issue will have a commissioned article on CDT. or some issue soon to appear.

2. **Jack**
   July 26, 2005

   I very much doubt that Smolin's article will convince anyone. He talks about the Newton/Leibniz [etc] dispute over absolutism/relationalism, decides that relationalism is obviously right, and then argues that what ails string theory is that it isn't relational. He even mentions Mach's principle and worries that general relativity doesn't really make acceleration relative [doh!]. Something tells me that string theorists [and others] are unlikely to slap their heads and say, "Goddamnit! Of course! The way to understand a small cosmological constant is to make everything relational!!" I'm afraid that the response is more likely to be, "So string theory is absolutist and not relationalist? Who gives the proverbial rat's ass?"

3. **Aaron Bergman**
   July 26, 2005

   Four equations in forty-six pages. Positively Banksian.

   I rather think it's quite an act of hubris, myself, to say that the "correct quantum theory of gravity must be" anything. It'll be what it is, and we'll have to live with it. Regardless, I think generally most people think that the end theory will be background independent, so I really don't why various loopy types spend so much time arguing for it.

   And just on a quick glance, it is certainly *not* always true (p. 24) that nonsupersymmetric theories contain a tachyon. The SO(16)xSO(16) heterotic (discussed briefly in Polchinski, I believe) is an example. As for his discussion for the meaning of the 'height' function in the landscape, it's not energy; it's just a term in the action. The stationary points are the vacua and they're stable if they have no massless scalars of tachyons.

4. **Juan R.**
   July 27, 2005

For the string theorist

“Not only, we are told, is string theory a consistent theory of quantum gravity, but it\uffffs a theory of everything, gives us wonderful new insights into gauge theories, and possesses a mathematical beauty that is so compelling that the theory simply must be correct.”

Sean.

It is many times more bold than Smolin claims, but i don’t see your efforts for critizing bold string theory claims.

Your

“I think generally most people think that the end theory will be background independent”

>was no true into string theory comunity only 12 years ago. Then string theorists claimed that one would not take GR “too seriously”. In fact, a theorist (James Graber) still maintain (three days ago in Cosmic variance) the old posture that one would ignore background independence and formulate causality in a flat metric.

He claims that we would ignore experimental data on favor of string theory!

But string theory community has a special facility for forgeting the history of the field.

Fortunately, history shows how wrong string theorists always were.

A waste of time!

5. **ksh95**
July 27, 2005

Aaron Bergman said:
“…As for his discussion for the meaning of the ‘height’ function in the landscape, it’s not energy…”

Which is precisely the point Smolin was trying to make.

The sad thing is that string theorists feel so embattled and animosity between camps runs so deep that enjoyable, non-technical, profound papers by very smart people are only given a “*quick glance”*.

The propaganda and indoctrination (from all camps) is amazing. It seems the more a camp is criticized, the more ardent in their beliefs they become. Often to the point that they’re unable to even consider the merits of another camps arguments.

…If you’re not a fellow string theorist everything you say is *a priori* wrong…If you don’t believe in Causal sets I don’t want to hear anything you have to say…

But then again, I shouldn’t be surprised. This same phenomena is present everywhere else (see modern day american policital discourse).

As I’ve said before, the same rules that govern the schmucks in the street, govern us in the Ivory towers.

6.
July 27, 2005

Wow. I’m sorta surprised that an alg. geometry conference billed as one of the largest gatherings doesn’t have some of the leading men in that area as part of their speakers–ie. Drinfeld, Beilinson, Deligne, etc etc.

7. **Aaron Bergman**
July 27, 2005

*The sad thing is that string theorists feel so embattled and animosity between camps runs so deep that enjoyable, non-technical, profound papers by very smart people are only given a “quick
glance”.*

Yes, that must be it. I feel embattled and angry. The fact is, a quick glance is more than the vast majority of the papers on the ArXiv get form me. There’s just too damn many of them, and only some percentage of them are about things I find interesting. This paper doesn’t particularly interest me because, generally, I have very little patience for philosophy in physics. As I said, I don’t think it is our place to say that an unknown theory “must” be anything. I just glanced at it this time because of this comment thread.

On the other hand, I do happen to believe that a final theory of quantum gravity will be background independent, so I don’t see where you’re getting that I’m going after Smolin on this point.

8. **Chris W.**
July 27, 2005

Has anyone in the string theory community systematically set forth some requirements or expected features of a background independent formulation of string theory? Should it be considered understood that M-theory will be the hoped-for background independent formulation, or is this a matter of disagreement?

9. **Aaron Bergman**
July 28, 2005

M-theory is a dream, not really any particular theory. String theory really has been developed in a form of a bottom-up approach. No one has gone and said, “this is what we need from the theory; let’s put it in.” Rather, people have just explored more and more and various things have fallen out of the theory. The eleventh dimension, for example, came about from investigating the strong coupling limit of the IIA superstring.

The one real nonperturbative theory we have, AdS/CFT, seems to strongly depend on the asymptotics of the spacetime. This is somewhat of an in-between case: the only part of the background that is fixed is what happens at infinity. What happens in the middle is background independent. This has led a lot of people to think that perhaps that’s the best we’re going to be able to get.

One principle that a lot of people think will be important for some final theory of quantum gravity is the holographic principle. One expression of this is that the theory of quantum gravity will be encoded in some nongravitational theory in one less dimension. In AdS/CFT, the boundary is the holoraphic screen, but in more general spacetimes, there will be other possible screens. Bousso has a proposal for this. Because this still fundamentally requires the idea of a real spacetime geometry, the principle is only semiclassical, but many people think that it will be a general feature of whatever form of emergent geometry appears in the end.

Really, it might be that the whole idea of background independence is a non sequitor. Geometry will arise only in some limit of the theory, and the fundamental theory will have some completely different set of degrees of freedom. As I said, I don't think we get to tell the theory what to be. We'll just have to see (hopefully in our lifetimes) how it turns out.

10. **Peter**
July 28, 2005

Hi meh,

It's a rather young conference, with relatively few of the the organizers, speakers and participants in their fifties or sixties. I'm kind of slumming here, since I'm not an expert in algebraic geometry, but I do notice that the people here include quite a few of those my department identified as the best young people in the field in internal discussions about who to try and hire.

11. **Doug**
July 28, 2005

Smolin's characterization of modern theoretical struggles, as really only a continuation of the old debate on the true nature of space and time, is not explicitly recognized very often these days, but I think it's right on. However, if the reason why string theory cannot meet the challenge of the landscape is that there is no background-independent formulation of it, then what does that imply for *any* background-dependent theory?

Juan Maldacena just posted a comment on Cosmicvariance stating his enthusiastic support for the study of the landscape. However, Smolin's argument that because the static probability distributions live on the "space of possible backgrounds," and the dynamics of the theory are to be done on this space, and thus must employ a fixed background in the study of the landscape, makes this effort an illogical endeavor, and he calls for "an alternative methodology for treating [it]"

Nevertheless, his alternative is not a background-independent formulation of string theory, but a background-independent quantum theory. I think this is very significant, because, as he points
out, the reason string theory fails is because it is background-dependent, which is what helps make it untestable and less explanatory, while background-independent theories are "more constrained" and therefore more "subject to law."

Ironically, then, this implies that the strenuous opposition to string theory found on this and other blogs appears to be a little like someone throwing stones while living in a glass house, doesn't it? I mean, if background-dependence is an indictment of accepted physical theory in general, which Smolin seems to think it is, then the sociological pathology, identified as the maddening fascination with string theory that so many physicists are caught up in, with the accompanying refusal to recognize its futility, turns out not to be due to the philosophical error of the misguided, pursuing a non-falsifiable theory, but the epistemological error of all of us, perpetuated now for generations.

This error is the assumption that we "know" what reality is, and that the grand edifice that has taken centuries to build, and that is built upon the assumption that space and time are non-dynamical structure, or even partly dynamical structure, is unassailable, is doing us in, just as surely as the old farmer was done in by his false assumptions.

As I have pointed out before, Einstein warned us of this very peril. Epistemologically speaking, assuming forces can exist autonomously, apart from the underlying motion from which they must proceed by definition, just because we cannot find such motion, is the fundamental error that has lead to the present predicament, because force requires a fixed background. Fields must evolve over time. Taking force out of the picture of gravity separately, by making the background partly dynamical, just avoids the issue in GR.

The fact is, gravity is a force, and as such must be the property of an underlying motion, but gravitational force is one that cannot be defined in terms of a quantum field on a fixed background of three space, for reasons that are clearly related to dimensions of the motion involved. But, unfortunately, since we think we know what space and time are, we can only talk in terms of the one-dimensional motion of objects "through" spacetime. Oh well.

Ironically, recognizing our errors in the understanding of the nature of space and time opens the door to formulating a truly background-independent theory, which is what we need, but how are we going to go that far back now?

12. **Thomas Larsson**
July 28, 2005

It is unlikely that ST possesses a background-independent formulation. Lee Smolin has informed me that a rigorous theorem rules out anomaly-free Fock quantization of background-independent theories, and I see no reason to doubt that. This explains why the conflict between LQG and ST is so fierce. ST gives up background independence, which to LQGists is the most profound lesson from GR,
and LQG gives up Fock QM, which string theorists can never accept. Hence the conflict will persist.

The loophole is that you can combine Fock QM with background independence, provided that you give up anomaly freedom. Most people think this idea is absurd, since classically a gauge symmetry is a redundancy of the description. However, there are examples where quantum anomalies break gauge symmetry, without violating unitarity. The subcritical free string is the best known example. This example is of course also very relevant to QG, since the free string is nothing but 2D gravity coupled to scalar fields.

13.
July 28, 2005

the paper is enlightening in general but doesn't treat CDT adequately.

CDT is more background independent than LQG (independence is not an all-or-nothing feature of theories, there are degrees)

Smolin schematizes degrees of background independence and discusses striving for a greater extent of independence as a strategy. but his paper does not acknowledge that dimension becomes a dynamical variable in CDT rather than being determined in advance as it is in LQG.

14. **Aaron Bergman**
July 28, 2005

It is unlikely that ST possesses a background-independent formulation. Lee Smolin has informed me that a rigorous theorem rules out anomaly-free Fock quantization of background-independent theories, and I see no reason to doubt that.

I'm not sure I want to steal someone else's thunder, but I have heard that one of the premises of that theorem is seriously flawed.

15.
July 28, 2005

Thomas Larsson: It is unlikely that ST possesses a background-independent formulation. Lee Smolin has informed me that a rigorous theorem rules out anomaly-free Fock quantization of background-independent theories, and I see no reason to doubt that.

Aaron: *I'm not sure I want to steal someone else's thunder, but I have heard that one of the premises of that theorem is seriously flawed*.

Aaron, you've gotten me curious. Could you please be more specific? What theorem has the questionable premise? What is the premise and in what way is it flawed?

16. **Aaron Bergman**
July 28, 2005

I've been under the impression that the theorem requires a sort of quantization that doesn't even apply to ordinary gauge theories, but I haven't looked at it — I don't even know the reference — so I'd rather not pontificate too much on it.

17. **Juan R.**
July 29, 2005

"*It is unlikely that ST possesses a background-independent formulation*."

Yes, M-theory is not so simple as a nonperturbative version of ST. It is something different (there the new name) that is not based in the old string theory framework. This is the reason that nobody formulate still M-theory.

M-theory is not a dream, it is the last hope for some guys 🙂

But string community is not being sincere. Since there exist not M-theory (matrix formulation does not work), it looks like a blanck paycheck.

Next the formula of everything

” ” = ” ”

that i discovered today. You can verify by yourself that reduces to M-theory in the joke regime (i.e. when jokes –> infinite).

Would string theorists not explain to public that after of 30 decades of futile efforts finally we know that **string theory will be not the final theory** and theoreticians need of a new theory that nobody (including Witten) know what is?

18. **Juan R.**
July 29, 2005

Uppps!

I mean 3 decades!!

Well exactly are already 4 (or 38 years).

19.
July 30, 2005

Motl wrote 12 pages on his blog about the new Smolin paper and, I thought, missed the point. Here in these comments we havent even restated Smolin's main message.

He announces this quite explicitly in italicized passages at the beginning and then at the end (with reference to the previous) so it's difficult to overlook.

–quote from Smolin introduction–

The reason that we do not have a fundamental formulation of string theory, from which it might be possible to resolve the challenge posed by the landscape, is that it has been so far developed as a background dependent theory. This is despite there being compelling arguments that a fundamental theory must be background independent. Whether string theory turns out to describe nature or not, there are NOW few alternatives but to approach the problems of unification and quantum gravity from a background independent perspective.

This essay is written with the hope that perhaps some who have avoided thinking about background independent theories might consider doing so NOW.

–end quote–

I have added the emphasis on the word NOW which I think is an essential part of the message. It is friendly advice. Should not raise the hackles of sensitive string theorists. It is trying to be constructive and reasoned. And it is urgent. Theorists have been saying for years that the eventual string theory should be background independent—but have postponed such reformulation. He encourages them to go ahead with it—also gives examples of background independent theories suggesting possibility, and points to his own recent work towards a background independent formulation of M theory.

Then right at the end he comes back to this theme

–quote Smolin conclusions–

…The former are more constrained, hence harder to construct. More of what is observed is subject to law, as there is no background to be freely chosen. Hence, it appears that relational, background independent theories are more testable, and more explanatory.

This is the reason for my provocative hypothesis. If it is true then *the reason that string theory finds itself in the situation described in the introduction is that no background dependent theory could successfully solve the five key problems mentioned there*. *If this is true, then the only thing to do is to go back and work on the less studied road of relational theories*.

At the same time, I have tried here to explain the key problems still faced by the relational road…

–end quote–

20.
July 31, 2005

Lubos Motl wrote a 12-page blog reacting to Smolin's "The case for background independence" that you mention here, and it contains misleading statements like this:

—quote Motl—
On the other hand, there are no successes whatsoever of the approaches that Lee wants to call "non-perturbative approaches". The main problem is that they don't care about physics, experiments, and the new principles that are revealed by them; they prefer philosophical dogmas from the 16th century. It is a waste of time to discuss these "non-perturbative" speculations in detail. In all cases (causal set theory, loop quantum gravity, triangulation models), the speculations are based on the naive picture of space as being composed of infinitely sharp points – like in the classical theory – which are moreover exactly discrete. All these approaches make incredibly strong assumptions about the physics at the Planck scale whose probability to be incorrect safely exceeds 99.9999999999%; all of them belong to the discredited category of "gravitational aether theories"…
—end quote—

This is at the end of the section "Background Independence of GR" right before the section "Background independence in string/M theory".

The nonperturbative QG approaches Smolin focused on and devoted sections of the paper to were Loop, Causal Sets, and CDT (currently the leading triangulations method).

Lubos blanket statement about spacetime discreteness in the nonperturbative approaches is in contrast to what the CDT developers say. They explicitly say they have found no evidence of spacetime discreteness or a minimal distance scale. So Motl is attributing to them what they neither postulate nor find as a result.

To illustrate, this from the introductory section, page 2, of a recent CDT paper hep-th/0505113

"The alternative we will advance here is based on new results from an analysis of the properties of quantum universes generated in the nonperturbative and background-independent CDT (causal dynamical triangulations) approach to quantum gravity. As shown in [5, 6], they have a number of appealing macroscopic properties: firstly, their scaling behaviour as function of the spacetime volume is that of genuine isotropic and homogeneous four-dimensional worlds. Secondly, after integrating out all dynamical variables but the scale factor a( ) in the full quantum theory, the correlation function between scale factors at different (proper) times is described by the simplest minisuperspace model used in quantum cosmology. We have recently begun an analysis of the microscopic properties of these quantum spacetimes. As in previous work, their geometry can be probed in a rather direct manner through Monte Carlo simulations and measurements. **At small scales, it exhibits neither fundamental discreteness nor indication of a minimal length scale**."

Also it is misleading to say as Motl does, that "*All these approaches make **incredibly strong assumptions** about the physics at the Planck scale whose probability to be incorrect safely exceeds 99.9999999999%*"

This evokes the canard that nonperturbative approaches are somehow wedded to precisely one version of the Einstein Hilbert action and cannot modify the action by additional terms. In CDT, to take one example, researchers are free to explore modifications of the microscopic dynamics and do indeed perform (monte carlo) computational experiments involving different versions of the action.
I fail to see what is "incredibly strong" about their assumptions.

It may also be that Lubos blanket statement (which he applied to all three approaches discussed by Smolin) is inaccurate as regards Loop gravity, as well as CDT. It may also be wrong for Causal Sets, but I cannot tell about that because I don't know much about that approach. Here I am using CDT to illustrate the misleading, over-the-top nature of his comments. They sound as if he does
doesn't know what he is talking about and is foaming at the mouth.

What is it about Smolin's central thesis (that it is now time for string/M researchers to get a background independent formulation together—that it is urgent given the present situation of string/M) — that disturbed Motl so much that he had to respond like this?

And why doesn't he address the main thesis of Smolin's paper, which is basically some friendly advice, coupled with the urgency?

Conference Roundup

July 28, 2005
Categories: Uncategorized

Lots of conferences are going on right around now, here's some of them, many with on-line versions of the talks.

Lattice 2005 in Dublin, with blogging from Matthew Nobes.

SUSY 2005 at Durham. See some comments by Clifford Johnson. There was also a Pre-SUSY 2005 workshop aimed at graduate students.

Also at Durham, a workshop on Geometry, Conformal Field Theory and String Theory, blogging from Paul Cook.

Introduction to Collider Physics, a summer program aimed at graduate students, taking place at the Institute in Princeton.

This year's SLAC summer institute is on Gravity in the Quantum World and the Cosmos. Sean Carroll is lecturing there and may have more to say about it over at Cosmic Variance.

There's a Summer Institute going on in Taipei, and a summer school in Dubna.

The summer meeting in Oporto has taken place. I'd love to hear from anyone who was there about Graeme Segal's lectures.

The Simons Workshop in Stony Brook has started, leading off with a talk by Cumrun Vafa on The Swamp Surrounding the Landscape. He seems to be suggesting that theorists should be spending their time investigating the "swamp" of possible effective field theories for which it is unknown whether they can be the low energy limit of a string theory. Why he thinks its a good idea to try and lead the field into a "swamp" is very unclear to me, although one could argue it is already there anyway….

Update: A commenter properly takes me to task for ignoring what's going on down under. There's been a Conference in honor of Ross Street's 60th birthday, together with one workshop on categorical methods and another one on noncommutative geometry and index theory, all covered extensively by bloggers over at the String Coffee Table.

Comments

   August 1, 2005

   Hi Lubos:
   So in addition to string prediction making no testable predictions, you now say you haven't much of a clue what it says is impossible? Great work.
   Nigel

2. **Lubo? Motl**
   July 29, 2005

   Cumrun's goal is to define what string theory is – and especially what string theory is not. For example, pure N=1 supergravity in 4 or 6 dimensions does not seem to arise in any stringy vacuum we know of. It would be great to find a kind of proof that various things are impossible according to string theory; we need these things to fully distinguish the predictions of string theory, even outside our Universe, from generic effective field theories.

   I think Cumrun would agree that we may be currently in swamp, and he may become the savior who will take us away from it. 😉

3. **Tony Smith**
   July 28, 2005

   In his paper The Swamp Surrounding the Landscape, Cumrun Vafa says "… The main difficulty in describing nature using string theory comes from the multiplicity of string vacua. …".

   David Gross said, in Chapter 11 of the book The Rise of the Standard Model – Particle Physics in the 1960s and 1970s, edited by Hoddeson, Brown, Riordan, and Dresden (Cambridge 1997):

   "… The bootstrap idea was immmensely popular in the early 1960s … it rested on the solid principles of causality and unitarity … It promised to … provide a unique value for all observables … This is of course false. We now know that there are an infinite number of consistent S-matrices that satisfy all the sacred principles. …".

   Is it fair to modify Gross's quote as follows:

   "… The superstring idea was immmensely popular for the past two decades … it rested on the solid principles of supersymmetry and gravity from loop gravitons … It promised to … provide a unique value for all observables … This is of course false. We now know that there are a huge (possibly infinite) number of consistent vacua that satisfy all the sacred principles. …"

   Is Edward Witten the present-day counterpart of Geoffrey Chew?

   Compare this Chew quote (from Capra's Tao of Physics)

   "… Our current struggle with the hadron bootstrap may thus be only a foretaste of a completely new form of human intellectual endeavor …"

   with this Witten quote (from Greene's The Elegant Universe)

   "… Understanding what M-theory really is – the physics it embodies – would transform our understanding of nature at least as radically as occurred in any of the major scientific upheavals of the past …"

6. **P P Cook**

July 28, 2005

Sean, I suspect the hiring process encourages bloggers to only report "nice" things about the people who may effect their careers. Of course you will have to worry about the "untouchable" bloggers who already have a secure career, oh and the insane 🙂

Peter, thanks for the link.

Best wishes,
Paul

7. **Sean**

July 28, 2005

Soon it will be impossible to make fun of anyone in a talk, as the chances will be good that whatever you say will show up on a blog within minutes.

Change in Software

August 1, 2005
Categories: Uncategorized

Since I accidentally deleted a post, so had to spend some time fixing things, I decided to go ahead with a long-planned project to try and change around the software here. The old Movable Type software is gone, replaced by Word Press. It seems to be working, but I still need to add in the old links, and fiddle with the configuration a bit. Let me know if anything seems to be broken.

Comments

1. **J.F. Moore**
   August 1, 2005

   Next page link at the bottom is "not found".

   I'm glad the comments are going the 'right' way now! It was hard trying to read them backwards.

2. **Ijon Tichy**
   August 1, 2005

   I find the font too small. It's not very kind to middle-aged eyes.

3. **Peter**
   August 1, 2005

   My eyes are also unfortunately getting rather middle-aged. You should be able to adjust the font size on your browser (I've checked and this works, at least on Mozilla and Internet Explorer). It's not so easily done from this end. This particular "theme" is one of the more legible ones.

4. **Ijon Tichy**
   August 1, 2005

   I think all you have to do is edit this file:

   http://www.math.columbia.edu/~woit/wordpress/wp-content/themes/default/style.css

   specifically, the first section after the comments, i.e.:

   /* Begin Typography & Colors */
   body {
   font-size: 62.5%; /* Resets 1em to 10px */

   Change 62.5 to 70.0 (or thereabouts) and it should look much better. And I'm pretty sure all text elements (including links) will scale accordingly.

5. **Peter**
   August 1, 2005

   OK, I made the change you suggested. I'll leave it like that for now (unless there are any complaints that it's now too big…)

6. **Ijon Tichy**
   August 2, 2005

   Thanks.

7. **Nigel Cook**
   August 2, 2005

   How about starting a thread for a discussion of how to replace string theory with more rational, testable physics? At some stage string theory will have to give way to more productive work.

8. **Ivo**
   August 2, 2005

   One thing I find annoying in this theme (Steam IIRC) is that there is no 'Home' button, apart from the title in the header image. People tend to miss that one. You may want to consider adding that somewhere.

9. **Daniel Doro Ferrante**
   August 2, 2005

   Congratulations, Peter!

   I myself have been dwelling on whether i should move from Movable Type and replace it with WordPress… but, after some "time investment" in building my blog the way it is right now, i'd really like to avoid any kind of "transition". 😉

   Anyway, this "real time preview" is pretty sweet!

   Rock on!

10. **James Graber**
    August 2, 2005

The new look is ok, maybe even better than the old one. I hope your links come up soon; I really miss them because I used them a lot. Let me take the time to say I really appreciate your blog.
Jim Graber

    I like the new look – especially the graphic. Nice.

New York Times on Toronto Panel Discussion

August 2, 2005
Categories: Strings 2XXX

I didn't have much luck when I tried here to find out exactly what had happened at the panel discussion in Toronto at Strings 2005 last month. One graduate student (Florian Greimer) commented on Jacques Distler's weblog that he felt quite depressed after listening to it, earning a slap-down from Jacques, who evidently found it so upsetting that he got up and left halfway through it, and later wrote about why such discussions were a waste of time.

Today's New York Times has a report on the panel discussion by Dennis Overbye entitled "Lacking Hard Data, Theorists Try Democracy", which makes it clear why many of the people in attendance were depressed and/or upset. The title of the piece refers to the previously reported fact that the audience voted overwhelmingly against the idea that the anthropic principle was what explains the value of the cosmological constant. What I hadn't heard before is that the panel itself, representing the leadership of the field, voted rather differently, splitting evenly (4 to 4, with abstentions) over the issue. It looks like Susskind's point of view has gone from being a minority one among leading string theorists to one that half of them are willing to publicly sign on to. I can see why the audience was depressed. Overbye reports the reaction to the audience vote as "'Wow', exhaled one of the panel members, amid other exclamations too colorful to print here."

The article also includes some truly bizarre and delusional quotes, which it is hard to believe were not taken out of context. Michael Douglas is reported as saying that "We've done very well for the last 20 years without any experimental input", which is just so weird I don't know what to say about it. Andy Strominger deplored the increasing pessimism about string theory, trying to rally the faithful with the promise of glory in the after-life: "Sooner or later we will get there, and when we do we'll all be heroes."

Susskind gave his vision of the immediate future of the field: "there's nothing to do but just hope the Bush administration will keep paying us", and Amanda Peet has stolen one of my favorite lines, saying that string theory should be trying to get government funding as a "faith-based initiative".

Comments

1. **Robert**
   August 2, 2005

   So Peter, what are we supposed to do, completely forget about quantum gravity? Don't you agree, that physical scenarios where both quantum theory and gravity matter likely involve Planck scale energies and are thus out of reach for a very long time?

   The loopy people claim they make predictions that are mostly about violating relativistic dispersion relations for high energy gamma rays. Do you believe those? I cannot make up my mind if those predictions are just due to a 3+1 split that breaks Lorentz invariance.

2. **LM**
   August 2, 2005

   'Andy Strominger deplored the increasing pessimism about string theory, trying to rally the faithful with the promise of glory in the after-life: "Sooner or later we will get there, and when we do we'll all be heroes.??'

   Ha! Suicide theorists! Sacrifice yourself and there will be 71 Nobel prizes awaiting you in paradise!

3. **woit**
   August 2, 2005

   Hi Robert,

   First of all, I don't think there is any one thing that people should be doing, they should be trying a lot of different things. The big problem of the last 20 years is that almost all of the effort in the field has gone into one very speculative idea about quantum gravity.

   As for other things to try, if you want to just think about how to quantize gravity, you are kind of stuck without having experiment to help you. In that case all you have to go by is mathematical consistency and elegance, and you need to behave a lot more like a mathematician. By this I mean you need to be very clear about exactly what your theory is, what you understand about it, and what you don't understand. You can't get away with just sweeping problems under the rug the way you can when there are experiments around that tell you whether you're on the right track or not. You shouldn't go around claiming you have a "consistent theory of quantum gravity" when you don't, e.g. when all you have is a divergent series that you hope is asymptotic to some unknown, but consistent theory.

   I've always personally felt that the real question is not how to quantize gravity, but how to quantize gravity in some way that tells us how the geometry of space-time is related to the geometry of the standard model. It would be disappointing if these two things have nothing to do with each other, and the danger is that there may be lots of ways of "quantizing gravity", and with no connection to experiment you could never choose amongst them. String theory became so popular partly because it held out hope for being able to put the standard model and gravity into the same structure. But there's no reason to believe it's the only way of doing that, and people should be trying different things in order to come up with some new ideas.

4. **LM**
   August 2, 2005

   "Theoretical calculations suggest it should be 1060 times larger than what astronomers have measured. "

   Wow, they've gotten the discrepency down to three orders of magnitude? That's pretty good.

5. **R.R. Tucci**
   August 2, 2005

   YA GOT TROUBLE

   Well, ya got trouble, my friend.
   Right here, I say trouble right here in Jersey City
   Why, sure, I'm a stringy player
   Certainly mighty proud to say,
   I'm always mighty proud to say it
   I consider the hours I spend pulling out all my hair are golden

Help you cultivate horse sense and a cool head and a keen eye

Now, folks, let me show you what I mean
You've got one, two, infinitely many stringy vaccua
Vaccua that mark the difference between a gentleman and a bum
With a capital 'B' and that rhymes with 'Stree' and that stands for 'String'

And all week long, your Jersey City youth'll be fritterin' away
I say, your young men'll be fritterin'
Fritterin' away their noontime, suppertime, choretime, too

Ya got trouble, folks, right here in Jersey City
with a capital 'T' and that rhymes with 'Stree'
and that stands for 'String'

May I have your attention, please? Attention, please
I can deal with this trouble, friends,
with the wave of my hand, this very hand
Please observe me, if you will I'm Professor Harold Hill
and I'm here to organize a quantum computer band

Oh think, my friends, how can any stringy guess
ever hope to compete with a gold Q comp
Rah, rah, rah-da-da-da-da, rah-rah
Remember, my friends, what a handful of Apple players
did to the famous, fabled walls of I B M
Oh, corporation walls come a-tumblin' down

Oh, a band'll do it, my friends, oh yes
I said a Q C band, do you hear me?
I say Jersey City's gotta have a Q C band
and I mean she needs it today
Well, Professor Harold Hill's on hand
and Jersey City's gonna have her Q C band
Just as sure as the Lord made little green apples
and that band's gonna be in uniform

6. **Tony Smith**
August 2, 2005

Peter, in reply to Robert's question
"… So Peter, what are we supposed to do … ? ",
you said
"… I don't think there is any one thing that people should be doing, they should be trying a lot of different things. … people should be trying different things in order to come up with some new ideas. …".

With respect to "different things", some commonly mentioned such as LQG and Dynamical Triangulation do have some institutional support, although nowhere near as much as conventional superstring theory, so they are actually in the process of being evaluated by the physics community.

Others such as the models of Quantoken, Matti Pitkanen, Jack Sarfatti, and others, and my model, are (afaik) pretty much individual works with little or no institutional support, and may be regarded by many as crackpot.

Even if some of the individual works contain crackpot elements, it may be that other elements of those individual works might contain seminal insights that might, with further development, grow into a useful unification of gravity and the standard model.

Therefore, my proposal would be that a chunk of superstring money and manpower should be diverted from the abyss of the landscape/swamp and used to do detailed evaluation of all aspects of the individual models. My guess is that even if none of the individual models were totally free of flaws, there would be enough germs of truth that the evaluators would come up with at least one, or maybe more, serious alternative candidates for realistic unification of gravity and the standard model.

My proposal would require agreement of the powers-that-be in physics that any grad student or postdoc doing evaluative work should get credit for work done in evaluating, no matter how many or few (if any) positive results emerge.

Politically, I feel that my proposal is unlikely to be implemented, but I feel that the alternative is to watch fundamental physics sink into the quicksand of the landscape/swamp and remain for the forseeable future in a New Dark Age.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **simplex**
August 2, 2005

the report said the panel split 4 to 4 with abstentions, but the panel was advertised as consisting of these 8 people (plus the moderator Shenker):

Raphael Bousso
Shamit Kachru
Ashok Sen
Juan Maldacena
Andrew Strominger
Joseph Polchinski
Eva Silverstein
Nathan Seiberg

maybe they added more people to the panel at the last minute, but if it was just those 8, plus Shenker, it doesnt quite add up to have 4+4 + abstentions.

My guess is that they foresaw that issue coming to the fore and they handpick BALANCED the panel on that issue. So automatically they got a 4+4 vote. the only thing meaningful, or not prior arranged, was the unbalanced way the audience voted.

8. **Peter**
August 2, 2005

I think one can pretty accurately guess who voted how:

Pro-Landscape:
Bousso, Polchinski, Kachru, Silverstein (note, all from West Coast)

Anti-Landscape:
Maldacena, Seiberg, Sen, Strominger (not from West Coast)

noncommittal: Shenker

Maybe there were one or two other people there not listed (Douglas and Witten are quoted in the article), but I'd bet this division is more or less right.

I doubt the panel was chosen specifically to balance landscape/anti-landscape, but since the topic was the future of the field, I'd guess an attempt was made to choose younger people
working on the latest, hottest topics (I think just about everyone on the panel is under 50, or at most, barely over it). For better or worse, the landscape is the one new idea in the field (the KKLT paper is the only recent one with a large number of citations), so that's probably why the landscape side of the argument was well represented.

9. **Aaron Bergman**
August 2, 2005

Douglas and Witten were both in the audience. I don't remember anyone else on the panel off the top of my head. Somehow, I seem to remember Juan being the fourth anthropic vote, but I very well could be wrong.

10. **Thomas Larsson**
August 3, 2005

Robert,

Nobody expects you to care about Peter's opinion any more than Smolin cares about what you and Policastro write.

Nevertheless, if you seriously want an advice, mine would be to get rid of some excess baggage. The dominant ideology dictates that every gauge anomaly is inconsistent. Of course, we know where this prejudice comes from: the chiral anomaly in Yang-Mills theories leads to unitarity violation and it is indeed inconsistent. Alas, to generalize this result to rule out every gauge anomaly is manifestly wrong; it is clearly stated in GSW that the free subcritical string is consistent, despite its conformal gauge anomaly. Incidentally, it is funny to see how Lubos wriggles when I point out this well-known fact. Last time he started to babble about flux compactifications and Eva Silverstein, as if either had anything to do with the no-ghost theorem.

Do with this whatever you like. But to believe that every gauge anomaly must lead to an inconsistent theory is manifestly false, and I don't see how a manifestly false prejudice could be a good guiding principle.

11. **Ingemar**
August 3, 2005

Think the numbers in the NYT article should be 10^500 and 10^60 right?

//Ingemar

12. **Thomas Larsson**
August 3, 2005

I note that Joe Polchinski voiced one of my favorite theses: That the third string revolution has already happened and it was anthropic.

13. **Nigel Cook**
August 3, 2005

"Others such as the models of Quantoken, Matti Pitkanen, Jack Sarfatti, and others, and my model, are (afaik) pretty much individual works with little or no institutional support, and may be regarded by many as crackpot.

"Even if some of the individual works contain crackpot elements, it may be that other elements of those individual works might contain seminal insights that might, with further development, grow into a useful unification of gravity and the standard model.

"Therefore, my proposal would be that a chunk of superstring money and manpower should be diverted from the abyss of the landscape/swamp and used to do detailed evaluation of all aspects of the individual models." Tony Smith

Tony, this is not going to happen even over the dead bodies of string theorists. What will happen when string theory sinks will be a reversion to the situation of the late 19th and early 20th century, with personalities like Maxwell and Kelvin speculating and ignoring criticisms and new evidence. Kelvin never accepted Maxwell's displacement current or his theory of light, nor did he accept Rutherford's interpretation of radioactivity. I don't see how radical new ideas can be treated in any other way than as crackpot nonsense in the commercialised science of today. There is too much money at stake for democratic let alone liberal attitudes.

14. **Quantoken**
August 3, 2005

Peter said:

"As for other things to try, if you want to just think about how to quantize gravity, you are kind of stuck without having experiment to help you. In that case **all you have to go by** is **mathematical consistency and elegance**, and you need to behave a lot more like a mathematician"

Peter, you sounds like beginning to sing the praise songs of super string theoretists. Those are the exact arguments repeated many many times by super string theoretists:

1.QG is very hard because the technology is not available to do experiments, and super string theory is the clear winner, being the most hopeful theory. It just will take much longer time.

2.Super string theory is the only self consistent quantum theory of gravity, and it is so elegenat, so beautiful, so rich in mathematical structures and it is impossible that it could turn out to be wrong and irrelevant to nature.

I see no one ever attempted to dispute that two arguments, despite they being reiterated many times. And I see Peter is clearly nodding his head and hence ready to join the pro-super-string camp. Looks like the only complaint he still has is that "give some more money to none-super-string alternative approaches."

I say No to both accounts. First on the self-consistency and elegance. A theory has to be logically self consistent to even begin to be considered. If it contradicts itself logically, then it's automatically disqualified without having to do any experiment. So self-consistency is really a minimal necessary condition, and is far from being sufficient to say whether a theory is right or not. As for the elegance, it is NOT even a necessary condition. In history many more elegant theories are replace by counter parts that's less elegant, but agree with experiment better. For example Newton Mechanics is certainly more elegant than Einstein's SR and GR. Newton needs just one universal clock and one ruler for measurements. But Einstein needs lots of clocks and rulers in every corner of the room. Only when all things else considered are equal, then we prefer the more elegant one due to our natural human nature of appreciation of beautiful and elegant things.

Now on the experiment end, I say NO, too. There ARE very accessible, and already done experiments to check against theories. For example we have measured the cosmological constant, and know its value. So that's one experiment evidence that's out there, and none of the existing theory can explain why they can not come up with the correct value of CC. They try to get around that piece of hard experimental evidence by the anthropic principle and landscape craps of nonsenses, and then turn around to say there is NO experimental data available to further their theory research. That's ridiculous!!!

Please try to explain the **currently KNOWN, and UNEXPLAINED experiemental facts**, before demanding experimentalists to discover more unknown and unexplained experimental facts! Please explain CC, explain why the supposedly ridiculously high vacuum energy density is not observed and none-exist, and explain other un-explained observational facts. Until you do that, we are in a situation where experiments far lead the theory, instead of theory being far more advanced than experiments, as some theoretists claim.

Quantoken

15. **Scott**
August 3, 2005

It seems the times piece would have been better titled "Lacking Hard Predictions, Theorists Try Democracy.?? It is interesting that string theories inability to reproduce the predictions of quantum mechanics let alone make a precise prediction on what energy supersymetric particles or other stringy effects appear can be blamed on lack of hard data especialy when hard data such as the CC exists as Quantoken pointed out.

The Science writer also seemed to be under the impression that in 1984 "it was shown that a consistent theory of all the forces of nature could be constructed from strings." Which is of course not even really true today let alone in 1984. Also the writer seems to not understand what Smolin means, or at least doesn't point out to his readers with little knowledge of the anthropic principle, when he says "I'm not sure it will be the next revolution, but I am sure it will be the last," and the same goes for the faith based initiative comment, which, along with the defensive comments about not everyone haveing to be a string theorist, lead me to wonder if there was a lot more negativity then implied at the end of the panel when it was opened to comments from the audiance.

16. **Zelah**
August 3, 2005

Reply to Quantoken rant!

I have looked at your attempts at explaining the universe at:

http://www.livejournal.com/users/quantoken/

and frankly, if String Theory is Not Even Wrong well you are Not Even Right!

Let point out some facts. QFT does not explain the CC data or the asymptotic zero energy of the vacuum either! Nor does Loop Gravity or anything else. String Research ashould definately continue until some better comes along

Any SERIOUS suggestions!

17. **simplex**
August 3, 2005

hi Scot,
you mention a lot of evidence of pessimism but you include Smolin's remark (about reformulating string/M to be background indep would be the last) which is extremely optimistic and hopeful, so it doesnt belong with the other cases. this is just a minor correction

you said…*writer seems to not understand what Smolin means, or at least doesn't point out to his readers with little knowledge of the anthropic principle, when he says "I'm not sure IT will be the next revolution, but I am sure it will be the last,?? … a lot more negativity*

IT does not mean Anthropery here, it means B-indep. Smolin's message is that string has great potential but is stuck now, can't be predictive and falsifiable, because they havent grappled with the problem of making it background indep

and that might not be the NEXT because there is no limit to how long they can or will procrastinate, but Smolin's opinion is that it will be the FINAL reinvention of the field because that will be what it takes to bring it to a predictive falsifiable condition, which is all one can ask of a theory—the rest is testing.

he spells this out in "The Case for Background Independence"
http://arxiv.org/hep-th/0507235
where the main point is that background DEpendence is what is wrong with string and moving in the direction of INdependence makes theories have fewer assumptions and be more predictive. he says it is the way out of the Landscape.

this is a radical message, but it might be right. if it is right, then it is hopeful because there IS a clear way to proceed.

so there was nothing gloomy about Smolin epigram comment from audience, about B-indep not being the next but being the last.

he wasnt talking about Anthropistics. he was talking about weaning the field off the prior metric.

18. **Scott**
August 3, 2005

oh my bad, I thought the last comment by smolin was about anthropic and was disconnected from his previous comment on string theory not being background independent. Also I didn't really think it was possible that string theory could be made background independent, that string theory was fundamentally background dependent, and so that helped add to my confusion.

I am going to disagree with you that the idea that a quantum gravity theory must be background independent, which i think to be highly likely, is in some way radical as I think the idea has been around since people were first trying to formulate a theory of quantum gravity.

19. **simplex**
August 3, 2005

that's a friendly disagreement, Scott. I grant you could well be entirely right!

20. **Tony Smith**
August 4, 2005

In his 2 August 2005 New York Times article, Dennis Overby says that "… string theory …" has achieved "… success in formulating a mathematically consistent theory that unifies gravity and the rest of nature …".

If the Standard Model is included in "the rest of nature", then where is the concrete example of a string theory model that does in fact unify gravity and the Standard Model ?

Although my E6 string model at http://www.valdostamuseum.org/hamsmith/E6StringBraneStdModelAR.pdf does unify gravity and the Standard Model, it is not supersymmetric, and so does not qualify in Dennis Overbye's mind as a "string theory" because Dennis Overbye says "… Supersymmetry is predicted by string theory …".
As far as I know, there does not now exist an example of such a supersymmetric "string theory" model that in fact "unifies gravity and the rest of nature".

Further, Dennis Overbye's article says "… What physicists most expect to discover with the Large Hadron Collider is a new phenomenon called supersymmetry (which would manifest itself as a passel of new particles) …". In my opinion, at least a substantial number of physicists don't believe in supersymmetry at all, because it has never been observed in searches that have seen all the particles of the Standard Model other than the Higgs. As to the Higgs, I thought that the primary motivation for the LHC was to study Higgs phenomena.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

21. **Alejandro Rivero**
August 4, 2005

Tony, I'd not put the hand over the fire to swear that a given model is not supersymmetric. Just check Catto and Lichtenberg works; they are following the scent of SUSY between quarks and diquarks, Which has sense by two reasons: one from, cof, strings: that diquarks are allowed to sit in an extreme of the QCD strings, as quarks do. And other from the standard model spectrum: if you allow for "quark antiquark" diquarks (aka mesons), then the mu lepton is very near in mass to a family of diquarks, and the tau lepton is near to other one, so this SUSY extents to leptons.

22. **Tony Smith**
August 4, 2005

Alejandro indicated that I should not swear that my model is not supersymmetric, citing possible supersymmetries more subtle than the 1-1 fundamental fermion – fundamental boson supersymmetry that is conventionally used in superstring theory.
I agree. In my comment, I should have said that my model does not have the simple 1-1 fundamental fermion – fundamental boson supersymmetry that is conventionally used in superstring theory. I expect that the simple 1-1 supersymmetry is what Dennis Overbye meant when he mentioned "supersymmetry" in his NYT article, so i t probably remains true that my model would not fall into the class of (super)string theories described by Dennis Overbye in that NYT article, and my point that I know of no Overbye-type (super)string theory model that does in fact unify gravity and the Standard Model remains unchanged.
I should also have pointed out that my model does have a correspondence between fundamental fermions and fundamental bosons. Although it is not a simple 1-1 correspondence between fundamental fermions and bosons (I have sometimes referred to it as a subtle supersymmetry), it is well-defined and may be useful in ultraviolet finiteness calculations.

August 4, 2005

Peter,

I'm curious whether you have any comment on the paper:
"Violation of Quantum Gauge Invariance in Georgi-Glashow SU(5)"
by Martin Ambauen, Gunter Scharf
http://arxiv.org/abs/hep-th/0409062

Strings for Dummies

August 6, 2005
Categories: Uncategorized

Joe Lykken just finished giving a series of talks at the SLAC summer school, now entitled "String Theory for Physicists". This was changed from the original title, "String Theory for Dummies" (still on the poster). Presumably somebody realized that the title could be taken the wrong way, giving the impression that string theorists think non-string theorists are stupid.

Lykken's talks are actually unusual for this kind of exercise in expounding string theory to non-string theorists. They begin with a long list of the pros and cons of string theory. I'd disagree with him about some of the "pros" he lists, but it is remarkable that he gives a detailed discussion of the problems with string theory. I've never seen a string theorist do that before. During the last few months I've been sensing a definite change in the atmosphere surrounding string theory. String theorists are on the defensive, and many science journalists and members of the general public are starting to get the idea that there might be something funny going on. For the first time there was open pessimism and defensiveness expressed at the panel discussion at Strings 2005 and the recent New York Times article about it had a somewhat mocking tone.

There's a posting at cosmicvariance.com by JoAnne Hewett about the panel discussion and Times article, and many comments, including some from yours truly. Jacques Distler proves that he thinks anyone who doesn't agree with him about string theory is just ignorant (OK, maybe he just thinks that I'm the only one who is ignorant) with his trademark tactic when he's on the losing side of an argument: take something perfectly accurate that your opponent writes, change the wording to something else that can be interpreted as inaccurate, then use this as evidence to back up a sneering put-down of your opponent. Jacques seemingly can't help himself from doing this. For an all-time classic, check out his contribution to one of the first postings here, where he attacks me for saying that the standard model is a chiral gauge theory.

Unfortunately, Jacques isn't the only string theorist who thinks that this is an intelligent way to behave. Besides another well-known string theory blogger I could mention, at one point I had a remarkable experience with an unknown "prominent string theorist" (I'm pretty sure it wasn't Jacques) who was asked to referee something I'd written about string theory. This referee wrote a report saying that I was just so wrong it wasn't worth explaining why, but that they would give one example. Their example was constructed by taking a sentence out of context, then changing a singular to a plural to allow the sentence to be construed as saying something inaccurate. Some string theorists seem to be willing to go to any lengths to preserve their belief that any criticism of the theory is based on ignorance. My impression is that a lot more criticism is coming their way, and it will be interesting to see how long they try and keep claiming that their critics are just dummies.

Update: Lubos Motl is back from vacation, with a posting about the Toronto panel discussion.

   'String theorists are on the defensive, and many science journalists and members of the general public are starting to get the idea that there might be something funny going on.'

   Like a conspiracy of string theorists to put over stuff that would look like science fiction if it wasn't so boring? There is little physics coverage because it is becoming so awful. There is a decline in physics A-level uptake in Britain, and a large number of university physics and maths departments have shut here.

   'Children lose interest … because a natural interest in the world around them has been replaced by an unnatural acceptance of the soundness of certain views, the correctness of particular opinions and the validity of specific claims.' – David Lewis, You can teach your child intelligence, Book Club Associates, London, 1982, p. 258.

   August 6, 2005

   Peter,

   Respectfully, I must point out that you're misrepresenting several things here, in this post and others. (You are of course entitled to do this because it is your blog). First: The fact that you have not seen a string theorist point out the problems with string theory does not mean that it does not take place quite regularly. Second: As was discussed over at Cosmicvariance on several threads which I know you've read, there are several string theorists all around the world working on many things other than the landscape and anthropic issues that you have made central to your argument that string theory is in a crisis. Third: You fail to point out that there is at least one example of a string theorist blogger (perhaps not as prominent as the others you mention) who has been extremely welcoming to you, your comments, and who has taken the time out to address some of your objections (and clear up some of your misconceptions). I refer to myself.

   Your comments here on your own blog seem to be constructed to perpetuate your preferred mythology that all string theorists are on the defensive, and that they are all arrogant and think that all non-string theorists are dummies. I know that you used the phrase "some string theorists" in some places, but it was somewhat lost in the overall thrust and tone of your post.

   In summary: There is a much wider program of activity in string theory than you seem to acknowledge, and a much wider range of motivations. There is a much wider range of temperaments of string theorists than you seem to allow for. Oh, and the theory is not in a crisis, and there is nothing "funny" going on, assuming that you mean "peculiar".

   Finally, The New York Times' attitude to a body of scientific activity cannot be used as evidence of anything, in view of the fact that even when they are supportive of something, they often get the content, emphasis, and overall point woefully wrong. (There are several articles on string theory which fit that description. It is, however, good that they at least try to cover this activity, I must add.)

   Finally finally, it would be nice to think that the courtesy we've shown you over at Cosmicvariance would result in you making an effort to paint a less narrow and bitter characterization of the valuable discussions that have taken place there. There were several people addressing points you'd made besides Jacques, some of them also active string theoriest with a valid point of view, who quietly explained things to you, and listened to what you had to say.

   Best,

   -cvj

3. **woit**
   August 6, 2005

   Hi Clifford,

First of all, I was in no way referring to you in my complaints about string theory bloggers. You're right that you've always been welcoming to me and willing to engage in very reasonable discussion on all issues. I appreciate that. I also should say that in many of my discussions at cosmic variance as well as in hundreds of private discussions over the years I've found the great majority of string theorists to be reasonable people willing to respectfully discuss issues we disagree about (and we often find we agree about more things than we would have expected). I take your point that I should acknowledge this more often.

That said, until you came on the scene, the two most prominent string theory bloggers have been Jacques and Lubos, and the behavior of both of them is atrocious. I can forgive Lubos a lot, I too was once young and foolish, but Jacques is a middle-aged man and there is absolutely no excuse for the kind of bullying behavior he chooses to engage in. I'm not going to put up with it.

While Jacques is one of relatively few string theorists who behaves this way, he's not the only one who chooses to react to the problems of the subject by engaging in intellectually dishonest and bullying behavior. When I first posted an article criticizing string theory I got a lot of positive responses, a small number of highly hostile responses personally attacking me, and zero reasonable, intelligent reactions from professional string theorists. What most surprised me were how many people complimented me on my courage, saying they agreed with me, but didn't dare say so publicly for fear of retribution. There's a really ugly side to the way string theory has come to dominate particle theory, and the Jacques Distlers of the world are a big part of the story.

As for whether the field is in crisis, that's a matter of perspective, and is something on which I think we do fundamentally disagree. But I assure you that my perspective is not purely a personal one, I've found that many graduate students, postdocs and more senior people agree with me about this. A few years ago I found it wasn't uncommon for string theorists I talked to to agree about this. They often felt the lack of new ideas or forward motion was reaching the point of crisis. More recently I've found an even larger number of people agreeing with me, with very many sharing my point of view that a sizable and increasing fraction of the string theory program has been taken over by research which is pseudo-science, not science. Looks to me like a crisis. By definition a crisis doesn't last that long, so we'll see what things look like in few years, and then may be able to evaluate which one of us was right.

4. **Urs Schreiber**
August 6, 2005

While I don't know if it does any good to try to discuss it, I am wondering where you think your arguments were distorted.

I had the feeling your comments received pretty good replies. Seems like you tried to argue that all valuable progress attributed to string theory is actually progress in field theory. It was pointed out that this is an odd point of view, and a pretty good analogy was given to illustrate this.

5. **Peter**
August 6, 2005

Hi Urs,

I don't have any problem with any of the replies I received to my comments except those from Jacques. I didn't actually say that "all valuable progress attributed to string theory is actually progress in field theory", but certainly anyone who felt that was what I was saying and wanted to challenge it was more than welcome. In response to some of the replies, to Aaron and to Clifford I explained in more detail what I meant to say. In particular I made the completely accurate and unobjectionable statement that topological string theory at a fixed genus is a QFT, and that the string theory sum over genera is not a QFT.

Jacques then began attacking me, first putting the words "topological string theory is just 2D QFT" in my mouth and saying I was "flat-out wrong". When I copied for him my earlier comment explicitly saying that it was only at fixed genus that it was a QFT, he then made an analogy with the QFT perturbation expansion and in that context again put the "topological string theory is just QFT" argument in my mouth, using it to proudly announce that I was "not a serious interlocutor".

At this point, I was pretty pissed off by Jacques's endless tactic of trying to find some way of twisting words that I write so he can find an interpretation of them in which they say something incorrect, and use this to attack my professional competence. I've had to put up with a large amount of this offensive behavior from him (and others), and am really sick of it. I pointed out to him that his own argument was worded incorrectly (he wrote "precisely equivalent" when he meant "precisely analogous"), but that I wouldn't accuse him of being ignorant about QFT based on this.

His rsponse was quite offensive (hint, in case this ever happens to you: if you have a Ph.D. in particle theory and someone carefully explains to you what a Feynman diagram is, then asks for a response that they announce will be "diagnostic", you're being insulted), so much so that he himself tried to retract it as "needlessly inflammatory".

Undoubtedly that's more detail than anyone wants, but that's what my posting and comments to Clifford are referring to.

6. **Aaron Bergman**
August 7, 2005

I can't help but find this:

> In particular I made the completely accurate and unobjectionable statement that topological string theory at a fixed genus is a QFT, and that the string theory sum over genera is not a QFT.

disingenuous. The discussion at hand was whether there was anything beautiful in string theory learned in the last 20 years (or something along those lines.) I responded with AdS/CFT and the topological string. Your response was that AdS/CFT dealt with field theory dualities and that the topological string at a fixed genus was just a field theory. The former is, as Clifford pointed out, wrong. The latter may be technically correct, but if construed that way, completely nonresponsive to the point. Given the context, it's fair to infer that you were attacking the topological string as being just field theory in disguise. Otherwise, why mention it?

7. **Jacques Distler**
August 7, 2005

Remarkably thin-skinned, coming from someone who, in a **single** recent post referred to me as

a) "completely delusional"
b) engaged in "educational malpractice."

I, fortunately, am rather thick-skinned. So, please, don't change your style just for me. Continue to inveigh away at what an evil, mean-spirited (and completely delusional) person I am.

I gather you have a loyal following, who just lap that stuff up.

8. **Quantoken**
August 7, 2005

I am not interested to make a judgement whether anything Peter said is right or wrong. Because it doesn't matter and doesn't change the fact that SST has so far unable to explain a single damn thing in nature. And that so far as it is unable to do that, it is a complete failure, and people like Jacques etc are a complete waste in their invain efforts to pursuit a goal that is simply wrong.

Lubos is OK. He some times behave a bit silly and a bit arrogant. But he is young and he does show evidence of intelligence some times, like on the matter of global warming. As for Jacques, I have lost every little bit of respect for him after this. Clearly he has zero IQ on matters unrelated to SST, and could not think for himself.

9. **Peter**
August 7, 2005

Aaron,
This is beating a dead horse, but let me try one more time:

First of all, you've changed what initially led to this exchange, which was Jacques's claim that

"string theory has turned out to be a vastly more beautiful and intricate subject than anyone suspected 20 years ago."

not

"whether there was anything beautiful in string theory learned in the last 20 years."

These are two very different statements. By changing what this discussion was about you're constructing a straw man argument I never made and don't agree with and putting it in my mouth. It's an annoying debating tactic which Jacques also loves to use, but at least you don't then go on to personally insult me.

I have no problem with the second statement, and recent work on the topological string is a good example of something beautiful coming out of string theory.

The first statement however is simply delusional (the beautiful part, not the intricate part, the subject sure is complicated). 20 years ago there was a conjectural idea about how to use string theory to produce a TOE, and many people made many public claims that this was an extremely beautiful idea. 20 years of work have shown just the opposite. All attempts to get a TOE this way lead to hideously complicated constructions which don't even work. As a TOE, which is the main way string theory has been and continues to be sold, the situation is the precise opposite of what Jacques said, with the theory vastly uglier than anyone suspected 20 years ago.

Some beautiful things have come out of string theory, but many of them are purely 2d QFT. Examples of 2d QFT results that I have in mind are the mid-late 80s work on CFTs, and the early 90s work on mirror symmetry (which involved topological sigma models with a fixed genus of the world sheet, often genus zero). In recent years there have been two related classes of results that truly are string theoretical and that truly are beautiful. They both come out of the idea of a having a precise duality between a gauge theory and a string theory. To be more specific they are:

1. AdS/CFT. Of course I'm well aware that this is a duality between a string theory and a QFT, not a duality between two QFTs. It was my mistake to try and make the debating point that often this duality is checked by doing a QFT (supergravity) calculation on the string theory side. My bad, that muddied the waters and is pretty much beside the point.

2. Topological string theory: As I've repeatedly said, there are certainly very interesting mathematical results about the full topological string theory expansion, and this full expansion is not a QFT. Among the most impressive things I've seen of this kind are the Gopakumar-Vafa results, and, correct me if I'm wrong, but part of the story is that these also come out of the idea of looking for a string/gauge theory duality, in this case using Chern-Simons as the gauge theory.

So, when I look at the beautiful mathematics coming out of the last 20 years of string theory research, two sorts of things seem to me the most striking: some older results that are purely 2d QFT, and some more recent results that are based on the idea of looking at precise string theory duals of a gauge theory QFT. From this perspective, what is interesting about string theory is not the idea that was initially used to sell it, that it could give the standard model QFT + supergravity as a low energy limit, but the fact that it can provide an alternate formulation of QFT.

If you want to challenge any of the above, go right ahead, I'm happy to discuss it further. If instead you want to ignore this elaboration of my earliest comments and make complaints about them based upon a misinterpretation of what I was saying, I don't really see the point of continuing.

10. **Peter**
August 7, 2005

Jacques,

Because of your continual insults of me as professionally incompetent, at some point I stopped worrying about whether my references to you were sufficiently polite or not. Perhaps this was a mistake, I hear they have a saying down in Texas about what happens if you start wrestling with pigs.

If you want to continue your tactic of trying to deal with my criticisms of string theory by making up things I haven't said and using them to insult me and to try and convince people that I don't know what I'm talking about, go right ahead. But it's slimy, pathetic, bullying behavior and you should know better. It may help you maintain your delusions about string theory, but the obnoxious way you and Lubos behave in the face of criticism makes clear to most people how little of a legitimate case you have on your side of the argument.

11. **Jacques Distler**
August 7, 2005

Well, then, you probably don't care that we were referring to the Gopakumar-Vafa papers on the duality with M-theory (I,II) — a highly nonperturbative rewriting of the Topological String free energy (summed over genera) — rather than to large-N Open/Close Topological String duality.

And, no, in the latter case, the Open String side only reduces to Chern-Simons theory in the special case of T^*S^3.

Anyway, I had forgotten why I avoid responding to your attacks. Thanks for reminding me.

12. **Peter**
August 7, 2005

You know Jacques, I think this is a mania, and you should consider seeking professional help.

Let's look at this and see the trademark Distler behavior in action. Recall how it works: first ignore the points at issue, and pick out one sentence in which some sort of reference is made to a particular technical idea that he knows something about. Then go on to interpret that reference in a way that can't be supported by the actual text, but that allows him to attack me as not knowing something that he knows.

In this particular case, the the technical thing at issue is results of Gopakumar-Vafa, about which I said, in toto:

"part of the story is that these also come out of the idea of looking for a string/gauge theory duality, in this case using Chern-Simons as the gauge theory"

I wrote "part of the story" specifically because I was only referring to, well, part of the story, the part that Jacques properly recognized as large N Open/Closed Topological string duality, and in particular the special case of the cotangent bundle of the 3-sphere. Note that I was very careful to not be claiming that this was a complete description of all of the Gopakumar-Vafa results.

It's pretty tedious to have to spend time writing comments like this very carefully, since I know Jacques is going to be spending his time searching them for something he can use to attack me as an incompetent. The thing that most amazes me about Jacques is that he just can't stop himself from doing this kind of thing. You'd think that once anyone had publicly made a fool of himself so many times this way they'd learn their lesson.

13. **Jacques Distler**
August 7, 2005

I can't resist point out that, in the same recent post in which you called me "completely delusional" and "[engaged in] educational malpractice," you *also* complained that, "This is the first time I can think of that he has actually used my name, even if as an insult."

So much for my "continual insults" of you and/or your professional competence.

Now, I *really* feel the need to shower off and stop responding to your … *umh* …. well-reasoned critiques.

14. **woit**
August 7, 2005

Sorry Jacques, you've won and caught me in an imprecision. For "used my name", I meant "used my name in his blog".

Your mania for avoiding the point and desperately trying to find something inaccurate in what I write continues. Get help.

15. **Urs Schreiber**
August 7, 2005

Even though this has become a flame war, I would like to make a comment that I hope is recognized as a technical comment, not intended to attack anyone personally.

It was Peter who wrote above:

> As a TOE, which is the main way string theory has been and continues to be sold, the situation is the precise opposite of what Jacques said, with the theory vastly uglier than anyone suspected 20 years ago.

'As a TOE' = 'as concerns it's quasi-realistic solutions found so far', yes indeed. Nobody can deny that and as far as I can see nobody around here is denying that.

The discussion over at cosmicvariance was however about the theory, not about any of its solutions (or about any way (anthropic or what not) to pick its solutions). This is a big difference. Newtonian mechanics is beautiful. Specifying the solution to some billard problem, say, in Newtonian Mechanics is generically not so.

It seems to me that the argument here became heated because the distinction has been blurred between statements *like*

> There are many beautiful aspects to be discovered once certain CFTs are interpreted as describing strings propagating in certain target spaces.

on the one hand side and

> Such interpretation has however so far not led to a nice derivation of the standard model.

on the other side.

I believe there is no disagreement on the truth of either of these two statements between Peter and anyone else. The whole point is that Peter feels that the truth of the second statement totally undermines the usefulness of the first statement, while many others feels that the truth of the first stament is ample indication that we can eventually remove the 'so far' from the second statement.

16. **Chris Oakley**
August 7, 2005

I believe there is no disagreement on the truth of either of these two statements between Peter and anyone else. The whole point is that Peter feels that the truth of the second statement totally undermines the usefulness of the first statement, while many others feels that the truth of the first stament is ample indication that we can eventually remove the 'so far' from the second statement.

Not proven, I'm afraid. Just because something is "beautiful" (a very subjective thing anyway) it does not that mean that it is likely to be right. This obsession with mathematical beauty has led precisely nowhere, and it is high time that you people stopped pretending that what you do has more than a passing resemblance to physics.

You can fool all of the people some of the time, etc.

17. **Quantoken**
August 7, 2005

Jacques:

You clearly do not know anything you talk about. Are you **really sure** you have READ the Vafa paper carefully? I think you have NOT! To show how ignorant you are, please tell me, without go a read that paper again, exactly how many equations have occured and exactly how many pages that paper contains. You can't answer that without cheating, can you?

The point I want to make is the **technicality details are totally un-interesting and unimportant**. The important thing is even if you memorize everything Vafa ever published and down to the detail of page numbers and word counts, you are still a complete idiot and not knowing what you are talking about. The whole SST business is completely meaningless except it could be otherwise interesting to a few paid nerds like your kind. Clearly SST is unable to make any prediction so it belong to a category worse even than astrology, which at least makes predictions, right or wrong.

Have you figured out which end of yours emit the kind noxious smell that contributed greatly to global warming, Jacques? I never thought that's an important detail to know but you clearly had a different opinion.

18. **Aaron Bergman**
August 7, 2005

> "string theory has turned out to be a vastly more beautiful and intricate subject than anyone suspected 20 years ago.??
>
> not
>
> "whether there was anything beautiful in string theory learned in the last 20 years.??

I'm sorry, but there is almost no difference in the plain wording of these statements besides the word 'vastly'. That you choose to interpret the former one as somehow implying that the use of string theory towards finding a realistic vacuum (and things along those lines) has become more beautiful is bizarre. It's just not there in the sentence. At the risk of putting words in Jacques's mouth, the sentence means precisely what it says, that string theory, as a subject, has turned out to be more beautiful and intricate, again, as a subject, that anyone suspected 20 years ago. The proliferation of candidate vacua in the past few years does little to negate this statement.

> From this perspective, what is interesting about string theory is not the idea that was initially used to sell it, that it could give the standard model QFT + supergravity as a low energy limit, but the fact that it can provide an alternate formulation of QFT.

Nobody has said, Peter, that the vast areas of beauty are all part of the idea that was initially used to sell it (although many of these new understandings hav gone into the constructions of vacua.) You're so fixated on this point that you cannot respond to the actual words that people are writing.

And, you're still wrong on the topological string. You can carefully word your statements as much as you like; you're still using them to support your conclusion:

> So, when I look at the beautiful mathematics coming out of the last 20 years of string theory research, two sorts of things seem to me the most striking: some older results that are purely 2d QFT, and some more recent results that are based on the idea of looking at precise string theory duals of a gauge theory QFT.

Now, when someone points out that your statements don't actually support this conclusion, by pointing out that they involve things beyond field theory and field/string dualities, you appeal to your careful wording. In other words, you *claim to be aware* of the fact that your statements, precisely parsed, do not support your conclusion. Given your claims to greater knowledge, your careful wordings come across as simply deceptive.

19. **JKG**
August 7, 2005

Hi,

On his first slide Lykken says „string theory is a consistent theory of quantum gravity??. Lee Smolin uses to stress that there is no proof that string theory is renormalizable to all orders, so this statement seems to be not exactly correct, but I have even more naïve question. Namely could anybody explain, what are the arguments that string theory is (contains) a theory of gravity, and not merely just a theory of spin 2 field moving on some backgrounds. Could one derive equivalence principle from strings? Is it possible to derive Newtonian potential (with some corrections perhaps) for point mass(es)?

Thanks

JKG

20. **Aaron Bergman**
August 7, 2005

One can find the consistent backgrounds on which one can do string perturbation theory. It turns out that these backgrounds are exactly those that satisfy the Einstein field equations (plus higher order corrections). String perturbation theory also gives rise to a spin 2 field, ie, perturbative gravity, and this contains the Newtonian potential.

21. **Chris Oakley**
August 7, 2005

Aaron,

This was the question:

Could one derive equivalence principle from strings? Is it possible to derive Newtonian potential (with some corrections perhaps) for point mass(es)?

Your answer seems to be "we hope so" rather than "yes". For some of us, this is not good enough.

22. **Aaron Bergman**
August 7, 2005

In what way does my answer seem to be "we hope so"? The equivalence principle (for various definitions thereof) fails for strings, but this isn't a big deal. As I said, you can compute perturbative gravity and show that any background has to satisfy the EFEs. What more do you want?

23. **woit**
August 7, 2005

Hi Urs,

I'm glad to have someone commenting here who seems interested in having a reasonable discussion. A couple comments of my own:

First of all, it's not so clear in this case what is "the theory" and what is "the solutions to the theory", so the ugliness of the latter is not irrelevant to the question of the beauty of the former. To discuss the issue of the beauty of "the theory" that is supposed to be a TOE we have to first agree about what "the theory" is. If you want to very precisely tell me what "the theory" is, we can try and have a discussion about its aesthetic properties, positive and negative.

Secondly, about the two statements you give, I'm not completely happy with your formulation of either one. In the first statement, you need to specify precisely what CFTs and what target spaces you're talking about before I'll sign on. I'll happily agree with this statement if we're talking about the topological string and target spaces where string theory has led to calculations of the full sum over genera. But I suspect you have in mind other CFTs and other target spaces. Your second statement is misleading: not only hasn't work on string theory led to a "nice" derivation of the standard model, it hasn't led to any derivation of the standard model, nice or not nice.

24. **JKG**
August 7, 2005

Hi Aaron,

You say

"String perturbation theory also gives rise to a spin 2 field, ie, perturbative gravity, and this contains the Newtonian potential"

I understand that you compute entirely within string theory the scattering of two particles mediated by graviton, go to the static limit and get Newtonian potential. This sounds reasonable. Is it then obvious that from the first principles it follows that the relevant charge is to be mass (inertial one because you do not have anything else to start with), or you just put it by hand, somehow? In the first case you would have more-or-less the equivalence principle.

Thanks

JKG

25. **Aaron Bergman**
August 7, 2005

The violation of the equivalence principle comes from the fact that string theory really gives dilaton-gravity.

26. **woit**
August 7, 2005

Hi Aaron,

First of all, look at what you are doing in defending Jacques's statement. You argue:

"the sentence means precisely what it says, that string theory, as a subject, has turned out to be more beautiful and intricate, again, as a subject, that anyone suspected 20 years ago."

I don't have any problem with your changing "string theory" to "string theory, as a subject" (it actually doesn't clarify the tricky point of what "string theory" refers to), but the "vastly" you decided to drop is a big part of the problem.

In standard use of the English language the two questions of

whether string theory is "vastly more beautiful … than anyone suspected 20 years ago"

and

"whether there was anything beautiful in string theory learned in the last 20 years.??

are quite different and have very different truth values. To make the second one true you just need to demonstrate one beautiful thing about string theory learned in the last 20 years, and there are plenty of candidates.

To make the first one true, you have to first understand what people thought about the beauty of string theory 20 years ago. Note that Jacques didn't just say that string theory is more beautiful than the average string theorist thought, he says that it is "more beautiful than anyone suspected" back then, so you have to identify the maximal amount of beauty that any string theorist suspected the theory might have back in 1985.

I have a bit of an advantage over you here in that I was there, spending lots of time talking to people and going to talks about string theory. Unlike many people who have problems with string theory, my problem is not that I object to being guided by mathematical beauty, especially when you don't have experimental results to help you. Many people at the time were going on about the beauty of string theory and I was having trouble seeing this. The quantization of the string never seemed to me a beautiful business (and still doesn't). Part of what people generally seemed to mean about the beauty of the theory was the way anomaly cancellation conditions picked out 10d and a gauge group like SO(32) or E8xE8, together with the way conformal invariance picked out approximately Calabi-Yau spaces among all possible 6d spaces. Some people were quite taken with the beauty of the geometry of these Calabi-Yau complex threefolds. Algebraic geometry is a beautiful subject.

So, 20 years ago, at least some practicioners would have claimed that string theory was a very beautiful subject, with one of their arguments being the beauty of the Calabi-Yau condition in picking out an attractive class of algebraic varieties, one of which would soon explain all of particle physics to us. Fast forwarding 20 years, much of this "beauty" has collapsed, as it has become clear that to get anything that looks like physics, you can't just use a Calabi-Yau, but have to add in all sorts of ugly, complicated and poorly understood structure.

Sure, some beautiful things have been discovered about parts of string theory having nothing to do with its use as a TOE, but I still think you have to be delusional to think that these are "vastly" more beautiful than the maximalist claims of beauty for the theory that were being made back in 1985.

Perhaps like Urs you're also of the opinion that one can consistently claim that the ugliness problems of string theory come just from its solutions, not the theory itself. If so, see my response to him about this.

As for the rest of your comment, you seem to be objecting to my conclusion describing what, to me, are the most beautiful things coming out of work on string theory: things coming from 2d QFT and things that come from the discovery of various string/gauge theory dualities. That was a personal statement describing my aesthetic reaction to those things I have learned about by following research in string theory. No I don't claim to understand everything going on in string theory, and if you know of something you find significantly more beautiful than the things I mentioned and want to tell me about them, I'd be happy to learn something.

27. **Aaron Bergman**
August 7, 2005

Again, you miss the point. Our understanding of string theory has expanded. Expanded vastly, even. And, there has been a whole lot of beauty in those new areas that have been discovered. These are areas and directions that no one suspected back when string theory first became popular. As best I can tell, you don't disagree with any of these facts. Nonetheless, you seem so obsessed with the vacuum situation that you automatically interpret the statement that the field is vastly more beautiful as referring to that. Did the people in the early 80s suspect AdS/CFT? Did they suspect mirror symmetry? Did they suspect dualities? I could go on. Are these ugly ideas? You're attacking as 'delusional' statements that nobody has made.

> As for the rest of your comment, you seem to be objecting to my conclusion describing what, to me, are the most beautiful things coming out of work on string theory

I was objecting to your implication that various areas of beauty I mentioned were, in fact, just field theory and not string theory. You're welcome to find beauty whereever you care to look. What I dislike is when you misrepresent the facts of a situation (even when carefully worded to be technically correct) in order to score cheap points.

28. **Peter**
August 7, 2005

Aaron,

You're just repeating yourself and showing no signs of even bothering to read anything I write. You're continuing to go on about how I'm claiming that certain subjects are just field theory, long after I've repeatedly wasted a lot of my time acknowledging that some of these subjects are definitely string theory, not QFT and trying to be precise about which is which. I'll take your lack of response to my last question as at least indicating that we're in agreement that the most beautiful things to come out of string theory are various ideas about 2d QFT, and various examples of string/gauge theory duality.

You seem to agree that what I'm saying is technically correct, but you find it a misrepresentation of the "facts" of the situation. What's going on is that I have a very different interpretation of the significance of and lessons learned from a lot of the undeniable advances achieved in work on string theory over the last 20 years. If you want to argue against it, you're welcome to do so and we might both learn something. But you first have to at least read what I write and pay some attention to it.

29. **Aaron Bergman**
August 7, 2005

> One would naively expect that the effective potential strengthens at short distances due to the extra dimensions appearing; Do you know a quantitative estimate for the deviation from Newton and would experimental evidence that the potential actually weakens (relative to Newton) be a hint that string theory is wrong?

I don't know of any way to explain it with what we currently know about string theory (or field theory, for that matter.) Is it a hint that string theory is wrong? I don't feel that we understand string theory well enough to say. That's one of the reasons I'm not particularly enthusiastic about the attempts to do string phenomenology these days.

It would, however, pretty much rule out all the large extra dimension scenarios that I know of.

Peter,

George Bush never actually said outright that Saddam Hussein and Al Qaeda were linked, but he damn well implied it. That's the feeling I get from your argument here. Your careful wordings seem tactical and designed to give a wrong impression while remaining technically correct.

I've already mentioned what I find most beautiful these days: AdS/CFT and the topological string. In fact, it's exactly a subject on the intersection of those two that is frustrating me right now.

30. **Aaron Bergman**
August 7, 2005

No. String theory is the only known consistent *quantization* of a gravitational theory in more than three dimensions. There are plenty of different theories of gravitation. We know that the vanilla perturbative string gives supergravity in ten dimensions. Compactifications of this give gravity in lower dimensions.

The theory is not well-developed enough to be falsifiable (to my knowledge) by anything less than a probe of the Planck scale.

31. **Gordon**
August 7, 2005

Aaron,

You may always regulate gravity in the same way string theory is,
when you take the low-energy limit. The GR theory is sensible, and
even models string theory. What do you expect string theory to
be at scales below the Planck scale? You are not going to see all
of the states, but rather some theory that we call gravity (which
is regulated the particular way).

32. **Peter**
August 7, 2005

Hi Aaron,

If you're concerned about people who use wording designed to give the wrong impression, check out hep-th/0508034 by Michael Douglas, which just came out and which I just started looking at.

"we begin with compactification of the heterotic string on a three-complex dimensional Calabi-Yau manifold. This was the first construction which led convincingly to the Standard Model"

And, by the way, referring to string theory as giving a "consistent" quantization of gravity, somewhat strains the conventional meaning of the word "consistent".

If I'm behaving like George Bush, some others have to be compared to the Iraqi information minister.

33. **Michael Sanford**
August 7, 2005

Dr. Woit and Dr. Distler,

For the most part, I enjoy reading the differing opinions found on this blog. I have learned some interesting things as well. However, this flame war between the two of you is unprofessional. It does not put either of you in a good light. It is obvious that neither of you are going to agree on the subject of String Theory or about each other personally. So, can you two take the high road and agree to disagree?

I look forward to more spirited (but polite) discussion here.

34. **Gavin**

August 8, 2005

Peter,

I've been following your comments on several threads, and just want to make sure I understand. I would welcome any corrections.

QFT makes a ton of predictions about all sorts of low energy experiments once you pick the particle content, masses and couplings. There are many choices you can make, but there are some restrictions, the most obvious being that the theory has to be renormalizable and anomaly free. We actually have a set of particles and couplings, the standard model, which matches very well with experiment, and the theory is renormalizable and anomaly free. All very nice.

The only bad news is gravity, which is not renormalizable. Based on our current understanding of QFT, gravity should be left out. Opps.

String theory looks like QFT at low energies, so if we could find a "standard vacuum" that gives the right particle content and interactions, then string theory would be as good as QFT, although needlessly complicated. There is one advantage, however, which is that string theory predicts gravity where QFT recoils.

If we lived in ten dimensions, then we could do a lot better. With only a handful of string theories to chose from, it would be pretty exciting if the low energy spectrum matched the massless modes of one of the string theories. If the spectrum was different, then string theory would be out.

Living in four dimensions means there are tons of vacuums, so practically anything is possible. This makes it hard to see how string theory is any better than QFT.

Am I on track with this?

Gavin

35. **Aaron Bergman**
August 8, 2005

Wolfgang, do something about your wrapping, please. There's a preview right below the entry box.

> By the way, does anybody understand why and how M-theory compactifies to 4D ? And also why this compactification "stops?? at small distances? (Roger Penrose raises this question in his book.)

The better question to ask is, why do four dimensions become large, not why do however many become small. Everything was small at one point if you believe in the big bang, after all. Is there a definite answer to this question? No. There are plenty of attempts at answering it (Brandenberger-Vafa being the most famous, probably), but nothing is close to definite. It's an open problem. There are lots of them. I don't understand the second question.

If I understand Gordon's comments as being against the idea that you can get too many funky modifications to gravity in the IR, my response is that string theory has surprised us in the past and will probably do so again in the future. Given that there already are weird linkages between the UV and the IR in the theory, I'm not comfortable making definite pronouncements about anything.

For Peter, I'm not here to defend Douglas (whose philosophy on landscapy things I generally disagree with). The statement does seem weasely to me. I'll stand by 'consistent', however, unless you can point out anything inconsistent in string theory. Goedel's theorem, of course, tells us that anything consistent must be incomplete and string theory certainly is that.

(joke)

36. **Nigel Cook**
August 8, 2005

Gavin: string theory doesn't 'predict' gravity. General relativity is testable, string theory isn't. Eddington in his 1920 book Space Time and Gravitation counted 200 other speculative theories for gravity. None made testable quantitative predictions, so none were really science. If they don't make testable predictions, they are crackpot. Witten in Physics Today, April 1996, claimed that string theory 'predicts gravity' which is extremely misleading, as Penrose points out in The Road to Reality. This is the real crime of string theory, these distortions of the facts. They make it heavy going for everyone trying things outside string theory.

37. **Arun**
August 8, 2005

Something that Peter Woit wrote, about not trusting mathematical beauty to be a guide to the world, resonated with something I just read by biologist Sean B. Carroll. The context is how structure arises, and in particular varoius regular patterns arise, in a biological organism that starts off from a single cell.

> For several decades, mathematicians and computer scientists were drawn to the periodic patterns of body segmentation, zebra stripes and seashell markings. Heavily influenced by a 1952 paper by the genius Alan Turing (a founder of computer science who helped crack the German Enigma code in World War II), "The Chemical Basis of Morphogenesis", many theoreticians sought to explain how periodic patterns could be organized across entire large structures. While the math and models are beautiful, none of this theory has been borne out by the discoveries of the last twenty years. The mathematicians never envisioned that modular genetic switches held the key to pattern formation, or that the periodic patterns we see are actually the composite of numerous individual elements."

(From "Endless Forms Most Beautiful : The new science of Evo Devo".)

Not precisely on the topic of string theory, but I hope relevant nonetheless.

38. **woit**
August 8, 2005

Hi Gavin,

"Am I on track with this?"

In a word, yes. However, one important difference between the standard model and string theory is that in the standard model case we have a non-perturbative formulation of the theory (although there is an interesting caveat about chiral gauge couplings), whereas there is no workable non-perturbative formulation of string theory that includes the standard model as a limit.

39. **Aaron Bergman**
August 8, 2005

I don’t have Penrose’s book, so I can’t comment.

Bogdanovs on Wikipedia

August 6, 2005
Categories: Uncategorized

I've never really understood how Wikipedia works, especially how it protects itself from getting filled with nonsense. The entry about the Bogdanovs has evidently recently been the subject of repeated attempts by the Bogdanovs to modify it, one can follow the history here. This sort of thing seems to be enough of a problem that steps are being taken to prevent this kind of abuse.

Comments

1. **Nigel Cook**
   August 6, 2005

   Wikipedia stores previous versions of itself so changes can be indentified and reverted to the original easily if necessary. There is also a discussion facility for each entry where the rationale for a change can be argued. The battle is won by those nerds who have nothing else to do but keep changing or reverting entries to the way they want. So the Bogdanovs will probably win by sneaky tactics.

2. **Stan Seibert**
   August 7, 2005

   I also suspect the vast majority of Wikipedia articles are not controversial or "interesting" enough to attract the sort who would engage in such edit wars. Articles on slime molds and Happy, Texas aren't go to be targets for this sort of abuse. But when it's bad, it's really bad.

3. **JF Moore**
   August 15, 2005

   Never underestimate the penchant for control among some people.

   It's what keeps many forums moderated.

Strings on the Beach

August 6, 2005
Categories: Uncategorized

The KITP in Santa Barbara, a few steps from the beach, is running a semester long program on Mathematical Structures in String Theory that started this past week. Some of the talks are already on-line.

On the other coast, as part of the Simons Workshop at Stony Brook, Witten will be giving a talk at Smith Point beach on “Gauge theory and the Geometric Langlands Program”. This sounds like it might be very interesting and mercifully off the main topic of the workshop, which seems to be swamps not beaches.

Mathematics and Narrative

August 6, 2005
Categories: Uncategorized

A group called Thales and Friends, based in Greece and sponsored by MSRI, has organized a recent conference about Mathematics and Narrative that took place last month on Mykonos. Their web-site has abstracts of the talks and some other interesting material.

Update: There's an article about this in the Independent.

Comments

1. **Chris Oakley**
   August 6, 2005

   Hi Peter,

   Re: Mathematics generally: on my web site I say something to the effect that String theory belongs in the mathematics department (rather than physics). Obviously this is not the first time anyone has said this, but I am not confident about saying this: you have suggested on at least one occasion in the past that the study does not belong here either. Could you elaborate?

2. **woit**
   August 6, 2005

   Hi Chris,

   There are some parts of string theory, e.g. mirror symmetry, topological strings, conformal field theory, which could reasonably be characterized as mathematics. The people working on these subjects might even benefit from being in a math dept. There are many others though that certainly aren't mathematics. Some of these are perfectly good physics (e.g. AdS/CFT), others aren't even really physics at all (landscape studies), and there are some where you could argue about whether they're physics or not (string phenomenology, string cosmology, etc.), but they're certainly not mathematics.

3. **David Corfield**
   August 7, 2005

   The meeting is reported in a 2 page article in this week's edition of the journal Nature (4 August).

New Theoretical Physics Institute in Florence

August 8, 2005
Categories: Uncategorized

A new institute devoted to theoretical particle physics has been organized, the Galileo Galilei Institute for Theoretical Physics, which will be located in Florence. The purpose of the institute is to organize advanced workshops, the first of which will take place next spring. There will also be an inaugural conference next month. The institute is clearly modeled after the KITP in Santa Barbara, and its web-site design looks very familiar…

Panel Discussion Video

August 8, 2005
Categories: Strings 2XXX, Uncategorized

Video of the panel discussion at Toronto is now available, so one can hear some of the context of the comments that were reported in the recent New York Times article. As reported, the audience voted 4 or 5 to 1 against the anthropic principle. Unfortunately the camera was not on the panel during the vote, so one can't tell from this video how the panelists voted.

Some other things that weren't reported: while Andy Strominger commented that he saw no reason for pessimism, he also said he thought the odds were against any data relevant to quantum gravity or string theory coming out of the LHC. Steve Shenker said that he was very much bothered by the fact that it was starting to look as if one could associate some sort of "quantum gravity" dual to any quantum mechanical system whatsoever, so any notion of uniqueness was completely gone.

There were several skeptical questions from the audience. Someone with a Russian accent pointed out that it was becoming increasingly difficult to argue the case for string theory in the physics community, and asked what argument he should use in its favor. The panel didn't seem to want to address this, but Shenker finally said "Only consistent theory of quantum gravity". The next question wasn't really audible, but had something to do with "it's been 20 years". Shenker's response was something like "most of us don't want to think about this, we haven't done as well as in other 20 year periods". Later on someone asked "Can you imagine any experiment in the next 20 years that will falsify string theory", getting no real response except "You're not supposed to be asking that" from Shenker. Another question from the floor was about why none of the panelists had mentioned M-theory, which didn't get much of an answer except from Nathan Berkovits who commented that in particle theory problems not solved in five years stop being discussed.

In their speculation about the future, many of the panelists invoked the possibility of having to change quantum mechanics. From the floor Witten speculated that quantum mechanics was only valid in asymptotic regions of space time, with something different needed to understand the interior. Also from the floor Susskind speculated that the splittings into different universes of the many-worlds interpretation of quantum mechanics were the same as the cosmological bubbling off of different baby universes. Several panelists responded that they had no idea what he was talking about.

The emphasis on vague ideas about the foundations and interpretation of quantum mechanics led Martin Rocek to point out that there was one field of study in physics that had gone nowhere in the last eighty years: the study of the interpretational issues in quantum mechanics. Lee Smolin rose to the defense of this field, claiming that it had led to recent ideas about quantum computers.

Also now available online are videos of the public talks by Dijkgraaf and Susskind. Susskind tells the audience that there is a "War" or "battle of intellects" going on between two groups of physicists, which he describes as being "like a high-school cafeteria food fight". The two groups are the "As" (A for anthropic), and the "Es" (E for elegant). He describes the belief by the Es in mathematical elegance as "faith-based science", and says that they are in "psychological denial" about the existence of the landscape, then goes on to give the standard arguments for the landscape and the anthropic use of it to "explain" the value of the cosmological constant. He refers to belief in the existence of a vacuum selection principle as analogous to belief in the Loch Ness monster. He ended his talk by claiming that the As were winning the war, with the Es in retreat.

Dijkgraaf's talk was completely standard string evangelism, and except for a couple slides mentioning D-branes and black holes, could easily have been given, completely unchanged, twenty years ago.

Comments

1. **Kea**
   August 8, 2005

   "Steve Shenker said that he was very much bothered by the fact that it was starting to look as if one could associate some sort of "quantum gravity?? dual to any quantum mechanical system whatsoever…"

   Why should he be bothered? It's wonderful. That's the whole point. They just need to give up the idea that String theory is physics and there wouldn't be any anthropic problem.

2. **Dave Bacon**
   August 8, 2005

   While it is certainly true that David Deutsch began dreaming of quantum computers as a way to "test the many-world's interpretation" I'm not sure whether the connection between interpretations and quantum computers is all that tight. After this initial major step (Deutsch is the first to seriously consider the computational advantages of quantum computers over classical computers. His result with Richard Jozsa in 1992 was the result which set the quantum algorithm ball rolling.) there really has not been a huge amount of interaction between those who study interpretation and those who study quantum computation (with notable exceptions, for example, Chris Fuchs and Robert Spekkens)

   It's very interesting to hear people comment on modifying quantum theory. From a computer science prospective this seems very dangerous. The reason is that many of the modifications of quantum theory which we have been able to dream up, lead to modified quantum computers with pretty astounding computational abilities. Now, it could be that our universe does provide such strong computation, but there are definitely reasons to be very troubled by such a turn. See for example, Scott Aaronson's article, quant-ph/0502072: "NP-complete Problems and Physical Reality" for interesting thoughts on this matter.

3. **Wolfgang**
   August 8, 2005

   Just a really naive thought about this issue:
   The wavelength of macroscopic bodies is typically much smaller than the Planck length. One would thus assume that modifications of quantum theory for macroscopic bodies a la Penrose are possible if not likely.

4. **Quantoken**
   August 8, 2005

   Peter said:

   "In their speculation about the future, many of the panelists invoked the possibility of having to **change** quantum mechanics. From the floor Witten speculated that quantum mechanics was only valid in asymptotic regions of space time, with something different needed to understand the interior. "

   I wonder what makes them think so? And if QM is to be changed at certain small scale, what they are going to change it to? A QM with a different value of hbar, or no

QM at all but return to classical limit at small scale? I really don't know what Witten was thinking. QM is all about uncertainty principle. You either HAVE an uncertainty principle, which is QM, or you DON'T have an uncertainty principle, which is classical. It's a yes or no and there is no third possibility, so there is really nothing to be modified of QM, even at small scales.

It is also true that QM received far more rigorous experimental tests at microscopic scales than GR does. What needs modification at small scale is GR, not QM. Graviton, as a naive prediction of **quantized** gravity force, does NOT exist and does not need to exist. When people DO realize that graviton can not exist, then that's a death sentence for super string theory, since super string theory would have **wrongly** predicted the existence of graviton, something that just does not exist in nature.

Quantoken

5. **Robert**
   August 8, 2005

   From what I can tell from listening to the realaudio is that someone asked "Can you imagine any experiment…, that someone is Jan de Boer and the person with the Russian accent is Sergei Ketov oder Djordje Minic.

6. **Nigel Cook**
   August 8, 2005

   "… Susskind speculated that the splittings into different universes of the many-worlds interpretation of quantum mechanics were the same as the cosmological bubbling off of different baby universes. Several panelists responded that they had no idea what he was talking about."

   What a character Susskind is. Feynman, 'QED', says wavy electron orbits occur due to path integrals interference in the small atomic space, and in a footnote he says path integrals get rid of the problems with Copenhagen Interpretation. He could have added that it also gets rid of the many-worlds. Path integrals is useful, even if Feynman didn't derive the Schroedinger equation directly from it. Bohm did that using hidden variables in 1952, using chaotic brownian motion of electrons, caused by wave interference.

7. **Lee Smolin**
   August 8, 2005

   If, as is true, quantum computers were invented by someone seeking a way to test ideas about the foundations of quantum mechanics, then that is a pretty tight connection. What I see is that quite a few of the people working in quantum information theory (QIT) were and still are motivated by issues in foundations,besides those mentioned these include Anton Zeilinger, Lucien Hardy and many others. And while there are QIT people with no interest in foundations and foundations people with no interest in QIT, I observe quite a healthy interaction among people working in the two fields. But the point I wanted to make to Martin Rocek is much simpler. When we were students together people advised us to go into high energy theory rather than foundations of quantum theory because there would be much more chance for contact with new experimental discoveries. Looking back on the last 30 years, one would have to say that there were more opportunities for a theorist to propose new phenonomena that were confirmed experimentally in foundations than in high energy theory. And if the field turned out to spawn a whole new technology, then supporting the few theorists with the courage to think about foundations will have turned out to have been a good investment.

   And I agree that Scott Aaronson's paper is well worth reading.

   August 8, 2005

   Wow, I leave for a week and the Blog is filled with string propaganda. Peter's become a shill for blighted stringers 🙂

   -drl

9. **Fyodor Uckoff**
   August 8, 2005

   Somebody should really call Susskind on his deliberate confounding of the existence of a landscape [generally accepted, and no big deal — did anyone criticize Maxwell or Einstein because their theories admit lots of solutions?] and the anthropic principle. The idea that there exists a probabilistic vacuum selection principle just seems like the kind of thing quantum mechanics does for us all the time, and shouldn't be controversial. The Tye group at Cornell even have concrete ideas about how it might work, though of course their models are very basic so far. [See Tye's presentation at Strings 2005]

10. **Peter**
    August 8, 2005

    I think Susskind did address this in his public talk. He referred to the vacuum selection principle as "the Loch Ness monster", something that lots of people claimed to have seen, but no one actually knows anything about. If you know what the selection principle is, let's hear about it and see you use it to, like, select a vacuum. The Tye stuff is very far from being able to do anything like this, and I see no good reason to believe it ever will.

    Susskind would say that people like you are just in denial and engaging in wishful thinking. For once, I'd agree with him.

11. **Dave Bacon**
    August 8, 2005

    Hey Lee! I don't disagree that there isn't more talk between the interpretation crowd (whatever that is!) and quantum information science (whatever that is!), but when I think of the main results of quantum information science (Peter Shor's quantum algorithm for factoring, Lov Grover's quantum algorithm for searching, the theory of fault-tolerant quantum computation, quantum cryptography, and the main results of quantum information theory (Schumacher quantum data compression, entanglement concentration, etc.)) the results aren't "directly" related to foundational questions. On the other hand, most of the results and the people who invented them are extremely interested in foundational questions, I think. This is, I think, because a healthy understanding of foundational questions means leads one to a very good understand of what quantum theory is and what it is not. For example, in quantum teleportation, understanding what role a quantum wave function plays seems essential to making the jump to the protocol of transfering that quantum state using entanglement and classical communication. So the main results are unconnected to foundations, but by studying foundations it's easier to come up with results that cut to the heart of what quantum theory is! (And I say this with the caveat that some of my work has been motivated by interpretation questions, but this lead directly to something which feels very non-interpretational: the communication cost of simulating quantum correlations.)

    Peter, sorry for turning your comments into a quantum computing discussion, but, you know, I just couldn't resist 😉

12. **Dave Bacon**
    August 8, 2005

Oh, and as for my personal views, I'm very sympathetic to the notion that the foundations of quantum theory have something important to say about the problems of quantum gravity. Just what it has to say, however, is something else!

13. **Tony Smith**
August 8, 2005

Peter's blog entry said "… Witten speculated that quantum mechanics was only valid in asymptotic regions of space time, with something different needed to understand the interior …" and that "… Lee Smolin rose to the defense of … the foundations and interpretation of quantum mechanics … claiming that it had led to recent ideas about quantum computers. …".

Perhaps quantum theory does NOT need to be modified, but is actually a good alternative to conventional superstring theory as a "framework" for a unified physics theory.

For instance, in http://xxx.lanl.gov/abs/quant-ph/9512022 , Negative entropy and information in quantum mechanics, N. J. Cerf and C. Adami said:
"… Quantum information theory … allows for negative conditional entropy even though this is forbidden classically. This leads us to propose that such quantum informational processes can be described by diagrams — much like particle physics reactions — involving particles carrying negative (virtual) information. By analogy with anti-particles, we refer to them as anti-qubits. … This analysis suggests the possibility that a qubit (the fundamental quantum of information) could have an analogously defined anti-qubit (a quantum of negative information), formally equivalent to a qubit traveling backwards in time … this leads us to conjecture that these processes can be recast into reactions involving information quanta … described by diagrams, much like particle physics reactions. …".

Taking such an information – particle physics correspondence seriously is one of the primary motivations I have had in constructing my Clifford-algebra related physics models. It is a puzzle to me that Clifford-algebra physics models have not become a well-funded school of physics. AFAIK, the only work on Clifford-algebra physics models closely related to information theory (as opposed to just reformulating existing physics models in terms of Clifford/Geometric algebra) has been done by David Finkelstein and his students (I am one of his former students, and that is where I learned my Clifford algebra stuff).
Maybe there might be interesting socio-political reasons why Lenny Susskind's anthropic superstring stuff is well-funded with a horde of rabidly devoted followers, while David Finkelstein's Clifford-algebra stuff is largely ignored (and in the case of some of those who learned from him, such as me, even blacklisted).

14. **rof**
August 8, 2005

One question: Dan Friedan, a man who is, arguably, responsible for the present-day understanding of the relationship between string theory and gravity, says that string theory neither predicts gravity nor spacetime quantum field theory (see hep-th/0204131, which is cited on your home page, Peter). I understand that the relationship between string theory and gravity is "a matter of interpretation", meaning that the occurrence of something which looks like Einstein's equations as the condition for the vanishing of the beta function of string theory (prescribing reparametrization scale invariance of the world sheet) , has yet to be universally accepted as a secure indication of a consistent theory of quantum gravity (indeed, the successful reproduction of the Hawking entropy formula would hardly have been considered an additional successful accomplishment, if the "vanishing of the beta function implies general relativity" argument had already been fully accepted as a proof that the theory in question is a coherent theory of quantum gravity). Nevertheless, my question is instead about the claim that string theory reproduces spacetime quantum field theory as a consequence, at low energies. Dan Friedan claims that this is unproved. I have not seen anything which even claims to be a proof of this rather important statement. A senior string theorist (who shall not be named here, unless he cares to step forward and name himself) has told me that a proof was to be found in Green, Shwartz and Witten. I inspected the said tome and instead found a section which claimed that a proof would be too unwieldy to provide in such a slender volume, and that the correct procedure was to assume in advance that there was a QFT which corresponded to the low-energy limit of a string theory, and that merely matching the S-matrices of each sufficed (obviously, duh), to establish that one was the low-energy limit of the other. Now, you've read Friedan's article, and presumably GSW, so what's your opinion? With all due respect to everybody involved, I have never heard a coherent articulation of both the question and the answer from a single individual, apart from Dan Friedan, who advocates studying his own personal theory instead of string theory.

15. **Matti Pitkanen**
August 9, 2005

A comment concerning possible modifications of quantum mechanics mentioned by Witten and therefore belonging to the topics of discussion (as I dare hope).

At algebraic level the modification could reduce to a choice between different types of von Neumann algebras. Von Neumann algebras allow hyper-finite factors of type II_1 which differ from factors of type III encountered in Poincare invariant relativistic quantum field theories and from type I_n and I_infty factors encountered in non-relativistic quantum theory.

Hyperfinite Type II_1 factors emerge when you provide infinite-dimensional separable Hilbert space with spinor structure such that unit operator has unit trace. Von Neumann thought that probability interpretation requires this property and regarded factors of type III pathological. Unit trace could be defended also by the finiteness of quantum theory of infinite systems. These algebras emerge naturally when you have an infinite-dimensional configuration space with Kaehler metric and spinor structure (the space of 3-D surfaces in certain 8-D imbedding space, the "world of classical worlds", in the case of TGD).

The mathematics of inclusions of hyper-finite factors has a close relationship to that of conformal field theories, quantum groups, braid groups, knot and 3-manifold invariants, etc… The sequences of Jones inclusions of these algebras have interpretation in terms of sub-system-system inclusions. A model for topological quantum computation led to the idea about the quantization of hbar in terms of Beraha numbers so that hbar would become a characterizer of Jones inclusion and would be dynamical and quantized. Large hbar phase would be of obvious interest from the point of view of quantum computation.

A generalization of braid diagrams to Feynman diagrams suggests strongly itself together with a symmetry principle generalizing string model duality. Diagrams would be classified by the topology of the lowest genus two-surface allowing the imbedding of diagram and all diagrams with homologically trivial loops at this genus are equivalent to a minimal diagram characterized by its homology class for the miminal genus. The absence of homologically non-trivial loops has in TGD framework straightforward interpretation: there is no path integral over all possible 4-surfacace since configuration space geometry assigns an almost unique space-time surface to a given 3-surface identifiable as a generalized Bohr orbit. Almost uniqueness means the failure of strict classical determinism: this makes it possible to assign space-time correlates not only to quantum states but also quantum jump sequences.

I have been working out the consequences of this picture for more than year year with a particular emphasis on macroscopic and macrotemporal quantum coherence and understanding of dark matter as large hbar phase. See 'What's New' links of various books about TGD at http://www.physics.helsinki.fi/~matpitka/ and my blog site http://matpitka.blogspot.com.

Matti Pitkanen

16. **Fyodor Uckoff**
August 9, 2005

If you know what the selection principle is, let's hear about it and see you use it to, like, select a vacuum. The Tye stuff is very far from being able to do anything like this, and I see no good reason to believe it ever will.

Well, if you actually bother to read their papers, they do argue that their version of Hartle-Hawking selects the KKLMMT vacuum. Of course they are open about the fact that their methods are very primitive, but their results are sure a hell of a lot more impressive than Susskind's….which are what, exactly?

Susskind would say that people like you are just in denial and engaging in wishful thinking. For once, I'd agree with him.

So now you find yourself in eager accord with Lubos Motl and Susskind. If that isn't a warning sign, then what is?

17. **Thomas Larsson**
August 9, 2005

Vacuum selection is only a problem if you accept the premise that string theory has anything to do with quantum gravity. If the right problem rather is to quantize gravity coupled to the standard model in 4D, as experiments indicate, vacuum selection is not an issue anymore. But you have to do it right, of course, and not ignore anomalies, which we know exist already in 2D gravity.

Besides, I observe that mr FUckoff is either too incompetent to publish even a single paper on the ArXiv, or too coward to use his real name. Either way, I don't understand why anybody should care about his comments.

18. **Alejandro Rivero**
August 9, 2005

I think we should praise Toronto Committee, they started very slow, but they have made a very good work on availability of the talks.

As for these "20 years periods"… can anyone inform me what kind of milestom do they use? I count between 30 and 35 years since last batch of significant theoretical events.

19. **Alejandro Rivero**
August 9, 2005

(milestone)

20. **Peter**
August 9, 2005

Alejandro,

Everyone is using "20 years" to refer to the fact that it was the fall of 1984 – early 1985 when the huge amount of effort going into the study of string theory started. The last really big, successful new piece of our understanding of particle physics was probably the discovery of asymptotic freedom, over 32 years ago.

Fyodor,

In this war I agree with both sides. The As aren't doing science and the Es are in denial about what has happened. There's an obvious point of view under which they are both right….

Matti (or anyone else),

Please do not post here attempts to start off-topic discussions about things like your favorite alternatives to quantum mechanics. In this case, if you inside information about what Witten had in mind, it would be interesting to hear it, but otherwise please don't do this.

21. **Thomas Larsson**
August 9, 2005

From Peter's post I in fact got the impression that Witten was contemplating giving up QM, perhaps replacing it by something like 't Hooftian Planck-scale determinism. Instead, he pointed out the rather obvious fact that if your quantum theory is defined in terms of asymptotic data, things become murky if your spacetime does not allow for the right kind of asymptotia. He is probably worrying about the positive CC, which leads to de Sitter spacetime, which indeed has precisely this kind of problems. Witten made this point in [hep-th/0106109](hep-th/0106109), and I doubt that anything really has changed since then.

22. **Luboš Motl**
August 9, 2005

On my blog, http://motls.blogspot.com/ , you may find a discussion of the achievements of the interpretation of quantum mechanics research, and about uniqueness of quantum gravity and its compatibility with holography.

23. **Ben**
August 9, 2005

Please pardon my ignorance as a non-physicist reader of this blog, but WRT Shenker's comments that one can associate a quantum gravity model with any quantum field theory, should one take out of this that: (a.) there is no unique quantum gravity theory, (b.) one just needs to find the right field theory, or (c.) there is a unique theory of quantum gravity, but it won't be coming from string theory? I'm a bit confused…

24. **Peter**
August 9, 2005

Hi Ben,

You're not the only one who is confused about this, I think everyone is, thus Shenker's worries. See Lubos's blog posting that he mentioned for some comments about this, although I don't think they'll really answer your question.

The problem right now for the string theory program is that their best argument, that strings give a quantum gravity theory, suffers from the embarassment that, if correct, it seems to give an infinite number of quantum gravity theories. I think the standard hope from 20 years ago that string theory will lead to a unique TOE has now become essentially untenable (although Lubos does his best to come up with a scenario to rescue things). People have reacted to this in two ways

1. The anthropic/landscape scenario: there's an infinite number of possibilities out there, all we can do is study them all and see which ones can support life, then try and

get some prediction of something out of that.

2. Deciding that any attempt to connect string theory to a TOE is just premature, arguing that the existence of these string duals to interesting QFTs is one thing that makes string theory very much worth continuting to invest time in. Maybe once one learns more about string theory a path to a TOE will become clear.

25. **Lee Smolin**
August 9, 2005

Regarding quantum gravity and the foundations of quantum mechanics: it can only be good news if Witten, Lobus and other string theoirsts are finally coming to terms with the possibility that the problems of extending quantum theory to cosmology may force us to revise the foundations of quantum theory. This is a welcome development, as those in the quantum gravity world have been thinking about this for decadees and have already published several concrete proposals for how quantum theory may be modified to include cosmology. These include 1) 't Hooft, in his original formulation of the holographic principle and subsequent work. 2) Penrose's proposals for non-linear modifications of the Schrodinger equation motivated by quantum gravity, which by the way leads to real experiments. 3) Gell-Mann, Hartle, Butterfield ,Isham and other attempts to formulate a generalized quantum theory for quantum cosmology. 4) The proposal of relational quantum theory, by Crane, which in some ways anticipated the holographic principle, developed by Rovelli and others. 5) Quantum causal historeis, proposed by Markopoulou as an alternative formulation of quantum cosmology. 6) a hidden variable theory inspired by LQG, published by Markopoulou and myself, 7) reinterpretations of matarix models, including the BFSS model, as hidden variables theories, by Adler, Starodubtsev and myself and 8) proposals by Dowker, Sorkin et al related to causal sets.

Perhaps if string theorist get involved in this question they can do better; that would be very welcome.

So we don't have to debate how useful foundations research has been, so long as we agree that the problem of quantum cosmology forces us to revisit the issue. I would only suggest that anyone wishing to think about this problem woud do well to study the literature, as in any field of sciience, to learn about the good ideas already under development and to prevent repeating mistakes already made.

Lee

26. **Chris W.**
August 9, 2005

A reminder: Stephen Adler presented his ideas on an alternative foundation for quantum mechanics and quantum field theory in a book published about a year ago. A draft appeared on arXiv.org in 2002.

27. **rrtucci**
August 9, 2005

In my opinion,

(1)There is a good chance that Quantum Computing/Quantum Information (QC/QI)
can shed some important insights into Quantum Gravity

(2)QC/QI can be practiced in an interpretation neutral (i.e., shut up and calculate) way, following the standard rules of QM (i.e., no tinkering with its foundations). 99% of the QC/QI papers in arxiv are like that. So, it's misleading to imply at this point in history a big overlap between (QC/QI) and (Foundations of QM or Interpretations of QM)

(3)QC/QI can and will be tested in the lab MUCH sooner than String theory. Furthermore, unlike String Theory, QC/QI promises to yield useful devices.

28. **Aaron Bergman**
August 9, 2005

I completely agree with #2 and #3. But, especially #2. #1, who knows?

29. **Peter**
August 9, 2005

rof,

I realized I didn't respond to your question. I'll leave that one to the string theory experts, admitting that I'm not intimately familiar with every argument in Green-Schwarz-Witten. This isn't something I've ever thought much about, largely because the claim that at low energies string theory reduces to a QFT seems quite plausible. The time I've spent learning about string theory has been more devoted to trying to understand the claims about the theory that seem to me implausible, not the plausible ones.

30. **Scott Aaronson**
August 9, 2005

Regarding the question of whether quantum foundations has gone anywhere in the past 80 years: I think one needs to distinguish carefully between "results-oriented" and "non-results-oriented" research. The "results-oriented" side of quantum foundations typically involves either experiments or nontrivial theorems (even if the theorems seem trivial in retrospect — like Bell's Theorem, the Kochen-Specker Theorem, or the dense quantum coding theorem). The "non-results-oriented" side typically involves assertions that a particular stance toward the double-slit experiment is the correct one, and that if other people fail to see that, then it must be because they're too dense. I would characterize the results-oriented side as having made phenomenal progress (especially from the interaction with quantum information over the last 15 years), and the non-results-oriented side as having made zero progress (except when it 'accidentally' stimulates a result, similarly to how Mach stimulated Einstein's work on GR). I know that sounds like a tautology, but I think it's a useful tautology for choosing quantum foundations problems!

31. **rof**
August 9, 2005

Thanks, Peter. It would be good if a string expert can shed some light on the question. It seemed almost trivial to me as well that string theory would produce something like QFT at large distances until I read the article and thought about it a little harder. To say that it will look like QFT at long distances is really to extrapolate from short-distance physics to long-distance physics.

On the subject of revising the foundations of quantum mechanics, there are two senses in which one can read the word "revise". The writings of Heisenberg and Von Neumann are still among the clearest expositions of what quantum mechanics is all about. Somewhere over the last eighty years, a shift occurred in the attitude of physicists to the role of the observer. It's now considered common sense that the observer should be treated as just another part of the system, but for the founders of quantum mechanics, the observer played a crucial role.

Von Neumann said, in "Mathematical Principles of Quantum Theory" that one must always split the world into observer and observed, or else one proceeds vacuously, since the purpose of quantum mechanics is to provide relationships between the results of measurements, and without an observer, there are no measurements to relate to one another, and all that is left is empty formalism.

One important development in the foundations of quantum mechanics over the last eighty years has been the almost universal rejection of Von Neumann's (and Heisenberg's and Bohr's) understanding of what quantum mechanics is fundamentally about. It didn't come about because of a research program, though, but rather because of the gut feeling that every physicist has that the observer should play no special role in the theory.

32. **rof**
August 9, 2005

One other point: The purpose of examining the foundations of any subject isn't to produce new results and new technologies, but is rather to develop a clear understanding of what the subject is and why it is the way that it is.

If the foundations of quantum mechanics are dismissed as unworthy of study because studies of them haven't produced any new results lately, then this is like saying that elementary calculus shouldn't be studied because it hasn't produced any new results. The measure of value is inappropriate.

It might be argued that physicists have done very well over the last eighty years without knowing much about the foundations of quantum mechanics, so why start thinking about them now? Lee provides the answer in his post above: when it comes to cosmology, there can't be an outside observer, and so the present formulation of quantum mechanics is incompatible with the idea of taking the whole universe as a single quantum system.

33. **Nigel Cook**
August 9, 2005

Lee's seven promising options include one of causality and two of hidden variables. It would be nice to have a convergence toward consensus, which is vital to avoid a disintegration of the research-education infrastructure. Without consensus, it's very hard to teach with interest at lower levels, because it looks a bit like speculative gambling or the disintegration of central ideas. It would be nice to see some things unified carefully, like path integrals and some hidden variables. This is not regression to determinism, because you still have uncertainty, you just have a cause for it like chaos due to wave interference. 'Caloric', fluid heat theory, eventually gave way to two separate mechanisms, kinetic theory and radiation. This was after Prevost in 1792 suggested constant temperature is a dynamic system, with emission in equilibrium with the reception of energy. The electromagnetic field energy exchange process is not treated with causal mechanism in current QFT, perhaps if it was it would turn out to be the missing hidden variable needed.

34. **Kea**
August 9, 2005

"From the floor Witten speculated that quantum mechanics was only valid in asymptotic regions of space time, with something different needed to understand the interior"

I don't understand why people find this surprising. Asymptotic regions are, after all, what we are used to. Of course we want QM to hold in this domain, but we should also expect it to be extended (or 'altered' if you like) in a theory of quantum gravity. I don't think Witten meant anything complicated. Maybe someone could ask him.

35. **Dave Bacon**
August 9, 2005

Kea: Not surprising. Just (1) hard to do, and (2) not the main path advocated by the majority of theoretical physicists.

36. **Chris W.**
August 9, 2005

Nigel,

Lee Smolin referred to *quantum causal histories* and *causal sets*. He didn't use the loose term "causality".

37. **Not a Nobel Laureate**
August 9, 2005

This talk of the "need" to modify QM reminds me of the one-upon-a-time talk of the "need" to modify QFT to describe the Strong Nuclear force. Before the discovery of quarks/partons and the development of QCD and asymptotic freedom.

Will String Theory suffer the same fate as Regge Pole Theory?

It would certainly be interesting if someone could come up an alternative to QM that would survive the battery of possible experiments.

I'll admit to being rather "old-school". I still think that physics is an experimental science.

38. **garrett**
August 9, 2005

Hey Peter,
Have you considered starting a group weblog for physics phd's who don't like string theory and are actively pursuing alternatives?
-Garrett

39. **Tony Smith**
August 10, 2005

Not a Nobel Laureate commented:
"… This talk of the "need?? to modify QM reminds me of the one-upon-a-time talk of the "need?? to modify QFT to describe the Strong Nuclear force. Before the discovery of quarks/partons and the development of QCD and asymptotic freedom.
Will String Theory suffer the same fate as Regge Pole Theory? …"

As I have commented in another thread on Peter's blog:
"… David Gross said, in Chapter 11 of the book The Rise of the Standard Model – Particle Physics in the 1960s and 1970s, edited by Hoddeson, Brown, Riordan, and Dresden (Cambridge 1997): "… The bootstrap idea was immmensely popular in the early 1960s … it rested on the solid principles of causality and unitarity … It

promised to … provide a unique value for all observables … This is of course false. We now know that there are an infinite number of consistent S-matrices that satisfy all the sacred principles. …??. …".

It seems to me that the 20 years of Witten's superstrings (1984-now) is similar to the 20 years of Chew's Bootstrap (1950s-mid1970s).

Chew's Bootstrap fad did not end until the Standard Model emerged in the mid-1970s.

I doubt that Witten's superstrings fad will end unless or until an alternative model that is as connected to experiment as the Standard Model is recognized and accepted. Barring that (unlikely in view of the blogs and comments over the past few weeks) event, I expect that bureaucratic inertia will be sufficient for conventional superstring theory to maintain its dominant position for the forseeable future (at least through Lubos's retirement). From my point of view, that amounts to a New Dark Age of physics.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

40. **Matti Pitkanen**
August 10, 2005

Tony,

I am again and again astonished by the extreme orthodoxy of both string theorists and also many of those who do not like string theory. To me it looks utterly inconceivable that a theory created during first five centuries of physics and containing obvious logical paradoxes (mention only quantum measurement problem) could be final and that the only challenges would relate to purely technical problems of M-theory as Lubos argued in complete seriousness in his blog.

What also surprises me is the extremely hostile attitude towards new well-formulated ideas and theories making precise predictions when the authority provided by a formal academic position is lacking. It seems that all that we are allowed to do is to try to interpret casual remarks made by Witten or some other name. This extremely authoritarian atmosphere really brings in my mind dark middle age.

Quite concretely, for some time ago Science reported a statistical survey which suggests that rate of technological discoveries per capita was at maximum at thirties and has now reached the level of 1600 century. Although information technology was not included in the study, I tend to believe that the survey reflects the reality. Perhaps it is not accident that the shut-up-and calculate philosophy was fully established in physics after thirties. Together with the reductionistic and materialistic world view and heavy censorship this makes intellectual breakthroughs impossible at the level of collective.

Matti Pitkanen

41. **Fyodor Uckoff**
August 10, 2005

Anomalies Larsson said:

"Vacuum selection is only a problem if you anomalies the anomalies that string theory has anything to do with anomalies. If the right anomalies rather is to quantize anomalies coupled to the standard anomalies in 4D, as anomalies indicate, vacuum anomalies is not an anomalies anymore. But you have to anomalies it right, of course, and not ignore anomalies, which we know anomalies already in 2D anomalies."

What is the sound of one pot cracking?

Anyway, back in the real world, most string theorists do think that the landscape idea should be explored — see the very sensible remarks by Denef and Maldacena over at cosmic variance.com. That is a long, long way from endorsement of anthropic ideas. People are looking for a vacuum selection principle; the search has only just started, precisely in response to this situation. Prof Tye is outspokenly "misanthropic", and says so in his papers. No crisis, no big problem, unless someone can prove that there is something *technically* wrong with the whole vacuum selection idea.

42. **Quantoken**
August 10, 2005

"…unless someone can prove that there is something *technically* wrong with the whole vacuum selection idea"

Sure there is something technically wrong with the vacuum selection business. The problem is there is a huge gap of magnitude difference between the expectation value of these vacuas, and the value of cosmological constant. It's 10^120 order of magnitude difference. 10^500 vacuas is NOT nearly enough to allow at least one vacua with small enough value to be the correct one. For an analogy, there are 10^10 global population, but I can safely bet that you can NOT find even one single human being who is less than 1/4 the height of the tallest person, despite the huge population.

Let's say the order of magnitude of the energy density of the 10^500 vacuas observe a normal distribution, centered some where around Planck Scale, and the sigma is one order of magnitude. What's the order of one of them being 120 orders of magnitude smaller than "usual", i.e., deviate from the norm at 120 sigma? It would be roughly exp(-(120)^2/2) = exp(-7200) = 10^-3127. A value which is effectively zero when times 10^500.

And maybe some one can prove none of the vacuas can be lower than a certain threshold, which is well above CC. Then you are done with the vacua and landscape business for good.

Quantoken

43. **Alejandro Rivero**
August 10, 2005

"From the floor Witten speculated that quantum mechanics was only valid in asymptotic regions of space time, with something different needed to understand the interior??

Er, early string theoretists (pre-1985) used to say that their origins are rooted in S-matrix theory, which after all was supposed to be the Theory of asymptotic states.

44. **Thomas Larsson**
August 10, 2005

Alejandro,

As I pointed out before, Witten expressed similar concerns already in hep-th/0106109. The keyword "asymptotia" is used frequently both in this paper and in his comment from the floor.

It is remarkable that people like ‘t Hooft, Smolin and now perhaps Witten express doubts about QM. It must be a sign of some kind of crisis, mustn’t it? Let me emphasize that my opinion differ – I do not believe that QM needs any fundamental revision. No matter how wacky my comments may seem, they are in fact a logical consequence of taking both Fock QM and background independence seriously.

45. **Nigel Cook**
August 10, 2005

Thomas: the doubts are probably due to the untestable wacky ideas that some formulations of QM lead to, many-worlds etc. Nobody is going to disprove any part of QM which is experimentally established, but the frontier is at the interpretative boundary. To view Coulomb’s law with QFT as photon energy exchange delivering momentum to produce force is not serious physics, but to have baby universes bubbling off everytime a wavefunction collapses it!

46. **Peter**
August 10, 2005

Fyodor,

It’s just not true that “the search has only started” for a vacuum selection principle. For 20 years it has been clear that some principle was needed to explain which of the many Calabi-Yaus corresponds to the real world, and people have been looking for it, failing utterly.

47. **Peter**
August 10, 2005

Garrett,

Unfortunately I think I’m already spending too much time on the weblogging stuff, but I encourage other people to start other blogs, perhaps even group ones. It’s not that hard, but does take up time.

48. **garrett**
August 10, 2005

Peter,
I can sympathize on the lack of time. Right now you are the strongest voice in the world speaking out against string theory. But, as only one person, you have to carry this off and do all the work yourself. It’s not surprising that it takes a huge chunk of your time to constantly be debating the legions of string theorists. But, you don’t have to carry this flag yourself — there are other theorists out there who think string theory is a red herring. I’ll bet a few would be happy to contribute to a group weblog if you were to host it. Plus, right now, blogs are hot in the media, and group blogs get more attention than lone voices. So, I think you could host a group blog with minimal effort that has a better chance of influencing the direction of physics research a bit. On the technical side, it would just mean mirroring your existing blog and picking out a few researchers to post top level threads. Oh, and it would need a name.
-Garrett

49. **Alejandro Rivero**
August 10, 2005

One year ago in physicsforums we threaded a “quantum gravity haiku”, which can be interesting to mention here again… (on topic now!)

We asked, using classical gravity, for which radius will a test particle to sweep one unit of Planck Area in one unit of Planck time, when orbiting around a particle of mass M.

50. **cvj**
August 10, 2005

Garrett, I’m puzzled and saddened. Why is there a need for a group blog speaking out against string theory? Is there a group blog out there speaking out in favour of string theory? No. There are maybe three sites that are dedicated to regularly discussing results in string theory, and other blogs (such as cosmicvariance) that has some discussion of strings from time to time, none devoted to promoting any particular theory – there are certainly no group blogs of that nature.

You’re promoting the business of doing science by seeing who can shout the loudest? That’s very sad. Wouldn’t it be better to form a blog to do something *positive* where you might often calmly and rationally discuss the alternatives approaches to string theory, rather than existing purely in opposition to something? Come on. Let’s not demean ourselves as a community in this way.

-cvj

51. **Gordon**
August 10, 2005

I agree, Garrett, there is no need for another blog, especially
another site speaking against the string theory, however important
that it is.

52. **cvj**
August 10, 2005

By all means have another blog. Just have it for positive reasons, not negative ones. -cvj

53. **simplex**
August 10, 2005

here is Garrett’s original suggestion posted 9 Aug around 11PM

Hey Peter,
Have you considered starting a group weblog for physics phd’s who don’t like string theory and are actively pursuing alternatives?
-Garrett

I dont think such a blog, of people doing Quantum Gravity alternative to string, would necessarily “demean us as a community” as Clifford evidently fears.

I can see why Peter would not want to set up such a blog, it would have to be set up by one or more people who are ACTIVELY PURSUING ALTERNATIVES on a professional basis. One or more postdocs or young faculty who are involved with the main nonstring lines of QG research.

It would be better, if there were going to be one, for it to be set up by someone like Etera Livine who is a postdoc at Perimeter engaged in nonperturbative/backgr. indep. QG, also possibly in quantum computing.

Maybe if Livine happened to be friends with Willem Westra or Dario Benedetti (both at Utrecht) they could set up something like "Nonperturbative Coffee Table" analogous to String Coffee Table.
This would report on conferences and research gossip. Someone
in Loop cosmology at the postdoc level, maybe Parampreet Singh.

this is just a pipedream. not a real idea. but it would be nice to have
some regular source of news and views from young researchers in QG analogous to string coffeetable.

criticism of string, which Clifford seems to fear would dominate such a blog, would I think hardly be an issue. these people tend in my experience to be too busy with their own interests to bother criticising the string-that-be establishment. have to run, so must leave this
post in rough shape

54. **cvj**
August 10, 2005

Simplex, Do read my post again. You seem to have misunderstood it. Perhaps it was because you were in a hurry. That happens. Let me help you by repeating: I am advocating blogging postitively about alternative approaches and cautioning against blogs set up purely to be in opposition to a specific approach, which is rather different. You use the word "fear". Yes, I fear pointless and wasteful negativity taking over from positive and constructive discussion. I do not fear constructive criticism of string theory. I hope that your positive suggestions are implemented in some shape or form, since I for one would like to learn more about alternative approaches, for my own education about what other people are doing, if nothing else. This is an important quest we're all on; no good idea -in any field- should be wasted.

Best,

-cvj

August 10, 2005

About Garrett's suggestion:

First of all, in any case I can't do this. For one thing, while I think it's appropriate for my department to be hosting my current weblog, it probably wouldn't be an appropriate place to host a group weblog like Cosmic Variance. More importantly, the time and energy to coordinate the activities of several very different people would be significant. Especially if they're chosen for not wanting to follow the most popular path in particle theory, they're likely to have strong opinions about how things should be done, and dealing with this would strain my rather limited political skills.

What I 'd really like to see is just a lot more good people setting up their own weblogs, perhaps cooperating to the extent of coordinating with a site that aggregates content from many different places. Alejandro Rivero's physcomments.org is one version of this kind of thing.

As for Clifford's comment: I didn't interpret what Garrett had in mind as an "anti-string theory" site, but rather as a place for people interested in alternatives to string theory to be able to have a forum to exchange ideas. There's a strong feeling of frustration among the people I talk to who aren't happy with string theory about the lack of an active intellectual community that they can participate in. The only one that really seems to exist is the LQG community, to the extent that Simplex just assumed that this is what an alternatives to string theory weblog would be about.

Anyone should soon realize if they follow my postings on this site that I'm fundamentally a particle theorist, not a relativist, and don't see quantum gravity as the most fruitful thing to think about. There's not a shred of experimental evidence about quantum gravity, and little in the way of prospects for getting any during my lifetime. If you believe the most extravagant claims discussed at the Toronto panel, every QFT is dual to a consistent quantum gravity theory, so there is no lack of those. The real problem is not finding a quantum gravity, but finding a quantum gravity that simultaneously explains what is going on in the standard model. String theory became so popular because it promised a solution to this problem, a promise which has not been fulfilled.

I think Garrett and others share in varying degrees my point of view that what is needed is a much deeper understanding of the mathematical structure embodied in the standard model, and a frustration at how difficult it is to sometimes even get other theorists to acknowledge that this is a reasonable thing to be thinking about. Over the past twenty years the reaction I keep getting from many string theorists is that anyone who is still thinking about QFT itself is probably just not smart enough to be working on string theory.

Simplex, whoever he or she is (and by the way, I'm really tired of having my professional qualifications challenged by people who cowardly hide behind the cloak of anonymity) contrasts me to "people who are ACTIVELY PURSUING ALTERNATIVES on a professional basis" who he or she identifies with "postdocs or young faculty who are involved with the main nonstring lines of QG research". Well, believe it or not, there are people out there, actively pursuing alternatives on a professional basis, who aren't involved with the main nonstring lines of QG research. It's a difficult path to follow, largely because there is no active intellectual community to participate in, and much of the physics community, like Simplex, seems to believe that something that doesn't fit into string theory or LQG, like hep-th/0206135, doesn't count as "real" research.

So I think I understand what Garrett would like to see, and I would too, but the difficulties are very large. I've devoted so much time to making the case that string theory has failed as a way of understanding the standard model because I believe that the physics community is not likely to be willing to take an interest in speculative alternative approaches as long as the perception remains that "string theory is our best hope for a unified theory". Why should anyone waste their time on anything but the best hope?

56. **simplex**
August 10, 2005

sorry Peter, my mistake
didnt for a moment intend to challenge your prof. qualifications!
I see how my careless assumption that your research is
not on alternatives to string may have seemed insulting

57. **Peter**
August 10, 2005

My last comment crossed Clifford's, and his reminded me of some other points I wanted to make, especially since I think I'm very much in agreement with him. I don't think that setting up a purely "anti-string theory" blog is a good idea, and despite appearances, that's not what I intend this one to be. As I periodically remind people, "Not Even Wrong" refers to speculative theories that are not well-defined enough to be testable, and I'm all in favor of work on such theories. Such work is the necessary starting point for getting to a theory that is testable. My objection to string theory is not to its speculative or mathematical nature (I'm in favor of those), but to the way in which the field has both immunized itself against any honest evaluation of whether it is getting anywhere or not, and simultaneously made it difficult for other speculative research programs to get any attention.

I try to cover here newsworthy things that seem important to me. These include any news about experimental high energy physics, both any current experimental results and prospects for possible ones in the relatively near future. They also include a lot of material about mathematics, concentrating on those aspects of mathematics that seem likely to me to ultimately have something to do with particle theory. I'm frustrated that there's not more of this kind of thing to write about, unfortunately the area of overlap between mathematics and particle theory that seems most promising to me has had very few people working in it in recent years.

Probably about half the material here is about string theory, and much of that is negative. In my last comment I explained why it seems important to me to try and make the case to the physics community that string theory is not the "best hope" around for unification. It's also true that this is a form of journalism and the string theory story is one in which a lot of amazing things are happening. A novelist couldn't make up things like Lenny Susskind and the "high-school food fight" he sees himself engaged in. It's a fascinating story, I can't wait to see what will happen next, and years from now I think people will look back on this as a truly remarkably weird era in the history of physics.

Well, as an example of the kind of positive thing I think people should be paying attention to, a few days ago I reported that Witten would be speaking today at Smith Point Beach about "Gauge Theory and the Geometric Langlands Program". I should stop this and go listen to his talk, the audio of which has just appeared on the net. Also, should go and check to see if there's anything worth reading on the arXiv, and, yes, finish doing my laundry.

Simplex, just saw your latest comment. Sorry I misinterpreted your earlier one, my error for being overly sensitive about some things.

58. **garrett**
August 11, 2005

I've been out all day, and in coming back I see the suggestion I made has been digested, thought about, and in the end properly interpreted, which — just being a random commenter here — I'm very pleased to see. To elaborate a bit, and since Peter has a good idea of what I was suggesting but it isn't super clear, I want to give the background I had in my head when I proposed it.

I have a group of friends I talk with regularly who are a-religious, and we have a mailing list for random discussions. Sometimes the discussions that pop up are pointing out, making fun of, and/or just shaking our communal head at crazy religious stuff happening in our world. This provides a bond for the group, and some dark humor value. But the group overall is very upbeat and constructive. And more often discussions arise about new technological or interesting scientific developments. It's a good time. But the community wouldn't hold together without its common, and uncommonly held, bond of appreciation for science and complete lack of tolerance for religion in its worst forms.

This is what I had in mind when envisioning an a-string-istic group weblog. Peter's posts exactly capture the dark humor inherent in the dominance of string theory and it's inability to explain our world. But there needs to be a constructive side too. And there are many people, including but not restricted to people doing LQG, CDT, etc., working on alternatives. The sane ones hold two things as sacred: quantum field theory and general relativity. These, I think, include many of the people reading this weblog. And, looking among them, I see a lot of people holding threads that, optimistically, may be hanging off the same piece of cloth. Peter's manifesto suggests everything has to be about connections. Tony Smith sees Clifford algebra behind the standard model. Matti Pitkanen sees everything as related to CP2. I've seen how fermions can arise naturally as the BRST ghosts conjugate to gauge degrees of freedom in a certain formulation of GR. And Gordon, who I've known since we were undergrads, has a different angle on QFT. And all of these people (and I'm sure some reading this whom I've left out), working completely independently, have things that overlap significantly in their models.

And Peter, perhaps the strongest critic of string theory, does post constructive things in this weblog, so I thought he would best get the idea of what I'm suggesting. But, I'm afraid Peter is right and it would be intractable to moderate a group weblog involving such vigorously independent folk. It would be like trying to herd cats. The postings would more than likely digress to each person espousing their work and not looking into the work of the others. The same spark that drives these people to strike out on their own is the one that keeps them from playing well with others. So I can see it would probably just be ugly to try to gather a group of fierce individualists.

We can only hope that someone out there on their own working on crazy ideas will come up with ideas crazy enough to be true.

August 11, 2005

Don't abandon the idea entirely. Let it be a bit incoherent, that's ok. I think it would be great to have a place where someone (one or a few people) simply make posts on what is going on in the "alternative approaches" world, describing for the benefit of everyone what the idea is behind a given peice of work that someone has published, how it fits into the scheme of things, what it is trying to do, and whether there are connections with anything else. Nobody has to moderate it per se – let the cats do what they want in the comments; the posts will speak for themselves – it would still be of value to the entire community to have a place where people can know that alternative ideas are being showcased and discussed. It would relieve some of the frustration that people have because they percieve that string theory is running a closed shop – there'd be a place you can "gather" and have your own chatter, on your own terms – and it would be good for the stirng theorists too, since there'd be less of that random posting of alternative theories right in the middle of a discussion of something else. No matter the value of that alternative, it is hardly ever useful to do that – it just derails any discussion because it would take too long to digest the new material…but people do it. Now they can place a link to a discussion of it on another blog. Everybody wins! Garrett – just do it! It would be a valuable service if you keep high the scientific integrity and the quality of discussion. Start out doing it yourself and simply invite guests to blog from the blog platform every now and again. Some of them might then stay on if the fit is right.

August 11, 2005

I disagree with the notion that Peter is the strongest anti-string critics. Actually I think it's exactly the opposite. He seem to be rather strange in his stands. The strongest argument he ever presented against super string theory research, is that 20 years passed and it doesn't seem to be able to predict anything yet. That argument is rather weak and it hardly even convince himself that SST is wrong, and is easily refuted by noting that QG itself is a difficult topic and 20 year may just not be enough to make progress. There is indication that Peter himself believed **as much as most SST researchers** that there is possibility one day STT **MIGHT** come out all right and all figured out. And Peter nod his head in agreement and sing the praise song with the mob when SSTers point out that there's too much math beauty found in SST that simply could not be wrong. Clearly Peter believes that the argument of math beauty is so strong that he is persuaded by it, too. At the end of day Peter is really not anti-string, but merely complaining the lack of progress, which all but make him a member of the SST camp.

It is rather strange that Peter paid a tremendous interest in every single act of the top SST researchers, and every single word they utter, down to very details. For example he desperately wanted to know how 8 of the SST guys voted in a **behind door settings** (which to me sounds like a silly childish **religious ritual**.) Another example is he paid extremely close attentions to every thing Witten ever says or does.

If one truely believes that SST is the wrong approach that leads no where, then Witten etc are simply wasting their time and they are destined to go no where, and there is no chance they ever discover anything physically significant, then who would one pay **so much close attention** to Witten et al.? To the point that Peter almost looks like a dissiple of Witten as much as Tom Cruise is a dissiple of Ron Hubbard. Why?

62. **Tony Smith**
August 11, 2005

Garrett says:
"… an a-string-istic group weblog … would be intractable to moderate … It would be like trying to herd cats. The postings would more than likely digress to each person espousing their work and not looking into the work of the others. The same spark that drives these people to strike out on their own is the one that keeps them from playing well with others. So I can see it would probably just be ugly to try to gather a group of fierce individualists. …".

cvj says:
"… Nobody has to moderate it per se – let the cats do what they want in the comments; the posts will speak for themselves – it would still be of value to the entire community to have a place where people can know that alternative ideas are being showcased and discussed. It would relieve some of the frustration that people have because they percieve that string theory is running a closed shop … and it would be good for the stirng theorists too, since there'd be less of that random posting of alternative theories right in the middle of a discussion of something else. … Everybody wins! …".

As one of Garrett's cats, my opinions may be relevant, so here they are:

Garrett is correct that it is likely that the cats would "digress to each person espousing their own work". For example, although Matti (another cat) and I agree in using M4xCP2 as a fundamental spacetime geometry, Matti wants to vary hbar and I want to fix hbar as a constant. There is no way that Matti and I can devise a single model that does both at once, so on that point at least Matti and I could never arrive at a consensus model that makes both of us happy.

cvj says such a blog would "relieve some of the frustration" that I have because I do in fact "percieve that string theory is running a closed shop", which closed shop even extends to me being blacklisted from posting on arXiv.
I disagree, because even if such a blog resulted in the production of a consensus alternative model that all the bloggers (and the blog moderators) considered to be realistic, it could not be posted on arXiv if it involved
elements due to blacklisted people (including, but not limited to, Matti and me), and my frustration level might even be increased.

cvj also says "… it would be good for the stirng theorists too, since there'd be less of that random posting of alternative theories …". I do not disagree with cvj that conventional superstring theorists would be happier if alternative theories were hidden from their sight in a ghetto blog that they felt free to totally ignore.

In other words, cvj's remark "Everybody wins!" really means only that "Conventional Superstring Theorists win!".

In my opinion, the main real problem is that there is no mechanism in the physics establishment to evaluate alternative theories, such as, for example, by giving alternative theorists opportunities to defend their work before an establishment forum that would actually consider, criticize, and evaluate the alternative theories.
Given the current political structure of the USA physics community, I feel that it is unlikely that any such forum will ever be set up.

As I have said before, current conventional superstring theory has much in common with Chew's bootstrap theory, which was so socially powerful that even Gell-Mann was intimidated into apologizing that his quarks were not real, just mathematical abstractions that might be useful.
Chew's bootstrap theory remained powerful until the acceptance of the Standard Model, which emerged from Harvard and Princeton with the help of Kobayashi, Maskawa, and 't Hooft.
Until an alternative to conventional superstring theory is accepted by a similarly powerful group of institutions and individuals, it is clear to me that inertia will keep conventional superstring theory in power.
A ghetto blog such as suggested by cvj is highly unlikely to get any alternative accepted by such institutions and individuals, so I agree with Garrett that it is an impractical idea given the culture of the current physics community.

drl, your point is additional motivation to rethinking QM in the context of gravity, is not?

64. **Chris W.**
August 11, 2005

Tony,

There can be advantages to being in a ghetto, if you have intelligent company, and time to think about, develop, and discuss your ideas. Maybe this assertion reflects a prejudice of mine, which is that the problem (quantum gravity/unification) is suffering from a surfeit of formalism combined with a shortage of truly significant insights, lucidly expressed. In the end such insights may also be precisely what highest on Peter's agenda — a deeper understanding of QFT and gauge theory. Indeed, how could they not be?

(PS: I wonder if Perimeter Institute would be willing to host such a group blog?)

65. **rof**

August 11, 2005

DRL said:

Alejandro said:

> drl, your point is additional motivation to rethinking QM in the context of gravity, is not?

DRL is more accurate here, because the distinction needs to be made between gravity and cosmology. I can drop a book in a lab and see it fall and so it is necessary to incorporate gravity if I want to predict the results of experiments.

On the other hand, the quantum formalism, which essentially tells us to represent the state of the system under investigation as a formal sum of measurement results (hence a|up> + b|down> etc), is inapplicable to the universe as a whole, considered as it is in itself, rather than as a set of measurement results obtained by an observer.

Something must yield – either the notion of considering the universe as a whole system seen from the point of view of no observer, or quantum mechanics. Witten, 't Hooft, Penrose and so on seem to be suggesting that it is quantum mechanics that will yield. No doubt they have carefully considered the alternative and rejected it for good reasons which they consider too obvious to need mentioning.

66. **simplex**
August 11, 2005

getting back to the toronto panel video, it occurs to me to ask what happened after each time Lee Smolin spoke. I will go back and check. If there's a pattern, it might be interesting to notice as a way of gauging the receptiveness to ideas from outside, on the part of string theorists in a group. Maybe there's something quite different to learn from the reaction (who can say in advance?).

besides the exchange about quantum computing and foundations (connections between those two lines of research) there were two main instances I can remember.

One was when Smolin urged string researchers to put more effort into background independent reformulation–giving arguments why such a reformulation was urgent, possible, and could lead to testable predictions. this came quite early in the open discussion — around 1:09 to 1:12 (I checked–it was 1:08:45 to 1:12:25 by my counter.)

The other occasion I recall was, I think, after Jan de Boer raised the issue of falsifiability. this was about time 1:44. (I checked–it was 1:43:45) Replying to de Boer, Smolin spoke about predictions of modified Lorentz invariance coming out of LQG and possibly other non-string QG. And he mentioned two tests: one (AUGER) already collecting data and one (GLAST, Smolin didnt name it) scheduled for orbit in a year or so.

This is all I remember, may have to correct or add some significant detail after another hearing.

67. **Chris W.**
August 11, 2005

Another reminder, regarding the search for testable QG consequences: There is some recent work indicating that violations of Lorentz invariance associated with quantum gravity may be generically more acute than previously assumed, unless some sort of fine tuning — or symmetry — suppresses them. A paper following up on this work examines a well known supersymmetric model (Wess-Zumino) and finds evidence that supersymmetry can provide the desired suppression.

See hep-ph/0502106 and its cited preprints.

68. **Alejandro Rivero**
August 12, 2005

About that group blog… it is in principle possible to rent cheap web space with php scripting included, for instance my physcomments.org is lodged in aruba.it, a italian company, just to avoid local institution problems of the sort Woit insinuated above. Now, is there some interest on having such blog backed by a strong entity, as Chris seems to be suggesting?

Geometric Langlands on the Beach

August 11, 2005
Categories: Langlands

I've written a bit about the Geometric Langlands Program and its relation to physics here late last year, confessing to being confused about what it was supposed to have to do with N=4 supersymmetric Yang-Mills. Yesterday Witten gave a talk on the beach at the Simons workshop going on at Stony Brook. I've just finished listening to it, and it clarified things quite a bit for me.

Only having audio and no video is a bit frustrating, since not all the details of the equations get spoken, so sometimes you have to guess what the equation really is. In this case it's a bit charming since you get to listen to the seagulls, waves and kids playing on the beach in the background. Maybe at some point lecture notes will be posted, and presumably Witten is writing up a paper on this material that will appear sooner or later, at which point I'll try to get a better understanding of the details of this.

The idea seems to be to use a TQFT given by a twisted version of N=4 supersymmetric Yang-Mills, a slightly different one than the one studied by Vafa and Witten back in 1994. Then one does dimensional reduction using as 4-manifold a Riemann surface times the upper-half-plane, and ends up with a sigma model of maps from the upper-half-plane to the Hitchin moduli space of flat connections on the Riemann surface. The boundary degrees of freedom are branes, and the S-duality of the 4-d theory is supposed to give a duality at the level of the sigma model that corresponds to the fundamental duality one is trying to understand in the geometric Langlands program. The Hecke eigensheaves studied by mathematicians in this language are related to "magnetic eigenbranes". Witten makes use of Wilson and 't Hooft operators studied in this context by Kapustin, and also mentions some related purely mathematical results of my colleague Michael Thaddeus and his collaborator Tamas Hausel.

Jean Dieudonne

August 11, 2005
Categories: Uncategorized

Pierre Cartier has written a short biographical article about the remarkable French mathematician Jean Dieudonné. Cartier estimates that Dieudonné wrote about 80,000 pages of mathematics over the course of his career. He was a driving force behind Bourbaki, often taking on the bulk of the writing tasks. With Alexandre Grothendieck he co-wrote EGA, the huge foundational text on algebraic geometry (some people note that, considering the French meaning of his name, this text could be described as "God-given").

Comments

1. **D R Lunsford**
   August 12, 2005

   I was told in such a way as to believe it, that one of those "new math" Bourbaki tomes boasted about the lack of diagrams and heuristics to be found within – as if to say, knowledge must be gained in some exquisite way in order for it to have value. This is the heart of the string debacle. Academics have become exquisites.

   -drl

2. **Alejandro Rivero**
   August 12, 2005

   Yep, Bourbaki in some introduction boasts a bit about this, ie about not using didactics as a substitute of proofs. It aims, as Streater/Wightman, for precision.

   I can not think about any string book similar in style (nor precision) to the ones of Bourbaki, so perhaps it is a bad comparison.

KITP Weblog

August 11, 2005
Categories: Uncategorized

The KITP program on Mathematical Structures in String Theory has a new weblog associated with it where Andrew Neitzke has been posting summaries of the talks given there. The idea of having such weblogs attached to programs like the one at the KITP seems to be an excellent one, it will be interesting to see how it works out.

   FYI — I got a warning about an untrusted security certificate when accessing this site. (The URL's protocol is https.) I guess it's because the issuer is KITP, which is not a recognized certificate authority.

2. **Quantoken**
   August 12, 2005

   Chris:

   No no no. What you said is not true. I happen to know all the intimate details of HTTPS and have actually worked on a HTTPS based product that's being widely used. So let me explain what it is.

   The certificate your web broser received is not trusted because it is a root certificate (self signed certificate) sent over the wire. Which is WRONG way of implementation. Because any self signed certificate can pretty much be replaced by any machine in the middle, allowing easy man-in-the-middle attack and allow password etc be stolen.

   And it is not even a well formatted self-issued certificate!!! The certificate identity is not spelled correctly. The people who implemented this web site is a complete idiot. Even a dummy would know to buy a certificate from recognized RootCA, and do things in proper ways. This is the most bizzar HTTPS web site I ever see!!!

   Quantoken

3. **rof**
   August 12, 2005

   It's probably just because the site is new. A lot of sites use self-issued certificates during testing phases and only pay up to a third company later. I was at the KITP at the end of last year and their computer people seemed reasonably competent, although the wireless signal wasn't great.

4. **Quantoken**
   August 16, 2005

   Wrong again. See my latest comment on Lubos's blog.

John Horgan's New York Times Op-Ed Piece

August 12, 2005
Categories: Uncategorized

Today's New York Times contains an Op-Ed piece by science writer John Horgan entitled In Defense of Common Sense. In it, Horgan takes an iconoclastic view of this year's many celebrations of the 100th anniversary of Einstein's great work of 1905, writing "In the midst of all this hoopla, I feel compelled to deplore one aspect of Einstein's legacy: the widespread belief that science and common sense are incompatible."

Horgan stirred up controversy in 1996 with the publication of his book The End of Science, where he claimed that most of the big discoveries in science have been made, forcing scientists to instead engage in what he calls "ironic science". By this he means science done in a "speculative post-empirical mode", something more like literary criticism, where claims are made that can never be shown to be right or wrong. While he saw this phenomenon taking place in many different areas of science, theoretical physics was where he had his strongest argument, pointing to controversies over the interpretation of quantum mechanics which seem to never be resolvable by experiment, and especially to string theory, which he describes in a later book as "science fiction in mathematical form." Publication of his book made him rather unpopular in the science community and ultimately led to his leaving his position as an editor at Scientific American. At the time I thought he somewhat overstated his case, especially in trying to see the same pattern in a wide range of different sciences, but he had the insight and courage to put his finger on something very important that was going on in physics. Since 1973, the field has been a victim of its own success, suffering greatly from the fact that the Standard Model is just so good that it has been impossible to find experimental results that disagree with it, as well as impossible to find any convincing improvement on the model that would address any of the issues it leaves open. Horgan's critique of string theory was forceful and on target, although to me his depiction of Witten seemed unnecessarily personally unkind.

I have mixed feelings about this latest piece of his, both strongly agreeing and strongly disagreeing with his defense of "common sense". This comes down to what one means by "common sense". One aspect of common sense is basically the standard scientific method and the norms traditionally used by scientists to evaluate what is good science and what isn't. The sub-headline on Horgan's piece "Beware of scientific theories that can't be tested" involves this aspect. It's just common sense to be skeptical of people who are making grandiose and radical claims unless they've got some good evidence for them, and string theory violates this notion of common sense. But I'm afraid Horgan conflates this kind of common sense with a different kind of "common sense", the common sense about how the physical world behaves that is built into us based on the evolution of our species and our growing up in an enviroment where we interact with the world on a very specific scale of distances. This kind of common sense may not help us at all to understand how nature behaves at the atomic scale, near a black hole, etc., instead quantum mechanics and relativity are required, and these are subjects that don't fit well with our notions of "common sense", in the second of the two meanings. But even if they were initially counter-intuitive, both quantum mechanics and relativity were based on a wide range of detailed experimental evidence, something that overcame people's qualms about whether they were violating "common sense". Absent this kind of evidence, string theory is a very different story….

On a completely different topic, Lubos Motl has a posting about amazon.com censoring any criticism of a certain crackpot physics book. He's started a contest, grand prize $3.00, which people may want to participate in.

Update: Lubos seems to have trouble telling apart John Horgan and John Hagelin….

   'It's just common sense to be skeptical of people who are making grandiose and radical claims unless they've got some good evidence for them…'

   Eddington, who verified GR in 1919 wrote in his 1920 book Space Time and Gravitation, p. 152: 'The great stumbing-block for a philosophy which denies absolute space is the experimental detection of absolute rotation.'

   The best example of Einstein's problems was the twin's paradox, which is resolved by absolute acceleration, requiring general relativity, not special.

   It's the popularisations of relativity, based on out of date stuff, which discredit common sense. Or else they go with one 'interpretation' and quote Bohr (defending Copenhagen Interpretation wavefunction collapse) saying: 'Anyone who is not shocked by quantum theory has not understood it.'

   This means that commonsense approaches, like the simple mechanism for gravity that Feynman discussed in a 1965 BBC lecture (click my name), are not encouraged, even if they give more testable predictions than string theory, and are consistent with general relativity!

2. **GWB**
   August 12, 2005

   More and more pundits grab upon the oxymoronical phrase "common sense" to justify their weak arguments. Wisdom is valued precisely because, in the face of complexity, sense is never common. So when I read Hogan's Op/Ed this morning, I was turned off almost immediately by the use of the phrase "common sense". Advances in science must be arrived at through the scientific method. This isn't common sense, it's science.

3. **Arun**
   August 12, 2005

   "But I'm afraid Horgan conflates this kind of common sense with a different kind of "common sense??, the common sense about how the physical world behaves that is built into us based on the evolution of our species and our growing up in an environment where we interact with the world on a very specific scale of distances."

   I read Horgan differently. He's saying because scientists found that physics doesn't follow "common sense" in the above sense, scientists discard common sense altogether. That is, Horgan is saying that he recognizes the difference, while super string theorists, among other scientists, no longer do so.

   Namely, he says the following is the common exchange:

   Horgan: "Your theory is cannot be tested by experiment and so common sense leads me to say it is dead-end speculation"

   Scientist: "Quantum mechanics and relativity have taught us not to rely on common-sense".

4. **Nigel Cook**
   August 12, 2005

   String theorist: "Quantum mechanics and relativity have taught us not to rely on common-sense??.

5. **LM**
August 12, 2005

Ha! When I looked at Lubos's crackpot book on Amazon, it was paired with Weinberg's 'Dreams of a Final Theory'.

6. **rof**
August 12, 2005

"…a more convenient method of being defiant without any insight, viz., the appeal to common sense. It is indeed a great gift of God, to possess right, or (as they now call it) plain common sense. But this common sense must be shown practically, by well-considered and reasonable thoughts and words, not by appealing to it as an oracle, when no rational justification can be advanced. To appeal to common sense, when insight and science fail, and no sooner-this is one of the subtle discoveries of modern times, by means of which the most superficial ranter can safely enter the lists with the most thorough thinker, and hold his own. But as long as a particle of insight remains, no one would think of having recourse to this subterfuge. For what is it but an appeal to the opinion of the multitude, of whose applause the philosopher is ashamed, while the popular charlatan glories and confides in it?" – Immanuel Kant, Prolegomena

7. **Nigel Cook**
August 12, 2005

'Bohr was notorious for the obscurity of his writing. Yet … Bohr's obscurity is attributed, time and again, to a "depth and subtlety" that mere mortals are not equipped to comprehend. Perhaps disclosure of another editorial oversight will demonstrate my point. In a widely used compendium of papers on quantum theory, edited by John Wheeler and Wojciech Zurek, the pages of Bohr's reprinted article are out of order. This paper (Bohr's response to the famous 1935 Einstein-Podolsky-Rosen critique of the standard Copenhagen interpretation) is widely cited in contemporary literature by physicists and philosophers of science. Yet I have never heard anybody complain that something is wrong with Bohr's text in this volume. The mistake, it seems, is rarely noticed, even though it occurs in both the hard- and the soft-cover editions.

'When physicists failed to find meaning in Bohr's writings, no matter how hard they tried, they blamed themselves, not Bohr.'

– Mara Beller (Barbara Druss Dibner Professor in History and Philosophy of Science at the Hebrew University of Jerusalem, Israel):

"There is nothing new to be discovered in physics now, All that remains is more and more precise measurement."

http://zapatopi.net/kelvin/quotes.html

Note the date. Here we go again!

9. **Tony Smith**
August 13, 2005

Peter, you said:
"… quantum mechanics and relativity … don't fit well with our notions … of "common sense??, the common sense about how the physical world behaves that is built into us based on … our growing up in an enviroment where we interact with the world on a very specific scale of distances. …".

I disagree.
Quantum mechanics is absolutely required to explain such aspects of our environment on our scale as interference patterns from double slits, not to mention the radioactivity of glowing watch dials and the change of color (red to orange to yellow) of heated iron.
Relativity is absolutely required to explain such aspects of our environment on our scale as the constant speed of light.

The only difference between the concepts of QM and R and concepts recognized earlier in human history, such as a sphere, is that children were playing with balls long before humans did double slit and speed of light experiments.

In fact, I believe that QM and R could be taught to children very early if their parents and teachers would show them how to experience the relevant phenomena.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

10. **Nigel**
August 13, 2005

Tony: when they observe interference in the double slit experiment, how do you explain it? Young's explanation is that two light waves collide at a dark fringe, cancelling one another. Feynman says that nothing arrives at the dark fringes because the interference is caused by path interference with wave effects going through both slits even when just a single photon is used. So Young's interpretation is false and path integrals are right. This also disproves Copenhagen since they would have the wavefunction collapse when someone sees the light from the interference fringes, when in fact you have to account for the two slits affecting a single photon. I don't think Feynman used path integrals to explain the interference in his 1963 lectures, but he did after 1965.

11. **Arun**
August 13, 2005

Lubos Motl now has a post on John Horgan's essay; and it almost perfectly illustrates my point made a few posts above.

Horgan wrote :

"The strings (or membranes, or whatever) are too small to be discerned by any buildable instrument, and the parallel universes are too distant. Common sense thus persuades me that these avenues of speculation will turn out to be dead ends."

and as expected, to evade this, Lubos Motl goes into a paean of how well-accepted physics defies common sense (i.e., the physical intuition that everyday life gives us). He does not address the common sense idea that the reason we accept common-sense (of the physical intuition type) defying physics is because the experimental evidence is overwhelming; all that Horgan is pointing out is that string theory is deficient in the common sense idea of having experimental support.

IMO, Lubos Motl has also confused John Hagelin with John Horgan; and in general does everything he can, casting a wide net to examine all of John Horgan's beliefs, to avoid facing John Horgan's central point in this essay. The problem as always is that a person can be wrong on many things, but still right on one thing; the wrongness of all the other things does not provide any evidence on the one thing. This way of arguing is distasteful and resembles politicking more than scientific discourse. It resembles using Newton's theology to discredit his physics.

12. **Simon**
August 13, 2005

I agree with the points Arun just made. Can't think of anything to add.

13. **Chris W.**
August 13, 2005

On [Cosmic Variance]() Sean Carroll summarized some recent remarks of David Z. Albert which seem relevant here:

> After some hesitation, David decided to go, and thought very carefully about the talk he would give. I can't do justice to the precision with which he worded his presentation, but the basic message was essentially this: "When you are trying to figure out how the world works, there are two ways to proceed. One is to invent a story about Nature which serves to say something flattering about yourself. The other is to listen to the story that Nature itself tells, no matter what it may turn out to be. What you are doing is the former; science is the latter.??

Most appeals to common sense sound like self-flattery, or shallow appeals to conventional opinion. There is a core to common sense which is not self-flattery, and is also at the core of science: When you suppose some assertion to be true, ask yourself, "how could I check this, ie, how could I know if this statement was false?"

John Horgan is starting to sound like Gregg Easterbrook. When he says "I have also found common sense – ordinary, nonspecialized knowledge and judgment – to be indispensable for judging scientists' pronouncements, even, or especially, in the most esoteric fields" for what exactly does he take common sense to be indispensable?

14. **Alejandro Rivero**
August 13, 2005

"Common sense" is a buzzword in philosophy of the language, a science that usually gets interesting politic scents. It is not to be confused with "lore" or with "culture" (the "conventional opinion" Chris mentions), and it implies the ability to travel thought logic inferences. To put an extreme example, to swim across Euclid book should be considered an ability of common sense.

15. **Chris W.**
August 13, 2005

From Albert Einstein:

> The years of anxious searching in the dark, with their intense longing, their alternations of confidence and exhaustion and the final emergence into the light – only those who have experienced it can understand it.

This does not describe the experience of the confident, self-assured professional, or the ordinary man settled in his beliefs and secure in his application of common sense and generally accepted knowledge to the problems of living.

However, it describes the nature and depth of the problems currently confronting fundamental physics. Much (most?) of the general public is unimpressed and even repelled by such intellectual struggle, and prefers the calm effectiveness of competent professionals acting within their domains of expertise. Ask any physician, attorney, or business executive why they are often so anxious to present such a front, although the underlying realities of medical care, law, and business, not to mention many other fields, are quite different. The professionalization of science has put scientists in the same predicament.

16. **Peter Shor**
August 13, 2005

I'd like to defend common sense a little bit. Einstein's original derivation of the theory of relativity seems to me to use a lot of common sense (at least it uses intuitive reasoning of the type that somebody as smart as Einstein might consider common sense, as well as several decidedly non-intuitive already-verified facts about physics). And I suspect that people with enough experience in doing quantum field theory calculations can also make some progress using intuitive reasoning. If string theory is so far removed from our intuitive reasoning ability that we can't make head or tail of it, this may explain the current impasse in string theory.

17. **Luboš Motl**
August 13, 2005

Yes, I confused Horgan and Hagelin. That's painful but hopefully, others will understand that neither of these two Gentlemen is on the top list of my interests.

Sorry for the error and tell me if there are other errors.

18. **Arun**
August 14, 2005

Chris W. asked:

"John Horgan is starting to sound like Gregg Easterbrook. When he says "I have also found common sense – ordinary, nonspecialized knowledge and judgment – to be indispensable for judging scientists' pronouncements, even, or especially, in the most esoteric fields?? for what exactly does he take common sense to be indispensable?"

It would be nice to be able to ask John Horgan directly this question. The common sense as applied to the most esoteric fields is – where is the empirical evidence? – otherwise, those esoteric fields degenerate into theology. "I'm doing super-duper something which you ignorant rubes can know nothing about" is acceptable from a scientist only if said scientist can point to experiments that bear him out.

19. **finestructure137**
August 14, 2005

Hogan says"
"In the midst of all this hoopla, I feel compelled to deplore one aspect of Einstein's legacy: the widespread belief that science and common sense are incompatible."

Its preposterous to claim that this was Einstein's legacy. Horgan uses common sense to justify his argument while my common sense tells me that common sense is a term that doesnt have any definite meaning. If common sense is what is generally and appropriately called intelligence, it is the most important virtue of a scientist and no rational person can defy that in their study of nature. Nonetheless, one can acquire higher understanding and profound insight after persistence. If John Horgan is claiming that to be a bad thing then I must say that that he cannot really distinguish between science journalism and evolution of scientific ideas.
P.S I posted the same comment in Lubos's blog

20. **Andre**
    August 16, 2005

    You can read a response by Susskind on Edge.org.

21. **Alejandro Rivero**
    August 16, 2005

    A poor response. Susskind substitutes “common” by “intuitive”, or implies this translation in mouth of Horgan. Can anyone confirm or deny if Horgan does explicitly this equivalence? Susskind corrects himself two paragraphs below, after the main argument has been done under this equivalence.

    Worse, Suskind seems to tell that concepts as force and acceleration are in the intuitive range. (he uses the verbe “to grock”). I could buy about acceleration, but force?

22. **Alejandro Rivero**
    August 16, 2005

    On other hand it is a clue about what is happening with science. Instead of following mathematical and logical deductions, which is possible with common sense, they need to rewire towards the “uncommon sense” invoked in the title. No math anymore, finally the promised High Road that Archimedes denied us is available, just rewire yourself.

23. **Alejandro Rivero**
    August 17, 2005

    Oh my, finally I have got to read Horgan beyond the introduction and it is horrible, it changes his view of “common sense” two or three times along the article. And the best one he gets is from a notorious non-sensical defender of Darwin (poor Darwin gets bad defenders, that is politics).

Edgy Attacks on Horgan

August 16, 2005
Categories: Uncategorized

A commenter points out that the Edge web-site has put up John Horgan's recent New York Times Op-Ed piece about science and common sense, together with some quite hostile [responses to it](). I've already explained [what I think about Horgan's piece](), and I agree with some of the points of his critics, but I think their reaction to his quite accurate point that string theory is untestable is pretty remarkable.

John McCarthy, a computer scientists, writes the following bizarre paragraph:

"When Horgan says that string theory is untestable, he is ignoring even the popular science writing about string theory. This literature tells us that the current untestability of string theory is regarded by the string theorists as a blemish they hope to fix."

Ignoring the peculiar characterization of the untestability of a theory as a "blemish" rather than a serious problem, does this make any sense to anyone? McCarthy seems to be trying to make the argument that one isn't allowed to point out a problem with a scientific theory if the scientists involved agree it is a problem and say they wish they could do something about it.

McCarthy at least has figured out that string theory is currently untestable, unlike Lenny Susskind, who invokes the heavy artillery of big names to (seem to) claim that it is:

"Finally I must take exception to Horgan's claim that "no conceivable experiment can confirm the theories as most proponents reluctantly acknowledge." Here I speak from first hand knowledge. Many, if not all, of the most distinguished theoretical physicists in the world — Steven Weinberg, Edward Witten, John Schwarz, Joseph Polchinski, Nathan Seiberg, Juan Maldacena, David Gross, Savas Dimopoulos, Andrei Linde, Renata Kallosh, among many others, most certainly acknowledge no such thing. These physicists are full of ideas about how to test modern concepts — from superstrings in the sky to supersymmetry in the lab."

First of all, his parenthetical elaboration "" isn't quite right, Horgan never said anything about "cosmological eternal inflation", although he did criticize as untestable claims for the existence of "parallel universes". Susskind attacks Horgan's claim that string theory is untestable by claiming that he and lots of illustrious physicists have ideas about how to test "superstrings in the sky to supersymmetry in the lab". Note that Horgan never said anything about supersymmetry not being testable. The "superstrings in the sky" presumably refer to Polchinski's claims that in some of the infinite variety of possible string theory scenarios there are cosmic strings that might be observable. I fail to see how this counts as a "test" of string theory, since if, as is likely, astronomers don't see these things, that in no way shows that string theory is wrong.

After this piece of intellectual dishonesty, Susskind ends with the favorite tactic of string theorists on the losing side of an argument, the ad hominem attack:

"Instead of dyspeptically railing against what he plainly does not understand, Horgan would do better to take a few courses in algebra, calculus, quantum mechanics, and string theory."

Comments

1. **Simon**
   August 16, 2005

   I think there is something of a misunderstanding here. Maybe some string theorists claim that we can make testable predictions based on our current understanding of string theory, but some certainly acknowledge that at present we cannot.

   Perhaps I can explain why string theorists in the latter class react the way they do when some critics point out that there are currently no testable predictions. The reason is that this is a typical criticism of nonsense theories and religious explanations of phenomena – systems of thought where predictability is *not even acknowledged as a virtue*. String theorists are not such people, and understandably do not want to be associated with them; who wouldn't love to find a definite observational consequence of string theory?

   One may then decide (as you seem to have done Peter) that this wish is unlikely to be fulfilled, and theorists might better spend their time thinking about other approaches to particle physics if not quantum gravity. Maybe that's right …

2. **LM**
   August 16, 2005

   I think Lenny is now practicing what a prominent theorist once described to me as "Hollywood style physics".

3. **rrtucci**
   August 16, 2005

   Who cares about what is said on the Edge? I consider the Edge hilariously pompous, elitist trash, because it doesn't allow readers to post comments. That is THE WAY of the Internet, and any Internet publication that doesn't understand this, is certainly not on the Edge.

4. **D R Lunsford**
   August 16, 2005

   Well Susskind is behaving just like a scholastic philosopher. GSW is their *Summa Theologica*.

5. **Peter**
   August 16, 2005

   Hi Simon,

   In my experience most string theorists are well aware that they don't know how to make testable predictions, and that this is a big problem. I can understand this, as well as their getting upset if someone seems to be accusing them of not even being interested in having a testable theory. You're right, I happen to believe that the program they're pursuing isn't going to lead to testable predictions, so think people should give up and do other things, but it's a matter of judgement and reasonable people can disagree.

   But I have real trouble understanding the behavior of Susskind, Kaku, and some others, who bald-facedly deny the problem, and/or start twisting the meaning of what it means to make a scientific prediction to evade the problematic position they're in. Fundamentally I guess I think this is just dishonest, and shouldn't be tolerated in a scientific community.

6. **Tony Smith**
August 16, 2005

Peter, you say that you guess you think that "… the behavior of Susskind, Kaku, and some others … is just dishonest, and shouldn't be tolerated in a scientific community. …".

If you are correct (and I agree with you), then:
Does the fact that,
although they may be criticized internally as Lubos criticizes Lenny,
they are NOT disavowed by the conventional superstring community with respect to the general public and the politicians who provide funding,
imply that the conventional superstring community is NOT a scientific community, but is a political club whose purpose is to maintain its status quo of dominance of theoretical physics jobs and funding.

In turn, does that not imply that scientific methods, such as honest intellectual criticism of conventional superstring theory, are doomed to be ineffective in challenging the dominance of conventional superstring theory.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **The Original Simon**
August 16, 2005

Tony,
good analysis. indicates an important job for the press
(getting internal criticism out to general public and politicians)

8. **The Former (now Ex-) Simon**
August 17, 2005

Simon,

I'll take a guess that you are Simon Ross, welcome.
I hadn't realized you were posting here at Peter's blog.
Glad to hear your views.

9. **Peter**
August 17, 2005

Nope, not Simon Ross, a different Simon….

10. **Simon**
August 17, 2005

Well it's nice to be confused with a physicist as smart as Simon Ross!

Peter – I haven't followed Kaku's or Susskind's opinions on the future of string theory too closely. But I don't find Susskind's response to Horgan objectionable.

String theory is not a theory we understand well enough right now to make a prediction. I believe the physicists he lists are expressing their confidence that one day that will change and their ideas for how it might happen. The string theory they refer to is the hypothetical complete theory, rather than our present glimpse of it. One may not share their confidence in the existence of such a theory, or in our ability to find it.

As for Horgan, his argument against the testability of string theory is essentially that one can't do accelerator experiments at the relevant energy scales. Well this is really a bad argument. There are many ways even in QFT that observations far below the characteristic scale of the theory can tell you lots.

A spectacular example of this is the electroweak theory. The existence of strong interaction bound states allows one to observe beta decay without building an accelerator. From the kinematics one can deduce the existence of a massless neutral fermion, and then it's not such a big leap to the Fermi 4-point theory, which describes scattering very well at energies less than 300 Gev. At this energy, the theory violates unitarity, so one can wonder how to alter it so as to conserve probability. One starts adding particles with charges and couplings chosen appropriately. To be consistent with the success of the Fermi theory, one can show that you have to add a massive charged spin 1 particle to mediate the 4-point interaction (W). But then scattering of longitudinally polarized W's causes new unitarity violations, which require the introduction of at least 2 more particles. If one wants to add only 2, then there are just 2 options. One is a neutral massive spin 1 (Z) and a neutral scalar (Higgs). The other is a neutral fermion, and a neutral scalar. Picking the first option, one then chooses the couplings and masses to avoid unitarity violation in WWZ and vvZ scattering, and amazingly the result is the electroweak theory, with exactly the masses and couplings found from the spontaneously broken gauge symmetry analysis! The other option predicts the W mass to be about 50 GeV, which is ruled out again by experiments well below the electroweak scale.

I left out most of the details, but the argument is spelled out beautifully in a book called 'Introduction to Electroweak Unification: Standard Model from Tree Unitarity ' by J. Horejsi. Of course this isn't how the electroweak theory was found, but it does show that by thinking hard enough, one can sometimes learn about high energy physics from observations at lower energies. I imagine this is what people have in mind when they suggest that we can learn about string theory by looking at the CMB, or cosmic strings if they are found.

11. **Who**
August 17, 2005

I will be Who then.

(that is not a question)

12. **Who**
August 17, 2005

I liked Simon's statement very much and I thought that he might be a string theorist I could respect and trust. So I wanted to ask him a question.

for me a kind of test of a QG researcher is the quality of awareness and interest he or she shows in other alternative-QG lines of investigation.

A while back Aaron Bergman (in spite of the fact that I often dislike and disagree with what he says) impressed me positively because he was volunteering real interest in recent Ambjorn-Loll work in CDT type nonperturbative QG.

the kind of string theorist one wants to listen to is one who is not contemptuous and dismissive of other QG, especially (since string is perturbative) the background independent approaches. so many of them have some stock response.

So I wanted to ask this Simon (whether or not he is a real Simon and doing string, which is merely my guess) what QG alternative(s) to string do you find especially interesting or promising, if any?

13. **Simon**
August 17, 2005

Who – I'm sorry to disappoint you, but I'm just a lowly graduate student, and mainly I'm interested in the more mathematical side of string theory. I agree that one shouldn't be contemptuous or dismissive of other approaches to quantum gravity. But in all honesty I know very little about them. Perhaps someone can clarify for me why background independence is so important?

14. **Nigel**
August 17, 2005

'… what QG alternative(s) to string do you find especially interesting or promising, if any? '

What if nature turns out to appear boring or unpromising? What do you do then, if your expectations of an elegant or beautiful mathematical structure can't be fulfilled? If you look back, you see that nature is often unexpected. People didn't want evolution because it lacked elegance and beauty of creationism. If you don't know the answer in advance, can you afford to have prejudices?

An approach to QG which is the opposite of string theory, just a fluid Higgs pressure shielding mechanism, offers many testable (tested) predictions and solutions to other issues. It's amazing that people are so dismissive of alternatives to string theory.

Andrew M Wray, publishing editor of Classical and Quantum Gravity, wrote me a letter dated 14 July 1997 stating: '… we do not publish this type of article…' PRL, Nature, arXiv, and New Scientist didn't either, but Electronics World (60,000 circulation) and the cern server did 6 years later. Nobody in physics knows about it. The problem is, people were then and still are obsessed by superstrings.

Dr Bob Lambourne of the Open University wrote me on 23 April 1997: '… the ultimate "cause" of gravity is an ill-defined concept… Rather the issue should be "what kind of theory is best suited to describing a certain range of phenomena in broad conformity with our current knowledge…" At the present time such a discussion would probably focus on superstrings.'

Strings are therefore the only really rational way to even discuss quantum gravity. If you don't want to talk strings, you aren't serious. The physics community is sure about this for some reason. I won't bore you with my predictive, well tested model.

15. **Peter**
August 17, 2005

Hi Simon,

I agree that Horgan's argument, as stated, is too crude, or incomplete. His two sentences about the lack of testability

"My problem is that no conceivable experiment can confirm the theories, as most proponents reluctantly acknowledge."

and

"The strings (or membranes, or whatever) are too small to be discerned by any buildable instrument"

are both true, but the implication that the second sentence implies the first isn't correct. In Horgan's defense, the true situation here is complex enough that explaining it correctly to a general audience would take up the entire length of his Op-Ed piece. In this kind of very short piece, it's hard to not sweep a lot of complexity under the table.

Of course, if string theory really were a TOE, it should imply the full range of phenomena we see at low energies and you should be able to calculate them and compare these calculations to experiment. Horgan does ignore this point.

The true situation of course is that there is no well-defined theory, so one really can't calculate anything, at low energy or high energy. In the approximate versions of a theory that one has, one can do calculations of what the low energy excitations of the theory look like, and, basically, the problem is they come out wrong. I'll not here go into the long story of attempts to get the standard model out of string theory constructions, but the bottom line is that no one has gotten the full standard model in detail yet, no matter how complicated a construction they use.

Here's a more detailed version of what I take to be Horgan's argument, one that would avoid the incorrect implication in his simpler version:

"After more than twenty years of effort, no one has managed to come up with a consistent well-defined version of string theory that reproduces what is known about physics and makes further predictions that can be tested. One of the main reasons for this is that the conjectured fundamental excitations of the theory are too small to ever be directly measured, so we can't directly check the idea of higher dimensional fundamental excitations by going out and looking for them. String theorists have hoped that the existence of these higher dimensional excitations will have characteristic effects at low, observable energies, but so far this hasn't worked out at all. The most recent work on the theory implies that these hopes can never be realized, since the theory, if it makes sense at all, seems to have an infinite variety of possible low energy behaviors."

On the other hand, what Susskind writes is clearly designed to give the impression that a long list of distinguished people are full of ideas for feasible tests of string theory. This is simply untrue and Susskind knows it. You have to parse his words very carefully to see that he's not quite saying this. Again, I think this is just dishonest.

16. **Who**
August 17, 2005

Simon, thanks for your response. You say:
Who – I'm sorry to disappoint you, but I'm just a lowly graduate student, and mainly I'm interested in the more mathematical side of string theory… Perhaps someone can clarify for me why background independence is so important?

I would be happy if one or more others would discuss background independence. I will take a whack at it from the standpoint of a physics-watcher. There are several ways to respond, some of which you may find less persuasive than others. I won't try to fit the argument to the listener—I will just lay out several responses.

1. Gen Rel is background independent. So it is likely that any successful QUANTUM spacetime dynamics will also have to be.

2. Go read Smolin's recent paper "The Case for Background Independence" hep-th/0507235, which argues that it would help string theory resolve the landscape confusion and become more predictive if an effort were made to formulate it in a less background dependent way. I won't summarize his argument unless you ask. Ignore Motl's hostile paraphrase. Just read the introduction and conclusion sections of Smolin.

3. There are degrees of background independence. Gen Rel is B.I. in the sense that does not need a prior metric. (By contrast, stringy perturbative calculations require a prior metric to start from.) But Gen Rel is NOT as B.I. as the Triangulations approach that recently became prominent (Ambjorn-Loll, CDT, for instance hep-th/0505154) in the nonperturbative quantum gravity community.

Why? Because CDT does not assume that spacetime is a differentiable manifold, only that it can be APPROXIMATED using a path integral sum involving (triangulated) differentiable manifolds. This means that the continuum does not have to have uniform dimensionality at all scales.
It is not required have to have an atlas of coordinate charts. One can calculate in CDT and there are indications that it reproduces Gen Rel at large scale. But it DOES NOT ASSUME the manifold structure that Gen Rel assumes. Because it assumes less prior structure it is more background independent than General Relativity.

On the other hand, the various Stringy models, seem all to be LESS background independent than General Relativity. Indeed they seem on the whole to be PERTURBATIVE. So, well, maybe that does not interest you Simon but it is a stark contrast and, speaking personally, it gets my attention.

4. As a general rule, theories which assume less prior structure are on that account more predictive. If a theory is having trouble making unambiguous falsifiable predictions, one obvous helpful suggestion is to make it more background independent.

5. There ain't no absolute spacetime. Newton invented that idea (he called it the sensorium of God) and it prevailed since it is a technical convenience.

As soon as I post this I will think of something I said wrong or left out. But regardless of that, you are asking a good question and some sort of response is needed, so here is one to get started with.

yours truly,
Who

August 18, 2005

Peter – let me divide your (rather complimentary) paraphrase of Horgan's argument into two pieces. The first piece ends at "so far this hasn't worked out at all". The second piece is just the next sentence.

Imagine if in piece one, the expression "20 years" was changed to "3 months". I'm guessing you would no longer think the criticism was reasonable. It's really a judgement as to how long it's worth working on an approach that hasn't so far yielded concrete predictions. Presumably this depends on many other things, e.g. whether the theory has interesting mathematical spinoffs, whether other approaches are promising, etc. I don't want to get into those issues – I honestly have no idea how to decide what is the right amount of time to work on a theory like string theory. And I'm pretty sure Horgan has no sensible idea either. I don't find 20 years a shockingly long stretch of time.

The second piece concerns the landscape – the apparent plethora of consistent string backgrounds. You are right that it isn't too encouraging, and I think if it's correct (i.e. if these are indeed consistent string vacua) it could force us to change our idea of what we hope to get out of string theory. As far as I understand, this is the content of the 'east coast — west coast' debate. I don't understand this subject too well, but I don't see any reason to rush to the most pessimistic position.

To emphasize just how little is currently understood about the space of string vacua, note the tension between the statement that standard model-like vacua seem to be very difficult to find, and the statement that vastly many of them exist. To me this indicates that it's premature to ditch string theory because of the landscape.

By the way – I think I understand why Susskind tells Horgan to go take some classes. I suspect that people who say that extra dimensions are 'preposterous' would also think quantum mechanics and special relativity were preposterous if they understood them.

18. **Who**
August 18, 2005

Simon, glad to see you are still around! Have to leave (day at the ocean) in a moment, no time to read or respond to posts. However you asked about Background Independence issue earlier and I gave you my response—for contrast or whatever reason you might also like to glance at very different views on this at String Coffee, starting with a post by Robert Helling.
http://golem.ph.utexas.edu/string/archives/000621.html

Different notions of what background independence means arise there, defenses are thought of against Smolin's urging that string theorists work out a B.I. formulation. Concern is expressed that outsiders will be (naively or mistakenly) critical of string because of its background dependence, and so on. Interesting, if rather intricate, set of reactions to Smolin's hep-th/0507235.

19. **Scott**
August 18, 2005

Simom,

If you noticed Horgan did imply several times that QM and relativity are preposterous but that a wealth of experimental data makes that not matter. That was his main point that common sence reasoning should not be abandoned without good experimental reasons. The reason people started studying string theory was not because of some experimental result like the inability to discover motion throught the ether, the photoelectric effect, and the spectrum of blackbody radiation, but because the mathematical construct of string theory produced an unobserved massless spin 2 particle which previous failed theories to quantize gravity had also predicted to move particles along the geodesinc(or however its spelled) determined by the metric which the mathematical construct of string theory had no mechanicsm to produce. This slim "evidence" that string theory has something to do with nature has led to many "crazy" predictions of particles being one dimmensional loops, then the world having a bunch of extra curled up dimmensions and now that all sorts of branes exist. All of which, while possible, has no basis in the real world other then the fact that some people think the way to reconcile relativity and QM is to quantize gravity and string theory happens to contain a particle similar to the one usualy predicted when someone tries to do this and fails.

20. **Simon**
August 18, 2005

Who – thanks for the references. I'll do some reading!

21. **Peter**
August 18, 2005

Simon,

You're right that if people had only been working on string theory for 3 months no one would be complaining about its present state. Personally I waited about 16 years before starting to publicly complain about what was going on. But, sorry, 20 years (actually 21 and counting since the "First Superstring Revolution") is a shockingly long time for thousands of the smartest people to work on a speculative idea, given that not only have they not made any progress on using it to come up with a TOE, but they're much farther from their goal than when they started. I don't think anything remotely like this has ever happened in the history of physics.

If the landscape is correct it could "force us to change our idea of what we hope to get out of string theory"? How about calling a spade a spade and changing that to "force us to admit this idea has failed completely and we have to do something else"? One of the most annoying things about the way many string theorists express themselves is that they act as if it is completely inconceivable that string theory as a TOE is simply a wrong idea that will need to be completely abandoned.

Susskind's telling someone who was a senior writer at Scientific American for many years that he should go take a high school algebra class is just a stupid, juvenile insult, one that I recognize all too well from personal experience as a standard kind of thing some string theorists say when challenged about the problems of string theory.

22. **Simon**
August 18, 2005

Peter – I don't think it's really fair to compare current research to previous research in physics. It's not the same problem, and it's not such a surprise to me that as experiments at higher energies become more and more expensive, theoretical progress slows down too. I have a vague recollection that this slow-down of theory was even predicted by Feynman.

I agree with you that it could turn out that when we fully understand the landscape (if it exists), we'll have to give up on string theory as a TOE, but I have no idea if that's how things will go. In the meantime, I'm glad some people are trying to figure out if that's the situation.

I'm sorry you've had unpleasant experiences dealing with some string theorists. The reason I defended Susskind a little is that I also found Horgan's article obnoxious. Not because of anything he said about string theory though. Rather it's because he rather deviously uses 'common sense' as a rhetorical device when lost for a logical argument. As you said above, he makes a couple of statements about string theory which are true if interpreted charitably, but the implied logical links between them are absent. That works for me as a description of the whole article. It's just not good writing.

It's also arrogant and self-aggrandizing:
"Needless to say, I reject that position, and not only because I'm a science journalist (who majored in English). I have also found common sense — ordinary, nonspecialized knowledge and judgment — to be indispensable for judging scientists' pronouncements, even, or especially, in the most esoteric fields."

23. **Scott**
August 18, 2005

Simon I am not sure what you find arrogant and self-aggrandizing in saying that ordinary, nonspecialized knowledge and judgement (which is what he defined common sense as) is indespensible in judging various ideas even in esoteric fields. He goes on tell which parts of ordinary knowledge and judgement(common sense) are usefull, namely that things involving how humans behave are unlikely to be dirrect effects of a single cause and that extroardinary claims should require extraordinary proof(expirmental results).

24. **Dr. Cal**

Hollywood Physics

http://physicsmathforums.com/showthread.php?p=403#post403

FOR IMMEDIATE RELEASE:

ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

"As contemporary physics is about money, hype, mythology, and chicks," Ed Witten explained from his offices at the Princeton Institute for Advanced Study, "The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy."

Brian Greene, the famous String Theorist who will be played by David "the truth is out there" Duchovney, explained the plot: "String theory's muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone, and I win the Nobel prize for showing that M-Theory is in fact the dark matter it has been searching for."

Greene continues: "At first my character is reluctant to stop theorizing and start postulating, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he's doing in my soul, and he explains that the answer is contained in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. And he shows me God in all her greater glory, as he points out that we can make more money in Hollywood than writing coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler. I am quickly converted, and I agree to turn my back on String Theory's hoax and save Jessica Alba."

But it's not that easy, as standing in Greene's way is Michio "king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this" Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the "ironic" pretense his salary, benefits, and all-expense paid trips depend on. "WE MUST HOLD BACK THE YOUNG SCIENTISTS WITH OUR NON-THEORIES!! WE MUST FILL THE ACADEMY WITH THE POMO DARK MATTER THAT IS STRING THEORY TO KEEP OUR UNIVERSE FROM FLYING APART, OUR PYRAMID SCHEMES FROM TOPPLING, AND OUR PERPETUAL-MOTION NSF MONEY MACHINE FROM STOPPING!!" Kaku argues as he delivers a flying back-kick, "There can be ony ONE! I WILL be String Theory's GODFATHER as referenced on my web page!! I have better hair!"

But Greene fights back as he signs his seventeenth book deal to make the hand-waving incoherence of String Theory accessible to the South Park generation, senior citizens, and starving chirldren around the world. "Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket)," Greene shouts. "It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!!"

"Time travel is also theoretically impossible, but there's a helluva lot more money for us in flushing physics down a wormhole. Nobody knows what the #&#%&$ M stands for in M theory ya hand-waving, TV-hogging crank!!! Get it?? Ha Ha Ha! We're laughing at the public! We're the insider pomo hipsters! Get with the gangsta-wanksta-pranksta CRANKSTER bling-bling program!!"

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We'll all just have to wait!

But in the meantime, how do you think it will play out?

Will theories with postulates ever be allowed in physics again? Or will the well-funded, tenured pomo String Theory / M-Theory (Maffia-Theory) Priests send their armies of desperate, snarky postdocs and starving graduate students forth to displace and destroy all common sense, logic, reason, and physics in the academy? It must be so–for the greater good of physics, the individual physicist, and thus physics, must be sacrificed.

If you guys want to talk about quantum gravity please drop by blog (click on my name). I just started the blog recently and learning to keep it steady. (I deleted some comments left by some of you accidently-sorry)

Electric Dipole Moments

August 16, 2005
Categories: Uncategorized

Chad Orzel has interesting posts here and here about electric dipole moment experiments and their implications for particle physics. He claims that these experiments will ultimately be capable of getting down to three to four orders of magnitude below the current limits, and since they already put constraints on beyond the standard model physics, these results could be very significant.

Comments

1. **Thomas Larsson**
   August 17, 2005

   There was an article about "The Search for a Permanent Electric Dipole Moment" in the June 2003 issue of Physics Today. It is available online here, but you need to be able to log in. The results seem already to be difficult to reconcile with SUSY.

2. **Not a Nobel Laureate**
   August 21, 2005

   Is it an accident or a reflection of the field that the one post by Dr. Woit referring to actual experiments attempting to probe "beyond the Standard Model" generated the least comments.

3. **Peter**
   August 21, 2005

   I do try and write a significant number of posts about experiments relevant to particle physics, but you're right that these generally don't attract many comments, unlike the ones about the string theory controversy. However, one recent post did get even fewer comments, the one about Witten's talk on geometric Langlands. And that one was definitely not about something relevant to experiment….

4. **D R Lunsford**
   August 22, 2005

   Well I was going to comment, so now I will!

   One can think of the magnetic field as the "small" correction to the electric field required by Lorentz invariance and necessary for propagation. Likewise, one can think of the "bottom half" of the Dirac spinor in the std rep (which encodes the idea of antimatter) as the "small" correction to the Pauli 2-spinor required by Lorentz invariance and the necessity of propagation of the Dirac field (Klein paradox).

   The "small" part of the Maxwell field has no direct sources (monopoles) and so the lowest order manifestation is the dipole. At low energy it is possible to treat magnetic dipolar phenomena almost independently. Thus, the illusion of two theories, electrostatics and magnetostatics. What is the analogy in the Dirac theory? You can think about this for a while. (It should be clear that there is *no* actual separation of the world into matter and antimatter independently.)

Snowmass Workshops

August 18, 2005
Categories: Uncategorized

This week and next there are workshops at Snowmass on the particle and accelerator physics aspects of the proposed International Linear Collider (ILC). There's a new weekly newsletter and a new website devoted to the ILC project which has twice-daily updates from the Snowmass workshops. Kind of like blogging, except done by professionals. Soon every conference or workshop will have their official blogger (two ongoing mathematical physics ones that link to blogs on their website are at the KITP and at Oberwolfach. I really should write more about twisted K-theory here sometime….)

For more about plans for the ILC, and for a presentation about CERN's plans for the future, see the talks from the EPP2010 meeting at Cornell earlier this month.

In other particle physics news, the RSVP project at Brookhaven has been terminated.

Update: There's another collider physics workshop going on in the Colorado mountains, this one is at Aspen and is concentrating on LHC physics.

2. **Urs**
   August 19, 2005

   > I really should write more about twisted K-theory here sometime….)

   I'd enjoy reasding it.

   BTW, I was wondering about the following, but couldn't find the answer here in Oberwolfach:

   Given a space X, its K-theory is the set of homotopy equivalence classes from X to the space of Fredholm operators [Map(X,Fred)].

   One gets twisted K-theory from that by allowing these maps to really be sections of a Fredholm-*bundle* E associated to a PU(H)-bundle, [Gamma(X,E)].

   But noting that a map is just section of a -1 gerbe and a bundle-section is really the section of a 0-gerbe, it almost seems like there is a pattern emerging here.

   What would we obtain if we considered homotopy classes of sections of a Fredholm-structure associated to a PU(H)-*(1-)gerbe* (or a PU(H)-n-gerbe)?

   (Of course I am aware that it might not be totally obvoious what an associated gerbe is supposed to be.)

3. **Chris Oakley**
   August 19, 2005

   Re: the academic scandal – Ma seems to have failed to acknowledge that a graduate student has no status and that putting up with shabby or perceived shabby treatment by one's supervisor is part of the deal. Of course, when he threatened them with a lawsuit, they just closed ranks. What did he expect?

4. **Peter**
   August 19, 2005

   Quantoken and Chris,

   This is completely off-topic and I feel highly constrained in commenting in a public forum about something that has been the subject of a court case, since the last thing in the world I would want to do is to stir up renewed litigation over this issue. So I won't say anything about Shepp or Ma other than that my personal opinion, knowing most of the facts of the case, is that they're the ones in the wrong here.

   I can comment in more detail about Phong, who I know quite well and whose interactions with his students I've seen quite a lot of over the more than fifteen years I've been at Columbia. Phong is one of the best advisors of Ph. D. students our department has, one could easily make the case that he is the best we have. He works extremely hard at advising students, and is incredibly generous to them with his time and his ideas. He has had very many students, quite a few who have gone on to successful careers. He's a very straight-forward guy, and the accusations made against him are highly implausible if you know him and the student involved.

   The department did look into Ma's accusations carefully, and the people who did this are also people I know well and who have high ethical standards. Repeated attempts were made to find some way for Ma to complete a Ph.D. here.

   I'm afraid that's all I can say here about this story. Please don't post anymore about it here. It is off-topic, and I find it very frustrating not to be able to say what I think about the details of this and the people involved.

5. **Peter**
   August 19, 2005

   Hi Urs,

   Sorry, but I can't help you with your question, since I haven't thought much at all about the abstract point of view that you're asking about. The cases I've found twisted K-theory and gerbes useful involve specific equivariant projective vector bundles, not the abstract definition you ask about.

Peter

6. **Nigel**
August 21, 2005

String theorist Lubos Motl has a new post on the beauty of using maths to fight cancer: http://motls.blogspot.com/2005/08/beauty-of-math-vs-cancer.html

It makes a lot more sense to describe useful and potentially beneficial uses of maths with emotional words, than the usual propaganda of calling useless string theory elegant/beautiful. String theorists could become cancer theorists and actually do something useful. Hopefully they will when they finally grasp that strings are a dead end, wasting time and money! It is terribly tragic that the finest brainpower in the world has been wasted for over 20 years.

7. **Luboš Motl**
August 21, 2005

Dear Nigel,

let me admit that the word "beauty" was mostly referring to something else that you had to miss.

Of course I think that the beauty of string theory is much more striking than any beauty that can be found in the models you mention; on the other hand, these models may be more useful for practical applications.

All the best
Luboš

8. **Nigel**
August 21, 2005

Dear Luboš,

I am glad you are honest and admit that work in other areas are more useful for practical applications than string theory.

If beauty lies in the eye of the beholder then you are entitled to see strings like that. But my teachers told me the arts are subjective, since beauty is not really a testable scientific concept. This is because everyone sees beauty differently. But science is different, being based on quantitative facts, and no theory is worth anything until it has after survived experimental tests. This is why extra dimensions/strings cannot be viewed as science. There are other possibilities out there which are not treated as serious science because of the excessive attention on strings. Crackpot theories are crowding out some genuine alternatives to string theory because string theory itself is so hard to distinguish from a crackpot theory. One positive claim about string theory is that it has brilliant people working on it: but if you look back to the 19th century, many brilliant people worked on Kelvin's theory of vortex atoms, which turned out to be a dead end. So mistakes happen.

Best wishes,
Nigel

9. **Luboš Motl**
August 21, 2005

Dear Nigel,

it may be difficult for you to distinguish string theory from a crackpot theory. But one should notice that it is difficult to distinguish any correct theory from any wrong theory for anyone who simply does not have a sufficient intellectual capacity to understand the relevant questions.

So unless you're Nigel Hitchin, I highly recommend you to think about the implications of your ignorance. If you will think enough, one of your conclusions will be that you should be silent – or at least modest – about things that you have no chance to understand.

Best
Luboš

10. **Nigel**
August 22, 2005

Dear Luboš,

I'm not saying mathematics is not beautiful, just that it is ugly for you to keep sounding off emotionally about string theory. Science is fragmenting because most professors are locked into one particular idea which they defend emotionally like a girlfriend!

(Is string theory really more 'beautiful' than Franziska Michor, who you interviewed about the maths of cancer?) Applying the term 'beauty' to useless string theory shows a corruption of science.

If string theory is not tangible or even testable. It is like ESP and UFOs or aliens. To use propaganda like 'beauty' is just missing the point: beautiful equations can be wrong.

Please be aware I studied QM and general relativity and the beauty of those theories occurs where they have been checked by experimental tests. Einstein's views on cosmology were disproved experimentally, and his fault was pushing general relativity too far, by adding unobservables to make it model his prejudiced view of a static universe.

Luboš, I do not understand why string leaders become dictators of 'beautiful' speculative science, but that ignorance on my part is no reason to be silent. Any dictator can say his critics are ignorant of the hidden dimensions of his philosophy. Really, it is the not the critics who are really the ignorant ones. I've done some research and string theorists will not be objective enough to read it and let it be published and debated properly. It might be just as well, because they are so emotional about strings they aren't objective.

Best wishes,
Nigel

11. **Nigel**
August 22, 2005

http://news.bbc.co.uk/1/hi/education/3580742.stm :
'There are more pupils taking A-level psychology than physics – and if current trends continue, the declining science subject will be overtaken by sociology.'

I wrote about the fall in A-level physics uptake in Britain in the editorial/opinion piece for Electronics World, Oct 03. It coincides with the rise of superstring speculation at the top. Teachers can't do anything because nobody at the top listens, they say all critics are ignorant. At that time, the physics department of my local university, Essex, had just closed because there were too few students. All the string theorists who wrote letters in said (rudely) that Kaku's popular string theory book sold well, so I was ignorant. But that book had no maths or physics and may have been selling to people who also like crop circles and the paranormal, and whenever pushed, Kaku tries to use Dirac's tested equation – which is so beautiful he says it made him cry when he first saw it – to defend strings (entirely different). To have a dead end untestable theory at the top of physics sends out the wrong message to students: the whole subject seems like a dead end.

12. **Lubos Motl**
August 22, 2005

Dear Nigel,

string theory is beautiful in a different way than Franziska Michor – although it may be less different than one would a priori think. 😉 I've already written some texts about the beauty of string theory but let me add a few words.

String theory is beautiful because it makes the union between a diverse family of mathematical concepts and theorems inevitable. It is beautiful because all the potential inconsistencies always evolve in the right way so that all problems eventually disappear; something like that can't happen in a generic theory that would use the same or similar fragments to do calculations.

It is beautiful because if one studies an extreme limit, any potential singularity is always smeared out and fixed by a new kind of effect, new massless modes – much like if one follows the ideal curves of an ideal lady. 😉 It is beautiful because it unifies all good ideas in physics and all good ideas are naturally melting into each other in its framework. It is beautiful because it has been the generator of new striking physical paradigms such as holography. It is beautiful because it is so incredibly unique. Your comparisons with the other "beautiful but wrong" theories are completely ridiculous. The physicists have never had a theory as beautiful as string theory, and the only thing that you may show by disagreeing with it is your ignorance.

One may sometimes be confused what a beauty of physical theories means. But if one is not confused, then it's almost true that so beautiful theories just can't be wrong. Your attempts to make your opinions about string theory relevant – although, as you say, your knowledge does not go beyond elementary QM and GR – are completely ludicrous.

Thanks for your understanding
Lubos

13. **Nigel**
August 22, 2005

Dear Luboš,

Holography was invented by Dennis Gabor in 1947 and was not generated by ST. You are being misleading. Similarly, Witten in 1997 claimed ST 'predicts gravity', which is vacuous. ST doesn't give us testable predictions like GR. Everyone knows that any real success of ST would be in the news, and it is not happening.

To give a specific example, ST cannot give any information on the strengths of fundamental forces. I've seen defensive, arm-waving talk that gravity must be weaker than electromagnetism because it is spread over 10 dimensions not 4, but this vague argument gives no quantitative prediction. The earliest use of extra dimensions in GR in the 1920s spilled out solutions which seemed to predict Maxwell's equations (in tensor form) and give a unified electromagnetism-gravitational theory, but this turned out to be useless. Any unification requires an explanation of why the forces are different. The difference in strengths of weak nuclear and electromagnetism for instance is predictable from electro-weak theory, which is why that is a tested scientific theory.

ST shows no signs of being on the right lines. It has not a single tested prediction. Luboš, you are being misleading when you say: 'It is beautiful because it unifies all good ideas in physics and all good ideas are naturally melting into each other in its framework.'

This is the sort of emotional trash you find being used by crackpots to defend nonsense. ST doesn't unify anything properly, let alone everything. Quantitative tests are required to claim unification.

It is therefore fact, not my ignorant 'ludicrous' opinion, that ST is untested speculation. GR with a fluid source (Higgs field) and viewing Hubble's law as a spacetime recession (not just recession with distance but as time past, since both are equivalent in spacetime we observe) predicts gravity quantitatively using Feynman's pressure shielding mechanism. You demonstrate a love for ST, but that just makes it seem more crazy to most students, who see nothing but a love for mathematics detached from reality.

Best wishes,
Nigel

14. **woit**
August 22, 2005

NIgel and Lubos,
Stop using this place to carry on this kind of argument that leads nowhere. I'll delete any further similar comments here.

WMAP Status

August 22, 2005
Categories: Uncategorized

The WMAP mission has now been in place and taking data near the L2 Lagrange point for four years, with two more years still to go. Spectacular results from the analysis of the first year's worth of data were reported in Feb. 2003, and the second year's data was initially supposed to appear a year later, in Feb. 2004, but they're now a year and a half late. For some reporting on this, see this site with cosmology news. Just recently the WMAP team has put up something new on their mission status page, where they state:

While the first-year results were based mainly on temperature measurements, the continued mission operations are now primarily focused on the much weaker polarized signals – an invaluable "stretch" goal of the extended mission. Analyses of these weaker signals are more difficult and continue with steady progress. The data and results will be provided as soon as calibration and systematic error analyses have been completed, and the data files have been adequately documented for use by researchers.

Are they seeing the effects of gravitational waves in this polarization data? Anyone with inside information want to take advantage of the ability to post here anonymously and tell us what is going on? Or e-mail me, I promise to protect the confidentiality of my sources, even going to jail with Judith Miller if necessary.

   Why are they "keeping secrets"? Cosmologists just can't be trusted 🙂

   I'm assuming that light and gravity are related, and the effects are galaxy-local and solar-system local, and superimposed.

   -drl

2. **WMAP boss**
   August 22, 2005

   Let me use the anonymous character of this forum. We've looked at the polarization and gravitational waves data in detail and they perfectly confirm the string-theoretical scenarios of inflation. In fact, when we read the data carefully, they say "the opponents of string theory are incredible morons".

   We are a very careful team so we must still double-check all of our procedures and calculations before we publish the results. 😉

3. **woit**
   August 22, 2005

   OK, Lubos, thanks for the inside information. I'll carefully protect your anonymity….

4. **WMAP boss**
   August 22, 2005

   Thanks for giving me an alias and for protecting my anonymity, and happy wishful thinking!

5. **D R Lunsford**
   August 22, 2005

   It's obviously dipole moments associated with the various planes determined by life on Earth. It's the anthropic principle for real!

   -drl

6. **Fyodor Uckoff**
   August 22, 2005

   Jokes aside, it is simply incredible folly for the WMAP people to carry on like this. Far from establishing their credibility, they are undermining the credibility of the 2003 data release. Way to go guys. Not.

7. **D R Lunsford**
   August 23, 2005

   If there were simply a correlation with the ecliptic one would have reason to doubt their methods. But correlation with both the ecliptic and galactic planes makes one believe they are afraid to release the data because the Big Bang Inflator priesthood would be offended and they would be shown the instruments of torture.

   "E pur sono correlato."

   -drl

8. **Quantoken**
   August 23, 2005

   Obviously Peter is more interested in crackpot theories that explain the microwave radiation background of the milky way galaxy using gravitational waves, rather than the obvious fact that why some of the WMAP team members had to leave. There is no way they would allow release of data that could challenge the orthodox theory, nor would Peter tolerate it either.

   It's the natural **local** background, stupid!

   Quantoken

9. **woit**

August 23, 2005

I have no idea why some people are posting comments here about members of the WMAP being forced to leave or being unwilling to release data because it disagrees with one theory or another. If anyone has specific information about WMAP scientists being forced out, that would be interesting, but otherwise, stop repeating nonsense.

As for whether these scientists are willing to release data that doesn't agree with a theory, remember that they aren't theorists, so have nothing invested in any particular theory. If their data could kill the standard consensus cosmological model, I think they would be elated, since this would surely win them a Nobel prize. But before releasing this data, they might want to take the time to check carefully for other explanations.

I have no idea whether things are taking so long because the WMAP people are seeing something unexpected and exciting in the data, or whether they aren't and it is just a lot of work to carefully analyze the possible systematic errors in their results before releasing them. If anyone actually knows anything about this, let's hear from them. Completely uninformed attacks on the scientific ethics of the WMAP scientists will be deleted.

10. **D R Lunsford**
August 23, 2005

Two words: open source.

-drl

11. **mikejones**
August 27, 2005

The lack of openness about what is going on with the WMAP project is a problem. To their credit, the WMAP team gave some explanation for the delay. I'd be even happier if they gave even a rough time table for the next data release, however. Many other space science projects give weekly or at least monthly status reports. Take the other big player in cosmology these days, the SDSS; the SDSS team announce when new data releases will take place and the previous releases have been on time.

The WMAP satellite has finished taking all four years of observations as of this August. There is even talk of an extension of the mission for another four years. I predict that the reason for the delay is two-fold: (i) there is much more data to be analyzed, and (ii) the amplitude of the polarization signal is ~10% of the temperature signal. I am a fan of the standard cosmological model. After years of being labeled a branch of metaphysics (cosmology) it is nice to see that humanity is getting gaining a substantive understading of the size, shape, and evolution of the universe. If I had to bet, I'd put my money on the next WMAP release providing us with a stunning and resounding confirmation of LCDM.

12. **Kea**
August 27, 2005

"If I had to bet, I'd put my money on the next WMAP release providing us with a stunning and resounding confirmation of LCDM."

How much money?

13. **woit**
August 27, 2005

By the way, just to show that I'm not much of a cosmologist, what does "LCDM" stand for?

Not Even Wrong: The Book

August 23, 2005
Categories: Favorite Old Posts, Not Even Wrong: The Book

There's a project I've been working on for the last couple years that I haven't wanted to write about here until it was further along, but now seems to be a good time. I've written a book, also entitled "Not Even Wrong", and the British publisher Jonathan Cape is bringing it out in England, publication date March 16th from what I last heard. It will presumably appear later in the U.S., with the publisher here still to be arranged. Right now I'm putting some final touches on the manuscript, and hope to have a final version within the next week or so. You can take a look at the latest version of the cover art, and someone last night wrote to tell me that Random House in Canada has a catalog entry for the book.

The book contains material on several related topics, including a history of the standard model from a mathematically-informed perspective, a description of the history, current status and prospects of high energy accelerators and particle physics experiments, some of the history of recent interactions between mathematics and physics, a history of supersymmetry and string theory and attempts to use them to get beyond the standard model, comments on the notion of "beauty" in theoretical physics and on the sociology of how particle physics is pursued and supported, especially in the U. S.. There's also a section explaining exactly what the problems with supersymmetry and string theory are, making the case that these are ideas that have failed conclusively, together with an explanation of what the whole "landscape" controversy is about.

The story of how the book came to be is roughly as follows. I started writing it in 2002, and had something pretty well finished by the end of that year. Early in 2003 an editor from Cambridge University Press heard about what I was writing and stopped by to see me when he was visiting Columbia. He got interested in the idea of having Cambridge publish the book, but I think he had no idea of how controversial this topic was. During 2003 the manuscript went through a couple iterations of refereeing at Cambridge. The first round of referee reports included a very positive report from a non-string theory particle theorist, a non-committal report from a mathematician who works on things related to string theory, and an extremely negative report from a string theorist.

I'd been quite curious to see how a string theorist referee would respond to the manuscript, since I was pretty sure all my facts were right, and I assumed that they would have trouble recommending against publication of something without being able to show that it said something incorrect. This first string theorist referee was described to me as a "well-known mainstream string theorist". He or she dealt with the problem of not being able to find anything wrong with what I had written by claiming that arguing against string theory was like arguing against teaching evolution, and that "I think that you would be very hardpressed to find anybody who would say anything positive about this manuscript", using this as an excuse for only coming up with one example of something incorrect in the manuscript. By now I'm pretty used to the tactic that was used to do this, but at the time I was pretty shocked by it. A sentence I had written was taken out of context and one of the words was changed from a singular to a plural, allowing the referee to construe the sentence in a way that allowed him or her to claim I wasn't aware of some important developments in physics.

This experience convinced me that at least some string theorists were in far worse shape than I had imagined, suffering from the delusion that no one who knows what they are talking about could possibly criticize string theory, and willing to stoop to pathetic levels of dishonesty to maintain this point of view. I had off and on been worried that I was being too harsh in some of my criticisms of the behavior of string theorists, but after seeing this report I stopped worrying about this.

The Cambridge editor seemed to believe that the negative referee report lacked credibility, and that it even gave some evidence for the problems I was claiming existed in the string theory community. But for Cambridge to publish a book, a board of academics who act as advisors have to sign off on any decision. The editor felt that this round of referee's reports would not be enough to convince them, so the manuscript was sent out to two more referees, both theorists who have worked on string theory. It took quite a while for these reports to come back, and when they did, one of them was very positive and recommended publication. The second however was quite negative. This referee found nothing inaccurate to complain about, but said that while he or she agreed with many of my critical comments about string theory, basically string theorists were the ones who should be evaluating the theory, and Cambridge shouldn't be publishing the opinions of the likes of me. I couldn't really disagree with this; string theorists are the ones who should be critically evaluating what has happened in the field, but the problem is that they're not doing it.

At this point the editor still felt that he would have trouble getting approval to publish the book, and offered to try another round of referees, but this seemed to me a waste of time. String theorist referees were clearly willing to strongly recommend against publication even when they couldn't point to anything inaccurate in the book, and the way the Press works, it was unlikely to publish something over the strong objections of some very prominent people. I then circulated the manuscript to editors at several other university presses. Two of them wrote back that while they found the book very interesting and well-written, a university press just could not publish something so controversial.

A friend of mine then put me in touch with a prominent New York literary agent. Her advice was that, if the manuscript was extensively rewritten to remove some of the more technical discussion, she thought she would be able to easily sell it to a trade publisher. I had mixed feelings about this idea, since if I removed some of these more technical chapters, I would be in the position of criticizing string theory, while not giving the details of what the problems with it were. I had also sent the manuscript to a few quite prominent mathematicians and physicists to ask them for advice about what to do with it. This led to some very interesting e-mail exchanges that I learned a lot from. Finally I heard from Roger Penrose, who offered to put me in contact with his publisher, Jonathan Cape. The editor at Jonathan Cape decided that they would like to publish the book, and that they were perfectly happy with it having some technical parts (which, after all, were quite a bit less technical than much of Penrose's recent book, which has been a great success).

So, that's the story until now of the book. I'm certainly curious what reaction it will get when it is published, and of course hope that it will stir up a serious debate on the issues currently surrounding string theory. I also hope the book will provide some explanations of what has been going on at the interface of particle physics and mathematics that a wide range of people will be able to get something out of, from members of the general public with an interest in science and math to professional researchers in both fields.

Update: Commentary on this here, here, here, and here.

Comments

1. **Quantoken**
   August 23, 2005

   Peter:

   Do you really want to sell your book? Listen your cover art needs a total re-design. From an artistic point of view it's totally un-attractive. The color is monochrome and boring. There is no balance of the values and shapes, no harmony, no contrast. It's simply un-appealing and looks ugly. I must admit that blue is my most favorite color. But even to me, the pale blue just look so ugly to me that I wouldn't even touch it if I see it in a book store.

   Now, the physics part. You think those spiral shape resembles what people gets on a high energy collider? It's **laughable**. The Spiral shape, if it spirals inward, describes a picture where the charged particle loses energy by EM radiation and hence spiral inward. That's a classical picture which is proven wrong and be replaced by QM. And the small curvature radius tells the energy is low, not high. Get some thing real! Or use something totally different.

   Also, do not use the word "failure" on the cover. Negative words on the cover is a turn off. I would rather use something like "controversy", "debate", "paradox", or other words that ring a bell. Helps you sell your book.

And hide your name on the hinge side, not on the cover. Make the big title bold and red, not black.

Quantoken

2. **woit**
August 23, 2005

Hi Quantoken,
Thanks for the marketing and design advice, but I'm mostly leaving those issues to the professionals. If you look at the Random House link, you can see the original subtitle for the book, but I agreed with my editors that a more descriptive subtitle was needed. It's true that part of this book is about a not very inspirational story, which may limit its readership, we'll see.

The graphic is essentially a bubble chamber photograph, the designer didn't make up those spiral shapes.

3. **Quantoken**
August 23, 2005

OK, that surely looks like a bubble chamber photograph, in which particles do lose energy in decaying spiral orbits. But bubble chamber is an instrument for low energy study, it has nothing to do with today's high energy collider, which is done in vacuum chambers, not bubble chambers. And it surely has even less to do with string theory, which today still makes no connection whatsoever to anything in the particle world, low energy pr high energy.

So a bubble chamber really does not match the topic you want to describe.

Better to use a favorite **toten** or icon the string theorists love to use. I do not know what it could be. But presumably something that must be drawn in 10-D space, not a 3-D image 🙂 And maybe an image of a alchemist sort of thing, too?

Quantoken

4. **sunderpeeche**
August 23, 2005

Quantoken is correct in both postings above. I recognized the cover as a bubble chamber picture and my first thought was "that 1960's stuff" ~ out of date. You should be able to get a nice picture of tracks from a collider event. While it is true that you may not have (much) control over the graphic art, who decided to use a bubble-chamber picture anyway? (probably a file photo?) Probably someone not as well-informed as you on modern physics.

It is also true that words like "failure" will be a strong negative. Are you trying to write a negative or positive viewpoint? Your post above has a much better subtitle, why not use it? "… a history of the standard model from a mathematically-informed perspective, a description of the history, …"

Subtitle ~ "A history of the Standard Model of particle physics from a mathematically-informed perspective with sociological commentary and prospects for the future" (this may be too long … omit "with sociological commentary")

Remember that it is the cover that sells the book, whatever the merits of your text may be. People won't open it if the cover doesn't appeal.

One further point — the preface must be well-written (you don't have a preview of the preface, so one cannot comment on your text). For those who pick up the book, the next step is to read the preface. The preface is the second selling point of the book. It must be good.

5. **Chris Oakley**
August 23, 2005

Well done, Peter! I am proud that it was my nation that was able to help you get this into print. It's about time.

<aside>Mind you … your experience does show you how the system works. Get one of the "big guns" to support you (Penrose in this case) and you'll be fine … otherwise, forget it. </aside>

The fears about the preface, by the way, are unfounded, if the January 2005 copy of the manuscript I have is anything to go by, anyway … the book is compelling reading from beginning to end.

6. **The Anti-Quantoken**
August 23, 2005

Don't listen to them, Peter; the cover art is cool, and the negativity is *precisely* what you are going for. This is an attack on string theory! You're done mincing words; the theory is a failure, a failure so far removed from valid science that it's Not Even Wrong, right? I don't know what planet Quantoken is from, where seeing a negative word on a book cover makes people cry and wet themselves, but when I see a book call a popular and well-regarded theory a "failure," I want to read that book.

Congratulations on your success. I'll be buying a copy.

7. **Tony Smith**
August 23, 2005

Peter, you say, about your book:
"… The first round of referee reports included a very positive report from a non-string theory particle theorist, a non-committal report from a mathematician who works on things related to string theory, and an extremely negative report from a string theorist. …
… the manuscript was sent out to two more referees, both theorists who have worked on string theory. It took quite a while for these reports to come back, and when they did, one of them was very positive and recommended publication. The second however was quite negative. …".

With respect to that I will quote from an e-mail message that I received some time ago:
"… retrospective studies have shown that the folks who went on to make truly big breakthroughs, get Nobel prizes, etc. , usually did NOT get all excellents when their ideas were first coming in for review at NSF. More typically, they get a MIX of excellents and poors. Much more can be said… but excluding work based on a kind of "min norm" aggregation of comments is one of the best ways to move towards total mediocrity and zero real research productivity. … The problem of Local heresy and Local conventional wisdom is very serious in every branch of science and engineering I have tracked. …".

Tony

8. **Cameron**
August 23, 2005

Peter,

Last month's issue of Discover spotlighted spring theory. The editors asked Michio Kaku to respond to criticisms that string theory is not testable. In the article, Michio describes several upcoming experiments that would provide indirect evidence in support of string theory, depending on what kind of data is reported. Have you read it, and if so, what is your opinion? Looking forward to your book,

Cameron

9. **woit**
August 23, 2005

Cameron,

I wrote about that article when it first came out, see

http://www.math.columbia.edu/~woit/wordpress/?p=219

I've talked to some people associated with Discover magazine who suggested I contact the editor there about them publishing some sort of rebuttal to the Kaku piece, but, to be honest, I just haven't had the time to follow up on this.

10. **Scott**
August 23, 2005

I aggree with the anti-quantoken, the cover art looks cool, and most people won't really care that it is a bubble chamber and not a vacuum chamber, the point is that it is experimental data(at least i am guessing thats the point) which is what science should be based on. Anyways, I can't wait to buy a copy of your book.

11. **Who**
August 23, 2005

this is really great news
also i like the cover art and the revised title a lot

12. **woit**
August 23, 2005

Sunderpeeche,

A significant part of the book is about history, so the bubble chamber photo seemed appropriate to me. For a while Cape was suggesting a cover with a geometric sort of figure of the kind that Calabi-Yaus tend to inspire. I argued against that and for an image coming from a particle physics experiment, partly because my point of view is that the wealth of experimental evidence and successful theory concerning particles is likely to be much more important for future progress than untestable ideas about quantum gravity. I pointed them to a database of these kinds of images, and the designer chose the one they thought would work best as a book cover.

The book has both negative and positive aspects and I think the current subtitle reflects that. It's far from simply a criticism of string theory. But the editors and I felt that the subtitle should both indicate what the book was about and not be mealy-mouthed. The current version agressively leads with the controversial part of what I am saying, but I'm happy to stand behind that.

13. **a.spring**
August 23, 2005

So, who have you signed for the movie version?

14. **rof**
August 23, 2005

I agree with Anti-Quantoken. The occurrence of the word "Failure" in the title will help sales in this case. String theory has become a household name, so news of its failure will be more striking to bookshop browsers than the idea of yet another history of physics.

A google search for "Woit" and "Failure" produces a coincidentally relevant result.

Incidentally, it would be nice if somebody (you're somebody, Peter) collected the reactions of string theorists and non-string theorists to the book and presented them side by side on the web. Not for the sake of rebutting their criticisms, but just to see if there really is a statistically significant correlation between being a string theorist and hating the book. Presenting the reactions of non-string theorists who are competent to address the issue (Penrose is good for a start) will allow you to refute the argument which will be presented by string theorists, namely that only string theorists are intelligent enough to make judgments about these matters.

15. **D R Lunsford**
August 23, 2005

Well done Peter!

-drl

16. **woit**
August 23, 2005

rof,

I edited your comment so it has the correct link to the page I think you were mentioning. Pretty funny. As far as I know, D. Woit is not a relative.

17. **Chris**
August 23, 2005

I’m with the Anti-Quantoken. The cover art looks good and the word “failure” guarantees sales! I’m buying a copy when it comes out.

Do you plan on providing an online version before book publication? Seems the thing to do nowadays.

18. **woit**
August 23, 2005

Chris,

Cape is a commercial publisher and trying to make some money at this, so I’m sure they don’t want me making the book freely available. When it gets closer to the publication date perhaps I’ll get together a web-page for the book which may include some material from it, such as the table of contents and preface.

19. **Johannes Weickert**
August 23, 2005

I’m very pleased to learn you’re working on this book! It’s going to be near the top of my reading list.

20. **anon**
August 23, 2005

Lubos:

Mr. President, you know what a good Junior Republican I’ve been, what with voting for you (if I could), and poo-pooing global warming and women’s brains and liberal commies… Now, it is I who needs your help. Could I borrow Carl Rove for a small job? The background of a certain book author needs some clarification in the media. I don’t mean to take Carl away from the Cindy Sheehan case. It would just be a part-time loaner.

Bush:

Well, of course, Lubos. You’ve earned it. Maybe, in return, you could give a talk at my Bible Studies class about the latest Physics theories: String theory, Intelligent Design, etc.

21. **Alejandro Rivero**
August 23, 2005

Following the horizontal line between NOT and EVEN, and about 1/8 from the right margin, there is a decay event of a neutral particle into a pair of charged ones. The V of the pair points towards the main collision point, so one can assume the particle has been produced there and travelled by about one half of the width of the word WRONG. Just for curiosity, can anyone identify it?

(ah, does compulsive means the same that compulsory? I guess not.)

22. **Tom Weidig**
August 23, 2005

Hi Peter,

I like the title page fine.

But I am not sure putting up a comment by Roger Penrose is appropriate.

In fact, he is a good example of exactly what you seem to be fighting against namely theorists that go wild and spread theories that are not even wrong.

Roger Penrose has put forward a theory of consciousness that is not even wrong (to a greater extent than string theory), and especially his “partner-in-crime” Stuart Hameroff has been pushing their agenda with a lack of any reasonable sense of scientific enquiry.

On the other hand Roger Penrose’s achievement in standard theoretical physics are of course outstanding.

Best wishes,
Tom

23. **Who**
August 23, 2005

(ah, does compulsive means the same that compulsory? I guess not.)

no, it means “Compelling reading”
but it does not sound good to some people to have two consecutive gerunds (“…ing”).

Penrose made a bad literary choice to get away from “two ings in a row”

He should have bitten the style bullet and said
“Compelling reading”

24. **woit**
August 23, 2005

Hi Tom,

On the whole, how the book gets promoted is mainly up to the publisher, although if I really disagreed with what they were doing and told them so, I’m sure they’d change it. In this case I’m happy to have Penrose’s support and think it will probably be effective in getting many people’s attention.

A point I continually have to make is that I’m in no way opposed to people working on or promoting speculative ideas that are “not even wrong”. At this point in history, particle physics desperately needs new ideas. Any really new idea is likely to start off in a form where it is so poorly understood that no one knows exactly what its implications are or whether it will ever lead to solid, testable, permanent scientific knowledge. Penrose engages in lots of different sorts of such speculation, and I suspect that most of this ultimately won’t lead to anything, although in some cases he may end up having really been on to something (my best bet would be on twistor theory, where some day someone may figure out that it is a very important piece of the story of how internal and space-time symmetries get unified).

The problem with any particular “not even wrong” speculation only arises if it completely takes over a field and drives out other competing attempts to come up with new speculative ideas. I don’t think any of Penrose’s work shows any signs of causing this sort of problem.

25. **LM**
August 23, 2005

Hey Peter, is your publisher going to send Lubos a review copy?

26. **woit**
August 23, 2005

I was going to make sure they sent the other LM a review copy, but he has just posted a review of the book on his blog, so I guess I don’t need to. At least I get two stars….

27. **Lubos Motl**
August 23, 2005

Congrats, Peter. It’s a great idea to earn some bucks, although not exactly the most moral one. Based on the discussions on your blog, it is pretty clear that there are thousands of morons who are dumb enough that they will like the kind of arguments like “string theory is like intelligent design” and clap their hands. Well, I’ve encountered many of them already, and assuming that at least 10% of them can waste 50 bucks for an apparently useless book, you’re gonna be a bit rich. 😉

One more thing: you don’t believe that the string theorists are never asking important, conceptual, and philosophical questions, do you?

28. **woit**
August 23, 2005

Hi Lubos,

Judging from traffic on my weblog, a large fraction of the people who buy the book may be string theorists, and while there are a lot of them, I fear that there aren’t enough to make me rich.

Not sure what your last question is about. Sure I think string theorists are asking important, conceptual and even philosophical questions, but just don’t think they’re coming up with good answers or even promising ways of getting good answers.

29. **Wolfgang**
August 23, 2005

Peter,

I see your book listed in the category: Social Science and Popular Culture.
I find this pretty funny, but I doubt that you have any influence on that ?

30. **Lubos Motl**
August 23, 2005

Dear Peter,

if you were relying upon string theorists as your future customers, your chances to become rich would be poor indeed. 😉 Maybe you should lower your idea about the readers; they will have IQ lower by a few orders of magnitude than what you would like to believe. Your readers will be likes of DR Lunsford. 😉 In other words, complete morons.

As you know, I consider your opinions about the mathematical framework of string theory and its ability to generate new physical insights and predictions to be roughly as important as the noise generated by the chimps in zoo. But what I want to comment on is your proposal that the physicists should study “many other ideas” such as Chern-Simons theory – to go beyond the framework of the Standard Model.

You seem to misunderstand the difference between mathematics and physics completely. Chern-Simons theory is simply not a theory that is designed as a competitor of string theory to unify the known physics.

Chern-Simons theory is a theory that admits a similar type of (quantum-field-theoretical) description as some physical theories, but that apparently lacks the physical strength to have anything to do with the observed particle physics.

Chern-Simons theory is just an effective description of D-branes in topological string theory. A small subsector of an unrealistic vacuum of string theory. A few numbers. Discrete math. Nothing.

The main problem of yours is that you have completely lost your knowledge of physics and especially the idea which mathematical ideas may be relevant for which physics. When you talk about the “wide range of ideas” that physicists should be talking when they try to go beyond GR+SM, you obviously don’t know what you’re talking about.

There exist no general conceptual frameworks to surpass the existing theory except for string theory, and if someone tries to force people to work on these non-existent ideas, he is doing the same job as the Intelligent Designers. It just can’t work. There exist “small” ideas how new phenomena behind the Standard Model could look like, and this is what phenomenologists work on. But there is no unifying deep structure except for string theory. It’s not a theorem yet but it may well become one next year.

You will never be capable to understand why these alternatives to string theory can’t work – because you’re probably just too old for these things and you have not learned these important technical things in time. But you should at least try to understand that there is a crucial gap in your knowledge that makes all your “big conclusions” totally worthless.

You just can’t judge string theory without knowing anything about its math, its physical implications, and its uniqueness, and if you try to make big conclusions anyway, then you’re a crackpot.

Best wishes
Lubos

31. **Who**
August 23, 2005

oh hello Lubos,
Please tell us again why the loop and dynamical triangulations approaches to quantum gravity cannot possibly be right. It sounds better and better each time you explain.

waiting in rapt attention,

Who

32. **Lubos Motl**
August 23, 2005

Dear "who",

we have wasted roughly 100 times more time with these stupidities than what I would find appropriate.

See some standard texts such as

http://motls.blogspot.com/2005/01/very-meaningful-paper-on-loop-quantum.html

or

http://motls.blogspot.com/2004/10/objections-to-loop-quantum-gravity.html

and the preprints cited therein.

Best
Lubos

33. **The Anti-Lubos**
August 23, 2005

Does anyone, anywhere like Lubos? Just as a person, I mean. I can't imagine him as anything except universally despised, on a personal level.

34. **Kea**
August 23, 2005

Peter

Could you give us a sneak preview, or is that also in the hands of the publisher?

35. **.**
August 23, 2005

no.

36. **Kea**
August 23, 2005

"Does anyone, anywhere like Lubos? Just as a person, I mean."

I like Lubos. He seems like an honest guy.

37. **Lubos Motl**
August 23, 2005

Thanks, Kea. You'll always find a place in my heart. 😉

38. **Lubos Motl**
August 23, 2005

And yes, I definitely want my copy (and 10% of the royalties for making advertisements to you and encouraging the readers of limited intelligence to be interested in the debate). However, I am not sure whether you're brave enough and ready to see your work being deconstructed, Peter. 😉

39. **Quantoken**
August 23, 2005

Lubos:

Unlike many of the peers in your camp, like Kaku, who must have made tons of money selling books and going to TV programming claiming super string theory explains everything, my judgement is this is a money losing deal for Peter to spend all these time and effort to write a book that not many would buy. He could have spent the time doing something else and make more money. But he is doing a public service by salvaging a few pity souls who could otherwise waste a lifetime pursuing something unfruitful.

Why don't you write your own book and make a few quick bucks, too, Lubos? It's fashionable every one else in your camp is ready doing it? Mean while, by Peter's own admission, through intelligent selection of parents, he probably doesn't give a damn about the small amount of royalty from selling a few thousand books. Go get a better life if you are envy of that, Lubos.

Quantoken

40. **Luboš Motl**
August 23, 2005

Let me say that the ideal primary reason to write a book should be that the author has something new and interesting to say. Money may be fun, Quantoken, but you can't buy the most important things for them. On the other hand: yes, when certain conditions are gonna be satisfied, it would become irresistable to write things for which a book is the only appropriate format.

41. **Arun**
August 23, 2005

Congratulations! I look forward to reading your book!

42. **Gordon**
August 23, 2005

Thank you for writing another book on the subject, and I will
read it.

But I am curious. If there is not string theory, what does one
expect to find at energies of 10^30 eV or so…

43. **D R Lunsford**
August 23, 2005

Lubos, you omitted "physical" questions (of course).

-drl

44. **Interpretor**
August 23, 2005

Lubos said:

"You will never be capable to understand why these alternatives to string theory can't work – because you're probably just too old for these things and you have not learned these important technical things in time. But you should at least try to understand that there is a crucial gap in your knowledge that makes all your "big conclusions?? totally worthless.

You just can't judge string theory without knowing anything about its math, its physical implications, and its uniqueness, and if you try to make big conclusions anyway, then you're a crackpot."

Interpretation:

I have wasted 10 years of my life learning this crap and now you are trying to spoil the party. I will be left without funding, hype or hope. You are a worthless old whistle blower.

45. **Luboš Motl**
August 23, 2005

Dear Interpretor,

Peter Woit himself knows that what you write is complete rubbish. I have absolutely no reasons to fool myself, and your comments about the career and hype are irrelevant because I am planning no career whatsoever – especially because of other reasons to change the environment. My opinions are as pure and independent as you can get in this partially corrupt world.

I know that it may be annoying for many to hear it so often, but it is really incredible what kind of trash – both intellectually and morally – is contributing similar anonymous and sometimes less anonymous comments to Peter Woit's blog. I don't want to idealize Peter himself, but I am sure Peter Woit himself must feel to vomit when he reads comments like yours all the time. You should be ashamed.

Best
Luboš

46. **Peter**
August 23, 2005

Well, I'm able to easily control any nausea generated by the endless Lubos/anti-Lubos comments, but I do wish there wasn't so much of this. Lubos brings a lot of this on himself with his tirades, but you shouldn't encourage him.

We both have strong beliefs, and aren't in this for the money (you'd have to be pretty stupid to go into theoretical physics for the money). For better or worse, this new internet technology allows us to make the case for our opposing viewpoints (which aren't even always opposing, we seem to at least partially agree about the anthropic/landscape stuff). Up to you to decide who is making the most sense.

47. **Suresh K Maran**
August 23, 2005

If you guys want to talk about quantum gravity please drop by blog (click on my name). I just started the blog recently and learning to keep it steady. (I deleted some comments left by some of you accidently-sorry)

48. **Quantum_Ranger**
August 24, 2005

Peter, the cover picture is actually cover art!
This picture has been used on many occations, it's abstract..it's convergence by Jackson Pollock!

http://www.soho-art.com/cgi-bin/shop/shop.pl?fid=1056115418&cgifunction=form

I have the same image on the cover of a book entitled:How the Universe Works, which is an Open university course here in the UK.

I also believe the picture was dubbed “Particle Pollack” by Marcelo Gleiser?..used in the Stephen Hawkings ‘Universe’ documentry..or it may have been Franck Close lecture:Cosmic Onion.

It is a definate must to invoke abstract thinking into a very “abstract” Subject.

49. **ppcook**
August 24, 2005

Dear Peter,

Congratulations on finishing your book. It’s very important that important scientific debates are carried over to the mainstream public press. There are many popular science books that engage their readership with the mysterious implications of string theory, amongst others, but there are few that are willing to talk about the 30+ year struggle to get it to the shape it’s in now. It’s my opinion that popular science is very important, future scientists can get a beginner’s picture of the field they might wish to devote their lives to, and generally popular science books focus on the exciting and positive aspects of a story. Consequently all the popular science I have read about string theory gives the impression that it is all but a fait accompli and while I feel string theory is the best candidate to date, it’s important to emphasise that it isn’t complete, and that there is not a consensus amongst the informed (no matter how you define informed). So long as your opinions do not impinge on facts, which I’m sure from reading your blog they don’t, then you’re doing a very decent thing in taking the time to popularise your opinions about string theory. The truth will out eventually (either way), but besides this it’s important that the state of play is reported fairly, and I admire your stance of honestly presenting your doubts about string theory. There must be at least 3 anti-string theory popular science books now, versus 10+ or so in the implicitly pro-string camp; of course when it comes to text books the gap is wider ;).

With regard to the pro/anti-Lubos debate, I must say that I also admire Lubos very much for almost all the same reasons that I congratulate you, i.e. honesty and a desire to communicate ideas. Keep up the good work.

Best wishes,
Paul

50. **ksh95**
August 24, 2005

Peter: Congrats

Quantoken: Your comments are absolutely disgusting. Jealosy is the ugliest of all traits.

Anti Lubos: I like Lubos for the same reasons I like Peter. They believe what they believe and they stick to their guns.

51. **Luboš Motl**
August 24, 2005

Concerning the spirals, Brian Greene had a similar picture on the first French edition of The Elegant Universe.

http://www.amazon.fr/exec/obidos/ASIN/2221090659/402-4337920-0695356

See the other 25 or so covers of The Elegant Universe at:

http://www.physics.rutgers.edu/~motl/brian/

52. **Wolfgang**
August 24, 2005

> [..]
> I must say that I also admire Lubos very much for almost all the
> same reasons that I congratulate you, i.e. honesty and a desire to
> communicate ideas.
Very well put. This is exactly my opinion.

53. **woit**
August 24, 2005

Hi Paul,

Thanks for your comments. I’m glad to see that at least some people studying string theory recognize that the popular literature on the subject is rather one-sided, and that the other side of the argument deserves some exposure.

After this project is done, maybe I’ll start work on the anti-string theory textbook (AKA, a book about mathematics and QFT…)

54. **Alejandro Rivero**
August 24, 2005

The spirals (aka trajectories of charged particles) in Green book are to me a bit more strange, perhaps due to the enhancement. I am not able to were the big spiral starts and where it ends. Does it says what kind of collider it is?

As for the event in Woit picture, I am whinking about a kaon, could it be?

55. **woit**
August 24, 2005

The original source for the image is:

http://www.interactions.org/imagebank/search_detail.php?image_no=CE0057

I’ll leave it to you to do the analysis…..

56. **cvj**

August 24, 2005

Dear Peter,

I posted these two next comments on the cosmicvariance.com thread about your book. They were addressed to you since you had a comment there, but I am not sure if you are rreading that thread any more, so I will put them here too. I hope you don't mind. Come over to CV and give an answer at your leisure, and feel free to copy it here…or the reverse….put a pingback.

So they follow.

Cheers,

-cvj

57. **cvj**
August 24, 2005

Dear Peter,

As a result of several discussions on other comment threads on this blog, I was under the impression that we'd all made some progress in sorting out what were well-posed disgreements you have with some approaches research in string theory, what were "gut-feelings?? that you have (over which we can simply agree to disagree), what were misconceptions based on not being an active researcher in the field, and -very importantly- what were simply your misattributions of a minority view to that of the whole field. Recall that I spent a fair amount of time trying to clear these up. I refer you to the comment thread of the Landscape post, for example. I thought we arrived at some agreement that your views about what is actually going on in the field need a bit of re-balancing. If so, will these refinements be incorporated into the book before it is published? Or will your pre-cosmicvariance position be published? I do hope that these "finishing touches?? might involve significant rebalancing some of your emphasis to reflect the outcome of the enlightening discussions that have taken place here. Otherwise, it will be a missed opportunity for you to put out a book that is a useful alternative view, and not just a view based on an exaggerated chariacature of research in string theory.

I'd like to ask you to please make the effort. It probably won't delay publication at all, and even if it did, it will be worthwhile: It will improve your book, and thereby enhance your reputation. If it comes across as an uninformed rant, however, you'll do service to nobody's cause at all, which would be sad, at the very least.

Cheers,

-cvj

58. **cvj**
August 24, 2005

Dear Peter,

I refer particularly to your comment # 67 in that thread, although it is worth reminding yourself about the discussion that led up to that point. Quoting you entirely:

> Peter Woit on Aug 15th, 2005 at 8:42 pm
>
> Clifford,
>
> Sorry for harassing you into stating the obvious that once one has shown a theory is unpredictive, it's wrong (or not even wrong…) and one has to give up on it, but I think this discussion was worthwhile, it certainly helped me clarify some things for myself. And it's helpful to see that we share fundamental criteria for evaluating science. I'm afraid that I sometimes share what I take to be Lee's perception that for some string theorists, the possibility that the idea of string-based unification is just wrong seems to be something they won't even admit to be a possibility.
>
> No, I'm not going to take you up on your suggestion and devote myself to working on string theory. There are already many, many smart people doing this, and they appear to me to be doing a good job of slowly accumulating evidence that the string theory unification idea doesn't work. I don't think I could significantly speed that process up. I'll stick to pointing out what other people have already found, and trying to develop what seem to me to be more promising ideas.
>
> The main thing this clarified for me is the whole issue of falsifiability. You and Sean are right that it's a good idea to think about the analogy between the gauge theory and string theory frameworks, although I draw different conclusions from this analogy. I guess I do think that the difference is one of degree, but that differences of degree are crucial. Whatever theoretical framework one has, one can generally find some way of making it fit the facts. If it's a good theoretical framework it's easy, if it's not you have to engage in all sorts of ugly contortions. Thus, in evaluating theoretical frameworks, a sense of aesthetics is crucial, and claims like those that Susskind is making that it doesn't matter if things are really ugly are dangerous. I've been thinking a lot in recent years about this kind of "aesthetic?? issue, and the connection to falsifiability is something I hadn't thought about before.

So, will the refinements of your views mentioned by you in the above be reflected in the book? (Not to mention other points I mentioned which you agreed with elsewhere on the thread?)

Cheers,

-cvj

59. **cvj**
August 24, 2005

Link to comment thread of the Landscape post, in which many valuable exchanges were had:

here.

Cheers,

-cvj

60. **Scott**
August 24, 2005

I find it interesting that although I followed the discussion clifford is talking about I did not get the impression of peter substantially changing his oppinion at all, just admitting that not all string theorist are luny and or very worried about the landscape(something which I have no knowledge of him ever implying) and admitting that the falsifiability of a theory is obviously a matter of degree.

personally I think String Theory is in more danger of being not even wrong because there is no actuall theory that meets all of the assumptions/conjectures that string theory is built on rather than having too many consistant theories.

61. **woit**
August 24, 2005

I'm copying here my response to Clifford over at cosmicvariance.com. There should be a better way of carrying on some of these cross-blog discussions….

Hi Clifford,

Yes, the discussion here has had an effect on some of the changes I'm in the middle of making, specifically the new insight into the falsifiability issue that discussion here helped me with is one of those changes.

As for the other issues you mention, I should point out that I have a somewhat different point of view about parts of our discussion. In some cases what to you may have appeared to be a clearing up of misconceptions on my part to me seemed to be just my clarifying some things that I hadn't written carefully enough, allowing them to be too easily misunderstood or misconstrued. In any case, the book manuscript is written more carefully and at greater length than my web comments, so it shouldn't have so much of this kind of problem.

One thing you've properly taken me to task for is sometimes attributing to all string theorists views held only by a minority, or at least appearing to do so. To some extent this is hard to avoid. The sheer complexity of the range of different opinions is hard to do justice to in any piece of expository writing about these issues, so one has to oversimplify to some degree. I'm well aware that many if not most string theorists are eminently reasonable people I can agree with about most things, who don't hold unreasonable or indefensible views. Some of my best friends are string theorists, and I never have trouble talking about the subject with them.

On the other hand, there are a significant number of string theory partisans out there who seem to me to be unwilling to engage in rational discussion of the issues surrounding string theory, and often engage in the offensive behavior of assuming anyone skeptical about the theory is just stupid and ignorant. I've had a lot of this to put up with in the last day or so since publicly announcing my book project. These people are presumably overrepresented in internet forums, and range from fools hiding behind pseudonyms like F. Uckoff, to Harvard junior faculty, to respected senior faculty at major research institutions. I've just wasted some of my time trying to respond on Dave Bacon's blog to Greg Kupferberg, a mathematician string partisan who holds the unshakeable belief that my objections to string theory are of the same sort as Intelligent Designers' objections to the theory of evolution and that my only motivation is unwillingness to do the hard work necessary to learn string theory. I think Lubos Motl's comments here and elsewhere speak for themselves.

So, while I'm willing to believe that the majority of string theorists are reasonable sorts, that's not so clear from what goes on on the internet, and some of my experiences somedays leave me feeling not especially charitable. While there are certainly some stupid comments left on my weblog by people bashing string theory, I'd like to think that if any of these were coming from serious people in respected positions (e.g. Harvard faculty members), I'd be taking them to task for their behavior and I can't help noticing that this doesn't seem to be something any string theorists are willing to do.

About the landscape: my own view of the issue is extremely simple. Any theorist working on a theory who ends up deciding the theory leads to something that ugly and that unpredictive has to just acknowledge failure and do something different. I understand that there's a wide range of opinions about this among string theorists, but don't think this is a subtle issue. The book was largely written in 2002 before the landscape controversy got going, so material about it is kind of added on, and given the way I see this, I haven't had the interest or energy to go into too much detail about the various issues that people often get into when talking about this.

Finally, I don't want to put you on the spot in public, but will soon contact you privately with a proposition about the issues you raise. Maybe you can help me out…

62. **Luboš Motl**
August 24, 2005

Dear Peter,

if someone if being stupid or ignorant, then it's important to point out this fact, especially if the person is arrogant enough that he wants to decide about the direction of theoretical physics as much as Cumrun Vafa or Edward Witten, to say the least.

Let me emphasize that you don't know even the basics of the theory and the idea that this is a good starting point for a rational discussion about string theory is simply stupid. You seem to think that because your superficial insults against the whole field are supported by a gang of incredibly dumb readers, you have the right to expect that the leading theoretical physicists will discuss with you as with a peer. But that's completely crazy.

It's also important to say that F. Uckoff much like the senior string theorists you mentioned are very fine and smart people.

Sincerely Yours
Luboš

63. **Thomas Larsson**
August 24, 2005

It may be worth pointing out the Lubos Motl has proven to be quite ignorant about basic string theory himself. For the past five years, he has repeated, with the perseverence of a drunken parrot, that gauge symmetries are redundancies of the description. If he had understood chapter 2 of GSW he would have realized that this is not a general truth; the subcritical free string has a ghost-free spectrum despite its conformal anomaly. That consistency singles out 26D for the **free** bosonic string is just the lies-to-children (or lies-to-junior-Harvard-faculty) version of the no-ghost theorem.

64. **cvj**
August 25, 2005

Well Scott. Amusingly, Peter seems to disagree with you -see his post below yours- so it's probably a good idea in future to let him speak for himself, don't you think?

-cvj

65. **Nigel**
August 25, 2005

Dear Luboš,

You write above 'if someone if being stupid or ignorant, then it's important to point out this fact' and then you say 'you don't know even the basics of the theory'. Right, see how you like this.

Luboš, you don't need to eat a whole cow just to decide if the meat is bad. ST is past its sell by date. People don't need to sample the entire package to discover that it is poisoning physics. You just can't grasp this, although you string theorists have plenty of hypocrisy.

Notice that all I have to do is ask 'what does ST predict quantitatively?' If you say 'wait a year and I'll answer' you're wasting my time. Why should anyone study stuff which has led physics nowhere in over 20 years?

Now I don't have a postdoc in ST so I'm not 'intellectual' enough to comment, or well qualified enough to be serious, or just perhaps too juvenile in sticking to simple, testable ideas which work 🙂
Best wishes,

Nigel

66. **Alejandro Rivero**
August 25, 2005

http://www.cerncourier.com/objects/2004/cernbub10_7-04.jpg is a picture of the machine where the picture was done. The BEBC was not a old machine as some post could suggest; it worked during the seventies.

67. **Scott**
August 25, 2005

clifford,

Actually it is not that surprising that three different people would have three different perceptions about what transpired, I just figured that while you waited for peter's responce, I would point out that you were describing your perception and not neccessarily peters by stating my own perception (which was much closer to peters that most of discussion was just clarification of what you both thought). I find it interesting that you thought I was trying to speak for peter instead of just pointing this out especially when i started the comment by saying "I find it interesting…"

68. **The Statistical Mechanic**
August 25, 2005

" [..] Peter Woit thinks that superstring theory is not a scientific theory in the usual sense, being incapable of making concrete, testable predictions and he announced that he is finishing a book with the same title as his blog: Not Even Wrong. [..]"

69. **Who**
August 26, 2005

I followed the link given here to The Statistical Mechanic, to see what more Wolfgang had to say about the book, and found a strong recommendation of Capitalist imperialist Pig, and this link:
http://capitalistimperialistpig.blogspot.com/2005/08/bad-vibrations.html

to the "Bad Vibrations" blog entry by said Pig.
Gist: Pig tried to have a conversation about Peter's book and it ended unsatisfactorily. Pig then reflected on this.

Wolfgang's recommendation of the Pig blog is as follows:
"One of the better blogs is written by CapitalistImperialistPig. He usually has an independent, yet sane, point of view and discusses mostly US and world politics, but sometimes also physics and other stuff."

70. **anonymous idiot**
August 26, 2005

Who says: I read the colloquy between Pig and Lubos slightly differently. Pig teased Lubos – Lubos said "you are stupid, stupid, stupid, and an idiot moron," whereupon Pig retreated to his own blog and bitchslapped LM.

71. **Nigel**
August 26, 2005

http://motls.blogspot.com/2005/08/book-that-is-not-even-wrong.html :

Luboš resorts to the argument that Witten is best to judge if ST is right, as he is the most qualified in ST. (By the same argument, the best way to find out if a criminal is guilty is to ask him.) Luboš then repeats Witten's misleading claim (disproved by Penrose) that ST is proved by predicting graviton right (see my home page for quotes).

Quantoken replies to Luboš: 'Einstein says there is no distinction between acceleration or gravity attraction. If gravity is exchanged by a boson called graviton, then the two cases can in principle be distinguished by observing whether any graviton has actually been absorbed by the object or not, breaking the equivalence principle.'

I think that gets rid of gravity nonsense coming from the ST lobby! 😉 So now we know ST is as vacuous as cold fusion. 🙂

72. **pablo mora**
August 26, 2005

Dear Peter,

I found it very interesting your 'enigmatic and delphic' comment on the'quantumpontiff' blog about Chern-Simons theory, which provokedan furious andoutraged answer from LM.
In fact i am interested in CS gauge andgravity theories in higher dimensions. I would very much like it if you can elaborate on that, either in your blog or a personal e-mail.Thanks,

Pablo

73. **A Theorem, You Say?**

August 26, 2005

Lubos,

do you mean anything specific by “it is not a theorem now, but may be so next year”? (re: canonicity of ST).

If so, what did you have in mind? Is there some specific conjecture rather than a warm fuzzy feeling about the majesty of string theory?

74. **woit**
August 26, 2005

Hi Pablo,

Sorry to be enigmatic, but what I had in mind probably won’t help you. Right now I’m way behind on everything I’m supposed to be doing, but once the new semester here gets going, this fall I hope to spend time writing some long postings about things like the Chern-Simons idea I mentioned. People sometimes quite legitimately complain that there’s too much negativity on this weblog, which is probably right, and I should be spending more time writing about positive ideas that I find interesting.

75. **MC**
August 26, 2005

Peter,

Your cover art closely resembles that of my copy of “What is the World Made Of: Atoms, Leptons, Quarks, and Other Tantalizing Particles” by Gerald Feinberg (1977). Unfortunately, I can’t seem to find a picture of it online to show you.

76. **woit**
August 26, 2005

Hi MC,

Thanks for letting me know. I think the Columbia library has several copies of this (Feinberg was on the faculty here), so I can take a look at one of them on Monday. Maybe it’s just that many bubble chamber photos look alike, maybe both used the same CERN image. In any case I know where the Cape designer got the image and it wasn’t from Feinberg’s book. But if they’re too similar I’ll let Cape know and they can decide if they want to do something about that.

77. **woit**
August 29, 2005

Took a look at the Feinberg book. The cover may or may not be the same CERN bubble chamber, but definitely is a different picture.

More on WMAP

August 23, 2005
Categories: Uncategorized

In reference to my recent posting about the status of the WMAP experiment, an anonymous (but as far as I can tell, well-informed) source writes:

Hi Peter,

*I am *not* a WMAP person, and would appreciate you not mentioning my name or my institution, but here is the story in the interests of keeping things sane:*

1. WMAP is fine.

2. They are being very, very careful with their analysis.

3. Polarization foregrounds are difficult to model.

4. I doubt WMAP has detected GWs. Someone would have leaked that by now.

5. Note that WMAP does not have the sensitivity to detect the GWs predicted by inflation, it is hard to see how any simple, reasonable models could produce a GW signal much larger than that, and so a GW signal would be truly revolutionary if WMAP saw it.

6. The conspiratorial "Cosmology News" that you have linked to looks pretty slanted to me. They are talking about the famous missing power in low multipoles, discussed in the first year data release. Note that COBE also saw this missing power. IMO, I very much doubt this is due to systematics, as that site alleges, and statements that the team thinks – at the late date of 2004 — otherwise are almost certainly made up.

2. **Who**
   August 24, 2005

   DRL, you might be interested in this
   http://www.arxiv.org/abs/astro-ph/0508047/
   which just came out this month.

   it is by the same people and reviews earlier results,
   drawing stronger conclusions

3. **Quantoken**
   August 24, 2005

   hmm…VERY VERY **INTERESTING**!

   After reading the above paper. I completely changed my opinion regarding the mistery surrounding the WMAP data. I originally thought that it's a known fact that many local astronomical objects do emit microwaves, so what's big deal the data is contaminated by some foreground signal, which shows some characteristics ligned up with the solar system?

   But in reality it is a totally different story. Seeing something you do not expected see is one thing (which can be explained away by signal contamination), but seeing something you **expected** to see **COMPLETELY MISSING** from the data, is quite a different story, and it can not be explained away by data contamination!!!)

   Quote:
   "To conclude, using the multipole vector decomposition we have shown that the quadrupole and octopole of the microwave
   background sky are correlated with each other at a level that is excluded from being chance in excess of 99%. This comes about from a preponderance of peculiar correlations and is statistically independent of their observed lack of power. This observation is **in bold contradiction** to the predictions of pre-existing cosmological model, and **argues against an inflationary origin** for these fluctuations. In addition, there is strong evidence (again of greater than 99% confidence) that the microwave background at these multipoles is correlated with the geometry and direction of motion
   of the solar system. The observed signal is most **unlikely** to be due to residual contamination of the full-sky microwave background maps by known Galactic foregrounds."

   Any comment?

   Note the authors are NOT the WMAP team members, who would be too timid to make such bold and politically incorrect statements!

   Quantoken

4. **D R Lunsford**
   August 24, 2005

   Thanks Who, that is a real paper.

   -drl

5. **Matti Pitkanen**
   August 24, 2005

   The lack of correlations for angular scales above 60 degrees implies the smallness of quadrupole and octupole moments: see http://www.cerncourier.com/main/article/44/10/4.

   I have proposed an explanation in terms of many-sheeted space- time. The space-time sheets along which incoming photons arrive have finite size. For large angular separations it is probable that they arrive along different space-time sheets so that there is no correlation.

   See the subsection "Fluctuations of the microwave background as a support the notion of many-sheeted space-time" at http://www.physics.helsinki.fi/~matpitka/tgd.html#cosmo .

   Could this be explained by non-uniform distribution of mass in the universe? I.e. what if all the supposed dark matter is inside some giant black hole lurking somewhere, could that black hole affect CMB photons in a way to produce such anomalies?

7. **D R Lunsford**
   August 29, 2005

   Could this be explained by non-uniform distribution of mass in the universe? I.e. what if all the supposed dark matter is inside some giant black hole lurking somewhere, could that black hole affect CMB photons in a way to produce such anomalies?

   This is the problem with teaching and endorsing fantasies. Students start to think of fantastic (that is, absurdly unreal) scenarios instead of sticking to sane physics.

   The issue is that the data indicate an unexplained local contribution to the MB, after which the C in CMB is practically irrelevant, the BB plain wrong, and inflation an opium smoker's pipe dream.

   -drl

8. **D R Lunsford**
   August 29, 2005

   This is off topic but important.

   Today we had an authentic physics miracle – once the eye was past New Orleans, the equally strong west winds pushed the storm surge back out to sea. It's tempting to think of this as simple superposition of waves but wave motion is essentially different in even vs. odd spatial dimensions – in any case the equal and opposite winds on the south side of the eye tended to mitigate the storm surge.

   Now the amazing thing is, the storm turned right by just the right amount to be able to use the storm's own rotational energy against itself. This is, to all purposes, a near miracle.

   -drl

9. **Artem Khodush**
   August 30, 2005

   The issue is that the data indicate an unexplained local contribution to the MB

   I dont' get why it's assumed local. Just because it's aligned with ecliptic? Or are there other reasons in the article which I overlooked?

10. **D R Lunsford**
    August 30, 2005

    Because the "horizon", the ultimate non-local, defines a (projective) metric, which in turn imposes an order – of magnitude – on influences. There are two scales – cosmic and local – because of the cross-ratio, which essentially is a quotient – and is the basic invariant of projective geometry. The claim so far is that the MB is cosmic only.

    -drl

11. **D R Lunsford**
    August 30, 2005

    I see I misread your question – I actually answered the question "Why you can't assume it's cosmic". To answer the actual question – if aligned with the ecliptic then, since the final radiation field can be expanded in spherical harmonics, there is a pre-defined relation between all the various multipole terms, because the symmetry is now planar and not spherical – a favored direction. That is, space is not isotropic. In fact the most interesting part of this work is that the octopole and quadrupole are aligned, with each other, regardless of the ecliptic.

    -drl

12. **Artem Khodush**
    August 31, 2005

    Thank you DRL for the explanation. Looks like I misunderstood the term "local" – actually it can be anything anywhere that defines a favored direction. And doing wild guesses is pointless unless I could put that in the equations, solve, and compare result, which I can't. Sigh. Thanks again.

13. **D R Lunsford**
    August 31, 2005

    Well people are imagining bizarro worlds with complicated topologies instead of just admitting the simple answer, that not only does light fall – gravity glows.

-drl

14. **island**
August 31, 2005

So, Einstein was right if the universe is rotating, then it has a center of rotation, and a center of gravity. If the assumption about the universe being unbounded can be demonstrated to be false, then the Copernican Cosmological principle takes a big hit and BB theory gets more realisitic applied to a universe that has volume when a big bang occurs without a singularity.

I'll buy all of that even if I did have to say it myself… 😉

15. **D R Lunsford**
September 1, 2005

"The Universe is rotating"

With respect to what?

How can you even WRITE such a sentence?

-drl

16. **island**
September 5, 2005

I know what you're saying, but it falls out of Quantoken's quote, maybe as more of a figure of speach… or wouldn't this result in quadrupole and octopole moments?

> In addition, there is strong evidence (again of greater than 99% confidence) that the microwave background at these multipoles is correlated with the geometry and direction of motion
> of the solar system.

The pattern indicates a rotating universe, since this incoherence manifests via octopole and quadrupole components in a bound universe, so there should be a center of gravity at the center of the visible universe with the universe rotating as a black hole might… with respect to what… I have no clue.

Oberwolfach Workshops

August 24, 2005
Categories: Uncategorized

There have been two quite interesting Oberwolfach workshops this summer with some relation to my favorite ideas about K-theory and quantum field theory. The most recent was a workshop on Gerbes, Twisted K-theory and Conformal Field Theory, with blogging from Urs Schreiber at The String Coffeee Table. Jouko Mickelsson gave a talk on “Twisted K-theory and the index on G” which from Urs’s description was mostly about the material in Mickelsson’s paper Families Index Theorem in Supersymmetric WZW Model and Twisted K-theory. This is closely related to the Freed-Hopkins-Teleman theorem, and their construction of a twisted K-theory class using Dirac operators on a circle, parametrized by connections on the circle.

Urs wasn’t sure what to make of this talk or how to connect it to string theory. My own point of view is that this is very interesting not because of the relation to strings, but because one can think of it as a possible new way of describing the Hilbert space for 2d chiral gauge theory. Perhaps this can provide a 2d toy model to test out new approaches to gauge theories in 3 and 4 dimensions. From this point of view, the QFT involved is best thought of not as the supersymmetric WZW model, but as a chiral fermion coupled to a gauge field, with BRST gauge fixing. In some sense what is going on here is an index-theoretic version of BRST.

Earlier in the summer there was an Oberwolfach workshop on Geometric Topology and Connections With Quantum Field Theory. One of the main topics there was recent work on elliptic cohomology, with a survey talk by Graeme Segal and Jacob Lurie speaking on a new “derived algebraic geometry” approach to the related theory of “topological modular forms”. Greg Moore’s talk looked interesting, especially his comments on various QFTs which he thinks of as special cases of AdS/CFT, and generalizations of the Chern-Simons/CFT correspondence. In a footnote he writes “It would constitute a major step forward in mathematics if someone could state the AdS/CFT correspondence in a mathematically precise way.”

The same Oberwolfach workshop also had a talk by Nitu Kitchloo on “The Baum-Connes Conjecture for Loop Groups”, which really was also about Freed-Hopkins-Teleman in disguise. I’ve talked a little bit with Paul Baum about this idea that FHT is Baum-Connes for loop groups, but Kitchloo has tried to do something with it. The general idea behind Baum-Connes is that one can study the representation theory of a group in terms of the topological K-theory of a classifying space for the group. In the case of loop groups, the classifying space is the space of connections on a trivial bundle over the circle, and the topological K-theory is FHT’s twisted K-theory of the group. The information about the loop group representation theory is encoded in the Verlinde algebra. An ongoing project of mine is to try and sort out the relations of this story to 2d QFT (see comment above about Mickelsson’s work), hoping that if one gets the right point of view on the 2d case one can use this to define gauge theories in 3 and 4 dimensions in terms of some sort of K-theory, implementing some sort of Baum-Connes correspondence for higher dimensional gauge groups.

1. **John Baez**
   September 6, 2005

   How come whenever you talk about something with some mathematical substance, nobody ever comments on it, while they are happy to argue endlessly over X being rude to Y in Z’s blog?

   Sigh….

   I think there’s got to be a much slicker way to formulate and prove the relationship that the Freed-Hopkins-Teleman result addresses, but so far my best attempt is the paper I wrote with Alissa Crans, Urs Schreiber and Danny Stevenson relating the fundamental gerbe on a compact Lie group G to a 2-group (= categorified group) that one can also build from the central extension of the loop group of G.

   I guess I need to go further and study how the representations of this central extension are connected to the K-theory of vector bundles on G twisted by the fundamental gerbe.

2. **woit**
   September 6, 2005

   Hi John,

   I’ll take a close look at the paper you mention, and see if you can convince me that I really need to think about Lie 2-algebras and 2-groups. My main interest in this is still QFT; I think there’s a beautiful QFT story going on here, one which I’ve only partly worked out, but have yet to see how the 2-group point of view helps.

   You’re right that it’s kind of discouraging that my more substantial posts don’t get many comments. Partly my fault I think, for just referring to things without taking the time to write out some explanations of what is going on with this stuff (the kind of thing you do in TWF). This fall I hope to have more time for this and to get organized to be able to put formulas in these postings in some simple way. Maybe that will help.

   I can’t really blame people though. The ongoing train wreck that is string theory and the bizarre behavior it is leading to is pretty fascinating to watch and hard to resist commenting on.

arXiv Trackbacks

August 24, 2005
Categories: Uncategorized

As discussed here, here, here, and here, the arXiv is now putting on each abstract page a link to trackbacks from weblogs which contain a link to the paper in question. This is an interesting mechanism for integrating the discussion of various papers on weblogs with the arXiv site.

I remember more than ten years ago Paul Ginsparg talking about the idea of setting up a mechanism for having commentary on papers on the arXiv, but this idea seems to have not gotten off the ground at the time. Part of the idea was that the author of the paper would be able to delete any posted commentary he or she didn't like. When asked about whether this would stop people from being able to use the commentary section to point out that a paper was wrong, Ginsparg noted that if there was no commentary on a specific paper, did you really care whether it was because the author had deleted the comments, or because no one thought the paper was worth commenting on?

My latest posting from earlier this evening contained a couple links to arXiv papers (I didn't know about this trackback business at the time). Jacques Distler explains that one's weblog has to be on a list of "serious physicist-bloggers" in order for one's trackbacks to appear. So far mine haven't, so I guess I'm not a "serious physicist-blogger" by the standards of Jacques (or whoever is managing this thing).

Update: The trackbacks are there now, as pointed out by Sean Carroll. Not sure when this happened, partly because there seems to be a bug in their system. The abstract page for the Mickelsson paper I linked to counts only one trackback, when there really are two (the other, from Urs Schreiber was there yesterday).

   > Jacques Distler explains that one's weblog has to be on a list of "serious physicist-bloggers?? in order for one's trackbacks to appear. So far mine haven't, so I guess I'm not a "serious physicist-blogger?? by the standards of Jacques (or whoever is managing this thing).

   In my experience, WordPress doesn't support trackback autodiscovery, so a casual link to an abstract isn't enough: I have to deliberately ping the http://arxiv.org/trackback/… address. I've verified this in experiments from my own page with arxiv. Manual trackbacks register (after a short delay), but simple links don't. Of course, we're using different versions of WordPress.

2. **woit**
   August 25, 2005

   Thanks Steve. But I'm still confused. Notices of trackback pings from me appear in other weblogs when I post something with links to them, even if I don't put the trackback in manually. I just tried putting in the two arXiv link trackbacks manually, but it looks to me like I'm getting a message that these were "already pinged". Anyway, I'll check after a while to see if the manual trackbacks had any effect.

3. **Suresh**
   August 25, 2005

   the trackback mechanism is semi-reviewed, in that it has to go thru some processing before the trackbacks are registered. this is probably why you haven't seen it yet.

4. **Sean**
   August 25, 2005

   Looks like your trackbacks are there now.

5. **woit**
   August 25, 2005

   Thanks Sean,

   I'd checked earlier this morning, but the fact that their trackback counter doesn't seem to be working may have kept me from realizing that mine was there.

6. **Steve Thorsett**
   August 25, 2005

   The page headers at arxiv aren't being set correctly with a new "modified" date when the trackback counter changes, so you are pulling the page with your cache with an old value. Force a refresh (shift-reload in firefox) and the counter will be correct. This caught me last night.

A First Course in Modular Forms

August 29, 2005
Categories: Uncategorized

I recently got a copy of a very interesting new textbook entitled A First Course in Modular Forms by Fred Diamond and Jerry Shurman. Fred was a student of Andrew Wiles at Princeton, and came here to Columbia as a junior faculty member at the same time I did. He now teaches at Brandeis.

The title of the book is a bit deceptive, what it is really about is what used to be called the Taniyama-Shimura-Weil (or some subset of those names) conjecture, but now is often known as the Modularity Theorem. Most of this theorem was proved by Andrew Wiles (with help from Richard Taylor), who famously used his result to prove Fermat's last theorem. More recently, the proof of the full theorem was completed by Fred, together with collaborators Christophe Breuil, Brian Conrad and Richard Taylor. Stating the modularity theorem precisely requires some serious mathematical technology, an imprecise statement is the "All rational elliptic curves arise from modular forms". This fits into the Langlands program of establishing a correspondence between arithmetic objects (in this case elliptic curves over the rational numbers), and analytic objects (in this case modular forms). If one can do this, typically the fact that the analytic objects are pretty well understood allows one to get a vast amount of very deep information about the more mysterious arithmetic objects (e.g. being able to count solutions to equations over the rationals or integers).

The book takes an interesting approach to the Modularity Theorem, not trying to actually prove it. The proof involves highly sophisticated mathematical technology, and really understanding it is still the province of experts. If one wants to try and learn this technology, two places to look are the volumes Modular Forms and Fermat's Last Theorem and Arithmetic Algebraic Geometry, which are the proceedings of two different instructional conferences. Instead of trying to give a proof, Diamond and Shurman's book explains exactly what the various related versions of the Modularity Theorem say. This covers a range of beautiful mathematical ideas, much of which hasn't before had a particularly readable exposition. Until now, the main reference for some of this material has been Shimura's Introduction to Arithmetic Theory of Automorphic Functions, a famously difficult text.

The book is advertised as "A First Course" and attempts to minimize the prerequisites necessary to read it, making it conceivable to even use the book with advanced undergraduates. This is a worthy goal, but may be a bit over-ambitious. I suspect most people will get more out of the book if they already have had exposure to some of this mathematics at a slightly more basic level. One place to get this is Neal Koblitz's Introduction to Elliptic Curves and Modular Forms. But this really is a wonderful book, making accessible parts of the really beautiful mathematics which mathematicians have been making great progress in understanding over the last decade.

Comments

1. **owen**
   August 29, 2005

   I'm not qualified to comment on the mathematics contained in this book, but I would like to mention that I had Jerry Shurman for an introductory math class when I was a freshman. He was a fantastic teacher – possibly the best I had (along with David Griffiths) during four years at Reed. I consider this to be an impressive achievement, considering the general caliber of professors at Reed. He had a knack for conveying information clearly and concisely without being dull in the least. It's no surprise that this book succeeds at "making accessible parts of really beautiful mathematics."

2. **iso42**
   August 29, 2005

   I have a naive question.
   If only a handful of people understand and can check a proof a la Wiles, how can we be sure that there is no hidden problem with it?
   Is there a formalized, automated or semi-automated way to do this?
   I know that long reviews were done on Wiles' proof but I wonder if the mathematics could be formalized enough to check it (to some extent) on a computer.

3. **woit**
   August 29, 2005

   As far as I know, at the level that Wiles is working the arguments are difficult to completely formalize so that a computer could check them. One thing to keep in mind though in a case like this is that his argument was gone over with a fine-toothed comb by some very good people, including some who wish they had solved this problem themselves, so were highly motivated to find something wrong with it. Also, many other people are now using his techniques to try and do other things. If there were a problem with his use of one of them, it's quite likely someone would notice this when they tried to use it to do something else.

   When not many people care much about a result, it is quite possible for a wrong argument to get in the literature and be accepted. In this case it seems extremely unlikely.

Warped Passages

August 30, 2005
Categories: Book Reviews

A couple days ago I got ahold of a copy of Lisa Randall's new book [Warped Passages: Unraveling the Mysteries of the Universe's Hidden Dimensions](), and finished reading it last night. It's a book intended for a popular audience, containing an overview of modern physics, but concentrating on the idea of extra dimensions beyond the standard four we know about. The last part of the book attempts to explain at a non-technical level work by Randall and others that generically goes under the name of "braneworld scenarios", and involves various versions of the idea that our four dimensional space-time is embedded in some higher dimensional space. The specific ideas she describes in some detail are:

1. Work with Raman Sundrum (hep-th/9810155) on solving the flavor-changing problems that occur in supersymmetric models by "sequestering" the supersymmetry breaking sector on another brane, separated from ours.

2. The Arkani-Hamed, Dimopoulos and Dvali idea (hep-ph/9803315) of large extra dimensions, which explains the weakness of gravity as due to the large size of some of the extra dimensions, with gravity propagating in them, but not the other forces.

3. The Randall-Sundrum warped geometry with two branes (hep-ph/9905221).

4. The Randall-Sundrum warped geometry with an infinite extra dimension, using AdS geometry (hep-th/9906064).

5. Work with Karsch on "localized gravity" (hep-th/0011156).

I afraid I've never found these brane-world scenarios to be at all compelling. They don't really seem to me either aesthetically appealing or able to explain in a convincing way any of the things we don't understand about the standard model. They're not derived from any fundamental theory, so the rules of what branes you're allowed to postulate and what properties you can assign to them seem very loose, allowing all sorts of things. At one point Randall writes:

Other branes might be parallel to ours and might house parallel worlds. But many other types of braneworld might exist too. Branes could intersect and particles could be trapped at the intersections. Branes could have different dimensionality. They could curve. They could move. They could wrap around unseen invisible dimensions. Let your imagination run wild and draw any picture you like. It is not impossible that such a geometry exists in the cosmos.

which I guess is meant to be inspiring, but makes me worry there's not enough structure to this game to make it useful. One virtue of some of these models is that they lead to new phenomena at potentially accessible energy scales. If the LHC sees the kinds of effects predicted by these models, there will be some well-deserved Nobel prizes for the people involved in this story, but this seems to me highly unlikely. Randall says in her book that she really does believe in these sorts of extra dimensions, but most particle theorists I know of (string theorist and non-string theorist) tend more to the opinion that while these are models worth investigating (since you may learn something, and it gives experimentalists something more specific to look for), there's only the most outside chance that they correspond to what the LHC will see.

The one problem of the standard model that braneworlds do provide an interesting answer for is the hierarchy problem, that of why the weak and Planck scales are so disparate. In these scenarios, the fundamental gravitational scale is not the Planck scale, but something closer to the weak scale, so (unlike in the standard picture) gravity is not weak because the Planck scale is so large, but because braneworlds provide various mechanisms for making the gravitational force much weaker than the others. The idea that the gravitational scale may be closer to and maybe even directly related to the weak scale, and that this is somehow related to the electroweak symmetry breaking mechanism that we still don't understand, is an appealing one, but the ways braneworlds accomplish this removes much of the appeal (at least for me). The choices just seem too arbitrary, and while there is some geometry involved, it is geometry of a crude sort. The standard model involves fascinating and beautiful spinor geometry and the geometry of Yang-Mills fields, which is pretty much ignored in these scenarios, which try and get everything out of simple Riemannian geometry and general relativity sorts of considerations.

There's a lot about string theory in the book, with Randall clearly skeptical about many of the claims made for the theory. I remember a few years ago at a debate over string theory held at the Museum of Natural History here in New York, she scornfully responded to the argument that "string theory predicts gravity" with "sure it does, gravity in ten dimensions." Here she says *I'm an agnostic on this subject – I don't know what string theory will ultimately be or whether it will solve the questions of quantum mechanics and gravity it sets out to address*. She's similarly agnostic about GUTs: *Although unified theories have some appealing features, I'm not really sure whether studying them will lead to correct insights into nature. The gap in energy between what we know and what we extrapolate to is huge..*

Randall describes being a student in 1984 at Harvard, seeing the field split into two camps that were at odds with each other: Gross/Witten doing string theory at Princeton, Georgi/Glashow doing model building at Harvard. About Princeton she says :

Physicists there were so certain that string theory was the road to the future that the department no longer contained any particle theorists who didn't work on string theory – a mistake that Princeton has yet to correct.

She tells the story of the relation between model builders and string theorists over the last twenty years as follows;

Early on, the battles between the merits of the two opposing viewpoints – string theory and model building – were fierce, with each side claiming better footing on the road to truth. Model builders thought that string theorists were in mathematical dreamland, whereas string theorists thought that model builders were wasting their time and ignoring the truth.

Fortunately, things have now changed. ….many of us now think about string theory and experimentally oriented physics simultaneously. I have continued to follow the model building approach in my research, but I also incorporate ideas from string theory…. The communities are no longer so rigidly defined, and there is more common ground. Both scientifically and socially, there are now strong overlaps between model builders and string theorists.

The fact that branes are an important part of modern string theory meant that string theorists took an interest in this kind of model-building, with Randall noting that:

In fact, because our research didn't directly challenge string theory models, the string theory community actually accepted and recognized the significance of our work sooner than the model-building community.

In particular, the fact that the Randall-Sundrum model uses the same AdS geometry and has interesting relations to AdS/CFT has drawn a lot of interest from string theorists. Whatever you think of all this as physics, as academic politics it was an absolute stroke of genius, defusing a bitter conflict. I confess to finding this unholy alliance between the model-builders and string theorists rather problematic. I'd much prefer to see the model-builders holding string theorists accountable for the theory's inability to actually predict anything or even lead in any well-defined way to a specific class of models that could be tested. By reaching an accomodation with string theorists and agreeing on a central role for string theory in particle theory research, the model-builders have made the string theory juggernaut pretty much impregnable, leaving anyone interested in alternatives to string theory very much marginalized within the particle theory community.

In the acknowledgements, she prominently thanks one of her Harvard colleagues:

Lubos Motl, a brilliant physicist and dedicated science communicator (whose specious ideas about women in science we'll ignore), read everything, even before it was readable, *and gave extraordinarily useful suggestions and encouragement at every stage*.

Update: Lubos has a new posting about Randall's book. He ends by referring to some forthcoming book containing "dumb insults against the physicists". I guess the rumors that he's written something for publication must be true then.

Comments

1. **Chris Oakley**
   August 30, 2005

   In the absence of any evidence for hidden dimensions, especially those in need of unraveling, the title, "Warped Passages: Unraveling the Mysteries of the Universe's Hidden Dimensions" is somewhat misleading.

   I would prefer, "Exploring the possibility that extra dimensions might solve some problems in physics".

   But, hey, when did honesty sell books?

2. **Very**
   August 30, 2005

   >The choices just seem too arbitrary, and while there is some >geometry involved, it is geometry of a crude sort. The standard model >involves fascinating and beautiful spinor geometry and the geometry >of Yang-Mills fields, which is pretty much ignored in these scenarios, >which try and get everything out of simple Riemannian geometry and >general relativity sorts of considerations.

   Crude??? The "beautiful" spinors you write about are one of the renormalizable local representations of the Poincare group, which is why they appear, not because of their underlying "beauty". Similarly, gauge theories arise because when you try to describe massless spin-1 bosons using a vector field, we come up with unphysical gauge degrees of freedom. The only consistent way to make those massless spin-1 bosons self-interacting is if they happen to arrange themselves into a Lie algebra. There's no underlying mathematical beauty here either.

3. **Chris Oakley**
   August 30, 2005

   Very-

   Beauty is very much in the eye of the beholder, but I agree to the extent that the beauty of Yang-Mills evaporates as soon as one tries to quantize. If gauge fixing, ghosts or renormalization is beautiful then the Incredible Hulk ought to win Miss America.

4. **woit**
   August 30, 2005

   Very,

   Some of us happen to think that the fact that gauge fields are connections and connections are the fundamental objects in modern geometry means that they're mathematically beautiful. You're welcome to the philosophy that this is just a coincidence, that what's important is what gives consistent quantization of a massless spin-1 field, but my philosophy is different. We can't really have a rational discussion about what is mathematically beautiful and what isn't, but I'll point out that I just spent a year teaching our graduate course in geometry in the math department here, so I have some idea what mathematicians consider the deepest and most beautiful constructions in the subject.

   Similar remarks apply to spinors. As to "crude", Riemannian geometry is 19th century mathematics, spinor geometry and the geometry of general connections is 20th century mathematics.

5. **woit**
   August 30, 2005

   Chris,

   I agree with you that the way gauge invariance is handled in quantum Yang-Mills theory is not a pretty sight. It gets the Feynman rules right, but opens all sorts of other questions. I suspect there are better, more beautiful ways of doing it, and these are very much worth working on.

6. **Shantanu**
   August 30, 2005

   Peter, does this book discuss Loop quantum gravity , dynamical
   triangulations or anything else besides string theory?

7. **woit**
   August 30, 2005

   Shantanu,

   Nothing about loop quantum gravity, dynamical triangulations, etc., and very little about quantum gravity. Randall makes it clear she's fundamentally a particle theory model builder, interested in making models of particle physics that have some hope of being tested at future accelerators or other particle physics experiments.

   I undoubtedly overemphasized how much there is about string theory in the book, since I was interested in her relation to string theory, and she does write extensively about this. But most of the book is basically a particle physics book, aimed at getting to and explaining her work on braneworld scenarios in particle physics.

8. **Who**
   August 30, 2005

   Shantanu that is a great question
   **does [the Randall] book discuss Loop quantum gravity , dynamical
   triangulations …?**

I'm inclined to think that at this point any book that pretends to be about contemporary views of spacetime and does not give an adequate description of the loop and triangulation pictures is appealing to self-indulgent fantasists rather than to interested lay readers.

So I am curious too. Maybe Peter will tell us. (Must say I dread the answer.)

9. **woit**
August 30, 2005

Who,

Already answered that question above. This is not in any way, shape or form a book about quantum gravity, and actually I think that's fine. The problem of quantum gravity is not the only important one out there!

Although after writing this comment I thought better of it. The assumption that the gravity scale is much lower than the Planck scale does mean one is saying something about quantum gravity in these braneworld scenarios. But Randall isn't much interested in any of the standard conceptual problems about quantizing gravity, or in the question of what happens at very high energies, whether the theory is finite, whether there's a background independent theory, etc. She's taking a very pragmatic approach, not asking fundamental questions about space and time of the sort that normally are part of the subject of quantum gravity.

10. **dan**
August 30, 2005

"Lubos Motl, a brilliant physicist and dedicated science communicator (whose specious ideas about women in science we'll ignore)"

i'm kinda curious as to what lubos' ideas about women in science, as we all clearly know his views on LQG.

11. **woit**
August 30, 2005

He seems to have gotten himself into trouble with his colleagues over this. Basically he was strongly supporting Summers in the recent controversy at Harvard over women in science. Like Summers, he seems to believe that the reason there are a lot fewer women than men in science is that, on the whole, they're dumber.

Oh, and please don't start up a discussion of this whole controversy here, it's been done to death already many places on the internet. So unless someone has a really informative and original comment on this (or Lubos wants to defend himself against mischaracterization of his views), I'll probably delete more comments about this as off-topic.

12. **Gordon**
August 30, 2005

You should realize, that none of theories you advertised are quantum consistent. They explode upon quantization. I still
dont know what to do about this, besides many months of work.

13. **Jean-Paul**
August 30, 2005

You described the book without any comments on its quality — very diplomatic.
So is it a good book? A possible best-seller?

14. **Chris Oakley**
August 31, 2005

Well, Gordon, don't quantize, then.

15. **Thomas Larsson**
August 31, 2005

Very,

What you say about spinors and connections is technically correct, but why don't you think that this is beautiful? Mathematical beauty is usually connected with symmetry, and groups (and infinitesimally Lie algebras) are the language of symmetry.

You can regard differential geometry (DG) as the representation theory of the group of diffeomorphisms. All objects of interest in DG, like tensor fields, connections, exterior and covariant derivatives, etc., have a natural formulation in diffeomorphism group language. This is obvious, since DG is about well-defined objects, and an object is well-defined precisely when it transforms as a representation under arbitrary coordinate transformations.

You are of course free to think that DG is trivial or ugly. However, you cannot coherently argue that DG is beautiful and that diffeomorphism group representations are not, because the former is a special case of the latter.

A major insight of conformal field theory is that in addition to the classical reps relevant to 1D DG (primary and secondary fields), there are also quantum or lowest-energy reps, with energy = L_0: Verma modules, Fock modules, minimal models, etc. These quantum reps are directly applicable to the physics of 2D phase transitions, and also play an important role in string theory; the special role of D=26 follows immediately from the Virasoro algebra.

Algebras of diffeomorphisms and gauge transformations admit similar quantum representations also in higher dimensions. I have tried to educate the physics community about this remarkable fact for several years, so far in vain. People unwilling to learn are simply not susceptible to edification.

16. **a**
August 31, 2005

From a phenomenological point of view the AdS/CFT duality means that the Randall-Sundrum model is the same thing as "walking technicolor". So, it is curious that almost no phenomenologist likes to work on technicolor (because disfavored by precision electroweak tests), while its dual Randall-Sundrum version attracted a lot of attention. Luckily LHC will start in a few years, allowing us to restart doing real physics.

17. **woit**
August 31, 2005

Jean-Paul,

No clue whether it will be a best-seller. Intellectually, I think it's a better book than many recent ones of the same genre, because there's less gee-whiz evangelizing for very speculative ideas that probably don't work. In this case the author only does a bit of this, and mostly only for her own work. Every scientist should have the right to write something overly optimistic about their own work for the general public, and I think anyone reading such a thing does so well aware that people tend to have an exaggerated opinion of how wonderful their own children are. About ideas like supersymmetry and string theory, Randall is even-handed, saying the jury is out and explaining what some of the severe problems with these ideas are.

The book is written so as to be in principle understandable by someone with no knowledge at all of math or physics, which is a worthy goal, but I'm not sure how realistic this is. Some simple ideas are explained in great detail, with several different analogies and related stories. I confess to having skipped most of this, since it wasn't aimed at me, and it's hard to tell how effective these parts of the book will be. I just finished my own book, and spent a lot of time thinking about how to explain some sophisticated ideas to as wide a range of people as possible, without using equations. In my case I decided to mostly avoid analogies and just give the clearest short explanation I could come up with. People with more background hopefully will get something out of these explanations, people with less will find some paragraphs baffling, but hopefully just move on to the next paragraph.

The danger with writing a long explanation, with lots of analogies is that people can get lost in these things, and if not chosen very carefully the analogies can do more harm than good. They can confuse people who focus on the wrong part of the analogy and miss the point, or convince people they understand a concept when all they've learned is that X is like Y, where they know what Y is, but still don't have a clue as to what it is about X that is like Y. Anyway, I can't really tell how well Randall succeeds at communicating these ideas to someone who starts not knowing much at all about this stuff, for that you need to hear from a different reviewer.

18. **rrtucci**
August 31, 2005

I don't like analogies too much either; but, physics/math figures (including graphs), I consider vital. (e.g. Penrose's latest book is brimming with figures) Pedro, how many figures will your book have? Even before you answer, I will ask my next question: Do you think such a paltry number of figures is enough? If it's still possible, I think you should add a few more.

19. **woit**
August 31, 2005

Hmm, the book has a few figures, but not enough. How did you know?

Actually I'm about to start dealing with the figures next week, will take your excellent advice to think about smuggling in more.

The figures in Penrose's book are truly amazing, definitely one of the best parts of his book. He's an excellent draftsman, did them himself I hear. Just thinking about the amount of work that went into them scares me.

20. **plato**
September 1, 2005

He's an excellent draftsman, did them himself I hear.

With his tessellations and influence of Escher one understands why I think.

September 2, 2005

I just browsed through this book at a nearby bookstore and in the
acknowledgements Lee smolin has been thanked.

25. **Nigel**
September 17, 2005

Just read Warped Passages and think it brilliant. Especially where Lisa writes on page 295 that ‘even if string theory is correct, we are unlikely to find the many additional particles it predicts. The energy of current experiments is sixteen orders of magnitude too low. … because the string length is so tiny and the string tension is so high, we won’t see any evidence to support string theory at the energies achievable in accelerators, even if the string description is correct.’

In addition, she admits the fact that not only are these speculations impossible to test convincingly, they are also extremely vague because there are many variations of the extra-dimensional theories. She remarks on page 456: ‘We now know that extra-dimensional setups can come in any number of shapes and sizes. They could have warped extra dimensions, or they could have extra large dimensions; they might contain one brane or two branes; they might contain particles in the bulk and other particles confined to branes. … Which, if any, of these ideas describes the real world?’

Quantum Gravity Commentary

September 2, 2005
Categories: Uncategorized

During the last couple days, some interesting commentary on quantum gravity has appeared at a couple places on the web. One is at John Baez's latest edition of his proto-blog This Week's Finds in Mathematical Physics. John is mainly writing about operads, but he begins by saying a bit about why he's working on pure math rather than quantum gravity these days:

Work on quantum gravity has seemed stagnant and stuck for the last couple of years, which is why I've been turning more towards pure math.

He mentions the "landscape" and the problems it is causing for string theory, suggesting a reason Susskind's "anthropic" nonsense is getting attention:

perhaps it's because nobody really knows how to get string theory to predict experimental results! Even after you chose a vacuum, you'd need to see how supersymmetry gets broken, and this remain quite obscure.

But instead of spending time bashing string theory, John admirably also has a critical take on his own side of the LQG/string theory controversy, noting that

it has major problems of its own: nobody knows how it can successfully mimic general relativity at large length scales, as it must to be realistic! Old-fashioned perturbative quantum gravity failed on this score because it wasn't renormalizable. Loop quantum gravity may get around this somehow… but it's about time to see exactly how.

Jacques Distler also has an interesting posting about quantum gravity, based on his introductory lecture to the string theory class he is teaching this semester. He explains what some of the generic problems with quantum gravity are, from an effective field theory/renormalization group point of view, and how string theory gets around them. There are also some interesting comments about observables in quantum gravity and the signficance in this context of non-trivial gauge transformations at infinity. Unfortunately, unlike John, Jacques doesn't believe in being very explicit about the problems his side is having (to be fair, maybe that's the topic of another lecture). He does mention background independence and refers to discussion elsewhere, where students could learn about the lack of a non-perturbative formulation of the theory. But his claim that string theory "provides a unique, or nearly unique UV completion" seems to me seriously misleading, and deserving of elaboration lest the uninitiated get the wrong idea.

Jacques does deal in a somewhat peculiar way with a commenter named Jason who is happy with the idea of a quantum gravity theory that can't predict anything at all at the Planck scale. Instead of making the obvious point that believing in a theory that can't predict anything is not what scientists do, Jacques writes

Careful, Jason. A certain self-anointed String Theory gadfly might hear you.

Perhaps Jacques meant to write "self-appointed", since I'd never thought of myself as a "gadfly" until Sean Carroll recently referred to me as such. If I were the sort to self-anoint, I suppose I'd prefer something more serious sounding than "String Theory gadfly", maybe "String Theorist's worst nightmare"…..

Comments

1. **garrett**
   September 3, 2005

   This quote is also from John Baez's TWF post:
   "Math is (at least for me) a less nerve-racking pursuit, since the truths we find can be confirmed simply by discussing them: we don't need to wait for experiment. Math is just as grand as physics, or more so. But it's more wispy and ethereal, since it's about pure pattern in general – not the particular magic patterns that became the world we see. So, the stakes are lower, but the odds are higher. "

   This seems like such a cop out! I mean, yes the stakes are high and the odds low when working with the fundamentals, but if the most qualified people don't work on this — and it does desperately need to be worked on — who will? And what is tenure for if not working on risky endeavors? I do agree the math itself is beautiful, but it's so much better and more important when it's the universe's math one is trying to figure out.

   I guess this just emphasizes the fundamental dilemma with pure math from a physicists point of view, and the dance theoretical physicists and mathematicians do around one another. Quite often mathematicians wandering away from physically motivated math and into their own creations will make something up that is later found to apply to the physical world, but even more often it doesn't. For mathematicians this is not a gamble at all, but for a physicist this is the biggest gamble there is.

   Gadfly — heh, yah, you're a gadfly the same way the kid who said the emperor had no clothes was a gadfly.

   Hey Peter, I don't know if I should ask you this via email, or in comments, or where, but do you know much about the geometry of BRST transformations? I figured you would and I wanted someone to talk with about it. Email would be my first choice.

   -Garrett

3. **Thomas Larsson**
   September 3, 2005

   gadfly: n. a fly that bites horses and cattle
   – Oxford paperback dictionary

   Swedish: broms. Norvegian and west Swedish dialects: klaegg.

4. **Lee Smolin**
   September 3, 2005

   Dear Peter,

   Thanks for this. It is good to lay out the strengths and weaknesses of all the approaches. It is true that the big challenge facing all background independent approaches is showing that the classical spacetime geometry is recovered in the low energy limit. But my own view is that John is too pessimistic. There have been for years results which show that LQG has semiclassical states, and that predictions, such as for the possible deformation of Lorentz invariance, can be gained by studying their excitations. (See summary and references in section 4.5 and 5.1 of hep-th/0408048.) So it is wrong to give the impression there are no results supporting the conjecture that the low energy limit of LQG is GR. And we should not forget the rigorous results that show that LQG and spin foam models are finite theories, so the question of the low energy limit is well posed, something not achieved in earlier theories.

Of course if the theory is right-and we never assume so-we must show more. We must show that the ground state is semiclassical, by solving the dynamics. This is a hard problem, analogous to showing that the ground state of water is a solid. But as this is the focus of attention there are beginning to be significant, non-trivial results on how classical spacetime can emerge from a background independent quantum theory. The best so far are not in LQG, they are the Ambjorn- Jurkiewiczcy-Loll results on CDT, hep-th/0404156. More is coming, I know of 3 papers in preparation by different authors that contain interesting new approaches or results on this problem. So stay tuned and (to John) don't loose heart.

Having said this, I should also say that my own view is that it is not likely that LQG, CDT or anything else now on the table will simply be the right thing. I believe these are all models, necessary steps from which we learn how to do non-trivial calculations in background independent, diffeomorphism invariant quantum field theories. As we gain control over them we are beginning to use the new language and tools gained to address not only quantum gravity but the other big problems such as unification and quantum cosmology. The right theory will solve all of these. And I believe it will do so by featuring a genuine emergence of classical spacetime geometry from something more fundamental.

As for string theory being the unique UV completion, the claimed uniqueness requires imposing two physically unjustified assumptions, 1) that it makes sense to an arbitrarily high energy to separate the spacetime geometry into a fixed background and gravitons of arbitrarily high energy and 2) those graviton states transform under the ordinary Poincare transformations, no matter how high the energy. The first appears false in any consistent non-perturbative unification of gravity and quantum theory including CDT and LQG. The second is much less compelling since we learned that Poincare invariance may be deformed, as in deformed or doubly special relativity theories. These allow the relativity of inertial frames to be consistent with energy and/or momentum cutoffs. At least in 2+1 gravity coupled to matter, we know this is how the theory achieves consistency. And there are indications (far from proofs) that the same will be true in 3+1 when we get the low energy limit sorted out.

Of course, the best news is that AUGER and GLAST will in only a few years tell us the fate of Lorentz invariance. The need to firm up our predictcions before the experiments report is what keeps us working hard on these problems.

-Lee

Garrett,

John Baez is a very good mathematical physicist who knows a lot of physics, so I've been kind of sorry to see that recently he hasn't been directly working on physics. It's a loss for the field. But for most mathematicians, I think it's a good thing if they learn some physics, but then instead of directly working on it, use what they have learned to come up with some new mathematics. What physics is really suffering from these days is a lack of needed new tools, and when mathematicians pursue good new mathematics, they often end up generating the kind of tools physicists need, even if that's not what they were trying to do.

About BRST: I've been thinking a lot about this in recent years, but it's a complicated subject and here's not really the place to say much about it. From the Hamiltonian point of view, BRST is basically Lie algebra cohomology, but in a somewhat exotic "semi-infinite" context. From the Lagrangian point of view, it's related to the whole Mathai-Quillen formalism for constructing Thom forms, explicit representatives of the Poincare-dual of a slice of the group action. In this context I suspect there's more to the relation between the Hamiltonian and Lagrangian point of view than many people think. If you're interested in talking about this stuff, we should do it by e-mail for now, although I should also write more about this here or in another form. I'm hoping once the semester gets started, I'll finally have time for this sort of thing.

Lee,

Thanks for you comment, it's very interesting and helpful. The contrast between the evangelism and refusal to acknowledge problems that characterizes many string theorists, and the much more straightforward and scientific attitude of the LQG community is really remarkable.

6. **Arun**

Distler wrote:

http://golem.ph.utexas.edu/~distler/blog/archives/000612.html#AdviceF1

> The principle of Universality — that the same infrared physics allows for multiple, distinct, ultraviolet completions — is what makes effective field theory possible. But it also, ultimately, dooms any attempt to study quantum gravity in a field-theoretic context. Anyone who tells you, "First, I'm going to quantize pure gravity, and then we can add whatever matter and gauge interactions we need, later.?? is trying to sell you a bill of goods. Nothing sensible can come from such an approach.

Comments?

7. **woit**
September 3, 2005

Arun.

I've always felt that ultimately a successful theory of quantum gravity has to also explain where the standard model comes from, partly for the reason Jacques explains, partly for the reason that I don't see how a quantum gravity theory can ever be tested unless it also has something to say about particle physics (I'm less optimistic than Lee about finding tests of quantum gravity using experiments like AUGER and GLAST).

I don't think Lee or other LQG people really disagree with this. If you look at his comment here, he is clear that he sees LQG and related approaches to quantum gravity not as a final theory, but as worth studying to get a better handle on background-independent theories, something that might then point the way to the right theory, one which would tell us about unification. Similarly, the more sensible among string theorists acknowledge that current ideas about getting unification out of string theory don't work, but see further investigation of string theory and its relation to QFT as the most promising thing to think about that might lead to new ideas that do work.

Jacques is right to point to a basic problem that LQG must face up to, but he ignores even more serious basic problems that string theory unification faces. The fact that the vacuum energy is the order parameter for supersymmetry breaking is an even less subtle problem that one could say dooms any attempt to quantize gravity using any supersymmetric theory, including the superstring.

If you believe Jacques that his argument "dooms any attempt to study quantum gravity in a field-theoretic context", so you should give up on field theory, you should also give up on string theory because of the vacuum energy argument (and a host of others….). But once you've given up on field theory and string theory, you may not have any ideas left to work on, which creates kind of a problem.

8. **Wolfgang**
September 3, 2005

Lee,

Lubos Motl wrote a long comment to the same two opinion pieces by John Baez and Jacques Distler on his own blog. Would you dare to comment on Lubos' remarks against LQG, especially the argument(s) that it cannot get the BH entropy right ?

Thank you,
Wolfgang

9. **Lee Smolin**
September 3, 2005

Hi Wolfgang,

Thanks for asking. It is always good to have critics and a few of the points Lubos mentions are correct. But not most. I 'll avoid the temptation to get into a point by point rebuttal and would just ask those interested to read the section on frequently asked questions in my review hep-th/0408048, which covers most of the points. On recent developments, he appears to mischaracterize Rovelli's new paper, gr-qc/0508124, which is to my understanding significant progress. There is a lot in that paper and it also depends on a series of technical developments that directly address some of the issues Lubos raises, for example about observables, that Rovelli and his collaborators have carried out over the last few years. Rovelli et al impose a boundary to define a convenient set of observables, but this is not, as Lubos seems to think, the same as giving up background independence.

The situation with regard to black hole entropy, Immirzi, and quasi normal modes is still evolving and I don't think Lubos's characterization is correct. My own current understanding is contained in a new version we just posted of hep-th/0409056.

I agree that background independent quantum theories of gravity, including LQG, must address the problem of unification. We have some new ideas and results about this that I'm pretty excited about which will be announced at the Loops 05 conference.

-Lee

10. **Arun**
September 3, 2005

So, e.g., that 2+1 general relativity has been successfully quantized is a red herring (done without constraining the matter content of the 2+1 theory); success in a similar program in 3+1 general relativity without constraining the matter content of the 3+1 theory would simply yield another toy model with conceptual and technical insights that might apply to a physical theory? That is, a "quantum general relativity" may exist, but by the Georgi/Distler argument, cannot be a theory of physics?

11. **Gordon Chalmers**
September 3, 2005

Censored again. Ever tried holography, Woit. It is not science fiction, and believe me it does require string theory. Your book panning string theory has got the biggest denial of my entire life.

12. **woit**
September 3, 2005

Gordon,

I deleted some of your comments because they didn't make a lot of sense or add anything to the discussion here. Sorry, but doing this seems to be necessary to keep you and others from filling up this forum with off-topic or non-sensical stuff. If you don't like the fact that this space is moderated, and want to be able to say whatever you want, get your own blog, it's free and easy to set-up.

Before criticizing the book, you might want to first read it.

Unless you have comments that make sense and are on the topic of the posting, please don't submit them, I'll continue to delete them.

13. **ksh95**
September 3, 2005

I don't know much about deformed lorentz symmetries, diffeomorphi-la-shi-siscms, or ringing black holes (although I do have vague memories about some BRST ramblings).

Anyway. . . as a condensed matter theorist I do know about discrete topological objects, spin networks, verticies and edges, etc. I also know that it is impossible to get long-range-anything unless there are extra terms in the lagrangian/free energy. Meaning you have to add interactions or some background pressure or temperature fields. . .something. (I don't need any theorems to tell me that, I know it's true).

Now, I speak condensed mattereeze fluently but I've only taken quantum graviteeze 101. Nevertheless, I will attempt to translate.

You can have spin networks/foams and discrete topological objects all day long, but until you add interactions (whatever that means) or some other background stuff you will never have long range order.

14. **Moshe Rozali**
September 3, 2005

Peter,

Quick factual correction: the vacuum energy is an order parameter for SUSY breaking only in globally SUSY theories (where this does not matter since it is not measurable). In supergravity this is no longer the case, as there are some positive and some negative contributions when SUSY is broken, and vacuum energy can be anything.

15. **Nigel**

September 4, 2005

Peter,

If you click on my name you go into a disussion of the fifth dimension as being the spacetime fabric responsible for gravity:
http://eskesthai.blogspot.com/2005/08/fifth-dimension-is-spacetime-fabric.html

This looks like a more sensible approach than the usual 'consistent theory of quantum gravity' that ST is supposed to provide, since this approach unlike usual ST actually seems to predict things.

Nigel

16. **woit**
September 4, 2005

Moshe,

The argument I gave was certainly over-simplified, you're right that it's only for global supersymmetry that supersymmetry breaking implies positive energy and you get a direct connection between the supersymmetry breaking scale and the vacuum energy.

But if you try and get around this by breaking supersymmetry using supergravity, it's true that you no longer have the above argument, and the vacuum energy is not necessarily positive, but its scale is now typically the Planck energy, no? So, to get a small enough vacuum energy you have to fine-tune the theory for no good reason to one part in 10 to the 120th or whatever, right? Correct me if I'm wrong, I've spent a fair amount of time trying to understand models of supersymmetry breaking, but still find the subject very complicated with all sorts of possibilities. But from what I have understood of the subject, as far as I know no one has an idea for a supersymmetry breaking mechanism that gives a vacuum energy of anywhere near the right scale. As far as I can tell the reason this is so hard comes from the fact that, depending on how you break supersymmetry, the scale of the vacuum energy involves the supersymmetry breaking scale and/or the Planck scale.

Is there some known way to get an appropriately small energy scale when you spontaneously break supersymmetry in supergravity (i.e. without fine-tuning or anthropism)?

17. **Moshe Rozali**
September 4, 2005

Peter,

The statement you had before, about having a positive CC in theories where SUSY is spontaneously broken, would have amounted to falsifying SUSY back in the days when the CC was thought to be exactly zero. Also troubling is the relation between SUSY breaking scale and the vaccuum energy. In any event, one has no choice but to think about things in SUGRA, the vacuum energy is not measurable otherwise (and also, of course, we do have gravity in our universe).

\
Sure, no good way of solving the CC problem dynamically is known, in SUGRA or otherwise, as I said the vacuum energy could be anything. If I knew how to answer this I would not post it as a comment on a blog…
\

In the context of SUGRA there is really no direct relation between the SUSY breaking scale and the vaccum energy. Also, none of the scales is Planckian- the SUGRA modifications to the vacuum energy are suppressed, not enhanced, by the Planck mass (so that one gets the right limit in the globally SUSY case).
\
In that context there is the old idea of no-scale models where you get zero CC as a consequence of some symmetry (till you break the no-scale structure, which you have to do…). These are typically the models one gets as the low energy limit of flux compactifications.

best,

Moshe

18. **woit**
September 4, 2005

Hi Moshe,

I wasn't trying to imply that the direct relation between vacuum energy and supersymmetry breaking in the global supersymmetry case falsified the idea of supersymmetry, that would be just about a mathematical theorem, and too easy. Of course you have to couple to gravity somehow, which makes the question much more complicated. But this still seems to me analogous to Jacques's renormalization group argument: it's not a rigorous no-go theorem, but shows that generically you've got a big problem of principle, one you have to find a way around somehow.

Thanks for your clarifications, but I'm still confused about some things. For any given supersymmetry breaking mechanism the vacuum energy should be computable in terms of the various energy scales in the problem, including ones we know about (Planck scale, weak scale…), as well as hypothetical ones for things like messenger particles and supersymmetry breaking in various sectors. Do you know of a good reference that explains how this works out in various possibly realistic scenarios? The papers I've looked at where people try and get implications for phenomenology out of various supersymmetry breaking scenarios seem to mostly ignore the vacuum energy problem.

Finally, I'd assumed that KKLT sort of scenarios led to vacuum energies generically at the Planck scale, just because of the often-heard argument that the existence of more than 10 to the 120th of these things implied that some were likely to have small enough vacuum energy. What does set the vacuum energy scale in these scenarios?

19. **Moshe Rozali**
September 4, 2005

The CC is of course a "big problem of principle", and there is always fine tuning involved. In the context of SUSY it is not immediately obvious the required fine tuning is allowed, but it is. Given that, I am not sure if SUSY makes the problem any better or worse.
\
In KKLT, or earlier SUGRA models, the CC comes as a difference of two positive definite quantities, each of which is of the order of the SUSY breaking scale (which is typically low in these scenarios). Most of the effort in these directions is to be really careful that EFT methods are justified, so among other things there are no Planckian energy densities involved.
\
For reviews you can look at Nilles' famous one, and there is a physics reports on no-scale supergravity (both have over 500 citations, so they are easy to find).

20. **woit**
September 4, 2005

Hi Moshe,

Thanks a lot for the references, that's very helpful and I'll take a look at them.

From what you say about KKLT and earlier SUGRA models, they give a vacuum energy of order the SUSY breaking scale unless you fine-tune, no? That's what I'd very naively expect, if you've managed to avoid introducing Planck-scale effects. Granted it's only in the SUSY/SUGRA context that the whole question of the vacuum energy is well-posed, but this has always seemed to me evidence that there's something fundamentally wrong with the idea of SUGRA based unification, or, less negatively, it's missing something very important.

>desperately need to be worked on — who will?

It's not clear that quantum gravity (or particle physics) "desperately needs to be worked on". There are a lot of problems, like finding a vaccine for AIDS, that desperately need to be worked on. Quantum gravity and particle physics are different.

First of all, nobody is dying for lack of a solution to these problems. Secondly, these problems will only get *easier* as time passes. Right now our technology lags far behind our knowledge of physics. We are nowhere near making the kinds of machines our current knowledge of physics would let us build. If we let technology catch up for a few decades – or centuries – we'll be in a better position to do experiments and make astrophysical observations that could give us some extra clues. Also, our understanding of mathematics will keep getting better, and it's quite possible there's some math we don't know that's holding us back.

Mind you, I'm *not* saying everyone should wait before working on quantum gravity. I dived in and worked on it for about 10 years, and other people should too – and other people will regardless of whether I think they should! But, there's no need for anyone to work on this stuff who doesn't want to.

So, I've decided that before I get too old I'd like work on some stuff that I'm *sure* will be good. In my work on quantum gravity I came up with some quite nice math, but most of this math will only be *really* exciting if the physical theories I was pondering turn out to be right, or at least a step in the right direction. Luckily, I also have the option of working on math that I'm *sure* is exciting, regardless of how things go in physics.

>And what is tenure for if not working on risky endeavors?

Tenure is for working on big projects that you wouldn't dare start without having job security. This does not imply you have to pick projects that are unlikely to succeed.

> I do agree the math itself is beautiful, but it's so much better
> and more important when it's the universe's math one is
> trying to figure out.

Certainly this is what physicists think, but I'm in a math department, and mathematicians are allowed to hold quite different opinions on this subject.

Mathematicians tend to feel that the most important math is math that would be important *regardless* of what the laws of physics turn out to be: fundamental stuff that applies all over the place. Certain patterns are so powerful that calling them merely "beautiful" drastically understates their importance. We haven't found all of them yet – there are a lot staring us in the face that we're just beginning to recognize – and tracking them down is incredibly exciting.

So, I don't feel it's a copout for someone to work on math instead of physics, as long as they're good at it, they like it, and they try to tackle the biggest, most important problems they can.

In short: it may be less important to work on physics when there's a high chance one is barking up the wrong tree and ones work will wind up in the dustbin of history, than to do math that's clearly good.

This issue, of course, is part of what Peter's blog is all about.

But, I understand the disappointed feelings you are expressing, because physics is a wonderful quest. It's very hard to give it up, even in times like ours when it's hard to tell if real progress is being made.

22. **John Gonsowski**
September 5, 2005

John, could you perhaps take a longer look at Tony Smith's math? The patterns do not get more beautiful. There's even still some physics.

23. **Alejandro Rivero**
September 5, 2005

*First of all, nobody is dying for lack of a solution to these problems. Secondly, these problems will only get *easier* as time passes.*

Now you mention it, it could be worth to point out that, actually, everyone is dying because time passes.

24. **JC**
September 5, 2005

John Baez,

What things could possibly convince you to go back to quantum gravity research?

At this point the only major thing which could possibly convince me to ever go back to doing any quantum gravity research, is if somebody ever finds a way of getting around the anthropic/landscape stuff in string theory without making things any worse. From a quantum field theory perspective, it would be impressive if somebody ever found an easy way to get around the Sagnotti nonrenormalizable 2-loop result for "pure" quantum gravity, without resorting to any paradigms like strings and/or loops.

25. **Yacine**
September 5, 2005

There's no such thing as the anthropic/landscape principle. Since when G is interpreted as an anthropic argument in Newton's Law of gravitation ?? Cause sure you can find an anthropic reasoning for about everything. It's just like numerology, if you look for it you'll find it everywhere.

If you fine tune your theory using so called parameters and you're still able to make predictions that's nothing of a short coming. Sure you won't get the ultimate-theory-of-I-don't-know-what, but you'll do some physics.

26. **Who**
September 5, 2005

JC: *impressive if somebody ever found an easy way to get around the Sagnotti nonrenormalizable 2-loop result for "pure?? quantum gravity, without resorting to any paradigms like strings and/or loops*.
If you haven't already seen it, you might be interested in some work of Martin Reuter and others. This is a recent paper with references going back.

http://www.arxiv.org/hep-th/0508202

This is an earlier paper
http://www.arxiv.org/hep-th/0112089
Towards Nonperturbative Renormalizability of Quantum Einstein Gravity
Abstract: "We summarize recent evidence supporting the conjecture that four-dimensional Quantum Einstein Gravity (QEG) is nonperturbatively renormalizable along the lines of Weinberg's asymptotic safety scenario…"

27. **Who**
September 5, 2005

John Baez: *in short: it may be less important to work on physics when there's a high chance one is barking up the wrong tree and ones work will wind up in the dustbin of history, than to do math that's clearly good*.

Historians might consider the image of a dustbin unfortunate because it makes them out to be Dumpster Divers. And others as well, including physicists, who learn from the successes and failures of the past. Maybe history is not exactly a dustbin.

Apparently it was Leon Trotsky who coined the cliché. I found this account in a NY Times review:

…mutinies in the army, land seizures in the countryside and intrigue and conspiracy in the cities. The Bolsheviks were the chief beneficiaries of the disorder, and in November armed Bolshevik detachments in St. Petersburg and Moscow dealt the tottering provisional Government its death blow. When the Mensheviks protested, a onetime Menshevik turned Bolshevik, Leon Trotsky, scornfully consigned his former comrades to "the dustbin of history."

http://www.nytimes.com/books/98/01/18/reviews/980118.18issermt.html

Aside from the bad press that history gets in John's post, I see a lot of truth and little to object to. It's great when people are free to work on what they are enthusiastic about and perceive as going forward. There are good reasons why a person who sees quantum gravity research as stalled and stagnant for the past couple of years should work on something else. I think that how one sees it must be to some extent a personal vision reflecting one's individual point of view. In my case, I see the field as having been especially active since the May 2004 Marseille conference which John reported in
http://math.ucr.edu/home/baez/week206.html
and therefore as not at all stagnant.

28. **Carl Brannen**
September 5, 2005

Alejandro Rivero: *Now you mention it, it could be worth to point out that, actually, everyone is dying because time passes*.

It's my understanding that neither quantum mechanics nor relativity possess a notion of "now". I recall reading that Einstein made reference to this in a letter he wrote within a few months of his death: *"For those of us who believe in physics, this separation between past, present, and future is only an illusion, although a persistent one."*

Carl

29. **John Baez**
September 5, 2005

JC asked: *What things could possibly convince you to go back to quantum gravity research?*

Well, first of all I'd be unable to completely quit quantum gravity research even if I wanted to, because I have two grad students working on spin foam models: Derek Wise and Jeffrey Morton. But this is a good thing, because I don't want to completely lose track of this field.

Among other things, we're working on Freidel, Louapre, Barrett et al's ideas on how to describe particles in 3d quantum gravity as "spin networks with loose ends" – a wonderful realization of Wheeler's old dream of "matter without matter". Spin networks with loose ends are also mathematically related to D-branes, especially in topological string theory. We want to clarify these ideas using n-categories, following the strategy outlined in last year's quantum gravity seminar at UCR (see my website). Crudely, there's a 2-category with:

particles as objects
spin networks going between particles as morphisms

spin foams going between spin networks as 2-morphisms

and this fact, when worked out in detail, gives a rather beautiful new picture of how matter, gravity and spacetime could fit together – at least in 3 spacetime dimensions! Building a realistic theory along these lines would be a lot harder, since many of the details use mathemagical features special to 3d spacetime.

But, to answer your question, what could get me working *harder* on quantum gravity is some evidence that we can find a mathematically elegant background-free quantum theory that can reduce to general relativity in a suitable limit. I see no reason why such a thing can't be found if we drop the restriction on "mathematical elegance" – but I like things that use beautiful math.

This is precisely why I mentioned Carlo Rovelli's new paper. Getting the two-point function for gravitons on Minkowski spacetime out of loop quantum gravity would be a marvelous bridge between the background-free approach and perturbative quantum gravity. Carlo does it in a rough-and-ready way: can we fill in the details? I'll be in Marseille next February talking to him about this.

I just don't want to burn myself out staying up all night struggling with these issues when I could be having fun doing cool math. If it works, it works. If it doesn't, it doesn't.

From a quantum field theory perspective, it would be impressive if somebody ever found an easy way to get around the Sagnotti nonrenormalizable 2-loop result for "pure?? quantum gravity, without resorting to any paradigms like strings and/or loops.

Someone has pointed out the papers of Lauscher and Reuter, which are quite fascinating and fit together suggestively with the work of Ambjorn, Jurkiewicz and Loll. I urge you to check them out.

30. **Who**
September 6, 2005

John Baez: *Someone has pointed out the papers of Lauscher and Reuter, which are quite fascinating and fit together suggestively with the work of Ambjorn, Jurkiewicz and Loll*. *I urge you to check them out*. That someone was I. Here are the links again:
http://www.arxiv.org/hep-th/0508202
http://www.arxiv.org/hep-th/0112089
Towards Nonperturbative Renormalizability of Quantum Einstein Gravity
Abstract: "We summarize recent evidence supporting the conjecture that four-dimensional Quantum Einstein Gravity (QEG) is nonperturbatively renormalizable along the lines of Weinberg's asymptotic safety scenario…??

Ambjorn Jurkiewicz and Loll point out the connection of CDT results with Reuter's QEG in their new survey paper
http://www.arxiv.org/hep-th/0509010
on the first paragraph of page 24, right before the conclusions.
the connection is that both QEG and CDT get a macroscopic 4D space with an approximately 2D fractal structure at very small scale. It is a striking convergence since the two approaches appear very different.

31. **Wolfgang**
September 6, 2005

Another reason I find these results interesting is because it also works the other way around. If you start with 2D gravity you find that the fractal dimension of your lattice is actually 4. This is an old result of dynamical triangulation/lattice gravity.
Of course it is also true that in 4D gravity the action is concentrated on the 2D triangles.
What is perhaps interesting from this for the spin-foam guys is the idea that collapsing 4-simplices do not necessarily mean everything is wrong.

32. **Wolfgang**
September 6, 2005

I am sorry to post twice in a row.
But I would just like to add that in Regge Quantum Gravity and other lattice gravity approaches (in the Euclidean sector) one finds two phases. In one the 4-simplices tend to collapse and in the other they do not (this is usually called the "well-defined" phase). Changing the coupling parameters gets you from one phase into the other.
If the phase-transition would be 2nd order, the problem of quantum gravity would have been solved 15 years ago.
Recently it has become clear that the phase structure of lattice gravity theories is quite complicated, but the CDT results are definitely encouraging.

33. **Who**
September 6, 2005

IMO you should not worry about posting twice-in-a row Wolfgang. These are interesting things and if you have more to say I hope you will not always wait for others to reply!

34. **John Gonsowski**
September 6, 2005

Two interesting posts in a row by one person is certainly better than two posts in a row by two people that say nothing except it is OK to have two interesting posts in a row by one person.

35. **Not a Nobel Laureate**
September 6, 2005

>Work on quantum gravity has seemed stagnant and >stuck for the last couple of years, which is why I've >been turning more towards pure math.

Some pedantry.

Physics, unlike math, is an experimental science.

The probability of someone discovering the nature of quantum gravity by "pure thought" is on the order of someone guessing the "right" vacuum of the string landscape or all of the molecules in the room where I'm typing this comment ending up in a cubic centimetre in the corner.

Theoretical particle physics was at it's most productive when there was a flood of new experimental data in need of explanation.

When there's a similar flood of quantum gravity experiments, then we may have similar progress.

36. **Arun**
September 7, 2005

I'd put it the other way – we won't know we've had progress until there is a flood of quantum gravity experiments.

37. **Fabien Besnard**
September 7, 2005

"When there's a similar flood of quantum gravity experiments, then we may have similar progress. "

Well when Einstein discovered GR he was not driven by experiments. It is only when the theory was there that experiments could be proposed. Who would have think of measuring the difference in time flow in the gravity field before ?
I think that quantum gravity phenomenon are likely to be even more remote from our intuition. Maybe they are plenty of them we already know of but don't reckognise as such. Einstein said something like "it's the theory which tells what we can observe".

Furthermore, trying to make quantum theory and GR compatible in some way is something someone ought to do, if only for "the honour of the human mind".

38. **Wolfgang**
September 7, 2005

> Well when Einstein discovered GR he was not driven by
> experiments.
An important input to GR was the equivalence principle, derived from empirical evidence.

In contrast, one important input to M-theory/string theory is supersymmetry and unfortunately there is no empirical evidence for it (yet). This may change with the LHC.

I assume that one or more important idea, based on empirical evidence, is needed to find a quantum theory of gravitation.
Maybe we have such evidence already and just do not understand how to turn it into a basic principle, but maybe we have to be more patient until somebody finds the missing clue.

39. **dead kurt**
September 7, 2005

Come on, now: Entertain us

This has gone on for too long.

Move on

40. **Who**
September 7, 2005

Fabien: *Furthermore, trying to make quantum theory and GR compatible in some way is something someone ought to do, if only for "the honour of the human mind??.*

Hello Fabien! I have often enjoyed reading your excellent blog. An extra pleasure to have the opportunity both to read French and get some comments on conferences taking place in Paris from the local perspective.

I agree that upholding the honor of the human mind is a good aim. Have the highest admiration for those rare researchers whose work does this.

Peter has a link to Fabien's blog at the righthand margin, so I wont paste it in here

41. **woit**
September 7, 2005

Will try and come up with further entertaining material, preferably unrelated to quantum gravity, real soon. The semester has just started here and my first class (multi-variable calculus) met yesterday. That and other beginning of semester business has been keeping me pretty busy. Soon we'll return to your regularly scheduled programming….

Yacine Says:

> There's no such thing as the anthropic/landscape principle. Since when G is interpreted as an anthropic argument in Newton's Law of gravitation ?? Cause sure you can find an anthropic reasoning for about everything. It's just like numerology, if you look for it you'll find it everywhere.

I'm NOT advocating string theroy, but I disagree, and this is why:

The common denominator in every case is that life only occurs almost exactly between whatever relevant spectrum of "coincidental" potential.

For example, and without **assuming** stuff about inflation and whatnot:

The Big Bang produced numerous principles and laws that have yet to be broken in spite of a lot of projections and theoretical speculation about the eventual and final fate of the usable energy of our expanding universe.

The inevitable heat death of the universe is one of the more obvious projections of an expanding "entropic" universe, but this conclusion doesn't completely justify the fact that the extremely small positive value of the cosmological constant means the big bang actually resulted in a near perfect balance between runaway expansion and gravitational recollapse, which actually puts the universe about as far away from the tendency toward heat death as you can possibly get, and yet still be heading in that direction. The principle of least action says that it is no coincidence that this near-perfectly symmetrical configuration is also the most energy-efficient means for dissipating energy, because this means that tendency toward "heat-death" is most economically restricted to the most-even distribution of energy possible.

The universe actually expresses a grand scale natural preference toward the most economical form of energy dissipation, so if the second law of thermodynamics is telling us that the entropy of our expanding universe increases with every action, then the anthropic principle is telling us that this will occur by the most energy efficient means possible, since the flatness of the universe is one of the many coincidentally **ecobalanced** requirements of the principle.

If the second law of thermodynamics points the arrow of time in an expanding universe, then the anthropic principle determines that time is maximized.

The anthropic principle is relevant!

43. **dan**
September 8, 2005

Hello John Baez,

Since Loll's causal dynamic triangulation appears to have a well-behaved semi-classical limit, with non-trial predictions on the planck scale, shouldn't that excite you to doing research in QG?

dan

44. **Who**
September 8, 2005

dan: *Hello John Baez,*
Since Loll's causal dynamic triangulation appears to have a well-behaved semi-classical limit, with non-trial predictions on the planck scale, shouldn't that excite you to doing research in QG?

that is such a fascinating question it's no fair not to open it up and let others besides JB answer

my guesses are that (1) mathematicians need to refurbish and revitalize their imagination by regular treks into pure math

if it is time for that it wouldnt matter what was going on with modeling spacetime dynamics

(2)I don't think anyone has yet seen how to apply elegant high algebra and categories to Loll's approach.

Loll's picture of spacetime does not even have a uniform-at-all-scales DIMENSIONALITY. Indicators of what dimension you are in correspond to observables. When you are in that place and you want to know what dimension it is in your surroundings, you take a reading from some selfadjoint operator.

so there is no off-the-shelf differentiable manifold to build structure on.

probably there is a new category of object in the briarpatch

I'm just speculating irresponsibly. I think it might take a while before any categorist or algebraist "discovers" Loll CDT

a creative mathematician should never have to justify the motions of his imagination and curiosity

45. **Who**
September 8, 2005

in http://arxiv.org/hep-th/0508202 it looks like you can get away with using a differentiable manifold if you allow it to have an infinite sequence of metrics, all describing the same system but at different scales or energies

quote Reuter et al:*But since the quantum spacetime is characterized by the infinity of equations (1.1) with k = 0 to infinity, it can acquire very nonclassical and in particular fractal features*.

I suppose there is a category of such manifolds equipped with infinite sequences of metrics.

well whether there is or not, Reuter gets similar results to Loll, like largescale 4D going down to near 2D at small scale. and maybe what Reuter is talking about is more amenable to elegant treatment.

46. **h**
September 9, 2005

Some comments, from the perspective of a (more-or-less) mathematician:

"Physics, unlike math, is an experimental science."

No. Math is experimental, too (and always was). Especially since we have computers (labs of the mathematicians…).

"so there is no off-the-shelf differentiable manifold to build structure on."

It would be *very* naive to expect that spacetime is anything remotely resembling to a manifold (of course it resembles, in large scales; but i'm not talking about that), or even that it is off-the-shelf. For starters, it "is" noncommutative (math speak for quantum :). And i like to think that spacetime is an emergent phenomenon, whatever it means.

If Loll's spacetime does not have an uniform dimensionality, i look that as a promising sign…

September 9, 2005

h said:

"No. Math is experimental, too (and always was). Especially since we have computers (labs of the mathematicians…)."

Well, computers are made of matters that follow quantum mechanics, so there is randomness and uncertainty, and there is a possibility the computer makes a mistake, like say in one out of every 10^17 instructions. It's an extremely small possibility, but nethertheless computers are not 100% error-free, due to quantum mechanics.

We humen are made of quantum mechanical matters, too. And so we could make mistakes, too. And we make far more mistakes than a computer does. How do you avoid that? You build redundances. If several computers or several person come to the same output, it is very unlikely all simutaneously make the same mistake. But the possibility is still not zero.

Because of quantum mechanics, nothing is completely certain. Therefore, that renders mathematics **an experimental science**.

For example, Perelman proved the Poincare Hypothesis. But we do not know for certainty whether his proof is correct or not. So we invite a couple of experts to exam his proof. But the process is difficult and takes two years for a complete proof read of the paper. And there is always a chance that you made at least one mistake during two years, and draw the wrong conclusion. Several experts draw the wrong conclusion at the same time is more unlikely, but it is still something of none-zero possibility. So, proofs like Perelman are quantum mechanical: you can approach the classical limit of 100% certainty, but you can not reach 100% certainty.

And without 100% certainty, mathematics is rendered an **empirical experimental science**.

I must also point out that the odd of a large group of people make mistakes simutaneously is actually much higher than you would expect. Just look at the 2004 US election, or look at how people at various levels reacted in this labor day hurricane of 2005.

Quantoken

49. **Doug**
September 9, 2005

Perhaps related to Quantum Gravity are two relatively recent articles:

[1] 'Wave acceleration of electrons in the Van Allen radiation belts by Richard B. Horne et al [http://www.nature.com/nature/journal/v437/n7056/abs/nature03939.html]

[2] 'Observational Evidence for Extra Dimensions from Dark Matter' by Bo Qin, Ue-Li Pen, Joseph Silk [http://xxxDOTarxivDOTorg/abs/astro-ph/0508572]

These articles led to the following question that Quantum Gravity and Superstring Theory strive to answer.

How would one recognize dark matter or dark energy if or when detected?

Clearly the torus [a folded doughnut] described in [1] by Richard Horne [et al] is a three dimensional unseen entity of non-optical electromagnetic energy generated by the Earth's magnetic core. These radiation belts trap particles that apparently do not react with optical electromagnetic energy. Some sources state that the primary populations are protons for the inner belt and electrons for the outer belt. [http://farside.ph.utexas.edu/teaching/plasma/lectures/node22.html]

Joseph Silk [et al] refer to dark matter 'betrayed by the gravitational tug' [2] which does not seem to rule the possible association with electromagnetic fields, sequestered protons or electrons.

Could these two papers be related?
Are non-optical electromagnetic fields within the realm of dark energy?
Are 'naked' protons and electrons in the realm of dark matter?

50. **Matti Pitkanen**
September 10, 2005

TGD based interpretation of dark matter relies on dynamical hbar having a spectrum of values and various hierarchies predicted by TGD, in particullar the hierarchy of space-time sheets characterized by p-adic length scales.

The first guess was that dark matter represents a new quantum coherent phase of matter with large value of hbar. Even laser beams could represent Bose-Einstein condensate of dark photons which through decoherence transform to ordinary photons. Large hbar would not mean in perturbative context any change to classical predictions.

During the last year it has however become clear that entire hierarchy of (relatively/partially) dark matters accompanied by a hierarchy of electroweak and color physics is predicted. This hierarchy provides interpretation for the predicted classical long ranged weak and color fields in all length scales as correlates for corresponding scaled down fractal copies of standard model physics. Since the particles in question are very light and interact only via gravitation with ordinary matter, contradictions with experimental facts are avoided.

One could say that TGD Universe is like Mandelbrot fractal which has suffered inversion. Zooming is replaced by its inverse and reveals endlessly new worlds with scaled down particle mass spectra and scaled up Compton lengths.

Light dark matter is predicted to be a grey eminence even in nuclear and condensed matter physics. In particular, in the physics of living matter scaled down color interactions and electro-weak interactions with weak length scale of order atomic length scale or longer would explain among other things large parity breaking effects in living matter. Needless to say, this picture makes sense only in many-sheeted space-time.

Various aspects of this developing vision are discussed here (astrophysics), here (elementary particle level), here (nuclear physics), here (condensed matter), and here (general vision).

See also my blog page TGD diary at http://matpitka.blogspot.com.

53. **John Baez**
September 10, 2005

dan writes:

>Since Loll's causal dynamic triangulation appears to have a
>well-behaved semi-classical limit, with non-trivial predictions
>on the planck scale, shouldn't that excite you to doing research
>in QG?

It does excite me; I think it's one of the most exciting things to come along in quantum gravity during the last few years! Everyone should read this for a less technical description of what Ambjorn, Jurkiewicz and Loll have done – or these for more detail. I talked about this stuff in the issue of This Week's Finds covering the 2004 Marseille conference on loops and spin foams, so you can also read that.

Unfortunately the most important work being done by these authors isn't the sort of thing I'm good at. It involves lots of computer calculations. I've tried to get some computer whizzes interested, but so far nothing has come of it. So, I expect I'll watch from the sidelines for a while.

There's one place I can *imagine* helping out. Their theory makes crucial use of a time coordinate. This should wash out when they take the continuum limit, but it might not – in which case they would be studying not quantum gravity, but some other theory in a different "universality class".

One can investigate this issue numerically. But it would be nice to find a variant of their model which did not make use of a chosen time coordinate, to simply sidestep this issue.

That's the sort of thing I can *imagine* being able to do… but I haven't actually been able yet. Since I'm making so much more progress on various kinds of math, I've been doing more of that.

54. **dan**
September 11, 2005

"There's one place I can *imagine* helping out. Their theory makes crucial use of a time coordinate."

Perhaps you should help them out. To what extent can CDT be applied to LQG or spinfoam, or to what extent can LQG-spinfoam, including calculations of BH entropy, be applied to CDT?

Cosmic Hype

September 9, 2005
Categories: Uncategorized

The latest issue of Astronomy magazine has two articles hyping the landscape/multiverse/anthropic principle and cosmic superstrings. Many well-known theorists are quoted supporting the anthropic principle and the multiverse, including Joe Polchinski, Nima Arkani-Hamed, Martin Rees, Max Tegmark, Alexander Vilenkin, Alan Guth and Lenny Susskind. The only negative quotes are from Paul Steinhardt and David Gross (whose quote is just one word: "virus", that he used to refer to the anthropic principle a couple years ago).

Max Tegmark is quoted as saying the kind of thing that motivated John Horgan's recent NYT Op-Ed piece: "I fully expect the true nature of reality to be weird and counterintuitive, which is why I believe these crazy things." Funny, I thought scientists were supposed to believe things, crazy or not, because of experimental evidence for them. At a Templeton Foundation sponsored conference on the multiverse, supposedly Martin Rees "was confident enough of the multiverse's existence to stake his dog's life." And Andrei Linde "went further, claiming he would put his own life on the line." Horgan might point out that neither Linde nor Rees's dog are in much immediate danger since no one has any plausible idea of how one could ever show that there is no multiverse.

Linde, Vilenkin and Susskind acknowledge that they don't know how to use the anthropic principle to predict anything, with Linde noting the problem of an infinite number of possible vacuum states: "There are many different ways of counting infinities, and we don't know which methods are preferable." Vilenkin is quoted as saying the problem has to do with the lack of the right "statistical techniques", which is kind of misleading, since the problem isn't one of mathematical technique. Susskind actually sounds the most sober of the lot, saying it will be a long time before the anthropic principle can be used to predict anything and "At the moment, it's telling us more about what not to do than what to do." Polchinski on the other hand, goes for maximum hype value, claiming that "The value we now measure for the cosmological constant is precisely what Weinberg predicted." Of course, by "precisely", he means "off by one to two orders of magnitude, much more if you allow not just the cosmological constant to vary."

The article on cosmic superstrings also contains quite a lot of hype from Polchinski, who not only is pushing the idea that the "CSL-1" object is a galaxy lensed by a cosmic string, but that "We're likely to go from one event to 1,000 events in 10 years" and "We're really at the dawn of a new era of science." For more about this, see the latest posting on Lubos Motl's weblog.

Over at Cosmic Variance, Clifford Johnson has a posting about an article in the Guardian about wacky science stories in the media by Ben Goldacre, who runs the Bad Science weblog devoted to this topic. Clifford is quite critical of media coverage of science, but the only examples he gives are ones related to health scares. String theory inspired wacky science stories like the ones in Astronomy aren't mentioned, neither is the fact that here the problem may not be incompetent science journalists, but the fondness for hype of some of his prominent colleagues.

In other popular science magazine news, I learned from David Appell's weblog that the New York Times is reporting that Discover magazine is being sold by Disney to Bob Guccione Jr. Guccione says that he intends to add a humor column to Discover and to create two new print magazines devoted to science. He claims that scientists are kind of like rock stars: "a bunch of people with strong egos and God complexes. That sounds like rock 'n' roll to me." I guess he liked Michio Kaku's recent cover article.

Comments

1. **Dick Thompson**
September 9, 2005

   The bas science media stories I always look for is the annual one where some lab or other has "demostrated faster than light communication" and thereby "overthrown Einstein". The New York Times, continuing its great tradition ("A rocket in space won't work because it has nothing to push against") is a regular venue for these stories.

2. **woit**
September 9, 2005

   Actually, in recent years I think the New York Times science coverage has been much better than what I remember from many years ago. On stories that I know something about they generally don't get all that much wrong. These days, at least in theoretical physics, when there's nonsense in the Times articles, it's often because they're quoting, accurately, some prominent physicist.

3. **cvj**
September 9, 2005

   Hi, Peter, I have to say that I'm less concerned about hype (alleged or otherwise) by string theorists about string theory research in the media than I am about hype concerning health issues. I think that misinformation about the latter is a more immediate concern with regards innaccurate science stories. I'm not obliged to mention string theory in everything I talk about, right? There's more to this universe than just strings…There's branes, for example. … 😉

   -cvj

4. **Maynard Handley**
September 10, 2005

   Perhaps journalists wouldn't write quite such stupid articles on physics if physicists writing textbooks, pop physics books and blog articles didn't think it a point of pride to go on and on about how "wacky" QM is, how "no-one in the world understands it", and similar drivel.
[I'm not attacking Peter here, he's pretty good about this. On the other hand Cosmic Variance goes in for this big time.]

5. **cvj**
September 10, 2005

   > On the other hand Cosmic Variance goes in for this big time.

   What?! Speaking of drivel….

   -cvj

6. **woit**
September 10, 2005

   I agree with Maynard that there's a lot of drivel out there from people who should know better about how wacky and incomprehensible quantum mechanics is (actually I take the extreme point of view that QM is simpler, mathematically deeper and more coherent than classical mechanics). But promoting this kind of drivel isn't something I'd ever noticed anyone at Cosmic Variance being especially guilty of.

Clifford,

Nothing wrong with being concerned about the health-related nonsense in the media. Personally I think I stopped reading such articles about thirty years ago, when I realized that most of them weren't based on any serious science. Maybe I'll start paying attention again as I get older and develop more health problems.

But I still think you should take the problem of hype in physics more seriously. Ideally I think we'd all like the average person to understand what real scientific evidence is, and to be able to evaluate any news article they read about science in terms of whether there is real evidence to back up the claims being made. The danger of physicists promoting highly speculative ideas based on virtually no evidence that are most likely wrong, and continually announcing that "we're at the dawn of a new era of science" is that the credibility of the field can be destroyed. I don't see how you can both explain to people that they should reject ID, astrology, etc. as wishful thinking not backed up by any evidence, while at the same time promoting the multiverse as the latest serious scientific advance.

7. **Not a Nobel Laureate**
   September 10, 2005

   More pedantry.

   In their day,
   dispersion relations, Mandelstam representation, Regge poles, S-matrix theory, N/D method, and bootstrap dynamics, were the fashionably dominant theories.

   In each case, they were superseded by, what was then, "obscure work".

   Progress was possible because the "obscure work", for example Yang-Mills fields, were able to explain some aspect of the flood of experimental HEP data that the popular theories of the day could not.

   The difference with string theory along any current "obscure work" is that there is a drought of experimental observations that could differentiate between the various approaches.
   That is, any of the current "theories" could actually make experimental predictions to begin with.

   Thus we have the sad, if not pathetic, situation of very clever people confusing their opinions with physical reality.

8. **Not a Nobel Laureate**
   September 10, 2005

   The truly interesting work today is instead being done in condensed matter physics and optics.

   Disclaimer: don't work in either field.

9. **island**
   September 10, 2005

   > Linde, Vilenkin and Susskind acknowledge that they don't know how to use the anthropic principle to predict anything, with Linde noting the problem of an infinite number of possible vacuum states: "There are many different ways of counting infinities, and we don't know which methods are preferable.??

   phhht… Try, none. In order to use the anthropic principle to predict anything, you must first give up trying to apply it to anything other than the observed universe where it belongs. Evobiologists could use it as it stands right now in its incomplete and tautologous form to make testable predictions about life, if they weren't anti-fanatically motivated to *believe* that it represents proof of god's existence if we're here for any other reason than by pure accident. Cosmologists could use it in its biocentric form to predict that we won't find life on Mars or Venus, and that we will find life on the bands of spiral galaxies that are about the same age as ours… etc…

   Peter wrote:

   > I don't see how you can both explain to people that they should reject ID, astrology, etc. as wishful thinking not backed up by any evidence, while at the same time promoting the multiverse as the latest serious scientific advance.

   'Dear Holiest man on Earth…

   I appeal to your highest mortal authority in order to ask that you please tell your peeps not to say stuff that hurts the popularity of my crackpot theories… '

   Thanx in advance…

   Luv, Larry
   http://genesis1.phys.cwru.edu/~krauss/papalletttxt.htm

10. **Peter Shor**
    September 10, 2005

    This is pretty off-topic, so I'll apologize, but what happened to all the popular science magazines anyway? There were quite a few more a decade ago, but now, at least on newsstands, it seems to have dwindled to Scientific American, Discover (which is being sold!), American Scientist, and a handful a specialized ones. I don't think Scientific American is as good as it used to be, either. Is this a symptom of the decline of the popularity of science in America?

11. **Not a Nobel Laureate**
    September 10, 2005

    P. Shor wrote: "This is pretty off-topic, so I'll apologize, but what happened to all the popular science magazines anyway? . . ."

    I've noticed the same.

    Scientific American was worth reading every month, now it's worth avoiding.

    New Scientist used to be an excellent British science news publication (it's actually where I first read an article by Penrose about his Twistor program) but is now the National Enquirer / World Weekly News of science reporting.

Science has not only lost popularity in the US, but also respect.

Interesting article here about math and science education in N. America:

http://globeandmail.workopolis.com/servlet/Content/fasttrack/20050906/COASIA06?section=Education

I'll also apologize for going off topic.

12. **woit**
September 11, 2005

Not really off-topic, the question of what if anything is happening to popular science magazines is interesting, and I'm certainly curious what the significance of Guccione buying Discover and getting into the science magazine business will be. Scientific American was one thing that got me interested in science when I was a kid, and part of that was the fact that it was quite serious and intellectually demanding, something I fear is less true these days.

One thing that has affected all magazines in one way or another over the last decade is the internet, and many people are getting information this way that they used to get from magazines. So it's not clear a declining number of magazines means less interest from the public. It's my impression that there are actually a lot more popular science books being published than there used to be, and books aren't affected in the same way as magazines by the internet (just about nobody wants to read a book online). So maybe there is more popular interest in science, but magazines are just less important.

13. **cvj**
September 11, 2005

Peter. I agree with your comment that it is very important. I just happen to think that misleading health-science stories are a lot more damaging to far more people. But these things are all connected, of course. But in an article or post that I'm writing, if I want to mention a few examples of dangerously misleading science reporting, I am more likely to mention examples such as the misrepresenting of the results of drug trials than I am the results of string theory. Call me old-fashioned if you want to, but this will always be the case. This has nothing to do with me being a stirng theorist, (perhaps trying to hide some non-existent theorectical physics community conspiracy to delude the public) and everything to do with me trying to be a responsible citizen of the planet first and foremost.

Cheers,

-cvj

14. **J.F. Moore**
September 11, 2005

Spin and Gear were OK for what they were. Guccione the younger's main problem seems to be keeping his publications in the black. Frankly, Disney managing anything is more financially viable, but they have no compunctions about stong-arming producers, editors, etc to enforce the party line, which is a moderately conservative, family values, thoroughly corporatist, although secular viewpoint.

Given the growing storm over ID, and the opportunity to make science "cool" to a new generation, this change might not be that bad. Incidentally, my favorite articles in Discover have consistently been the "Vital Signs" pieces, because of the way they are written and the fact that I always learn something reading them (I'm not a medico).

I will also point out that while SA has been watered down, they threw down the gauntlet rather dramatically over the assault on darwinism with the "april fools" editorial.

New Scientist has become an embarrassment, almost as bad as Wired now.

15. **J.F. Moore**
September 11, 2005

Sorry, but I have to respond after reading that op-ed piece "Not a Nobel Laureate" linked. Pedagogy is infinitely debatable – personally I think hers is terrible – but the author seems either ignorant or willing to ignore the basic facts involved in her argument about outsourcing. US companies are not outsourcing due to any shortage of talent or because US science students are lousy. They are outsourcing primarily programmers and clerical technical workers because they can be had for much less salary in India and China. This is not only obvious, but can be thoroughly sourced in business literature. To the extent that there is scientific outsourcing, a significant number of those scientists, you will find, were educated in the US.

These comparative tests that rank various countries are a joke. One thing they don't account for is the much more eglatarian basis of US education compared to many other countries, which essentially doom the majority of their population to trade labor at an early age. So our average sample is pitted against a German gymnasium (for example). Administrators and politicians keep their mouths shut about this outrage because they get more money being ranked low than they would if we were near the top.

The difficulty to get students to go to grad school or take a career in science in the US exists because the opportunities just aren't there afterward. Other professions are a much safer bet. Again, that should be obvious.

16. **JC**
September 11, 2005

I agree with J.F. Moore on this issue.

The job market has always been dictated by supply and demand. Brainpower, skills, abilities, etc … have always been a secondary issue when it comes to hiring decisions and/or the clueless HR drones. As long as the demand for particular jobs is significantly greater than the supply of those particular jobs, the PHB's (ie. "pointy hair bosses" in Dilbert) will always pick and choose whoever they want to hire. For a long time engineers, scientists, computer programmers, etc … have been a "dime a dozen" as far as the PHB's are concerned. (The only significant exception to this in the recent past was during the dotcom bubble of the late 1990's). With major outsourcing overseas, scientists and engineers have become more like a "nickel a dozen" or even a "penny a dozen". Many PHB's are mainly interested in their own paycheck and bonuses, and how much their stock is worth.

It's not entirely encouraging for freshman university students, when they see so many computer programmers, engineers, scientists, etc … out of work and/or significantly "under-employed" (ie. an engineer working as a clerk at a Wal-Mart). Parents may be less likely to dole out the cash for tuition when they see the poor job opportunities awaiting their kids. Increasing the number of science/engineering degrees will only compound the problem even further. This would be like the equivalent of significantly increasing the supply WITHOUT a corresponding increase in the demand.

Whether there is a significant correlation between the declining numbers and quality of scientific magazines with the decline of science/engineering jobs, I don't really know at this point. Though it sure seems like many kids are going into areas where the money and jobs are (ie. they're following the money). At the present time it seems to be areas like accounting, real estate, oil/energy industry, etc …

17. **Amitabha**
September 12, 2005

Hope you had a wonderful birthday, Peter! And hope you continue to debate the future of theoretical physics for many years to come.

On the off-topic comments above, J.F.Moore is right in pointing out that outsourcing is based solely on financial reasons. There isn't enough reason to believe that science and technology work is being outsourced to India/China because the workers there are better qualified. In fact many, if not most, of the top science and engineering students in India (and perhaps also China) end up on Western shores for graduate education and further research anyway. On the other hand, some Indian recipients of the outsourcing work do employ top-of-the-class science and technology graduates.

There is a recent trend among the school boards in India to make school education more fun and also easier. I guess time will tell if this leads to more students interested in serious science.

18. **D R Lunsford**
September 12, 2005

"Astronomy" is to "Sky and Telescope" as "Lubos Motl" is to "Socrates". It's been a miserable fishwrapper since the day it first appeared.

October AMS Notices

September 9, 2005
Categories: Uncategorized

The October issue of the Notices of the AMS is now available on-line. It has an interesting historical article about Henri Poincare, and a short expository article called WHAT IS… a Pseudoholomorphic Curve by Simon Donaldson. Counting these pseudo-holomorphic curves is what topological sigma models do, and they have turned out to have many different kinds of mathematical applications, including the new field of so-called Gromov-Witten theory, as well as several others.

There's also an extensive interview with Fields medalist Heisuke Hironaka. I've heard that Hironaka is a celebrity in Japan, with one of my colleagues once telling me that during a trip to Japan he was surprised to see Hironaka on a billboard selling something or other.

Comments

1. **Not a Nobel Laureate**
   September 10, 2005

   Is there a good exposition about Hironaka's singularity work for the non-specialist. It sounds very interesting and I'd like to learn more about it.

2. **Walt Pohl**
   September 11, 2005

   There was a good introduction in the Bulletin of the AMS, which is available online at http://www.ams.org/bull/2003-40-03/S0273-0979-03-00982-0/home.html.

3. **Chris Oakley**
   September 11, 2005

   HAPPY BIRTHDAY, PETER!

   I was just thinking … if the publishers don't like the title of your book, how about "Born on September 11" as an alternative?

4. **woit**
   September 11, 2005

   Hi Chris,

   Thanks for the birthday wishes!

   I think I'll stick with the current book title…..

5. **Not a Nobel Laureate**
   September 11, 2005

   Walt Pohl wrote:

   Great.

   Thank you.

Comedy

September 11, 2005
Categories: Uncategorized

I realize that this is a low form of entertainment, but reading Lubos Motl's blog today has definitely livened up my birthday, which in recent years has been a rather sad occasion. It's hard to say what is the funniest thing there since it's all great stuff, including:

1. Crazed, heavily ideological attacks (here and here) on climate scientists, who unlike Lubos, actually know something about the subject. The comment sections feature mathematician Greg Kuperberg, who has the hilarious idea that it's possible to try and have a rational discussion with Lubos on this subject.

2. Kuperberg's attempts to endear himself to Lubos by attacking the evil Peter Woit, announcing that even though he doesn't understand string theory (something he has shown a perverse interest in demonstrating publicly, besides his comments on Lubos's blog, see here and here) he believes it because "string theorists seem credible, seem talented, and have appointments at top universities."

3. Lubos's response to said attempts, comparing Kuperberg to some of his more "out-there" commenters.

4. Lubos's claims that neither Lee Smolin nor I know what we're talking about when we point out that perturbative finiteness of the superstring is not yet proved beyond two loops, followed by his claim that QFT perturbation series are Borel-summable, nonsense that Jacques Distler then writes in to correct.

Some may object that it's highly unfair to use the fact that some of its practitioners and supporters are out of their gourds to make fun of string theory, but, hey, it's my birthday, so I can do what I want today, right?

Comments

1. **icecube**
   September 11, 2005

   happy birthday!

2. **J.F. Moore**
   September 11, 2005

   Happy birthday Peter. I've enjoyed reading your blog, with the exception of Motl's insult-laden comments, and I look forward to buying a copy of your book when it comes out.

   Internet Schadenfreude is OK, but be sure to have some real life fun as well today!

3. **cvj**
   September 11, 2005

   Happy Birthday Peter!

   -cvj

4. **Who**
   September 11, 2005

   Happy Birthday, Peter!
   Kind of a special one since you have a book coming out shortly.
   Thanks for your blog–the intellectual quality and energy.
   Enjoy the next year, whichever number it is for you.

5. **Luboš Motl**
   September 11, 2005

   Happy birthday! I am very pleased that you like the gift(s) from me. Next year – assuming that there will be something like 2006 (because you probably believe that the last one will be The Day After Tomorrow) – I may try to explain you why the perturbative finiteness of string theory is a proved fact. But be prepared that Lee may be a bit faster in learning this elementary material.

6. **The Statistical Mechanic**
   September 11, 2005

   Peter,

   if I am not mistaken, September 11 is also a special day for Lubos (the day of his thesis defense).
   You two should celebrate together – oh I see that you do already …

   Happy Birthday,
   Wolfgang

7. **Luboš Motl**
   September 11, 2005

   Hi Wolfgang,

   yes, we already celebrate together. 😉 Sorry, in 1 hour we go for a dinner with FM and a renowned climate scientist.

   9/11/2001 was a day that I will never forget.

Best wishes
Lubos

8. **Tom Weidig**
September 11, 2005

You forgot to mention that Lubos also censures i.e. deletes relevant posts / opinions that he doesn't like.

He should better stick to physics than politics. It is amazing to see how his mind falls for logical fallacies once politics kicks in. Not to speak of his boundless naivety regarding policies and its implementability.

I think we should make him a politician for a week and let him leave his protected academic ivory tower…

9. **Moshe Rozali**
September 11, 2005

Happy Birthday!

Moshe

10. **Kasper Olsen**
September 11, 2005

Happy Birthday, Peter!

I'm looking forward to reading your book (even though I'm not sure I'll agree with your conclusion, well…, let's see 😉

Kasper

11. **iccutrr**
September 11, 2005

some entries from Lubos' diary

Sept/10/05: W called me again at 1 in the morning. Wanted me to hear his newest Biblical evidence for String Theory. Says Carl Rove too busy to work on Woit case right now. Carl in a frenzy; frantic with spin control for W, Brownie, FEMA, Condolezza, Chertoff. Et tu, Barbara.

Sept/11/05: Another bad 9/11. Got punched in the mouth, again, after telling dinner companion, a world renowned climate scientist, what a moron he is. His IQ must be less than 90. I think he doesn't like me. How can that be. My arguments were flawless, as usual.

12. **Arun**
September 11, 2005

Happy Birthday!

Here's something to chew on. Over at Panda's Thumb,
http://www.pandasthumb.org/archives/2005/09/dembski_quote_m.html

they're talking about a Richard Dawkins quote:

Richard Dawkins wrote:

"Instead of examining the evidence for and against rival theories, I shall adopt a more armchair approach. My argument will be that Darwinism is the only known theory that is in principle capable of explaining certain aspects of life. If I am right it means that, even if there were no actual evidence in favour of the Darwinian theory (there is, of course) we should still be justified in preferring it over all rival theories??.

Apart from the "(there is, of course)", don't the defenders of string theory sound exactly like the above?

13. **Dick Thompson**
September 11, 2005

Happy Birthday, a little late. Long may you wave and be an irritant to Lubos and his ilk. Sto Lat!

14. **Arun**
September 11, 2005

Yes, this is probably the funniest September 11 since 9/11. Maybe things are looking up, even though we still haven't caught the ultimate responsible for 9/11.

15. **woit**
September 11, 2005

Thanks to all for the birthday greetings, one thing I didn't expect today was to have so many string theorists wishing me a happy birthday. Thanks!

Spent part of the morning cleaning my apartment, which was unusually exciting, since it involved trying out my birthday present from my brother, a little "Roomba" robotic vacuum cleaner. The thing runs around the apartment vigorously vacuuming, doing its best to get into every possible nook and cranny. It only gets into trouble with electrical wires and the fringes of oriental rugs, otherwise does a great job, while providing a certain amount of entertainment.

My brother is in town this weekend, so after playing with the robot, we went out to brunch at a nearby Provencal sort of bistro (Cafe du Soleil). It was a gorgeous day here in New York, and late in the afternoon I rode my bike along the river downtown to meet my brother and mother for dinner. We went out to Bonelick Park, a barbeque place on Greenwich Ave. Had an excellent meal including some wonderful baby back ribs.

After dinner, looking downtown one could see the "Tower of Light" lights rising from the World Trade Center site. These have been turned on specially tonight to commemorate the date. Rode back uptown along the river, quite a beautiful ride at night. From my apartment now, looking out the windows to the south, I can see the World Trade Center lights, although much dimmer up here than from downtown.

Well, I'll stop with this sort of thing now, don't want anyone to get the idea that this blog is going to start having anything like Clifford's charming postings at Cosmic Variance. Enough's enough.

16. **Shantanu**
September 12, 2005

Hi
Peter
belated happy birthday. Always wanted to ask you one thing.
Does your colleague Brian Greene read your blog and your
critiques of string theory?

17. **Michael Sanford**
September 12, 2005

Happy Birthday Dr. Woit.

18. **fooltomery**
September 12, 2005

Happy Birthday, Peter…may your book become a best-seller.

And don't mind Luboš…his conviction that no aroma accompanies his defecations won't survive his denial of tenure at Hahvud.

19. **Robert**
September 12, 2005

I'm late but nevertheless: Happy birthday Peter!

20. **Eric Baum**
September 12, 2005

Peter,

Happy Birthday.
I can't help remarking on the apparent irony between your first two points.
How are readers to distinguish your respect for climate scientists from
the possibility that it derives from their seeming credible, talented, and with
appointments at top universities?

BTW, since I know you are interested in the sociology of Science, I highly
recommend reading Bjorn Lomborg's Reply to Scientific American, which
you can find at http://www.greenspirit.com/lomborg/ScientificAmericanBjornLomborgAnswer.pdf

Eric

21. **woit**
September 12, 2005

Hi Eric,

I actually have no idea who is right in the various climate science debates. What I found laughable was Lubos's absurdly ideological discussion of the issue. From the way he goes on about Bush, communism, etc., etc., it's clear that rationally weighing the evidence is the furthest thing from his mind. Perhaps a sizable part of the climate science community is so politicized that you have to evaluate all research in the field very skeptically, and in any case one certainly shouldn't rely on reputation to decide who is right. But if you want to try and do so, you have to approach the data and the subject seriously, not just engage in ideological ranting.

And please folks, don't start up a discussion of this controversy here….

Shantanu,

As far as I know Brian doesn't read the blog.

22. **Luboš Motl**
September 12, 2005

Dear Eric,

that's really bizarre what you say. Climate science and climatology has always been – and it still is – attracting the weakest students of physics and related fields in most universities I know; and for a very good reason. So if Peter Woit supports the mainstream climate science because it is done by the weak people, it is absolutely consistent with his approach to physics.

Best
Lubos

23. **Eric Baum**
September 12, 2005

Actually, Peter, Lomborg's reply to Sciam does a remarkable job of clarifying
issues all by itself. Lomborg's book went through a long series of environmental issues (GW, species diversity extinction, etc etc) and argued in each case that the popular understanding, the press version, and the pronouncements of many scientists on the one hand were wildly at odds with the actual results in the scientific papers on the other, and described the actual state of knowledge, simply quoting relatively authoritative sources such as UN reports and reviews by top scientists. Scientific American then asked 4 of these top experts to review relevant sections of the book.

Lomborg's reply goes through each of these reviews, answering it line by line. The interesting punchline comes when he gets to the end of the review,

and it's the same in each case. The punchline is: "Now I've gotten to the end of the critique, and you can see that scientist X nowhere in his critique challenged my main conclusion of Y."
Each of these critiques are tendentious in the extreme, seemingly throwing up as much dust as possible to cloud the issue, but none of them even challenges Lomborg's main scientific conclusions (e.g. the best estimates are that species diversity is vanishing at a ridiculously tiny rate, not a vast rate). This is perhaps not surprising, since all Lomborg did in the first place was to quote the scientific papers of these very scientists, but that's what emerges.

I find it highly interesting from a social standpoint that these scientists are happy, perhaps not even fully realizing what they are doing, to make all kinds of comments in public media of dire political outcomes that seem to contradict their actual scientific understanding, but I find it extremely positive that they are nonetheless unwilling to actually make clear false statements in scientific publications, even sciam, and that they still seem to be able to treat the science fairly carefully.

Anyway, since they don't even challenge his conclusions, you can maybe assume they are mostly valid as far as scientific understanding goes, even without trying to sort it out in detail, and his conclusions in every case are rather ridiculously more positive than much of what you may believe.

Eric Baum

24. **Scott**
September 12, 2005

Peter,

Happy birthday yesterday. I find it funny that he invokes Feynman about junk science while feynman himself thought string theory was a waste because of it disconnect from experiment.

Eric,

I remember reading both the scientific american reviews and his online responce and then the authors of the critiques responces(online somewhere) to his online responce. I remember seeing tons of logical errors in his responce before reading the responces which frankly blew him out of the water. Have you read those responces?

25. **Quantoken**
September 12, 2005

Peter:

I could not believe you are so narrow minded. I posted a comment which is on the very topic that you discuss whether Lubos's objection to GWT is reasonable or not. And as always, you erase it because of fear that **TRUTH** be told.

Remind you, this is NOT a crackpot theory that the earth's oil will be depleted. You must have thought it's a numerology number that the gas prices are over $3 a gallon. But it's not numerology and people are paying if from their wallets. And it's just the beginning.

I find it ridiculous that no one is even interested in talking about it. Am I the only one who still lives on the earth, and ever one else, including Peter, has moved to extra dimentions, multiverse, or ont of the the other 10^500-1 landscapes? All the number I cited are official ones and no one even disputed those numbers.

Quantoken

26. **woit**
September 12, 2005

Quantoken,

The question of how much extractable oil is still out there is completely off the topic. The only relation to what I wrote is that Lubos undoubtedly has some ill-informed views on the matter, but he's got ill-informed views on lots of things and I don't want this weblog filled up with an endless discussion of them.

About climate science discussions in general: honestly I know nothing more about these controversies than what I've gathered from reading a few articles in the newspaper. This has convinced me it's a complicated subject, full of people who have a political ax to grind and no real dedication to objectively looking at the science. I'm also convinced that if one wants to, one can read up on this and learn enough to figure out who is doing serious science here and who isn't. But this is a time-consuming business, and I don't have the time for it. If people want to discuss this, I think they should do so in a forum run by someone who actually knows something about this subject, and there seem to be several of those around.

September 12, 2005

Happy Birthday Peter, hope your next year is a fine one.

28. **Eric Baum**
September 12, 2005

Scott,
don't know if I've read *all* the responses, in fact I just did a quick web search, and found a response that I hadn't read by Holdren to Lomborg's response to his Sciam critique. I don't have to get past the paragraph 2 to feel strongly that its more of the same tendentious obscurantism. Paragraph 1 has no content except insult. Paragraph 2 is:

"As my review for Scientific American acknowledged, Lomborg�s energy chapter does contain a number of propositions that are correct (such as the observation that there is large potential in renewable energy sources and energy-efficiency improvements).The problem with the chapter–and the rest of the book as well–is that, as a famously brief review of a long paper submitted to a professional journal once put it, `What is right in this document is not new, and what is new is not right.' "

Yeah, Lomborg couldn't have put it better himself. He doesn't claim anything new. He just claims to be surveying the literature, contrasting popular and political statements with the contents of the scientific papers. Sounds to me like Holdren still doesn't want to challenge anything of content in what Lomborg is saying.

Eric

29. **LM**

September 12, 2005

Lubos Motl says: “Climate science and climatology has always been – and it still is – attracting the weakest students of physics and related fields in most universities I know”

A-ha! Now we see the reason for Lubos’s hostility- he sees the climate scientists as poaching prime recruits for string theory!

30. **Scott**
September 12, 2005

eric this is peter’s blog so I am not going to get into this with you but you read the first paragraphs of a 7 page responce, and decided how the rest of the article was be. Your retarded.

31. **Scott**
September 12, 2005

oops, i meant, “was going to be”. so i guess i’m retarded too.

32. **woit**
September 12, 2005

This kind of argumentation about scientific issues that sheds no light whatsoever on them and degenerates into personal attacks just annoys me. Please discuss this topic elsewhere, I’ll delete any further comments here about this.

33. **island**
September 12, 2005

> This has convinced me it’s a complicated subject, full of people who have a political ax to grind and no real dedication to objectively looking at the science.

As Arun’s ‘food-for-thought’ indicates, this also stereotypically includes most of the same ideologically pre-inclined that commonly argue both sides of the creation/evolution debate.

Politics destroys honesty in science.

Happy birthday.

34. **Eric Baum**
September 12, 2005

Scott,

Not really. If it was going to have content, it wouldn’t have begun with paragraph of gratuitous insults. In fact, it would be hard to imagine a
presumably respected scientist writing a paragraph of gratuitous insults, much less beginning a paper with it, if I hadn’t seen it.
And it follows a previous critique (Holdren’s first one) which was basically
the same deal. And it’s not like Lomborg didn’t have content. He said:
A is my message, and X didn’t anywhere object to it. If X wanted to
come back and say yes he did, and if he was a scientist used to communicating to other busy scientists, he would have placed a topic sentence somewhere near the beginning that said “A is in fact wrong for the following reasons, as the remainder of this paper will show”.

The fact that your correspondance is about on the level of Holdren’s should either make you proud, or serve as further evidence of the intellectual weakness of the position, which do you think?

Eric

35. **woit**
September 12, 2005

Eric,

I’ll leave this comment in place since Scott is the one who started the name-calling. But please, stop. I didn’t want discussion of this topic here because I was pretty sure that it would quickly deteriorate, but I had no idea of how quickly….

36. **Theo**
September 13, 2005

Happy birthday Peter from someone who has read your blog quite a lot recently but been lax in writing any comments so I just wanted to say thanks for the entertainment and insights.

37. **misslemon**
September 13, 2005

I wonder how most “string theorists”* or physicists would feel about having the verdict drawn up on their research by climate scientists, chemists or biologists. Get my point?
*note separate category

38. **CapitalistImperialistPig**
September 19, 2005

Happy Birthday Peter – very belated. Even though I don’t know enough string theory to have a strong opinion, I think it’s very valuable to have critics like yourself to try to keep them honest.

And Lubos – happy Phd-averssary!

The Equation That Couldn't Be Solved

September 13, 2005
Categories: Uncategorized

I just finished reading an interesting new book by astrophysicist Mario Livio. It's called The Equation That Couldn't Be Solved, and the subtitle is "How Mathematical Genius Discovered the Language of Symmetry". Livio's topic is the idea of a symmetry group, concentrating on its origins in Galois theory.

The first part of the book contains a wonderful detailed history of the discovery of the formulas for the roots of third and fourth order polynomials, and the much later proofs that no such formulas existed for general fifth order polynomials. The romantic stories of the short and tragic lives of Abel and Galois are well-told, in much more detail than in other popular books that I've seen. Galois was the one responsible for first really understanding the significance of the concept of a group, and using it to get deep insights into the structure of the solutions of polynomial equations.

The latter part of the book deals with the important role of symmetry in modern theoretical physics, and this is a topic treated in many other places in more detail. Livio gives the standard party-line about string theory, but he does do one very interesting thing. He notices that while string theory implies various sorts of symmetries, e.g. supersymmetry, it lacks a fundamental symmetry principle itself, and this leaves open a very important question. Does physics at its most fundamental level involve a symmetry principle, or are symmetry principles an artifact of our throwing out complexity and only focussing on simple situations that we can understand? Perhaps symmetry is not fundamental, but only an artifact of our limited abilities to understand things. Livio asks several people this question, and gets the following answers:

Weinberg: symmetry might not be the most fundamental concept in the ultimate theory, and "I suspect that at the end the only firm principle will be that of mathematical consistency". (I don't think I really understand what Weinberg has in mind here)

Witten: "there are still missing, or unknown ingredients in string theory" and "some concepts, such as Riemannian geometry in general relativity, may prove to be more fundamental than symmetry."

Atiyah: "We come to describe nature with certain spectacles… Our mathematical description is accurate, but there may be better ways. The use of exceptional Lie groups may be an artifact of how we think of it."

Dyson: "I feel that we are not even at the beginning of understanding why the universe is the way it is."

There is one interesting thing that Livio gets wrong. He explains Klein's Erlangen program of identifying the notion of symmetry with the notion of a geometry, but then says that this is precisely what Riemannian geometry is. This isn't really right, since the non-Euclidean geometries Klein was using are basically homogeneous spaces of Lie groups, whereas Riemann's notion was more general, just insisting that the geometry be locally Euclidean. To unify these two points of view, you need the later ideas of Elie Cartan about Cartan geometries and connections. A related distinction is that Klein was considering finite dimensional symmetry groups, whereas in Riemannian geometry you don't have a global symmetry group. You do have infinite dimensional groups of local symmetries, e.g. the diffeomorphism group, and the gauge group of frame rotations. By the way, a nice article about the early history of gauge theory has just appeared on the arXiv.

My main problem with Livio's book is that he only discusses the groups themselves, and doesn't even try to explain what a representation of a group is. For the applications to quantum mechanical systems and to particle physics, it is this notion of a representation of a group that is absolutely crucial.

Comments

1. **Andreas**
   September 13, 2005

   Interesting review, and maybe Livio avoids to write about specific representations because he intuitively knows that the truly interesting symmetries of nature do not admit any non-trivial representation?

2. **Quantoken**
   September 14, 2005

   Weinberg said symmetry might not be the most fundamental concept in the ultimate theory, and "I suspect that at the end the only firm principle will be that of mathematical consistency??. (Peter said: I don't think I really understand what Weinberg has in mind here)

   Well, I understand. On first thought you would think that mathematical consistency is a necessary condition. If the math is inconsistent then the theory is useless regardless of anything else.

   Wenberg probably belong to the group of people who believes that the ultimate theory can explain everything from **pure mathematical principles**, like an exact formular to calculate alpha.

   If the ultimate theory is pure math, then, probably, being mathematically self-consistent is all that is required to be correct in mathematics. That must be what Wenberg had in mind.

   I do not believe the ultimate theory will be pure math. There will be at least one thing unexplainable in pure math, and that remains physics.

   Quantoken

3. **D R Lunsford**
   September 14, 2005

   The paper mentioned misses the point (as usual) about Weyl's 1918 work – namely that Weyl does NOT find a suitable action at all, because the equations for g are 4th order. In fact it is not possible in 4 dimensions to find a suitable action in this theory. Only first in 6 dimesions does it become possible to find an action leading to 2nd order equations for the g's and have the g and A fields essentially coupled, without arbitrary constants.

   http://cdsweb.cern.ch/search.py?recid=688763&ln=en

   See

   -drl

4. **John Baez**
   September 15, 2005

   Peter Woit writes:

   > My main problem with Livio's book is that he only discusses the groups themselves, and doesn't even try to explain what a representation of a group is.

   It's forgivable not to explain what a representation of a group is. It's unforgivable not to explain what an action of a group is.

   Groups naturally arise as symmetries of sets with extra structure, and in this situation we say the group **acts** on the set. The first and most important way people discovered groups was by finding them acting on sets. We call these "concrete groups". This is the sort of group Galois ran into: the group of symmetries of a field fixing some subfield. I don't see how Livio could discuss Galois theory without at least implicitly talking about group actions, or at least concrete groups.

   Only later was the concept of "abstract group" achieved. This is an incredibly powerful concept. But now, horribly, there are some abstract algebra texts that discuss group theory without a good discussion of group actions – of which representations are a special case.

   Of course, anyone working on quantum theory needs the concept of group representation.

5. **Richard**
   September 15, 2005

   Yes, and sadly if group actions are discussed at all within the context of abstract algebra, it's action on an abstract set with no additional structure. Much interesting theory arises when you attach a topology to an infinite set and consider notions such as orbital almost-periodicity and proximal and distal relations under action by the group. Everyone should know how concepts of periodicity can be supported within the context of co-compact (syndetic) subsets of the acting group, even when the spaces involved are not even necessarily metric spaces.

   Concepts of group actions really should be woven more completely into the math curricula, and much theory is readily accessible even to undergraduates.

6. **JM**
   September 21, 2005

   Given your critics, what book does give a good introduction to group theory? Let's assume for example the reader to be an engineer with only trivial knowledge of quantum mechanics.

7. **woit**
   September 21, 2005

   Unfortunately I don't know of a good book that explains group theory and how to use it in quantum mechanics at an elementary level. Quite possibly such a thing is out there, but I just haven't run across it. If anyone has any suggestions, I'd like to hear about them.

8. **D R Lunsford**
   September 21, 2005

   Not to butt in, but I love recommending books 🙂

   There are any number of good books but the all-time classic for physicists is "Theory of Groups and Quantum Mechanics" by Weyl. This reprint suffers from horrible typesetting but is otherwise a masterpiece.

   For a great introduction to the entire worldview of group theory, read "Elementary Mathematics from an Advanced Standpoint" by Felix Klein, both volumes (short but very intense).

   For a standard textbook, try "Group Theory and Quantum Mechanics" by Tinkham.

   A little formal algebra couldn't hurt, for which I recommend "Abstract Algebra" by N. Herstein.

   There must be modern texts that are readable but I don't know of any.

How Much Mathematics Does A Theoretical Physicist Need To Know?

September 13, 2005
Categories: Uncategorized

Mathematician Dave Morrison is giving a colloquium talk tomorrow at the KITP with the provocative title [How Much Mathematics Does A Theoretical Physicist Need To Know?]() It should soon be available for viewing on the KITP web-site, and I'm looking forward to seeing what he has to say.

I'm not at all sure myself how much mathematics a theoretical physicist needs to know, it certainly depends on what they're trying to do. But there does seem to me to be a well-defined list of what mathematics goes into our current most fundamental physical theories, and anyone who hopes to work on extending these should start by learning these subjects, which include (besides the classical mathematical physics of PDE's, Fourier analysis, complex analysis):

Riemannian geometry
More general geometry of principal and vector bundles: connection, curvature, etc.
Spinor geometry
Lie groups and representation theory
deRham cohomology

I'm sure others have different ideas about this….

Update: Dave Morrison's talk is now on-line here. He began his talk my noting that it had been advertised here on "Not Even Wrong", and he put up a slide of my posting and people's comments as an example of people's lists of what mathematics theoretical physicists should know. He did say that that his talk wasn't intended to provide such a list, but rather various comments about how physicists can fruitfully interact with mathematicians.

He began by giving several examples of people who had to construct new mathematics to do physics: Newton, Fourier, Heisenberg, and Gell-Mann. David Gross correctly objected that SU(3) representation theory was already known before Gell-Mann started using it, even though at first Gell-Mann wasn't aware of this. As for more recent interactions, he mainly mentioned the connection between the index theorem and anomalies, as well as various math related to the quantum hall effect. For some reason he decided not to go into the relation of string theory and mathematics, which has been quite fruitful. He did say that he still believes there is some unknown more fundamental way of thinking about string theory that will involve now unknown mathematics. His general advice to physicists was that they should be willing to acquire mathematical tools as needed, but should be aware that if they ask a mathematician questions, they are likely to get answers of too great generality. He ended his talk early, opening the floor to a long discussion.

Comments

1. **Haelfix**
   September 14, 2005

   I would say you have the majority of what is necessary (you probably want some functional analysis as well). Then again there have been several successful theorists who's knowledge in certain of those subjects is sorely lacking (read nonexistant).

   In general people adapt pretty quickly in physics to what they need to know for the problem at hand. For instance, (a subject close to your heart), I have a few friends working on the landscape and they are more or less pouring over extremely sophisticated books on probability and analysis (lots of Bayesian statistics etc).

   So what does a theoretical physicist need above all else? Well, pretty much he/she needs to be a quick learner.

2. **Fabien Besnard**
   September 14, 2005

   I agree that physicists are quick learners. I come from the mathematical side and I'm often amazed how quick physicists assimilate concepts that took me ages to understand. The problem is that they often turn these concepts into something I don't recognize 🙂
   But of course it is most useful to have both insights. By the way, I am very grateful to the physicists who occasionally write formulae in clean mathematical notations, it saves me to do the job myself and helps me a lot in understanding what they say.

3. **Wolfgang**
   September 14, 2005

   I see a problem if Bayesian statistics is considered extremely sophisticated 😎

4. **Pindare**
   September 14, 2005

   As you said Peter, depends very much on what we want to do, but I'd like to add 'dynamical systems', a glaring omission IMHO. There's a nice little book "A First Course in Dynamics" by Hasselblatt & Katok for example.

5. **robert**
   September 14, 2005

   Times have moved on from when J.M. Ziman claimed to have 'contrived to give the appearance of doing research in theory .. with little more serious analytic equipment than could be learnt from … Dirac's Quantum Mechanics', for more than twenty years. Is this an altogether good thing?

6. **Brett**
   September 14, 2005

   Frankly, this choice of topics rather surprises me. I am a theoretical particle physicist, but I was trained as both a physicist and a mathematician. Although I understand all the topics listed, I have almost never found the geometrical ones useful in my research. (I do agree with Lie groups and algebras are ubiquitous though.) If one is interested in incorporating gravity into a theory, then there is surely reason for working with differential geometry. However, there is plenty of interesting work that can be done with no (or almost no) reference to gravitational interactions. What I work on is undoubtedly "physics beyond the standard model," yet it is done mostly within the context of quantum field theory. In fact, the only time I have ever had occasion to use any tools of differential geometry, it was of a much deeper and more complex variety than anything listed here. (And that line of investigation turned out to be a dead end anyway.)

This brings me to my second point. I wonder what exactly it should mean in this context to "know" a subject. My experience has certainly not been that physicists have an easy time mastering sophisticated concepts in mathematics. Most theoretical physicists possess a set of tools drawn from higher mathematics; however, their understanding of the underlying structure of what they're doing is usually minimal. For example, take Lie theory, which is something every theoretical physicist really does need to be familiar with. In graduate school, I took three classes in this subject; however, for the practicalities of physics research, I could have gotten away with just one, the most elementary class in Lie algebra structure. That is about the level of understanding that I see in most physicists.

There is one area of topology that I think theoretical physicists do need to learn, and that is homotopy theory. This has applications in standard model physics and is a much more general subject area than DeRham cohomology. The mathematician in me says that ideally, physicists working on topological issues should master the full machinery of homology theory as well, but this is just not going to happen. Homotopy theory is very intuitive though, and it can be used to analyze just about all the issused that are likely to occur in physical theories living on manifolds.

7. **Hektor Bim**
   September 14, 2005

   This is an interesting idea, because lots of things that condensed matter theorists might consider important aren't here. For example, there is no discussion of numerical techniques, optimization, graph theory, etc.

   I've used all of that a lot more as a condensed matter theorist than I have Riemannian geometry.

   Does theoretical physicist in this context really mean theoretical particle physicist – that is, the only theoretical physicists are those working to extend the standard model?

8. **island**
   September 14, 2005

   robert Says:

   > Times have moved on from when J.M. Ziman claimed to have 'contrived to give the appearance of doing research in theory .. with little more serious analytic equipment than could be learnt from … Dirac's Quantum Mechanics', for more than twenty years. Is this an altogether good thing?

   Only if you believe that anybody's really going anywhere… or aren't they still just trying to rationalize-away the flaw that prevented Dirac from unifying QM and GR…?

   http://www.lns.cornell.edu/spr/2005-06/msg0069755.html

9. **Kaveh**
   September 14, 2005

   Why did you omit dynamical systems and topology?

   I would encourage knowing (real) analysis (spectral theory in particular and maybe advanced probability theory) and modern PDE's but I understand that they have so much overlap with everything else that you might not need to take a course to learn them.

10. **Brian**
    September 14, 2005

    I assume there is a mantra for theoretical physicists:

    Must … learn … more … math!

11. **Dick Thompson**
    September 14, 2005

    A little symplectic topology; how to calculate characteristic classes, what is an almost complex structure and when, and so on. Goes with the homotopy theory. Any finitely presented group is the fundamental group of some symplectic manifold; stick that in your landscape and smoke it.

12. **woit**
    September 14, 2005

    Just to clarify. I think different kinds of theorists studying different aspects of theoretical physics need different kinds of mathematics. The list I gave was one for the specific case of particle theorists interested in how to better understand the standard model and find some way of improving upon it.

    Some people mentioned more topology, especially Brett who mentioned homotopy theory. I'm very fond of topology myself, and had to resist putting K-theory on the list. I still think though that deRham cohomology is the basic thing most theorists should know about. It gives specific integral formulas for topological invariants, and most of the topological invariants that come about in standard model related QFTs can be computed in terms of cohomology, not needing homotopy (especially important is Chern-Weil theory, which computes topological invariants of bundles in terms of connections and curvature). There are some places where the fact that a fundamental group is Z2 is important, but otherwise cohomology covers most of the topology physicists need.

13. **John Baez**
    September 15, 2005

    I'm surprised that nobody has mentioned this story yet:

    When Weisskopf was asked "how much mathematics does a theoretical physicist need to know?", his answer was:

    More!

14. **Tony Smith**
    September 15, 2005

    What "new mathematics" was "constructed" by Heisenberg in order "to do physics" ?
    Bear in mind that according to http://mooni.fccj.org/~ethall/quantum/quant.htm
    "… Hilbert suggested to Heisenberg that he find the differential equation that would correspond to his matrix equations. Had he taken Hilbert's advice, Heisenberg may have discovered the Schrödinger equation before Schrödinger. …".

    Tony Smith

http://www.valdostamuseum.org/hamsmith/

15. **Hongbao Zhang**
September 15, 2005

On Differential geometry(DG) in particle physics, I think tranditional particle physicist's language is not easy to understand. DG can make many topics more clear. The examples include
Neother theorem's presentation
angular momentum for spin nonzero particle
which both involve the Lie derivative concepts and Lie group

16. **Nigel**
September 15, 2005

"… several examples of people who had to construct new mathematics to do physics: Newton, …"

Peter, Newton uses standard geometry of 300 BC (Euclid, "Elements of Geometry" stuff) in his Principia, not calculus. There is no evidence he invented calculus for the physics in Principia. Newton also delved into Biblical numerology and alchemy. Archimedes' "Method" shows that Archimedes used a type of calculus to work out the volume of a sphere and cylinder, but merely used that as scaffolding to help him work out a geometrical proof. Although both Archimedes and Newton worked on calculus, both were careful to express all results for physics classically. They didn't need to provide critics with ammunition to sneer at by taking a sum of an infinite number of infidesimal slices to get a result. It was better to use geometry which people understood and respected, not a newfangled approach.

The same happened with Einstein. Professor Morris Kline describes the situation after 1911, when Einstein began to search for more sophisticated mathematics to build gravitation into space-time geometry:

'Up to this time Einstein had used only the simplest mathematical tools and had even been suspicious of the need for "higher mathematics", which he thought was often introduced to dumbfound the reader. However, to make progress on his problem he discussed it in Prague with a colleague, the mathematician Georg Pick, who called his attention to the mathematical theory of Ricci and Levi-Civita. In Zurich Einstein found a friend, Marcel Grossmann (1878-1936), who helped him learn the theory; and with this as a basis, he succeeded in formulating the general theory of relativity.'

(M. Kline, Mathematical Thought from Ancient to Modern Times, Oxford University Press, 1990, vol. 3, p. 1131.)

17. **Matti Pitkanen**
September 15, 2005

I would add to the list of interesting mathematics some new items (I confess immediately that they relate to my personal favorite theories;_)).

No one has mentioned number theory yet. The zeros of Riemann's Zeta seem to be closely related to quantum chaotic systems and conformal symmetry and Riemann hypothesis could relate in a very deep manner. The generalization of quantum physics to p-adic number fields and fusion of quantum physics in different number fields to single super structure is highly attractive idea with which I have worked for a more than decade now. The notion of primeness is incredibly general and the direct analogy with the notion of elementary particle might serve as an inspiration for an imaginative theoretician. For instance, the construction of infinite primes can be interpreted as an iterated second quantization of super-symmetric arithmetic quantum theory.

There has been no mention of infinite-dimensional geometries, which might be of interest for string model builders. Loop space Kaehler geometries are essentially unique from the mere requirement that they exist mathematically as shown by Freed. Kac Moody symmetries as isometries guarantee the existence of Riemann connection. Curvature scalar is however infinite which suggests that strings are quite not enough.

This inspires the idea that physics might be unique from the mere existence of Kaehler geometry and corresponding spinor structure for infinite-dimensional configuration space, "the world of classical worlds". My own bet is that the space of 3-surfaces in certain uniquely determined 8-D imbedding space is the correct guess and leads to a physics unique from its mere mathematical existence. This approach is a diametric opposite for the M-theory approach where imbedding space can be almost anything and leads to landscape problem.

A third fascinating branch of mathematics not yet mentioned relates to von Neumann algebras. The so called hyper-finite factors of type II_1 are obtained by requiring that the infinite-dimensional unit matrix has unit trace. The Clifford algebra of a separable Hilbert space realizes this algebra. The Clifford algebra of spinors of an infinite-dimensional "world of classical worlds" can be regarded as direct integral of these factors. Hyper-finite type II_1 factors have fascinating connections with conformal field theories, knot and braid theory, 3-manifold invariants, etc..

In wave mechanics factors I_n, n=1,..,infty, appear. In algebraic quantum field theory factors of type III_1 appear and possess very counter-intuitive properties. Could it be that hyper-finite factors of type II_1 provide the solution to the problems of QFT via the geometrization of the fermionic Fock algebra in terms of gamma matrix algebra for the world of classical worlds?

Matti Pitkanen

Advice from a bygone age: J.E. Littlewood responded to a stduent's request for a background reading list with a curt
'Nothing is neccessary – or sufficient'

Serge Lang 1927-2005

September 15, 2005
Categories: Obituaries

I just heard that mathematician Serge Lang passed away this past Monday. Lang was a well-known number theorist and algebraist, a member of Bourbaki and recipient of the 1960 AMS Cole Prize. He was a professor here in the Columbia math department for fifteen years, leaving in 1972 for Yale, where he spent the rest of his career. Lang was an amazingly prolific author of mathematics textbooks, and famous for his outspoken views and "files" on various controversies. In recent years some of these had become increasingly cranky, especially on the topic of AIDS. He was truly one of the most remarkable characters of the mathematics research community.

Update: There's an obituary at the Yale Daily News (thanks to David Goss for pointing this out).

Update: The New York Times ran an obituary of Lang today.

Comments

1. **icecube**
   September 15, 2005

   Oh boo…he was quite a character. His algebra book is, like, the best algebra book in the world ever (reading one of his differential geometry books at the moment as well, it's quite nice).

2. **John Baez**
   September 15, 2005

   When I was a postdoc at Yale sometimes I would stay up late working in my office. Serge Lang was the only person I'd see, regularly working past 2 am, sometimes rushing off to the copier room to print out copies of his "files" to send to people.

   He was quirky but fascinating – incredibly energetic, too.

   When I was his TA for calculus he insisted that derivatives could be taught in 15 minutes: explain the idea, give the definition, show how to compute some examples… done.

   I heard he would take a trans-Atlantic cruise each summer and produce a book during this time. I'm not sure that's true, but it would help explain his prolific writings.

   It's a pity he's gone.

3. **Daniel Doro Ferrante**
   September 15, 2005

   I thought myself Linear Algebra, Complex Analysis and some Differential Geometry from Lang's books.

   As an undergrad, S. Lang, M. Spivak and T. Apostol were my "mathematical icons"!

   It's really sad to know that he's gone…

4. **James Borger**
   September 15, 2005

   This is sad. I've been spending a bit of time lately looking at some of his books, and he was on my mind a lot. I remember one time when I was a grad student, I was standing next to him at tea while he was explaining to a first-year that analysis is just "number theory at infinity". I said Come on, that's not true. He immediately turned up the volume, challenging me to stop bullshitting and give an example. I said OK, p-adic analysis, and then walked away. But I've always wished I had stayed to see what his reaction would have been. We need more trouble makers like him.

5. **Walt Pohl**
   September 15, 2005

   I guess that I'm in a minority here, in that I hated most of his books. I thought his Real Analysis was okay, but his Algebra is by and large a horrible book (it does have a few good chapters). I'm told his Differentiable Manifolds book has a truly outstanding number of mistakes in it.

   I'm sorry to hear that he has passed, though.

6. **Edgar van Tuyll**
   September 16, 2005

   He told me that when he read about a subject, he would write down everything he could find out about it. At the end, this could be made into a book. When he saw that you were impressed by how quick he was, he said that he did not have the gift of physicists who could watch an experiment and immediately visualise the equations that explained it. His was an uncompromising mind, and in non-mathematical conversation, he often asked you to define the words you used, or to perform a calculation in the field in the middle of a pop science explanation he was giving at a dinner. I have to thank him for the gift of a lifetime passion for mathematics he gave me, and I miss him and to know that I shall never stumble upon a new book by him in a bookshop makes me sad.

7. **AJ**
   September 17, 2005

   Lang used to spend every summer at Berkeley. Arguing with him at tea time was enormous fun. I'm going to miss him.

8. **Yevgeny Vilensky**
   September 17, 2005

   I was an undergraduate at Yale. I never had Lang for a prof., but I knew him through the math club, of which he was an advisor. He was a tireless advocate of precision and rigor even in every day speaking. While I think that sometimes went too far, it was good that there was someone pushing things in that direction in a world in which people were losing rigor in their everyday speech more and more. I used to argue with him all the time. His defense of Shafarevich when Shafarevich was repressed by the Soviets and a second time, when the NAS to its discredit, decided to expel him for his views was highly laudable. I think that he was a bit unfair to Sam Huntington, and I sometimes disagreed with his views on pedagogy (he thought that his way to understand a subject is the only correct way). But surely, he will be missed by everyone who knew him (save for Sam Huntington, perhaps).

9. **Christian Claiborn**
September 21, 2005

He was at Berkeley this summer, too, and gave a lecture on analysis to undergraduates before he left. He was in good spirits and was cheerfully dismayed by our ignorance. I was honored to meet him.

10. **John C. Howe**
September 21, 2005

This past year, Professor Lang gave a wonderful presentation to the San Jose Mathematics Circle at San Jose State University.

He led the circle in an inspiring discussion of the numerical constant Pi. He opened new avenues of thought on this very old topic. In his leading the Circle, we could feel the presence of his greatness.

While Professor Lang was one of the world's great mathematicians, he was also at ease in working with the youngest students in the Circle. He had a natural sense of humor that immediately caught the attention of young people.

A student that I mentor, Bowei Liu (who was then a gifted sixth grader), was influnced by his gentle nature and fine-tuned art of using a version of the Socratic Method to gain understanding of a deep mathematical topic. Bowei went on to win the Mu Alpha Theta Achievement Award at the Synopsis Silicon Valley Science and Technology Championship, across all grade levels 6-12, for his researched-based project on Pi entitled "Experimental Mathematics: The Relative Efficience of Estimating Pi."

Whether it was Bowei, or someone like myself, who struggled to understand his "Algebra" textbook, we have all benefitted by his remarkable lifetime of achievement in mathematics. He was a "magister."

My life has been enriched by having had the opportunity learn both about mathematics and dissent in a free society from the late Professor Serge Lang.

11. **david friedman**
September 26, 2005

Serge was my advisor as an undergrad back in the early 1980's. He was a tremendous moral, intellectual and musical influence. I'll never forget that after we first met over dinner at the Law School, upon hearing that I knew no Baroque lute music, he walked me over to Cutlers records on Broadway and bought me an album of Julian Bream and Peter Pears.

Sadly, I was out of touch with him for many years, although I tried to get in touch with him at the beginning of the Summer. I will really miss him.

One of my favorite of his rejoinders: "that is a true statement that happens not to be relevant."

12. **Alexander Russell**
September 26, 2005

Some ill-informed and ignorant person sated above: "In recent years some of these had become increasingly cranky, especially on the topic of AIDS." Lang did not become cranky: he just asked questions concerning the anomalies amd contradictions regarding the redundant and unproven 'HIV/AIDS' hypothesis. Richard Horton of The Lancet could never answer any of Lang's questions regarding the 'HIV' fraud: Horton, as well as Robert Gallo, Luc Montagnier and David Ho have never proven that 'HIV' exists or causes 'AIDS'. In fact no one has: all the theories on 'HIV' are bassed assumptions and suppositions which have never been scientifically proven. Lang will be remebered for 'Challenging' the current 'HIV' myth making mathematical models!

13. **M. H. K.**
September 30, 2005

I suspect that I am the only person who had Professor Lang wait on the telephone. Early in the 90s our Departmental secretary left me a message Professor Lang wanted me to call him. We never met and I was excited that he knew me to call me! At that time making a long distance call from my office was a little hassle. I went to the secretary and told her that I wanted make a long distance call and gave her the number. I thought that she would inform me when she was making the call. A little after she called me in my office to tell me that Professor Lang was on the phone in her office. I was stunned that I had him waiting on the phone. I think he was a little annoyed with me but his attitude changed right away and he asked me for a reprint of one of my articles.

Later I received an e-mail from one of his students stating that Professor Lang received the reprint I sent him and wanted me to send him other reprints as well. Professor Lang, I think, immediately had the student e-mail me again that he wanted preprints as well as reprints. I will always remember and be appreciative of his interest in my work.

14. **Marvin Jay Greenberg**
October 3, 2005

I got my B.A. at Columbia in 1955 and went to Princeton for graduate study in math. In my first year I studied with Lang's thesis advisor Artin (among others). Artin returned to Germany after that year and asked Lang, who was then on the Columbia faculty, to commute to Princeton to continue teaching algebraic geometry, which Artin had introduced to a few of us – an extraordinary request by Artin and an extraordinary acceptance by Lang.

At that time algebraic geometry was not yet fashionable. and after a while, I was Lang's only student in that subject, which he continued to teach. Two years later, I wrote a Ph.D. thesis under his direction, proving a conjecture he had made. He was a perfect advisor for me, sensing exactly when to be nice and when to yell at me, inspiring me with his passion for the subject and his uncompromising intellectual honesty.

I will forever be grateful to him.

Dangling Particles

September 18, 2005
Categories: Uncategorized

Lisa Randall has an Op-Ed piece in today's New York Times entitled [Dangling Particles](). The title seems to have little to do with the piece, but I suppose it is a play on words on "dangling participle", a term for a sort of faulty grammar. Randall's topic is the difficulty of communicating scientific topics, and her comments on the problems caused by scientist's different use of words and by the complex nature of much science are true enough and unobjectionable.

But I still find the sight of a string theorist lecturing the public on how to properly understand science to be a bit jarring. Randall tries to claim that the difference between the colloquial usage of the word "theory" and the way it is used by scientists is a source of problems with the public understanding of science. She writes

For physicists, theories entail a definite physical framework embodied in a set of fundamental assumptions about the world that lead to a specific set of equations and predictions – ones that are borne out by successful predictions.

Yet she keeps on referring to "string theory", although the subject is distinctly lacking in specific equations and predictions (she does note that "theories aren't necessarily shown to be correct or complete immediately", but the problem with string "theory" is not that we don't know whether it is correct or complete, but that it isn't really a theory, rather a hope that one exists).

Instead of devoting their time to writing for the public about the scientific status of issues that they're not really experts in (e.g. global warming), it seems to me that string theorists would do better to first address the outbreak of pseudo-science now taking place in their own subject. When the intelligent design people get around to noticing how much of the highest level of research in one of the traditionally most prestigious sciences is now being conducted without any concern for falsifiability or traditional norms of what is science and what isn't, the fallout is not going to be pretty.

Update: Sean Carroll has a posting about the Randall Op-Ed piece over at [Cosmic Variance](). He quotes approvingly Randall's claim that Intelligent Designers don't make a distinction between the colloquial usage of "theory", meaning an idea not necessarily better grounded than a hunch, and the way real scientists use the term. As for whether string theory deserves to be called a "theory", here's a quote from Gerard 't Hooft (from his book *In Search of the Ultimate Building Blocks*):

Actually, I would not even be prepared to call string theory a "theory?? rather a "model?? or not even that: just a hunch. After all, a theory should come together with instructions on how to deal with it to identify the things one wishes to describe, in our case the elementary particles, and one should, at least in principle, be able to formulate the rules for calculating the properties of these particles, and how to make new predictions for them. Imagine that I give you a chair, while explaining that the legs are still missing, and that the seat, back and armrest will perhaps be delivered soon; whatever I did give you, can I still call it a chair?

Update: Lubos Motl has some [comments]() about Randall's Op-Ed piece and about my posting. As usual, I come in for a fair amount of abuse, but at least this time I'm in good company ('t Hooft's views are characterized as "just silly").

Update: John Baez points out that the article is now up at the [Edge web-site](). Over at Pharyngula, there's a posting about [Danged physicists](). Evidently biologists are not amused at all about Randall's comments about evolutionary biology. They seem to think that string theorists are arrogant and prone to going on about things they don't really understand.

Comments

1. **Nigel**
   September 18, 2005

   Peter, she does comment on this issue in chapter 4 ('approaches to theoretical physics') of her book 'Warped Passages' although you didn't focus on that in your review of the book. Lisa there says candidly: 'The choice could also be phrased as "Old Einstein vs. Young Einstein".' She then launches into a discussion of string theory, saying that it seems the only way to consistently unify quantum mechanics and general relativity.

   The two issues with string theory, that there is no hope for tests it because the energies required are 16 orders of magnitude too high, and that there are no end of differing versions of string theory (different brane models, different explanations for the different strengths of gravity and the other fundamental forces). Thus string theory with its 10/11 dimensions and fanciful claims is a bit like Alice in Wonderland, as Lisa admits (it was her inspiration).

   Witten is the man who seems to be responsible for the current mess, and it would be nice to see him defend his arm-waving propaganda claim that string theory 'predicts gravity'.

2. **logopetria**
   September 18, 2005

   Of course, there's another distinct technical use of the word "theory", namely in mathematics, where *X theory* can just mean 'the general field of study that addresses X'. For example, graph theory is the study of graphs, not a particular theorem about graphs. Maybe this is a better way of understanding the name 'string theory' – it's just the whole mathematical field of study of strings, and what they'd be like if they existed. (Although I'm not suggesting this is how string theorists think about it themselves).

3. **Nigel**
   September 18, 2005

   This 'string theory' issue was the problem 100 years ago with 'ether theory'. There was no single ether theory, there were multiple versions, all contradictory ad hoc models, and not one predicted quantum theory or radioactivity. This was why 'it' was really abandoned. You had to have faith to believe in all the ad hoc models, because they were impossible to experimentally prove (as per Michelson-Morley test), just as string theory can't be proved today. The genius of relativity was bucking the mainstream of his day, by making testable predictions.

4. **Scott**
   September 18, 2005

   > And string theory is not about strings that you tie around your finger that are made up of atoms; strings are the basic fundamental objects out of which everything is made.

   and she was saying something about better communication?

5. **dan**
   September 18, 2005

Would you consider the dectection of SUSY-particles or extra dimensions at LHC a successful prediction of string theory? what about deviations from GR some forms of string theory predict?

6. **woit**
September 18, 2005

No, the things you mention may be consistent with string theory but aren't predictions of string theory. String theory doesn't tell us what the properties of superpartners will be, how many extra dimensions of observable size there are, what the deviations from GR are, etc. etc. It makes no real predictions: zero, zip, nada.

7. **jobhunter**
September 18, 2005

Given how it is easier today to get a professorship at a major American university as a string-theorist than as a non-string theorist (witness Sean Carroll's recent public praise for string theory just before entering the job market), I do believe that a genuine legal case could be made that this constitutes discrimination on the basis of religion.

8. **woit**
September 18, 2005

Hi Jobhunter,

That's very funny. String theorists will whine that they don't get all the jobs, phenomenologists and cosmologists get some too. The one religious belief that now makes you truly unemployable in physics departments in the US is Einstein's belief in the existence of a deep mathematical and geometrical structure to physical reality.

9. **Arun**
September 18, 2005

Motl is now using the Dawkins argument, namely

Richard Dawkins wrote:

"Instead of examining the evidence for and against rival theories, I shall adopt a more armchair approach. My argument will be that Darwinism is the only known theory that is in principle capable of explaining certain aspects of life. If I am right it means that, even if there were no actual evidence in favour of the Darwinian theory (there is, of course) we should still be justified in preferring it over all rival theories??.

10. **anon**
September 18, 2005

A confusing writer criticizing confusing writing? I find myself re-reading Lisa's convoluted sentences and saying, heck, she could have expressed the very same thought with a much simpler, clearer sentence. Also, I find that adjacent sentences in her article are often curiously disconnected. I'd say she has a problem with dangling sentences and dangling thoughts. The title of the piece is emblematic of this problem: it's left dangling and unexplained.

11. **absolutely**
September 19, 2005

Perhaps string theory is more of a "system of theory" than a single theory. By that I mean a generator of theories for specific domains.

12. **Thomas Larsson**
September 19, 2005

Dan,

Would you consider the **non**-dectection of SUSY-particles or extra dimensions at LHC as an indication that string theory is wrong? Remember that for almost 20 years, Ed Witten kept stating that string theory makes one prediction, supersymmetry (and one postdiction, gravity). For some reason, he seems to have stopped making these statements now that the LHC draws near…

Personally, I would consider the discovery of sparticles a strong hint that string theory may be on the right track. However, I would like hard evidence; a sign-bug in the Schoonship program is not good enough for me.

13. **Chris Oakley**
September 19, 2005

IMHO the New York Times and Lubos are going to be the main agents for bringing about the end of Superstrings. The former runs articles on Superstrings with alarming regularity, but in each case it will be evident to anyone who can be bothered to read it (i) that there has not been any significant progress since the previous article and (ii) that after more than 20 years the subject still has not made contact with reality. Lubos's contribution to the demise of Superstrings will just be that if the most vocal advocate of their subject is a petulant, raving brat, and if they continue to make no more than token efforts to rein him in, then something has got to be fundamentally wrong.

14. **dan**
September 19, 2005

re: thomas larrsson,

I personally would think the non-detection would rule out certain forms of string theory, those with a relatively low SUSY-breaking value, just as the non-detection of proton decay in SuperKakomoke rules out certain forms of GUT such as SU5.

almost everyone agrees that the non-detection though would not be fatal to all string theories, just as the absence of proton decay has not ruled out all GUT's.

personally such non-detection, though I hope will stimulate research in other QG programs, esp CDT.

15. **dan**
September 20, 2005

re: The one religious belief that now makes you truly unemployable in physics departments in the US is Einstein's belief in the existence of a deep mathematical and geometrical structure to physical reality.

Peter,

Witten and Lubos and Randall would describe string M theory as a vindiction of Einstein's belief in the existence of a deep mathematical and geometrical structure to physical reality. the top universities all employ string theoriests, although personally, i wish they would employ quantum gravity theorists as an independent category to string theoriests.

16. **Tony Smith**
September 20, 2005

dan said:
"… Witten and Lubos and Randall would describe string M theory as a vindiction of Einstein's belief in the existence of a deep mathematical and geometrical structure to physical reality. …".

Would Witten and Lubos and Randall have the gall to "describe string M theory as a vindication of Einstein's belief" that a really good physics model should meet the criterion of being:
"… a theorem which at present can not be based upon anything more than upon a faith in the simplicity, i.e., intelligibility, of nature: there are no arbitrary constants … that is to say, nature is so constituted that it is possible logically to lay down such strongly determined laws that within these laws only rationally completely determined constants occur (not constants, therefore, whose numerical value could be changed without destroying the theory). …".

See Wilczek's article in the winter 2002 issue of daedalus.

17. **D R Lunsford**
September 20, 2005

Chris O, amen!

-drl

18. **John Baez**
September 20, 2005

Lisa Randall's article "Dangling Particles" has appeared on The Edge, a chat forum for the self-proclaimed "digerati":

Lisa Randall – The Edge

So, there will probably be some discussion of this article there soon.

19. **D R Lunsford**
September 22, 2005

Bravo! It is correctly pointed out that Randall (and other STers) behave exactly like the IDers, and their schoolmen forebears, in forcing the argument into a pattern designed to produce the predetermined conclusion.

Nice find Peter!

-drl

20. **John Baez**
September 23, 2005

Apparently Brockman doesn't expect discussion of Lisa Randall's piece on his Edge website. He just included her essay there because the New York Times version left out parts, which somehow contributed to evolutionary biologists becoming incensed at it. I haven't compared the versions, so I don't know what this is all about.

Here are a few remarks I was going to contribute to that discussion, had it taken place:

…………………………………………………..

Lisa Randall mentions how different uses of the word "theory" provide a field day for advocates of "intelligent design".

True – but it's not only here that the definition of "theory" has gotten pulled into the rhetorical struggle over a scientific issue. The same thing happens with the phrase "string theory".

Here's what James Watson of DNA fame says in an essay introducing the book "Darwin: The Indelible Stamp":

> Let us not beat around the bush – the common assumption that evolution through natural selection is a "theory" in the same way as string theory is wrong. Evolution is a law (with several components) that is as well substantiated as any other natural law, whether the law of gravity, the laws of motion or Avogadro's law. Evolution is a fact, disputed only by those who choose to ignore the evidence, put their common sense on hold and believe instead that unchanging knowledge and wisdom can be reached only by revelation.

Compare what the physicist Gerard 't Hooft says in his book "In Search of the Ultimate Building Blocks":

> Actually, I would not even be prepared to call string theory a "theory" – rather a model or not even that: just a hunch. After all, a theory should come together with instructions on how to deal with it to identify the things one wishes to describe, in our case the elementary particles, and one should, at least in principle, be able to formulate the rules for calculating the properties of these particles, and how to make new predictions for them. Imagine that I give you a chair, while explaining that the legs are still missing, and that the seat, back and armrest will perhaps be delivered soon; whatever I did give you, can I still call it a chair?

The point here is that string theory does not yet make any specific predictions about what we might see in experiments.

So, “theory” lies on a rhetorical continuum that ranges from “not even a theory” to “not just a theory” – and even real scientists fight about where a given “theory” lies on this continuum.

Jaron Lanier's Review of The Road to Reality

September 18, 2005
Categories: Uncategorized

A correspondent points out to me that the latest issue of American Scientist has a wonderful review of Roger Penrose's new book The Road to Reality by computer scientist, author, artist, etc. Jaron Lanier, much better than my own effort along these lines. Despite not being a theoretical physicist, Lanier does a great job of recognizing and explaining what is great about Penrose's book. He also is dead-on about string theory ("mob mentality", "pompous triumphalism").

The same issue of American Scientist also has a very good review by Lee Smolin of Gravity's Shadow: The Search For Gravitational Waves by Harry Collins. It also contains a nowhere near as good review by yours truly of Sneaking a Look at God's Cards, a book about interpretational issues in quantum mechanics by Giancarlo Ghirardi.

Comments

1. **Nigel**
   September 19, 2005

   Penrose's book reminds me of Maxwell's Treatise on Electricity and Magnetism, being a mixture of ingenious physical ideas and really awful mathematical methods. Quaternions feature prominently in both Penrose and Maxwell, without any real justification.

   Whenever I see the picture of Penrose's twistor, I automatically wonder what the lines are, electric field, magnetic field, or Poynting vector of energy transfer? The same happens with field lines in electromagnetism. If you have a Poynting vector going around in a simple circle, you get a dipole magnetic field which looks similar to Penrose's twistor, while the electric field lines spread out radially.

2. **andy.s.**
   September 19, 2005

   I didn't think I had the background to fathom the book. Now I'll have to take a look at it. So you guys think a mere math B.S. can digest the thing?

3. **woit**
   September 19, 2005

   My own impression of the book was that to fully understand everything Penrose is doing, you probably need a graduate level background in math and physics. But large parts of the book are quite accessible, especially if you have some basic university level mathematics background, so if you're willing to skip some things that seem too difficult, you should find much of the book well worth time spent with it.

4. **John Gonsowski**
   September 19, 2005

   Maxwell was just thinking ahead to the weak force and Penrose is just thinking ahead to conformal gravity. I attended a presentation by Penrose once, it was great but as usual I felt like the AFLAC duck wanting to yell out "TONY SMITH". Smith upgrades quaternions to octonions and gravity to conformal gravity.

5. **Eric Dennis**
   September 19, 2005

   Hi Peter. I've been a lurker here for a while and am looking forward to your book. Good luck! In your review of Ghirardi's book, you write:

   "Most physicists generally believe that quantum mechanics, in its relativistic version as a theory of quantum fields, is a complete, consistent and highly successful conceptual framework. They assume that there must be some well-defined way of describing the entirety of a physical system, experimental apparatus and human observer, appropriately dealing with the confusing interpretational issues. As a result, the study of the sorts of questions examined in this book has often been considered somewhat of a backwater."

   I can understand that belief as contributing to the view of foundational research as a backwater, but I would suggest something more sociologically profound is going on. The belief amounts to the non sequitur "we are sure there is an explanation, but we don't know exactly what it is, so we look askance at anyone who tries to explicitly figure it out." Not exactly a normal, scientific attitude. The high energy frontier is perhaps not the only unstable orthodoxy in physics.

   Given the above quote, I'm curious if you think that the foundational issues are somehow attenuated in (relativistic) field theory. I'd say they just get harder. When field theory is introduced into the discussion, it's usually intended to downplay the significance of Bell Inequaltiy violation, since it's not clear how to formulate Bell's argument in terms of in/out state scattering. But this is just an inadequacy of the standard field theory measurement formalism, not a solution to the problem.

   Regards,
   Eric

6. **Nitin**
   September 19, 2005

   When I saw how big the book is, I thought, and still think, it will take me some time to read it (also, I am busy with graduate work, so time for leisure is quite restrained these days). So I bought the book as a present for a good friend. Hopefully, he'll tell me a nice story at some point (he has not given any feedback so far). I did majors in pure maths, applied maths and physics, so I think the necessary background is there. ;)

   From Down Under

7. **woit**
   September 19, 2005

   Hi Eric,

   I'm really not an expert on interpretational issues, so from one point of view wasn't the best person to review that book. But I'm interested in the topic, and think my prejudices about it are pretty common ones among theoretical physicists, so part of what I wanted to do was to explain what those prejudices are.

One thing that this kind of QM and string theory seem to me to have in common is being largely insulated from experiment, and full of people who have an ideological ax to grind. What I've seen of the QM literature is often as depressing as the string theory literature. Without the discipline of experiment, theoretical physics seems to easily degenerate into nonsensical blather. I'd like to believe that QM will get more interesting as people figure out how to manipulate more interesting quantum mechanical systems. Maybe this is overly optimistic, we'll see.

I have no idea whether the resolution of interpretational problems requires thinking about quantum field theory. But quantum field theory is far and away the best fundamental theory we have. It seems to me that, absent any interesting experimental data to chew on, theorists of all kinds should be spending a lot more time thinking deeply about QFT. My own approach to this is mathematical, I suspect there are mathematically much deeper ways of thinking about QFT than the ones we know about. If and when we figure these out, maybe they'll shed some light on the interpretational issues, maybe not.

8. **fooltomery**
September 20, 2005

Here's a paragraph from Lanier's review of Penrose's book, Peter:

> Reading this math section is eerily liberating. It is shocking that so much can be explained so well. The obvious comparisons are to *The Feynman Lectures on Physics* or George Gamow's *One, Two, Three . . . Infinity*, but the achievement here is greater, because the book starts at such an elementary level and soars to such heights, without any glitches along the way. It's a magical escape from the bounds of gravity.

Perhaps you feel that you're obligated to say nice things about Lanier's review since your own book review was published in the same issue of the magazine and you might like to publish there again, but, really, if your BS detector doesn't peg after reading that paragraph, I'm going to have to reconsider my estimate of the seriousness of your devotion to debunking. Comparing the Feynman lectures to Gamow's little trade book? And then suggesting that Penrose's book (which I've read, BTW) is superior to both?

If Lanier even understood most of the words in Penrose's book, I'd be quite surprised.

9. **Nigel**
September 20, 2005

Penrose undertakes a difficult task and I was surprised how enlightening his treatment of electromagnetic theory is in tensor notation, chapter 19. If you look at Maxwell's theory in Feynman's lectures, you find that Feynman avoids tensors altogether, sticking to vector calculus (divergence and curl, which do what their labels say). Where Feynman tries to explain GR without tensors, he comes up with the ingenious physical contraction of space in the radial direction only around a mass, which indeed is precisely the special feature of the contraction term that Einstein introduced. However, the Feynman lectures by keeping to simple mathematics, are limited. Gamow's 'One Two Three … Infinity' falsely debunks the idea that the Lorentz contraction can be considered a physical pressure effect of moving against the spacetime fabric. Gamow tries to obfuscate by claiming different materials would contract differently, when in fact the compression forces involves are always electrical and the contraction would be similar. So for all their skills in physics, I don't see how anybody can learn sufficient physics from the popular books of Gamow and Feynman. The Penrose book excels at sticking to mathematics and physical facts, without the self-opinionated interpretational baggage…

10. **fooltomery**
September 20, 2005

Nigel, my point was that Lanier sets up a sort of parity between the Feynman Lectures and Gamow's book, which is silly (and leads me to suspect that he's not spent a lot of time reading either book). Then, lumping these two very unlike texts together, he asserts that Penrose's book is superior to both.

As a loose analogy, consider equating the acting skills of Sir Laurence Olivier and Jon Lovitz, and then going on to say that Russell Crowe is better than both. The initial equation calls one's judgment into question, even though it might well be the case that at least in some respects Russell Crowe *is* a better actor than both (although the standard Crowe must beat is much higher in the case of Olivier than in the case of Lovitz).

With apologies to the Master Thespian, of course…

11. **woit**
September 20, 2005

Sorry, but I was really legitimately very impressed by Lanier's review, and wasn't saying nice things about it because the folks at American Scientist just paid me a fee in the high zero figures. His language may be a bit over the top, but Penrose's book is something very unusual, so this level of enthusiasm seems to me not inappropriate. I don't remember Gamow's book, I think I probably read it more than thirty years ago. The comparison to Feynman is appropriate, that's one of the few other books of at all similar scale and ambition. Penrose is much more of a mathematical physicist, so his book is much more mathematical. If your taste runs more to mathematical than physical arguments, Penrose's is definitely a better book than Feynman's. For purely physical arguments though, you're better off with Feynman.

I don't know Lanier personally, but do know people who do, who had told me he's a very impressive character, with knowledge of a wide range of subjects. His review certainly demonstrated this. He correctly pointed out many of the best and most striking things about the book, made a wonderful analogy to the book that made Camille Paglia famous, and did a fantastic job of situating Penrose, his point of view and what he was trying to accomplish with the book in the context of contemporary theoretical physics.

Lanier's comments about string theory certainly did endear him to me, so if you want to accuse me of being seduced into feeling obligated to say something nice about the review, it would be those that did it, not the American Scientist connection. But I can assure you that I thought the review was great and at no time felt I had to say nice things about it for any other reason.

12. **fooltomery**
September 20, 2005

Okay, I'll let you slide on this one. Heck, I wouldn't have sold out for $0 either. They would've had to pay me at least $&epsilon for some ε>0.

And for the record, I, too, read Gamow's book decades ago and have little recollection of its details. But I'm not the one who mentioned it in a published review, so I'm cutting myself (and you) some slack on that score.

Regards…

13. **fooltomery**
September 20, 2005

Lost a semicolon after that first epsilon, I see. Dang.

14. **John Gonsowski**

September 20, 2005

Nigel, where is Feynman limited by not having tensors? He can't unify GR and electroweak/color I suppose but tensors can't do that either. You need something like SU(5) GUT which from a spacetime point of view could be like adding Kaluza-Klein-like dimensons.

Some interesting history from Tony Smith's site:
http://www.valdostamuseum.org/hamsmith/HeisHist.html

15. **Dan P**
September 20, 2005

How many times does this book mention Godel's theorem?

16. **Carl Brannen**
September 20, 2005

I was a grad student at U. Cal. Irvine back when Joe Weber taught there (he was also teaching at U. Maryland, if I recall). Most of the small amount I know about gravitation I learned in his class, which he taught out of his book. He died quite recently.

Carl

17. **woit**
September 21, 2005

The book has a couple pages about Godel's theorem.

18. **Nigel**
September 21, 2005

John: Feynman pulls his simple formula for contraction of space around a mass out of thin air, like magician pulling a rabbit from a hat. Penrose goes into mathematical physics a bit deeper. In your link Tony Smith deals with Feynman's lectures on gravitation (1995 publication), not the lectures on physics.

19. **hongbaozhang**
September 22, 2005

Today, I received a copy of Sir Penrose's The Road to Reality. After a brief glimpse, I think it is the graduate's Feynmann's Lectures on physics!
It tells us with caution what we did know, what we are now doing and in what directions shall we go?
But here is a question in Page 659: why the commutation(anticommutation) relations involve the imaginary number i?

20. **Maynard Handley**
September 24, 2005

Peter,
I found your review extremely frustrating because it didn't answer the single most important thing anyone reading a review wants to know: should I devote some of my precious and very limited time to reading this book. The book, apparently, covers material we have all seen many times and, as least as far as your review goes, says absolutely nothing that wasn't said thirty years ago.
Bohr, EPR, entanglement, Bell, Aspect, it's all very mysterious, blah blah.

It sounds like the only thing they have to offer is the sort of stupid ad hoc modifications people were making in the 50's to non-relativistic QM. I honestly don't know why people waste their time with this crap — it's so clearly not going to fit into the larger structure. It's like approaching rotation as something algebraic, and dicking around with the algebra, rather than viewing it as something geometric and making modifications that match that geometric view.

So the answer to my question would appear to "don't waste your time, unless you've never, in your life, met this material before". Is there a single thing they say that is not either a waste of time, or that would come as news to an intelligent 2nd yr grad student?

Is this a fair conclusion, and it was politeness and the conventions of the review format that prevented you from saying so outright?

21. **woit**
September 25, 2005

Hi Maynard,

I suppose I should have made this clear in the review, but the Ghirardi book is aimed at people who don't know much about interpretational issues in quantum mechanics. If you've thought about this stuff, read about it elsewhere, and have a graduate-level background in QM, the book isn't aimed at you. It has a bit more about Ghirardi et. al.'s own approach than you'll find in other books, but not that much. If you have some background and want to know about what they have done, you should read their papers.

I thought the best thing about the book was the way it wasn't either too gee-whiz, or pushing a specific viewpoint. Some introductory books like this act as if QM is some complete mystery, Ghirardi doesn't. He also doesn't push his own research strongly, acknowledging that it has problems. It's basically an even-handed introduction to the subject, aimed at the non-expert.

22. **dan**
September 28, 2005

speaking of roger penrose, what do his peers think of his suggestion that gravity is what divides the quantum realm to the classical realm?

2005 Physics Nobel Prize

September 21, 2005
Categories: Uncategorized

After my initial success last year, I've retired from the business of predicting who will get Nobel prizes. This year's physics prize will be announced in less than two weeks, on Tuesday, October 4. Anyone else want to make a prediction?

Last year there was a Nobel Prize Market, but it doesn't seem to be in operation this year.

For the last few years Thomson Scientific has been issuing Nobel prize predictions based on citation counts. They're not doing very well in physics, basically because every year they predict it will be Green, Schwarz and Witten. This year's prediction is here. In 2003 they rather petulantly commented:

Most observers believe the Nobel Prize will not be awarded for theoretical work. If, however, citations reflect real influence and prizes ought to be awarded for influential work, the Nobel Committee should consider recognizing string theory and M theory, whose leading figures have been Green and Schwarz, the pioneers, and Witten, who extended their work. Witten, it should be noted, is the most-cited physicist of last two decades.

Their idea that the Nobel prize is not awarded for theoretical work is kind of strange, and wrong. Last year's award was to theorists. The people at Thomson seem to not be able to tell the difference between theoretical work that is confirmed by experiment, and work which isn't. So far the Nobel committee seems to be able to make that distinction, and doesn't just count citations. Presumably this will still hold true for this year. While I won't predict who will get the prize, I will predict that Green and Schwarz won't get it, and if Witten does, it won't be for his work on string or M-theory.

Comments

1. **LM**
   September 21, 2005

   To Leonard Susskind, for pioneering work in the field of Quantum Tautology.

2. **Wolfgang**
   September 21, 2005

   To Lubos Motl for his contribution to the physics of global warming,
   determining the heat capacity of ice.

3. **Belizean**
   September 22, 2005

   David Deutsch, one of the fathers of quantum computation.

4. **Haelfix**
   September 22, 2005

   I hate to be biased, but we do have some astrophysicists who are worthy of four of five nobel prizes by now. If theoretical work in the absense of 11 decimal precision is ever to be awarded, I would think that field would and should be the first one to be signaled out.

   Yes we do have experimental verification, no its unfortunately nothing like detector confidence, yes our work is pretty important.

5. **a**
   September 22, 2005

   Nobel prize of not-this-year:

   M.W. Goodman and E. Witten for
   DETECTABILITY OF CERTAIN DARK MATTER CANDIDATES (1985)
   and the experimentalist that will possibly do
   DETECTION OF CERTAIN DARK MATTER CANDIDATES (200?).

6. **Zelah**
   September 22, 2005

   Hi,

   I have a courageous prediction for the nobel prize.

   I believe that it should go to Vera Rubin of Dark Matter fame, with relevant coawardees.

   The reason is that Sir Martin Rees, and James Peebles won the Crafoord prize in 2005 for Dark Matter! I consider this scandalous! I have nothing against Rees or Peebles, who have done wonderful work regarding Dark Matter, but ignoring Vera Rubin is quite astonishing!

   I do not have much hope in this regard but who knows?

   To be fair to the nobel committee, there are plenty of experimentalist Physicist who are just as worthy.

   An Amateur Mathematician

7. **hongbaozhang**
   September 22, 2005

   Time flies fast, this year's Nobel prize will come!
   I guess this year will be given to some quantum optics physicist:)

8. **D R Lunsford**
September 22, 2005

How about BRST? (Becchi, Rouet, Stora, and Tyutin) That's real physics at least. If Witten gets it I'll go on a ten-day drunk out of despair for my lost civilization.

-drl

9. **Tony Smith**
September 22, 2005

For physics Nobel, how about Kobayashi and Maskawa ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

10. **Quantoken**
September 22, 2005

I do not know who will receive it, but if the Nobel is awarded to string theory related research, it would be the unprecedent because this will be the first time a Nobel price is awarded to some **highly speculative ideas** that has **no confirmation** whatsoever by experiment. It would be a joke and could make Nobel a **laughing stock** and respected scientists would refuse to be recognized by the Nobel prize, if at the end of day super string theory is proven to be totally wrong and irrelevant to the nature.

I do not think that will happen.

Remember Nobel prizes are not awarded to mathematics?

Quantoken

11. **Nigel**
September 22, 2005

Einstein got the prize for the maths of the photoelectric effect, which was experimentally first noticed by Edison. Edward Witten could get it for superstrings, on the basis of being the only mathematical approach which ties up the standard model.

12. **hong-bao zhang**
September 22, 2005

If Nobel prize give string theorist, how about Hawking and Penrose?
Hawking's radiation gives the most important hints on string theory.
Penrose's spinor technique much influences Witten's work.

13. **blank**
September 22, 2005

Noticed there weren't any MacArthurs awarded to physicsts this year.

14. **D R Lunsford**
September 22, 2005

Tony – good suggestion, and it's classic "this works but God knows why" phenomenology!

-drl

15. **ali**
September 22, 2005

I agree with Haelfix:

I'll be betting on Rashid Sunyaev (too bad Zeldovich isn't still around). They might also give it to some experimental cosmologists.

Someone deserves credit for showing the universe is flat based on CMB measurements…

16. **Not a Nobel Laureate**
September 22, 2005

One hopes that the Nobel Prize in Physics will be awarded for physics.

Offhand;

Goldhaber, Grodzins, and Sunyar: neutrino helicity

Sajeev John et al: photonic bandgaps and photonic localization

David Awschalom et al: spin Hall effect

Unfortunately Chien-Shiung Wu (parity violation) died in 1997.

On the other hand, Susskind et al are highly qualified candidates for the Ubu Prize in Pata-Physics or at least the IgNobel Prize.

17. **biophysics**
September 22, 2005

Here are a couple theorists who most might've passed over. How about giving the prize to Edward Lorenz for opening up the study of chaos, which has had both immense mathematical and physical research associated with it?

Ok that's one idea. The other one I got by looking at the list of winners of the Dirac Medal – how about J.J. Hopfield for his pioneering work in theoretical biophysics?

Yeah, yeah totally biased and all, but the physics of complex systems is definitely one of the most exciting fields of modern theoretical physics and it would be a fine idea, in my opinion, to recognize some pioneers in the arena.

18. **misslemon**
September 23, 2005

Guth? Tyson (J.A.)?

19. **Matthew**
September 23, 2005

No way will it go to particle physics again this year. If I had to guess, something to do with the CMB seems a reasonable bet.

20. **Mike Bacon**
September 23, 2005

I second the nomination of David Deutsch.

21. **Jeremy**
September 23, 2005

What about Jim Peebles? or Peebles and Sunyaev?

I don't think there has ever been a prize for theoretical cosmology, which is scandalous. Well, Bethe won, but that was for stars. It's too bad Dicke and Wilkinson aren't with us any more.

22. **Not a Nobel Laureate**
September 23, 2005

I "second" the CMB.

Regarding J.J. Hopfield, interesting work, but what is it's predicitive ability in what I agree is the very exciting field of biophysics?

23. **Chris**
September 23, 2005

Fowler got it in 1983 for his work in big bang nucleosynthesis.

c

24. **misslemon**
September 23, 2005

David Deutsch?!? Really? And seconded?!

25. **Eric Dennis**
September 23, 2005

Why don't we wait until a quantum computer is actually built — or at least something with more than like 5 qubits — before we start getting behind Deutsch (or better Peter Shor) for a Nobel.

Not at all to diminish the relevant achievements, but 1) there is no new physics here, it's all quantum engineering; 2) after the initial breakthrough in error-correcting codes around 1996, nothing much has happened in this field of fundamental importance or significant help to experimentalists in building anything remotely resembling a useful machine; 3) at present, building a quantum computer seems about as likely as performing an experimental test of string theory.

While at least in quantum information the theoretical side has not divorced itself from real physics, the hype surrounding the whole enterprise (and generated just as much by the experimentalists in this case) is not that different in terms of its calculated half-truthfulness from that of string theory.

26. **Quantoken**
September 23, 2005

Dennis:

Who said that enginnering work can not be awarded a Nobel prize? Last year's Nobel Chemistry prize was awarded to a Japanese for inventing a measurement trick that gained wide usage. He didn't even have a Ph.D. and was just a technician.

There are quantum computers around. Any quantum system is a quantum computer in a broad sense. According to [Seth Lloyd at **http://www.edge.org**](), the whole [universe is a quantum computer]().

Quantoken

27. **Scott Aaronson**
September 24, 2005

Eric: as someone who works on the theory side of quantum computing, I agree with you that the Swedes should wait for more experimental successes before awarding any prizes in this field. That would be in keeping with their past practices.

But if it's true that "there is no new physics here, it's all quantum engineering," then it's strange that at least two Nobel physicists ('t Hooft and Laughlin) think building a quantum computer is fundamentally impossible! Maybe the right way to say it is this: quantum mechanics is 1920's physics, which becomes 21st-century physics when taken completely seriously.

28. **Pseudo-string-fan**
September 24, 2005

I watched a TV program which said Susskind was the first one who proposed string theory. Therefore, he should be awarded the Nobel prize if string theory can be proved true. Right?

29. **biophysics**
September 24, 2005

Ok I think I agree that Hopfield getting a Nobel physics prize might be a stretch (for the same reason that other Dirac medal winners don't get Nobels, like Daniel Freedman, for example..while experimentalists righly get Nobels for inventing devices that have furthered physics, theorists do not to get prize for their 'theoretical devices' until at least some experimental substantiation has come about to validate the use of those 'devices').

But Lorenz I think is eminently qualified for the Nobel – chaos and nonlinear dynamics have become a huge part of the modern theoretical frontier, and the existence of deterministic chaotic motion has been borne out by grade school experiment 🙂

30. **Zelah**
September 24, 2005

I find the pushing of Mr Lorenz for the nobel as extremely strange!

The truth of the matter is that Chaos was well know to mathematicians! KAM Theory anyone! It was the physicists who needed to catch up!

Essentially, Chaos Theory if you have studied it is just a subsection of Condensed Matter Physics in disguise!

The only person who could POSSIBLILY win the nobel prize for Chaos is Feigenbaum of Feigenbaum constant fame!

An Amateur Mathematician.

31. **Luboš Motl**
September 25, 2005

I have not written the first comment by "LM" – but actually it is not such a bad comment. 😉

32. **Aswin**
September 25, 2005

Penzias and Wilson got a nobel.. and the WMAP team deserves one too! The Supernova team ??.. may be later.
These days, Weinberg (and many others) seems to be interested in comparing Cosmology-of-today to PP of 70s. With support of such powerful voices, I guess cosmology is in for some good time 😕

33. **Aswin**
September 25, 2005

oops..I meant COBE.

34. **Nitin**
September 25, 2005

What about having a group of researchers getting the Nobel? Maybe the guys who found out that the expansion of the universe is accelerating (Aswin's supernove team), or the WMAP team (again Aswin thinks the same)? Alan Guth would be a good choice. My guess is this year's Physics Nobel is going to a cosmologist/astrophysicist (see how the picture of the universe on the large-scale has changed in the past 2 decades). It's hard to say who though, hard. hmm…

35. **Thomas Larsson**
September 26, 2005

Nitin, the Nobel is traditionally awarded to at most three individuals. That's probably why Ward wasn't recognized with Glashow-Salam-Weinberg for the electroweak theory.

36. **Nitin**
September 26, 2005

Ok.. maybe the conditions are different for different Nobels? Because I remember the Medecins Sans Frontieres getting the Peace Nobel.. maybe I'm wrong on this point as well.
Toutes mes excuses.
Nitin

37. **Thomas Larsson**
September 26, 2005

Yes, I was thinking about the sciences (including economy). Peace is different. So is literature, which AFAIK has never been shared.

38. **Sergei Popov**
September 26, 2005

Last year on the Nobel prize Market I suggested Michel Mayor for the discovery of exoplanets. Still, I think, he's a good candidate.

Prizes are not given for unprooved theories, so nothing for Witten, but I have to mention Linde & Co. for inflation theory.

39. **Eric Dennis**
September 26, 2005

Scott,

I didn't know 't Hooft was a skeptic. Do you have a reference? As for Laughlin, while I have great respect for some of his heterodox views, from what I've seen his polemics against the possibility of quantum computing are pretty flimsy, and quite poorly articulated besides. I think we would agree that if someone actually demonstrated the impossibility, or exhibited a currently unknown physical effect that would somehow in general prevent a quantum computer from being realized, that would be entirely unexpected and almost certainly itself merit a Nobel.

Perhaps you could be more concrete though. Could you give an example of important new physics that has been discovered in connection with quantum information research? (Again, I don't think the absence of such is necessarily a bad thing, I just think it's relevant for something like a Nobel decision.)

Regards,
Eric

40. **Mike Bacon**
September 26, 2005

My 'second' of Deutsch had to do with his groundbreaking work in quantum computing. Pariticularly now, with rapid progress being made in "cluster quantum computing" (i.e. robust and scalable quantum computation using both stationary qubits (e.g. single photon sources made out of trapped atoms, molecules, ions, quantum dots, or defect centers in solids) and flying qubits (e.g. photons)). It's the case that theorists do not to get the prize for their 'theoretical devices' until at least some experimental substantiation has come about to validate the use of those 'devices.' While quantum computation has been 'proved' in theory (and carried out with a limited number quibits), it does now seem that this fundamentally new form of information technology is about to blossom. Whether this supports Deutsch's philisophical views is another matter — however, the work is turning out to be hugly significant.

41. **Not even a physicist**
September 26, 2005

I agree that CMB is a good candidate. Will it go to COBE, WMAP or both?

How about neutrino oscillations? Davis and Koshiba were awarded for detection of cosmic neutrinos, but not for oscillations. Is there a possibility of another prize for neutrino physics?

Is there any chance for Nambu, either for his work on symmetry breaking, or for introducing colors?

42. **Scott Aaronson**
September 28, 2005

Eric,

I completely agree with you about Laughlin's arguments. A reference for 't Hooft is gr-qc/9903084 (especially pages 12-13). My response to some of the skeptics (mainly computer scientists) is at quant-ph/0311039.

As for whether quantum information is "new physics": would you say the uncertainty principle was new physics? What about Feynman's sum-over-histories picture, or the Bell inequality? All of these were "mere" mathematical consequences of the quantum formalism, yet today they're almost inseparable from QM itself.

I would argue that the following results from quantum computing and information have deepened our understanding of QM in an analogous way:

* Shor's and Grover's algorithms
* The optimality of Grover's and other quantum algorithms (showing why QM often *doesn't* yield exponential parallelism)
* Quantum error-correction and fault-tolerance
* Adiabatic computation and QMA-completeness of the Local Hamiltonians problem
* Teleportation and dense quantum coding
* Holevo's Theorem, lower bounds for random access codes, and other results in quantum communication complexity
* Ideas from entanglement theory (like entanglement swapping and purification)

But maybe it's just a matter of taste — I'd also give Aspect et al. a Nobel for confirming the Bell inequality violations, but it hasn't happened yet.

Best,
Scott

43. **Eric Dennis**
September 28, 2005

Scott,

I don't claim something is disqualified from being "new physics" just because it's ultimately a mathematical consequence of standard QM. Presumably high temp superconductivity is completely understandable in terms of some many-body Hamiltonian, and that's certainly new physics. But high temp superconductivity — as opposed to Grover's algorithm or channel bounds or the other things you list — actually exists. It's not just some idea we have about something we could make.

The actual physics in quantum computing, the ion traps or QED cavities, is not really part of quantum computing reserach itself. It's condensed matter or quantum optics or whatever. Things like adiabatic or anyonic computation may at some far future date straddle this boundary, but that's only when something computationally non-trivial is actually built.

Eric

P.S. I definitely don't regard Bell's inequality as new physics. It's really great, but it has no special connection to any theory of physics (including QM) other than providing a necessary condition for locality. I won't bother commenting further on path integrals etc.

44. **Scott Aaronson**
September 28, 2005

Eric,

This seems like a semantic debate — e.g. were Bose-Einstein condensates not a legitimate part of "physics" until someone actually created one?

But I don't think we disagree that much in practice — we both think the Nobel committee should continue to award prizes only for theories that have actually been confirmed, or things that have actually been built. That acts as a useful brake on unrestrained speculation.

–Scott

45. **Eric Dennis**
September 29, 2005

I don't think it's semantic, and that's why we seem to disagree about the status of Bell's inequaltiy. I am saying that if an experimentalist were to succeed tomorrow in assembling a bunch of coupled quantum dots or something and implement fault-tolerant codes and factor 10^100 + 1, that would be miraculous, but there's no new physics. Perhaps the superconductivity comparison wasn't clear. Each of the little quantum dot widgets in the computer, and the cavities, and etc. — that's the physics, and that's not really part of QC research. Having built this computer, no basic new aspects of nature would have been discovered. Something wonderful would have been built, but that's not the same. Perhaps you could say some mathematical aspects of the world would have been discovered, in the same way that some mathematical aspects of the world are discovered in the course of designing and running a classical silicon-based computer.

The reason I persist here, is that the physics-ization of QC research strikes me as similar in certain respects to the physics-ization of string theory. In terms of physics rather than math or CS, both of these things are constructions, not discoveries. QC isn't trying to be a discovery, and it need not be one, but some of its practitioners find it useful to talk as if it is one. String theory is trying to be a discovery, and it's failing badly, but some of its practitioners also find it useful to talk as if it is one.

Anyway, I suspect we won't agree. Nice arguing with you.

46. **kaushik**
September 30, 2005

James Yorke…..pioneer of chaos. Its such a huge field in itself, and is an integral part of physics now and has application is so many fields.
Yorke, and few other pioneers of the subject deserve a nobel

47. **Jack**
October 2, 2005

I predict Kosterlitz and Thouless for the KT transition. It really opened up the area of 2D physics and its originality and applicability make it Nobel Worthy. Future prizes that will be awarded have to eventually include Michael Berry for his geometric phase. that would also be high time to recognize Aharonov.

48. **"A guy who does not believe in String theory"**
October 3, 2005

A prize for cosmology would be nice! Two guesses: either Bennett, Page(?) and Spergel (???) from WMAP, or Guth, Linde & Steinhardt for inflation (although I think they will wait for the detection of GW, the B modes of CMB, to award inflationists).

49. **Neil**
October 3, 2005

It is time to recognize the theoretical and practical achievements in photon localization and photonic band gaps (Sajeev John and Eli Yablonovitch). The visionary discoveries in the field of light localization and photonics will lead to revolutionary real-world applications, greatly exceeding what was achieved in the past century using the discoveries in electronics.

50. **Muthiah**
October 3, 2005

I think Benoit Mandelbrot, deserves a Nobel prize for his work on fractals?
Im not sure.

51. **Bumerang**
October 4, 2005

When you talk about Chaos theory, you completely forget russian school. Arnold, Sinai and Chirikov, for example.
Unfortunately, the Chaos theory does not have a strong power for implementations.

52. **James**
October 4, 2005

My predictions:
Shuji Nakamura and Yoshinori Tokura for diodes and semiconductors resp.
or
Exo planet searches — Marcy and Butler

Dont expect Guth to win — his intial inflationary proposal was flawed (but he realised this) and had to be modifed be Linde and Steinhart. Also, beyond the superfical level, inflation makes predictions, e.g. a flat universe, in terms of probabilities, which mind you are exponentially close to 1 or 0. It is not a "confirmed" theory as some of you suggest above, merely an exciting theoretical idea. I believe the theory is correct from a phemonological prespective, but it is far from a finished theory, and the mechanisms that drives inflation in the very early universe is unknown.

In line with the usual criteria Guth and co will not be awarded a nobel.

As many of you said above, string theory will not be awarded a nobel in the near future. Until the theory can be understood at a level to make firm experimental predictions, and those predictions tested, string theorists will have to wait.

Cheers

James

53. **Jimbo**
October 4, 2005

If anybody who has worked on superstring/M-theory gets it, then a terrible & irrevokable precedent has been set, namely the negation of the 3 centuries-old covenant with the scientific method for establishing the veracity of physical theory thru observation.
However, if this radical leap `must' be made, it should clearly go to Hawking, for two obvious reasons. One, the universal respect & awe in which his work is held, and two, the tragedy the world of physics will have to live with, if we wake up one morning & find that ALS has finally claimed Stephen's life, without him getting the Nobel

prize he so truly deserves.

54. **OJP**
October 4, 2005

I think actually hongbaozhang actually guessed correctly (at least the field). See Sept. 22 entry.

OJP.

Dirac’s Hidden Geometry

September 24, 2005
Categories: Uncategorized

There’s an interesting article by Graham Farmelo in last week’s Nature, entitled [Dirac’s Hidden Geometry](). Most people think of Dirac as a brilliant algebraist, but he himself claimed that his motivations and way of thinking were much more geometrical than algebraic. Farmelo’s article contains an amusing account of how Roger Penrose tried to get Dirac to explain how projective geometry had influenced his work in quantum mechanics. Dirac gave a talk about this at Boston University in 1972, but, after giving a presentation about projective geometry, stopped before explaining the relation to quantum mechanics. Penrose, the moderator, asked Dirac about the relation to quantum mechanics, and in answer “Dirac gave his trademark shake of the head, and declined to speak.”

Several historians of science have tried to figure out what Dirac’s geometrical motivations were. This question is dealt with in Olivier Darrigol’s very interesting book (which is now available on-line) [From c-numbers to q-numbers: The Classical Analogy in the History of Quantum Theory](). The material about Dirac and projective geometry is in chapter XI. On the same topic, there’s also an article by Peter Galison published in 2000 in the journal Representations, entitled [The Suppressed Drawing: Paul Dirac’s Hidden Geometry]().

   Wow..that’s really fascinating…never knew about that before.

2. **Fabien Besnard**
   September 25, 2005

   Unfortunately I don’t have access to the first and third link, but nevermind, the Darrigol’s book seems very interesting, thanks a lot for this.

3. **Alejandro Rivero**
   September 25, 2005

   Hmm, at least in one paper Dirac was explicit about the geometric character of his non-commutative p, q.

4. **Nigel**
   September 25, 2005

   ‘Most people think of Dirac as a brilliant algebraist, but he himself claimed that his motivations and way of thinking were much more geometrical than algebraic.’

   What strikes me in reading chapter XI of Darrigol is Dirac’s love of relativity. This must make it strange for many that Dirac followed Einstein into ’embarrassing’ ideas about a 3-D fabric of spacetime:

   ‘… with the new theory of electrodynamics we are rather forced to have an aether.’ – P.A.M. Dirac, ‘Is There an Aether?,’ Nature, v.168, 1951, p.906. See also Dirac’s paper in Proc. Roy. Soc. v.A209, 1951, p.291.

   ‘Looking back at the development of physics, we see that the ether, soon after its birth, became the enfant terrible of the family of physical substances. First, the construction of a simple mechanical picture of the ether proved to be impossible and was discarded. This caused to a great extent the breakdown of the mechanical point of view. Second, we have to give up the hope that through the presence of the ether sea, one co-ordinate system will be distinguished and lead to the recognition of absolute and not only relative motion. … After such bad experiences, this is the moment to forget the ether completely and to try never to mention its name. We shall say our space has the physical property of transmitting waves and so omit the use of a word we have decided to avoid. The omission of a word from our vocabulary is of course no remedy; the troubles are indeed much too profound to be solved in this way. Let us now write down the facts which have been sufficiently confirmed by experiment without bothering any more about the ‘e—r’ problem.’ – Albert Einstein and Leopold Infeld, Evolution of Physics, 1938, pp. 184-5

   ‘The idealised physical reference object, which is implied in current quantum theory, is a fluid permeating all space like an aether.’ – Sir Arthur Eddington, MA, DSc, LLD, FRS, Relativity Theory of Protons and Electrons, Cambridge University Press, Cambridge, 1936, p. 180.

   ‘It has been supposed that empty space has no physical properties but only geometrical properties. No such empty space without physical properties has ever been observed, and the assumption that it can exist is without justification. It is convenient to ignore the physical properties of space when discussing its geometrical properties, but this ought not to have resulted in the belief in the possibility of the existence of empty space having only geometrical properties… It has specific inductive capacity and magnetic permeability.’ – Professor H.A. Wilson, FRS, Modern Physics, Blackie & Son Ltd, London, 4th ed., 1959, p. 361.

   ‘To deny the ether is ultimately to assume that empty space has no physical qualities whatever… Recapitulating, we may say that according to the general theory of relativity, space is endowed with physical qualities… therefore there exists an ether. According to the general theory of relativity space without ether is unthinkable.’ – Albert Einstein, Leyden University, 1920. (Einstein, A., Sidelights on Relativity, Dover, New York, 1952, pp. 15, 16, and 23.)

   ‘But if, meanwhile, someone explains gravity along with all its laws by the action of some subtle matter, and shows that the motion of planets and comets will not be disturbed by this matter, I shall be far from objecting.’ – Isaac Newton, Letter to Leibniz, 1693.

   ‘The Michelson-Morley experiment has thus failed to detect our motion through the aether, because the effect looked for – the delay of one of the light waves – is exactly compensated by an automatic contraction of the matter forming the apparatus.’ – A.S. Eddington, Space Time and Gravitation, Cambridge, 1921, p. 20.

   Weird.

6. **D R Lunsford**

September 25, 2005

Dirac's book on GR is one of his miraculous works. It's only 69 pages long and reads like one of his papers. I remember it used to sit next to MTW on my shelf – here was this burlesque routine filled with hot air and dubious leaps of faith, and there was Dirac.

This is good:

http://arxiv.org/abs/gr-qc/0301097

The papers about deSitter space are fascinating and should be read by anyone interested in extra dimensions.

7. **plato**
September 27, 2005

Interesting…..

These pictures were not for pedagogical purposes: Dirac kept them hidden. They were not for popularization—even when speaking to the wider public, Dirac never used the diagrams to explain anything. Astonishing: across the great divide of visualization and formalism that has, for generations, split both physics and mathematics, we read here that Dirac published on one side and worked on the other.

And I Thought My Office Was Bad…

September 24, 2005
Categories: Uncategorized

Via For God, for Country and for Your Name Here, it seems that Alan Guth had the winning entry in a Boston contest for the messiest office. He won an office make-over, check out the before and after photographs.

Comments

1. **Chris Oakley**
   September 24, 2005

   It looks like the "before" office was an ingenious attempt to model the early universe – before galaxies started to form.

2. **Steve**
   September 24, 2005

   The very early office probably started out in a low-entropy ordered state with just a little disorder, eventually undergoing about 64 efoldings in clutter.

3. **Chris Oakley**
   September 24, 2005

   There also seems to be an information loss issue, as Janet of Go Simple made him donate his Physical Review collection to the MIT library. Maybe Hawking's original view of Black Holes, as applied to the initial singularity, was correct after all.

4. **Mark Trodden**
   September 24, 2005

   Fantastic! I've been in that office many times and it is by far the messiest one I've ever seen. As a postdoc Ionged for this day.

5. **Brett**
   September 24, 2005

   Keep in mind, that's Guth's NEW office. The old one, as I recall, worse.

6. **Kellstrom**
   September 24, 2005

   I give him 4-6 weeks, the office will return to its previous messy state. In other words, it will return to equilibrium, as is the eventual and inevitable fate of all perturbed systems.

7. **fantomas**
   September 25, 2005

   Theoretical physics is so passé. These days, it's all about Feng Shui.

   But wait a second, is Feng Shui even falsifiable ? Cause we all know the answer for inflation.

8. **Quantoken**
   September 25, 2005

   Kellystrom said:

   "I give him 4-6 weeks, the office will return to its previous messy state. In other words, it will return to equilibrium, as is the eventual and inevitable fate of all perturbed systems. "

   No it's not equilibrium. How do you go from zero entropy to a huge amount of entropy in virtually no time? **Inflation theory** is the answer 🙂 You bet inflation will happen in Guth's new office, which would quickly grow into a bubble universe 🙂

   His old office is really impressive. My guess is the amount of entropy probably has broken the Beckenstein Entropy Bound of blackholes.

   Quantoken

9. **Quantum_Ranger**
   September 25, 2005

   Guth would have noticed that, in his previous office he could tolerate things being moved to about 15 decimal places, things could be moved around his office freely, at least fifteen times before he could no longer retrieve any of his things, and would have to re-calculate where he last remembered where he seen what he was looking for!

   I calculate, in his new office he would have to fine-tune his sloppy filing nature down to about 1 decimal place, due to the fact that his office space is more restrictive, and thus moving any object from A to B would be a near improbable event!

10. **Chris Oakley**
    September 25, 2005

    Theoretical physics is so passé. These days, it's all about Feng Shui.

    Are you suggesting that if Alan Guth had a north-facing office behind a mountain, and no knives in his drawer (or whatever), then his office would not have got so messy? Or would that just be the condition for people to take inflation theory more seriously?

11. **fantomas**
September 25, 2005

Since inflation was about free lunch, I guess everything is possible.

Seed Magazine

September 26, 2005
Categories: Uncategorized

The science magazine Seed is being relaunched, and the first issue of its new incarnation is now on the newsstands. Their motto is "Science is Culture", and Clifford Johnson over at Cosmic Variance has an enthusiastic appreciation of what they are doing. The magazine is strikingly attractive, with impressive photography and graphics. One photo essay pairs photos with important equations.

There's a piece by Lisa Randall promoting her recent work with Andreas Karch on what she calls the "relaxation principle". I guess this is meant to be a sort of vacuum selection principle, contrasted to the "anthropic principle". In her Seed article she describes what she is doing as follows :

The challenge for physicists, and the problem I tackle in my own work, is find all possible qualitatively different universes — and to search for principles that determine which of these universes is most likely to exist.

Unfortunately there seem to be an infinite variety of possible such universes, and examining them all could easily take up the efforts of all particle theorists for the next few centuries. There's zero evidence for any sort of vacuum selection principle that will pick out the standard model from this infinite array of possibilities, so setting out on this path means probably abandoning any hope for ever explaining much of anything about particle physics. Karch and Randall try to give an argument for why there are 3 space dimensions, ending up with an argument for the survival of both 3 and 7 dimensional branes if one starts out with branes of all dimensions. This is a very, very long way from getting any non-trivial information about particle physics.

This issue of the magazine also has a short piece entitled "A New Force? How blogs are revolutionizing physics" by Joshua Roebke, an ex-string cosmology graduate student who now works at Seed. Joshua devotes a sizable part of his piece to telling about "Not Even Wrong" and some of the effects it has been having. Earlier this summer I had lunch with him here in New York and was encouraged to see that Seed has someone on staff with a good theoretical physics background.

Update: Lubos Motl also has a posting about the new Seed magazine. He comments on the Karch-Randall "relaxation principle", saying that he "kind of worked on it", but

frankly, I don't really believe it – because of the devil hiding in the details that just don't seem to work – much like many other proposals that have appeared in recent years.

   September 26, 2005

   Hello Peter,
   I forget if i've asked this before, but apart from SUSY, higher-dimensional geometries, and string theory, what are plausible ideas for going beyond the standard model (or explaining the SM) that do not involve string theory, SUSY, and higher-dimensions? Why is it we never hear about them?

   I know I did ask about other QG's such as LQG and CDT, but are there other ideas in particle physics that do not involve string theory?

3. **Chris Oakley**
   September 27, 2005

   I forget if i've asked this before, but apart from SUSY, higher-dimensional geometries, and string theory, what are plausible ideas for going beyond the standard model (or explaining the SM) that do not involve string theory, SUSY, and higher-dimensions? Why is it we never hear about them?

   One reason why you have never heard about them is that they have been starved out. When I was applying for post-docs around 84-85 just about everyone seemed to be switching to Superstring theory, and if you did not want to join the 10/26-dimensional circus yourself, you were unlikely to be shortlisted for a job.

5. **Thomas Larsson**
   September 27, 2005

   Dan, given that essentially all experiments are well described by the standard model coupled to gravity, perhaps the ultimate ToE will turn out to be SM coupled to GR. If so, the quest for something beyond the SM (except for gravity) would turn out to be fundamentally misguided.

Sure, this theory has some well-known mathematical problems – QM and GR are incompatible, the SM is somewhat ugly in the Higgs sector, QED breaks down at the Landau pole, etc. But these problems are mathematical rather than physical in nature, and may very well be resolved with a better mathematical understanding of field theory. At least we know that the mathematics underlying field theory is related to real physics.

6. **Dissident**
   September 27, 2005

   How about the most conservative approach of all, yet another parton layer, i.e. quark and lepton substructure?

   http://cosmicvariance.com/2005/09/05/dark-matter-and-extra-dimensional-modifications-of-gravity/#comment-4091

7. **Thomas Larsson**
   September 27, 2005

   Adding another parton layer is hardly conservative. As in string theory and supersymmetry, you have to posit the existence of an invisible world for which there is zero experimental evidence. But unlike string theory, you cannot argue that field theory infinities are absent, so GR will still be unrenormalizable. So you sacrifice the connection to reality without gaining anything mathematically.

   Technicolor is a variant of this idea. Here it is the Higgs boson which is a bound state of fermions (unless my memory fails me here), much like Cooper pairs in superconductivity. The experimental status is similar to that of SUSY and strings: the simplest and natural models are ruled out by experiment, but by adding new parameters you can avoid confrontation with experiment forever.

8. **D R Lunsford**
   September 27, 2005

   TL, that's more or less the end of that idea 🙂

   I wonder why such simple reasoning is in such short supply? …

   -drl

9. **dan**
   September 27, 2005

   re Thomas Larsson Says:

   one of the motivations for going beyond SM+GR is that certain astronomical phenomena appear to be unexplained, and i am referring specifically to dark matter, dark energy, cosmological constant, hierarchy problem, matter/antimatter asymmetry, BH information paradox, etc., that string theory and LQG are attempting to address.

   is your position that SM+GR can eventually explain the above phenomena and will not require new physics? if so why all the effort being poured into string theory?

10. **Chris Oakley**
    September 27, 2005

    One of the things – no, *the* thing I enjoyed most about Peter's forthcoming book (he kindly gave me a copy of the manuscript in January) was an honest survey of the various schemes, stringy and non-stringy, for going beyond or fixing the problems in the standard model. All too often the state of each particular art is explained by one of its enthusiastic exponents, and one gets somewhat of the Monty Python Pet Shop Owner effect ("No, this parrot's not dead, he's resting … pining for the fjords, etc.")

11. **anon**
    September 27, 2005

    WoW! Off topic but eye popping:
    a post by Martin Rocek at Lubos' website.

12. **Dissident**
    September 27, 2005

    > Adding another parton layer is hardly conservative.

    Yes it is.

    > As in string theory and supersymmetry, you have to posit the
    > existence of an invisible world for which there is zero
    > experimental evidence.

    You miss the little detail that unlike strings, an underlying parton structure would not need to wait until the Planck scale in order to reveal itself. As for zero experimental evidence, what do you make of the anomalous magnetic moment of the muon? It's already been pointed out that it can easily be accomodated by a composite muon.

    > But unlike string theory, you cannot argue that field theory
    > infinities are absent, so GR will still be unrenormalizable.

    Who said partons are supposed to fix GR? By the same logic, quarks are no good since they don't fix GR either.

    > So you sacrifice the connection to reality without gaining
    > anything mathematically.

    Seems to me somebody is confusing mathematics with reality here…

13. **Thomas Larsson**
    September 27, 2005

    GR+SM as formulated today is certainly not the end of the story. Astronomical observations are a minor problem here, compared to the fact that the two theories are mutually incompatible. However, there are good reasons to expect that a deeper understanding of the mathematics underlying QFT can lead to a unification of QM and GR, without adding much on the physics side.

More specifically, I am thinking about gauge symmetries. Recently I had a look at Rudolf Haag's book on Local Quantum Physics. A striking claim there is that no intrinsic quantum formulation of the gauge principle is known, despite its central importance in the SM. The gauge principle is of course well understood on the classical level, and that's what matters in the path-integral formalism. An exception, where a gauge symmetry is understood on the quantum level, is conformal symmetry in string theory.

The lack of such a quantum gauge principle is quite obvious from my point of view. In order to understand how a gauge symmetry acts on the (kinematical) Hilbert space, we must first understand how it can act at all, and this is precisely the subject of the representation theory of gauge algebras. The most striking observation is that all interesting quantum representations have anomalies, and that one must explictly introduce and quantize a clock's worldline in order to formulate these representations. This appears to me as the key missing idea.

I have of course no real idea how the astronomical observations should be understood, and I think that it may be premature to address that problem without a theory of quantum gravity. However, i would guess that the CC is somehow related to anomalies – this is at least the case in 2D and 3D gravity.

14. **Thomas Larsson**
September 27, 2005

Dissident, quarks are good because they explain many experiments. An extra layer of partons would be equally good if they fixed some glaring cracks in the SM. Last time I checked, there were no such cracks.

Besides, I thought muon g-2 was explained by a sign bug in the Schoonship program.

15. **Dissident**
September 27, 2005

Really. I guess you should tell these guys then:

http://www.g-2.bnl.gov/

16. **woit**
September 27, 2005

Thomas is right that there was an error in the muon g-2 calculation (I don't know if Schoonschip was to blame). Fixing the error reduced the difference between the theoretical and experimental values. At this point as far as I can tell, given the uncertainties in the theoretical calculations and in the experimental results, there is no convincing conflict between theory and experiment.

17. **Matthew**
September 27, 2005

Just for the record, the g-2 for the muon is indeed out by over a sigma from the standard model prediction. However, the errors and stability of the hadronic part of the theory are "questionable". There's no reason to expect the hadronic number to stay where it is. In fact, there's two different hadronic numbers, and they disagree with each other. hep-ph/0402206 is a good place to start.

In short, the hadronic part of the muon mm is way too uncertain to go about claiming a 2 sigma difference is "evidence" of anything.

18. **John Baez**
September 27, 2005

Thomas Larsson writes:

> Dan, given that essentially all experiments are well described by the standard model coupled to gravity, perhaps the ultimate ToE will turn out to be SM coupled to GR. If so, the quest for something beyond the SM (except for gravity) would turn out to be fundamentally misguided.

This ignores the 800-pound gorilla: dark matter! Barring drastic revisions of our theory of gravity, about 23% of the energy density in the universe is dark matter, while only 4% is ordinary matter. (The rest is dark energy – these are the WMAP findings.)

So, while I think it's *crucial* to pay close attention to the details of the Standard Model, I think that someday we'll find a beautiful theory that includes the Standard Model particles *and a bit more*.

Looking for this theory is one of my hobbies….

19. **Dissident**
September 27, 2005

Dark matter? Nah! 🙂
As I have pointed out elsewhere

http://cosmicvariance.com/2005/09/05/dark-matter-and-extra-dimensional-modifications-of-gravity/

there are now several interesting alternatives:

http://arxiv.org/abs/hep-th/0410119

http://arxiv.org/abs/astro-ph/0506370

20. **Dissident**
September 27, 2005

Almost forgot: the current g-2 deviation from the standard model prediction is 1.6 sigma.

http://www.npl.uiuc.edu/exp/g-2/g-2Main.html

By all means, pooh pooh it all you want. 😉

21. **woit**

September 27, 2005

No matter what I write about, sooner or later people want to start discussing their favorite alternatives to GR. Please don't do this here, it's off-topic, and the last thing in the world I want to do is to try and moderate a discussion of this subject.

I've had to delete a bunch of such comments, then deal with people complaining about this and accusing me of censorship. This is not sci.physics and I'm not going to let it turn into that.

22. **Nigel**
September 28, 2005

John Baez wrote:

'This ignores the 800-pound gorilla: dark matter! Barring drastic revisions of our theory of gravity, about 23% of the energy density in the universe is dark matter, while only 4% is ordinary matter. (The rest is dark energy – these are the WMAP findings.)'

All the evidence for dark matter and dark energy is from cosmology models, so why can't the basis of cosmology be re-examined? It is entirely possible to incorporate into general relativity a model for gravity which eliminates the dark matter problem (which is due to the false assumption that gravity has no cause within the universe, correcting that just leaves invisible dust contributions), and the dark energy problem results again from ad hoc force-fitting the theory to the observations. This is not the way to do physics. The theory should not keep getting fiddles to make it fit the facts, that is what went wrong with epicycles in ancient cosmology.

23. **Who**
September 28, 2005

Vafa article posted today—-relates to earlier post by Peter on this blog.
Here is the article:
http://www.arxiv.org/abs/hep-th/0509212
The String Landscape and the Swampland
Cumrun Vafa
9 pages

since this post is not on topic, I'd hardly object were it deleted. Just wanted to let folks know in case of interest.

Into the Swampland

September 28, 2005
Categories: Swampland

Last month Cumrun Vafa gave a talk at Stony Brook entitled The Swamp Surrounding the Landscape. Tonight he has a new paper on the arXiv entitled The String Landscape and the Swampland. Vafa appears to be suggesting that, faced with the huge landscape of possible string vacua and the attendant inability of string theory to predict anything about physics, the thing to do is not to abandon string theory, but to head off into the even larger "swampland" of effective field theories that may or may not correspond to string theory vacua. He gives various arguments for why certain effective field theories may not correspond to string theories, but most of these are just something like "the string theory constructions we have looked at so far can't give this kind of effective field theory". Since one still doesn't know what string theory really is, one probably can't do much better than this. He also assumes that the rank of the cohomology groups of Calabi-Yau threefolds is bounded, which is a conjecture that at least some algebraic geometers don't believe in.

Throughout his article, Vafa assumes that string theory must be true, asking "how" it will connect to experiment, not "whether" it will. For more than twenty years, string theorists have led particle physics deep into a swamp. It seems peculiar in the extreme that Vafa is now suggesting that, instead of hiking back out of the swamp to dry land, particle theorists should push on deeper into the swampland.

Update: Lubos Motl has a posting about the Vafa paper. It includes the news that Andy Strominger
believes that the program has two basic flaws: the conjectures are trivially correct in every theory of quantum gravity independently of string theory; and moreover they are wrong.

Some of my commenters claim that what Vafa is doing is designed to make string theory falsifiable. I don't see this, and Vafa doesn't make this claim himself. This seems to me an example of a common phenomenon. People take a string theory paper that already is going way out on a limb with not very solid arguments, then make a wild extrapolation that goes far beyond what the author claims and use this to promote the importance of the paper in a completely unjustifiable fashion.

To falsify string theory along these lines, one would have to show that it can't lead to the standard model as an effective low energy theory. Vafa doesn't claim this is conceivable, and his arguments can't possibly do this. Most of the examples he gives of effective theories that may not be low energy limits of a string theory are gauge theories of high rank. It's certainly conceivable that one can argue for something like a bound on the rank of the effective field theory gauge group if it comes from string theory, but there's absolutely no reason to believe that such an argument can rule out the rank 4 case we care about (SU(3)xSU(2)xU(1)). I suppose one can argue that, if say Vafa can show the rank must be less than 500, and the LHC discovers a new gauge theory sector with rank 501, string theory would be falsified. But that's kind of like saying that string theory is falsifiable, because if dragons emerge from the LHC interaction regions, string theory would be wrong.

Update: Jacques Distler also has a posting about the Vafa paper. He says he'll wager that it is "far, far from true" that "'anything' is realizable somewhere on the Landscape", and that "we will learn much" if we investigate this swamp. He doesn't explain why it's a good idea for the particle theory community to enter this swamp to investigate it carefully.

Comments

1. **A.J.**
   September 29, 2005

   What Vafa is suggesting is utterly reasonable. Even if you are string theory true believer, you can at least admit that studying models which are at least very similar to string theory is a good way to learn more about string theory.

2. **Anonymous**
   September 29, 2005

   Don't you think you're being unreasonable? You press for string theory to be good science, and argue that it isn't falsifiable. Someone outlines a program that could *make* it falsifiable — granted, a difficult program to carry out — and you complain. Would you be satisfied by anything less than Vafa completely renouncing string theory?

3. **Luboš Motl**
   September 29, 2005

   Dear Peter,

   the fact that some people don't believe that the number of Calabi-Yau topologies is finite does not mean that the physicists are not allowed to investigate physics with the opposite assumption that is consistent with all known facts.

   If one felt pressure not to investigate a scientific theory (or conjecture) just because there exists someone who does not like it, we could also stop doing physics or string theory because some people at Columbia think that physics beyond the Standard Model is not even wrong.

   Such a thing will certainly play no role whatsoever for me. I leave this method of deciding about science to the numerous crackpots who like to visit your blog assuming that it is a serious reading.

   You should be pleased if people start to study swampland – it is a step towards the research of f**kland. I explain on my blog why this should really please you. 😉

   All the best
   Luboš

4. **Wolfgang**
   September 29, 2005

   It seems that the main argument of this paper is that the "landscape" of truly consistent vacua is of zero measure compared to the "swampland" of models only seemingly consistent as semiclassical effective theories. In this sense (far away from the Planck scale) M-theory is predictive and I am waiting for ref [8].

5. **Arun**
   September 29, 2005

   There is a point to this – it does open a way to falsification of string theory. If one understands the types of effective field theories string theory cannot produce, and shows that e.g., our universe is governed by an effective field theory that is not stringy, then we can move string theory entirely to the math. department.

6. **woit**
September 29, 2005

I added something to the posting about the falsifiability issue.

A.J.: I don't understand your argument why this is utterly reasonable. The kind of models Vafa is talking about are atrociously complicated, far more so than the ones in the landscape, (thus the "swamp"). Why is it reasonable to spend time looking at these things? They're hideously ugly and have nothing to do with the Standard Model or the real world. The only justification for entering this yucky swamp is the belief that understanding just how yucky string theory can be is important, given that we already know that it can be very, very yucky. I don't understand why anyone thinks this is a sensible way to spend one's time.

Anonymous: If string theorists like Vafa want to say that string theory is too poorly understood to believe in the landscape, so they intend to keep working on it, that is not unreasonable, and such work sometimes even leads to interesting things (e.g. work on topological strings). But once they accept that the landscape exists and string theory is a radically non-predictive framework, if they are honest scientists, they should admit that the idea should be abandoned.

Lubos: people are welcome to investigate whatever assumptions they want, I was just pointing out that this particular assumption is not one where the experts on the subject (algebraic geometers) are agreed about what is likely to be true. And as to the crackpot level of readers of my blog, have you taken a look a look at your own comment section recently?

Wolfgang: What's a specific experimental prediction of M-theory that comes from Vafa's work?

7. **Wolfgang**
September 29, 2005

Peter,

as I understand it, Vafa's paper outlines a research program on how to make string theory predictive far away from the Planck scale. It argues that there should be a large number of field theories which are not consistent with M-theory and thus should not be observed in nature. The "swamp" of such models should be very large compared to the "landscape" of consistent vacua.
This should/could provide for testable predictions at some point.
The paper does not yet provide examples of such models;
I expect subsequent papers (e.g. ref[8]) to be more specific.

8. **woit**
September 29, 2005

Hi Wolfgang,

I don't see anything in Vafa's paper that comes even close to giving a plausible way of coming up with a legitmate prediction from M-theory. He's assuming the existence of the landscape, and once you do this there seems to be no way to predict anything. The question of how big the swamp is seems irrelevant to making real predictions. I don't see why if he had a serious idea about how to predict something, he wouldn't put it in his first announcement, keeping it secret until the later paper.

9. **A.J.**
September 29, 2005

Hi Peter,

All I was attempting to say — and I hope you'll forgive the vagueness; I spent most of yesterday typing — was that I think studying a far wider class of models is a good idea. I don't care whether people do it with the intent of learning more about string theory, or with the intent of showing that the Standard Model actually lies somewhere in the swamp. The bottom line is that (I'm speaking here as a mathematician) we don't really understand that much about any of these theories. Having a broader selection of examples might teach us a few things.

10. **Brett**
September 29, 2005

I think it's a perfectly reasonable idea that there should be vastly more field theories that cannot exist as string theories than those which actually could arise as string theory vacua, say. However, given the complexity of either kind of theory, I would expect that that boundary between the two in parameter space is probably not going to be anything simple; it will likely have a fractal struture, and it is my guess that any randomly selected theory, even if it exluded as a string theory, will nonetheless be "close" to an string theory version.

11. **Renormalized**
September 29, 2005

I sometimes wonder if Lubos Motl is working on any publishable material or has any original ideals about physics. His real talent is in making useless arguments about crackpots and those less intelligent than himself. This includes the whole world since he thinks of himself as the smartest of all. It is easy to insult others work and ideas when you have none of your own to be criticized. His pompous imperturbable egoism is as worthless as his contributions to science.

12. **Not a Nobel Laureate**
September 29, 2005

You're all wrong.

The Theory of Intelligent Falling is the Answer.

Evangelical Scientists Refute Gravity With New 'Intelligent Falling' Theory

http://www.theonion.com/content/node/39512

August 17, 2005 | Issue 41•33

"Closed-minded gravitists cannot find a way to make Einstein's general relativity match up with the subatomic quantum world," said Dr. Ellen Carson, a leading Intelligent Falling expert known for her work with the Kansan Youth Ministry. "They've been trying to do it for the better part of a century now, and despite all their empirical observation and carefully compiled data, they still don't know how."

13. **Matti Pitkanen**
September 29, 2005

The proposed theoretical activities in infinite-dimensional infinite-volumed swampland unavoidably create an association to monkey, typewriter, and Shakespeare's sonnet. Another association is a story in Mathematical Intelligence about Baron Monty Carlow and his ingenioius method of measuring the area of lake by randomly bombing the county and counting the fraction of bombs hitting the lake.

The pioneers of Monte Carlo method of TOE building
deserve all encouragement in their challenging task,

14. **Arun**
September 29, 2005

If our universe is indeed hidden somewhere in the landscape, what is the rational reason for abandoning string theory? Nature could be both subtle and malicious.

15. **Aaron Bergman**
September 30, 2005

Some of us continue to hope otherwise, though.

16. **woit**
September 30, 2005

Arun,

Before you start believing in something completely absurd like the landscape, how about first asking for some experimental evidence? I can't believe people are abandoning the most elementary aspects of the scientific method. This is something we are teaching to children in elementary school these days, why can't professional physicists understand this?

A less elementary aspect of the scientific method is that you can always try and make a wrong idea work by making it more and more complicated, desperately trying to avoid confrontation of the idea with experiment. It should be completely obvious by now that this is what is happening with string theory.

17. **Wolfgang**
September 30, 2005

Peter,

Jacques Distler conjectures on his blog that only models with 3 fermion generations are consistent (in Vafa's sense) but not 1 or 2.
Would you consider this a valuable post-diction ?
(It would have been really nice as a prediction, but sometimes the calculations just take a looong time.)

18. **rrtucci**
September 30, 2005

Peter, just had an idea for "the special-edition cover" for your book: a picture of Lubos' head (wearing a harvuhd tie), the head superimposed on the body of a tiny ant, which is at the focal point of a large magnifying glass, which in turn is being illuminated by the sun. Maybe also a smarter ant, with Witten's head, running away. And an ant with Vafa's head caught in a swamp.

19. **woit**
September 30, 2005

Wolfgang,

No, this is not a prediction or post-diction, since you have no idea of what the masses of the particles are. Remember, experimentally all we know is the number of light generations (more specifically, the number of generations with a neutrino less than half the mass of the Z). It's entirely possible that the number of generations is really >3. If we had only observed 1 or 2 generations, and string theory really needed at least 3 generations, we wouldn't falsify string theory because more generations could just be at higher mass.

In general, a "prediction" of the number of generations is operationally meaningless without also knowing at what mass scales they are going to occur.

I'm no expert on these constructions, so I'm not sure which difficulties in constructing models with one or two generations Jacques is referring to. My guess is that it is the fact that in the standard way of using Calabi-Yaus, the number of generations is the Euler characteristic, and it is hard to construct Calabi-Yaus of Euler characteristic one or two. But I suspect there are many ways around this, and that an expert in these constructions could come up with one way or another of getting one or two generations if they really wanted to. Again, since you don't know the masses, one or two light generations, the rest heavier than we can observe, is no problem.

20. **Arun**
September 30, 2005

Peter,

Why don't I ask for experimental evidence? Because I know there is none. But if we're into dealing with reality, then it is a given that Vafa, Motl, Douglas, etc., are not going to abandon string theory any time soon, or resign from the physics department. Then, all I can ask for is that they pursue the approach that is most likely to produce an experimental signature for string theory. Is this approach the right one? I don't know, but until the string theorists explore it a bit more, we won't know.

-Arun

21. **woit**
September 30, 2005

Arun,

I think by now it's completely clear that the things that are known about string theory are insufficient to make any contact with physics and predict anything. Under these circumstances, it's not unreasonable to try and come up with some better understanding of string theory, e.g. to work on trying to figure out what M-theory is. It is unreasonable to deny that this is the situation and promote the idea that you can get physics out of the Landscape.

22. **Shantanu**
September 30, 2005

    Peter have you read hep-th/0509157 ? any comments on that?
    It has been discussed at http://web.mit.edu/cabi/www/blog/

23. **woit**
September 30, 2005

    Shantanu,

    Yes, I saw that. I was thinking of putting together a posting very soon of various links including that one. I'm not sure what one can sensibly say about it though. Do you see anything in that paper that looks at all like a promising idea about how to connect string theory to real world particle physics? I didn't.

Thinking Big

September 30, 2005
Categories: Uncategorized

Philip Anderson has a piece in the latest Nature entitled Thinking Big. It's about the interpretation of quantum mechanics, and in it he claims that Fritz London was the first one to really have the right idea about the problem. Commenting on the Bohr-Einstein debates on the subject, Anderson says "In reading about these debates I have the sensation of being a small boy who spots not one, but two undressed emperors." Instead of the Bohr or Einstein positions, Anderson promotes a point of view he attributes to London, who wrote a paper about it in 1939 with Edmond Bauer. He says "Taking London's point of view, one immediately begins to realize that the real problem of quantum measurement is not in understanding the simple electron being measured, but the large and complicated apparatus used to measure it" and that "The message is that what is needed is an understanding of the macroscopic world in terms of quantum mechanics."

I take Anderson's point to be that the classical physics of a measuring apparatus is an "emergent phenomenon", and understanding this is the real problem of interpreting quantum mechanics. He ends with his favorite slogan: "more is different!".

Comments

1. **Eric Dennis**
   September 30, 2005

   Interesting that your paraphrase of Anderson's comments is exactly the position of Einstein and exactly the opposite of Bohr's position. Specifically, Einstein demanded that the previously known physics on the large scale emerge deductively (at some appropriate level of rigor) from the new microscopic theory. Bohr wanted to retain classical objects (measurement devices) as irreducible elements of the new theory. As I understand it, this, and not any question of indeterminism, was at the heart of Einstein's criticism of Copenhagen QM.

2. **Who**
   September 30, 2005

   Not on topic and may fairly be erased: thought NEW readers might like to look at the Freeman Dyson article on Feynman
   http://www.nybooks.com/articles/18350
   occasioned by the publication of a collection of Feynman's letters.
   Dyson sketches his own ideas of Feynman's style of thought, approach to physics, accomplishments, character.
   Free download—not restricted to paying subscribers of the NYRB.

3. **woit**
   September 30, 2005

   Just added that Dyson article to a new posting containing a list of assorted interesting links.

4. **Maynard Handley**
   September 30, 2005

   Anderson (like Robert Laughlin) seems to following in Chomsky's footsteps. For thirty years he has been peddling emergence (like Chomsky's deep structure), yet I still have no concrete idea what he is actually talking about. My understanding is that what he means is something like saying "a computer can look at the waveform of speech, but it does not *understand* speech, ie there is something more to speech than just the waveform" to which one can reply
   * the theological position: yes there is some sort of magic fairy dust that animates speech and macro-physics
   * the Dawkins position: there is no fairy dust, the waveform is all there is, you just lack the appropriate way (so far) to extract info from the waveform

   Anderson and followers irritate me because they seem to speak in the theological mode, but when pushed revert back to the Dawkins mode. If you accept Dawkins, then WTF is the big deal? Yes, we don't have all the appropriate tools yet, but no-one, not even Weinberg or any of the other Anderson demons claims that, so what it their beef. Yes, they want more money for solid state research, I get that, but this mystical mumbo-jumbo is not the way to get there.

5. **Eric Dennis**
   September 30, 2005

   Maynard — I agree with you about the slipperiness of this "emergence" concept as used by Anderson and Laughlin. The latter's popular book does a very poor job at trying to spell out the ideology and his papers aren't much better.

   It's a shame because the emergent quantum gravity idea (the geometry of space-time as a mathematical convenience for describing the physical effects of a condensed matter ether) is intriguing and fully consistent with your "Dawkins" position.

6. **Arun**
   September 30, 2005

   The "appropriate way" to extract information from the speech waveform is the emergent property.

7. **Chris W.**
   October 1, 2005

   To expand on what Arun said, the problem of interpreting (extracting information from) a speech waveform is very much like interpreting a data stream coming over a wire. If one knows nothing about network protocols and encoding methods one will have a hell of a hard time getting beyond a crude physical and statistical description of the signal. (Ditto for interpreting signaling in the nervous system.)

   What is emergent, in the sense that biological complexity is emergent, is the scheme for speech generation and processing that our biological and cultural evolution has worked out over several million years. At the physical level what is being produced is still just some aperiodic acoustic signal (often supplemented by hand gestures and facial expressions). We *homo sapiens* have a grasp of this scheme the way a batter has grasped a solution to the problem of connecting his bat with a baseball coming at him at 80+ mph. Objectifying this grasp of the problem, and implementing it in a computing device, is inherently difficult; nobody has or will supply us with the relevant technical specs or theoretical background.

8. **Chris W.**

October 1, 2005

Reinforcing the first comment (posted by Eric Dennis) John Stachel asserted 15 years ago in his contribution to Conceptual Problems of Quantum Gravity (Ashtekar and Stachel, editors) that Einstein's position on the indeterminism of quantum theory has been widely misunderstood. He said that Einstein objected to the fact that the theory offers no explanation for the *extent* of its statistical description. If the physical world is not (in effect) a deterministic machine, then why shouldn't it be so totally chaotic as to utterly defeat any attempts to rationally investigate it?

Fortunately for us (and for that matter, all living things) such radical chaos does not reign, but Einstein felt that we still don't understand this as well as we can and should; quantum theory is not the last word on the subject.

(By the way, in the last few months Stachel has produced some *interesting* papers on foundational questions in quantum gravity.)

ICM 2006

September 30, 2005
Categories: Uncategorized

The International Congress of Mathematicians (ICM) takes place every four years and is the most important international conference in mathematics. The 2006 ICM will take place next August in Madrid. One thing that happens at each ICM is the announcement of the winners of the Fields Medal. This has traditionally been considered the most prestigious award in mathematics, and the closest analog to a Nobel prize in math, although the recently instituted Abel prize may now compete for this honor. The Fields medal is awarded to between two and four people at each ICM, and recipients must be under the age of 40 on Jan. 1 of the year of the ICM. I have no inside information about who will win this year, but in gossip with mathematicians two names that tend to come up are those of Grigori Perelman (for his work on the Poincare conjecture), and Terence Tao.

The other important thing about the ICM is the list of invited talks. The speakers are carefully chosen and are supposed to be people who have done the most important work in mathematics during the past four years. Looking over the list of speakers gives a good idea of who the most prominent names in the business are, as well as what are the hottest topics. It's an especially great honor to be chosen as a plenary speaker, and the names of these have been recently announced. The invited speakers in the various sections have also been announced, one section covers mathematical physics.

Comments

1. **Zelah**
   October 1, 2005

   I have been reading your blog regard ICM2006.

   Now Grigori Perelman is problematic, as I believe he may be 40 next year! This has come up before! Infact, this problem is quite serious for mathematics as frankly, essentially all of the TRUELLY great mathematics in the last decade has been done by the over forties (e.g. Oded Schramm of Brownian Frontier Fame!) So much for math being a young man's game!

   Now, you have really got my interest with Terence Tao. Now as an amateur mathematician I am a sort of a math junkie and have been looking at the work of various mathematicians over various fields
   I investigated Terence Tao because of his work on harmonic analysis!

   But I must admit he was not on my list of Field Medallists! I am interested in why Terence Tao work crops up! Please explain!

   Here is my list of Field Medallists.

   1. Warwick Tucker

   Warwick Tucker has given a rigorous proof that the Lorenz attractor exists for the parameter values provided by Lorenz. This was a long standing challenge to the dynamical system community, and was included by Smale in his list of problems for the new millennium.

   I must add that He is working within a new computational field called interval analysis which allows one to solve simultaneous ODE RIGOUROUSLY. Now if you have tried to solve Nonlinear ODE, you will realise this is one of the holy grails of Applied Mathematics!

   2. Elon Lindenstrauss

   Already, in joint work with Katok and Einsiedler, he has used some of the ideas in this work to prove the celebrated conjecture of Littlewood on simultaneous diophantine approximation for all pairs of real numbers lying outside a set of Hausdorff dimension zero

   What I love about this work is that it continues the pathbreaking work of in my opinion, the greatest female mathematician of the 2nd half of the 20th Century, Maria Ratner and her theorem about unipotent flows.

   I believe that the work on unipotent flows will be the next revolution in function theory. In particular, I believe it will lead to solutions to many problems in Quantum Field Theory eventually! Watch out!

   3. Mark Groves

   Someone who has no chance in reality, but his work is something I fully understand!
   Winner Richard Von Mises prize in applied mathematics.

   What did he achieve?

   Solutions to something called the Water Wave problem. But what is important to me is that they confirm an intuition about Nonlinear Wave I have always held.

   Essentially, for a large class of multidimensional nonlinear systems, the behaviour moves from linear to solitons to chaotic along various semigroups!

   This very simple statement actually provides a small piece of a puzzle about chaos, which has been mysterious for a long time. Basically how does chaos create order in nature? Well, it appears that certain nonlinear systems generate semigroups spontaneously, which does not align itself with the natural semigroup time! This means that chaotic functions can be thought of as acting like solitons in a highly nonlinear environment.

   Unfortunately, I do not have any women for the Field Medal at this time. Do not get me wrong, there are many female mathematicians doing great work, but difficult to discern if it is of Field Medal Caliber.

   An Amateur Mathematician

2. **Zelah**
   October 1, 2005

   I have had a look at the ICM2006 site, and it appears that there is a new prize called the Gauss Prize.

   Sound interesting.

An Amateur Mathematician

3. **John Baez**
   October 1, 2005

   An Amateur Mathematician exclaims:

   > I investigated Terence Tao because of his work on harmonic analysis!
   >
   > But I must admit he was not on my list of Field Medallists! I am interested in why Terence Tao work crops up! Please explain!

   He and Ben Green showed there are arbitrarily long arithmetic progressions of prime numbers.

   And, he's won some prizes already for other things, including his work with Allen Knutson, in which they proved Horn's conjecture. This says what the eigenvalues of a matrix A+B can be, given the eigenvalues of two hermitian matrices A and B. It's equivalent to a lot of other nice conjectures.

   So, he's cracked some hard problems that are easy to state.

4. **a graduate student**
   October 2, 2005

   Just to keep the gossip going, Dennis Gaitsgory (recently tenured at Harvard) and Manjul Bhargava are two other names that have popped up during tea at my department.

5. **Pindare**
   October 2, 2005

   The only plenary speaker under 40 (if my google checks are ok) is Terrence Tao, so that's in the bag IMHO. Besides he's really a good bet as John said, with lots of prizes and big invited lectures already (next are his Chern lectures at Berkeley.)

   In fact, he's got such a wide array of expertise that there's already only a few people left who could possibly introduce all his work (Bourgain, Gowers…) so the Fields commitee can't really wait much longer anyway… 😉

   As for Perelman, well if his birthdate is indeed the one given on wikipedia, then he's definitely *done* his work before being 40…
   http://en.wikipedia.org/wiki/Grigori_Perelman

   Personally I'd expect Artur Avila to win it one day, barely 26 and already quite impressive…

6. **Zelah**
   October 2, 2005

   Hi Everyone!

   Thanks for all of the wonderful tips!

   Unfortunately from my point of view, it appears that the bias against applied mathematics will continue. I am hoping that the Gauss Prize will correct this obvious problem and they will pick someone really wonderful like Kiyosi Ito of Ito Calculus fame.

   I am also hoping that the Abel prize commitee pick a Woman next time as there are in my opinion women who are deserving. Karen Uhlenbeck or Maria Ratner would do fine!

   An Amateur Mathematician

Is N=8 Supergravity Finite?

September 30, 2005
Categories: Uncategorized

Zvi Bern gave a talk yesterday at the KITP in Santa Barbara entitled The S-Matrix Reloaded: Twistors, Unitarity, Gauge Theories and Gravity. He surveyed recent progress on computing perturbative amplitudes in QCD and N=4 supersymmetric Yang-Mills, some of which involves using twistor methods. The most striking thing though were his last few transparencies (here, here, and here). He notes that all previous studies of divergences in supergravity rely only on power-counting and supersymmetry, assuming that if these two principles allow a divergence to occur, it will. Actually doing the full computation to see if the divergences are there is too hard and no one has done it. Bern notes that in these arguments the extra structure seen by the recent twistor methods is not taken into account, and when one does this, so far all complete calculations show that N=8 supergravity has exactly the same degree of divergence as N=4 Yang-Mills, even though one would naively expect the supergravity amplitudes to have worse behavior. He ends by suggesting that "Serious re-examination of the UV properties of multi-loop N=8 supergravity using modern tools is needed."

If N=8 supergravity turns out to be renormalizable, this raises an interesting question about string theory….

Comments

1. **Ben Compson**
   September 30, 2005

   I don't understand — supergravity has been around for at least 25 years. How can we only now be asking if N=8 supergravity is renormalizable??? What else have theorists been up to all these years?

2. **woit**
   September 30, 2005

   "What else have theorists been up to all these years?"

   Hmm, have you heard about this idea called string theory?

   More seriously, divergences in N=8 supergravity don't occur until at least 5 loops. Ever tried to do a 5-loop calculation in N=8 supergravity?

3. **Wolfgang**
   September 30, 2005

   Since 3 loops is good enough for superstrings, 5 loops should be more than sufficient ?

4. **logopetria**
   October 1, 2005

   Sorry to inject such a basic question, but this is something I've never been able to find out: in these "N=4", "N=8" etc theories, what does the 'N' denote? Is it a variable that can take on arbitrary integer values? Is it like a coupling constant, or what?

5. **Urs**
   October 1, 2005

   > Is it like a coupling constant, or what?

   N is the 'number of supersymmetries'. Very roughly and schematically, this means there are N different odd-graded quantities that square to the generator of (time) translation.

6. **logopetria**
   October 1, 2005

   Thanks. I'm not sure I understand much, but at least I know *what it is* that I'm not understanding! Does "the number of supersymmetries" dictate how many superpartners each ordinary particle has? That is, does "N=1" say that the electron is partnered with the "selectron", while "N=2" say that there are 2 flavors of selectron? Or am I way off target here?

7. **Field-Theorist**
   October 1, 2005

   Even if N=8 happen to be finite, it is not clear that we can embed the standard model in it. Moreover, in contrast to string theory there is no deep reason why it should be finite. Historically, until the first superstring revolution it was considered as an interesting theory, but soon after the superstring revolution people abandoned it.

8. **woit**
   October 1, 2005

   logopetria,

   Basically, yes. When you have multiple supersymmetries, particles come in multiplets more complicated than just fermion-boson pairs.

   Field theorist,

   If Bern is right, N=8 supergravity may be renormalizable because of a combination of supersymmetry and twistor geometry, which would be arguably a deeper reason (symmetry) than the reason for the (conjectured) finiteness of the superstring.

   Yes, it's hard to get the standard model out of N=8 supergravity, which is one reason people gave up on it. But this may be a much more fruitful starting point than string theory, where the problem is not that you can't get the standard model, but that you can get anything. And working with a well-defined theory instead of a vague hope that a theory exists might also be a good idea.

   The reason people gave up on N=8 supergravity was not just the problems getting the standard model, but everyone believed it was non-renormalizable. At this point, about the only argument you can give for string theory is that it is the only way to combine gravity and quantum mechanics. If that collapses, I suppose string theorists will keep on arguing for string theory unification, but they won't have any legitimate arguments left.

9. **Moshe Rozali**
   October 1, 2005

   This is fascinating, I was under the false impression that Bern and company proved that theory to be non-normalizable, but apparently that was for 11dim SUGRA. Zvi has a review in living reviews in physics (which presumably gets updated regularly) on the subject, and conjectures about N=8 SUGRA being more finite than it should be apparently already appeared before the twistor connections.
   \
   In case N=8 turns out to be finite because of some deep relation to twistor space, that would be absolutely spectacular. Right now it is not clear though (to me) what could be this deep structure (maybe a string theory? just kidding…).
   \
   I am wondering though how can one break SUSY and get more or less realistic spectrum (I was in high school when these things were all the rage). If one has to add matter and thus break the symmetry, the magic is likely to be gone.

10. **woit**
    October 1, 2005

    Hi Moshe,

    I was in grad school at the time, so I did learn a bit about this, but I've forgotten most of it and would have to go look this stuff up. From what I remember, unless you start adding other things in, two big problems are that

    1. you get an SO(8) gauge theory, and SO(8) isn't big enough to include the standard model gauge groups.

    2. the spectrum is vectorlike, not chiral as needed for the standard model.

    As for supersymmetry breaking, that's always been a huge problem for any supersymmetric theory.

    Even if the theory is renormalizable, you're right it's not clear this would survive whatever one did to try and get around the above problems.

11. **John Baez**
    October 1, 2005

    Thanks for pointing out this talk by Zvi Bern – it's really interesting!

    For one thing, it shows that you should never trust a physics "folk theorem" until you see how people convinced themselves of it, and know what the loopholes are.

    For another thing, it's more evidence that there's a lot left to understand about perturbative quantum field theory. Connes and Kreimer have been doing cool work on this subject for a while, and now comes this twistor business. I wish I understood more about both!

    If you read Predrag Cvitanovic's autobiographical remarks entitled Search Without a Plan, you'll see he's one of the few people who have added up thousands of Feynman diagrams in QED… and you'll see he discovered something interesting!

    While field theorists typically guess that the sum of all nth-order diagrams grows like

    n^n (alpha/pi)^n

    with the whopping nn term coming from the combinatorial explosion in the number of diagrams, he found empirically that there were lots of cancellations, leaving a result more on the order of

    n (alpha/pi)^n

    If this were actually true, one could sum all Feynman diagrams in QED and get a finite answer! – contrary to the usual folk wisdom.

12. **Moshe Rozali**
    October 1, 2005

    John,

    I am confused, I thought we already know by the existence of non-perturbative effects (in asymptotically free theories) that perturbation theory cannot converge, regardless of any diagram counting. Maybe there is something special about QED, or maybe one cannot really check explicitly any statements about asymptotic values of n…

13. **Robert**
    October 2, 2005

    I think the world expert regarding counter terms for gravity theories is Anton van de Ven. He worked for several years to show that the two loop divergence for (N=0) gravity is in fact there but was beaten by Goroff and Sagnotti:

    QUANTUM GRAVITY AT TWO LOOPS.
    By Marc H. Goroff (Caltech), Augusto Sagnotti (UC, Berkeley & LBL, Berkeley),. CALT-68-1263, UCB-PTH-85/18, LBL-19512, Apr 1985. 13pp.
    Published in Phys.Lett.B160:81,1985

    and

    TWO LOOP QUANTUM GRAVITY.
    By A.E.M. van de Ven (Hamburg U. & SUNY, Stony Brook),. DESY-91-115, ITP-SB-91-52, Oct 1991. 51pp.
    Published in Nucl.Phys.B378:309-366,1992

    The first paper is not covariant whereas van de Ven uses covariant methods (background field gauge, heat kernels etc). The last twenty years, he has worked on the N=1 version of this, where the divergence is supposed to appear at three loop level. As an intermediate result, he (and his student Jan Peter Börnsen) did a three loop YM calculation.

Anton supevised my master thesis (Diplomarbeit) which was about some minor property of heat kernels in superspace. I should not forget to mention that he now lives in Utrecht and has a teaching position at some high school type institution.

Maybe there is something special about QED, or maybe one cannot really check explicitly any statements about asymptotic values of n…

Yes, it's confusing – as Cvitanovic himself admits, his observation is "heretical". His calculations only apply to QED, not asymptotically free theories. But even here, an old argument by Dyson suggests that the power series in the coupling constant can't really converge: if it did, there should be a sensible version of electrodynamics for particles of small imaginary charge, which would *attract* each other… and Dyson argues that this is implausible.

Maybe someday someone will compute the magnetic moment of the electron in QED up to a really huge order in the fine structure constant, and we'll see if Cvitanovic's observations hold water.

Or, maybe someday people will discover some math that sheds more light on these issues.

15. **Arun**
October 3, 2005

Why can't the QED perturbation series sum to something that has a branch cut going from zero to negative infinity?

16. **Moshe Rozali**
October 4, 2005

Arun,

Such function is not analytic at zero, in other words does not have a convergent power series expansion in small coupling.

Assorted Links

Some assorted things I've run across recently that may be of interest:

Talks from the annual meeting of the SLAC Users Organization.

A dialogue between Barry Mazur and Peter Pesic about imagination and mathematics.

An Op-Ed piece in today's New York Times by my colleague Brian Greene called That Famous Equation and You.

Some sensible comments by John Baez about string theory.

A survey of the state of string field theory by Leonardo Rastelli.

A "description of some important issues in supersymmetry and string phenomenology" entitled Twenty-five Questions for String Theorists. The authors think these questions may have answers that will help connect string theory and phenomenology, although this seems to me unlikely. Serkan Cabi also has some comments on this paper.

An article about Feynman by Freeman Dyson in the latest New York Review of Books.

A talk about theoretical physics in the Netherlands.

Update: One more, a report by Paul Cook on an interesting talk by Roman Jackiw.

   John Baez wrote (from the URL provided)

   > The saddest the LHC could find is a complete
   > confirmation of the Standard Model, Higgs particle and all. Then we're
   > back to pondering these puzzles without benefit of extra clues.

   Could the absence of extra clues be a clue? The good thing would be that one doesn't have to wait for the LHC to start working on that. 🙂

2. **Wolfgang**
   October 1, 2005

   I have to assume that in the current environment any deviation from the standard model observed at the LHC would be (initially) understood as indication of supersymmetry.
   A good example was the deviations recently observed for g-2 experiments.

3. **Alejandro Rivero**
   October 1, 2005

   After two years in the swamp, my position is that we already have extra clues. Wasting the "single self-advertisment post" rule that Woit gave time ago, here come three examples from my own:

   hep-ph/0405076 (and related preprints) indicates that a "lamb balance" could be hinting us the points where massive particles are.
   hep-ph/0505220 (and Dr. Koide's work cited there) hints that quarks and leptons should be, if not composite, supersymmetric to diquarks and mesons.
   hep-ph/0507144 hints that the above is related to the properties of the Z0 particle. Note also that the decay of Z0 has properties usually derived from GUT theories

   If LHC comes with confirmation of standard QFT (eben with non-minimal higgs), I'd hopw theorist to start looking seriously for missing extra clues. Also, at these times the LEP colaboration files should already be open in the field for everyone to explore, should them?

4. **John Baez**
   October 1, 2005

   Wolfgang writes:

   > I have to assume that in the current environment any deviation from the standard model observed at the LHC would be (initially) understood as indication of supersymmetry.

   Yes, I worry about that too, but I believe (and hope) that the experimentalists are more careful about these things than the superstringers.

   I recently participated in a PhD oral exam of a physics student who is building detectors for the LHC. He spoke about signatures of nonminimal Higgs bosons. One of the physicists on the committee noted that there are ways to tell the difference between various kinds of nonminimal Higgs bosons and the specific sort which appears in the MSSM (the minimal supersymmetric extension of the Standard Model). So, while superstringers will initially proclaim any hint of a nonminimal Higgs as evidence for the MSSM and "therefore" as evidence for string theory, experimentalists are less likely to jump on this bandwagon without good evidence.

   The student also claimed that among the 105 (!) adjustable parameters in the MSSM, only a couple affect the behavior of the Higgs. So, it may not be quite as much of a morass as I'd thought. I'm still a bit concerned, though.

   You probably know the old saying:

   With 7 parameters you can fit an elephant.

I had worried that with a 105 adjustable parameters, even the LHC short-circuiting and exploding could be explained by the MSSM.

People interested in this issue may enjoy reading about a computer program called Fittino that's supposed to do a best fit of 24 MSSM parameters based on LHC data.

5. **Aaron Bergman**
October 1, 2005

There are not 105 adjustable parameters in the MSSM. There are ~100 (109 is the number that comes to mind, but whatever) adjustable parameters in the soft susy breaking lagrangian. One expects many relations amongst them from however susy ends up being broken.

6. **woit**
October 2, 2005

But until someone figures out what the susy breaking mechanism is, John is right that there are at least around 100 adjustable parameters. The idea that SUSY exists in the real world and that SUSY is broken by some physics that can be parametrized by a small number of parameters looks more and more like wishful thinking. People have been trying to do this for more than 25 years, and there still is no theoretically convincing model for supersymmetry breaking, or even a shred of experimental evidence.

7. **Aaron Bergman**
October 2, 2005

I'm curious about "more and more" there? SUSY itself has some trouble with the Higgs mass, but SUSY breaking looks just as ugly as it always has. I don't see any change there.

Regardless, the weak susy breaking lagrangian is a phenomenological lagrangian. There are plenty of real problems with susy, but the number of parameters there isn't one of them.

8. **woit**
October 2, 2005

By "more and more" I mean that, besides the increasing amounts of fine-tuning needed, as people have learned more and more about supersymmetry breaking it's become more and more clear what a gory business it is. 25 years ago one could have thought that this was just because there hadn't been enough work on the subject, so people hadn't had time to discover a simple way to break supersymmetry that would lead to some predictions. As time goes on, it get more and more clear such a thing probably doesn't exist.

9. **John Baez**
October 2, 2005

Aaron Bergman writes:

> There are not 105 adjustable parameters in the MSSM. There are ~100 (109 is the number that comes to mind, but whatever) adjustable parameters in the soft susy breaking lagrangian. One expects many relations amongst them from however susy ends up being broken.

Maybe so (or maybe not). But, I was talking about experimentalists with the the practical chore of looking for hints of supersymmetry in the LHC data. Unless someone figures out some relations before data analysis begins (optimistically around 2008), these folks have about 100 adjustable parameters to fiddle with. And they're busy trying to figure out how.

I'm no expert on this stuff. I got the figure of "105" from various including the "Fittino" program I mentioned – check 'em out! This figure apparently excludes the roughly two dozen parameters already built into the Standard Model.

10. **Alejandro Rivero**
October 3, 2005

One of my interests last year has been to try a measure of information content beyond "free parameters". Of course I haven't got any succes. The only reasearch I am aware of comes from a bayesian statistics, I.J.Good. The point is that the act of selecting a theory, or a method of symmetry breaking, or a special set of islands, can also be considered as information you input in, and it should be counter between the parameters if there are in the town other theories (or symmetry breaking patterns, or sets of islans) equally sound.

11. **Arun**
October 3, 2005

Hmmm:
http://arxiv.org/abs/hep-ph/0412012

> It is impossible to determine all 105 possible parameters of L_MSSM simultaneously. Therefore, assumptions on the structure of L_MSSM are made. All complex phases are set to 0, no mixing between generations is assumed and the mixing within the first two generations is set to 0. Thus the number of free parameters is reduced to 24 (MSSM-24).

24 doesn't seem so bad.

Mucking About in the Swampland

October 1, 2005
Categories: Swampland

A little while ago I wrote about the recent Vafa paper on [The String Landscape and the Swampland](), as well as about postings on the subject by [Lubos Motl]() and [Jacques Distler](). Lubos's contribution to the subject was introducing the new terminology of "s**tland" and "f**kland". Jacques's was to claim that you can't get anything you want out of string theory, his main example being the supposed impossibility of getting one or two-generation models. This didn't sound right to me, but I'm no expert on the subject. Well, it turns out Jacques had no idea what he was talking about, which Volker Braun [pointed out to him in a comment]().

Given the high quality of the comments by Lubos and Jacques, I was surprised to see that if you look at the [trackback page for the Vafa paper](), you'll note that [trackbacks]() to their postings are there, but not to mine, which evidently has been censored. Not all my trackbacks have been censored, but it appears that, as far as papers about the Landscape and the Swampland are concerned, the arXiv policy is that trackbacks to postings about the subject that are ignorant or scatological will be allowed, but not ones critical of the whole idea.

Update: I've heard from someone associated with the arXiv that it's not their intention to allow trackbacks to my postings to be censored and that part of the problem has been both difficulties they've been having with new software and with deciding how to handle moderation of trackbacks. A trackback to my posting on the Vafa paper is now there. Jacques Distler has [updated his posting]() to include an explanation of Volker Braun's proposed construction of a one-generation model.

Comments

7. **Luboš Motl**
   October 1, 2005

   Dear Peter,

   as some readers have pointed out, I am not the first one who wrote about Scotland and the Falkland Islands.

   It would be interesting if you constructed a one-generation or two-generation model. I don't claim that no one will be able to do it, but I am pretty sure that *you* won't be able to do it. 😉

   Incidentally, Cumrun is saying so incredibly nice things about you. Too bad that you can't reply in a similar fashion. And Cumrun deserves it so much!

   All the best
   Lubos

8. **woit**
   October 1, 2005

Hi Lubos,

Sorry for misinterpreting your island terminology….

I've had the highest respect for Cumrun's intellect since we were both graduate students, and also for his many achievements since then. It's precisely because he is such a talented physicist and mathematical physicist that I find this swampland business upsetting. Seeing fools doing this kind of thing wouldn't be surprising or worth much comment, but seeing the best people in the field do it is shocking and depressing.

I think physics has suffered immensely during the last few years as people like Cumrun, the best theorists in the world, have devoted their impressive talents and energies to trying to somehow make a failed idea work, instead of giving up on it and trying to come up with something new. I'm not happy to be spending my time criticizing what Cumrun and others are doing, but very much wish things were otherwise.

So, I think you're right I should try and balance my criticisms and say some of the nice things about people that I think. The above applies not just to Cumrun, but somewhat to you too Lubos (although renormalized a bit…)

Peter

9. **Luboš Motl**
October 1, 2005

Dear Peter,

thanks for having said nice things about Cumrun. It was the easier part of the goal of my comment, of course.

If you think that this kind of research – and probably not just this one – is not useful, you may imagine that such a criticism will only feel material – as opposed to hot air – once you offer some new vision that may have a chance to be more useful.

Sorry to say, but to worship the divine power of the Dirac operator for 24 hours a day is not yet the right solution.

All the best
Luboš

10. **D R Lunsford**
October 1, 2005

Lubos, I love the way you tell everyone what they can and can't do, when we don't have one original line from you yet. One of these days you'll have to stop living off your boyish charm and have an idea.

-drl

11. **Quantum_Ranger**
October 2, 2005

After reading the Vafa paper, one can only conclude that the Swampland is actually more like Quicksand! and the island made out of Quicksand rather than any stable material.

Any theorist venturing forth had better make sure they have all the equipment needed to survive?

Clampons for attaching some pretty heavy/lightweight Strings, a self-preserving life jacket, patented of course, and made from "bubble-wrap" as opposed to B-O-N.

Oh yes, and no theorist should venture forth unless they have the latest up to the minute pair of "Anti-Anthropic Gravity boots", to get out of the quicksand, they are going to have to do a lot of Anthropic Walking..which is really a transform of 'Talking' , as opposed to any physical reality act of actually "walking".

Talk is cheap, it seems that many stringtheorists are having "closing-down-sale"s !

12. **Thomas Larsson**
October 2, 2005

One claim in physics/0102051, namely that string theory has been spectacularly successful on public relations, does not seem to be true anymore. The anthropic landscape, the swampland and Lubos Motl can hardly be viewed as very successful inventions from a PR point of view.

Words matter. When Vafa and Motl use words like swampland, s**tland and f**kland, they are, consciously or not, sending a message both to budding young theorists and to future grant committees.

13. **woit**
October 2, 2005

Hi Thomas,

Yes, I think over the last year or two string theory is finally starting to have problems on the public relations front.

There are two things that strike me as bizarre about the Vafa paper. One is the whole idea and that he is encouraging others to work on it. But the second is the name he chose. If one wanted to promote a piece of one's own work and get others to take it seriously, why choose the "swampland" terminology? This whole subject just gets more and more weird all the time.

14. **Haelfix**
October 2, 2005

Peter, I don't see anything wrong perse with what Cumrun is doing. He's looking for defacto features of the landscape that are theoretically universal and hence presumably falsifiable at some point down the road. He is no advocate for anthropic principles etc

This seems to me to be the *right* direction to take, rather than studying statistics on what generic feature is more *likely*.

I am also of the mind that you can't just get anything in the world out of the landscape, in fact im not even convinced the 'real world' is sitting in there either, at least with the current toy models. No one has shown that, or picked out a minimal standard model. All generic models tend to have exotics or as yet to be seen experimental phenomenological points, about the only thing people can do is push those to arbitrarily high energies in a somewhat adhoc manner.

15. **woit**
October 2, 2005

Haelfix,

I suppose one can argue that the swampland stuff is better than the anthropic nonsense, but that's not saying much. I'm still not seeing any plausible hope of making string theory falsiiable by the kind of thing Vafa is doing. The kind of constraints he's looking at are so far from the standard model that I don't see any relevance to the real world. If he has an idea about how to show that string theory can't ever reproduce the standard model, I'd of course think that was well worth pursuing.

The other thing that strikes me about all this is that Vafa and people who think this is a great idea like Distler are specialists in the more formal aspects of string theory. They don't have much experience with the wide range of constructions that "string phenomenologists" have come up with. My suspicion is that as they try and come up with conjectured "universal" consequences of string theory, they'll just find that these are all violated by some sufficiently clever and complex string theory construction. This has already happened to Distler. People seem to have an endless optimism that the current string theory framework has some rigidity to it, despite ever increasing evidence to the contrary.

16. **J.F. Moore**
October 2, 2005

It is a standard strategy to use a perjorative on oneself, to take ownership of that term and devalue it for the opposition.

It does seem strange that they would not be concerned about appearances of being closed to thoughtful criticism, at the least.

17. **Tony Smith**
October 2, 2005

Haelfix said "… you can't just get anything in the world out of the landscape, in fact im not even convinced the 'real world' is sitting in there either, at least with the current toy models. No one has shown that, or picked out a minimal standard model. …".

There does exist a string theory model that has the minimal standard model.
It can be found on the CERN preprint server at CERN-CDS number EXT-2004-031.

Peter says "… Vafa and people … like Distler are specialists in the more formal aspects of string theory. They don't have much experience with the wide range of constructions that "string phenomenologists?? have come up with. My suspicion is that as they try and come up with conjectured "universal?? consequences of string theory, they'll just find that these are all violated by some sufficiently clever and complex string theory construction. …".

The model at CERN-CDS number EXT-2004-031 is probably complicated enough that it fits Peter's description of something beyond what sting formalists such as Vafa are considering.
That model was constructed based on usenet discussions in 2004 on sci.physics.research and sci.physics.strings, beginning with an spr thread "photons from strings?" started by John Baez. Participants in the subsequent discussions included Lubos Motl, Urs Schreiber, Aaron Bergman, and others.
To build the model, I started with a suggestion by Urs Schreiber to consider a 25-brane in 26-dim bosonic string theory as giving the U(1) photon gauge group, and I proceeded by modifying it by several steps until it gave the standard model.

As to evaluation of that model by string formalists, Lubos Motl attacked it by saying "It is not true" that String theory is fundamentally 26-dimensional because, according to Lubos: "String theory" is a shorthand for "superstring theory" which is at most 10-dimensional – and its extension "M-theory" is 11-dimensional. …".

On the other hand, another contributor to the discussion said "A Matrix theory such as Tony Smith's would then be a nice formulation of (bosonic) M-theory (as Susskind refers to the 27-dimensional theory), from where we work down dimensionally … to recover fermions. …".

Why do the Vafa-type string formalists fail to consider in detail the relevant string phenomenology work?

What would be so bad about a non-super string model being successful?

———-

Unfortunately, while composing the above message, I discovered some disturbing facts.
Both of the preceding remarks, as well as the bulk of the discussion about the model that is now at CERN-CDS number EXT-2004-031, occurred in May 2004 on a sci.physics.strings thread entitled "Re: Speculation: E6 and 26-dim. string theory",
and all but 2 messages in that thread seem to have been removed from sci.physics.strings (there had been at least 6 messages in the thread),
as have
all but 1 message in a related thread "Re: Calculation of Standard Model parameters" (there had been at least 12 messages in the thread).

I am particularly unhappy with the fact that of the 2 messages remaining in the thread "Re: Speculation: E6 and 26-dim. string theory", one (dated 18 July 2004) is from Lubos Motl (an sps moderator) who says in part: "… This is my favorite speculation. I want to start with a theory in 26 dimensions that already has a E8 gauge group … A superstring spacetime would be a sort of codimension-16 brane in the bosonic string theory. …".
It seems to me that Lubos is trying to use the structure that I described with respect to my E6 model for his E8 model, but the messages describing my work have been removed from the relevant sps threads.
Further,
the removals got rid of the sps record of Lubos's rather embarrassing statement that 26-dim bosonic string theory is not a part of string theory.

19. **Quantum_Ranger**
October 3, 2005

There appears to be an increase in the scientific community, of war-cries..rallying-of-troops, and a general dissagrements spilling out into Academic Castles such as Stanford-v-Rest of the World?

In a recent documentary about Susskind v Hawking:
http://www.bbc.co.uk/sn/tvradio/programmes/horizon/hawking_prog_summary.shtml

the programme shed some light on Susskind's affiliation with a "used car salesman" :Werner Erhard.

A little skeptic has written page here: http://skepdic.com/est.html

It is quite amazing that the straglehold of the String Community is precariously teetering upon a total system breakdown, instigated by the proponants themselves? from the BBC documentary above, Susskind spoke of the first early days of "self-hypnosis" seminars he and other "later-to-be stringtheorists", attended.

To quote from Susskind himself talking about the early days before stringtheory:They would put people in a room, keep them there for 16 hrs, not let them go to the bathroom, harrang them harrass, them and as a consequence of this they would emerge completely different people!

A lot of Academic pressure has built up from Stringtheorists, who are insistant upon arguing with "Counter-Information" Anthropic reasonings?

A ventriloquist can only throw his voice so far, thats why there are strings attached to "dummies", and not to the audience of listners.

At Stanford, there are a lot of "Twangs-n-Bangs" being heard as the strings finally snap, and the dummies fall by the way-side?

20. **Bryan**
October 3, 2005

In the current issue of New Scientist, Susskind is quoted (on the issue of the reality of the Casimir force) as suggesting he wants to outlaw all use of the word 'real' by physicists.

21. **D R Lunsford**
October 3, 2005

There is just no shame any more. Shame is the critical missing ingredient in our corrupt civilization.

Susskind is a blithering moron, who does physics the EST way. Hey! Don't knock if you haven't tried it!

On the question of arXiv trackback censorship favoring one side of a controversial issue, please have a look at this:

http://www.arxiv.org/tb-display/hep-th/0507235

Concerning Lee Smolin's "The Case for Background Independence", the only two trackbacks are to Distler and Motl blogs. It seems to me that there was discussion elsewhere, to which Smolin may have contributed.

Perhaps more to the point, look at this:
http://www.arxiv.org/abs/hep-th/0501114
http://www.arxiv.org/tb-display/hep-th/0501114

There was discussion of the Nicolai et al paper "Loop quantum gravity: an outside view" here at N.E.W., to which Smolin contributed a letter replying to Nicolai. A trackback could be valuable and shed additional light. But the only trackback link at the Nicolai abstract is to Distler's own blog.

24. **D R Lunsford**
October 3, 2005

JE, what, me whine? Fulminatio ergo sum!

This retinue of loser-exquisites gets on my last engram – sorry.

-drl

25. **Who**
October 3, 2005

DRL and JE, about whining and fulmination. do you consider my concern over possibly biased screening of trackbacks on the arxiv to be exaggerated or misplaced? Trackbacks are new (at least to me) and I don't know if they matter much.

Nicolai's paper was the first of two topics in Peter's blog #145, in January.
http://www.math.columbia.edu/~woit/wordpress/?p=145
There was a letter from Smolin replying to some points in Nicolai's paper. I don't know if Peter would want to put in a trackback to that. My question is this: if he sent one in would it be erased by the censor?

The only trackback now is to an entry in Distler's blog which doesnt seem to say much of anything—it is some 5 lines long and essentially just says "LQG is no good and I approve of this criticism of it."

By contrast, Smolin's letter replies to specific points in the paper and goes into considerable detail.

26. **Wolfgang**
October 3, 2005

Dear Dr. Who,

it seems to me that Lee Smolin and friends need to get their own blogs and into this trackback business.

27. **D R Lunsford**
October 3, 2005

Who, I don't think either Peter or Tony would chase chimeras. And remember, just because I'm paranoid doesn't mean I'm wrong!

October 3, 2005

Dear Wolfgang,
you write:
it seems to me that Lee Smolin and friends need to get their own blogs and into this trackback business.

How would that address or remedy, or address the issue of, biased censorship of the arxiv.org trackbacks?

Or would it?

29. **Wolfgang**
October 3, 2005

> How would that address or remedy, or address the issue of, biased censorship of the arxiv.org trackbacks?

If there really is censorship it would become obvious. You need more than 1 or 2 incidents, which could be just mistakes.

30. **Who**
October 3, 2005

>If there really is censorship it would become obvious. You need more than 1 or 2 incidents, which could be just mistakes.

I see what you mean. thanks for clarifying Wolfgang.

DRL you say:
>I don't think either Peter or Tony would chase chimeras. And remember, just because I'm paranoid doesn't mean I'm wrong!

I dont think they would chase chimeras either. If Peter chases something it is probably a rat and not a chimera. thanks for your reply, and I will try always to remember that.

31. **Volker Braun**
October 4, 2005

I do not agree with what you make out of my comment. When I am not sugarcoating my questions then this does not mean any disrespect. I know Jaques Distler since i took his string theory class many years ago, and I know that you can ask him scientific questions and expect an honest answer.

Now we made serious progress this year to find compactifications with three generations, and no anti-generations. It is still true that nobody succeeded there in the previous decades. Moreover, we never published that we might also be able to find one and two generation models, so it is hardly fair to blame Jaques for not knowing about them.

If anything, this shows that there is progress string theory every year. Even though you probably will not agree 🙂

32. **woit**
October 4, 2005

Hi Volker,

I'm certainly no expert on this kind of question and didn't realize you were referring to unpublished work.

Still, I'm in no particular mood to apologize for pointing out the fact that Jacques's posting on this subject was misinformed, for several reasons:

1. While he may respond to certain scientific questions honestly, his behavior towards me in the past has repeatedly been disgraceful and dishonest. He has on several occasions taken things I have written, changing them around and then using these fraudulent constructions to attack me as professionally incompetent. When presented with evidence that this is what he has done, he has not once apologized for his behavior. While he may be a technically competent physicist, he's a complete ideologue when it comes to string theory, to the extent of being willing to repeatedly engage in nasty and dishonest behavior.

2. I'm not sure why trackbacks to my postings related to string theory are not appearing at the arXiv. The system is completely untransparent and the person I tried to contact there hasn't responded to my e-mail. As far as I can tell though, it seems likely that Jacques is the one responsible for moderating these trackbacks. If so, it is rather rich that he is censoring links to my accurate but critical postings, while allowing them to his own inaccurate posting.

3. I think this story gives strong evidence for part of my own reaction to the Vafa paper, which was that claims that "one can't get low energy effective field theories with property X out of string theory" are likely to just indicate that either the person saying this isn't very well informed, or no one has tried all that hard to do this.

That every year there is new progress towards showing that string theory is inherently vacuous and one can get anything one wants out of it is something on which I guess we can agree…

Best wishes,

Peter

    Your trackback seems to have appeared.

Pauli and Not Even Wrong

October 1, 2005
Categories: Uncategorized

When I first started thinking about using "Not Even Wrong" as the title of a book, I did some research to try and find out where the supposed Pauli quote came from. No one seemed to have any information about this, other than the attribution to Pauli, and various different stories existed about the context in which he had used the phrase. I started to worry that these stories, like many of the best ones about Pauli, might be apocryphal, so I contacted a few physicists who had some connection to Pauli to ask them about this. Prof. Karl von Meyenn, the editor of Pauli's correspondence, wrote back to tell me that the phrase doesn't occur in his correspondence. He pointed me to a biographical notice about Pauli written soon after his death by Rudolf Peierls as the best source for the story of Pauli using the phrase.

Peierls writes

No account of Pauli and his attitude to people would be complete without mention of his critical remarks, for which he was known and sometimes feared throughout the world of physics…

No doubt many of the stories of this kind circulated about him are apocryphal, but the examples below come from reliable sources or from conversations at which the writer was present…

Quite recently, a friend showed him the paper of a young physicist which he suspected was not of great value but on which he wanted Pauli's views. Pauli remarked sadly 'It is not even wrong.'

The Peierls article is in

Biographical Memoirs of Fellows of the Royal Society, Vol. 5 (Feb. 1960), 174-192.

It is on-line via JSTOR.

Just recently, Oliver Burkeman wrote a short piece for The Guardian about the Pauli phrase and its recent uses. I talked to him on the phone about this and his article contains some accurate quotes from me, together with a link to this weblog.

   Apparently Pauli is still into Jung's synchronicity.

Nobel Prize Announced

October 4, 2005
Categories: Uncategorized

Well, it looks like I was right to not try and guess this year's Nobel Prize, since it has been awarded for work in an area of physics I know nothing about. None of the commenters here managed to guess correctly either. The prize goes to Glauber, Hall and Hänsch for work in the field of optics.

Roy Glauber is 80 years old now, and taught the first quantum field theory course I ever took. At the time I was an undergraduate at Harvard and the course was way over my head. All I remember from it now is that it involved a lot of writing down and manipulating long formulas involving mode expansions and annihilation and creation operators. I did end up with some facility in doing this, but didn't much understand what it all meant. Buried somewhere in my office should be notes for that course, perhaps I'll try and dig them up and take a look at them, since I suspect I can probably now appreciate much better what Glauber was trying to teach than I could way back then.

Congratulations to Glauber, Hall and Hänsch!

Update: Hongbao Zhang didn't guess the prize winner's names, but he did correctly guess that it would go to physicists in the field of quantum optics. Congratulations!

   October 4, 2005

   Hi everyone,

   Although I am disappointed that Astrophysics and in paticular Dark Matter did not win, I have been educated about a little known field called Quantum Optics.

   Personally, I am now trying to see how QOptics have effected the other fields of physics!

   Congratulations

   Glauber Hall and Hansch.

7. **Eric Baum**
   October 4, 2005

   Hi Peter,
   I took Glauber's course, with similar comments to you. (Maybe the year before? Or were we in the same course?) But aside from the annihilation and creation op calcs that went on for months which I was struggling to follow, what I remember clearest was Ginsparg's reaction. He was a year or two older, and may well have completely understood the stuff (he definitely aced the tests) and rather pointedly read the newspaper in class every day by way of hinting to the old prof that he should move on to something more current ;^)

8. **woit**
   October 4, 2005

   Hi Eric,

   Probably the same course. You were a year ahead of me, but I was taking this course at a point I was ridiculously unprepared for it. That's what happens when you have an undergraduate advisor who will sign anything you put in front of him.

I also remember Ginsparg and his newspaper. But I was never sure whether or not he did that in all his classes.

9. **Eric Baum**
October 4, 2005

I was helaciously unprepared for it too. I think I must have been a soph, because I know Ginsparg was a year ahead of me, and we took Glashow's group reps together the next year (which I also was not sufficiently prepared for and struggled in.) You couldn't have taken Glauber as a frosh, could you?

10. **woit**
October 4, 2005

No, I was a sophomore, I think you must have been a junior. It was the academic year 1976-77.

I just found my old notes together with problem sets, exams, etc. The things Glauber did in the course that weren't part of a normal course these days included some many-body physics, as well as more about the physics of electromagnetic fields, coherent states, resonances, etc. No path integrals, all done by canonical quantization of oscillators.

Looking at my problems sets and exams, I'm surprised to see that I didn't do that badly, considering how little I knew at the time.

11. **D R Lunsford**
October 4, 2005

Peter – funny 🙂

I had an odd thought just now – I think equations have literally "lost their value". That is, when people write the kind of things you see on the archive, things that are neither coherent nor interesting, and get away with it, and get promoted because if it, there has to be a deep reason. I think it started with the "coordinate-free" mania of some years ago – equations in a sense "lost their value" and one had (as in chess) both to keep in mind the trail leading from the symbol to the world, as well as the possible uses of that symbol, which, having been disconnected from numbers, is at a loss to express itself clearly. This is really why physics is (supposed to be) different from math, that is, the equations are supposed to imply a value of some sort – really "an evaluation", while the equations in most of these papers are really just short-hand expressions for a hand-waving argument of arbitrary dubiousness – one doesn't write equations and explain them, one explains one's viewpoint and then draws equations to embody it. (This also explains why these people are so loud – they're working!) The equations have no more connection, the one to the other, than does the torrent of verbiage that attempts to express the unreal – in real physics, one tends to be quiet and push on from point to point (see Einstein and Dirac).

That is why I think string theory is dead, and Nobel Prizes keep going to those people with evaluations in their papers.

12. **MathPhys**
October 4, 2005

Ginsparg was a postdoc at the time. He was many years older than any of you. He was a PhD student of Wilson at Cornell.

13. **woit**
October 4, 2005

Just checked Ginsparg's web-site. He got his undergraduate degree from Harvard in 1977, so Eric is right and he was one year ahead of him (Eric graduated in 78, I was in 79). Ginsparg then went off to graduate school at Cornell, came back to Harvard as Junior Fellow, later faculty member 1981-90.

14. **ksh95**
October 4, 2005

Peter Woit Said:
Looking at my problems sets and exams, I'm surprised to see that I didn't do that badly, considering how little I knew at the time

That always scared the hell out of me. Classes I was unprepared for, where I knew I didn't understand the material on a deep level…but somehow managed to get an A.

I guess that says something about a physicist's (at least this one's) abilty to mass produce problem solutions, regardless of deep understanding.

15. **Luboš Motl**
October 4, 2005

"..Nobel Prize, since it has been awarded for work in an area of physics I know nothing about…"

Wow, cool – it seemed finally like a Nobel prize for string theory. 🙂

16. **woit**
October 4, 2005

Hi Lubos,

Any predictions about something you might really know about, the IgNobels to be awarded Thursday evening at Sanders theater?

I'm predicting that string theory will be awarded an IgNobel before it gets a Nobel.

17. **JC**
October 4, 2005

Peter,

Who was your undergraduate advisor, who was willing to "sign anything put in front of him"?

18. **woit**
October 4, 2005

Hi JC,

My undergraduate advisor was Glashow, and he was the one who happily told me this was his policy.

19. **JC**
October 4, 2005

Peter,

I remember when I was an undergrad, my advisor was a bit of a "hard ass" where he wouldn't let anybody take courses for credit for which they did not have the prerequisites. Though I ended up sitting in on some graduate quantum field theory course (ie. not taking it for credit). I studied some basic field theory stuff on my own previously, so I wasn't completely unprepared. Though in the end I got lost after awhile. (It was a course which covered canonical quantization of scalar, fermion, and Maxwell fields, along with basic tree level computations. The next term covered Yang-Mills and renormalization stuff, but I didn't even bother sitting in on it after my experience of getting lost half way through the first term). Then again at the time, the courses I was actually taking for credit took priority over the field theory course. I suppose if I didn't go to as many parties in those days, I could have worked harder at understanding the field theory stuff. At the time it was easy to let things "slide", when one wasn't taking it officially for credits.

Besides quantum field theory, what other "advanced" courses did you take in undergrad?

20. **woit**
October 5, 2005

Actually I arrived at college with "sophomore standing" since I had passed a lot of advanced placement tests. I ended up staying four years and getting both a B.A. and an M.A. Beside's Glauber's field theory class, some of the other graduate classes I remember were a course on gauge theory from Weinberg, on the standard model from Alvaro de Rujula, and on particle physics from Carlo Rubbia. I also sat in on Coleman's field theory course one year and courses on groups and representations from Howard Georgi and on constructive field theory from Arthur Jaffe. All of these were great experiences and I learned an incredible amount. The standard model was very new in those days and there was a lot of excitement around Harvard as new confirmations of the model kept coming in.

21. **Chris Oakley**
October 5, 2005

Peter,

Your advisors/lecturers seem to be a "who's who" of particle physics. It is a pity you missed out on being taught by Feynman and Gell Mann. Or did you?

22. **Nigel**
October 5, 2005

He certainly has Feynman's views about ST. 😉

23. **Nigel**
October 5, 2005

My information for Feynman being critical of strings is the book Davies & Brown, 'Superstrings' 1988. I haven't read it since 1988 so cannot quote it, but seeing that Feynman died soon after, I thought it accurately reflected his view that ST is not even wrong.

However, searching the internet for Feynman and ST brings up claims that Gell-Man indoctrinated Feynman with it. However, I distinctly remember the interview of Feynman in 'Superstrings' where he point out it is useless.

24. **Tony Smith**
October 5, 2005

NIgel said: "… My information for Feynman being critical of strings is the book Davies & Brown, 'Superstrings' 1988. I haven't read it since 1988 so cannot quote it …".

Here are some excerpts from Feynman's statements in that book, at pages 194-195:
"… I do feel strongly that this is nonsense! … I think all this superstring stuff is crazy and is in the wrong direction. … I don't like it that they're not calculating anything. … why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none! … ".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

25. **Nigel**
October 5, 2005

Thank you very much, Tony! I thought so…

26. **Hongbao Zhang**
October 5, 2005

Thanks Woit for your congratulations.:)
Here are my naive reasons:
On one hand, as is well know, Einstein published his famous papers on photon and special relativity in 1905. When we treat the quantum optics, we must put it in the framework of special relativity, unlike the eletron, we have a FW approximation, which is essentially taken seriously in condensed matter physics. I think this year's Nobel Prize should give quantum optics in memory of our great Einstein. Cerntainly, it is the best way!(Einstein's own Nobel prize seemed to be late for his contribibutions to the fundamental phsics)
On the other hand, quantum optics deserves this Nobel prize in its own right. quantum optics not only plays a special role in demonstrating the striking properties of quantum mechanics, but also initiatiates many new technologies and possess wind applications.

27. **goeppert**
October 5, 2005

I think string theory was still in its earliest state of inception, which makes feynman's conclusion about ST rather premature . It should be taken with a grain of salt.

28. **woit**
October 5, 2005

In the mid-80s when Feynman was criticizing string theory it still seemed possible that the theory had only a small number of vacuum states, one of which would give the standard model. Even so, Feynman was skeptical that this would work, and I think the idea that the Landscape and other evidence of string theory's failure over the last twenty years would change his mind and make him favor the theory is kind of laughable.

29. **Tony Smith**
October 5, 2005

goeppert said "I think string theory was still in its earliest state of inception, which makes feynman's conclusion about ST rather premature . It should be taken with a grain of salt. ".

The date of Feynman's interview statement in the Brown and Davies book:
"… I do feel strongly that this is nonsense! … I think all this superstring stuff is crazy and is in the wrong direction. …"
was probably 1987, which seems to me to be long enough after Schwarz's talk at the 1984 APS DPF Santa Fe meeting for Feynman (who was at CalTech with Schwarz during that time) to have formed a NON-premature conclusion about superstring theory.

Here are excerpts from the Brown and Davies book that support a 1987 date for the Feynman interview: "… In 1987 we decided to review the state of superstring research by making a documentary on the subject of BBC Radio 3. … The programme … was broadcast in early 1988 … we felt that it would be worthwhile publishing the interviews in a fuller and more permanent form. …".

As to whether or not Feynman changed his mind at a later date, bear in mind that, according to the Brown and Davies book, Feynman "…died in early 1988.".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

30. **scott**
October 5, 2005

Just to corroborate Feynman's distaste for string theory. In the book Feynman's rainbow, by some dude who postdoced at tech, it was mentioned that string theory upset him so much that his doctor encouraged him not to discuss it. According to the to rumor, according to this book, schwartz was kept on(before the string fad caught on) as faculty because of Gell-Mann's influence and that he did this primarily to agravate Feynman. Also it seems his criticism was mostly about string theory's disconnect from experiment something which hasn't changed at all.

31. **Renormalized**
October 5, 2005

" I do feel strongly that this is nonsense! … I think all this superstring stuff is crazy and is in the wrong direction. … I don't like it that they're not calculating anything. … why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none!"

What a bomb up Motl's butt! Thats the price you pay for following the crowd. String physics should be reclassified as Speculative Physical Interpretation Translation. SPIT

32. **JC**
October 5, 2005

Besides Feynman, who else was anti-string in those days? I vaguely remember Glashow being somewhat vocal against string theory in the 1980's. Don't know about today if he's still anti-string.

33. **woit**
October 5, 2005

Glashow is as opposed to string theory as ever. He and Feynman are the only very well-known theorists I can think of who were very vocally anti-string theory in the mid-eighties. Many others were privately skeptical, but not about to complain publicly.

34. **D R Lunsford**
October 5, 2005

Finkelstein was of the opinion that it was "horseshit" in the mid 80s. (He was right.)

-drl

35. **Tony Smith**
October 5, 2005

Peter, you knew Weinberg through "… a course on gauge theory from Weinberg …" as a Harvard undergraduate in the 1970s, and you got your Ph.D. under Curtis Callan in 1984.

By any chance, did you attend the 1984 APS DPF Santa Fe meeting (October-November 1984) ? Curtis Callan gave a talk on "Anomalies and Fermion Zero Modes on Axion Strings", but my question is whether you have any recollection about how that meeting affected the course of superstring theory.

IIRC, at the meeting there was a lot of uncertainty about whether or not superstring theory should be accepted or not. Schwarz (with his colleague Hamidi) was to give a superstring talk, and Weinberg was at the meeting. Weinberg's influence then was HUGE, and almost everybody was wondering (1) would Weinberg attend Schwarz's talk and (2) if he did, would he like the superstring theory or would he just read newspapers*.
Schwarz's talk was in a large room, with front and back doors. Just before the talk, Weinberg was not seated, but just as the talk began Weinberg appeared, standing in the back doorway. At the end of the talk, Weinberg announced that superstring theory would be the approach that he would follow and (almost) everybody there immediately followed suit.

Around 1987, Weinberg also gave an interview that was published in the Brown and Davies book, in which Weinberg confirmed his enthusiasm for superstrings, saying "… string theory … is very beautiful, very promising and it's had qualitative successes so far in making a lot fof things come out right when it wasn't clear how they could ever come out right – things having to do with gravity. …".

Why do you think that Weinberg's enthusiasm had more influence over the late-1980s physics community than the skepticism of Feynman and Glashow?

IIRC, in the 1980s there was some rivalry between Weinberg and Glashow with respect to how much money they might be offered to move from Harvard to Texas (Weinberg) or Texas A&M (Glashow).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

* – IIRC, Weinberg was famous for reading newspapers during lectures by others. Could Ginsparg have picked up that habit from Weinberg?

36. **Peter**
October 5, 2005

Hi Tony,

Don't know where Ginsparg got his reading habits, but, with a few exceptions, the Harvard physics faculty consisted of people not exactly known for being considerate towards others.

There was a rumor that Glashow might go to Texas A and M, getting paid as much as the football coach ($500,000), and more than Weinberg. Supposedly Glashow's friends had a t-shirt made up, saying on one side $500,000, on the other "and worth every penny of it". Glashow and Weinberg were famous for not getting along, with Glashow referring to the Higgs mechanism in the Weinberg-Salam model as "Weinberg's toilet".

I didn't go to the 1984 Santa Fe meeting. That fall I had left Princeton and started a postdoc at Stony Brook. At that time, the person everyone was looking to for leadership was Witten not Weinberg. You just can't overestimate how influential Witten was at the time. He had for several years been producing a stream of amazing work, and the appearance of each of his papers was a huge event. By then he was working full time on string theory and telling everyone else it was the way to go. I'm sure Weinberg was heavily influenced by Witten in his decision to work on string theory. The fact that people like Weinberg fell in line behind Witten certainly added to the momentum behind string theory, but Witten was the driving force. By then I don't think too many people cared what Feynman thought, and Glashow was also no longer that influential. I think most people just saw Feynman as too old, and Glashow as getting old and not capable of learning the sophisticated mathematics needed to do string theory.

37. **Arun**
October 6, 2005

Q – is there a Nobel due for neutrino physics?

38. **MathPhys**
October 6, 2005

If I remember correctly, Green and Schwartz' SO(32) anomaly cancellation superstring paper appeared in August 1984. They wrote it during the summer meeting at Aspen.

Witten's first paper on superstrings, which starts with "In a stunning development", appeared about 2 weeks later, if not less. So that must have been September, at the latest.

The 3rd paper on the subject was by Green, Schwartz and West, and that was a couple of weeks after Witten's. It was really only after Witten's paper that everyone dropped whatever they were doing and jumped on the superstring bandwagon.

It should be easy to check these dates. All 3 papers appeared in Phys Lett B.

39. **John Baez**

These guys taught at Caltech, not at Harvard like the guys Peter mentioned.

Tony Smith writes:

> Why do you think that Weinberg's enthusiasm had more influence over the late-1980s physics community than the skepticism of Feynman and Glashow?

My guess is that particle physics had to go *somewhere*, and the people saying where it *shouldn't* go were unable to say where it *should* go.

Despite all the flaws of string theory, it's clearly been an incredibly rich research program, with lots of interesting things for lots of people to do. Feynman and Glashow presented no comparably rich research program.

Most of the really interesting results of string theory have been mathematical in nature: it may never win a Nobel prize, but there have already been at least 3 Fields medals based on work related to string theory (Witten, Borcherds and Kontsevich). So, it's possible that in the long run string theory will be seen as a research program that lured a bunch of very smart physicists into mathematics – not necessarily a bad thing, given the somewhat stagnant state of experimental particle physics.

40. **Chris Oakley**
October 6, 2005

John,

The bad thing is not that String theory lured physicists into mathematics; it is that these people pretended and continue to pretend that what they do is not only physics, but the most important physics anyone was ever doing. This is just dishonest.
It is also damaging, as it blocks those who have their own ideas about QFT but refuse to sign up for quasi-religious mathematical cults.

41. **Tony Smith**
October 6, 2005

John Baez said "… particle physics had to go somewhere, and the people … were unable to say where it should go. … string theory will be seen as … not necessarily a bad thing, given the somewhat stagnant state of experimental particle physics. …".

Chris Oakley said "… String theory … people … pretended and continue to pretend that what they do is not only physics, but the most important physics anyone was ever doing. This is … damaging, as it blocks those who have their own ideas about QFT but refuse to sign up for quasi-religious mathematical cults. …".

In fact, there were (and are) some possibly fruitful lines of work in physics, both experimental and theoretical, that were (and are) suppressed by the string-dominated physics community during the past 20 years. In other words, some of what John Baez considers to be stagnation, I consider to be caused by repression.

I will list a few examples, which I think support the position of Chris Oakley. Although some of them are related to my work, they are just as interesting if you totally disregard my work, so this list is NOT intended as a complaint about consideration (or lack thereof) of my work.

1 – Supergravity was abandoned, on the grounds that it was thought not to be finite at high orders. Ironically, the superstring people have quite recently sought to revive supergravity. If the superstringers had not suppressed supergravity work 20 years ago, maybe we would already know the answers to the supergravity finiteness questions now being raised by superstringers. (See Peter Woit's recent blog entry "Is N=8 Supergravity Finite?".)

2 – With respect to experiment, consider the analysis of experimental data about the T-quark. The book "The Evidence for the Top Quark", by Kent W. Staley (Cambridge 2004) says (here XXX represents the name of someone who afaik has not participated in Peter Woit's blog discussions – you can see who XXX is by reading the book): "… XXX … objected that "[w]ith the Godparents for the top analysis becoming a part of the closed analysis group the principle of independent internal review has been abandoned … XXX … thought … a top signal … was marginal and being railroaded through … XXX also complained that discrepancies appeared in some distributions … XXX … described "a few hints that the simplest hypothesis that the top candidate events are just the t tbar events and SM background may not be entirely correct" …". Perhaps non-consensus analysis of T-quark data might shed light not only of the nature of the T-quark, but also on whether or not the Higgs might be a T – Tbar composite, or closely related to such a composite.

3 – Work attempting to explore the connections between the math/geometric structures of bounded symmetric domains and particle theory has been suppressed, for example by a December 1989 Physics Today Reference Frame article by David Gross that ridiculed the work of Armand Wyler. I am not saying that Wyler found a good physics model, but I am saying that he found coincidences between the fine structure constant and math/geometric structures that should have been seen as good reason to do further work exploring the possible utility of such an approach, and that such exploration should be worthy of funding and support.

4 – SU(5) GUT models were and are totally abandoned, based on statements that proton decay neutrino observations showed a too-long proton lifetime, even though reasonable alternative definitions of background might give a proton lifetime within the range of GUT models. (See for example hep-ex/0008074.)

Of the above 4 examples (NOT an exclusive list, I regret to say), only 1 seems to me to be likely to get significant funding in the near future, and that is only because some superstringers have become hopeful that it might rescue their foundering attempts to connect with experimental results.

Townes Symposium

October 5, 2005
Categories: Uncategorized

The Townes Symposium will be taking place in Berkeley starting tomorrow, and if you've got \$500 burning a hole in your pocket, you might want to help subsidize the Templeton Foundation in its efforts to bring science and religion together. If you want dinner on Saturday that will be another \$300, although you could buy a whole "Laureate Table" for \$10,000, and presumably get to dine with one or more of the 18 Nobel Laureates that Templeton has convinced to attend.

Among those in attendance will be string theorists Raphael Bousso, who will promote the Landscape pseudo-science, David Gross, who won't be promoting the Landscape pseudo-science (I hope), Michio Kaku, who will speak on science fiction, and Leonard Susskind, who will promote the Landscape pseudo-science and his forthcoming book. One physicist that attendees won't get to hear from is Sean Carroll.

At some point during the symposium the new fq(x): Foundational Questions in Physics and Cosmology project will be unveiled. About all I know about this project so far is that it "is a multi-million dollar, multi-year effort to catalyze research and dialogue at the boundaries of physics and cosmology that are related to really big questions" and is based on the idea that "positivistic, deterministic, or materialistic philosophies no longer have secure places" because of modern physics and chaos theory. It will answer questions like "Why existence? What makes meaning?", and its domain name is registered to Max Tegmark.

Update: The fq(x) website has just appeared. On the whole the project seems more sensible and free of religious nonsense than I had feared. It is being run by Tegmark, assisted by astronomer Anthony Aguirre. The advisory board consists of real physicists (Barrow, Rees, Silverstein, Smolin, Wilczek and Zeh), not religion and science people. It looks like the Templeton Foundation has provided $5 million in seed money, to be spent over 4 years, with the idea that after 4 years the project would have attracted funding from elsewhere. They will announce the first competition for grants on December 1. Grants will be awarded based on "a competitive process of expert peer review similar to that employed by national scientific funding agencies, and will target research unlikely to be otherwise funded by conventional sources." They hope to "Expand the purview of scientific inquiry to include scientific disciplines fundamental to a deep understanding of reality, but which are currently largely unsupported by conventional grant sources." I wonder what kind of research they have in mind to fund that isn't getting funded by the current sources of funding, that will be interesting to see.

   It is good to combine string theory with religion in my opinion. The advantage is that heretics can be imprisoned if they publically ridicule an accepted religion.

   (A few centuries ago, they'd be burned at the stake for doing what you are doing! Can't you understand how dangerous you are?)

   One thing a free democracy prevents is ridiculing religion, because a purely belief system can't be defended rationally. People have a right to believe in witchcraft or 10 dimensional creation without a shred of evidence.

   In the Soviet Union, criticism resulted in being sent to a mental hospital. Too bad it collapsed. I say, string critics should be locked away so that everyone else can be brainwashed with claptrap.

   What is at stake is the reality of the world and the future of physics. How can you be so cold and rational, so heartless in dismissing the work of great mainstream men and women, who did their best and continue to do so, despite difficulty.

   Please buck up and start supporting your fellow scientists!

2. **ali**
   October 5, 2005

   It's good to know that in the event that supersymmetry isn't found at CERN and the NSF et al. decide to defund string theory, fq(x) will make sure that string theorists don't starve (or end up on Wall Street).

3. **Nigel**
   October 5, 2005

   "… Michio Kaku, who will speak on science fiction…"

   I'm confused. Do you mean he will be talking UFOs or string theory? Please be more lucid, Peter.

4. **Not a Nobel Laureate**
   October 5, 2005

   "I'm confused. Do you mean he will be talking UFOs or string theory?"

   As both have the same predictive ability to predict physical phenomena, what does it matter he if talks about strings, UFOs or both.

5. **Chris W.**
   October 5, 2005

   A little zinger from **A. Zee**:

   > We could suppose either that the entries in [the neutrino mixing matrix] V represent a bunch of meaningless numbers possibly varying from village to village in the multiverse landscape as advocated by some theorists of great sophistication or that they point to some deeper structure or symmetry as some theorists with a more traditional faith in the power of theoretical physics might dare to hope for. It is natural to imagine that there is a family symmetry [2] linking the three lepton families.

   (See hep-ph/0508278.)

   October 6, 2005

I'm really worried about famous scientists being involved in an entreprise funded by Templeton fundation. Don't they realize that their mere presence will almost certainly end up being used to give credit to stupidity and obscurantism ?
Something else worries me. The subjects fq(x) deal with have a priori nothing to do with religion. The funds by Templeton will contribute to the wrong but often quoted idea that highly conjectural but science-based ideas and religion converge. I'll take the example of the big bang, which is not conjectural anymore but was so in the past. The first opponents of big bang models (Hoyle for instance) did not like the religious flavour of it. Recently the Pope (the last one) said that the big bang was compatible with the religion (and in fact gives credit to it). Well the Pope and Hoyle were both wrong : the big bang has really nothing to do with a divine creation. If one wants to believe it has something to do with it, of course one has the right to do it, but there is zero scientific evidence for it. Moreover, a few century ago one could have been burned on the spot by the religious autorities just to say that the world was more than a few thousand years old… I think this example shows well that science and religion should be kept completely separate, and that scientists who wish to promote a religious point of view should do it on a strictly private basis without giving their scientific aura to an entreprise which has really nothing to do with science.
I should add that I'm really disappointed to see Smolin involved in this.

7. **Steve**
October 6, 2005

You don't have to try to separate religion from science. They are already separate as physics is separate from literature.

Now, I don't think Templeton Foundation is trying to use religious method in seeking scientific facts. I think the Templeton Foundation is doing the converse; They are trying to seek religious truth by scientific methods; And this is more a threat to religious people than to the scientific community because it is as stupid — I didn't say it's wrong, but it's not smart — as trying to prove that my mom loves me by quantifiable numbers and experiment. There are things in this world when seeking truth or facts where scientific method is not the best way; for example, mathematics.

But of course, when seeking the physical law of nature, there is nothing like the scientific method. So if you ask me why I believe in God, as a scientific person I cannot tell you anything; But as a human being, I might be able to convince you.

8. **Fabien Besnard**
October 6, 2005

Steve, of course you're right, but you assume that the Templeton people are intellectually honest and will tell it if they fail in their attempt. I can predict the exact opposite. I can predict it on the ground that it has always been this way : people who already have faith (be it in religion or in a political idea for instance) will never give up on their faith because of scientific evidence, but on the contrary will try to bend scientific evidence so as to match their views, even if they end up with gross distortion of the facts. A political example is the Lyssenko affair.
You say : "this is more a threat to religious people than to the scientific community because it is as stupid…". On this point I don't agree with you : first because religious people are long immunized against this sort of threat, they are even immunized against logical contradiction. Second, it can be a threat to the scientific community because the scientific people embarking on this sort of mixing between science and religion will end up being manipulated. This has already happened in France with something called "Université interdisciplinaire de Paris" which managed to "trap" some well known scientists.

9. **Who**
October 6, 2005

Fabien, thanks for warning that the category "interdisciplinary" can be a codeword or an euphemism for putting theo-spin on cosmology. You say:
Second, it can be a threat to the scientific community because the scientific people embarking on this sort of mixing between science and religion will end up being manipulated. This has already happened in France with something called "Université interdisciplinaire de Paris?? which managed to "trap?? some well known scientists.

I think I saw in the program of the Townes conference that there was someone talking on the subject of "interdisciplinary studies". Those inside the tent must carefully inspect each new hairy object that appears to discover if it is the Nose of the Camel.

To me, it seems that FQX is different from this already compromised Townes Conference and FQX is not necessarily a tool of Templeton, even though Templeton has given the seed grant. It may be that FQX will "take the money and run"—-that is, it may operate in an intellectually independent manner, which I believe is completely ethical.

Something I find interesting is that Smolin, on the advisory board of FQX, is indirectly associated with a cosmology model in which the classical "big bang" singularity has been removed and time extends back to a prior contraction phase—this is the Loop Quantum Cosmology model which Smolin's work indirectly supports and which he has discussed in his survey paper "Invitation to LQG".

This raises the possibility that the "big bang" has nothing to do with any creation at all—Divine or otherwise. It was simply not a moment of creation but rather a continuation of the cosmological model. So the issue of whether it was "purposive" or accidental does not arise.

This might have disappointed the late pope, if what you say is true:

Recently the Pope (the last one) said that the big bang was compatible with the religion (and in fact gives credit to it). Well the Pope and Hoyle were both wrong : the big bang has really nothing to do with a divine creation…

I remain undecided about the validity of FQX as a scientific research/education project. The presence of people like Smolin on the board gives it potential legitimacy. The fact of $5 million Templeton seed money potentially compromises its integrity. Have to wait and see.

10. **Fabien Besnard**
October 6, 2005

About the UIP (Université interdisciplinaire de Paris), I just learn from a friend of mine that it is funded by… the Templeton fundation ! The people engaged in this UIP (apart from those who have been lured into it) are well known for their irrational beliefs.
Who says : "It may be that FQX will "take the money and run??—-that is, it may operate in an intellectually independent manner, which I believe is completely ethical." Well this is this particular point about which I'm most worried. I don't think such an attitude would be ethical, because basically I don't think it is possible to "take the money and run". If you take the money you owe something, it's as simple as that.
"The presence of people like Smolin on the board gives it potential legitimacy. The fact of $5 million Templeton seed money potentially compromises its integrity." Precisely ! I really wish Smolin would reconsider working on this project.

As a sidenote : any cosmological model, with or without big bang, is unable to give credit/destroy a cosmogonical belief, for the latter is irrefutable (unfalsifiable). If the biblical tales were to be taken as scientific statements they would have been refutated long ago. This is why they are now said to be metaphorical, and for this reason can't have anything to do with any scientific theory whatsoever.

11. **Nigel**
October 6, 2005

Who, on big bang religion, please note Erasmus Darwin (1731-1802), father of Charles the evolutionist, first defended the big bang seriously in his 1790 book 'The Botanic Garden':

'It may be objected that if the stars had been projected from a Chaos by explosions, they must have returned again into it from the known laws of gravitation; this however would not happen, if the whole Chaos, like grains of gunpowder, was exploded at the same time, and dispersed through infinite space at once, or in quick succession, in every possible direction.'

Weirdly, Darwin was trying to apply science to Genesis. The big bang has never been taken seriously by cosmologists, because they have assumed that curved spacetime makes the universe boundless and such like. So a kind of belief system in the vague approach to general relativity has blocked considering it as a 10^55 megatons space explosion. Some popular books even claim falsely that things can't explode in space, and so on.

In reality, because all gravity effects and light come to us at light speed, the recession of galaxies is better seen as a recession speed varying with known time past, than varying with the apparent distance. Individual galaxies may not be accelerating, but what we see and the gravity effects we receive at light speed come from both distance and time past.

So the acceleration of universe = variation in recession speeds / variation in time past = c/t = cH where H is Hubble constant. The implication of this comes when you know the mass of the universe is m, because then you remember Newton's 2nd law, F=ma so you get outward force. The 3rd law then tells you there's equal inward force (Higgs/graviton field). When I do the simple LeSage-Feynman gravity shielding calculations, I get gravity within 1.7%.

It is suppressed like Tony Smith's prediction of the top quark mass by arXiv.org

12. **Who**
October 6, 2005

Nigel that Enlightenment (1790) Big Bang story is fascinating, so he was writing a Gunpowder Genesis right around when Mozart was writing the Magic Flute, great days.

Fabien I like several of your points and will not try to argue against those I disagree with, but rather wait to see if other people want to argue.

What I disagree with is what you say here: *If you take the money you owe something, it's as simple as that.*. I think that someone who accepts funding for a scientific project is in fact ethically obligated to be intellectually independent.
It is the scientist who thinks he "owes" to his donors to put some bias or nice spin on his findings who is the unethical one, in my view.

13. **Fabien Besnard**
October 6, 2005

"It is the scientist who thinks he "owes?? to his donors to put some bias or nice spin on his findings who is the unethical one, in my view. "

He does not necessarily "thinks" he owes something. It may be unconscious. There's a french saying "on ne crache pas dans la soupe" (you must not spit in the soup).

14. **Eric Dennis**
October 6, 2005

There is an American saying. "One must not dip one's quill in the company ink." But that is an entirely different matter.

I think Fabien's admonition is correct and prescient. Of course a scientist must maintain independence. But by accepting a grant from an organization whose explicit purpose is profoundly anti-scientific, one has already compromised that independence.

15. **Nat Whilk**
October 6, 2005

[Steve:] "*it is as stupid . . . as trying to prove that my mom loves me*"

[Fabien Besnard:] "*The people engaged in this UIP (apart from those who have been lured into it) are well known for their irrational beliefs*."

Just so I get the terminology straight, is Steve's belief that his mom loves him irrational?

16. **Alain Riazuelo**
October 7, 2005

[Fabien B.] *Recently the Pope (the last one) said that the big bang was compatible with the religion (and in fact gives credit to it).*

As far as I know the last Pope was not involved in this. After Hoyle invented the word Big Bang in 1948 or 1950, the Big Bang model became known to Pope Pius XI who officially declared on 22 november 1951 that the Big Bang model was in agreement with the biblic *Fiat Lux* (probably after having realized that the model had been initiated by Catholic priest Georges Lemaître). Lemaître then requested an audience with the Pope, who later retracted his first statement on 7 september 1953 at some IAU meeting. I never heard John Paul II having had such ambiguous statements.

17. **Who**
October 7, 2005

Alain what you say about Pope Pius XI is interesting. Do you have any sources that you could give us.

Pope Pius XI who officially declared on 22 november 1951 that the Big Bang model was in agreement with the biblic Fiat Lux (probably after having realized that the model had been initiated by Catholic priest Georges Lemaître). Lemaître then requested an audience with the Pope, who later retracted his first statement on 7 september 1953 at some IAU meeting

If I understand you, Pius XI went in person to an IAU meeting in 1953 and retracted his official statement made in 1951.

Or did he perhaps send an emissary to read a retraction statement at the meeting for him?

It would be fascinating to read the two statements. Are they by chance online at the peternet site? Some historical documents are online there, if I remember correctly.

18. **Fabien Besnard**
October 7, 2005

Alain : in “a brief history of time” Hawking talks about is meeting with JP2 :
“He [the pope] told us that it was all right to study the evolution
of the universe after the big bang, but we should not inquire
into the big bang itself because that was the moment of Creation
and therefore the work of God. I was glad then
that he did not know the subject of the talk
I had just given at the conference – the possibility
that space-time was finite but had no boundary, which means that it had no beginning, no moment of Creation. I had no desire to share the fate of Galileo, with whom I feel a strong sense of identity, partly because of the coincidence of having been born exactly 300 years after his death!”
This implies that JP2 identified the big-bang with the moment of divine creation.

19. **Alain Riazuelo**
October 7, 2005

> Who

I got this from Jean-Pierre Luminet and also read it in several popular science books. Luminet is definitely reliable on this issue, I think. I will investigate and try to find online references. From what Luminet says in his website Pope Pius XII (and not Pius XI) went in person at the IAU meeting in 1953. See (in French, sorry) http://www.obspm.fr/savoirs/contrib/debat.fr.shtml .
More later.

20. **Who**
October 7, 2005

Alain’s link has this:
“…A côté de ces justes critiques, de faux procès sont intentés à la cosmologie. L’un d’entre eux a injustement gâché la renommée scientifique du plus grand cosmologiste de ce siècle: Georges Lemaître, inventeur du concept de big bang avec le russe Alexandre Friedmann. On lui a reproché de vouloir confirmer par la science le récit de la Genèse. Il n’en était rien: abbé, certes, mais brillant scientifique, Lemaître tenait à une distinction radicale entre science et religion, pensant que l’on ne pourra jamais réduire l’Être suprême au rang d’une hypothèse scientifique – comme le disait à Napoléon le mathématicien français Pierre Simon de Laplace. Cependant Lemaître joua de malchance : le 22 novembre 1951, le pape Pie XII déclarait devant l’Académie Pontificale : “Il semble en vérité que la science d’aujourd’hui, remontant d’un trait des millions de siècles, ait réussi à se faire le témoin de ce Fiat Lux initial. Vers cette époque, le cosmos est sorti de la main du Créateur”.

Farouche adversaire d’un tel “concordisme”, Lemaître demanda audience au pape et remit respectueusement les choses en place. Le 7 septembre 1953, devant l’assemblée générale de l’Union Astronomique Internationale, Pie XII tint effectivement un discours radicalement opposé : la cosmologie scientifique ne parlait ni de Fiat lux , ni de création.”

21. **Who**
October 7, 2005

Someone with better French please help. this is from JeanPierre Luminet and is posted at the Paris Observatory website. Maybe you think this exchange between Lemaître and the Pope is unimportant and merely involved a trivial misunderstanding, but I think it might be indicative of a longstanding problem and would like to have an approximate English translation.

False indictments (as well as these just criticisms) have been brought against cosmology. One of these unfairly damaged the scientific reputation of the greatest cosmologist of the century: Georges Lemaître, inventor of the concept of the big bang, with the russian Alexander Friedmann.

I have to go, back later to continue

22. **Who**
October 7, 2005

continuing with the passage from Luminet
‘…He was accused of wanting to confirm the story in Genesis by science. There was nothing in that: although certainly a priest, Lemaitre was a brilliant scientist and held to a radical distinction between science and religion, believing that one could never reduce the supreme Being to the level of a scientific hypothesis—as the French mathematician Laplace put it to Napoleon.

Meanwhile Lemaître had some bad luck: on 22 November 1951, Pope Pius XII declared in front of the Pontifical Academy “It seems true that today’s science, going back over a tract of millions of centuries, has succeeded in witnessing the initial Fiat Lux. Around that epoque the cosmos emerged from the hand of the Creator.”

Lemaître, who was a fierce enemy of this kind of “concordism” [my comment: we might say “Templetonism”], **requested a papal audience** and respectfully set things right. On 7 September 1953, before the general assembly of the International Astronomical Union, Pius XII took the radically opposite line: **scientific cosmology refers neither to Fiat Lux nor to creation.**‘

Nature Physics

October 6, 2005
Categories: Uncategorized

A new physics journal was launched this week, it's an offshoot of Nature called Nature Physics and will cover research in pure and applied physics. In an opening editorial, the editors of the new journal explain what its goals are. Back over at their mother publication, in their own editorial, the editors of Nature welcome the new publication, although they can't help pointing out that "Nowadays, thanks to the allure of biology's progress and benefits, physics is just another discipline."

Comments

1. **andy.s**

   October 7, 2005

   > loop 2005 is almost here. is anyone blogging on this?

   I'd bet you'd get to see a TWF or two about it 🙂

5. **dan**
   October 7, 2005

   i think it is next week. hopefully peter woit will offer comments/insights. i wouldn't mind lubos but he isn't very objective. do you blog urs?

6. **Urs**
   October 7, 2005

   > do you blog urs?

   Not from loops05, if that's what you are after.

   The next meeting that I plan to blog-report on is a MathPhys Colloquium here in Hamburg.

   However, my new colleague D. Bahns will be in Potsdam, giving a talk on 'Pohlmeyer invariants' (which are classical invariant observables of the Nambu-Goto and Polyakov string) (even though).

   So with a little luck I might be able to report on some second-hand information. Perhaps.

7. **Ken Muldrew**
   October 7, 2005

   Andy.s:

   A previous Nobellist in stamp collecting once proclaimed that, "All of science is either physics or stamp collecting."

   Physics used to be a big thing.

8. **Who**
   October 7, 2005

   andy.s congratulations on the plainspoken forthrightness of your remarks here
   http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/panel.html

   especially in the interval 1:26–1:29, as well as your panelmember talk starting at 52:00. I say this simply in the interest of giving credit where due.

   October 7, 2005

   WHY OH WHY OH HAVE YOU FAILED TO REVIEW THE NEW NOTICES OF THE AMS IN A TIMELY FASHION? RSS FEEDS MEAN THAT I NOW PROCRASTINATE WITH SURPASSING EFFICIENCY, AND I RELY ON CONTENT PROVIDERS (YES, THIS MEANS YOU WOIT) TO PROVIDE ME WITH THEIR OH SO DISTRACTING CONTENT POST-HASTE. I FEEL NO SHAME IN MAKING THESE DEMANDS OF VERY BUSY PEOPLE BECAUSE OF MY NEO-MODERNIST UPBRINGING. YOU SHOULD ALSO PROVIDE SPECULATIVE REMARKS ABOUT THE NEW MATHEMATICS THE QUANTUM HALL EFFECT EXPERIMENT WILL GENERATE AND COMMENT ON THE RECENT WORK OF DENCKER REGARDING NIRENBERG-TRENES. HURRY.

10. **andy.s**

October 7, 2005

Wow. This guy thinks I'm a Harvard string theorist.

Of course, on this blog that might not be a compliment.

11. **Who**
October 7, 2005

my mistake. hope you had a look at some of the toronto show.
you could do worse than be a harvard string theorist btw.

12. **Who**
October 7, 2005

dan wrote (October 6th, 2005 at 10:33 pm)
loop 2005 is almost here. is anyone blogging on this?

John Baez said he asked about videotaping and was told that the Loops '05 people plan on recording the talks and putting them online.

My understanding anyway is that we should eventually be able to download some or all of the invited talks (e.g. by Rovelli, Smolin, Baez, Loll, Reuter, Ashtekar and others)

Urs is right that one should expect Baez to report in TWF—most likely when he gets back from the conference, sometime after 15 October.

the slides for Baez talk, scheduled for Tuesday 11th, are already posted at his site, with links to related work.

13. **dan**
October 8, 2005

incidentally,
i am curious as to the purpose of these conferences, since presumably the material could all be retried from physics journals like arix. will there be any new material introduced, not reflected in journals

14. **Who**
October 8, 2005

dan writes:*incidentally,*
i am curious as to the purpose of these conferences, since presumably the material could all be retried from physics journals like arix. will there be any new material introduced, not reflected in journals

I will answer you as best I can. there certainly will be unpublished stuff brought out in the talks, and IDEAS for future papers. To see this, Just look at the abstracts of the talks: for example
Laurent Freidel says explicitly that he is going to extend something to 4D which he has not yet published—-John Baez has a new abstract, not at the conference website, and he will be talking mostly about stuff he has not published. Rovelli will be putting stuff together from half a dozen recent papers by him and others, and projecting from that to future research.
So there will be plenty talked about that is unpublished. but maybe that is not the point.

I think the point is that if you are a Gradstudent or a Postdoc then it is very important for you to know personally some of the other 150 people in the field so you know WITH WHOM TO TEAM UP IN COLLABORATION and also WHERE TO GO FOR YOUR NEXT POSTDOC and if you are a Faculty then you want to size up the horseflesh and see who of the postdocs looks good, then maybe you can bring good ones to your department. Everything is done by teamwork and interaction and people stimulating each others ideas. So it is terribly important to personally know all the promising people. when you know someone, then you know more than what quality papers they HAVE written. when you listen to someone you also get an impression of what quality papers they WILL write, and you get a sense if they would be simpatico to co-author with.
The people at Loops '05 come from several different QG approachs, canonical LQG, spinfoam, CDT, causal sets, also cosmology/phenomenology like Maartens, and numerical relativity, also consistent discretizations approach of Pullin/Gambini. They have to meet in order to trade ideas and postdocs and coallesce into a "nonperturbative quantum gravity" community. Ultimately they have to cross lines and converge results. there must be a lot that will happen besides what you get from reading each other's papers in isolation.

15. **Chris Oakley**
October 8, 2005

I agree with Who (World Health Organisation?) in that the function of conferences is mainly for networking, and what one gains in talking to people between sessions is actually far more valuable than the talks themselves. I don't know whether this is just me, but a general problem with the talks at conferences (or elsewhere) is that they always seem to assume that you too have been working on their particular problem for the last six months. After about the second transparency you therefore tend to not be able to follow the details, and switch off. When I gave talks on my own work I was well aware of this problem, and so tried to keep it interesting for the entire audience for the duration. The success of my methods was demonstrated by the fact that at a talk I gave at Harwell Laboratory in 1987, only one person fell asleep (although, admittedly, he was snoring loudly).

16. **Nigel**
October 8, 2005

'…the function of conferences is mainly for networking, and what one gains in talking to people between sessions is actually far more valuable than the talks themselves…'

Chris, what about the function of publicity which science conferences are sometimes used for (and not just those of political parties which pevent heckling using the Prevention of Terrorism Act).

String theorists have cried wolf so many times that physics has lost popular credibility. Can you imagine the media forever reporting endless speculations in ST without any hope of being tested? Then look at the decline in A-level physics students over the last decade (since M-theory hype in 1995), it's now behind social sciences, as everyone knows it is a dead end discipline.

17. **Chris Oakley**
October 8, 2005

Nigel,

… what about the function of publicity which science conferences are sometimes used for [?]

Having been at CERN relatively recently, you would probably know more about this than I do [the last international physics conference I attended was at ICTP nr. Trieste in 1983. I don't remember journalists being there … my clearest memory, in fact, is Abdus Salam's Mercedes being parked on a dais next to the main building – as director he did not seem to be obliged to use the car park like everyone else].

18. **Nigel**
October 8, 2005

Chris,

It's sad that physics is so dull that journalists don't report the conferences anymore, and while ST dominates, there will be no news from the theory end of physics (unless you want sci fi).

I've not worked for Cern, although their preprint server hosts an article on cosmology/gravity.

On QTF controversy, do you think it might be possible to find an easier way around the maths, at least for the first coupling correction? I'd like a simple explanation of magnetic moment factor 1 + 1/(2 x Pi x 137) = 1.00116 Bohr magnetons. All the renormalisation problems from the abstract maths look bogus to me, surely there is a more simple solution behind it? The 2 Pi is going to be a geometric correction and the 137 also has a physical explanation like the shielding factor of the charge of the electron core by the polarised virtual charge surrounding it? I can't exactly see the solution, but surely it doesn't need a vast amount of abstract theory? I can't see why QED is so applauded for trivia like the 10 decimals of the magnetic moment of an electron, when it does not address the physical mechanism of EM forces. OK, it has survived experimental tests (if you accept renormalisation), but it is hardly complete.

19. **Chris Oakley**
October 8, 2005

Hi Nigel,

I agree that the jewels in the crown of QED (the Lamb Shift and anomalous MM's) are not much more impressive than Ivan Boesky's miraculous prescience in regard to stock prices in 1980's, but at this stage I don't have much to add to what I have already said on my web site. Numerical coincidences are no more than that unless there is a meaningful theory behind it.

20. **dan**
October 8, 2005

thanks who.

was there a loops 2004, and is there a loops 2006 scheduled? personally i wish lubos attended, as he is a very punctual blogger

dan wrote (October 8th, 2005 at 11:08 pm)
thanks who.

was there a loops 2004, and is there a loops 2006 scheduled?

Here is the main webpage for last year's conference:
http://web.lpta.univ-montp2.fr/users/philippe/quantumgravitywebsite/

Last year it was called
Non Perturbative Quantum Gravity:
Loops and Spin Foams

It took place 3-7 May at Marseille. Before that conference it was not clear that there was going to be a yearly Quantum Gravity conference, so it was not called "Loops '04". The international organizing committee was much the same people as for Loops '05. They saw that the 2004 conference was a success, and enough was happening, so they decided to make it annual.

Last year there were 101 registered participants
http://web.lpta.univ-montp2.fr/users/philippe/quantumgravitywebsite/

This year there are 156 participants.
http://loops05.aei.mpg.de/index_files/Participants.html

The name "Loops '05" is very much a shorthand expression. On the main webpage for this year's conference
http://loops05.aei.mpg.de/
they say: "Loops '05…[this year] the annual international meeting on non-perturbative/background independent quantum gravity takes place from …"

In other words they just started the tradition of having an annual meeting of researchers in **non-perturbative/background independent quantum gravity** and they call it by the shorthand "Loops" although there are several different approaches, not just LQG but also spinfoams, CDT, QEG, causalsets.

dan, you ask about next year's conference. I will risk a guess that it has not been decided yet where to have it, but that there will be one, that it will called Loops '06, and that it will be in Utrecht. It could just as well be at Penn State, or at Perimeter Institute. The reason I think Utrecht is that Ashtekar will be there at least one semester in 2006—it tips the balance in that direction. But the location is just a wild guess.

Notes for Witten Lecture

October 8, 2005
Categories: Uncategorized

Witten gave a lecture on the beach at Stony Brook on the topic of gauge theory and the Langlands program two months ago, and lecture notes are now available. Lubos Motl has a posting about this, where he promotes the idea that people should stop referring to the "Langlands Program" and just refer to "Langlands duality". Somehow I suspect that mathematicians will keep doing what they have always done, using "program" to refer to the general, well, program, and "duality" to refer to the more specific, well, duality, that one would like to prove as part of the program.

An earlier posting of mine contains a lot of relevant links, to which should be added the notes from David Ben-Zvi's talk in Seattle this summer.

Comments

1. **Aaron**
   October 8, 2005

   It should probably be pointed out that what seems to show up in the physics is Geoemetric Langlands. The full Langlands program is a lot more than just that.

2. **plato**
   October 8, 2005

   I am trying to synopsize this conversation so I understand this issue.

   I was actually looking for "culminating mathematical visualizations" that could take us directly to the geometric design, and work backwards.

   Any idea here?

3. **QWERTY**
   October 8, 2005

   DID YOU NOT LISTEN TO ME? WHO GIVES A CRAP ABOUT GEOMETRIC LANGLANDS WHEN WE COULD BE TALKING ABOUT THE "IMAGING OF THE BRAIN" ARTICLE IN THE NOVEMBER NOTICES OF THE AMS. WITTEN HAS BETRAYED PHYSICS WITH HIS SUPPORT OF STRING THEORY THEREBY DIVERTING GLOBAL ATTENTION FROM BETTER THEORIES LIKE LQG. YOU SHOULD STOP GIVING UNDUE PUBLICITY TO WITTEN HOWEVER INTELLIGENT AND PRAISEWORTHY HIS MATHEMATICAL WORK HAS BEEN, FOR TRULY HE IS METHUSELAH INCARNATE. HE IS THE FIGUREHEAD OF THE STRING THEORY CULT AND MUST NOT BE GIVEN UNDUE PUBLICITY BY RIGHT-MINDED FOLKS.

   NOW DO SOMETHING USEFUL AND BLOG ABOUT THE AMS MATHEMATICAL SOCIETY NOVEMBER NOTICES PLEASE. I NEED VALIDATION FOR MY INSECURITY BY HAVING MY NEEDS ATTENDED BY PROMINENT PUBLIC MATHEMATICIANS. THANX.

4. **woit**
   October 8, 2005

   Sorry qwerty, but if you're looking for someone who knows something about imaging the brain (or prominent public mathematicians for that matter..), you're in the wrong place. And I'd much prefer that commenters attend to my needs and insecurities than expect me to do that for them.

   As for Witten, I don't think he's old enough to be Methuselah, and doesn't really deserve to be compared to Mephistopheles, which I think is what you had in mind. His recent work on geometric Langlands mercifully has nothing to do with string theory unification or the Landscape, and a lot to do with the relation of quantum field theory and mathematics, which is a hopeful sign.

5. **Luboš Motl**
   October 9, 2005

   Dear Peter,

   one of the reasons why I don't see why it's "program" is that it is not clear what kind open questions and eventual "big goals" i.e. future in general does it offer. Can you write something about it?

   Let me remind you that N=4 super Yang Mills, for example, is exactly equivalent to type IIB string theory on AdS5 times a five-manifold, a completely standard string theory with 10 dimensions, strings, D-branes, and all other objects that you so fervently dislike. So maybe your idea that something goes away from strings is confused after all. 😉

   All the best
   Luboš

6. **A.J.**
   October 9, 2005

   Hi Lubos,

   The Langlands Program is (amongst other things) an attempt to understand the Galois groups of number fields. The Galois group of a field extension, you'll recall, is the group of automorphisms of the extension field which fixes the original field. They're the central objects of number theory; understand all the Galois groups and you can answer almost any question in number theory. Understanding the Galois groups would be _huge_; it would completely change number theory.

   The nice thing about Galois groups is that they fit together into hierarchies, which mirror the hierarchies of field extensions — and even better, there is, for every number field, an uber Galois group which governs this entire hierarchy. This is the absolute Galois group, the Galois group of a number field's maximal field extension.

   Unfortunately, the absolute Galois group G is a pretty hard object to get your hands on. So mathematicians usually approach it by trying to understand its category of finite dimensional representations. This is an easier problem: representations are nice linear objects, and we can sort them by their rank. So, we can look at a simpler problem: trying to understand all representations G -> GL_n

Langlands insight was one can understand the n-dimensional representations of the Galois group by relating them to certain representations of the group of adeles of the original number field. By "certain" above, what I really mean is automorphic; we study the representations which exhibit a kind of modular behavior. A huge amount of work has gone into understanding these conjectures; the case of two-dimensional representations was basically the Taniyama-Shimura conjecture which implied Fermat's Last Theorem. We don't have anything resembling a complete solution for number fields yet though.

So we try to learn more about this Langlands correspondence by translating it into other fields. We can realize a number field as the field of rational functions on an arithmetic curve. When we do this, the Galois group gets reinterpreted as the fundamental group of our curve! So maybe we can learn something by studying the n-dimensional representations of the fundamental groups of algebraic curves? But these are the flat connections on principal GL_n-bundles on our algebraic curve! They're nice geometric objects. In particular, they make sense even when our curve is not an arithmetic curve. So we can study the Langlands phenomena over the complex numbers for instance. We don't even need to restrict ourselves to maps from pi_1(curve) to GL_n. We can replace GL_n by G. At this point, things start to look physics-y. Flat connections on a Riemann surface are instantons of Yang-Mills theory, the automorphic representations can be thought of as sections of certain line bundles living on the space of G-bundles, and the Langlands map starts to look a lot like mirror symmetry.

All of which is a long winded way of saying, we're borrowing ideas from physics to understand questions in algebraic geometry that originally arose in number theory. For myself, the main fun is that I get to think about relations between quantum field theory and the theory of moduli spaces.

Hope that was a satisfactory answer.

–A.J.

7. **woit**
October 9, 2005

Thanks A.J. for the explanation of the Langlands program.

Some other comments: while the Langlands program for number fields is a central idea in modern number theory and has proved its importance in many ways (e.g. the proof of Fermat), what geometric Langlands is good for is less clear. I know of number theorists who are dubious that it has anything useful to tell them, and other kinds of mathematicians who are also skeptical about it. Personally I've always found it fascinating because of its relationship to QFT. It involves many of the same mathematical structures that come up in 1+1 d QFT, including affine Kac-Moody representations, the moduli space of flat connections on a complex curve, etc. The kind of relationship to 4d QFT that Witten is talking about is yet a very different kind of relationship to QFT.

What has always fascinated me about the Langlands program in general is that one of the basic ideas is to look at the cohomology of a moduli space (actually a Shimura variety in the number field case), which gives you both an automorphic representation and a representation of the Galois group, establishing a relation between these. The TQFTs that come out of 2 and 4d gauge theories also are basically all about the cohomology of a related moduli space. And these TQFTs are just twisted versions of supersymmetric gauge theories not that different than the standard model QFT. There's some still not understood relationship here between perhaps the deepest ideas in physics and one of the deepest ideas in mathematics, and neither side of this story is well understood. If we understand this relationship better, we're likely to learn something new about QFT, number theory, or both.

8. **A.J.**
October 11, 2005

Hi Peter,

I have to admit: I don't care too much about the number theory side of Langlands. It's interesting in so far as its geometry, but the relations to physics are a lot more interesting. It's quite tempting to think that quantum field theories are in fact the cohomology theories of derived stacks.

Assorted Links

October 8, 2005
Categories: Uncategorized

An assortment of news and links that may be of interest:

The Tevatron has achieved a record luminosity for a hadron collider: $1.41\times10^{32}cm^{-2}sec^{-1}$. This is higher than the best luminosity at the ISR at CERN, and that was a proton-proton collider. Getting to high luminosity at the Tevatron is a lot harder since one need to create and store an intense beam of antiprotons.

The proceedings of this year's Lattice 2005 conference are now online.

Prior to the summer's big algebraic geometry conference in Seattle, there was a Graduate Student Warm-Up Workshop at which there were some excellent expository talks, for which lecture notes are online. A couple of these talks were specifically relevant to physics (Jim Bryan's and Ron Donagi's), but they are all interesting and worth reading.

The Bulletin of the AMS has a new editor and will soon have a new cover. One article soon to appear is a short piece by Michael Atiyah on Mathematics: Art and Science which contains a very interesting explanation of his views on mathematical beauty. Another is a review article Floer Theory and Low Dimensional Topology by Dusa McDuff. Floer theory has its origins in Witten's work on supersymmetry and Morse theory. McDuff goes over this, and explains recent results on Heegard Floer theory due to Peter Ozsvath and Zoltan Szabo. Ozsvath is my colleague here in the math department, and he has recently been joined by Mikhail Khovanov who moved here from Davis. The relation of Khovanov's new homology theory for knot invariants and the Heegard Floer theory is the subject of recent work by several mathematicians, including a second new Columbia faculty member, Ciprian Manolescu.

There's a fantastic new set of introductory lectures on quantum field theory by Luis Alvarez-Gaume and Miguel Vazquez-Mozo. In less than a hundred pages they cover a wide range of subjects including the basics of quantum field theory, anomalies, renormalization, external field problems and supersymmetry. Page for page it's by far the best introduction to the subject I've ever seen. For some other similarly excellent introductions to the subject, see one by 't Hooft and one by Pierre van Baal.

The last two items come from links on Gerard 't Hooft's excellent web-site which includes a useful page on How to Become a Good Theoretical Physicist. He has just put up a new page on How to Become a Bad Theoretical Physicist, where he notes that "It is much easier to become a bad theoretical physicist than a good one." This page is still under construction, I fear that he has a large amount of potential material for it.

Comments

1. **Jean-Paul**
October 8, 2005

   Atiyah's piece is very nice. It is very interesting that mathematicians' connection to art is always made through beauty, harmony etc. Well,
art historians would tell you that these are

2. **Tony Smith**
October 8, 2005

   't Hooft says on his web page at http://www.phys.uu.nl/~thooft/theoristbad.html:
"… Young and inexperienced students could surf the web and get seriously confused by what they find. Therefore … Here is my BLACK LIST. …".

   My personal opinion is that "Young and inexperienced students" should be exposed to all kinds of stuff – right, wrong, crazy, sane, etc – so that they can form their own ability to judge stuff. Further, such concern about "Young and inexperienced students" is what led to the death of Socrates.

   Tony Smith
http://www.valdostamuseum.org/hamsmith/

   PS – Although I have not yet made 't Hooft's BLACK LIST, 't Hooft goes on to say:
"… There are many more to add. I'll be back when I found their names.
G. 't Hooft …".

3. **D R Lunsford**
October 8, 2005

   I've done almost everything on t'Hooft's "good" list. This proves that I am a good theorist! Why didn't I know this 20 yrs ago?

   The primer on QFT was indeed very good, nice find.

   -drl

4. **Dissident**
October 8, 2005

   No D R L, at best it proves that you SHOULD be a good theorist… 😉

5. **plato**
October 9, 2005

   I like Atiyah's article as well…..to bad Jean-Paul didn't finish.

   *If theory is the role of the architect, then such beautiful proofs are the role of the craftsman. **Of course, as with the great renaissance artists, such roles are not mutually exclusive**. A great cathedral has both structural impressiveness and delicate detail. A great mathematical theory should similarly be beautiful on both large and small scales.*

   As the current story of the interaction between geometry and physics shows, the feedback from science to mathematics can be extremely profitable, and this is something I find doubly satisfying. Not only can we mathematicians be useful, but we can create works of art at the same time, partly inspired by the outside world.

Mathematics: Art and Science

Impressive, and always lots to learn.

It's always good to learn some history, as John Baez relates here

6. **Nigel**
October 9, 2005

'… There's a fantastic new set of introductory lectures on quantum field theory by Luis Alvarez-Gaume and Miguel Vazquez-Mozo…'

Thanks for this link, Peter. I like the explanation on p71: '… we find the electromagnetic coupling grows with energy. This can be explained heuristically by remembering the effect of the polarisation of the vacuum … these virtual pairs behave as dipoles that, as in a dielectric medium, tend to screen this charge, decreasing its value at long distances (ie at lower energies).'

If so, then shouldn't people be going all the way here, and developing a physical model of the polarised virtual field that will allow an alternative, more classical-type, calculation of the usual QED results, to avoid renormalisation? If only there was more of this heuristic explanation in physics, and less abject speculation (ST)…

7. **MathPhys**
October 9, 2005

Personally, I would have liked to see an introduction to non-perturbative aspects of QFT. I feel that students are sort of cheated by a purely perturbative approach. I thought that Luis A-G, more than almost anyone else, is qualified to write such an introduction.

8. **ks**
October 9, 2005

When mathematicians start to talk about the beauty of their discipline they end up returning to a 19-th centurys classicistic discourse: cathedrals, Bach fugues, white marble… *sigh*. I would wonder how indian or chinese mathematicians describe their discipline in aesthetic terms which conventional comparisons they use to describe their most inner feelings. Do japanese mathematicians compare proofs with cherry blossoms or do they find such comparisons as annoying then myself?

9. **Pseudo-string-fan**
October 9, 2005

It is quite amazing to know there is a how-to-be-a-good-theoretical-physicist recipe on t Hooft's webpage. Then, can we massively produce the good theorectical physicists by his magic suggestions?

10. **Arun**
October 9, 2005

t Hooft provides necessary, but not sufficient conditions.

11. **plato**
October 9, 2005

I would wonder how indian or chinese mathematicians describe their discipline in aesthetic terms which conventional comparisons they use to describe their most inner feelings.

Maybe as a Taoist figure topological expressed Ying and Yang, defined, as a Calabi Yua?

Tony Smith, might have an answer for you?:)

On my speculation could General Relativity understood these "momentum occasions" as inclinations of circles and ellipses in martial art forms?:)

Last comment I will make like this Peter, as I know you like to run a tight ship.

12. **Jean-Paul**
October 9, 2005

I see that ks is exactly on the same track as what I was going to say.
The connection from mathematics to art is usualy made through beauty and harmony, using the pre-XIXth century concept of art.
Take music: The tonal harmonic system ended (I would say Mahler gave it a final blow) more or less at the same time as quantum mechanics was born, and it was replaced by atonal, dodecapohony etc. Are mathematicians ready for such a radical step? Can anybody tell me whether there was any radical change in mathematics methodology except for the same old proofs getting longer and longer?

13. **plato**
October 10, 2005

Can anybody tell me whether there was any radical change in mathematics methodology except for the same old proofs getting longer and longer?

Now what does this have to do with the math?

Such a comparison I would think, was from the perspective of the artist himself and , not the completion of the 10th, although attempts as seen were made to do this?

http://en.wikipedia.org/wiki/Gustav_Mahler#Symphonies

Any way, was it meant as, "the shift to new mathematics" and not the death of tonal qualities in relation to perspective views on "sound " and views on the cosmo respectively? We know how this shift happened if held to Wayne Hu.

Would mathematicians concurr?

14. **sunderpeeche**
October 10, 2005

Did anyone read the Fermilab link? The peak luminosity is 1.41 x 10^30 (not 10^32 as reported in the blog). But still a record.

15. **woit**
October 10, 2005

    Actually the number was right:

    141 x 10^30=1.41 x 10^32

16. **D R Lunsford**
October 10, 2005

    On the assorted link front, we see this:

    http://xxx.lanl.gov/abs/astro-ph/0507619

    GR explains what NG can't. No dark matter!

    -drl

17. **ali**
October 10, 2005

    D R L:

    You might want to look at this response to the paper you mentioned. Apparently, their metric and assumptions aren't self-consistent:

    http://arxiv.org/abs/astro-ph/0508377

18. **blank**
October 10, 2005

    The above link was slashdotted today for some reason. I knew it sounded too good to be true.

19. **D R Lunsford**
October 10, 2005

    ali and blank,

    The rebuttal paper is by no means convincing. The posited matter distribution is not at all unreasonable, nor is it the only possibility. The remarkable thing is, someone actually bothered to solve the equations instead of invoking yet another hand-waving argument. I'm sure we'll see a "re-rebuttal" soon!

    -drl

20. **Arun**
October 10, 2005

    The idea that General Relativity provides only tiny corrections to Newtonian Gravity as far as galaxies are concerned is not a hand-waving argument, but a result from a well-developed expansion for an arbitrary source (e.g., see chapter 39 of Misner, Thorne, Wheeler). The expansion obviously doesn't hold if there is a singular mass distribution, and perhaps singular mass distributions are reasonable.

    The point is that it was not handwaving exercise to write off GR for galaxies.

21. **Nigel**
October 10, 2005

    The question is what the dark matter is, it could be mostly asteroids, comets, planets, small dim dwarf stars, or black holes. I've not seen any suggestion that most of the mass of a galaxy is dark matter to justify the rotation. You can't justify having 10 or so times as much dark matter as visible star mass in a galaxy without massaging the model to fit the 'critical density' prediction… So the rest of the dark matter is then assumed to be in the intervening spaces as exotic particles, a nice ST-type untestable prediction.

22. **D R Lunsford**
October 11, 2005

    Arun et. al, Copperstock and Tieu explicitly state

    "The absolute value of z must be used to provide the proper reflection of the distribution for negative z. While this produces a discontinuity in Nz at z = 0, it is important to note that this has no physical consequence since Nz enters as a square in the density and Nz does not play a role in the equations of motion. Moreover, the metric itself is continuous. This is analogous to the Schwarzschild constant density sphere problem that leads to a discontinuity in metric derivative across the matter-vacuum interface in Schwarzschild coordinates. In principle, other coordinates could be found to render the metric and its first partial derivatives globally continuous but this would be counter-productive as it would unnecessarily complicate the mathematics. As in FRW, our co-moving coordinates simplify the analysis."

    where of course FRW means Friedmann-Roberston-Walker cosmology.

    This IMO is conclusive. There must be something wrong with the rebutters' Killing vector argument.

    -drl

23. **Nigel**
October 11, 2005

    D.R. Lunsford, thanks for this analysis 🙂

24. **Arun**
October 12, 2005

It should be fairly easy to decide.
The z-dependence of N is

N= exp(- k |z|) , k is some constant

Now what is limit as y-> 0 of Integral(Nz^2 dz, { -y, + y))?

If the limit is 0 then Cooperstock has a point. If it is not zero,
then there is a delta function there, and that is the singular disk.

25. **DMS**
October 12, 2005

To the list of QFT notes, I would also add the tome Fields by Warren Siegel (hep-th/9912205).

26. **Nigel**

Physics Strings Us Along

October 11, 2005
Categories: Uncategorized

A commenter here wrote in to point out that Margaret Wertheim, a science columnist for the Los Angeles Times, has a new piece entitled [Physics strings us along](). She discusses [Lisa Randall's new book]() as an example of physics that has become completely unmoored from empirical evidence and instead "has become in effect a form of speculative literature" (much like John Horgan's characterization of this sort of thing as "science fiction in mathematical form"). Wertheim notes that it is becoming hard to distinguish theoretical physics from religion and magic, supposedly less rational practices, claiming that "in recent years science itself has been showing increasingly magical tendencies", concerning itself with "entire landscapes of universes for which there is no empirical evidence whatever. "

She is writing a book about "the role of imagination in theoretical physics", and she seems overly enthusiastic about how "Unchained by the fetters of verification, string theorists are free to dream, articulating through their equations vast imagined domains in which almost anything that is mathematically possible is deemed to be happening 'somewhere.'"

Comments

1. **Chris Oakley**
   October 11, 2005

   I saw the article. I also saw one in a March 2005 Physics Today where they interview Kaku. Someone seems to have likened him to Jerry Springer. Unfortunately, though, it seems increasingly unlikely that String Theorists will ever host a Reality Show.

2. **Lubos Motl**
   October 11, 2005

   I was personally not too happy with this article either. But let me mention that a physicist mentioned in your article 😉 may have had a different opinion.

3. **Rob Scott**
   October 11, 2005

   Chris, according to the article there must be many universes where string theorists do indeed host Reality Shows, after all it is mathematically possible:) It's just not this one.

4. **Egbert Humplebody**
   October 11, 2005

   It seems there's [another]() story in the news about how string theory can explain everything.

5. **Quantum_Ranger**
   October 12, 2005

   Rob Scott says "Chris, according to the article there must be many universes where string theorists do indeed host Reality Shows, after all it is mathematically possible:) It's just not this one".

   And thus, there is another Universe stringtheorists keep ignoring? This one!

   For if it is so that there are a multidude of Universes, then they have to admit that there is one Universe wherby the theory of strings does not exist?

   A stringtheorist who does NOT admit this fact, by their own scientific arena, methods of madness, must be 'string-calculating', inside this Universe, but the resulting evidence is elswhere!

   How can stringtheorists be so sure that stringtheory EXISTS in this Universe, and not in another perticular Unverse? by their own evidence of MW's, the evidence appears to be that Strings are elswhere, even though the theorists themselves, appear at first glance, to be residing in the same referenced Universe as the Human Race?

6. **MathPhys**
   October 12, 2005

   I'm not shocked by the rise and rise of M Kaku in the US media, afterall, we have Jerry Springer. What I find shattering is that a salesman who starts every talk by plugging his most recent paperback, actually gets invited, along with respectable people like Vafa and Witten to conferences such as the Alexandria Einstein symposium.

7. **Ranger**
   October 12, 2005

   http://physicsmathforums.com/showthread.php?p=403#post403

   FOR IMMEDIATE RELEASE:

   ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

   "As contemporary physics is about money, hype, mythology, and chicks," Ed Witten explained from his offices at the Princeton Institute for Advanced Study, "The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy."

   Brian Greene, the famous String Theorist who will be played by David "the truth is out there" Duchovney, explained the plot: "String theory's muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone, and I win the Nobel prize for showing that M-Theory is in fact the dark matter it has been searching for."

Greene continues: “At first my character is reluctant to stop theorizing and start postulating, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he’s doing in my soul, and he explains that the answer is contained in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. And he shows me God in all her greater glory, as he points out that we can make more money in Hollywood than writing coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler. I am quickly converted, and I agree to turn my back on String Theory’s hoax and save Jessica Alba.”

But it’s not that easy, as standing in Greene’s way is Michio “king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this” Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the “ironic” pretense his salary, benefits, and all-expense paid trips depend on. “WE MUST HOLD BACK THE YOUNG SCIENTISTS WITH OUR NON-THEORIES!! WE MUST FILL THE ACADEMY WITH THE POMO DARK MATTER THAT IS STRING THEORY TO KEEP OUR UNIVERSE FROM FLYING APART, OUR PYRAMID SCHEMES FROM TOPPLING, AND OUR PERPETUAL-MOTION NSF MONEY MACHINE FROM STOPPING!!” Kaku argues as he delivers a flying back-kick, “There can be ony ONE! I WILL be String Theory’s GODFATHER as referenced on my web page!! I have better hair!”

But Greene fights back as he signs his seventeenth book deal to make the hand-waving incoherence of String Theory accessible to the South Park generation, senior citizens, and starving chirldren around the world. “Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket),” Greene shouts. “It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!!”

“Time travel is also theoretically impossible, but there’s a helluva lot more money for us in flushing physics down a wormhole. Nobody knows what the #&#%&$ M stands for in M theory ya hand-waving, TV-hogging crank!!! Get it?? Ha Ha Ha! We’re laughing at the public! We’re the insider pomo hipsters! Get with the gangsta-wanksta-pranksta CRANKSTER bling-bling program!!”

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We’ll all just have to wait!

But in the meantime, how do you think it will play out?

Will theories with postulates ever be allowed in physics again? Or will the well-funded, tenured pomo String Theory / M-Theory (Maffia-Theory) Priests send their armies of desperate, snarky postdocs and starving graduate students forth to displace and destroy all common sense, logic, reason, and physics in the academy? It must be so–for the greater good of physics, the individual physicist, and thus physics, must be sacrificed.

MDT’s postulate: THE FOURTH DIMENSION IS EXPANDING AT A RATE OF C RELATIVE TO THE THREE SPATIAL DIMENSIONS IN QUANTIZED UNITS OF THE PLANCK LENGTH, GIVING RISE TO TIME AND ALL CLASSICAL, QUANTUM MECHANICAL, AND RELATIVISTIC PHENOMENA.

October 13, 2005

On the topic of Dr Lisa Randall, I think it sad that Scientific American made fun of her in the Oct issue, pp20-22.

The article is headed ‘The Beauty of Branes’ and has a big picture of her in front of a blackboard.

Underneath the picture is the caption: ‘Lisa Randall: Warped Thoughts.’

The article concludes by quoting her collaborator Andreas Karch of University of Washington: ‘I often don’t understand her. When she says things, they don’t make sense and I first think ‘she is crazy’. But I don’t say anything…’

With friends like these, who needs enemies?

9. **Rainey**
October 16, 2005

um actually i dont think the article was making fun of her at all. the actual article, on pages 38-40

concluded with the sentance:

“But I don’t say anything, because she is usually right. Lisa just knows the answer.”

Just pointing this out because if you read the above post Karch’s comment seems pretty patronizing. Add the final sentance and he just sounds ignorant.

Usually taking things out of context “warps” their meaning…;)

10. **Bryan**
October 17, 2005

‘…because she is usually right. Lisa just knows the answer.’

This fear of pointing out potential problems ‘because she is usually right’ and ‘just knows the answer’ in my opinion makes Lisa sound patronising, which is why I left it out. It has nothing to do with the point being made, that someone senses a problem, yet does not have the courage to say so.

11. **Nigel**
October 17, 2005

I hate the idea of personally ridiculing string theorists just because they are wrong scientifically, but who gave the idea to Laughlin for the following analogy in the San Francisco Chronicle?

“… skeptics suggest it’s the latest sign of how string theorists, sometimes called “superstringers,” try to colorfully camouflage the theory’s flaws, like “a 50-year-old woman wearing way too much lipstick,” jokes Robert B. Laughlin, a Nobel Prize-winning physicist at Stanford…”

Loops ’05, Again

October 11, 2005
Categories: Uncategorized

This week there’s a large conference in Potsdam on non-perturbative/background independent quantum gravity called Loops ’05. The programme is on-line, and there is live-blogging from Robert Helling.

Update: String theorist Robert Helling has more coverage of the conference. This includes the hilarious criticism (quoted approvingly by Jacques Distler) that too many of the talks were “so vague and speculative that they are not even wrong.” Helling does notice that the string theorist speaker (Stefan Thiessen) delegated to talk about what is going on in string theory had nothing to say, and just repeated the failed dogma from more than 20 years ago. Maybe at Strings 2006 they’ll even let someone from the LQG camp speak, or at least there will be live-blogging from an LQGer.

Note: This is a reconstruction of my original posting. Unfortunately I accidentally hit the wrong button when trying to edit a typo in a comment, deleting the posting and all comments. Thanks to Steve and Aaron for helping me retrieve the content of the posting, but unfortunately most of the comments were lost. If you have copies of them, please send them to me or resubmit them yourself.

Update: For something truly bizarre, see Lubos Motl’s comments on Loops ’05, where he attacks the talks there as “not even wrong”, while in the same posting respectfully reporting on a talk by Cumrun Vafa at Radcliffe on the Swampland, a talk at which several people evidently expressed the opinion that it could never lead to an explanation of anything about physics.

Update: There’s a bit more about Loops ’05 in the latest issue of John Baez’s “This Week’s Finds”.

Update: The talks from the conference are now on-line.

Comments

1. **Who**
   October 11, 2005

   great of Robert.
   meets the hunger for news from the conference and
   also the need always for a critical outside perspective.
   real gift. thanks Robert! Looking forward to more
   (e.g. Laurent Freidel on Tuesday, Loll and Reuter on Wednesday, and to Roberts choices of what talks to hear and his commentary on them)

2. **Shantanu**
   October 11, 2005

   Peter (in case you didn’t know) next week at Stony Brook there is an interesting symposium on geometry and universe which predominantly consists of relativists.
   http://insti.physics.sunysb.edu/itp/conf/GR2005/ were you planning to go for this?
   Maybe you can tell the readers about this conference and also let us know what the traditional GR community thinks of string theory (which will definitely be discussed at this conference).
   Shantanu

3. **a**
   October 11, 2005

   “traditional GR community thinks of string theory??

   Shantanu, what does the traditional GR community think of string theory?

4. **Robert**
   October 12, 2005

   I cannot reconstruct all I commented earlier. My main point was that Theissen gave a standard “strings for non-experts” talk rather than addressing the loop people and their prejudices directly. This way, they had seen it all before and he gave away the possibility of telling them something that is new for them and maybe even thought provoking.

5. **Lee Smolin**
   October 12, 2005

   Hi, if I can put a comment here I didnt figure out how to put on Robert’s blog:

   Thanks for the comments. If I’d known you were here I could have answered some of these questions in person.

   Let me emphasize first that the point of my talk was to emphasize important open issues. We are not afraid of emphasizing open problems but we do hope that people notice when they are solved. Hence, I would have hoped you noticed and reported that major progress was described concerning the problem of showing that classical spacetime honestly emerges from background independent theories. Rovelli derived the graviton propagator and hence Newton’s law. Freidel and Livine showed in detail that 2+1 quantum gravity with matter has a low energy limit which is an effective QFT on a non-commutative geometry with deformed Poincare invariance. Both results were derived from spin foam models.

   Hence, one can no longer say that there is no understanding of how classical spacetime and low energy qft emerges from these theories.

   There was still more. Perez showed how regularization ambiguities in the Hamiltonian constraint may be resolved. Markopoulou discussed a new approach to the low energy liimit based on her new paper with Kribs. Loll announced major results showing that 3+1 spacetime emerges from causal dynamical triangulations and that at short distances the theory scales as a 1+1 dimensional theory. Livine and Terno showed how to derive the log(area) corrections to black hole entropy and estimate the rate of Hawking radiation. Starodubtsev reported on work with Freidel in which quantum gravity is defined by a perturbation expansion around a topological quantum field theory where the expansion parameter is G Lambda. This is a very promising direction as there are indications (no proof yet) that this new pert. theory is renormalizable and the low energy limit reproduces QFT in DeSitter spcetime……

These, and other results were based on detailed calculations and are solid results. I would have hoped that your report would have focused on the presentation of these major result.

In the face of this kinds of impressive progress, I was not embaressed to emphasize open issues or speculate a bit about future directions. So my talk was certainly not representative. By the way, I would have thought that as a particle physicist you would have recognized that what I presented was just a preon model. It was translated into the language of LQG with the help of recent work by Bilson-Thompson. This is new stuff and much remains to be done. But you can also no longer say that there is no proposal for unification of matter and geometry in LQG.

Still to come are new results on rigorous formulations of the theory and at least one striking new results on quantum cosmology, of relevence for upcoming observations.

6. **Who**
October 12, 2005

a friend of ours was in Berlin and happened to attend Lee Smolin's public lecture. Here is Ratzinger's report:
—quote—
I'm in Berlin right now and found out that Lee Smolin is giving a public lecture, named "The unfinished revolution: finishing what Einstein started". So how could I resist?

He started with the question "what is at stake?". Answer: all the big questions (what is time, space, physical law? why is the universe hospitable to life?). After going through the three revolutions (Aristotle, Newton, Einstein) and their notions of space, time, etc., he stressed the importance of relationality in present-day world view, both in qm and gr.

(He said Leibniz was right about relationality, but he had no workable physical theory, so scientist followed Newton for 200 years. Mach and then Einstein rediscovered relational thinking.)

So what are the approaches to attack quantum gravity? There are two, according to Smolin.
1. Einstein's way (rethinking the concepts of space and time, and especially reworking qm)

2. everybody else's way (string theory, loops, etc.)

He admitted that he researches everybody else's way, but pointed out the need for radical and rebellious thinking the Einstein way. He also praised Penrose in that context.

He ended with saying that physicists are standing in the lights and shadows of Einstein. Lights: Einstein's theories, that they work with. Shadows: ignoring what is at stake and not sharing Einstein vision of a complete understanding of the universe by rejecting qm.

Edit: 1. I think Renata Loll was also sitting in the audience.
2. Smolin was very excited by the coming representation of Winkler and another guy on Friday.
—endquote—
http://www.physicsforums.com/showthread.php?p=785298#post785298

[my comment: the other guy is probably Abhay Ashtekar, whose talk on Friday will discuss what replaces the hole and bang singularities when the classical singularities are removed by quantum gravity methods. This would probably interest Lee Smolin since he has conjectured that the two regimes could be related—black hole pit expanding to form another spacetime region.]

7. **Who**
October 12, 2005

or the other guy, whose name Ratzinger didnt remember, could be Viqar Husain—-Husain is also giving a talk Friday and he and Winkler have a new QG way to remove the BH singularity.

8. **Nigel**
October 13, 2005

a: '…what does the traditional GR community think of string theory? '

I earlier posted that Sir Roger Penrose who is the only person that actually understands GR physically – or at least the only person who lets on that he does – thinks Witten is talking out of his hat where Witten says in a leading journal in April 1996 that ST: 'has the wonderful property of predicting gravity' (not an exact quote, but close enough).

Penrose has this issue that ST is at best just a perturbative calculating procedure which cannot predict – or lead to – the prediction of the strength of gravity.

Witten's praise of his own work on M-theory by calling it a wonderful prediction of gravity reminds me of the controversy when Edward Teller around 1983 hyped the 'wonderful' space-based nuclear explosion pumped x-ray laser as a thing the size of a suitcase which can shoot down the entire Soviet missile force, 'if in the field of view'. (After checking the equations, it turned out that the x-ray laser would need to be about 1000 metres long, and that as such it would only be able to shoot one thing at a time, and would be hard to send into space anyway.)

Sorry if I've gone off topic a bit 😉 On my weblog, I've got all kids of rubbish I can't delete because you have to keep pressing 'confirm to proceed to deletion' and 'are you really sure you want to delete this post, it looks so brilliant? please click here again before it can be deleted!' So I just give up trying.

9. **Robert**
October 13, 2005

Lee,

please reread what I wrote. I said I liked Rovelli's talk an recommended reading his paper. I gave some extended coverage of what you were saying but you have to admit your remarks on 'quarks', your remarks on CMB and the Poineer anomaly were quite bold to say the least. I expect to read some popular texts on LQG where these topics will be mentioned as 'understood/solved by the canonical approach'.

What Markopoulou said sounded to me (but that might be my fault) as an introductory lecture in block spin transformations and RG group in the 1D Ising model. The remarks on how evolution is like a channel in quantum information theory again were not very concrete.

And, as you will find stated in my second post, I had to leave Golm during Friedel's lecture to return to teaching duties so I could not report on what happened after Tuesday 10:40.

As far as the announced results on quantum cosmology go, I have to admit, I am sceptical. Loop quantum cosmology had one big result in the past, the fact, that the initial singularity is not there and the inverse area operator was bounded (i.e. the universe cannot get arbitrarily small). This result was celebrated as a huge step forward and all the publicity was collected in favour of LQG.

In the meantime however, Thomas Thiemann has shown, that this result was an artefact of the minisuperspace like approximation and that it the inverse area is unbounded in the full theory. As always everybody is encouraged to draw their own conclusions.

10. **Pindare**
October 14, 2005

Off-topic: there's a short article on string theory featuring Gabriele Veneziano (now chair at Collège de France) in today's edition of Le Monde at http://www.lemonde.fr/web/article/0,1-0@2-3244,36-698934@51-699012,0.html

Another one features Brian greene and Stephen Hawking and their popular science books.

This pops up because this week is the nationwide Sciencefest in France, and there's "a large public eagerly interested in theoretical physics" who read (part of) those books.

Of course this is just a tiny aspect of the Sciencefest, most other things are on less controversial topics, all the activities are listed at http://www.fetedelascience.education.gouv.fr/

11. **Arun**
October 14, 2005

If one goes to amazon.com and looks up David Lindley's book on Boltzmann ("Boltzmann's Atom: The Great Debate That Launched A Revolution In Physics"), then, at the end of the editorial reviews is an excerpt from the book. We learn of James Waterston who discovered some of the ideas of the kinetic theory of gases, but was ignored.

And the following contains probably useful advice for the 21st century as well:

> Waterston's achievement finally came to light in 1891, when the English physicist Lord Rayleigh, then secretary of the Royal Society, discovered the lost manuscript in the course of tracking down some old citations. By that time the kinetic theory amounted to a sophisticated and well-known body of knowledge, and Rayleigh immediately perceived the true merit of Waterston's ideas. He arranged for its belated publication as the first item in the first issue of the Philosophical Transactions for 1892, along with a brief commentary on its tortured history.
>
> Acknowledging that Waterston had submitted his work at a time when scientists thought very differently than they were accustomed to doing just a few decades later, Rayleigh admitted nevertheless he was surprised that the Royal Society's expert reviewers were so dismissive of the paper. "The omission to publish it at the time was a misfortune, which probably retarded the subject by ten or fifteen years," he wrote. Rayleigh suggested that Waterston might have done better to mention that he was working to elaborate ideas previously suggested by Daniel Bernoulli, whose reputation was unarguable; that might have made a reviewer hesitate. But Bernoulli's work had itself been forgotten, and it is the strength of Waterston's claim to unjust treatment that he indeed came up with his reasoning entirely by himself. On that score Rayleigh had another observation: **"Perhaps…a young author who believes himself capable of great things would usually do well to secure the favourable recognition of the scientific world by work whose scope is limited, and whose value is easily judged, before embarking on greater flights."** The reliable route to scientific fame, in other words, requires brilliance judiciously combined with careerism. Just as well, perhaps, that the already bitter Waterston didn't live to see this endorsement of his unrewarded endeavors.

12. **Dissident**
October 15, 2005

Great advice Arun. Surely it would have been much better for everybody involved if young Albert Einstein had concentrated on establishing a solid track record in molecular physics till he was 40 or so, to then tackle the big vision task of unifying mechanics and electromagnetism.

BWAHAHAHAHAHA!

13. **Chris Oakley**
October 15, 2005

Unfortunately Arun's advice is all too sound: if you concentrate your mind on how not to be a threat to the has-beens or never-weres who run the physics establishment, then they might, after forcing you to jump through a lot of hoops, offer you a permanent job. If your brain has not completely atrophied by then, then who knows, you might even have some infinitesimal contribution to make to the subject.

Relativity and Quantum Mechanics only happened because there were enough bright 23-25 year olds around in the early part of the last century brave enough to think for themselves. Although the research establishment then was just as much a gerontocracy as it is now, it was one of those situations where the old timers simply could not afford to ignore the youngsters.

14. **Dissident**
October 15, 2005

Arun's advice is sound only if the goal is to get a job in academia. Why anyone would be willing to sacrifice his or her intellect and creativity for such a lowly reward is beyond me. There are far more rewarding occupations which will let you exercise both to the fullest *and* which offer the very real possibility of reaching financial independence well before 40 (especially if you don't mind living on a theoretical physicist's budget). And then it's off to the races. 🙂

15. **Chris Oakley**
October 15, 2005

Actually, I *did* want a job in theoretical physics. I was prepared to put up with the low salary (less than a schoolteacher, by the way) in exchange for doing what I love doing. I will never have moral qualms about going in search of £££ in the City of London as leaving academia was a question of being pushed rather than jumping.

16. **The Statistical Mechanic**
October 15, 2005

"[..] Of course, Peter Woit followed up on this line, because it is his argument that superstring theory is not even wrong. [..]"

17. **Arun**
October 15, 2005

Dissident,

Albert Einstein did concentrate on molecular physics – that was his Brownian motion paper. Anyway, considering that Boltzmann committed suicide in 1906, in part we think because of opposition by Mach and Ostwald to atomic theory in general and Boltzmann's work in particular, molecular physics was not the place to be, either.

Anyway, Einstein's Nobel citation was "for services to Theoretical Physics, and especially of the law of the photoelectric effect." Perhaps another sign of the conservative nature of the establishment.

-Arun

18. **Dissident**
October 15, 2005

That's why I mentioned molecular physics, Arun (if memory serves, it was his thesis subject). But for how long did he "concentrate" on it?

And yes, that silly Swedish academy used the photoelectric effect to motivate his Nobel prize, so as to avoid openly endorsing relativity. It wasn't really controversial in the world at large by then, but apparently there were some local "heavyweights" in Uppsala who just didn't get it.

19. **MathPhys**
October 15, 2005

I'm disappointed that the coverage of Loops '05 has stopped after the first couple of days of talks. I would have liked to know what happened next. Can one find that anywhere?

20. **Lee Smolin**
October 16, 2005

Dear Robert,

Thanks, perhaps I misread you. I was perhaps over-reacting to your opening: "I sneaked into the Loops 05 conference…" I hope this was not how you really felt. Certainly, all were welcome, no one was checking badges.

But I also don't understand why, after doing a good job of just reporting, you feel the need to add comments like, "I expect to read some popular texts on LQG where these topics will be mentioned as 'understood/solved by the canonical approach'?" Perhaps you are used to an atmosphere in which people are not careful to distinguish conjecture, evidence and proof, but this is not us.

As to the other points, why not read the papers? Kribs and Markopoulou is gr-qc/0510052. Regarding singularity avoidance in the full QFT, the papers are by Johannes Brunnemann and Thomas Thiemann, gr-qc/0505032 and 033. Not surprisingly, the situation is quite a bit more complicated in the full theory than it is in the models, but their conclusion is not pessimistic. They do find states on which the inverse volume is not bounded. But they show it is bounded on a large class of coherent states. The last line of their abstract states, "After outlining what would be required, we present the results of a calculation for LQG which could be a first indication that our criteria at least for curvature singularity avoidance are satisfied in LQG."

If I may add, the atmosphere in the quantum gravity community is pretty open. Most of us know and easily acknowledge that what we are doing is high risk. Most of us are very self-critical and any honest critic will be made to feel very welcome because you cannot be more critical to us than we are to ourselves.

Looking forward to seeing you next time,

Lee

21. **Who**
October 18, 2005

John Baez TWF #222 is out.

Scroll 3/4 of the way down the page for his report on a couple of things of interest from Loops '05.

http://math.ucr.edu/home/baez/week222.html

22. **Who**
October 20, 2005

Unofficial word about when the VIDEO from Loops '05 will be made available at the website:

My understanding, based only on indirect report, is that they plan to have the videos of the talks up by beginning of next week.

Worth keeping an eye out for it. Thanks to John Baez for originally mentioning something about this.

23. **dan**
October 22, 2005

will there be a loop '06? incidentally, shouldn't all LQG researchers work on the semiclassical limit problem, for if it doesn;t reduce to GR, then it is not a viable theory of QG?

24. **Who**
October 23, 2005

will there be a loop '06? incidentally, shouldn't all LQG researchers work on the semiclassical limit problem,…?

Normally it might be better to wait until John Baez responds—since your question is one he can answer best. But he might not still be reading this thread, now that it is overlayed by other discussion. So I will take a shot at the question.

I havent heard anything official about a conference next year. It seems to me that enough is going on in the various allied research lines to make people want to have one next year. Last year it was at Marseille so it probably would not be there again so soon. It could be at Penn State (Ashtekar's institute) or a Perimeter in Waterloo, or it could be at several places in the UK, or possibly at Utrecht.

My private guess is that there will be Loops '06 and it will be at Utrecht. (Ashtekar seems to be taking his sabbatical there for at least part of 2006—the place has become a QG center.)

about the semiclassical limit problem, dan—-it does seem to me that there is a lot of focus on that now in several of the main QG research lines. I think your guess that they should is approximatley right and that they ARE focusing effort on that.

To get an overview, go to Loops '05 programme and take a quick look at several leading people's ABSTRACTS. Look at the abstracts of Rovelli, and Baez and Freidel and Loll.

All these people are focusing on this and related issues like including matter. Rovelli is explicit about this, also Baez, as you can see from the abstracts. Freidel has just finished showing that the 3D version of his spinfoam model DOES include matter and have the right largescale behavior. His program is to achieve success in 3D and then extend the results to 4D. He talked about the prospects for 4D at the conference. Still other nonperturbative QG approaches are those of Loll (CDT) and of Reuter (QEG)—where considerable effort is focused on these same issues.

So on the whole you are right, but there are exceptions. LQC (loop quantum cosmology) is almost a separate field. It may be possible to test it separately. There the semiclassical limit has already been shown. So the emphasis has shifted towards phenomenology—what might be some observable effects of LQC? Cosmology involves symmetry-reduced degrees of freedom (assuming isotropy and homogeneity simplifies the picture). One thing that can be explored is the relation to the full QG theory—-how similar will the predictions of full LQG (say in Thiemann's Master Constraint version) turn out to be to the "toy model" symmetry-reduced LQC?

Another complication is that, as is often pointed out, the field of (nonperturbative, non-string) QG includes several approaches—it isnt just the canonical LQG (described, say, in Hermann Nicolai's "outside view" paper). Offhand I can't think of anyone at Loops '05 whose abstract indicates they were talking about canonical LQG. The guy from Beijing Normal was discussing Thiemann's Master Constraint which is really a new QG approach. If you look over the programme and happen to see someone who is actually doing LQG proper, please let me know!
The terminology is really frustrating. Can of worms! People should really not ever say LQG. They should say "nonperturbative QG" (meaning Rovelli's spinfoam, Freidel's spinfoam, Loll CDT, Reuter QEG, Gambini CD, Thiemann MC,…) and when all these people get together they call it "Loops".

25. **dan**
October 23, 2005

"So on the whole you are right, but there are exceptions. LQC (loop quantum cosmology) is almost a separate field. It may be possible to test it separately. There the semiclassical limit has already been shown."

What is LQG and how is it there's so little word on its semiclassical limit? So it reproduces GR with quantum corrections on the planck scale?

26. **John Baez**
October 24, 2005

dan said:

will there be a Loops '06?

Probably; the idea of calling it Loops '05 was to make this an annual thing. However, we need someone to agree to run Loops '06 – and I don't think it's gonna be me!

Some obvious possibilities include Penn State, the Perimeter Institute, and Marseille, but they've all run conferences like this quite recently. So, Mexico and Utrecht are being mentioned.

I'm not sure Renate Loll will want to run something called Loops '05, since she considers her own approach – causal dynamical triangulations – quite distinct from loop quantum gravity, and more successful! Personally I think this year's conference should have been called something like QG '05, since there were talks on almost every approach to quantum gravity. Or maybe NOT VERY MUCH STRINGS '05. 🙂

Anyway, we'll see what happens.

dan said:

incidentally, shouldn't all LQG researchers work on the semiclassical limit problem, for if it doesn't reduce to GR, then it is not a viable theory of QG?

I think all loop quantum gravity researchers should work on this problem. That's why I keep talking about it every time I get a chance! I spoke about it at Marseille, at the Perimeter Institute, and at Loops '05. However, it's hard to get people to work on a very hard problem, when there are easier problems out there.

Similarly, I think all string theorists should be working on a background-free approach to this theory, and on finding a way for it to make specific predictions about particle physics. But at any given moment there are lots of easier things to do.

27. **Who**
October 25, 2005

I'm not sure Renate Loll will want to run something called Loops… since she considers her own approach… quite distinct from loop quantum gravity… Personally I think this year's conference should have been called something like QG '05…

QG '05 would have been a better choice (it seems now)
Names matter (you pointed this out somewhere not long ago) and a little thing like a name can be a bigger obstacle or source of trouble than one would expect—-I will spare everybody the Shakespeare quote.

For the first time I understand why they didnt simply announce at the end of Loops '05 that Loops '06 would be held at Utrecht Spinoza Institute. Damn. It is a shame. But I understand how Loll might object.

To me it looks different. If the Utrecht people would simply have Loops '06 at Utrecht and call it Loops, this would prove to the world that CDT IS LOOPS. It would show everybody that there is a collective research drive towards the goal of non-perturbative quantum theory of gravity which is not confined or characterized by one specific approach like canonical loop quantum gravity, or any particular path integral tactic either. So I see it for Loll as a good opportunity to establish a broad inclusive definition of the term "Loops".

28. **dan**
October 26, 2005

hello john & "who"

re: “However, it’s hard to get people to work on a very hard problem, when there are easier problems out there.”

from the standpoint of physics, if LQG & friends do not reproduce GR as its semiclassical limit, then is there any reason to continue researching it? so i’m not sure if it is wortwhile to work on the easier problems if LQG does not reproduce GR. Perhaps no-go thereoms that show background-independent QG does not produce GR might be an easier problem everyone should work on! has lubos published to this effect?

“who” would you call SST/m-theory “qg”?

incidentally John, you once wrote about de-emphasizing QG in your research, has loops 05 changed that?

Physics Demographics

October 17, 2005
Categories: Uncategorized

To some extent, if one wants to understand some of the recent history of physics, one should take into account important demographic trends in the subject. For particle physics in the U.S., in recent years the Particle Data Group has been conducting an annual Census of U.S. Particle Physics. The American Institute of Physics has a collection of reports available on-line. The NSF and other various other organizations periodically issue hysterical reports about there being too few physics students getting Ph.D.s. For some perspective on this, in 2003 there were a bit more than 1100 physics Ph.D.s awarded in the U.S., and during 2001-2002, about 230 retirements per year of permanent faculty. Due to large recent increases in graduate student enrollment, the number of Ph.D.s is expected to increase significantly during the next few years. There doesn't seem to be much danger that anytime soon U.S. universities will see any change in the current situation of having vastly more qualified candidates for academic jobs than actual permanent jobs available.

In the specific case of particle theory, the Particle Data Group figures show roughly 450-500 tenured faculty, and 400-450 graduate students. So, the entire U.S. tenured particle theory professoriate could be just about replaced by one 4-5 year cohort of graduate students. The theoretical particle physics job market will remain extremely competitive for the forseeable future.

Unfortunately, the main hope for young physicists who want an academic job is that current tenured faculty are getting old and have to retire or die sooner or later. The latest data I've seen (from a 2000 AIP membership survey) indicated that the average age of tenured physics faculty had reached nearly 60. If anyone knows of more recent data I'd be interested to hear about it. I don't know of any good on-line sources for historical data, but the December 1995 issue of Physics Today had an interesting article about demographic trends in physics entitled "What future will we choose for physics?". The authors of that article claimed that before 1970 the median age of physics professors in the U.S. was relatively stable and under 40. In 1970, the number of physics Ph.D.s awarded hit an all time high of nearly 1600, and faculty hiring essentially fell off a cliff. According to the Physics Today article, from 1970 on the median age of tenured faculty increased linearly at the rate of about 8 months/year.

One effect of the aging of the physics community is that Physics Today has been running an increasing number of obituaries, since it has a long-running policy of printing a picture and several paragraphs about each of their members for whom obituaries are submitted. As of this month, facing the prospect of having to devote an increasing fraction of space to this purpose, they have abandoned this policy, announcing that from now on they will only publish obituaries in special cases, setting up a separate web-site for on-line obituaries, since these won't be appearing in the magazine itself.

Update: Andre Brown wrote in to point out that the 1995 Physics Today article is available on-line.

   These statistics are even more shocking than I expected.

   I am not saying that I have all the answers to these problems (not in detail, anyway), but it is useful to examine some of the significant events in our subject. Off the top of my head … Gell Mann discovered the eightfold way at age 23; Einstein, photoelectric effect & SR, aged 26; Heisenberg, matrix mechanics, aged 25; Dirac, the relativistic wave equation, aged 26. De Broglie, wave-particle duality at 24 (or thereabouts). Schrodinger, an old man at 38 – mind you, he was only following up on his young student de Broglie's work. <shameless plug> Also, my great uncle W J van Stockum, Axially Symmetric solutions of Einstein's equations – the work was done before he was 26 – it is still regularly cited &lt/shameless plug>

   Perhaps next time some billionaire philanthropist wants to help advance physics, instead of spending $100mil on some fancy new research center, he should offer $100mil in incentives for 50- and 60-something professors to retire early.

   Granted, it's not as sexy as having a building named after you.

7. **JC**
   October 17, 2005

   Is there a specific reason why physics funding fell off a cliff around 1970? From what I read over the years, it seems like the government decided to stop funding a lot of things in the early 70's, such as the Apollo missions.

8. **woit**
October 17, 2005

JC,

From what I remember it was a combination of a bad recession, putting an end to somewhat of a bubble in research and academic spending. Throughout the 50s and 60s the economy was expanding, and especially after Sputnik in 57 ever larger amounts were going into funding research and expanding the size and number of universities. When the recession hit, and state and federal spending had to be cut, the universities and research funding were among the hardest hit. Since universities had just expanded greatly in size and hired a lot of new tenured people, when all of a sudden they stopped expanding there were virtually no jobs, since the faculty was so young that very few older professors were retiring. This effect has continued for much of the period since 1970, only starting to change recently as many people hired during the 60s are finally starting to retire.

Gell Mann discovered the eightfold way at age 23; Einstein, photoelectric effect & SR, aged 26; Heisenberg, matrix mechanics, aged 25; Dirac, the relativistic wave equation, aged 26. De Broglie, wave-particle duality at 24 (or thereabouts). Schrodinger, an old man at 38

Yeesh. What's the point of retelling this myth about young genius? That we should drive established thinkers out of academia? Or maybe that we should refuse to hire anyone who's done great work before the age of 30, on the grounds that their best years are behind them? 🙂

10. **D R Lunsford**
October 17, 2005

On a recent visit to 's physics department, I saw among the grad students and postdocs, not a single American face. Mostly Chinese, a smattering of Russians, Indians, and Pakistanis, a token German or two.

This is the direct result of the Faustian bargains struck among American deans and registrars, and those who desired wonder weapons. In the US, physics is done for power or profit, not for knowledge. Physics = weapons.

October 18, 2005

This is a bit off-topic, but being outside academia, the whole idea of tenure seems a bit odd. As I understand it, the idea is to give talented people the freedom to work in unfashionable/unpopular areas. This sounds great, but given human nature, how realistic is it to expect this to lead to improved results? Are there a lot of scientific results from, say, the past 50 years that were achieved by tenured professors, but would likely *not* have been achieved if tenure did not exist?

Maybe Andrew Wiles & Fermat might be an example, though that's not really science.

Perhaps my question boils down to this: I understand the benefit to professors of tenure. But what is the benefit to universities and to society at large?

12. **Doran**
October 18, 2005

There is some statistical correlation between ground-breaking work and how young a scholar is, though that is no reason to ship 40 & 50 year-olds off to the old folks home just yet. For those of us (myself only 21) still yet to turn 30, the young genius motif is even more frustrating because we only have those few years left before our brains turn to mush, though I imagine this isn't the care.

What is the most important characteristic of the giants in any scientific discipline is the ability to think differently. To head off the reservation and still keep your wits about you. Yes it may sound like a worn out platitude but it still makes sense. Just have to think outside of the ten dimensional box is all.

Being an undergrad in physics & history, I ended up being interested in the history of scientific theories and the many curiousities that abound in that study. Does anyone still do research along the lines of John Bell and hidden variable theories? I would really love to hear a physicist actually discuss this subject rather then snear at it for being "too much philosophy."

13. **Chris Oakley**
October 18, 2005

On the age issue, what I think can be changed is the emphasis. At the moment the most important thing is that a group of middle-aged and old men (the tenured professors) should have secure – if relatively poorly-paid – jobs. Demonstrably, this group is not the one most likely to be of most benefit to the subject. This is something that falls, in the vast majority of cases, to the under 30s. The emphasis could be changed so that the latter group is allowed more free rein. This would of course be at the expense of the old timers, but I simply do not accept that university professors are unemployable elsewhere. The bottom line is that they can always become schoolteachers (which would be some kind of poetic justice given how many of their graduate students will have had to find employment in this profession aged about 24).

Here is the kind of thing I would like to see:

(i) No tenure (at least not in research posts)
(ii) Research jobs/grants awarded on a 5 year rolling basis
(iii) Decisions about allocation of jobs and grant money made democratically, involving *all* engaged in research, i.e. from 2nd year graduate student upwards.

This is not ridiculously ageist anyway, as someone who continues to be a good researcher into their 30s and 40s is likely to continue to be re-elected to their research post.

The point is simply that, as history has shown, the young person's scepticism is the most valuable thing that science has. Instead of treating this as a dangerous threat (as happens at present), it ought to be harnessed and used in ways that actually advance the subject.

14. **Nigel**
October 18, 2005

With all due respect to them, a few words about the influence of Susskind, t'Hooft, and Hawking. Although Hawking radiation is undoubtedly a major contribution, Hawking has possibly made a couple of crackpot errors elsewhere. First, his application of Penrose's black hole math to the big bang, which seems to ignore the possibility that gravity might have a mechanism within the universe. Second, in 1976 he published 'The Breakdown of Predictability in Gravitational Collapse.'

This was taken seriously by Dr Leonard Susskind and Dr Gerard t'Hooft who were in the audience of Hawking's talk on the subject a few years later in San Francisco. Susskind is quoted in some BBC documentary saying that the lecture shocked him into believing that the Hawking 'breakdown of predictability' completely threw causality out of physics! Then in July 2004, Hawking announced he was wrong all the time…

15. **Thomas Larsson**
October 18, 2005

On young geniuses. Older people are usually better in normal science than youngsters because of their greater experience, but too much experience is a disadvantage when new thought patterns are necessary. Of course, people who did successful radical thinking in their youth can do great conventional science when they grow older. Just think of Dirac's wonderful work on constrained Hamiltonian systems, done at an age close to 60.

Witten is no counterexample. He was 33 when he, for better or worse, pulled the physics community through the first superstring revolution, and many others who jumped the string bandwagon were even younger. And most old-timers who did become string theorists, like Susskind, Veneziano and Gross, had once done dual resonance models or S-matrix theory, so they didn't really have to think in radically new ways. That Witten kept doing original mathematics for many years afterwards does not change this. He seems to have slowed down in recent years, though.

What 33-years-old today could, like Witten in 1984, change the direction of theoretical physics? Lubos Motl? 😉

16. **Chris Oakley**
October 18, 2005

Thomas,

We will perhaps never know what today's generation of youngsters engaged in particle physics research are capable of. At least, not as regards physics. Since the majority have been duped into believing that following the Superstring bandwagon is the only thing likely to be of any benefit to their careers, and since – on their own admission – this is still all light years away from actually *being* physics, we will never know what they might have achieved.

17. **Arun**
October 18, 2005

First, youthful creativity is most pronounced in mathematics and theoretical physics. This criterion should not be used in other areas where it is less true, for instance, great experimentalists have done crucial experiments at more advanced ages (and physics is primarily an experimental science, the discussion here shows that people say it a lot, but pay lip service to it, behaving as though Hawking and Witten and Einstein is all there is to physics).

Second, many of the breakthroughs wouldn't happen without the plodding work of actually dealing with messy reality. Who is going to do the actual work of measuring and building the enormous set of experimental results which are the bulwarks of theory?

Physics needs a balance of people – mess with that balance and you'll destroy the enterprise of physics.

18. **Not a Nobel Laureate**
October 18, 2005

It's certainly a truism that Physics is an experimental science. Pure reason will get you "proofs" like Hegel's that there can only logically exist seven planets.

However, given the how the number of HEP experiments has concentrated over the decades,
the usual suspects are still in charge.

Making bricks for the Pharoah, waist deep in mud and straw, is probably a better career choice.

19. **Dissident**
October 18, 2005

Doran, re. hidden variables, there's always this "old" guy:

http://www.phys.uu.nl/~thooft/

(scroll down to where he brings up "Fundamental aspects of quantum physics", check out the publications). His take is that both QM and GR will have to be modified in order to be reconciled. My own half cent's worth is that he's on to something. Penrose may or may not agree; his view seems to be more along the lines of QM, but not necessarily GR, being in need of revision.

Arun, " the actual work of measuring and building the enormous set of experimental results" is always going to be carried out by the same sort of people who've always done it: technicians, starving grad students and post-docs barely scraping by.

20. **Stephen**
October 18, 2005

Is anyone sure the supposed superiority of young physicists isn't just an example of [regression toward the mean]?

21. **Not a Nobel Laureate**
October 18, 2005

Always a pleasure to read about Physics

http://www.eurekalert.org/pub_releases/2005-10/jhu-neh101705.php

as an antidote to the Meta-physics of strings.

22. **Nigel**
October 18, 2005

QM and GR: the "stupid" physicist may be at an advantage in spending more time on this stuff, when brighter students are getting stuck into the delights of renormalised QED and ST.

"Dissident", are you sure that QM and GR need modification? Could be the maths is fine but GR can't be applied to cosmology (universe) because there is a gravity mechanism within the universe. This keeps GR maths intact, and perhaps makes the maths more clear physically.

As for QM and QFT, we know the fabric of space is filled with virtual particles. Normally particles like gas molecules can't carry transverse waves, only a solid normally allows transverse waves. But suppose the virtual particles have a spin, like real ones? Then you get transverse waves. Dr John Baez has some ideas on this for quantum gravity here http://math.ucr.edu/home/baez/loops05/ which seem to account for the light speed of gravity while preserving a pressure mechanism?

My understanding is that this is reinventing the wheel, since Maxwell's 1873 Treatise section 822-3:

"The … action of magnetism on polarised light [discovered by Faraday not Maxwell] leads … to the conclusion that in a medium … is something belonging to the mathematical class as an angular velocity … This … cannot be that of any portion of the medium of sensible dimensions rotating as a whole. We must therefore conceive the rotation to be that of very small portions of the medium, each rotating on its own axis… The displacements of the medium, during the propagation of light, will produce a disturbance of the vortices … We shall therefore assume that the variation of vortices caused by the displacement of the medium is subject to the same conditions which Helmholtz, in his great memoir on Vortex-motion, has shewn to regulate the variation of the vortices of a perfect fluid."

Am I alone in thinking we are going round in circles here?

23. **Quantoken**
October 19, 2005

Peter:

You described some observation of facts that we all know already. But what's your point? Are you saying it's a good thing or a bad thing? Are you complaining about something you don't like?

Yes it's going to be hard nowadays if a young man wants to get into an academic position and study physics. But is that a problem? I don't think there is any problem at all. We have a quite adequate number of physics professors teaching in universities, and actually, if anything, maybe a little bit too many of them, and if there is any shortage of professors, we can quickly replenish from freshly minted graduates. So what's the problem?

If a young man wants to become a physicist and he can't because the society doesn't need any more phycists than what it already has, then that's not a problem of the society, it's a problem of the young man himself. There are too many important things in the world that needs some young intelligent men to work on, so there could never be an over-abundance but shortage of the suply of real talents.

A while ago Mark Troden complained about the fact that not all of his students can get a faculty position, and he thought that's bad. I showed to him that if he educated just 12 students and each all becomes a faculty, and each of them also each educates another 12 students who all become physicists as they wished, so on and on. Then the simple math shows that the multiplication took less than 9 generations to exceed the earth's population. Such **exponential growth** is simply not possible.

So I told him a realistic expectation is he should expect at most one, and probably zero, of his students who could eventually become a faculty, and the rest evaporate, regardless how many students he put out, and regardless how hard his students work.

Quantoken

24. **Thomas Larsson**
October 19, 2005

QT, the physics community grew exponentially for almost century. In the US, the PhD production rate grew from about 1/year in 1870 to 1,000/year in 1970. It is unlikely that such a growth rate is sustainable for another century.

25. **Dissident**
October 19, 2005

QT, the problem is that physics professors are supposed to do two things: teach and research. As you point out, there is no major problem as far as the teaching goes. But if it is true that most breakthrough research is done by young people, the current situation with faculty averaging 60 means that breakthroughs are heavily disfavoured. This demographics is a a recipe for stagnation. And it does indeed seem to work pretty well…

26. **Somebody**
October 19, 2005

There is a saying that groundbreaking work seems to be mostly achieved by young physicists (say at age X), but on the other hand, if you look at any single, given physicist, his or her "best work" tends to be done at an age significantly greater than X.

It's population bias.

There are vastly more people in their 20s and early 30s working in particle physics than in their 40s and 50s, so it stands to reason that the former group produces a large fraction of the best work. On the other hand, they also produce a lot of not-so-great work, too, but those that do don't usually stick around into their 40s and 50s.

27. **Dissident**
October 19, 2005

Somebody wrote:
if you look at any single, given physicist, his or her "best work?? tends to be done at an age significantly greater

Maybe true of average physicists. Definitely not true of the true standouts like Newton, Maxwell, Einstein and the QM crowd.

28. **Paul Houle**
October 19, 2005

Senior physics think that a tight market for young physicists means they can skim the cream of talent. The reality might be the opposite: a bright young person who wants a career in science should choose any field BUT physics. Young people who stumble into graduate programs of physics today are the most clueless people about opportunities in science — the "gauntlet" doesn't select for the best people, but just for people who can take the most abuse.

29. **Dissident**
October 19, 2005

Paul, I remember an interesting piece of statistics from a few years back (maybe it's from the "What future" article?) showing that the fraction of top undergraduates in physics who choose to go on to grad school (in physics) has been declining since the 70s.

Nobody in the real world would be particularly surprised; it's a well known fact of business crises that the best people are the first ones to leave. They have the brains to see what's going to happen and they have the ability to find other lines of work. The last ones to leave are the clueless and those without alternatives.

30. **Doran**
October 19, 2005

Paul, pray tell how these physics undergrads are clueless of other opportunities in science, when we have been hearing about the horrible job market for academics in physics and watch our friends in biochemistry, engineering, and computer science pick up high paying jobs doing industry research for years. Also, why are departments still encouraging those who actually want to go to graduate school in physics despite more lucrative options in other fields.

Now physics is hard, and I can attest that the undergraduate curriculum does resemble a weeding out process, but thats how all the sciences at a top-level school are like. And who stick it out, those with the skills and the determination to master the material. Dissident, the first ones to jump ship are often those who came in thinking physics was easy and got a rude awaking.

I must admit my grades are not stellar, but I cannot help but feel a bit miffed by this. I believe most physics students who decide to go to graduate school are fully aware of the limbo that awaits them, but never-the-less are drawn to an intense and rewarding study of physics. To degrade that desire is only hurting the field, by dissuading anyone from even considering the subject to begin with.

I must agree with QT, that if one cannot find employment in academia, there are numerous other avenues that need intelligent technically trained individuals. My personal point is that maybe it would be better to encourage those interdisciplinary connections as well as the rigorous physics studies, rather then accusing the next generation of researchers as being adrift without a clue.

31. **Quantoken**
October 20, 2005

Doran asked: "why are departments still encouraging those who actually want to go to graduate school in physics despite more lucrative options in other fields"

Physics departments NEED to recruit and train large amount of graduate students, regardless whether the academy community needs that many new Ph.Ds or not. That's what university departments do and that's how they get fundings and survive at all. Can you imagine a Harvard physics department which no longer admit any graduate student for the next 10 years? Or can you imagine that Mark Troden trains just one student of his, instead of 12, knowing that the realistic expectation is at most one of his students can one day become a faculty? No he can't. Training students is part of Mark Troden's job that he gets paid for. So he will continue to train as many as he can, regardless of how his students will end up be.

It's like a fish would lay a couple million eggs at a time, most simply got eaten up by other fish and the realistic expectation is only one egg out of the millions will grow up to an egg-laying fish. Would a fish then lay less number of eggs so as not to be wasteful, or not to feed its enemies? No, a fish will still try to lay as many eggs as it can. Just like a physics professor will always try to train as many students as he can.

It's all Darwinism whether it's the nature or the human society.

Quantoken

32. **Thomas Larsson**
October 20, 2005

Chris,

Gell Mann did not discover the eightfold way at age 23. He was rather something like 33; I think he was born in 1927. Maybe you thought of the Gell-Mann and Low theorem from 1953.

33. **Chris Oakley**
October 20, 2005

Hi Thomas,

According to this:

http://www.answers.com/topic/murray-gell-mann

He was born in 1929 and invented the Strangeness quantum number (not the Eightfold Way as I originally said) at the age of 24.

Well, I did say that the information was off the top of my head.

Somebody called "Somebody" pointed out that the majority of people engaged in research are in fact quite young, i.e. PhD students and post-docs. This may be true but they definitely do not have the whip hand. Their relationship with the relics who actually run their departments is more like Apprentice/Jedi Master, and my point is simply that this is completely wrong, as the young person is the one who is far, far more likely to come up with the goods provided that he/she is given the space to do so. I have to be honest here – my D Phil (PhD) supervisor (between 1982 and 1984) was great about letting me do what I thought best. The problems only started to arise when I wanted to do post-doctoral work. At that point the old timers were able to demonstrate the consummate ease with which young, dissenting voices could be silenced.

34. **Dissident**
October 20, 2005

Sorry Doran, but you're looking at this from an undergraduate's perspective. The old guys contradicting you have been where you are now, and well beyond.

Sure there's a always a whole bunch of fresh undergrads going into physics, finding it too hard and "jumping ship". I don't think anyone (other than you) taking part in this discussion ever considered them. They really don't count. The people I and the other oldies here are writing about are those who do graduate; in particular, the top of the class.

I can not underscore enough what Quantoken already told you: physics departments run on grad students and post-docs. They are extremely cheap labour who do everything from teaching labs and correcting homework to doing the actual research which professors put their names on. This system is in essence the medieval one of apprenticeship. In modern terms, it's a system of exploitation, by the old of the young.

As if that weren't enough, funding also tends to be directly related to the number of students. If you can demonstrate a large demand for whatever it is that you teach, you will get more funding; if you can't fill all seats, you will see cuts and eventually be forced to fire faculty, maybe even shut down the whole department.

If you understand all this and still want to try for a "career" in academia, you have admirable guts and may even deserve to be cheered on. But do not delude yourself about what you're up against.

35. **weichi**
October 20, 2005

There seems to be a subtext here that physics is a particularly poor choice for people who want to go into science. But are job prospects in other fields of science really that much better?

My guess is that in academia the situation is no better, but there are more opportunities in industry for other fields – biosciences in particular, perhaps also for chemistry? Does anyone have any numbers for other fields?

We should also keep in mind that for certain fields of physics, there will never be job opportunities in industry. My understanding is that industry hires condensed matter experimentalists to do work that is at least similar to academic research in condensed matter, but I'm sure that no one gets hired by industry to do theoretical research that is similar to string theory. So choice of field within physics also has an effect, perhaps a large one.

36. **D R Lunsford**
October 20, 2005

About age: I suspect every physicist has (at least) one good idea, and when this shows up is not a function of age, rather insight (a combination of experience, technique, and intuition). And, one may have a good idea, but not realize for years. Certainly intuition is highest when inexperienced, because you don't know what you can't know!

So it's more like a Heaviside function, theta(X – age) where X is when you have your idea, and age could be anything between diapers and senility.

-drl

37. **Not a Nobel Laureate**
October 25, 2005

Anecdotally speaking.

It's unfortunate that the culture in academic physics is such that any other path than the academic one leading to a professorhips is seen as failure when the reality is that that most graduates will go on to do something else – the few perceptive ones by choice, the rest by default – often with considerable, but pointless, bitternes.

I've met many exceptionally bright people outside of academic physics – sorry to say, but these days the best and the brightest are no longer in HEP. HEP today "reads better than it lives".

38. **Eli Rabett**
October 25, 2005

A bit late, but a short comment on why the job market in physics dropped dead in the early 70s:

1. The costs of the Vietnam war, amplified by a recession limited the Federal budget for research

2. Universities that had been expanding like gangbusters to meet the demands of the baby boom, found there was a baby bust.

3. New universities established to meet the growth in enrollment (e.g. UMass Boston as one example) had hired complete departments of relatively young faculty in the mid-sixties, but then hired no one else for thirty years. This cohort is now retiring.

From one who was a bit late.

Hiding in the Mirror

October 18, 2005
Categories: Book Reviews

I've just finished reading Lawrence Krauss's new book Hiding in the Mirror: The Mysterious Allure of Extra Dimensions, from Plato to String Theory and Beyond, and it's very, very good. Scientifically, the book covers a lot of the same material as Lisa Randall's Warped Passages, but it's about half as long and has a wider perspective, with writing that is pithy and entertaining. Krauss's topic is not just the science of extra dimensions, but the history of various ways the idea has turned up in art and literature, and the whole question of why people find it so fascinating.

He begins by telling the story of an episode of the *Twilight Zone* TV program that had quite an impact on him when he was very young. It involved a little girl who falls into another dimension and is saved by intervention of a physicist. Krauss notes that "We all yearn to discover new realities hidden just out of sight", but that "Ultimately our continuing intellectual fascination with extra dimensions may tell us more about our own human nature than it does about the universe itself." He writes about a wide range of different writers and artists who have been fascinated by the idea of extra dimensions, and some of the historical and cultural context for their work. Much of this I didn't know anything about, although his description of the science fiction short story "And He Built a Crooked House" by Robert Heinlein brought back memories of my childhood, since I had found that story very striking, but hadn't thought about it in a very long time (it involves a house based on a tessaract, a 4d version of a cube). Another interesting piece of history he unearths is that Marcel Duchamp's famous piece *The Bride Stripped Bare by Her Bachelors, Even* (also known as the *Large Glass*), was heavily influenced by ideas about projecting from four dimensions, and that Duchamp spent a lot of time trying to learn about this, including reading Poincare.

Krauss writes that, while fascinated by the idea, he himself remains a skeptic (or at least agnostic) about the actual existence of physical extra dimensions. He tells the history of attempts by theorists to use extra dimensions, from 19th century conjectures that atoms were points where a four-dimensional etherlike field leaked into three-dimensional space, to Kaluza-Klein models and the heterotic string, ending up with recent braneworld scenarios. He describes the ideas behind this research concisely, and also explains exactly what some of the problems with these ideas are. Along the way he comes up with various obscure and interesting pieces of the history of physics I'd never heard before, for instance that in 1928 an English experimentalist named R. T. Cox found evidence of parity violation, but his results were not taken seriously.

On the topic of string theory and braneworlds, Krauss promises to be not like Fox News (i.e. actually "Fair and Balanced"), but he has truly scathing things to say:

But in the ever-optimistic string worldview, there are no embarassments… For these 'true believers', every new development provides an opportunity to confirm one's expectations that these ideas ultimately reflect reality.

… string theory might instead do for observational cosmology what it has thus far done for experimental elementary particle physics: namely, nothing.

In short, the as-of-yet hypothetical world of hidden extra dimensions had, for many who called themselved physicists, ultimately become more compelling than the world of our experience.

This embarassment is solved in the way other similar confusing aspects of string theory and M-theory are sometimes dealt with: Namely, it is assumed that when we fully understand the ultimate theory, everything will become clear.

Over the past five years, hundreds if not thousands, of scientific papers have been written considering cosmological possibilities that might be associated with Braneworld scenarios. One cannot do justice to all of them, but the greatest justice I could probably do to many of them is to not mention them here.

What the notion of large or possibly infinite extra dimensions has done is borrow some of the facets of string theory while ignoring the bulk of the theory (forgive the pun), about which, as I have explained, we have only the vaguest notions. It seems to me to be a very big long shot that an apparently ad hoc choice of what to keep and what to ignore will capture the essential physics of our universe.

This has resulted in yet another fascinating sociological metamorphosis of the theory, with warts becoming beauty marks.

… the anthropic principle is something that physicists play around with when they don't have any fundamental theory to work with, and they drop it like a hot potato if they find one.

This finally brings up back to M-theory. Faced with the prospect that the theory may ultimately predict a virtually uncountable set of possible universes, some string theorists did a 180-degree about-face. Instead of heralding a unique Theory of Everything that could produce calculable predictions, they are now resorting to what even a decade ago they may have called the last refuge of scoundrels. But, when string theorists take a position, they do it with flair.

…if the landscape turns out to be the main physical implication of the grand edifice of string theory or M-theory… we might be left with the mere suggestion that anything goes. What was touted twenty years ago as a Theory of Everything would then instead have turned quite literally into a Theory of Nothing.

Krauss ends his book with an epilogue describing conversations with Gross, Wilczek and Witten about string theory. Wilczek is a skeptic, annoyed by the excessive claims made for the theory. Witten is quoted as saying that string theory "is a remarkably simple way of getting a rough draft of particle physics unified with gravity. There are, however, uncomfortably many ways to reach such a rough draft, and it is frustratingly difficult to get a second draft." He justifies work on string theory partly through progress it has led to in the understanding of strongly coupled gauge theories.

Gross is described as convinced "that the theory is simply too beautiful *not* to be true", an attitude that strikes Krauss "as sounding like religion more than science." With this, Krauss ends his book by quoting Hermann Weyl:

My work always tried to unite the true and the beautiful, but when I had to choose one or the other, I usually chose the beautiful.

and concludes:

So it is that mathematicians, poets, writers, and artists almost always choose beauty over truth. Scientists, alas, do not have this luxury, and can only hope that we do not have to make this choice.

Here, to some extent I part ways with Krauss. As I've explained elsewhere, I don't find the 10 dimensional heterotic superstring compactified on a Calabi-Yau to be in any sense beautiful, and attempts to connect string theory with physics lead to appallingly ugly constructions, strong evidence that they are on the wrong track. Absent useful experimental results, the pursuit of compelling new mathematically beautiful insights into fundamental physics is one of the few promising ways forward. But to go down this road successfully you have to be honest about what is mathematically beautiful and what isn't.

All in all, this is by far the best book that I know of on the topic of recent speculative work on fundamental particle physics, and I strongly recommend that anyone who enjoys reading about this should get themselves a copy.

Update: An interview with Krauss about the book just appeared in the Cleveland Plain Dealer.

Update: It was pointed out to me that the way I compared Krauss's book to Randall's here wasn't really fair to hers since she was trying to do something different, so for non-specialist readers, the books have different functions. I submitted this review to Amazon, and edited it a bit so that it would be more appropriate for people looking for a comparison of the two books. The main change was the addition of the following paragraph:

"While they are ultimately concerned with the same speculative ideas about extra dimensions, Krauss and Randall's books are in many ways different. Randall is writing about her own research work, so on the one hand she is a partisan for these ideas, on the other she gets to tell the inside story of exactly how she came up with them. She goes to a lot of trouble to dig in and try and explain in as simple terms as possible the details of the physics that motivates this research, as well as exactly what it is trying to achieve, how it has evolved in recent years and where it seems to be going. Krauss also covers these topics, but is (justifiably in my view) more of a skeptic, and sets the whole story in a wider context of the long history of this kind of speculation. If you've read Randall's book, you should seriously consider reading Krauss for a different point of view. If you read Krauss and want a much more extended exposition on some of these topics, Randall is the place to go."

   "I don't find the 10 dimensional heterotic superstring compactified on a Calabi-Yau to be in any sense beautiful."

   I've read the above statement many times on this blog, but now it strikes me that I agree with you. The whole structure, looked at from a distance, seems unnatural and contrived: You start in 10 dimensions with lots of symmetries, then you have to get rid of 6 dimensions and most of the symmetries.

   On the other hand, starting with a type II string that has no internal symmetries in 10 dimensions, and obtaining these at the expense of the extra dimensions looks better. At this moment.

2. **Lubos Motl**
   October 18, 2005

   Dear Peter,

   are you serious that this book covers "very much the same material" as the Warped Passages? I find such a statement incredible. First of all, Krauss understands physics of extra dimensions roughly as well as you do, he's never worked or thought about them seriously, so it is physically impossible for him to write anything meaningful about them. Maybe you wanted to say that it tries to cover very much the same material as Abbott's Flatland?

   Best wishes
   Lubos

3. **woit**
   October 18, 2005

   Hi Lubos,

   Yes, I'm very serious that the book covers the same material as Warped Passages, but does a better job. I was going to put something in the posting about how string theorists' reaction to the book would be to denounce Krauss as incompetent, even before they read it…

4. **blank**
   October 18, 2005

   "… they are now resorting to what even a decade ago they may have called the last refuge of scoundrels."

   That sums it up pretty well. Particle theory over the past decade has been marked not by objective progress, but rather receeding standards.

5. **Anonymous**
   October 18, 2005

   The piling up of symmetries and dimensions that one has to then discard to match the real world resembles the cycles upon epicycles needed in the Ptolemaic theory of the solar system, 'cause circular motion was sacrosanct. Oh, for a Kepler!

6. **Tony Smith**
   October 18, 2005

   Peter, as you and Krauss noted, "… Marcel Duchamp's famous piece The Bride Stripped Bare by Her Bachelors, Even (also known as the Large Glass), was heavily influenced by ideas about projecting from four dimensions …". Here are some (in my opinion) relevant quotes from Duchamp, as found in the book Dialogues with Marcel Duchamp, 1966 interview with Pierre Cabanne, Plenum (Da Capo) (1971, 1987):

   "… I never was the scientific type. … What we were interested in at the time was the fourth dimension. … Povolowski … was a publisher, in the rue Bonaparte. … He had written some article in a magazine popularizing the fourth dimension, to explain that there were flat beings who have only two dimensions, etc. … That was working in my head while I worked, although I almost never put any calculations into the "Large Glass". Simply, I thought of the idea of a projection, of an invisible fourth dimension, something you couldn't see with your eyes. … I thought that … the fourth dimension could project an object of three dimensions, or, to put it another way, any three-dimensional object, which we see dispassionately, is a projection of something four-dimensional, something we're not familiar with. It was a bit of sophism, but still it was possible. "The Bride" in the "Large Glass" was based on this, as it were the projection of a four-dimensional object. … Only the "Large Glass" interested me, … I wanted to be free of any material obligation, so I began a career as a librarian, which was a sort of excuse for not being obliged to show up socially. … I … went to take courses at the School of Paleography and Librarianship. … I knew very well that I would never be able to pass the examination at the school, but I went there as a matter of form. It was a sort of grip on an intellectual position, against the manual servitude of the artist. At the same time, I was doing my calculations for the "Large Glass". … The "Large Glass" constitutes a rehabilitation of perspective, which had then been completely ignored and disparaged. For me, perspective became absolutely scientific. … It's a mathematical, scientific perspective. …".

   Could the "… completely ignored and disparaged …" perspective in art correspond, in today's world of physics, to the 1970s Standard Model plus Gravity view of physics based on detailed contact with experimental results ?

   Has the superstring community completely ignored and disparaged the building of physics models based on detailed contact with experimental results ?

   Does today's world of physics need a new Duchamp to rehabilitate the theoretical physics by building models based on detailed contact with experimental results from a

"… mathematical, scientific perspective …" ?

October 18, 2005

My only problem with Krauss was in one of his popular books on physics in science fiction. He claimed that the giant flying saucers in the movie Independence Day wouldn't have been able to levitate over the Earth without flattening everything beneath. I have no problem with F=MA, but hasn't he heard about neutrino drives? All the propulsive efficiency with none of that annoying matter interaction! (He also didn't stop to consider that the saucers could be made of single-molecule-ply superstrong materials with ultra-high strength to mass, but I wouldn't expect a particle guy to think about advanced materials.)

8. **D R Lunsford**
October 18, 2005

Most talk of extra dimensions is idle speculation, because the spine of physics, irreducibility, is optional.

-drl

9. **Aaron**
October 18, 2005

"string theorists"

Be careful with those generalizations, please.

10. **woit**
October 18, 2005

Hi Aaron,

Point taken, I should have mentioned that I was thinking of the reaction of certain string theorists, not all of them. I'm certainly curious to see how string theorists in general will react to Krauss's book. Will they respond to it with the seriousness it deserves, or like Lubos, just attack the author as not knowing what he is talking about? So far the count is 0-1. But the book isn't even quite in stores yet….

11. **Tung**
October 19, 2005

RT Cox, as mentioned here, had done important work on the foundation of probability theory, which has become the cornerstone of the view that probability is a kind of generalisation of aristotelian logic.

12. **Quantoken**
October 19, 2005

Lubos said: "…so it is **physically** impossible for him to write anything meaningful about them"

Absolutely correct! It is **physically** impossible for **ANYONE** to say anything meaningful about extra dimentions. Because extra dimentions are simply imaginative and none-physical. How could any one say anything physical about something that's pure imaginative? There is not the slightest evidence that any extra dimention exists in nature.

And I object to Peter using the term "science of extra dimentions". There is no "**science**" of extra dimentions. Because extra dimentions are simply not qualified to be scientific. You can say "research of extra dimentions", but it's not science. Not all research activities are science.

Quantoken

13. **Shantanu**
October 19, 2005

FWIW, Spires hepnames page indicates that Lawrence Krauss was the thesis
advisor of Raman Sundrum (of Randall/Sundrum)
See http://www.slac.stanford.edu/spires/hepnames/

14. **Richard**
October 19, 2005

So, Lubos, it is not possible to say meaningful things about things you are not professionally working on? Oh. So tell me, which is your latest paper about global warming?

15. **The Anti-Lubos**
October 19, 2005

I've asked it before, but I'll ask it again.

Does anyone like him? And if so, how and why?

16. **plato**
October 19, 2005

I for one, find this a very important blog entry from the perspective of responsibility, in explaining these extra dimensions.

I sense this in Peter's blog entry, and of course, the underlying skepticism about this is still no secret. There have been attempts to define this issue much clearer and directly, in experimental fashion.

So it is not without some historical implications that early thoughts could have been exceeded, to relate this issue, and try to make sense of it. It is still a responsible function that we recognize as necessary.

The artistic implicatons of "cubism" is one I found related to discrete measures, and to see this developing aspect in relation to science, is no less important as we engage how such extra dimensions might be seen as a continuity in topological form?

Would this be incorrect?

17. **Wolfgang**
October 19, 2005

Anti-Lubos,

> I've asked it before, but I'll ask it again.

PS: I like Lubos.

18. **plato**
October 19, 2005

Dissident:*If you perform an experiment in which some of the energy you put in seems to disappear somewhere, unaccounted for, then yes, you have some explaining to do. Conservation of energy is not something we'd give up lightly; rewriting all those textbooks would be exhausting… but large extra dimensions would certainly not top the list of things to consider.*

First of all, "missing energy?? is a normal feature of collider experiments, since you can't expect to catch all the stuff that comes out of them. You have two particle beams banging into each other inside a tunnel of finite width; any decay products flying off into the tunnel are lost. Around the collision point, you have detectors which, while huge and most impressive, also have blind angles and – most importantly – finite size.

19. **Dan**
October 19, 2005

Quantoken,

your extra-dementia clearly determines your opinion about extra-dimentions. How's your GUITAR?

20. **Quantoken**
October 19, 2005

Dan:
I am making pretty good progress in GUITAR but I have decided not to talk about it until I can figure out the whole thing in one piece.
Privately I wish large extra dimentions exist. It will make life much easier. Surgical incisions will not be needed for a doctor to operate on a patient's internal organs, for example. They can be reached through extra dimentions, without having to cut up the patient's chest. But there may be other inconveniences. Prison inmates may escape through extra dimentions without having to dig a secret tunnel. And compressed air within a tire could leak out through extra dimentions, even though the surface of the tire is perfectly tight.
Super String Theorists could save their time and energy in their invain effort to search for extra dimentions, by humbly begging the teaching of magicians, who are the only people who have figured extra dimentions out already. For there is no other rational explanation how they managed to cross one metal ring into another one and then remove them freely, without breaking the rings to do that. The topology simply does not allow that unless there is extra dimentions 🙂
Of course, that is not science.

Quantoken

23. **ks**
October 20, 2005

Maybe L. Krauss and Peters books will be the last critical examinations of ST by ST outsiders before dropout literature enters the market? Until than ST does not have to harm about an "objective enemy" (Stalin). By the way I find Lubos attitude towards Krauss somehow strange for a person who criticises climate research as a well informed ousider. If sectarianism or closed society counts so much one may ask for the amount of scientific papers he published in this area.

24. **Thomas Larsson**

October 20, 2005

Hmmm, that's not obvious to me. It's obvious that you could escape from prison through extra dimensions, but I'm not sure you could pull rings apart in any dimension.

Manifolds of dimension m and n embedded in D-dimensional space generically intersect along an (m+n-D)-dimensional manifold (i.e. codimensions add). They are knotted if m+n-D = -1. E.g., two curves (m=n=1) are knotted in D=3 dimensions, two 2D surfaces are knotted in D=5 embedding dimensions but intersect along a 1D curve in D=3, etc.

25. **Bryan**
October 20, 2005

'Maybe L. Krauss and Peters books will be the last critical examinations of ST by ST outsiders…' KS

I disagree, because when details come out next March there may be a Congressional inquiry into what went wrong with ST…

26. **Kris**
October 20, 2005

Brian, what are you expecting in March? Seems you have something specific in mind…

27. **Bryan**
October 21, 2005

Kris: was thinking of the publication of a book about ST being "Not Even Wrong". Think it might stir up trouble!

28. **Juan R.**

Well, perhaps, you forget that many particle physicists, and by extension string theorists, believe that they can talk about everything since are -they believe- more intelligent that other guys.

Newer have you heard abut fist class and second class scientists? Unfortunately some physicists still believe that a chemist is a kind of 'second-class physicist'.

This would imply -of course, it is a completely nonsense- that a physicist 'can' talk about physics, chemistry, biology, environment whereas chemists or biologists cannot talk about physics.

Some time ago, when i was in the *Colegio official de químicos de Galicia*, an 'iluminated' group of physicists proposed that, in Spain, physicists could gave courses of both physics AND chemistry in Schools but chemists can only gave courses on chemistry!

Of course, was a nonsense and the corresponding law newer was approved…

When people like Gross, Witten, Greene, Weinberg, Anderson, or even Gell-Mann talk about chemistry only say either irrelevant/wrong things or outdated stuff.

29. **Bryan**
October 21, 2005

http://www.indiadaily.com/editorial/5061.asp

The article above reports the discovery of extra dimensions. Is this premature, like cold fusion, or real. It mentions that the extra dimensions are really big so they will enable us to do the things Quantoken suggests, like operations without any need to cut skin or tissue at all, and it may account for punctures in tyres where you can't immediately see a hole. 😉

30. **Nigel**
October 21, 2005

Juan – I think Lubos is not the bad guy really, he has just got mixed up with the wrong crowd. The only reason he asserts views on every aspect of everything is that he is qualified to do this, since string theory – his expertise area – is a 'theory of everything'!

31. **Arun**
October 22, 2005

Now that I have Roger Penrose's "Road to Reality" in hand, I see that he has a plethora of objections to string theory. Are there available any coherent replies to Penrose's doubts?

32. **Wolfgang**
October 22, 2005

Arun,

Lubos Motl stated that the objections of Roger Penrose are "obvious nonsense", but from what he wrote it is clear that he never read the relevant parts of the book.

Some of the doubts have been expressed also by Lee Smolin and Peter (e.g the question if string theory is indeed finite and consistent) and have provoked some responses from string theorists.

I am not aware that the main argument of Penrose (M4xCY is unstable against perturbations, in particular in a classical approximation) has ever been seriously discussed or shown to be incorrect.

I am personally not too impressed by his argument(s), but I cannot say if his classical approximation is relevant or not.
Also, I am not convinced of his discussion of quantum theory in general.

33. **Arun**
October 23, 2005

Wolfgang,

Motl's remarks don't help me, they don't count as a coherent reply. Obviously, there is plenty of room for disagreement with Penrose.

What I'd like is the following type analysis, hopefully that addresses the same audience that Penrose is addressing; or if not, to Penrose himself, and he can tell us if he is adequately answered.

1. For some objections, Penrose is making an unwarranted assumption about the nature of reality, or he has utter misunderstood string theory.

2. For some objections, Penrose is on the mark, and this is an area where string theorists have to do further research to meet his challenge.

3. For some objections, there is a good physical argument, even if no mathematical proof, that resolves Penrose's objection.

34. **Steve Myers**
October 24, 2005

It's long been known that adding dimensions drives volume to the surface (it's called "The Curse of Dimensions"). So how does that affect a field?
Also remember you can always get a symmetry by adding a dimension — but there's no reason it is physically real.

35. **bryan2**
October 24, 2005

Thomas Larsson Said:
"Manifolds of dimension m and n embedded in D-dimensional space generically intersect along an (m+n-D)-dimensional manifold (i.e. codimensions add). They are knotted if m+n-D = -1. E.g., two curves (m=n=1) are knotted in D=3 dimensions, two 2D surfaces are knotted in D=5 embedding dimensions but intersect along a 1D curve in D=3, etc."

An easy way to visualize this is the case where m=n=0, and D=1. m and n are each 2 points separated by a fixed distance. They are knotted when a point from one is in between the point of the other. When D=2, m and n are no longer knotted since they have another direction to move in.

36. **Juan R.**
October 26, 2005

Nigel note i do not said that Lubos or other string theorists were "bad guys". I simply said that are a bit confounded.

Yes they believe that are working in the TOE, but this is false.

See my recent post on sci.physics.research.

I wait a hot debate on this

Juan R.

Center for CANONICAL |SCIENCE)

37. **Juan R.**
October 31, 2005

Deligne Conference

October 20, 2005
Categories: Uncategorized

Yesterday I went down to the Institute in Princeton with my friend Oisin McGuinness to attend one day of a conference in honor of Pierre Deligne that is going on there this week. Deligne has spent most of his career at the IHES and at the Institute, and this conference was in honor of his 61st birthday (I suspect they initially planned it for last year, but it got pushed back).

Deligne worked with Grothendieck at the IHES during the late sixties, and is perhaps best known for his proof of the Weil conjectures completed in 1974, an achievement which won him a Fields medal in 1978. The Weil conjectures motivated much of the work by Grothendieck and others in algebraic geometry during the fifties and sixties, and Deligne was able to finish a proof using Grothendieck's machinery as well as some different ideas of his own. For more about Grothendieck, visit the Grothendieck Circle web-site. Grothendieck left the IHES around 1970, and later became a recluse, increasingly hostile towards his former colleagues, especially Deligne, who he attacked in his long unpublished manuscript "Recoltes et Semailles." Several people told me that at the conference banquet held Tuesday night, after an array of different speakers rose to praise Deligne, especially for his generosity with his ideas and help to others, Deligne himself spoke and said that he was only repaying the debt he owed to Grothendieck, who himself was famous for such generosity.

One of the conference talks I heard was by Gerard Laumon, who described some of his work with Ngo Bau Chau on the Fundamental Lemma. Various lecture notes on this subject are available here. Laumon emphasized the role of equivariant cohomology in the proof, a method pioneered by Goresky, Kottwitz and MacPherson. Equivariant cohomology techniques are also crucially behind much work on topological quantum field theory, although of course the context is quite different there.

   October 21, 2005

   "Several people told me that at the conference banquet held Tuesday night, after an array of different speakers rose to praise Deligne, especially for his generosity with his ideas and help to others, Deligne himself spoke and said that he was only repaying the debt he owed to Grothendieck, who himself was famous for such generosity."

   Wow. That is very touching.

2. **Tom**
   October 21, 2005

   Thanks for reporting and for the lecture notes. Do you know by any chance if they made some videos of the talks ?

3. **MathPhys**
   October 21, 2005

   Grothendieck was very generous with his ideas (and 1000's of pages of published manuscripts) up to his breakdown in the late 60's and break up with the mathematical community. Things changed after that point, as he became increasingly bitter, and started accusing people of stealing his ideas and/or not giving him credit. Some of the things he said in his latter (autobiographical)writings were mean and paranoid.

   In honor of Weyl:

   What is the analog in distant parallelism, of Weyl's ansatz in distant measure (Riemannian geometry)? Has anybody investigated? A first guess is

   L(A) g_mn = Am An

   where L(A) is the Lie derivative. It looks to me like "distant parallelism" gets changed to "distant parallelism with respect to an arbitrary quadric" (just a guess, haven't investigated yet). It would be very interesting if the covariant derivative in this looked like dm + i Am.

   -drl

4. **biophysics**
   October 23, 2005

   Peter, I've seen a couple references to Nature on the site – how much of the journal do you manage to read? As a theorist in biophysics I actually feel like I have to get through most of Nature and Nature Genetics in addition to the physics journals (mostly PRL and PRE and, most of all, arxiv; of course I still indulge my particle hobby and glance at PRD and hep-th)..but I always wondered how many people (especially in the particle community) read Nature.

5. **woit**
   October 23, 2005

   I confess that my reading of Nature has always been kind of like just reading the cartoons in the New Yorker, i.e. I ignore the research articles (except on very rare occasions), and just skim the news items and things like book reviews and essays. Few technical articles in the fields I really know about (math and particle physics) ever appear in Nature, and when they do, they've often been placed there by people who are more interested in getting their names in the popular press than in communicating with their fellow physicists or mathematicians (who generally don't read Nature). Maybe "Nature Physics" will be different.

   Until a few months ago I used to skim copies of Nature when I saw them appear down in the library. More recently I tend to look at the online version.

   Nature 437, 1095 (20 October 2005) | doi: 10.1038/4371095a
   An explorer and surveyor

   Frank Wilczek1

   1. Frank Wilczek is at the Center for Theoretical Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts, 02142, USA.

   Top of page
   Abstract

   Hermann Weyl made prescient contributions to both mathematics and physics, but also strove to understand reality as a whole.

   Hermann Weyl was, according to Fields medallist Michael Atiyah, "one of the greatest mathematicians of the first half of the twentieth century". Every great mathematician is great in their own way, but Weyl's way was particularly special. Unlike most modern scientists who choose one or a few specific areas to explore and look neither sideways nor back, Weyl surveyed the whole world. He sought truth and beauty with a discriminating and far-seeing eye.

   Weyl's most unique work is Philosophy of Mathematics and Natural Science. No one else could have written it, and no other book I know is like it. I have consulted it many times, and each time I've come away enriched. My main purpose here is to direct readers to that book. But since space remains, let me add some background information.

Weyl, who died in 1955 at the age of 70, was a student of David Hilbert at the Georg-August University in Göttingen, Germany, and thus stood in the line of intellectual descent from Carl Gauss, Bernhard Riemann and Lejeune Dirichlet. Upon Hilbert's retirement, Weyl was invited to take up his chair, but conditions in 1930s Germany and an attractive offer from the new Institute for Advanced Study conspired to bring him to Princeton, where he stayed. With Albert Einstein and John von Neumann, Weyl made the trinity of refugee stars that gave the institute its inimitable scientific lustre.

Einstein and von Neumann had both grown up in the grand German literary and pan-European cultural tradition that was rocked and then shattered by the two world wars. But more than the rebellious Einstein or the protean von Neumann, Weyl embodied that tradition, and his Philosophy of Mathematics and Natural Science reflects it in focus, style and erudition.

The main body of text was written in German in 1926, as an article for R. Oldenburg's Handbuch der Philosophie. In 1949, for the English translation, Weyl altered many details and added seven appendices, comprising almost a hundred pages. These centre on relevant scientific events in the intervening years — his passages on Gödel's theorem, and on quantum mechanics and causality are especially brilliant. But the core of the book had its genesis in the vanished handbook tradition of magisterial reviews in natural philosophy.
Unfortunately we are unable to provide accessible alternative text for this. If you require assistance to access this image, or to obtain a text description, please contact npg@nature.com

ARCHIVES OF THE INST. OF ADVANCED STUDY

Hermann Weyl touched on questions that are relevant today.

In the introduction, Weyl declares the roots of his literary style: "I was bound by the German literary and philosophical tradition in which I grew up." As an example of that style, let me quote a passage that I think ranks among the most beautiful and profound passages in all literature: "The objective world simply is, it does not happen. Only to the gaze of my consciousness, crawling along the lifeline of my body, does a section of this world come to life as a fleeting image in space which continuously changes in time."

Weyl's work is also remarkable for its erudition. René Descartes, Gottfried Leibniz, David Hume and Immanuel Kant enter into the discussion as familiar friends. From time to time important literary or philosophical passages are quoted in the original French, German, or even Greek. Weyl's erudition is not vain display — he is far above that — but a touching assumption of shared culture. Of course the reader will feel at home in this milieu, he seems to assume.

In his biographical memoir of Weyl, Atiyah also talked about Weyl's work in mathematics, saying: "The last 50 years have seen a remarkable blossoming of just those areas that Weyl initiated. In retrospect, one might almost say that Weyl defined the agenda and provided the proper framework for what followed." Weyl's contributions in physics were more sporadic, but they were significant, and likewise remarkably prescient. In particular, Weyl proposed, and named, the concept of 'gauge invariance', which came to dominate fundamental physics during the second half of the twentieth century.

Evidently, Weyl's intuitions have an excellent track record. By now, parts of the Philosophy of Mathematics and Natural Science are dated, of course. Those parts retain interest as intellectual history, because Weyl's understandings, being close to the best that was possible in their time, serve as benchmarks. But beyond that, Philosophy of Mathematics and Natural Science touches great questions that remain very much alive. Near the end of the book, after a penetrating critique of the concept of causality, Weyl turns to what he calls the body–soul problem — what we know today as the problem of consciousness.

"It is an altogether too mechanical conception of causality that views the mutual effects of body and soul as being so paradoxical that one would rather resort, like Descartes, to the occasionalistic intervention of God or, like Leibniz, to a harmony instituted at the beginning of time.

The real riddle, if I am not mistaken, lies in the double position of the ego: it is not merely an existing individual which carries out real psychic acts, but also 'vision', a self-penetrating light (sense-giving consciousness, knowledge, image, or however you may call it); as an individual capable of positing reality, its vision open to reason; 'a force into which an eye has been put', as Fichte says."

The fullest enlightenment comes only to those who, like Weyl, discern its absence, seek it, and recognize it when it arrives.

Talks at KITP

October 21, 2005
Categories: Uncategorized

There have been several recent interesting talks at the KITP in Santa Barbara as part of their program this semester on [Mathematical Structures in String Theory]. Last week Greg Moore gave a beautiful talk on [Mathematical Aspects of Fluxes]. It's a sad commentary on the state of the field that he felt it necessary to begin his talk by apologizing that the work he was describing didn't seem to have anything useful to say about the Landscape.

This week Graeme Segal spoke about [On the Locality of the Statespace of Quantum Field Theory]. He is trying to understand the right way to axiomatize the way in which the Hilbert space of a QFT depends on the boundary of space-time in a local fashion. In his talk he worked out things for the case of a free scalar on an arbitrary manifold. Also this week, [Peter Teichner] and [Stephan Stolz] spoke on their work on generalized cohomology and QFT, motivated by trying to understand the relation of elliptic cohomology and conformal field theory. Teichner gave the [first part of the talk] on Tuesday, Stolz gave the [second part] on Thursday. For more about their work, see some [earlier comments of mine], their paper [What is an elliptic object?], and an [earlier survey talk by Teichner at the KITP].

1. **Dimitri Terryn**
   October 24, 2005

   Hi Peter,

   You might be interested in this. I recently translated an interview with Renate Loll of Utrecht. The article has a fairly critical view of String Theory, along with comments on her own research and the position of women in science (Lubos is going to love this 🙂).

   Here is an exerpt. If you want the entire article, give me word.

   Superstring Theory

   According to superstring theory the most elementary particles in the universe do not consist of points, but of a kind of vibrating ellastic bands, whose vibrations manifest themselves as particles, like electrons or photons. Although the theory initially seemed to be a promising candidate to bridge the gap between relativity and quantum theory, it seems to be more and more clear that the theory has her own share of problems. The most serious complication is that according to this theory our world is part of a ten dimensional universe, without us noticing in our everyday lives. Possibly is our threedimensional universe floating through higher dimensions, in the same way as a two dimensional flying carpet is flying throug three dimensional space, separated from a shadowworld that may be only a few tenths of a milimeter away, as Spinoza winner Robert Dijkgraaf recently decribed.

   Altough Renate Loll is careful with her formulation as to not antagonize any of her colleagues, it is clear that she does not think much of this line of research. "Initially, superstring theory looked to be very simpel and therefore attractive, but graduately there emerged more and more complications, making me to find it quite a far fetched theory now. In addition it is unclear wether the string approach will lead us somewhere. That's why I favour my own approach. That at least has produced some concrete results.??

   Gerard 't Hooft, just like Renate Loll, isn't at all convinced by string theorists. But wether the approach of his colleague from Utrecht is correct, is still a question according to him. "It is clear that Renate has made progress the last few years, but she's not there yet. It's even the question wether she is on the right track concerning QG. Although personally I tend to look in the direction of black holes I think that string theory still has the best hand. We have hit a number of obstacles, but none the less is that approach still more concrete and structured than other attemps to reconsile GR and QT. But that doesn't mean that Renate couldn't be right. My philosophy is, let everyone muddle on. She should continue with what she is doing, because the resolution of this problem will probably come from an unexpected direction.??

2. **MathPhys**
   October 24, 2005

   It's very interesting to hear that 't Hooft says that "string theory still has the best hand". Very interesting.

   Peter,

   I've posted the full article on my blog. You can find it on my blog.

Atiyah Talk at Santa Barbara

October 25, 2005
Categories: Uncategorized

Sir Michael Atiyah is here in the United States this month. Evidently he was at the Institute in Princeton last week during the Deligne conference, talking to Witten. Last Friday he gave a public talk at an AMS conference at the University of Nebraska on The Nature of Space, and will be giving another one tomorrow in Santa Barbara on the same topic.

Yesterday at the KITP he gave a talk on his own very speculative ideas about physics entitled Does the Universe Have a Memory?. He began by subtitling his talk “Crazy thoughts of an old man”, and noting that when he was at the Institute Witten had listened to him politely and then after a micro-second given him four reasons why his ideas wouldn’t work. One motivation he gave was that the current situation of string theory was somehow like Ptolemaic epicycles, with a fundamental idea that would drastically simplify everything still missing.

The speculative idea he was promoting was that perhaps quantum mechanics should be changed so that the future depends not just on the present, but on the history of the system during some short period before the present. So dynamics would be somewhat non-local in time. He hopes for some connection to the Connes version of the standard model, but this was all very vague. All in all, I fear that I wish Atiyah would go back to working on the relation between K-theory and physics….

Update: In a comment Doug provides a link to Atiyah’s public lecture.

Comments

1. **Chris W.**
   October 25, 2005

   That Atiyah would even give such a talk strikes me as a significant indicator of the level of disquiet that exists among leading figures in the string theory community and their allies in mathematics about the current state of work in the field, that is, about its presuppositions and goals.

   He adopted a clear position on the debate between those who would abandon continuity in favor of discrete models, and those who see too much power in the mathematics of continuous structures to accept taking such a step. I think this dichotomy is suspect; I’ll say more about it later.

2. **Arun**
   October 25, 2005

   If the theory of gravity induced by string theory has arbitrarily high degree of derivatives, then what’s the problem?

3. **Chris W.**
   October 25, 2005

   [*Oops! Sorry, I forgot to escape a < with a character entity…*]

   More on the above-mentioned dichotomy: *Please* read this discussion by Cosma Shalizi, and note the following:

   > The other reason for using symbolic dynamics is that there are important cases where one can find generating partitions — mappings into symbols where there is a one-to-one correspondence between continuous states and the symbol sequences they generate. In these cases, studying the symbolic dynamics is completely equivalent to studying the original dynamics. Remarkably enough, even with a generating partition, the symbolic dynamics can be stochastic for an underlying deterministic system. In this way, for instance, one can show that some kinds of (sufficiently chaotic) deterministic dynamics are in a sense completely equivalent to sources of independent, identically-distributed random variables.
   >
   > To go off on a tangent, there’s something of a movement in cognitive science which sets up an opposition between computation, conceived in the usual symbol-manipulation sense, and continuous nonlinear dynamics. This seems to me quite wrong-headed, if only because the existence of generating partitions shows how symbol-manipulating computation can be completely equivalent to a dynamical system. Computation is intrinsic to dynamics, but that’s another topic.

   Also, from Hendryk Pfeiffer (gr-qc/0404088):

   > It turns out that differential topology distinguishes the space-time dimension d=3+1 from any other lower or higher dimension and relates the sought-after path integral quantization of general relativity in d=3+1 with an open problem in topology, namely to construct non-trivial invariants of smooth manifolds using their piecewise-linear structure. In any dimension d<=5+1, the classification results provide us with triangulations of space-time which are not merely approximations nor introduce any physical cut-off, but which rather capture the full information about smooth manifolds up to diffeomorphism.

   ..and this from the body of the paper:

   > If quantum general relativity in d = 3+1 is indeed a PL-QFT, the following two statements which sound philosophically completely contrary,
   >
   > – Nature is fundamentally smooth.
   > – Nature is fundamentally discrete.
   >
   > are just two different points of view on the same underlying mathematical structure: equivalence classes of smooth manifolds up to diffeomorphism.

4. **Chris W.**
   October 25, 2005

   I must quote a bit more from Pfeiffer:

   > The diffeomorphism invariance of the classical observables then implies in the language of the triangulations that all physical quantities computed from the path integral, are independent of which triangulation is chosen. The discrete formulation on some particular triangulation therefore amounts to a complete fixing of the gauge freedom under space-time diffeomorphisms. The relevant triangulations can furthermore be characterized by abstract combinatorial data, and the condition of equivalence of triangulations can be stated as a local criterion, in terms of so-called *Pachner moves*. ‘Local’ here means that only a few neighbouring simplices of the triangulation are involved in each step. A comparison of Pachner moves with the block-spin or coarse graining renormalization group transformations in Wilson’s language reveals what renormalization means for theories with dynamical geometry for which there exists no *a priori*

background geometry with which we could compare the dynamical scale of the theory.

5. **Peter**
October 25, 2005

   Please remember this is NOT a forum for discussion of people's favorite ideas about quantum gravity. This is not what the topic of the posting was about.

6. **Kea**
October 25, 2005

   Chris W

   Atiyah did not deny this dichotomy between continuous and discrete. On the contrary, he endorses it (a) by indicating a preference for Connes' picture and (b) by saying explicitly that this Hale formalism for past dependent equations incorporates aspects of both.

   I enjoyed the talk! Forget the physics – it's full of subtle jibes and the sort of jokes that only very respectable old men can make.

7. **Nitin**
October 26, 2005

   Hi Peter

   Sorry to go out of subject here. I am wondering about something. I see a rather surprising number of physicists and mathematicians having weblogs these days. Even more surprising to me is that these people get the time to write about things they have heard, talked or thought about. Now, some of these postings are rather long (I cannot recall any unreasonably long posting of yours so far. I see a lot of this on Lubos' blog). Tell me… hasn't blogging affected your productivity at work? Clifford at Cosmic Variance writes frequently, you too… It seems to me that a lot of interesting things are being said most of the time, but aren't you better sometimes being busy at work or spending some time with friends away from the pc, or doing something different..?

   I would like to hear from you on this matter.

   Thanks
Nitin, Down Under

8. **Nitin**
October 26, 2005

   By the way.. I like the links you provide to interesting papers, notes, articles.

9. **Bryan**
October 26, 2005

   Hi Nitin: I think the problem is that guys like Peter have wireless connectivity to the internet all the time from their laptop or brain implant. It never gets turned off. Fortunately, they are able to do more than one thing at the same time…

10. **Ben Compson**
October 26, 2005

    Let's face it, if a theoretical physicist does 2 hours of good work in a day, that's a good day and the rest is his to do what he wants, like blog.

11. **Daniel Doro Ferrante**
October 26, 2005

    Following up on Ben's response: for a high energy theoretician, ~4h of good work in a day is a GREAT day.

    But, regardless, the sheer exercise of writing up, commenting, providing links, etc, etc, etc, is really good; it's a win-win situation: it's good for the audience (because they hopefully learn something new, leave interesting comments, etc) and it's good for the writer, beucase he gets a chance to clear his mind, making sure that his thoughts are cohesive and so on.

    So, say you teach, get 3h of good work and then you blog for ~1h, you may just have hit a pretty well rounded day: You can go home with a much better view of physics than when you came in.

    But, maybe it's just me… 😉

12. **woit**
October 26, 2005

    Hi Nitin,

    You're right that the weblog takes up a fair amount of time, and sometimes I do worry that it is taking away time I could be spending doing something more worthwhile, especially research. For now I think the time spent on this is worth it, but at some future point I may very well change my mind.

    I don't tend to write very long postings (I don't know how Lubos does it….), so the actual writing isn't that time consuming. Often I'm writing about things found by spending time looking around on the web, so in some sense the fact that I do a lot of that is the big time-waster, and there I'm probably not alone.

    I keep intending to try and write some postings that are more explicitly about the research work I'm doing. Then time spent on those would be in some sense time spent on research. One thing I need to do first is to try out various methods for putting equations on WordPress, I may get to this pretty soon.

    Peter

13. **John McCrone**
October 26, 2005

    A fun talk but – from a systems science point of view – it makes the familiar mistake of focusing on a "single-scale" discrete~continuous dichotomy and not the more fundamental "scalefree" dichotomy of local~global.

Atiyah suggests incorporating the uncertainty of QM by making just a single Planck-sized step into the past. A scale-free approach to memory would want to model a powerlaw distribution of "pasts". In this view the Planck scale defines not the fundamentally small (and discrete) but instead the fundamentally cogent (a web of interactions/gone to equilibrium).

Start by asking what is memory in a system. It is the general context within which a succession of particular states form. It is an ambience – a prevailing equilibrium in a system of interactions. So it is the "frozen" global view. And in hierarchical fashion, it exerts a downward constraint on any localised particulars. But of course, global constraint cannot "see" everything and so the local events (particle interactions, etc) are left with degrees of freedom. What we call their inertias.

So the memory of a system is its global coherent state which reflects some average of its past and – because the coherence is self-stable – also serves to predict the future for some reasonable distance. A universe that has developed certain constants, like the speed of light, is likely to continue to roll with those constants (barring a slow underlying evolution that eventually allows some further phase change to a new global vacua).

The point is that this globalised system memory is spread over all spatiotemporal scales. It is "scalefree" because the issue of scale has been thermalised.

So rather like a hologram, a very small "bite" into the past – like Atiyah's suggested Planck-scale step – would give some kind of snapshot of the whole, but it would be very fuzzy. By definition, it would seem to give the most uncertain view!

By being the closest to the localised freedoms of the system, it would see the least of the global constraints, the global memory. It would be like trying to observe the convergence nature of the system, its tendency towards a global remembered balance, from exactly the most open and divergent viewing position. To offer another analogy, it would be like trying to gauge the temperature of a gas by measuring some particular passing molecule.

Prigogine has some arguments along these lines in his modelling of QM in "The End of Certainty".

14. **Tony Smith**
October 26, 2005

In the .mov version of Atiyah's 24 Oct 2005 KITP talk at http://online.kitp.ucsb.edu/download/strings05/atiyah/snd/Atiyah_KITP.mov

Atiyah says (at about 1:12:24) that his class of models is based on "… the past history of a particle moving as a real particle …", which seems to me to be the past world-line of the particle.

An audience member describes to Atiyah (at about 1:05:02) "… a common thread between the class of models you are suggesting, Connes class of models, and some unsolved problems in string theory.
So,
one simple way to think about the class of models you are talking about is just to do a power series expansion of x(t-r) in t and … the higher derivatives of t so then you have an infinite order differential equation.
Similarly,
quantum field theory on a noncommutative spacetime can be expressed in terms of a star product which is an exponential of derivatives and therefore is also in some sense a differential equation with an infinite number of derivatives
and
the best nonperturbative formulation of string theory we have is string field theory which is expressed in terms of Witten's star product on strings which is also expressed in terms of some exponential of derivatives, but which we don't understand how to grapple with as well …".

It seems to me that a natural physical interpretation of that "common thread" is that strings should be interpreted as world-lines, NOT as individual particles or precursors of individual particles.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

15. **Quantum_Ranger**
October 28, 2005

Tony Smith says:"Atiyah says (at about 1:12:24) that his class of models is based on "… the past history of a particle moving as a real particle …??, which seems to me to be the past world-line of the particle".

An audience member describes to Atiyah (at about 1:05:02) "… a common thread between the class of models you are suggesting, Connes class of models, and some unsolved problems in string theory.

re:"So,
one simple way to think about the class of models you are talking about is just to do a power series expansion of x(t-r) in t and … the higher derivatives of t so then you have an infinite order differential equation".

The problem with this is that for evolving systems, specifically, from Quantum to Macro and equally, from Present to Future, the systems would have to be equivilent?

From Atyiah's talk of a "planck-memory" as representing some "past-initial-evolving-state", a little "it" from bigger "bit" if ever I heard one!, but there has to be a same/equivilent comparable 'worldline' from Present-time to Future-time?..this very notion would condem stringworld lines to the "Non-Renormable-Un-re-cyclable-Bin" correct me if I am wrong, but Aytiah notion of Relative/Quantum domains seems to be teetering on insane?..this I take to be the deliberate interuptions(spoiler in audience?) in the said lecture.

Aytiah's idea that a planck length is a Maximum Minimum "past-memory", of a "present-time", is no defferent from stating that the Present-time, is but a past memory of the 'yet-to-exist' future!

Just as a memory for any relative observer cannot contain 100% information (Reality is preserved in the Present-time), any worldline evolving from a planck domain, will contain very relevant Uncertainties?..you just cannot predict or construct, any present-time event from its past history!..if the speed of information recieved in any present-time event frame, exceeds the natural frequency of entropy, then theoretically, the Future, events that have not yet occured, could be manipulated directly from the Quantum past?

Slowing down an ordinary Photon would invoke a transformation in its "present-time", it would no longer have any Uncertainty association, you could design the Future with complete absolute accuracy?

The Quantum Mechanical domain would collapse, by the fact H.U.P would be nullified?
If one combines Atyiah's two-particle systems of [Past-Planck+Present-Time] with [Present-Time + Future Events], their equivilence would mean there is actually NO evolution whatso-ever.

16. **Tony Smith**
October 28, 2005

Quantum Ranger said, about the “common thread” comment by an audience member at about 1:05:02 in Atiyah’s KITP talk online at
http://online.kitp.ucsb.edu/download/strings05/atiyah/snd/Atiyah_KITP.mov

“… ..this I take to be the deliberate interuptions(spoiler in audience?) in the said lecture. …”.

That comment was made in the question and answer period following the lecture, so it was not a “deliberate interruption”.

Based on the context (Atiyah’s reply was “I agree with what you say” followed by extensive further discussion), it did not appear to me that the commenter was considered by those at the KITP talk to be a “spoiler”.

If you watch the .mov of Atiyah’s talk, you can see who made that comment. The camera shows him at about 1:07:58. I did not recognize him (but then I don’t know a lot of KITP people by sight).
Perhaps someone reading this can identify the one who made the comment.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

17. **Quantum_Ranger**
October 28, 2005

Tony, my appologies, I had watched the lecture, but found the constant interuptions by the “same” audience member quite annoying, I do so admire Atyiah, but actually felt a little sorry for him being so obviously “heckled”.

I am going to re-watch the ‘whole’ talk, and hopefully the Q/A I missed would enlighten me, a question I had been contemplating form Atyiahs idea, is what happens to the missing “planck-memory”, it seems to be forever evolving “backwards”, as for sure, even the Planck-memory has to been formated from a previous “past”?

18. **Who**
October 28, 2005

much of the interruption came from David Gross

during the QandA someone pointed out that there had really been two lectures going on, one by sir Michael and one by David, and reasonably enough that person asked David Gross a question related to HIS part of the lecture

the interruption was almost frantic and I think not malicious so much as instinctively defensive. If Atiyah ideas had been simply crazy it would not have been necessary to resist so hard. but the ideas, for good or ill, were somehow perceived (consciously or not) as plausible enough to be disturbing.

19. **Tony Smith**
October 28, 2005

Quantum Ranger asked “… what happens to the missing “planck-memory??, it seems to be forever evolving “backwards??, as for sure, even the Planck-memory has to been formated from a previous “past??? …”.

I agree that is a good question, and it is also something that nagged in the back of my mind (in the form of why should the memory / past world-line be cut off at the Planck scale).

If there were no past time cutoff, then the basic entity would be the entire (back to the big bang?) past history world-line of each particle. Maybe such a model would be like that of Andrew Gray, who said in http://xxx.lanl.gov/abs/quant-ph/9712037 (in the abstract) “… probabilities are … assigned to entire fine-grained histories. The formulation is fully relativistic and applicable to multi-particle systems. It shall be shown that this new formulation makes the same experimental predictions as quantum field theory …”.

The same Andrew Gray proposed a “Quantum Time Machine” in version 1 of http://xxx.lanl.gov/abs/quant-ph/9804008v1, but he withdrew that proposal on 8 Aug 2004, the same day that he posted version 2 of http://xxx.lanl.gov/abs/quant-ph/9712037. Therefore, it seems to me that although Andrew Gray felt his “Quantum Time Machine” was flawed, he still feels that his formulation of quantum theory in terms of “entire fine-grained histories”, which sounds to me a lot like Atiyah’s model without the Planck-scale cutoff, is valid.

I wonder whether Atiyah knows of Gray’s model, and, if so, how he (Atiyah) thinks it compares with his (Atiyah’s) model.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

20. **Doug**
October 30, 2005

For those who have been as frustrated as I have in trying to find Atiyah’s Nature of Space talk, here’s a link that actually works:

The Nature of Space

21. **Doug**
October 30, 2005

I have an innocuous question to ask: where would theoretical physicists generally tend to place Aityah, and his contributions, in their list of world-class mathematicians important to theoretical physics? And, BTW, what is the correct pronunciation of his name?

22. **Kea**
October 30, 2005

“where would theoretical physicists generally tend to place Aityah, and his contributions, in their list of world-class mathematicians important to theoretical physics?”

Very high.

23. **woit**
October 30, 2005

Hi Doug,

I agree with Kea. I'd put Atiyah among the top three mathematicians of the last half of the 20th century (with Serre and Grothendieck), and more important for theoretical physics than any great mathematician since Hermann Weyl. His work on instantons and anomalies during the late seventies and early eighties was wonderful, and his conjectures made in 1987 about the existence of various TQFTs were influential in Witten's amazing work in this area. Atiyah became less active in research mathematics after around 1990 when he became president of the Royal Society and master of Trinity College.

The pronunciation is Ah-Tee-Yaah.

24. **woit**
October 30, 2005

Oh, and thanks for the link to Atiyah's lecture!

25. **Tony Smith**
October 31, 2005

Peter, I agree with you that Atiyah is "… among the top three mathematicians of the last half of the 20th century (with Serre and Grothendieck), and more important for theoretical physics than any great mathematician since Hermann Weyl. …".

How does that square with the treatment of Atiyah by David Gross and Edward Witten?

As to David Gross, "who" said in a comment here: "… much of the interruption came from David Gross … the interruption was almost frantic and I think not malicious so much as instinctively defensive. If Atiyah ideas had been simply crazy it would not have been necessary to resist so hard. but the ideas, for good or ill, were somehow perceived (consciously or not) as plausible enough to be disturbing. …".

As to Edward Witten you (and Atiyah) said: "… Witten had listened to him politely and then after a micro-second given him four reasons why his ideas wouldn't work. …".

If I am correct in my opinion that any evaluation given after only a micro-second is NOT a considered evaluation (nobody, not even Witten is that smart), then it seems to me that
1 – Gross and Witten are very insecure about the superstring theory in which
they have invested their lifework
and
2 – Gross and Witten are incapable of fair evaluation of any alternative ideas.

Tony Smith

October 31, 2005

Hi Tony,

My take on Gross and Witten's reaction to Atiyah was rather different. Atiyah has taken pains to not be especially critical of string theory (I've corresponded with him about this, and, much as I would love to count him as a string theory critic, he makes clear that's not at all how he sees himself), so I don't think they were worrying about defending string theory from Atiyah. Gross did interrupt and make extensive comments at Atiyah's talk, but I took this as evidence that he was taking Atiyah seriously and trying to engage with him on his idea, even though it was pretty off-the-wall. I suspect Atiyah was exaggerating about the "microsecond", and in any case Witten probably had plenty of time to think about Atiyah's proposal while Atiyah was explaining it to him, enough time to come up with several pretty obvious problems.

Both Atiyah and Witten are extremely quick on their feet. I remember one time at MSRI talking to Raoul Bott, who had just walked away from Atiyah and Witten, shaking his head. He told me he found listening to the two of them "scary" since they were so much quicker than he was. Bott is a great mathematician also, but one who has to think everything through slowly and carefully to understand it, quite different than Atiyah or Witten.

What about Wheeler-Feynman & Aharonov 2-State QM in which present is a self-consistent global double loop 1/2(Advanced + Retarded)?

28. **Quantum_Ranger**
October 31, 2005

Thanks to Doug, I have just sat through the whole talk:The Nature Of Space.

My initial annoyance of the talk with D Gross was based on the lack of acoustics, not being able to hear what Gross was asking produced my unfounded accusation of "spoiler", this self-evaluation is made from after the above linked talk.

What becomes clear from the Atyiah talk, is that there are numerous area's of interpretations in nailing down what constitutes 'Memory'?..for instance a mathematician who calculates a simple formula, is performing a repetative function based on "memory", its an act of reproducing a "Time" and "information" event. In its simple way it is an act of "time-travel", via a thought function contained in the bio-mass of braincells.

Relativity, in its conception gives presedence to the Observer in Time, we are the only forms that can perform "time-travels" mentally?..this is what a memory is.

Now interestingly Atyiah is stating that a planck-memory, is a decomposition of a real-time event,(a past-moment) located at some instant in the present. Matter has a specific evolutional path, it tends to move from one location to the next in constant fashion. If one take's the electron and follows its trajectory, one finds that there is no continuation of its path, it can transfer itself from one location to another, without trancending the intervening space, from A to B, it can appear at B from the Future, without trancending the Present.

Feynman I believe made the "electron" statement:It is never located in the present-time, it always jumps from Past/Future or Future/Past?

The QM roots of H.U.P, contends that an Atyiah "planck-memory" must, at some moment along its timline evolution, make a transition from the Present-Time, to a Past-

Time, it makes a 'Jump' into the Past?..the "moment" this occurs, it loses its memory of where it jumped from, it is re-configured, without any memory at all!

The Virtual Quantity associated with any energy of Quantum status, means that any finite Planck-Memory (any componant with all its paramiters), after it reaches the transitional 'gap', it has no choice but to reconfigure, as if it is appearing from the Future, and it has a new set of Quantum Numbers!!

Calibrating a decomposed planck-memory from a 'present' Spacetime, with that of a 'future' Space,(there has to be particles contained within present-time space, that are scaled from the future) means that at in a finite limit, energy and its memory of its evolution, exchange with that of particles emminating from the Future, there would therefore be Particles comparable to that of Planck Scale, appearing with a lot more Energy, future re-tarded Quantums?

Where is Planck-Memory stored?..is it within the present or future, ordinary memory by a conscious observer is stored within the mind, somewhere in the Observers present-time, scaled down and stored, never to be recalled as 100%, it always has some missing information, else it would reproduce reality events 100%, is this information lost to the Future or Present?..it has to go into the construction of the future, the future always needs more information than the Present, just as the Present always needs more informaiton than the Past!

29. **Juan R.**
October 31, 2005

Almost all said by Atiyah is pure nonsense in the best string tradition.

A basic discussion of why most of Atiyah's remarks are completely *outdated* and some of them **completely wrong** is available at

http://www.physicsforums.com/showpost.php?p=806910&postcount=10

Jack Sarfatti said

October 31, 2005

juan r, the context of Atyiah's "planck-memory" is surely an inquisitive inquiry into cause and effect, does a past memory effect present events?..can the present,'whole', be created out of a finite memoric value, a minimum (planck) value?

At some moment the Present-time becomes the Past, and at the same instant the Future also becomes the Present?

If there is a "planck-memory", a Quantum value of energy at miniscule scales, then there is also a comprable Macro value at the intesection moments of Present to Future. The scale difference increase's at Present/Future boundaries, this is because the Future needs more energy/information, due to fact of increase in size, by volume?

If the future surely contains the same amount of energy(in discrete bundles of planck memory bits) as the Present, and consequently the Past energy, then symmetry could not be broken in a previous era?

At least 50% of 'present-time', is distributed into a past and future tense virtual domains. If planck scale "memory" is continueous in its attachment to a present spacetime location,then there is no cut-off point. If it is discrete at finite volume's, then it is "seperate" and isolated from the present-time, therefore it no longer has a memory of its origin, it could take,choice? of a "memory" of infinite proportional value.

Virtual particles have virtual histories?.. accountable in terms of no memory of a previous existence, which I believe Feynman asscerted to certain particles mentioned by Jack Sarfatti above.

Again Atyiah seems to be poking little 'peek-holes' into certain "canned" models and interpretations.

Some canned models, contain worm-holes.

I think there is a whole new can of Wormholes being inderectly opened/presented by Atyiah, some of the nagging 'worms' are going to be hard to swallow, especially for certain string models.

If you do not want to shoot yourself in the foot, then controlled experimental particle physics is the sure way to avoid using "elephant-guns" to exterminate "M", Theoretical mice!

I rate Atyiah as joint "number-2" in the context of greatness in contributing to scientific knowledge. There is no number one, this is yet to be filled, and he share's this position with a vast number of other greats, I have a personal distrust of league tables, as the importance of stature can be over-rated by association and personal tastes.

31. **Tony Smith**
October 31, 2005

Peter, as you say, "… Both Atiyah and Witten are extremely quick on their feet. … Raoul Bott, who had just walked away from Atiyah and Witten, shaking his head … told me he found listening to the two of them "scary?? since they were so much quicker than he was. Bott is a great mathematician also, but one who has to think everything through slowly and carefully
to understand it, quite different than Atiyah or Witten. …".

It is interesting that your characterization might be that Atiyah is a Hare and Bott is a Tortoise, yet working together they produced wonderful results. In an interview at http://www.ams.org/notices/200104/fea-bott.pdf Bott described his work with Atiyah, saying: "… In most of my papers with Atiyah he would write the final drafts and his tendency was to make them more abstract. …".
Bott went on to say: "… I like the old way of presenting things with an example that gives away the secret of the proof rather than dazzling the audience. … on the whole I like the problems to be concrete. I'm a bit of an engineer. For instance, in topology early on the questions were very concrete – we wanted to find a number! …".
Bott's "we wanted to find a number" remark sounds to me a Feynman-like attitude toward physics.

As to physics and physicists, Bott made an observation about the Princeton IAS under Oppenheimer: "… Oppenheimer had taken over, and he was very dominant in the physics community. He had a seminar that every physicist went to. We mathematicians always thought they ran off like sheep, for we would pick and choose our seminars! …”.

Maybe superstring theory under Witten and Gross is a the contemporary manifestation of physicists’ sheep-like behaviour.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

32. **woit**
October 31, 2005

Hi Tony,

Your characterization of Atiyah and Bott as the Hare and the Tortoise is apt, as is the Bott quote. Together they did some truly wonderful things.

It’s always been true that physics is much more faddish than math, with particle theorists generally desperate to somehow contribute something to whatever the latest, hottest thing is, mathematicians more interested in digging deeply into one particular thing that they can become one of the few experts in and make their own. In the past, when experimentalists were regularly providing theorists new and surprising results that pointed out the right direction to go, a somewhat faddish concentration on figuring out the significance of these new results made sense as a way to make progress. The problem is that particle theory still has that sociology in place, but the experimental impetus that made it work is gone.

33. **Doug**
October 31, 2005

Regardless of the merits of Atiyah’s ideas on how to approach the QM challenge, the merits of his assessment of the current situation in theoretical physics are priceless, in my opinion. As an icon in the coummunity (gathered from the respect expressed here), his emphasis of the role of simplicity and elegance in nature’s secrets is crucial. From this perspective, he indicts string theory with one devastating observation:

“If a final theory emerges soon from string theory, we will discover a universe built on fantastically intricate mathematics.”

His point is made in the “conudrum” of imaginary numbers that he describes. The conundrum is perplexing because, if, fundamentally, the origins of mathematics are found in nature, then the “fantastically intricate mathematics?? of string theory reflects something ugly and unsatisfying in nature, which would be so surprising, given humanity’s historical experience with her.

On the other hand, if mathematics is just a mundane tool for studying the physical structure of the world, and is no more than an invention of the human mind, how is it that its “biggest, single, invention,” imaginary numbers, show up in observed physical phenomena?!

He says that while his position is more moderate than Kronecker’s, he still believes that the origins of math are to be found in nature’s fundamentals, which then man develops and elaborates upon. Clearly, he’s implying that we have strayed too far from the origins of mathematics; that the vastness of string theory’s mathematical complexity has now taken on a life of its own, which abandons the vital reciprocal relation of math and physics.

It reminds me of Hestenes’ observation that

There is a tendency among physicists to take mathematics for granted, to regard the development of mathematics as the business of mathematicians. However, history shows that most mathematics of use in physics has origins in successful attacks on physical problems. The advance of physics has gone hand in hand with the development of a mathematical language to express and exploit the theory…The task of improving the language of physics…is one of the fundamental tasks of theoretical physics.

Coming from such eminent mathematicians, these are sage words indeed. Is Atiyah on a mission?

34. **John McCrone**
October 31, 2005

“From this perspective, he indicts string theory with one devastating observation: “If a final theory emerges soon from string theory, we will discover a universe built on fantastically intricate mathematics.??

String theory seems pretty natural if you have an organic metaphysics in mind – where something emerges as the constraint of a vaguer everythingness, rather than a creatio ex nihilio ontology.

So at the fundamental level, there is a chaos of potential with no mathematical structure. Then structure self-organises as resonances that lock into place. As this SO reduces dimensionality, the structure becomes more robust. Far out, you have only sporadic flashes of order – like the Monster lie group. Then as you get down to just 10 or 11 dimensions, the structures become increasingly robust.

Everything finally locks up pretty solid at three dimensions (with their emergent “fourth dimension” of a flow of time).

This is why we should expect a swamp as the fundamental ground for physical theory – it describes the vagueness, the potential, that would be a realm of “everythingness”.

The issue is then to understand whether the reduction of this raw potential to crisp (mathematically resonant and self-organising) structure has just one outcome, or a variety of possible outcomes. We could be the only possible kind of universe.

These points may seem off-thread but the metaphysics is important once you start asking whether maths is mechanically constructed or Platonically given. There is a third road which may be unfamiliar but was in fact widely prefered even in the time of Plato and Democritus.

Peter, you said “… All in all, I fear that I wish Atiyah would go back to working on the relation between K-theory and physics …”. Here are some related quotes and comments:

Bott, in his interview at http://www.ams.org/notices/200104/fea-bott.pdf , said “… the start of my long and wonderful collaboration with Michael Atiyah. We first of all gave a new proof of the periodicity theorem which fitted into the K-theory framework … Then Grothendieck, in the purely algebraic context, gave a … proof …[of]… the index theorem … using his K-theory in the formal, algebraic way. … Before, we had taken complex analysis or algebraic geometry as a given, so that the differential operator was hidden … here, suddenly the topological twisting of the differential operator came into the equation. Of course, Atiyah and Singer immediately realized that this twisting is measured with the homotopy groups of the classical groups, by the so-called symbol. Eventually the whole development of index theory fitted the periodicity theorem into the subject as an integral part. Atiyah very rightly chose Singer to collaborate on this project. …”.

In their book Spin Geometry (Princeton 1989 at page 277), Lawson and Michelsohn said: "… In 1982, E. Witten found a different approach … through consideration of symplectic geometry and supersymmetry. … he outlined a proof of the index theorem for the Atiyah-Singer operator … however … none of these methods [including Witten's] applies to prove the index theorem for families or the Cl_k – index Theorem (in their strong forms). These theorems in general involve torsion elements in K-theory which are not detectable by cohomological means. …".

In his book Introduction to Superstrings and M-theory (Second Edition, Springer 1999, 1988 at page 338), Michio Kaku said: "… new developments in supersymmetry have now made it possible to prove the Atiyah-Singer index theorem from a simple Lagrangian. Traditionally, the proof of the Atiyah-Singer theorem has been inaccessible to most physicists because of the intricacies of the mathematical formulation. …".

Reading those excerpts in sequence leads me to think that a reason that superstring physicists are so attached to supersymmetry is that it is only through Witten's supersymmetric approach that they can understand the Atiyah-Singer index theorem.

However, by restricting themselves to the Witten supersymmetric construction, the supersymmetry physics people are cutting themselves off from possibly very fruitful avenues of constructing new and possibly realistic physics models.

For instance, Lawson and Michelsohn, at page 270 of their book cited above, said [I have omitted some tildes etc from notation due to ASCII limitations]:
"… Given a real operator … in the basic case, no information is lost under complexification. This is not true, however, if one passes to the index theorem for families. The index of a family of real operators takes its value in the group KO(A), and .. for example … KO(Sn) = Z2 for n = 1 (mod 8) but K(Sn) = {0} in these dimensions.
For this reason Atiyah and Singer established a separate index theorem for families of real operators. It is a more subtle and profound result … the appropriate theory is not KO-theory … It is the more general KR-theory …".

If Kaku's assessment of physicists' inability to understand a KR-theoretical index theorem is correct, then I share Peter's sense of loss if Atiyah is not now "working on the relation between K-theory and physics".
However,
I respect Atiyah's right to follow his own intuition and to pursue his physics model based on Hale's book Functional Differential Equations. It may even turn out that there is some connection between the two areas, and that Atiyah is smart enough to sense such a connection.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

36. **Tony Smith**
November 1, 2005

My immediately previous post seems to suffer from an inadvertent smiley.

The smiley should be the number 8 and the equation should read

KO(Sn) = Z2 for n = 1 (mod 8) but K(Sn) = {0} in these dimensions.

As I indicated in the immediately previous post, the equation also suffers from suppression of such things as tildes etc due to ASCII limitations.

Tony Smith

37. **Juan R.**
November 1, 2005

quantum ranger, As already said Atiyah's talk is outdated.

Curiously the current tendency in the topic -Atiyah is of course NOT an expert- is **the contrary** of Atiyah's proposal.

Retarded diferential equations have proved to be computationally intractable during more than 40 years (moreover do NOT solve the famous problem of the arrow of time). Today, there is emphasis on the **abandonment** of this way by either Marklovian equations in a generalized space functional -e.g. 90s Prigogine proposal in a RHS- or the use of sophisticated memory kernel techniques eliminating the convolution (the 'memory') from the evolutor, transforming the retarded equation into a local time equations that can be computationally solved.

Literature in this topic is very extensive and complex.

Atiyah's talk is both outdated and wrong in several fundamental aspects. See above link for a dissection.

That universe has a memory is already very well-known, for example the standard Zubarev equation with an infinitesimal memory -Abel kernel-. Equations with memory are standard in many condensed matter disciplines. This is not new.

The discussion of Atiyah on causality structure of the universe is completely wrong and very outdated. It is unnecesary the appeal to Planck scale physics -see Prigogine theory for example, or CSM approach, or etc, etc, etc.-.

You would read *The End of certainty* by Prigogine

http://www.amazon.com/exec/obidos/tg/detail/-/0684837056/103-6383925-0546230?v=glance

for some recent views on the topic. Atiyah proposal would be good in the 50s and 60s. In fact, the first basic equation -generalizing mechanics- proposed by Prigogine was a retarded equation with a memory term and a complex diagranmatic technique acounting for all that cannot be explained via mechanics (see above book) or field theory. All of that is well-known in speciliazed literature. But further work did Prigogine and other abandoned that way. We are in the 2005!

Juan R.

38. **Adrian Heathcote**
November 2, 2005

I've read through the discussion above I can't resist expressing a point of disagreement.

I found Atiyah remarkably charming and urbane—but I was kind of expecting that—but I thought the continual interruptions from Gross rude to the point of obnoxiousness. Atiyah couldn't get two sentences out without being pulled up and forced to engage in a dialogue. This is not how one should behave in a talk, whether threatened, not threatened, malicious, not malicious. There is just no excuse for this boorishness. And it was very easy to sense Atiyah's frustration.

Sorry, but I thought this was pretty much a disgrace. I can't believe that the person chairing the talk didn't exert some control over his audience.

39. **Doug**
November 2, 2005

I felt the same way, but the person causing the disruption is the head of the Institute, so the chair of the talk wasn't about to try to exert any control. Which, of course, makes it all the more boorish.

40. **Adrian Heathcote**
November 2, 2005

Thanks Doug, that info does go some way to explaining it! I now see what others have been saying regarding his sensing Atiyah's talk as a threat. Any suggestion of even the possibility of a new idea, or the need for one, seems to have been taken as a five alarm fire—to be extinguished immediately.

Poor Atiyah had the hose directed at him the entire time!

41. **Adrian Heathcote**
November 2, 2005

I have a more substantial thought on Atiyah's talk which I think is on his side.

Modern explanations of EPR-like entanglement suggest that the composite system is in a pure state, whereas the component systems are in mixed states. The mixed states of the components do not uniquely determine the composite pure state—so some information resides in the state of the pair of particles (there from their anti-correlation origins) which does not reside in the component states. This is the so-called quantum holism, and it gives rise to the entanglement because of the non-commutativity of the operators that apply to the individual systems.

But then there is at least room for saying that the pure state contains information about the past of the system, which must be factored in when looking at the correlations at the time of measurement. I know it's sketchy but it does suggest that Atiyah's idea may have some kind of role to play.

Pardon the pun, but if string theory could go some way to explaining entanglement it would have done something interesting. But it doesn't even appear to be in the right ball-park. Or am I wrong here?

String Theory and Intelligent Design

October 26, 2005
Categories: Uncategorized

The latest Cosmic Log column on msnbc.com concerns Lawrence Krauss's new book Hiding in the Mirror and the author asked Krauss a question I'm expecting that physicists will be hearing more and more often as time goes on: "Why is string theory science but intelligent design isn't?"

Krauss gives a response that isn't completely convincing. He says that "the difference is that Ed Witten and the other good string theorists will, if an experiment comes along that demonstrates that supersymmetry isn't discovered in a definitive way, be the first to say the theory is wrong." This isn't really true. Since the scale of supersymmetry breaking is unknown, one can't hope to experimentally definitively show supersymmetry is not there. And the question at issue is string theory, not supersymmetry. Will string theorists abandon the theory when supersymmetry is not found at the LHC? We'll see in a few years, but I already see them hedging their bets and many undoubtedly will not see the lack of supersymmetry at LHC energies as proving string theory wrong.

The behavior of string theorists that Krauss identifies as most like religion is the argument that "the theory is so beautiful it must be true." I actually don't hear many string theorists making this argument these days. If the theory actually were beautiful in the sense of providing some impressive new understanding of physics in terms of some simple, compelling mathematical or physical idea, that actually would be a good reason for believing in it, although not a completely conclusive one. All attempts so far to connect the theory to real physics lead to hideously complicated and ugly constructions. Some string theorists such as Susskind, argue that one should believe in string theory anyway, and it is this argument which seems to me to be more like religion than science. It's my impression that Susskind and others are believing something for sociological and psychological reasons, something for which they have no rational, scientific argument. This behavior is not distinguishable from that of many of the intelligent designers, and if it becomes more widespread it ultimately threatens to do real damage to the public perception of science in general and theoretical physics in particular.

Krauss gets closer to the real difference between string theorists and intelligent designers when he says that string theorists "are trying to come up with predictions that actually do something". More sensible string theorists are well aware that what they are doing isn't going to be part of science until they figure out a way to use it to make real predictions that can be tested. In general, given a new speculative idea, it will not be obvious how to figure out all of its implications and see whether it can lead to real predictions. It can take years of work for this to become clear, and this sort of work is definitely science. On the other hand, if after a lot of work, there still is no indication that an idea can produce predictions, the continued pursuit of it at some point stops becoming science and starts becoming something more like religion. Susskind and other anthropic landscapeologists have already gone past this point: they have no plausible idea about how to ever get real predictions out of their framework. String theorists who argue that the theory is still too poorly understood, that more work is needed to understand whether there is some way around the radical non-predictivity implied by the landscape, are nominally still doing science. But at some point, as years pass without any progress in this direction, and evidence mounts that hopes for ways to get predictions aren't working out, this activity stops being science and it too starts being a non-scientific activity pursued for sociological and psychological reasons. We're close to that point, if not already past it.

Update: There's a defense of string theory against the charge that it's like intelligent design over at Kasper Olsen's blog. I don't find it very convincing, since it doesn't address at all the question of how string theory is ever going to do what a real science is supposed to do: make falsifiable predictions. Much of Olsen's list actually strikes me as a recitation of a catechism of supposed reasons why string theory is so wonderful, rather than a serious scientific argument. Some of these are also highly dubious (e.g. "the Standard Model can be reproduced in a very simple way"), they're things that one has to be a true believer to say, since they really don't accord with reality.

One commenter (Gavin), gave a very good reason for distinguishing string theory from intelligent design: "the former is trying to explain something that is already explained, while string theory is trying to solve a mystery" and he correctly notes that while string theory's scientific credentials may be weak, the problem is that there aren't really good alternatives (LQGers may argue with this…). John Baez's comment about the relationship of math and physics was also quite nice.

Comments

1. **BD**
   October 26, 2005

   "A non-scientific activity pursued for sociological and psychological reasons" seems an overly broad characterization, if it encompasses both religion and — as most people would characterize non-empirical string theory — abstract mathematics. Do you really want to be arguing that non-physics mathematics (which string theory may prove to be) is equivalent to religion? Even totally absent "predictions that actually do something," string theory as mathematics would still be a very different type of activity from religion, and would deserve a very different treatment in our schools (were a high school ever to attempt to teach totally abstract math).

2. **Arun**
   October 26, 2005

   "Why is string theory science but intelligent design isn't???

   Even if string theory is not physics, it is mathematics. Depending on your point of view, mathematics is the handmaiden or the queen of sciences.

3. **Subhash**
   October 26, 2005

   Now that it has been mentioned, one cannot deny that if "beauty" is the justification to do string theory then the same can be invoked for Intelligent Design (ID) also. The supporters of ID claim that it is more elegant than evolution, stressing that it is the messiness of probabilites that they are trying to banish.

   If some people are doing string theory because of its mathematics, then perhaps it should be done in the Math Departments. There is no question that falsifiability should remain the primary criterion of any physical theory.

4. **jack**
   October 26, 2005

   Well, it could be worse. At least the ID people propose an alternative to evolution, however crazy. They don't just tell us, year in, year out, that evolution is not science, that evolutionists are pursuing the theory for purely sociological reasons, etc etc etc, without ever proposing anything that even looks like an alternative.

5. **Quantoken**
   October 26, 2005

   Arun said:

   "Even if string theory is not physics, it is mathematics. Depending on your point of view, mathematics is the handmaiden or the queen of sciences."

I am sorry. Mathematics is not science. Mathematics is just a language, a language that is suitable to be used to describe science. But it is not itself a science. Mathematics do not make predictions and do not experiment with nature. So mathematics is NOT science. You can easily figure out how to calculate the surface area of a sphere in a hypothetical 26 dimentional space, using pure math, but such math constructs have nothing to do with nature, which is certainly not 26 dimentions.

Quantoken

6. **dan**
October 26, 2005

playing devil's advocate, SST/m-T does predict SUSY & 11-D which *could* be falsible.

also, one contact SST does make is reproducing the BH entropy

7. **an interested observer**
October 26, 2005

I agree and disagree with Quantoken. Yes, mathematics is not a science. No, mathematics is not just a language to describe science.

Modern mathematics, the way I look at it, is a creative endeavor in which we study abstract well-defined objects that we find intriguing, in a certain language (set theory, category theory, …) that's internal to mathematics. In particular, a priori, there's no connection of mathematics with any language that describes how the world works. That mathematics itself happens to be the best language to "do" science in, is co-incidental and a consequence of the fact that (historically) SOME PARTS (calculus, say) of mathematics were invented to solve problems external to mathematics, and SOME PARTS (representation theory, say) of modern mathematics, besides being of great interest within mathematics, simply HAPPEN to describe the real world spectacularly well. — it's a gross generalisation to say that all of mathematics is just a language to describe the real world. And yes, mathematics is not a science since, as defined above, it serves its own ends and does not attempt to describe how the "real world" works .

One may conclude from the above that, as BD does with Peter's post, that I believe mathematics is "equivalent" to religion. This seriously depends on the definition of equivalence. If two subjects become equivalent simply because they both arise from psychological motivations, then yes — mathematics and religion are equivalent. In this case, however, I think your definition of equivalence needs rethinking. After all, physics and biology (or even economics) arise from similar motivations — they both try to describe a certain aspect of the real world. Does this make them "equivalent"? I think not.

October 26, 2005

I disagree with the notion that math is not science. Mathematics relates to properties of objects in a formal system (that may or may not correspond with a physical system) together with rules of association amongst those objects. Since such formal systems are a product of our mind, mathematical truths are of fundamental importance and they may be viewed as extensions of logic. Obviously claims in a formal system are falsifiable excepting in cases where the system of axioms is not rich enough for one to prove or disprove an assertion.

9. **Doran**
October 27, 2005

Jack, I am really hoping your being sarcastic, for you have attributed to stringers what ID proponents have been doing since 1987 when Pandas and People was first published. Please go check out Pandas Thumb or Pharyngula if you need a refresher course on the sadness that is the Intelligent Design movement.

I believe Peter has made this analogy before, and I cannot help but wince. String theory has numerous problems, especially with regards to experimental testing. Intelligent Design is a socio-religious movement that wishes to repackage old school creationist trash in a form that will squeeze by the establishment clause. I doubt stringers have hired their own international PR firm, and are attempting to teach Gauge theory to fourteen year olds.

If there was any "religious quality" about string theorists it reminds me more of New Agers, whose theories while holistic, are absolutely worthless. I find Planck's original derivation of his radiation law beautiful due to its ingenuity, but its wonderful agreement with experimental evidence is just as aesthetically pleasing as the mathematics he used.

ID is far more dangerous and near term, for its proponents have sold their souls and intellectual integrity to promote a defunct faith and the bastardization of the scientific method.

10. **Arun**
October 27, 2005

What I wrote was intended in the following spirit:

"Mathematics is the Queen of Science, and Arithmetic the Queen of Mathematics. – C. F. Gauss"

"The Handmaiden of the Sciences. Eric Temple Bell (1883-1960), [Book by that title.] "

"Mathematics serves as a handmaiden for the explanation of the quantitative situations in other subjects, such as economics, physics, navigation, finance, biology and even the arts." – H. F. Fehr

Intelligent Design and "is mathematics science?" make for sterile arguments.

11. **Clark**
October 27, 2005

The problem with the claim mathematics is what distinguishes religion from science is that it runs into trouble when you consider numerology or pythagoreanism. There's been a lot of mathematical mysticism from the early days of Pythagoras on up to even the present. Go down to that goofy isle in Barnes and Noble that sells "metaphysical" books and you're bound to find at least one book that is complete silly gibberish but very mathematically.

The relationship between math and religion is quite old. Remember that Plato saw geometry as one of the best illustrations of his rather odd notion of an immortal soul and remembering. Since we weren't creating the geometric proof we have to be "perceiving" them in some sense or remembering them.

Complete balderdash, of course, but hugely significant. This rebirth of mathematics as religion can even be found in fairly prominent scientists. Read some of the discussions of Newton as a hermeticist to see this.

Anyway, I don't have much to say vis a vis ID or string theory. I reject ID and have my doubts about strings, as interesting as they are. But I didn't go far enough down that line of physics to be able to say much of worth to the science.

12. **Quantoken**
October 27, 2005

Subhash:

Has it been falsified, or not falsified, in mathematics, the statement that two parallel lines shall never cross? You've got to know neither case is right or wrong.

There is no empirical truth in mathematics. All math are logical derivations from a few fundamental rules which we probably took for granted, but which do not need to be taken for granted as truth, like the parallel line hypothesis. As such, all you could ever say is certain statement is either consistent, or inconsistent, with the set of hypothesises that your math is based on. There is no absolute truth.

Another example, you may take it for granted that 1+1 surely equals 2. But there is a hidden presumption here that you discuss the problem within the arithmatics rules built on the set of natural numbers. You could well establish an arithmatics system which is self consistent, for example one where the only numbers exist are 1 and 0. In that case, 1 + 1 gives 0, and 2 doesn't exist.

You might think an arithmatic system with only 0 and 1 and no other number may sound silly. But remember, for a long time, our math of geometry only dealt with 3 dimentional space, not anything more than 3-D, and certainly not infinite dimentionality. And it is still difficult for our limited mind to comprehend higher dimentionality than 3. What is true in a 3D world may not be true in other dimentionality.

So, there is no absolutely truth in math. All you can ever show is some statement are consistent or inconsistent with other statements.

Quantoken

13. **woit**
October 27, 2005

Thanks for all the interesting comments.

I've said this many times before, but I should be more precise about what aspects of string theory I'm criticizing as unscientific. What I have in mind is specifically the idea that one can unify the standard model and gravity using a 10/11-d string/M-theory. Things like AdS/CFT, where strings are used to construct a dual to a strongly coupled gauge theory, are certainly physics. Things like topological strings and their relations to Gromov-Witten invariants and much else are definitely mathematics. But the 10d superstring compactified on a Calabi-Yau is a very complicated mathematical structure, one that doesn't seem to have any special deep significance. Studying aspects of this complicated structure can lead to a lot of interesting mathematical work, but the full structure itself is not mathematically compelling, a good reason to believe it isn't going to be a successful TOE.

As for the mathematics/religion comparison, well they're quite different pursuits, although I'm sure one can find some relations between them. The mathematics/physics relationship is a very deep question, and I don't think we know enough about either subject to yet know precisely what the relation is. My own inclinations are kind of hyper-Platonist, thinking that ultimately we will see that the deepest mathematical structures and the deepest physical structures are very closely related.

14. **Amitabha**
October 27, 2005

Through a strange coincidence I received the following quote from Aldous Huxley in the mail yesterday:
Where beauty is worshipped for beauty's sake as a goddess, independent of and superior to morality and philosophy, the most horrible putrefaction is apt to set in. The lives of the aesthetes are the far from edifying commentary on the religion of beauty.

15. **John Baez**
October 27, 2005

Peter writes:

The mathematics/physics relationship is a very deep question, and I don't think we know enough about either subject to yet know precisely what the relation is. My own inclinations are kind of hyper-Platonist, thinking that ultimately we will see that the deepest mathematical structures and the deepest physical structures are very closely related.

It's interesting how your post about Lawrence Krauss' book provoked this almost totally irrelevant discussion about whether mathematics is a science, etcetera. I think there's a lot of what the economists would call "pent-up demand" for better understanding the relationship between mathematics and science – it bursts out at inappropriate moments, like just now.

The problem of course is that in the standard modern picture, science is empirical, based on induction, and tends to favor a materialistic ontology, while mathematics is non-empirical, based on deduction, and tends to favor a Platonist/Pythagorean ontology… yet somehow they need each other!

So, mathematics is not only the queen and handmaiden of the sciences – it's the secret mistress as well, a source of romantic fascination but also some embarrassment.

The hard-nosed physicist is supposed to treat mathematics as a mere "language", but finds himself becoming fascinated by its "beauty". He finds that the pursuit of beauty can lead to practical results that a merely pragmatic approach would never obtain – the "unreasonable effectiveness" of mathematics.

This is already puzzling enough, but the full story is even trickier: beauty – *or at least our possibly mistaken* ***notion*** *of beauty* – can seduce us and lead us astray! Is string theory beautiful and correct, beautiful and false, or actually ugly but pretending to be beautiful, like Cinderella's elder sister, struggling to fit the glass slipper on her oversized foot?

It's all so confusing. 🙂

16. **A.J.**
October 27, 2005

A shorter answer: String theorists are sincerely interested in extending known and tested science. Intelligent design "theorists" are interested in undermining the public's faith in known and tested science.

17. **Thomas Larsson**
October 27, 2005

Natural supersymmetry has **already** been ruled out by experiment, AFAIU. If no sparticles are found at the LHC, slightly unnatural SUSY will be ruled out as well, leaving very unnatural (split or supersplit) SUSY as the only possibility.

SUSY has long been invoked as a solution to the hierarchy problem, i.e. why the weak scale 100 GeV is so small in units of the Planck mass. Although SUSY reduces this problem, recent experiments (in particular limits on the Higgs mass and permanent dipole moments) rule out the possibility that SUSY will solve it completely. This is usually expressed by the phrase "SUSY requires fine-tuning at the percent level".

Let me add that this does not make me happy because I dislike SUSY. Rather, it's the other way around: I dislike SUSY because it seems very much to disagree with experiments.

18. **dan**
October 27, 2005

October 27, 2005

If we were to take an Hegellian approach and consider the theory of evolution, the thesis, and the intelligent design theory, the antithesis, then perhaps we need to seek a synthesis of the two. If we turn to physics, we find that the atom, indeed, any atom, is almost a perfect vacuum, closer to perfect than outer space. All objects in our physical universe are made up from molecules, which are in turn consist of atoms. As atoms are vacuums, then molecules would be vacuums, then so too is the substance of our universe. So our physical universe is almost a perfect vacuum, an absence of matter. There is next to nothing there. Of course, I am not suggesting that the physical universe is an illusion, but rather that our perception of it is illusionary. The universe is one big Disneyland! And it is simply the coarseness of our senses, that makes us believe that the physical universe is substantial.
Our eyes respond to visible light, which is electro-magnetic radiation with wavelengths very much larger than the diameter of an atom and at the same time the frequency of these radiations is very much lower than the frequency of electron orbits forming the shell of the atom. This means that visible light will bounce off an atom rather than pass through it. Sound and touch involve much much larger wavelengths than visible light, so they too would tend to find a physical object impenetrable. On the otherhand, cosmic rays have a wavelength much smaller than the diameter of an atom, and scientists going down into deep mines have found that cosmic rays can penetrate thousands of metres into the Earth.
It is one's minds which interprets his senses and passes it on to him, the inner self. The conscious, intelligent part of us. Oh dear! It would seem I'm making a case for intelligent design. Oops!

21. **JKG**
October 27, 2005

"Why is string theory science but intelligent design isn't??? its not really the question, the question is "Why is standard model (hot Big Bang cosmology, etc) science but intelligent design isn't???

All these questions refer to metaphysical foundations of sciences and are actually the core of the so called demarcation problem (of Popper). There is no good answer to that. One can presumably DEFINE science so that the standard model is science and intelligent design is not, though it is not trivial at all (for example by using Popperian conjectures and refutations program). One can also presumably DEFINE science so that the string theory is science and intelligent design is still not. One can also try to device a demarcation line between sciences and religion, for example by assuming that there is no transcendental knowledge, see what is left and call it science. One can also take the Spinozian pantheistic stand, and assume that the physical universe is just god (I am simplifying things here, of course), and then intelligent design is nonsense, logically.

Of course, intelligent design is just fiddling with judeo-christian-muslim image of god: an old man who treats the physical universe as his playground. If you accept this I can hardly see how you could do science at all since causality does not work any more (or at least there are uncontrollable exceptions).

But whatever you do, this is a metaphysical exercise, and not a scientific one (ie. one cannot define science from within the science itself.) So the question "Why is string theory science but intelligent design isn't??? is basically not even wrong

22. **AG**
October 27, 2005

It is notoriously difficult to draw the Popperian demarcation line, but surely there is a fundamental difference between string theory and intelligent design. When embarking on a scientific research program, it is not always possible to tell from the start what falsifiable predictions or practical applications might emerge, and theoretical scientists have to go on well-formulated hunches and search for ways to corroborate their hypotheses; nonetheless, their efforts can still be called science. Intelligent design, however, is not science– not because it cannot be falsified, but because it cannot, even in principle, be corroborated either. How can an ID proponent move forward with his "research program??? All he can do is attempt to expose places where evolution supposedly fails as an explanation… but this is not how science works. A scientist who spends his time trying to reveal gaps in loop quantum gravity is not doing string theory by default. Science doesn't work in the negative—you have to try to corroborate claims of your own hypothesis, not simply attack the claims of others. And clearly ID has no means of corroborating their "hypothesis?? in a self-contained, positive manner. Of course, it may prove to be impossible to test string theory's hypotheses directly, but actually this is where mathematics can step in and render string theory legit science. The power of mathematics is that it can reveal equivalences among physical statements that are in no way evident in science alone – and that's because 'science alone' consists of physical interpretations we impose upon mathematical structures. These interpretations are limited by imagination and physical intuitions, but mathematics is not. AdS-CFT is a prime example, and if string theory's structure can be shown to be equivalent to something we can better understand physically, and therefore test, its proponents' efforts will not have been in vain. Surely there are many mathematically equivalent physical theories all expressing the same basic truths about nature, so it can't hurt to pursue multiple lines and hope some clever scientists (or mathematicians) unveil their hidden relationships. On that note, I'm really curious to know if there have been any interesting developments in the search for a dS/CFT?

23. **Arun**
October 27, 2005

Prof. Motl's review of the book on amazon.com says that superstring predicts fermions.

To me that is stretching the meaning of prediction to an extreme, but your mileage may vary.

24. **Gavin**
October 27, 2005

One important distinction between intelligent design and string theory is that the former is trying to explain something that is already explained, while string theory is trying to solve a mystery. Intelligent design is useless because evolution is the right explanation for the origin of species. However, we don't have a theory of quantum gravity. String theory may be wrong, or even untestable, but I think that we should have a lot of freedom to speculate when we are trying to solve an open problem.

The biggest threat to string theory isn't experiment, it is somebody coming up with a straight forward way to quantize gravity without all of the extra dimensions, branes, etc. of string theory. The draw of string theory isn't its strong scientific credentials, it is the weakness of any competition.

Gavin

25. **Juan R.**
October 27, 2005

A couple of replies

Woit
I think that you are almost right in your personal valuation. Almost all of string theorists have spent much time on string theory research. But this is not the true problem; the problem has been the premature publicly in mass media. String theory was presented as 'fundamental', as 'the last theory'. This has generated a lot of hype around it. For example, it is usually thought by arrogant people that any guy working in string theory is a genius and *any* outsider is a 'mo – – n', etc. It is usually thought that any other theory is derived from string theory as a special case, etc. Of course, nothing of this is true.

I am rather sure that string theory community can be splinted into three parts:

– Workers. E.g. graduate students doing PhD because they did not find other area of research due to pressure of string physicists on research programs.

– Leaders. People who is a fanatic of the theory. For example Kaku, who has no problem in claiming, "*Absence of aliens in the universe is a sign of that string theory may be correct*??. The basis for such one bizarre idea is that they used string theory for travelling, via a hidden dimension, to other universe!

– Rest.

I think that only 'leaders' will continue to work in the theory even if they is experimentally proved to be incorrect. In fact, there is a very good basis for this thinking: the own history of the field. String theory was *always* refuted by experiment, and each new experiment or internal contradiction did that string theorists developed a new version or reparameterised previous one –curiously are always called 'string theory'-. There is a joke circulating in the Internet saying that if string theory is shown to be experimentally false like a theory of everything, the 'leaders' will explain that is due that string theory is really a theory of more than everything.

For anyone who do not know the history of the field, the joke is based in that when string theory failed in the nuclear regime and was substituted by QCD, string theorists as Schwartz claimed that the problem was that string theory was more that a theory of strong force and included also gravity and then began a new -more general- formulation. Curiously, that more general theory has not still explained the strong force like QCD has done during decades…

Regarding beautiful arguments, I simply want to say that beauty always was a subjective feature. I personally find all string theory research an ugly subject, with lot of irrelevant math and wrong physical stuff.

At least, some string theorists openly state that his belief on string theory is only that. James Gates recognizes "*the analogy to a religion has been noted by a number of people. In a sense that's right; it is kind of a church to which I belong. We have our own popes and House of Cardinals*.??

Arun

It is not true that string theory was mathematics.

People working in string theory is doing mathematical research because some parts of string theory need of mathematics still do not developed. That is VERY different from claiming that string theory 'is' mathematics:

Mathematics is Calabi-Yau manifolds and G2s, topology, K-theory, etc.

Chemists and mathematicians working in molecular structure have developed some useful techniques on graph theory, but chemistry is not math not graph theory a branch of chemistry.

John Baez

I respect you opinion but I follow Newtonian philosophy. Math is an idealized construct for the description of the physical word. Feynman explaining between geometrical lines and light 'lines' was brilliant.

Your claim about that "mathematics is non-empirical?? is being debated by own mathematicians. Have you heard about experimental mathematics?

Will be math sufficient? Any reply will be speculative. However, I begin to believe that for a 'real' understanding of world, math alone will be not sufficient. In my opinion, there is not a kind of marriage between math and physical world in the end. Math is a beautiful kind of simple intermediate language that contains many features of that we call physical world…

Probably the great failure of string theory is directly related that its main practitioners are people with mathematical-oriented minds… and therefore unable to really understand physical word. One only need the many paper on the subject.

We need is not another Witten in physics, we need a new Feynman 🙂

I guees this partly has to do with a somewhat naive application of Popper’s falsification method. Remember Popper wanted to distinguish between science and pseudo-science. Now we obvioulsy don’t want maths to be on the wrong side of the line, but a naive application of Popper runs precisely that risk. Has anyone checked what the great philosopher himself wrote about this? He was a clear thinker!

27. **Joao Leao**
October 27, 2005

Commenting on John Baez comment:

Funny on how a science/religion argument closes in on the math/physics question, indeed! A recent paper by Hut, Alford and Tegmark dives fully into this puddle curiously without touching string theory! The target happens to be **Penrose** himself a thorough critic of String Theory along Peter’s lines, seems to me. What strikes me is the tone of the discussion which is entirely set in religious terms advocating a plurality of “mind sets” rather than any self-critical departure. How postmodern!

Something for your one of your “This Week’s” entries, John? I would be curious to know your opinion on this gem…

-Joao

28. **Ygorff**
October 27, 2005

Peter, you say “topological strings and their relations to Gromov-Witten invariants and much else are definitely mathematics”, “dual to a strongly coupled gauge theory, are certainly physics” which is fine. Then you claim “But the 10d superstring compactified on a Calabi-Yau is a very complicated mathematical structure, one that doesn’t seem to have any special deep significance”.

This seems a contradiction to me, since all is the same.

GW invariants of topological strings are most interesting on CY, they do describe 4d strongly coupled gauge theory and in reverse most of the well studied 4d strongly coupled gauge theories are dual to (GW on) CY. Topological string on CY is nothing but a low energy sector of superstring on the same CY. So how can the same subject be relevant mathematics and physics and without significance at the same time.

29. **woit**
October 27, 2005

Hi Ygorff,

There’s no question that you can get some interesting mathematics or physics to study by looking at certain limits or subsectors of superstring theory. The examples I gave are what seem to me the most interesting ones for mathematics and physics. But just because something has a very interesting low-energy limit doesn’t mean it is necessarily especially interesting itself. By now there’s a huge variety of different things that people have looked into motivated by superstring theory. They’re not “all the same”, even if they have the same motivation. People need to carefully see which things have led to good mathematics and physics, pursue those, and abandon those parts of superstring theory that haven’t led to good math or physics.

If you want to promote the idea of working on superstring theory because it has a topological subsector that gives interesting invariants of certain complex three-folds, or because it might give a useful string dual to QCD, that’s fine. But that’s not what people promoting this research are doing; they keep pushing the failed idea that the full 10d superstring theory will give a unified TOE. It is this idea that not only doesn’t work, but leads to ugliness like the landscape, not to anything particularly mathematically deep.

30. **Blue Fog**
October 27, 2005

an interested observer said

…..That mathematics itself happens to be the best language to “do?? science in, is co-incidental and a consequence of the fact that (historically) SOME PARTS (calculus, say) of mathematics were invented to solve problems external to mathematics, and SOME PARTS (representation theory, say) of modern mathematics, besides being of great interest within mathematics, simply HAPPEN to describe the real world spectacularly well. — it’s a gross generalisation to say that all of mathematics is just a language to describe the real world. And yes, mathematics is not a science since, as defined above, it serves its own ends and does not attempt to describe how the “real world?? works ….

The above statement is an absolutely ridiculous idea. Math CANNOT be invented, it can only be discovered. New math was always a result of a need for explanation of observable fenomena in reality.
Calculus was NOT “invented” by Newton, he actually disovered that Euclidian geometry was not adequate to describe his physical observations. That process continue to happen now too, whenever physics is not able to describe an observable phenomena with available mathematical tools, we are going to see attempts to find new, adequate tools.

To think the opposite one would have to admit that there is no difference between math and fiction writhing. The only reason that math is the best language for science is that math indeed describes the real world because mathematical descriptions of reality are representing real physical qualities of matter.

Try to use your “invention” process and create a new math to describe any already settled physical theory, lets say, Carnot cycle, and tell me what you come up with. If you say that math is “invention”, you should not have any difficulties to do so.

31. **ygorff**
October 27, 2005

Peter, the point was, that if you compactify 10d string theory on 6d CY, you get a strongly coupled 4d gauge theory (very similar to QCD) and the internal part of the superstring in addition gives you the non-perturbative action, which you could hardly get from field theory.

A field theorist, who indeed would be strong enough to get the action from scratch, would necessarily reconstruct 6 extra dimensions in the form of a CY, whether she likes 10d strings or not. Even if she refuses to take these dimensions as physical, she would find that dynamical questions in the gauge theory have a mathematical structure that describes certain dynamics of strings on the internal 6d dimensions.

Whether or not you take the internal space and these strings on it as physical, this structure of 4d x 6d CY emerging from gauge theory is rather simple and efficient and this seems at odds with attributes like “complicated” and “without deep significance”, at least for me.

As for coupling to gravity, the very same argument also gives you the coupling of gravity to this field theory, by considering contributions from GW at higher genus. So the internal part of the 10d superstring is worth of a lot of interesting physics and mathematics.

Not too many string theorists would seriously claim that string theory as it is today is already the TOE of THIS universe, but most of them would agree on that unifying gauge theory and gravity is one of the main motiviations to study strings. The above example shows that the (pretty sketchy) ansatz of 10d superstrings on CY does already a surprisingly good job, a better job then any other known ansatz. A lot of work and ideas will be necessary to apply strings to this universe, but there is no reason whatever to worry about anything else but the reach of human brain power. So far things work surprisingly well and I don't see why you say the idea is "failed" or "doesn't work".

32. **Arun**
October 27, 2005

I think it is a reasonably well-defined question mathematically to ask what a quantum theory of extended objects would look like, and a reasonably well-defined mathematical answer is it would look like string theory. Hence string theory is at least mathematics.

Does such a theory have any physical relevance is the question, and the answer is, yes, it does, except perhaps not as much as the most rabid hypemeisters of theory proclaim.

33. **woit**
October 27, 2005

Ygorff,

Sure, you can try and study various strongly coupled supersymmetric 4-d gauge theories by constructing string duals using 10d superstrings compactified on a CY. But this is a complicated business and in general these are complicated constructions of unclear mathematical signficance. The physical significance is that you'd like to solve QCD this way. This hasn't yet happened. Maybe this will ultimately be the path to finding a string dual of QCD, maybe some very different idea using neither 10d superstrings nor CYs will be required.

Sorry, but to describe the current situation of attempts to unify the standard model and gravity using superstrings as "so far things work surprisingly well" is just absurd. We're at 21 years of work by thousands of smart people and counting, without a single prediction of any kind, and the best guess as to where this all leads is the landscape framework which is horrifically ugly and can't predict anything. By any reasonable accounting, this is an idea that has failed and doesn't work.

34. **woit**
October 27, 2005

Arun,

String theory is of course mathematics in the sense that it is a collection of mathematical formulas.

As for its physical relevance, it's not just "rabid hypemeisters" who are claiming you can unify gravity and the standard model this way. If most string theorists have actually given up on this idea, I think they should say so.

Has theological debate progressed any more than has science?

36. **Clark Goble**
October 27, 2005

Excuse the typos on my earlier comment. (It was late at night) Anyway, a few more comments on this very interesting discussion.

John Baez *The problem of course is that in the standard modern picture, science is empirical, based on induction, and tends to favor a materialistic ontology, while mathematics is non-empirical, based on deduction, and tends to favor a Platonist/Pythagorean ontology… yet somehow they need each other!*

Is mathematical platonism still dominant? I know that the quasi-realism of folks like Putnam has intrigued a lot of people. But I thought that the logicists and the constructivists were now dominant. Of course that might be more among the philosophically well read. So I couldn't even guess in the typical math department let alone physics department.

Woit *My own inclinations are kind of hyper-Platonist, thinking that ultimately we will see that the deepest mathematical structures and the deepest physical structures are very closely related.*

Doesn't that verge upon being more of a religious belief? (Not that there is anything wrong with that – so long as it isn't taught as science the way ID tries to portray itself) I just bring it up since it seems, as John Baez seems to suggest, that at this level where we're so far removed from empiricism many things more religious or aesthetic seem to dominate. I think that's true of ID and perhaps is an influence in some thinking about string theory.

"Blue Fog" *The above statement is an absolutely ridiculous idea. Math CANNOT be invented, it can only be discovered.*

That's true only in some formulations of mathematics. Other formulations say it is all invented/constructed. To say that math can't be invented is akin to saying a nuclear reactor can't be invented, only discovered. Unless one is clear about how to distinguish invention from discovery in an unambiguous fashion, I'm not sure this approach is useful.

37. **woit**
October 27, 2005

Hi Clark,

I don't think that my views on math or physics have much to do with religion, although they do have something to do with aesthetics. That deep mathematics and deep ideas about physics are sometimes closely related is an empirical fact about the history of physics and math. My belief that there is more along these lines is just a working hypothesis about where to look for promising ideas. It is based both on extrapolating from past history and some very specific conjectures about the relation of math and physics that look compelling to me, although much work needs to be done to see if they really make sense.

38. **Arun**
October 27, 2005

39. **Scott Aaronson**
October 27, 2005

Hi Peter,

Thought I'd contribute a "manual trackback entry" (since my blog software doesn't support trackbacks):

http://www.scottaaronson.com/blog/2005/10/insert-string-pun-here.html

[…] In short, if the ID'ers are armed squatters in the apartment building of science, openly scorning the materialistic concept of rent, then the string theorists are model tenants who often drop by the landlord's office to say good afternoon, and by the way, that check from 20 years ago should clear any day. (In their defense, the other tenants' checks haven't cleared either.) To me, this raises an interesting question: does science need a notion of "resource-bounded falsifiability," which is to Popper's original notion as complexity is to computability?

40. **woit**
October 27, 2005

Hi Scott,

Thanks. I just saw your blog posting and was about to link to it from here but you beat me to it. I love your analogy of science as apartment building and scientific predictions as rent.

Interesting to hear that Frederik Denef has been consulting with you on Landscape/computational complexity issues.

Blue fog said:

"Try to use your "invention?? process and create a new math to describe any already settled physical theory, lets say, Carnot cycle, and tell me what you come up with. If you say that math is "invention??, you should not have any difficulties to do so. "

Hey you make invention sound **so easy and trivial**. Let me ask you have you ever patented **anything** at all during your lifetime? I bet you have not applied patent for even one damn little silly invention, all your intelligence notwithstanding.

Mathematics is a language, invented and developed over thousands of years by the whole of human intelligence. It is a great invention so please do NOT trivialize it by challenge any individual to come up with an invention that is in par. We saw great civilizations in human history that built great palaces and cultivated plantations, but failed to develope modern science because they have not invented the necessary language to describe science.

Peter wonders how mathematics and physics are so close in describing nature. Maybe you should also wonder why English and French, two completely different language, happen to describe exactly the same thing in the reality world? The languages, whether it is English or mathematics, are invented to describe the world we observe. So they have got to be closedly related to nature.

Besides, mathematicians who study fields that more or less has some association with the reality world have a better chance of getting support and being able to forward the study, versus stuff that sounds totally silly and totally detached from reality. I predict that all the mathematics tools that folks developed in super string theory research will pretty soon be **completely forgotten**, once it's been shown it has no resemblance to the reality world.

42. **AJ**
October 27, 2005

ARUN: Yeah, but none of those Fields Medals have been related to the way string theory uses Calabi-Yau manifolds. CY manifolds are nice spaces, but they don't seem to be of fundamental significance in mathematics. It doesn't bother me that the Standard Model makes use of an object as random as SU(3)xSU(2)xU(1), but string theory purports to be fundamental. It's aesthetically disappointing it seems to require an arbitrary choice of Calabi-Yau manifold.

43. **Dan**
October 27, 2005

ygorff's point is very strong, and I might add, some people are strong enough to get the internal dimensions and their geometry from purely field theoretical considerations. Namely, Seiberg and Witten have shown that in their exact solution of d=4, N=2 SQCD a rather mysterious curve appeared, the period matrix of which described the effective couplings of the gauge theory. Soon it was realized that this curve is precisely the internal manifold on which you need to compactify string theory if you want to realize this SQCD theory on branes.

I'm kind of surprised Peter doesn't understand this point. So far I thought he was a hard boiled skeptic of the relevance of string theory to nature, but distinguished from pure crackpots by his realization that string theory does lead to highly non-trivial and useful results for a lot of semi- or non-realistic models — such as N=2 SQCD. Now it seems that Peter has given up his last piece of wisdom. I will not go as far as Lubos who labels him an "empty head", but…

44. **Chris W.**
October 27, 2005

The comments on this post haven't said all that much about Intelligent Design, despite its mention in the post's title. I thought I would add this modest contribution (with thanks to William Saletan of *Slate*, and Monty Python).

45. **woit**

October 27, 2005

Dan,

I think I've written that string theory is useful for studying supersymmetric gauge theories and and is a promising approach to understanding QCD several times already in this posting and somewhere between 10^2 and 10^3 times on this weblog.

There's some sort of weird and very specific disease that afflicts string theorists who read the words I write. Anything critical I write about string theory they interpret as meaning that I am not aware of the achievements of string theory methods in dealing with 4d supersymmetric gauge theories. This is really tedious. They also especially like to do this from behind the cover of anonymity.

Your notion that I used to understand this, but don't anymore, at least has the charm of novelty.

46. **plato**
October 27, 2005

John Baez:*The problem of course is that in the standard modern picture, science is empirical, based on induction, and tends to favor a materialistic ontology, while mathematics is non-empirical, based on deduction, and tends to favor a Platonist/Pythagorean ontology… yet somehow they need each other!*

This is a very interesting comment to me. No, not because of my name :), but because it really defines the process, doesn't it?

Putting ID aside, isn't this what would make string theory suitable?

If such inductive and deductive processes are indeed followed, as in any other model that you chose to use, furthers insight and development are indicative of advancement, in physics and mathematics?

I think this has already been pointed out, that modest gains may have some value in string theory as a model.

47. **Dan**
October 27, 2005

Hi Peter,

I'm afraid you don't get off the hook so easily. You said:

"Sure, you can try and study various strongly coupled supersymmetric 4-d gauge theories by constructing string duals using 10d superstrings compactified on a CY. But this is a complicated business and in general these are complicated constructions of unclear mathematical signficance. The physical significance is that you'd like to solve QCD this way."

This is plain wrong in the case of N>=2 SUSY. In particular, the meaning of the Calabi-Yau is *physically* clear from the *field theory* perspective. Your lip service that you understand the significance of string theory to gauge theories is contradicted by your own statements. It's not a matter how many times you claim you understood…

48. **Arkadas Ozakin**
October 27, 2005

John Baez said:

> The problem of course is that in the standard modern picture, science is empirical, based on induction, and tends to favor a materialistic ontology, while mathematics is non-empirical, based on deduction, and tends to favor a Platonist/Pythagorean ontology

I am not sure if you agree with this "modern picture", but here is a quote from the book *Complex Manifolds and Deformation of Complex Structures* by Kunihiko Kodaira that I find interesting in relation to the "induction/deduction" issue:

> The process of the development [of the theory of deformation of compact complex manifolds] was the most interesting experience in my whole mathematical life. It was similar to an experimental science developed by the interaction between experiments (examination of examples) and theory.

I have the feeling that this was not an isolated incidence in the history of mathematics, but that inductive/experimental approaches in mathematics are alive and well. I also remember reading strongly worded statements by V. I. Arnold on this issue (which I can try to dig up).

49. **plato**
October 27, 2005

I have the feeling that this was not an isolated incidence in the history of mathematics, but that inductive/experimental approaches in mathematics are alive and well.

I would say so. If you have situations in physics such as particle reductionism and you are reaching limits, why would you not say, okay, let's try something different and quite profound in our general concept makeup. Let's shake the foundation up?

Did string theory succeed? Did they point to a time where we knew good scietntists were working in conjunction with views on the cosmo?? It further refined our views on how we view the early cosmo? Guth's was the first three minutes, refinement, meant something else here.

50. **woit**
October 27, 2005

Dan, sorry but you're engaging in the really obnoxious behavior I've experienced time and time again from string theorists. The sentences you quote are not "plain wrong"; they are perfectly accurate. You're putting your own construction on them which has nothing to do with what I was saying, then using this to attack me as not knowing what I'm talking about, using your anonymity in a cowardly fashion. If you don't think something I wrote is correct, how about writing in to ask me to elaborate? Then if I don't know what I'm talking about, my elaboration should make this very clear and you can joyfully point this out. Or you might find out I just meant something different than what you thought.

I can't be sure, but I assume you're objecting to my final sentence, which had nothing at all to do with the "physical significance" of the Calabi-Yau in the constructions you're thinking of. I was referring to the potential significance to a real physical problem: that of getting non-perturbative information about 4-d gauge theories relevant to the standard model. I realize this is kind of strange behavior you may have trouble understanding, but when I use the term "physical", I'm just about always referring to the physics of the real world. By "physical significance" I meant "significance for physics", real world physics. In the real world the main reason you want to better understand non-perturbative gauge theory is QCD (a secondary reason is that you might believe in something like technicolor and want to use non-perturbative gauge theory behavior to break electroweak symmetry).

That's the elaborated version of the last sentence you quoted. If you think that it's "plain wrong" and evidence I don't know what I'm talking about, let's hear why. If your problem was with one of the other sentences, we can go over those too….

51. **dan**
October 27, 2005

playing devil's advocate here, if there was a house fire, one of two hypothesis as to the origin of explusion may be possible

1- it is of human origin (accident, or intentional)
2- it is the result of natural processes (i.e faulty wiring)

how would we tell apart 1 from 2? could such methods apply to biological organisms?

October 27, 2005

Dan said:

"A shorter answer: String theorists are sincerely interested in extending known and tested science??

String theorists are sincerely interested in extending known and tested science, into unknown and untested science.

"playing devil's advocate here if there was a house fire, one of two hypothesis ….."

Huh? Should have put this where most biological material coming from a back hole belongs.

53. **Steve Myers**
October 28, 2005

Math deals with all possible worlds; physics tries to select the one we live in. Math is Jules Verne; physics is Tolstoi. Intelligent design is situation comedy; string theory is Gertrude Stein turning Joyce"s "Finnegan's Wake" (without consulting Gell-Man) into an opera (music by John Cage).
Math is not only a language in the way French, English, etc., are languages since I can analyze the structure of languages with mathematics. As Russell (and Frege before him) showed, math is neither mental nor physical — it deals with an objective world (in the sense that the axis of the earth is real but neither mental or physical). Math ideas can start out as generalizations of the particular (Gauss' technique) or figues and systems created from basic abstract concepts (invariance, symmetry, etc.). The math I do has direct physical applications (temperature profiles of elastic extruder dies; power requirements of a splicer; gear ratios,etc.) but it all has a basis in fundamental concepts.

54. **Juan R.**
October 28, 2005

Next i will write a list with all correct physics has been already obtained **from** string, brane, and M theory.

– [ ]

– End.

P.S1: Witen Fields medal was not awarded for work in string theory.

The 1990 Medal was for Vladimir DRINFELD, Vaughan F.R. JONES, Shigefumi MORI (University of Kyoto), and Edward WITTEN. None of awards was for work in string theory.

Regarding Witten the award was for "*Completed an amazing proof of the classic Morse inequalities and gave a proof of positivity of energy in Einstein's theory of Gravitation*."

None of them directly based in string theory. In fact *a posteriori* one can search some link between string theory and part of Field Medals Witten's work, but the claim that Witten received the Medal for string theory is just an abuse of language, somewhat as "*string theory predicts gravity*". Both Newtonian gravity and general relativity were discovered before string theory!

P.S2: The myth says that Ed Witten is the new Newton. This is rather difficult to believe. Newton was a real mathematician with an insight beyond rest mathematicians of his epoque. Witten is more a particle physicist with a very good command of math.

String theory community over-popularizes Witten's contributions claiming that Witten is doing 'real' math and stating that string theory 'is' math. This distorted view is neglected by own mathematicians. The correct place of Witten in math is brilliantly explained as [*]:

Although mostly not in the form of completed proofs, Witten's ideas have triggered major mathematical developments by the force of their vision and their conceptual clarity, his main discoveries soon becoming theorems. His Fields Medal at the 1990 International Congress of Mathematicians acknowledged the growing impact of his work on contemporary mathematics.

Reading above, I understand Witten's work as a kind of 'pre-mathematics'. Newton did not "pre-mathematics", Newton did mathematics. From the mathematical side, string theory is a kind of 'pre-mathematics'.

[*] ICM-90 Kyoto, Japan, Notices Amer. Math. Soc. 37 (9) (1990), 1209-1216.

FOR IMMEDIATE RELEASE:

http://physicsmathforums.com/showthread.php?p=788#post788

Tied Up & Strung Out: Hollywood String Theory Movie!!! Looking For Extras!!!

ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

“As contemporary physics is about money, hype, mythology, and chicks,” Ed Witten explained from his offices at the Princeton Institute for Advanced Study, “The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy.”

Brian Greene, the famous String Theorist who will be played by David “the truth is out there” Duchovney, explained the plot: “String theory’s muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone, and I win the Nobel prize for showing that M-Theory is in fact the dark matter it has been searching for.”

Greene continues: “At first my character is reluctant to stop theorizing and start postulating, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he’s doing in my soul, and he explains that the answer is contained in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. And he shows me God in all her greater glory, as he points out that we can make more money in Hollywood than writing coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler. I am quickly converted, and I agree to turn my back on String Theory’s hoax and save Jessica Alba.”

But it’s not that easy, as standing in Greene’s way is Michio “king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this” Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the “ironic” pretense his salary, benefits, and all-expense paid trips depend on. “WE MUST HOLD BACK THE YOUNG SCIENTISTS WITH OUR NON-THEORIES!! WE MUST FILL THE ACADEMY WITH THE POMO DARK MATTER THAT IS STRING THEORY TO KEEP OUR UNIVERSE FROM FLYING APART, OUR PYRAMID SCHEMES FROM TOPPLING, AND OUR PERPETUAL-MOTION NSF MONEY MACHINE FROM STOPPING!!” Kaku argues as he delivers a flying back-kick, “There can be ony ONE! I WILL be String Theory’s GODFATHER as referenced on my web page!! I have better hair!”

But Greene fights back as he signs his seventeenth book deal to make the hand-waving incoherence of String Theory accessible to the South Park generation, senior citizens, and starving chirldren around the world. “Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket),” Greene shouts. “It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!!”

“Time travel is also theoretically impossible, but there’s a helluva lot more money for us in flushing physics down a wormhole. Nobody knows what the #&#%&$ M stands for in M theory ya hand-waving, TV-hogging crank!!! Get it?? Ha Ha Ha! We’re laughing at the public! We’re the insider pomo hipsters! Get with the gangsta-wanksta-pranksta CRANKSTER bling-bling program!!”

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We’ll all just have to wait!

But in the meantime, how do you think it will play out?

Will theories with postulates ever be allowed in physics again? Or will the well-funded, tenured pomo String Theory / M-Theory (Maffia-Theory) Priests send their armies of desperate, snarky postdocs and starving graduate students forth to displace and destroy all common sense, logic, reason, and physics in the academy? It must be so–for the greater good of physics, the individual physicist, and thus physics, must be sacrificed.

MDT’s postulate: THE FOURTH DIMENSION IS EXPANDING AT A RATE OF C RELATIVE TO THE THREE SPATIAL DIMENSIONS IN QUANTIZED UNITS OF THE PLANCK LENGTH, GIVING RISE TO TIME AND ALL CLASSICAL, QUANTUM MECHANICAL, AND RELATIVISTIC PHENOMENA.

Juan R.

That is why I said one if not two Fields medals arose from string theory. Borcherds’ work, according to the blurbs, used methods from string theory.

57. **ks**
October 28, 2005

Juan, I heartly disagree that mathematics has to be reduced to euclidean style theorem proving machinery in order to be labled as maths. But this is an old discussion that can be rooted back into ancient times of old greeks who didn’t accept Archimedes as a mathematician due to his heuristic style argumentation. I do think the distinction between what is mathematics and physics in the work of Witten is small-minded hairsplitting and philistine. It does not have any cognitive value at all and is a science-political one.

By the way I do not understand Peters argument against ST that it will be perpetuated for social and psychological reasons? This is obviously true for the whole endeavour of finding a “theory of everything” that fits well into a certain academic-cultural pattern that promises high payouts of symbolic capital and intellectual influence to those who make any progress. Denying progress and deevaluating the symbolic capital of researchers will naturally force them into defense and closing the lines against attacks – whether the research program gets stuck or not. This is not very special to ST.

58. **AJ**
October 28, 2005

That is why I said one if not two Fields medals arose from string theory. Borcherds’ work, according to the blurbs, used methods from string theory.

Borcherds? I thought you meant Kontsevich. Borcherds work belongs properly to 2d chiral conformal field theory. He’s studying a kind of sigma model, but there’s no coupling to worldsheet gravity, and hence no sum over Riemann surfaces. Not very stringy. Kontsevich’s work, on the other hand, does make use of such sums; he’s actually using the CFT to make string theory computations.

Kontsevich’s work on the other hand, does actually involve integrating sigma model correlation functions over the space of conformal structures.

59. **Juan R.**

October 28, 2005

Arun Said:

"*Juan R.*

That is why I said one if not two Fields medals arose from string theory. Borcherds' work, according to the blurbs, used methods from string theory."

I agree that Borcherds' work is related to 'string theory' in some sense, but your suggestion that "*Fields medal arose from string theory*" is another exageration.

In 1998 the Fields Medal was for

W. Timothy GOWERS, Maxim KONTSEVIC, Curtis T. McMULLEN, and
Richard E. BORCHERDS.

BORCHERDS was **explicitely** awarded for work in Kac-Moody algebras and automorphic forms.

b = d·h is math

F = m·a is physics

kc, of course, math is an 'independent' discipline. My emphasis was on the link math-reality, which cannot be done without physical sciences playing the role of 'intermediary'. Paraphrasing Feynman, "*Euclidean geometry lives in a mathematical word*" aplication of Euclidean geometry to real word is an approximation, strictly speaking there is no real object following rules of Euclidean geometry.

Even if string theory was correct (it is not of course). Nothing in the physical word could be identified with a string unnless one used certain methaphysical considerations outside of pure physics.

Juan R.

60. **Arun**
October 28, 2005

Juan,

I know nothing of the math. involved; I'm merely quoting from things like this, from a mathematical org. website:

http://www.icm2002.org.cn/general/prize/medal/1998.htm

" In his proof, Borcherds uses many ideas of string theory – a surprisingly fruitful way a making theoretical physics useful for mathematical theory."

Borcherds was awarded the medal for proving the "moonshine conjecture" which has something to do with the monster group.
Is that Kac-Moody & automorphic forms? I have no idea.

Of general interest, here is Faddeev on Witten:

http://www.mathunion.org/General/Prizes/Fields/1990/Witten/page1.html

Witten is cited for several contributions, of which item 3.
"Rigidity Theorems" is from string theory.

> 3. Rigidity Theorems : Witten [7] produced an infinite sequence of such equations which arise naturally in the physics of string theories….

61. **Arun**
October 28, 2005

http://arxiv.org/abs/math/9808136

62. **woit**
October 28, 2005

Arun,

All the work you're citing is 2d QFT, not string theory. I think AJ is right to point out that you're only really doing string theory when you integrate over the space of metrics on your surface (and sum over genera). If you're doing 2d QFT on a riemann surface with a fixed metric, that's just QFT, not string theory.

Witten's rigidity theorems come from looking at a supersymmetric 2d QFT on a torus. Borcherd's vertex algebras are basically an algebraic version of conformal field theory. Again, these are 2d QFTs, and he's not summing over the 2d metric or genus. It's certainly true that a lot of work on 2d QFTs has been motivated by hopes it will be useful in string theory (especially in the case of conformal field theory), but the things you're quoting are purely QFT results.

63. **John Gonsowski**
October 28, 2005

There would be some beauty if say it was obvious that all of physics came from something like Fibonacci numbers. Then you could say perhaps physics was coming from the most natural math. Fibbonacci numbers come from Clifford Algebra and CLifford Algebra may be the most natural math for physics, spiritual geometry, personality models, etc. The crack in the door that lets ugly things like SUSY in is that no matter what theory is right, there probably is some ugly symmetry breaking somewhere but SUSY seems too ugly. Symmetry breaking is supposed to reduce possibilities while SUSY adds a bunch of not needed possibilities before eventually reducing them.

64. **D R Lunsford**
October 28, 2005

This beauty issue is a canard. Things like GR and Dirac eqn are beautiful because they are actual solutions to standing problems, not imagined ones, moreover, they don't have the defect of overstaying their welcome when they are exhausted.

This issue isn't beauty – it's metaphysics, philosophy. The entire idea of string theory was obviously false from the first minute, because it was out of context all the way back to Democritus, and because it adopted whole cloth a discredited physical idea, Kaluza-Klein theory, also in disrespect to the tradition that says, when it's wrong, it's wrong.

-drl

October 28, 2005

Dear Peter,

Of course I'll have to object to your objection 😉 But you should consider the fact, that there is (at least) a 6 hour difference between your continent and mine (so, now it's around 3.00 AM). I'll update my comments as soon as possible…

66. **Daniel Elander**
October 29, 2005

Regarding platonic mathematics:

The foundation of math is a messy business. Typically one starts by developing a meta theory describing how to prove theorems. Each proposition is viewed just as a typographical string of symbols, which can be manipulated according to so-called rules of inference. You start out with certain strings which you call axioms, and if you can manipulate them according to the rules of inference, eventually reaching some more involved proposition (which is just another string of symbols), you call that new proposition a theorem. The meta theory describes how all this is done. The problem is of course that the meta theory really needs a meta meta theory to be rigorous, and so on ad infinitum. Also, all mathematics, including set theory, has to be formulated with the help of the meta theory, but the meta theory actually assumes some set theory! Namely, it is talking about the set of allowed symbols. So it's really quite messy if you think about it. In the end, you may even come to the conclusion that mathematics presupposes language, in some sense. Platonism seems to me like just a suspension of whatever doubts and concerns you might have about these kinds of issues ("the mathematical truths are alive and happy in math heaven" ;-)), rather than a real resolution.

67. **Gavin**
October 29, 2005

Peter,

Thanks for mentioning my earlier comment in your update. The same distinction I made between intelligent design and string theory can also be make between string theory as a theory of particle physics and string theory as a theory of quantum gravity.

String theory as a theory of particle physics is up against very strong competition from quantum field theory. There is nothing from particle physics experiments to suggest that quantum field theory is wrong. There was a hope at that string theory might predict certain features of the particle spectrum and interactions, but that path has not emerged.

However, string theory as a theory of quantum gravity is quite another story. There is no established theory of quantum gravity to unseat; the field is wide open. LQG is in the running, perhaps other ideas offer promise as well, but none of the theories are the "evolution" of quantum gravity. They are all speculative and untested.

This brings me to my concern about the "not even wrong" criticism of string theory, which is that it will apply to *any* theory of quantum gravity. Short of a complete miracle (like detectable large extra dimensions), the Planck scale is going to be out of experimental reach for a very, very long time. Maybe LQG has better prospects that string theory, but it is probably too young to tell. Even if there are certain regions of parameter space where quantum gravity theories offer low energy predictions, there will also be large regions of parameter space with nothing but QFT at attainable energies. If experiments fails to produce direct evidence for any of these theories, they will all be able to retreat to high energies and avoid falsifiability.

So my question, Peter, is should we be thinking about quantum gravity at all? Since no theory is going to be falsifiable, should we just call the whole thing off? If looking for a theory of quantum gravity is something that we should be doing, then certainly string theory is part of the program.

I'm concerned that the attack on string theory as unscientific is going to taint the entire pursuit of quantum gravity, a pursuit that I think is worth while. String theory is not a strong competitor for a theory of particle physics, but bad player in the major leagues can be a great player in the minors. We should make sure the player is in the right league, not kick him out of the sport. String theorists certainly have confused this issue as well. Having taken the lead in quantum gravity, we act like string theory is up 3-0 in the world series of physics.

I hope that we can turn the debate away from the unproductive question about whether string theory is star or a failure and toward a consensus about where string theory belongs.

Gavin

68. **Arun**
October 29, 2005

Peter:

Whatever. I don't have a stake in this either way. If Faddeev and Atiyah say that Witten derived something from string theory in their talk felicitating Witten on his Fields Medal, and AJ and you say its not string theory; or the Mathematical Congress puts out a press release saying that Borcherds used methods from string theory (the press release also says that string theory is controversial among physicists, so they weren't trying to get on a bandwagon) and here folks say nay, then I'll leave it for the historians of science to figure out who is correct.

Perhaps the mathematicians have a different understanding from physicists of what string theory is, and maybe it is the wideness and imprecision about what string theory is that is contributing to our collective irritation with it.

69. **Arun**
October 29, 2005

BTW, while I don't have a stake in the discussion, I do appreciate it. How else would I learn the fascinating fact (Borcherds, 1992) that "The monster Lie algebra is the simplest example of a Lie algebra of physical states of a chiral string on some orbifold."

70. **woit**
October 29, 2005

Hi Arun,

Lots of people claim that 2d conformal quantum field theory results are string theory results, and this is one of the main reasons mathematicians are so impressed by string theory. Personally I think this completely muddies important issues, and that people should be careful to keep straight what is really string theory and what isn't. Others undoubtedly disagree.

71. **Juan R.**
October 29, 2005

Gavin

String theory NEVER was a valid theory of particle physics. Never wad a real competition! Physical states in string theory are *supersimmetric masless* states. There is not such one thing is the standard model of particles.

Of course, all current models of QG are speculative because experimental QG does not exist still. However, string theory is not comparable to rest of alternatives. In general, the rest of alternative rely on 'direct' modifications of the already known. String theory is based in an unending introduction of speculations and unobserved things; with each new failure -since 40 years ago, experimental disproval, etc, string theorists introduce some new unobserved thing claimed to be fundamental.

Moreover it is not clear that any quantum gravity theory cannot be falsifiable. Remember that the scale of the string in string theory is introduced *by hand* and choosed to be the Planck scale. Perhaps some QG effect can be detected at usual but high energies in other formulations or perhaps QG was UNOBSERVED. In fact, this was the point of Dyson some time ago. He argued that gravitons may be unobservable and therefore any QG are outside of physics.

Is he right? I still unknow.

People does not attack string theory 'as unscientific'. In fact, this is the reason that other approaches to QG are NOT usually atacked. That people attacks is the arrogance of string theorists and premature -wrong- claims by guys like Kaku, Greene, Witten, Schwartz, etc.

People attack heavy marketing for public, loop theoreticians attack when string theorists claim in public that string theory is the ONLY approach to quantum gravity. Honest physicists attack books as "The Elegant universe" by Greene, Profesors attack the attempt to giving courses on string theory to students of physics, etc.

People attack the lack of honesty of many string theorists, who popularize string theory hidding all of its flaws. In fact, in personal communications and talks string theorists agree that string theory is not now a theory of strings -in M theory the D0 brane appears to be fundamental- but public still beoieve thst string theory claim that universe is done of small vibrating strings.

If you ask to string theorists why the name string theory is maintained in popular books and magazines they reply "*because marketing purposes*".

'If you ask to string theorists why the name string theory is maintained in popular books and magazines they reply "because marketing purposes".' – Juan R.

I sadly agree. Marketing is now deemed to be the problem of adapting a product to fit the customer.

73. **David Corfield**
October 29, 2005

Without wanting to be harsh on anyone, some philosophical input may be timely.

AG writes:

It is notoriously difficult to draw the Popperian demarcation line, but surely there is a fundamental difference between string theory and intelligent design. When embarking on a scientific research program, it is not always possible to tell from the start what falsifiable predictions or practical applications might emerge, and theoretical scientists have to go on well-formulated hunches and search for ways to corroborate their hypotheses; nonetheless, their efforts can still be called science. Intelligent design, however, is not science– not because it cannot be falsified, but because it cannot, even in principle, be corroborated either. How can an ID proponent move forward with his "research program???

For Popper, corroboration is the survival of an attempt to falsify, so you cannot have the possibility of one without the other. Popper doesn't develop a notion of positive evidence until his later rather ugly theory of verisimilitude. This is what marked Popper off from the logical empiricists who saw the need for a logic of confirmation. But AG is using the language of someone you generally teach after Popper, namely Imre Lakatos. The last sentence I quoted is thoroughly lakatosian. A program has a heuristic spirit. It isn't fully worked out. If it encounters problems, it needs to have the resources to move in progressive direction. It mustn't make *ad hoc* moves by, say, artificial exclusions of events from falling under a law, or unnatural borrowings from rival programs.

Lakatos is also interesting for adapting and welding ideas from Popper and the mathematician George Polya (with a sprinkling of Hegel). Polya had developed a probabilistic (Bayesian, without using the word) logic of confirmation for mathematics. Lakatos takes on a case suggested by Polya, the V-E+F=2 formula for polyhedra, and argues that mathematics is 'quasi-empirical'. He would disagree with:

Subhash wrote:

Has it been falsified, or not falsified, in mathematics, the statement that two parallel lines shall never cross? You've got to know neither case is right or wrong.

There is no empirical truth in mathematics. All math are logical derivations from a few fundamental rules which we probably took for granted, but which do not need to be taken for granted as truth, like the parallel line hypothesis. As such, all you could ever say is certain statement is either consistent, or inconsistent, with the set of hypothesises that your math is based on. There is no absolute truth.

Lakatos's idea was that Polya had been right to find a strong parallel between mathematical and scientific activity, but had erred in thinking that what was common was probability-based inductive reasoning. Instead, Lakatos suggests that what's common is a passage from certain observed facts to an explanatory framework for them, driven by the proposal of theories and the provision of counter-examples. The important point is that the language changes through this process. In the case of the Euler conjecture, the term 'polyhedron' is transformed from an imprecise, intuitive term to a mathematical definition. This courts the danger that something of the original intuitively understood domain may fail to be captured. About Subhash's mention of parallel lines, a Lakatosian story would tell the history of mathematical conceptions of space. If progressive, we're achieving an ever less partial understanding of space. This is clearly unfinished business. Read the second half of Pierre Cartier's great article '

A Mad Day's Work'. Any comments about my own attempt to move beyond Lakatos, explained in a paper 'How Mathematicians May Fail to be Fully Rational' (link form my webpage), would be welcome.

Peter wrote
My own inclinations are kind of hyper-Platonist, thinking that ultimately we will see that the deepest mathematical structures and the deepest physical structures are very closely related.

The closest to a modern philosophical account of this is Roland Omnes' 'Converging Realities'. Omnes (a physicist) calls it physism.

David

74. **Nigel**
October 29, 2005

David – I've read some of Lakatos' views which I quote on my webpage, namely his essay in a 1974 Open University book "Philosophy in the Open". He is critical of Popperian critical experiments and of Kuhnian revolutions because both always "turn out to be myths" caused by historical revisionism. Thus, caloric, phlogiston, and ether died out as their proponents died, not in a blinding flash of revelation when people like Priestley did experiments. Still today the FitzGerald 1889 interpretation of the Michelson-Morley experiment is heresy and cannot be discussed because it is actively defended by a group of crackpot dissenters.

While I respect Lakatos for pointing out that Popper's and Kuhn's views are total nonsense, I fear he is simplistic himself in claiming that revolutions occur when "progressive research programmes [British spelling – sorry] replace degenerating ones". In the case of string theory, which ultimately stems to Kaluza 1919, the whole speculative endeavour has been sustained by propaganda and make-believe, and people have done very well out of it. Is this progressive or degenerative? A-level uptake of physics and maths is falling off in the UK, but that just leads to demands for more "popularisation of string theory" to make the subjects more appealing. With no real rival, string theory will run physical science and maths into the ground, without "degenerating" in the despondent way Lakatos imagines.

Therefore, string theory need never collapse. When Peter's book "Not Even Wrong" appears next March, will ST collapse? No! Basically, Peter is doing the ST lobby a favour by pointing out to them areas which need to be dressed up more effectively, or worked on harder. His own ideas like http://www.arxiv.org/abs/physics/0102051 have not caused much impact yet: he says a good way to advance the standard model is SO(4) spinors and Clifford algebras, and analysing path-integrals. When you dig into the complexity of this, it is as technical as string theory but is in the opposite direction. It is also more realistic, and therefore further from science fiction of parallel universes and M-theory.

Is string theory going to shut up shop next March when his book "Not Even Wrong" comes out? I doubt it. Personally, I'm impatient with string theory. Not because I don't like 6 dimensional manifolds or vibrating strings, but because they are not building on what is known. If it turns out there is some evidence for any of this, OK, it would deserve some allocation of research. But it is just crackpotism, and then these people dismiss others who are struggling without any grants in bad conditions as being "crackpots". They have no shame but too much egotism.

75. **Nigel**
October 29, 2005

Whoops, the Woit ref I meant was http://www.arxiv.org/abs/hep-th/0206135 'Quantum Field Theory and Representation Theory: A Sketch'.

76. **A.J.**
October 29, 2005

Arun: Go read Borcherd's original paper. http://math.berkeley.edu/~reb/papers/monster/monster.pdf
He does say string theory in several places: He's studying a vertex algebra which describes the chiral states of a sigma model to an orbifold, and he's using a no-ghost theorem that was originally proved by string theorists who wanted to think of the sigma model's Fock space as the space of single string states for some string theory.

But Borcherds is not making any essential use of the string theory picture. He never needs to think of the string as interacting. So saying his result is inspired by string theory is true in a sociological sense, and it's also true in a rather weak technical sense: It's like saying a result in relativistic quantum mechanics is a result in quantum field theory.

I'm about done with this topic.

77. **ks**
October 30, 2005

In the case of string theory, which ultimately stems to Kaluza 1919, the whole speculative endeavour has been sustained by propaganda and make-believe, and people have done very well out of it. Is this progressive or degenerative?

In case of ST it resided a niche i.e. it did not have strong competitors to subdue. Lubos insistence in ST to be the only attempt of a unified theory reflects this (of course he is well aware about LQG but asserting that it is not a competitor is part of the same rhetoric). From Poppers analysis we can conclude that ST will wiped out only in presence of a better approach (simpler, more concise, fruitfull and falsifiable). From Lakatos we can conclude that history will be written and re-written by the victors who present a rational reconstruction (rationalisation of their victory).

Peter et al describe the crisis of ST, it's inability to return to the real. But in absence of a valid theory it might be the only possibility to survive in theoretical physics – as abstract art. Some find it beautifull.

78. **Thomas Larsson**
October 30, 2005

Arun, AJ, Peter:

The physically successful application of 2D CFT is in the theory of 2D phase transitions. This is part of condensed matter physics and has nothing to do with strings as a theory of quantum gravity. It is true that this discovery was made mainly by string theorists, who happened to have access to the relevant mathematical machinery. However, string theory is not a ToE even in statistical physics – it says everything worth knowing about 2D phase transition but nothing about the physically more relevant 3D case. In fact, this was my original motivation for generalizing stringy mathematics to higher dimensions, which led to my discovery of multi-dimensional Virasoro algebra and its representation theory.

Gavin:

Whereas string theory is not a successful theory of quantum gravity in 4D, there is no doubt that the worldsheet theory of the free string correctly describes gravity coupled to scalar fields in 2D. The most striking thing from this viewpoint is that gauge components of the metric becomes physical after quantization. This manifests itself in different ways: the Hilbert space in lightcone quantization cannot be reduced due to the conformal anomaly, or one must explicitly keep the trace of the metric (the

Liouville mode) as a dynamical field.
Analogously, one may expect that the metric field in 4D has more components after quantization than the two transverse graviton polarizations, due to diffeomorphism anomalies. This was another motivation for my generalization of stringy math beyond two (or rather one complex) dimension.

79. **David Corfield**
October 30, 2005

Nigel,

Your points are well taken. I think we must remember that Kuhn and Lakatos were in the business of describing historical cases of one paradigm/programme (I'm British too) superseding another, events seen as rational with hindsight. Leaving aside the point that Lakatos's own rationally-reconstructed 'histories' are often very far from historical reality, of the two Lakatos was more interested in isolating the rational component of the decision, and at one point he hoped that this could help with decision-making in current science, but by the end of his career he'd given up on the idea that conditions could be given which would rationally warrant one switiching programme. Instead, he just insisted that any scientist should be honest enough to acknowledge where his programme was on a scale running from degenerate to progressive.

When you say, "While I respect Lakatos for pointing out that Popper's and Kuhn's views are total nonsense, I fear he is simplistic himself in claiming that revolutions occur when "progressive research programmes [British spelling – sorry] replace degenerating ones?? ", pointing to string theory as a counter-example, he could reply in a number of ways. First, that rational change might need to be judged over lengthier periods of time. Nowhere does he say that progress must occur in a given period. Further, he could agree with you that ST is in a (permanent) degenerate phase. For the latter he would want us to judge how ST is doing according to his 3 criteria of progress: (1) Is it making new predicitions?; (2) Are these being confirmed, or can it explain already observed phenomena for which ST was not designed to explain; (3) when it encounters problems, does it engage in problem shifts leading to theoretical devleopment in the spirit of the programme.

I guess you'd argue that ST was not progressive according to these criteria. You might also same the same about other candidates for QG. I don't recall Lakatos suggesting what one should do in terms of institutional support in this situation. Presumably there are approaches which haven't been given enough support to reveal their potential. All he suggest is honest score-keeping.

I think there are problems with Lakatos, as I outline in the paper I mentioned. There I looked at the ideas of Alasdair MacIntyre. He would suggest that given an acknowledgement of weakness/resourcelessness of their own programme, some of its members should be encouraged to go and learn the languages of other programmes, as second first langauages, to see if they have the resources to understand these weaknesses. Perhaps this is one small piece of advice we philosophers can pass on.

David

80. **Nigel**
October 30, 2005

David,

Thank you for this detailed reply. I saw a couple of weeks ago a piece in New Scientist by Appleyard, where the historical revisionism in science was blamed for Marxism and Nazism, because Marx used a cranky scientific analysis of history to defend his ideas, while Mein Kampf utilised crackpot genetic theory. It seems absurd that science is to blame for Hitler and Stalin via crackpot official science. I'd better not push my luck here by mentioning the ST propaganda book "Warped Passages"… perhaps that will be used to justify future warped ideas.

What I'm curious about is what Peter intends doing to sort out physics. He says SO(4) can link with U(2) to produce the generations of leptons, etc., in the Standard Model. How far can this approach go toward replacing ST research?

81. **woit**
October 31, 2005

Gavin,

Thanks for another interesting comment. My own view on quantum gravity research is that it is worth doing, but needs to be done differently than most of the rest of physics, precisely because there is now no experimental data, together with the real possibility that there won't be any in this or even the next century.

Without experimental data to keep a field honest, research needs to be conducted more like in mathematics, with an emphasis on being completely precise and clear about what you have and what you don't have. If you have experimental results, you can afford to string together (that was an unintentional pun…) a bunch of not very solid arguments and see what you get. If you get something that agrees with experiment, you're on the right track, if not you try something else. I personally don't see the point of stringing together a lot of dubious arguments, and at the end claiming you've reached the holy grail of a quantum theory of gravity.

So, I think pure quantum gravity research is legitimate, but it really needs to be done with a higher standard of precise thinking than is usual. There's also a very serious danger that in the end one will discover that one has found an infinite array of different "quantum gravities", and, without any experimental way of telling them apart, the whole thing becomes not that interesting.

To me the "holy grail" of quantum gravity is not finding a consistent quantization of the classical theory, but finding some sort of useful relation between the (pseudo)-Riemannian geometrical degrees of freedom of GR and the geometrical degrees of freedom (gauge fields, spinors) of the standard model. If one could do that, one might be able to even make predictions about particle physics, in which case whether or not one had a rigorously consistent way of "quantizing gravity" wouldn't be the most important thing.

Put differently, I think the real problem is how to unify GR and the standard model, not so much how to unify GR and the general principles of quantum mechanics. Of course the latter may be a good thing to think about to get an idea about the former.

82. **Jack Sarfatti**
October 31, 2005

"String theorists are sincerely interested in extending known and tested science. Intelligent design "theorists?? are interested in undermining the public's faith in known and tested science."

This is false. While you can find SOME fundamentalists who say things like that, it is not true of people like Tipler & Barrow, or Fred Hoyle (his book "The Intelligent Universe" (1986). Remember Hoyle predicted a nuclear resonance (I think in Carbon) using WAP. So WAP is falsifiable. WAP of course is not enough for ID. I don't mean to suggest that.

83. **Juan R.**
October 31, 2005

Woit,

I completely agree with you that in absence of experimental data, research would be more careful and far from the media popularization until solid results are achieved. In fact, this was more the program of rest of quantum gravity researchers -except exceptions-. due to marketing and popular presure loop theoreticians began to popularize his own views.

It was a true scandal that a string theorist began one talk or a article on a popular magazine with the typical "string theory is the only approach to quantum gravity…"

But the question is: **is quantum gravity testable?**

Nobody know the reply still. *A priory* one may wait relevant phenomena at Planck scales, but this is not clear.

It is posible that in some configuration very small effect can cause a big measurable effect. I sincerely think that particle physicists continue thinking in the old 'linear' manner:

small cause ==> small effect

which is not true.

The best example are PV effects. ALL particle physicists -including important ones as Weinberg- claimed in the past that parity violating effects were so small that would be unimportant for all chemistry purposes.

Yes, they are very small, but chemistry is mainly a nonlinear discipline and some molecular configurations *amplify* those initial ultraweak effects even at level of being measured by us. Particle physicists were wrong and electroweak quantum chemistry has arised as a proper discipline.

Sincerely, i wait some kind of 'nonlinear' phenomena doing posible some quantum gravity effect visible at available high energies. Of course, i have **not** proven this still.

About your own insight on the "holy grail?? i think that you are in the wrong way.

1) By definition, quantum gravity is a quantization of classical gravity.

2) The Riemannian geometrization of GR is NOT fundamental (in fact, the Cartan extension proves that a pure Riemann geometry is not suficient and teleparallel gravity thought us that the traditional GR spacetime curvature view is a mere 'mathematical' artifact)

3) Far from current claims about success of the standard model i would solicit a bit of caution about the correctness of the model. In fact, recent published research in EM suggest existence of experimental data cannot be explained via traditional EM theory. Some recent research in this topic -e.g. Weber electrodynamics or mixed approaches- suggest that QED is NOT correct.

Recent research by Hoyle/Narlikar theory suggests that standard model is not completely correct. For instance, one of most fascinating outcomes of Hoyle/Narlikar theory is that the photon does not really exist, and, however, Hoyle/Narlikar EM reproduces all experimental effects of traditional QED and BEYOND. It appears that some extensions also explain recent experimental data on longitudinal EM forces, Marinov motor, railguns explosions, and some other experimental data -it is posible that some discrepancies on tokamaks reactors was also due to failure of usual EM, QED, and QCD theory (there is some relevant literature on this also published)-.

It has been also published some recent discrepancies of QED in chemistry [Radiation Physics and Chemistry 71 (2004) 611–617]

However, this may also suggest that the current
perturbative expansion is showing some limitations, or
that the renormalisation approach needs reinvestigation.
Of course, it is also possible that the approach of QED
has some particular flaws or limitations which experiment
might be beginning to illuminate.

4) It is not still clear that GR was the correct approach to gravitation even at the classical level. Many of GR tests are also passed by rival theories (e.g. FTG). And as emphasized by David Gross in one of his recent talks,

http://qd.typepad.com/24/2005/01/the_future_of_p.html

"does GR work for strong fields?"

5) The main problem of formulation of a quantum theory of gravity is that GR is clearly incompatible with QM. Therefore a direct -consistent- unification with the standard model is NOT possible. In fact, there is a large history in 'direct unification attempts' begining from Kaluza-Klein that you may know better than my. so far i know all direct atemps were abandoned.

October 31, 2005

Does string theory have any postulates or laws?

85. **Urs Schreiber**
October 31, 2005

> Does string theory have any postulates or laws?

Perturbative string theory does. The postulate is that the S-matrix is computed by summing correlation functions obtained from any one 2-dimensional superconformal field theory of central charge c=15 over genera (in a way that follows from a 2D gravity point of view).

The study of this postulate has shown that it has precisely all features expected of the perturbative expansion of a nonperturbatively defined theory. The totality of the latter is still unknown, though the existence of several hints of properties of this theory has made people come up with the working title 'M-theory' for it.

86. **Nigel**
October 31, 2005

Urs, just because you have postulates or laws does not mean you have science. Moses wrote down postulates and laws from God, but that was intelligent design, not science. Your belief in ST is irrational and pseudoscientific. Who told you 11 dimensional M-theory is the best way forward? Some authority figure I suppose?!

87. **Urs Schreiber**
October 31, 2005

> Your belief in ST

I don't believe in anything. I just answered Ranger's question. (Which for some reason appears below my reply.)

88. **Peter**
October 31, 2005

Sorry about that, WordPress is too stupid to keep track of Daylight savings time. My fixing this around noon today messed up the order of comments a bit.

89. **Gavin**
October 31, 2005

Peter,

I agree that many theorists have a "if you don't believe me, just do the experiment" attitude that is not appropriate in a field where experiments are not on the horizon. Can you point me to some quantum gravity research that does not suffer from this illness?

I'm also intrigued about the idea of "finding some sort of useful relation between the (pseudo)-Riemannian geometrical degrees of freedom of GR and the geometrical degrees of freedom of the standard model." However, I'm not quite sure what that means. Can you point me to any work being done in this area?

I am curious about these things because I am looking for a research direction myself. I earned my Ph.D. in 1999 and spent the next several years as at-home dad while my wife launched her career as a doctor (a path that seemed more practical than string-theorist). My son is in school now, so this summer I went to Strings05 and a couple weeks ago I was at Stanford (my alma mater) learning about what they are doing there. I learned that in six years away from the field, I didn't miss much.

Bad as things are for string theory, it is hard to see much else in the quantum gravity race that looks better. People wanting experimental results are hoping for a miracle. People who want rigor can't prove that Yang-Mills exists. People who want simplicity have to wave their hands just to find flat space. Quantum gravity is an exciting problem, but I can't find a strong horse to put my money on. If I shouldn't bet on string theory, then I should probably walk away from the race.

Gavin

90. **Peter**
October 31, 2005

Gavin,

The kind of thing I had in mind as quantum gravity pursued with an insistence on precise formulations is a lot of the things I've seen coming out of LQG, some of which are really rigorous mathematics. For a random example look at some of the papers of Thomas Thiemann.

I said I think the problem of relating the geometry of GR and the standard model is the big problem, I didn't say I have any good ideas about this… One I wrote about long ago involved trying to understand the electroweak U(2) as a subgroup of the Euclideanized Lorentz group. Some day I'll get around to working on this idea again and trying to come up with a more sensible version of it.

To my mind there is no really strong horse to put one's money on in the field of quantum gravity. More interesting things seem to be happening in LQG than in string theory these days and the subject is being pursued in a much healthier way than string theory, so if you want to do quantum gravity, LQG seems to be a more promising direction. There's also no strong horse for the other huge problem: electroweak symmetry breaking. There at least, maybe in 2008 they'll be new experimental results, but if one wants to think about this during the next few years, you have to be willing to deal with the situation that there aren't any good ideas around.

91. **Juan R.**
November 1, 2005

Urs Schreiber, perturbative string theory is ill defined and is incompatible with GR.

The scattering processes do not correspond to anything known of our world, AND, in complex disciplines like chemistry, the trivial S-matrix theory does not work. See

PRA 1996, 53(6) 4075-4103

Of course, ST S-matrix is not exactly equal to QFT S-matrix but above reference continues to hold.

As would i explain that string theory is both wrong and outdated?

Juan R.

Center for CANONICAL |SCIENCE)

92. **Kea**
November 1, 2005

Juan

Once you said that physicists were guilty of grossly underestimating the sophistication of chemists, and others, in their attempts to advance their understanding. Are you not being rather hypocritical?

93. **Gavin**
November 2, 2005

Peter,

The recent papers by Thiemann are too focused to be accessible to me at this point. However, they do point to a couple recent reviews, "Background independent quantum gravity: a status report," by Ashtekar and Lewandowski and "An invitation to loop quantum gravity" by Smolin. I also found a recent critical review, "Loop quantum gravity: an outside view" by Nicolai, Peeters, and Zamaklar. I hope that these in combination will be a fair introduction to the subject.

Your last post brings us back to the original topic of this thread. We agree that "there is no really strong horse…in the field of quantum gravity." Therefore, it seems very premature to declare any of the contenders "moribund." None the less, your informed and well reasoned assessment of the quantum gravity field has been extremely helpful to me. I wish that all of the discussion of this challenging topic could be carried out with the civility I found here.

Gavin

94. **Juan R.**
November 3, 2005

Kea,

Nature is multidisplinar. If you want understand nature you cannot do only physiucs. This is the reason of existence of Institutes as Santa Fe of Center like our.

It is not the paper in Physical Review A i cited in Woit weblog an elegant example of how ideas from chemistry -Prigogine group- have been applied to a generalization of QFT?

Remember P.W. Anderson's words in his famous *Science* article:

Biology is not applied chemistry.

Chemistry is not applied physics.

Juan R.

Center for CANONICAL |SCIENCE)

95. **Tony Smith**
November 3, 2005

Peter, I think that the question "Why is string theory science but intelligent design isn't???
is unfairly disparaging to "intelligent design".

I am NOT an advocate of or apologist for "intelligent design", but I note that "intelligent design" seems to be something that certain groups have adopted to replace "creationism" because they found it hard to defend "creationism".

In my opinion, the current landscape/anthropic/superstring theory is actually very similar to the "creationism" that has been abandoned even by the "intelligent design" people.

I use as a definition of "creationism" the doctrine that the world and everything was created in 4004 BC with all the fossils, stars, ratios of radioactive elements, etc being carefully set up by G-d to produce exactly what we observe today.

The "landscape" of possible superstring models
corresponds to
the set of all possible states of the world and everything as of 4004 BC.

The anthropic principle that selects "our world" out of all the possible "landscapes"
corresponds to
the divine creation by G-d that selected/constructed "our world" instead of any other of all the possible states of the world and everything as of 4004 BC.
Both are quite vacuous in that they say no more than that our world is as it is because it is as it is.

The landscape/anthropic/superstring stuff and the divine creation stuff both exactly describe "our world", and each is equally useful (i.e., totally useless) in making predictions (or even interesting postdictions) of particle physics data.

However,
since "intelligent design" implies some use of some intelligence by G-d or something
and
since no substantial intelligence whatsoever is required for landscape/anthropic/superstring stuff or "creationism" stuff,
I think that "intelligent design" is far superior to both landscape/anthropic/superstring stuff and "creationism" stuff.

Even so, for the record lest I be misunderstood, I should reiterate that I am NOT an advocate of or apologist for "intelligent design".
In other words,
I am not saying the "intelligent design" is good.
I AM saying that BOTH landscape/anthropic/superstring and "creationism" are EVEN WORSE.

Tony Smith

96. **Ranger**
November 4, 2005

Are postulates allowed in modern theoretical physics?

It seems that string theory has no postulates.

Correct me if I'm wrong but it seems that these are the rules of contemporary theoretical physics:

1) postulates are not allowed
2) experimental evidence is not necessary
3) only theoretical research programs that disallow posulates and experimental tests are allowed, as said research programs are best suited to greasing the perpetual-motion NSF money machine.

With no hope of proof one way or the other, and with nothing to prove in the first place, string theory is firmly ensconced as the anti-theory.

I hope I'm wrong, but this seems to be the case.

Please name a postulate or law of string theory.

Or just give me an equation.

Newton, Einstein, and Faraday all gave us postualtes, laws, and equations, and their physics received a helluva lot less funding than string theory.

so what's going on here?

97. **D R Lunsford**
November 4, 2005

Hi Ranger,

I have lots of equations for you! Highly non-linear! Fun for years! Gravity, charge, and light!

Cosmological Frontiers

October 31, 2005
Categories: Uncategorized

Last week the Perimeter Institute ran a Workshop on Cosmological Frontiers in Fundamental Physics and someone wrote in to point out to me that the talks are now available on-line. Much of the workshop was about mainstream cosmology, especially the more speculative ideas about inflation and what signals might be found in the CMB.

The particle physics component was heavily weighted towards Landscapeology (talks by Denef, Kachru, Kleban), with a workshop-ending talk entitled “50 Years since the LHC” by Nima Arkani-Hamed. Arkani-Hamed’s talk was supposed to be a prediction of what things would look like 50 years after the LHC, and he ended it with the prediction that “the LHC will put the last nail in the coffin of mono-vac theories” and that “the Landscape will be with us to stay”. Along the way he went over various possibilities for what the LHC might see and their implications for whether the cosmological constant and the weak scale are anthropically determined. He said that he believed the cosmological constant was anthropically determined, and half the time he thought the weak scale was too, the other half of the time he thought it wasn’t. He argued for giving up on coming up with new mechanisms for electroweak symmetry breaking since “working on the (N+2)nd variant on the (N+1)st model of EWSB is not worth it”, saying that instead people should participate in the LHC Olympics and work on the “inverse problem” of figuring out from LHC data the 105 parameters of the MSSM or some other model of beyond standard model physics.

Near the beginning of his talk he gave a graph representing (as a function of time) the average string theorist’s view of the probability that string theory could be used to calculate standard model parameters. This started out near 1 in 1985, dropping to a small number in 1995 after the duality revolution showed that strongly coupled strings didn’t get rid of the wide range of possible backgrounds, and further dropping to “a number close to the fine tuning of the cosmological constant” in 2000 after the advent of the Landscape and the non-zero cosmological constant. The same graph also included a plot for the views of “clueless popularizers and science journalists”, which had only recently started to head down slightly from 1. He claimed that such people are ten years behind the times and that it is “not going to be pretty” when they catch up with the current views of string theorists and realize the theory can’t predict anything.

While at Perimeter, (according to Lubos Motl) Arkani-Hamed was talking to LQGer Laurent Freidel about Doubly-Special-Relativity in three dimensions. It’s going to be a lot of fun to watch what Lubos has to say if and when some of his senior colleagues start working on LQG, something that seems entirely possible since string theory is now moribund, whereas LQG is in a much livelier state.

Landscapeology still seems to be making headway at taking over particle theory and ensuring that it becomes a pseudo-science. If you’ve got $250 and can get to an access grid facility, next week you can participate by video conferencing in a workshop at Ohio State on Strings and the Real World, which will have one day out of three devoted to the Landscape. I would have thought the title of the workshop would get into trouble with false advertising laws, since one thing that is clear is that absolutely none of the talks will be even slightly relevant to the real world.

For a horrific vision of where particle theory is headed, check out the website of the String Vacuum Project. The idea seems to be to get particle theorists spending their time developing software to do numerical computations searching amongst the infinite variety of the Landscape to find something or other. The section of the web-site on the connection of any of this to real particle phenomenology remains to be written.

   When the money and public support runs out, unemployed physicists can start landscaping businesses – “Calabi-Yau lawn service”, and so on. I’m sure there are some catchy names to be had.

3. **Quantoken**
   November 1, 2005

   No no no. How could they do landscaping business. They have too many choices for customers, 10^500, and they have not built a single landscape yet.

   The money will run out **much sooner** than one expects. There is already a US Congressional House Resolution about this huge paradigm shift. See also Apollo Alliance.

   What these string theorists can do, is pitch the research on **dark energy** in hidden dimentions as a viable research on sustainable alternative energy source to replace fossil fuel. And there will be huge fund for it. Not that I believe in these stuff. But people like Kaku have proven themselves to be good salespersons and good advertisers.

   This is an uplifting post. I’ve never felt better about leaving physics behind.

5. **logopetria**
   November 1, 2005

   “[Arkani-Hamed] said that he believed the cosmological constant was anthropically determined…”

   Can I just check what people like Arkani-Hamed mean by this? To say that some parameter X is ‘anthropically determined’ means that out of lots of different worlds (or universes), each having a different value of X, we know that only those with particular values of X will be habitable – and so obviously that’s what we observe. Is that right?

So, for example, the Earth's distance from the Sun is 'anthropically determined', because there are other planets, some are closer to their stars, some further away, and life will only arise on those that are at roughly the right distance. So 'anthropic determination' is a statistical selection effect (selecting from a large, already existent set of possibilities), rather than anything resembling a *mechanism* for fixing a parameter to a value?

6. **Nigel**
   November 1, 2005

   "The idea seems to be to get particle theorists spending their time developing software to do numerical computations…"

   Monte Carlo methods and even just numerical integrations of hard to solve anayltic functions are fun. Also, why not just fit a wave equation to the group behaviour of particles (molecules in air) and talk sound waves? Far easier than dealing with the fact that the sound wave has an outward pressure phase followed by an equal under-pressure phase, giving an outward force and equal-and-opposite inward reaction which allows music to propagate. Nobody listens to music, so why should they worry about the physics? Certainly they don't listen to explosions where the outward force has an equal and opposite reaction, too, which in the case of the big bang tells us gravity. Far better to stick to horseshit computing.

7. **Chris Oakley**
   November 1, 2005

   Hi logopetria,

   Right.

   Anthropically determined = Not determined by our theories.

   Landscape = We give up. Tell us, God, how *does* your universe work?

   Spacetime has N dimensions, where N > 4 = Our theory doesn't work, but we don't want to admit it.

   (You get the general idea).

8. **Dissident**
   November 1, 2005

   Speaking of moribund string theory, I assume everybody's noticed that Clifford Johnson over at comsmicvariance has now given undead theory a face:

   http://cosmicvariance.com/2005/10/30/chewing-things-over/

9. **Juan R.**
   November 1, 2005

   In standard particle physics exists something called vacuum. In the opinion of some of us that 'vacuum' is irreal and NEWER experimentally verified. This is easily proven via a number of recent published advances (e.g. Rev. Mod. Phys. 1995 67(1) 113-155). Then what play the role of the traditional vacuum of QFT? Hoyle/Narlikar theory explains us that the vacuum is really the 'thermal-bath' generated by the rest of the universe. Hoyle/Narlikar theory is a generalization of Wheeler/Feynman absorber theory.

   In Hoyle/Narlikar theory, a single 'quantum vacua' means a single environment. Since there is only a single environment in the observed universe, i see difficult how one could claim the existence of multiple vacua!

   About anthropy insanity, the best criticism i found on this topic was from M. Gell-Mann. I do not remember exactly the quote -i think that i read in his *The quark and Jaguar* book- but was some like

   I newer found a version of the anthropic principle that was not trivial or absurd

   P.S: Hoyle/Narlikar theory has been already extended -in press- for accounting some recent work in experimental failures of standard field theory and further mathematical research

   see PRE 1996 53(5) 5373, Phys. Lett A 1990, 146 (1,2) 6, etc.

10. **Kyle**
    November 1, 2005

    Why would this post make you feel better about leaving physics, Hack? It isn't as if HEP or theoretical HEP is particularly important to physics anymore.

11. **Chris**
    November 1, 2005

    It is difficult to avoid the conclusion that Arkani-Hamed and many theoreticians of his generation are primarily technicians. They have mastered a huge array of sophisticated formalisms and techniques, and they want to exercise them.

    "So, we have a MSSM with 105 free parameters? Great, get us some data, and we'll fit them to it. String theory leads us to the Landscape? Don't worry about it, and certainly don't waste time reflecting on what it means; get on with developing techniques to explore and characterize it. We impressed our elders and established our careers by getting good at this stuff, so let's keep doing it and expand our repertoire."

    That's what theoretical particle physics is becoming, five years into the 21st century. The bigger the labyrinth the better; it just gives everybody more to do.

12. **Adrian Heathcote**
    November 1, 2005

    This anthropic stuff continues to baffle me and I feel a little bit like Gell-Mann.

    Isn't the point that it is simply an example of our being able to rule out some theories because they will conflict with a pretty obvious fact about the universe, namely that we are here to make observations and theorise. It's a crude prediction that any true theory must make.

So the AP is just a coarse sieve to winnow out obviously false theories.

Which makes it baffling: how have people been able to invest it with an almost mystical significance? And why did anyone swallow it in that form?

cheers

13. **Syksy Rasanen**
November 2, 2005

Peter, what did you think of Burt Ovrut's talk on building realistic models in string theory?

14. **woit**
November 2, 2005

Adrian:

"Which makes it baffling: how have people been able to invest it with an almost mystical significance? And why did anyone swallow it in that form?"

Good questions. I'd claim it's because the string theory unification program has failed, but its proponents refuse to admit this. With a theory on their hands that can't predict anything, they've turned to anthropism in desperation to avoid admitting failure.

Syksy:

I didn't listen to the whole talk. Every so often I try and check out what progress has been made on this problem of getting the standard model. The kind of thing Ovrut is talking about has been pursued by many, many people for 20 years. My understanding of the current state of affairs is that they can, through a rather complicated construction, get something which at low energies is just the MSSM and lots of moduli fields. The problems with the moduli fields are well known. Their methods don't seem to allow them to calculate a single one of the 125 or so parameters of the MSSM, or predict anything about supersymmetry breaking. This all looks to me like what you expect to happen if you pursue a wrong idea: by complicating things enough you can reproduce some of the gross features of nature, but no matter what you do you can't come up with a real prediction, or even a convincing postdiction.

15. **logopetria**
November 2, 2005

"[String theorists have] turned to anthropism in desperation to avoid admitting failure."

This is something I still don't understand. As Adrian (implicitly) asks, what is there to the "anthropic principle" aside from "agreement with particular observed facts"? How does the fact that the universe is habitable rule out any theory, except to the extent that the theory has already failed to agree with other observations (about the coupling constants, particle masses etc)?

OK, so here's a way it could be different. Given a theory that fails to predict some quantity, one thing you could do is just put in the exact value of that parameter by hand, and show that the theory can at least accommodate it. But instead of that, you could do something different – you could just put in by hand the fact that these parameters lie *within a certain range* (i.e. the range required for life). That's a weaker constraint, but it might force some predictions out of the theory. So, for example, your theory might say: "If the speed of light has to be within a range compatible with life, then the only allowed value turns out to be exactly *c*". Then, it seems, something anthropic-looking would appear to be doing some predictive work. Is that what's going on?

16. **D R Lunsford**
November 2, 2005

Chris – re "technicians" – yes indeed, this was pointed out to me by my advisor – the machinery is so dense that you can crank out work without even thinking. Of course the latter is what goes missing, and without that one gets boredom.

These technicians also tend to rely on cults of personality, lacking as they are in the necessary mental wattage.

-drl

17. **dan**
November 2, 2005

"possible since string theory is now moribund, whereas LQG is in a much livelier state."

so what is the current story on
1- string theory entropy for "ordinary" BH's
2- LQG on BH (with the discussion of transcedental numbers and ln2 versus ln3)
3- do LQG still predict wavelength-dependent photon velocity deviations of c? — something that could be "tested"

18. **Juan R.**
November 3, 2005

Adrian

If you are devoted the best years of your life to a head horse.

If you are popularized your wrong theory in mass media before verifying that was correct -somewhat as cold fusion scandal- and moreover have used **dishonest** actions - as saying not the true, hidding the flaws of the theory, etc.-

If you have claimed in almost every talk, paper, popular book, etc. that people against string theory was either stupid or ignorant.

Then you have only two 'exists'.

1) Intelectual suicide

2) Continuous negation of evidence

It is interesting how some string theorists begin to claim that the problem of prediction is not with string theory. It is with our incorrect understanding of prediction.

Since string theory does not fit basic requirements of science. String theorists, who do not choose option 1 of above, are claiming that we may change scientific method!!!

This is a pure nonsense and reflects desesperation of the field

Ironic question: When Kaku will propose the travel of all humanity to an alternative ‘elegant’ universe where string theory fits data?

Juan R.

Nekrasov, Pure Spinors and the Berkovits Superstring

November 1, 2005
Categories: Uncategorized

There's a new paper out tonight by Nikita Nekrasov entitled [Lectures on curved beta-gamma system, pure spinors, and anomalies](). Motivated by questions about the covariant superstring quantization method being studied in recent years by Berkovits, Nekrasov considers a sigma model with target space the space of "pure spinors". For more about pure spinors I suggest consulting "Spin Geometry" by Lawson and Michelson, but in general they are a subspace of the full spinor space with remarkable properties. In $\mathbf{R}^{2n}$, a pure spinor determines a complex structure on $\mathbf{R}^{2n}$, one that doesn't change when you multiply the spinor by a complex scalar. Furthermore, modding out by the action of the complex scalars, the space Q(2n) of projective pure spinors is a Kahler manifold, isomorphic to O(2n)/U(n). This is a projective algebraic variety, and geometric quantization of it gives back the space of spinors. There's quite a lot of beautiful geometry in this story.

Unfortunately, in the Berkovits story the target space of the sigma model is not Q(2n), which is smooth and has every nice property one could ask for, but the space of pure spinors themselves which is a cone over Q(2n), and has a singularity at the origin. How to handle this singularity is the problem Nekrasov is addressing. This is a rather technical business, one about which I'm no expert (and I'm not sure there are many experts out there on this topic other than Berkovits and Nekrasov).

At the end of his paper Nekrasov makes what appear to be some remarkable comments. He describes two ways to deal with the singularity. The first is to just remove it and work with a non-compact target space. In his paper he shows that this removes certain potential anomalies, but he comments that doing this causes "some unclear issues with the definitions of string measure". The second way to deal with the singularity is to blow it up, working with the total space of a complex line bundle over Q(2n). Nekrasov claims that if you do this the superstring "would cease to be consistent beyond tree and one-loop level, thereby killing at once the landscape problem." The reference is to Susskind's [anthropic landscape paper](), although Nekrasov refers to Susskind as "Sussking".

I'm assuming this is some sort of perverse joke, since if the superstring is inconsistent on flat ten-dimensional space, there's every reason to believe it's also going to be inconsistent on curved 10d spaces and what gets killed is not just the landscape, but the whole idea of unification based on the 10d superstring. Nekrasov goes on to end with the comment that "This is of course one of the unrealized, so far, hopes to solve some pressing predictive issues of string theory by capitalizing on its unusual, from the conventional quantum field theory point of view, perturbation theory", referring to a 1987 paper of Greg Moore that I don't have access to at the moment.

I'm curious to hear what people more expert in this subject think of all this. There are various relevant blog entries: [Robert Helling]() and [Urs Schreiber]() on Nekrasov's talk a couple weeks ago about this in Hamburg, a recent posting by [Jacques Distler](), and a report on a talk by Berkovits at the KITP in August by [Andrew Neitzke](). For some relevant papers on the arxiv, see a paper by [Berkovits and Nekrasov]() from earlier this year as well as quite a few papers by Berkovits and other collaborators written over the last few years.

Update: A commenter wrote in to point out that the Moore paper is available [on-line as a scan of the preprint at KEK]().

After my post appeared, there were later posts on this topic by [Jacques Distler]() and [Lubos Motl](). Lubos seems to agree with me that Nekrasov's comment about an inconsistency in the quantization of the superstring in flat 10d killing the landscape is rather bizarre, since such an inconsistency would probably then hold in all backgrounds.

Funny, but if you look at [trackbacks for the Nekrasov paper](), they're there for Distler and Motl's blog entries but not mine, even though mine appeared earlier. I guess whatever the moderation policy is for trackbacks these days, I'm in a separate category.

Update: After inquiring with the arXiv about what was going on about this trackback, I just heard that it has been posted. It's still unclear to me what their moderation system is.

Comments

   -drl

3. **Wolfgang**
   November 2, 2005

   > Nekrasov claims that if you do this the superstring "would cease to be consistent beyond tree and one-loop level

   I thought it was explicitly shown that two-loop is consistent.
   So this would indicate that something is wrong with the PS approach ?

4. **Mafra**
   November 2, 2005

   Last month it was explicitly shown that the four point two-loop amplitude computation in the pure spinor formalism agrees with the RNS result (when all states are NS).
   So, there is no indication that the PS approach is wrong up to 2-loops.

5. **Urs Schreiber**

November 2, 2005

One needs to deal with the singularity of the pure spinor space. This is a technically issue of correctly working out the formalism.

One way one might *guess* to deal with it is to 'blow it up'.

If you'd blow up the singularity of the pure spinor space, *then* there'd be incosistencies above one loop.

So it's the wrong thing to do.

Unless you argue like Nekrasov mentions one could argue. You could argue that you *redefine* your theory to be given by the beta/gamma model on the blown up space of pure spinors, by definition. This is now a different gadget than the original theory. Since it is inconsisztent on flat target space, it is apparently more constrained than the original theory. So maybe (that's Nekrasov's idea), maybe there are only very few target spaces which would make a pure spinor string with a blown-up space of pure spinors consistent.

6. **anonymous**
November 2, 2005

it appears that the "moderation policy is that you have to submit your own trackbacks.

http://www.arxiv.org/help/trackback/

7. **woit**
November 2, 2005

OK, I just tried submitting a manual trackback and will see what happens. The documentation does seem to claim that auto-discovery of trackbacks is supposed to be supported.

8. **Matt**
November 2, 2005

Peter, it's not a secret that they won't post your trackback on the arxiv. The arxiv is for scientific exchange only, to which you have not contributed at least since 1989.

9. **woit**
November 2, 2005

Hi "Matt" (aka "Michael") from Brandeis,

Whoever you are, you're as much of a cowardly asshole as ever. What is it about string theory that causes its proponents to behave like this?

10. **D R Lunsford**
November 2, 2005

Peter, that's a more interesting question than anything about string theory proper. I have my own theories about it, which I will keep to myself.

-drl

11. **Who**
November 3, 2005

I see where Steven Weinberg has bet the life of Andrei Linde plus one dog, apparently on the string theory Landscape.

see the conclusions on page 13 of a paper by Weinberg posted today
hep-th/0511037

"As for me, I have just enough confidence about the multiverse to bet the lives of both Andrei Linde and Martin Rees's dog. "

Do I hear two dogs?

12. **D R Lunsford**
November 3, 2005

That is really distressing. "Gravitation and Cosmology" is still the best gravity textbook.

-drl

13. **D R Lunsford**
November 3, 2005

It reminds me of Hegel's "proof" that there were no more planets – just before Ceres was discovered.

-drl

14. **D R Lunsford**
November 4, 2005

OK I read the entire paper – what a mess. Apparently Weinberg has the now common attitude, "since I'm the smartest guy in town, and I can't figure it out, we have to change the definition of science so that I can". You'd think a little embarrassment would creep in.

-drl

15. **Chris Oakley**
November 4, 2005

Weinberg's paper is depressing, and ultimately, irresponsible. As one of the most influential people in particle physics it is his duty to try to make the subject attractive to bright young mathematicians and physicists currently at school or university. The promise of nothing better than the application of anthropic reasoning to research problems certainly would not have drawn *me* into the subject, and I rather suspect that the same applies to the majority of young people today.

Anthropic reasoning is in any case circular. We work out what we believe to be the physical processes necessary for life and then study the range of values of physical constants that allow this to work. But all we are doing is finding out what works for *our particular* form of life. What if a different set of constants led to varieties of life vastly different from our own? It is arrogant to assume that the set of nuclear and chemical reactions that led to us are the only ones possible.
I do not agree with his analogy concerning Kepler's unfulfilled wish to be able to predict planetary distances. At least Kepler and Newton had a full dynamical theory. With the string theory landscape *everything* is up in the air.

16. **Dissident**
November 4, 2005

That paper has a truly remarkable cringe factor.

17. **Arun**
November 4, 2005

Weinberg does say that it would help to know what string theory is (w.r.t. the work of classifying string vacua). So, we have to accept as a philosophical truth (as it is unverifiable scientifically) some conclusion from a theory which we cannot formulate completely?

18. **Juan R.**
November 4, 2005

Weinberg's paper is fascinating.

It is an open oportunity for any new 'Weinberg'.

Solve the problem that Weinberg cannot. This may be the message to the young generations.

I, at least, am sure that 'Weinbergs' born each 50 years.

Juan R.

Center for CANONICAL |SCIENCE)

19. **Wolfgang**
November 4, 2005

who,

I mentioned Weinberg's latest opus on my blog (just click on my name).
I would certainly not bet my dog on this …

20. **Chris Oakley**
November 4, 2005

I would happily bet my dog, car, house, life, your dog, your car, your life, anyone else's life or anything else in a bet where it is never possible to say whether either party has won.
What I would rather do, though, is to sell an option. Someone can pay me a million dollars now, and if it is established that a multiverse exists in some given time frame – twenty years, let's say (that is, twenty years in this particular universe for an observer not moving at relativistic speeds relative to this planet), then I pay ten million dollars back.

21. **MathPhys**
November 5, 2005

Is it possible that a certain arXiv moderator just doesn't like you, Peter? Seriously, I can imagine that certain string theorists would prefer not to divert too much traffic to this site.

Incidentally, what's the current job situation like, for string theorists, in the US, nowadays? In the mid 80's, only string theorists could get postdoctoral positions, in the mid 90's, no string theorists could get positions. What's it like it in the mid 00's?

Weinberg Goes Anthropic

November 4, 2005
Categories: Uncategorized

As a commenter here noted last night, and other commenters have discussed in the last posting, Steven Weinberg has just put on the arXiv an article entitled [Living in the Multiverse](). In it, he correctly points out that theoretical physics was immensely successful during the twentieth century as it adopted a fundamental paradigm of exploiting symmetries and quantum mechanical consistency conditions, using these to develop extremely powerful and predictive theories. Initial hopes for superstring theory were that it would lead to further progress along similar lines, but these have not worked out at all.

Faced with the failure of superstring theory to provide any new predictions based on a useful new symmetry principle or consistency condition, instead of drawing the obvious conclusion that it's just a wrong idea about how to get beyond the standard model, Weinberg instead proposes to dump the lessons of the success of twentieth century physics:

Now we may be at a new turning point, a radical change in what we accept as a legitimate foundation for a physical theory. The current excitement is of course a consequence of the discovery of a vast number of solutions of string theory, beginning in 2000 with the work of Bousso and Polchinski.

What Weinberg sees as "excitement" is what some others have characterized as "depression and desperation". His "radical change in what we accept as a legitimate foundation for a physical theory" seems to be to give up on the idea of a fundamental theory that predicts things and instead adopt the "anthropic reasoning" paradigm of how to do physics. Weinberg goes through various examples of his own recent work of this kind, announcing that the probability of seeing a vacuum energy of the observed value is 15.6% (this seems to me to violate my high school physics teacher's dictum about not quoting results to insignificant figures, but I'm not sure how you'd put error bars on that kind of number anyway). He also quotes approvingly recent anthropic work of Arkani-Hamed, Dimopoulos and Kachru, as well as that of his colleague Jacques Distler. All he has to say about the underlying string theory motivation for all this is that "it wouldn't hurt in this work if we knew what string theory is."

In his final comments he acknowledges that this new vision of fundamental physics is not as solidly based as the theory of evolution. Describing the strength of his belief in it, he says "I have just enough confidence about the multiverse to bet the lives of both Andrei Linde *and* Martin Rees's dog." One can't be sure exactly what that means without knowing how he personally feels about Andrei Linde, or cruelty to innocent dogs.

Weinberg's article is based on a talk given at a symposium in September at Cambridge on the topic "Expectations of a Final Theory". I haven't been able to find out anything else about this symposium, and would be interested to hear any other information about it that anyone else has. The article will be published in a Cambridge University Press volume *Universe or Multiverse?*, edited by Bernard Carr (the president of the Society for Psychical Research), about which I've posted earlier [here]().

I'm curious whether this Cambridge symposium was one of the infinite number of such things funded by the Templeton Foundation. Next week the Vatican will be sponsoring a Templeton-funded conference held in the Vatican City on the topic of [Infinity in Science, Philosophy and Theology](). It will feature a talk by Juan Maldacena on "Infinity as Simplification", and is part of a larger Vatican/Templeton project called [Science, Theology and the Ontological Quest](). This project is designed to promote the vision of scientific research outlined by Pope John Paul II in two encyclical letters, including the rule that scientific research must be "grounded in the 'fear of God' whose transcendent sovereignty and provident love in the governance of the world reason must recognize."

Update: Lubos Motl has some [comments on the Weinberg article](). This is one topic on which we seem to be in agreement.

Update (much, much later, May 2022): Rereading this posting many years later, I decided to check on the question of Templeton funding raised here. The Weinberg article was published in the volume [Universe or Multiverse?](), and the Acknowledgements section there has:

> First and foremost, I must acknowledge the support of the John Templeton Foundation, which hosted the Stanford meeting in 2003 and helped to fund the two Cambridge meetings in 2001 and 2005.

   (edited version)

   As a young physicist, I was looking for some career advice.

   After teaching all the labs and classes for years in grad school, writing all the grant proposals, and doing all the research, it would be fun to have a job and get paid someday.

   Should we completely cut off all relations with physics and reality, and instead fully devote ourselves to ingratiating the tenured dinosaurs who now say we must abandon the scientific method so as to turn their failures into success?

   Should we hide the fact that we have theories with postulates that are based in logic and reason?

   Should we bury all independent thought, and discard our theories which unify disparate phenomena with simple principles?

   What would you do if you wanted a job?

   Are there any journals out there taht favor logic, reason, and postulates over cronyism and nepotistic jargon?

   Thanks all!

   Having fun working on some lowly patents here. 🙂

2. **DMS**
   November 4, 2005

   Note also that
   The STOQ Project is aimed at developing the dialogue and the confrontation between Science and Religion, to face many theoretical, ethical and cultural challenges posed by current developments in science to the Christian vision of world, the human person and society.

   What possessed the Fields medallist Enrico Bombieri also to talk at such a forum? I wonder what these scientists think of Giordono Bruno, Galileo and Copernicus. This is very depressing indeed (not just silly, as in the case of Weinberg).

3. **woit**
November 4, 2005

Hi DMS,

One motivation for people to attend these Templeton sponsored things is that they tend to pay very well. Actually I found the STOQ Project and conference really silly, but the Weinberg article extremely depressing.

4. **R**
November 4, 2005

To me, this just seems like (justifiably) eminent thinkers who realize they are approaching the end of their usefulness in physics and want to think that they know what the next big thing will be — in order for them to believe they still have some small part to play.

5. **D R Lunsford**
November 4, 2005

What's perhaps most distressting – W wrote this paper using *quantum optics* grants. I'll bet he can't even point a telescope!

-drl

6. **JC**
November 4, 2005

Speaking of funding issues, has anybody with Weinberg's stature ever had their grants cancelled by the government funding agencies (ie. NSF, DOE, etc …)?

7. **Thomas Larsson**
November 4, 2005

I have heard Weinberg twice, I think. The first time was during the Nobel lecture in 1979. Back then, I was a sophomore and basically didn't get anything. The second time was when Rubbia and van der Meer won the prize in 1984, and Weinberg was on the panel during the Nobel lecture. This was the first time I realized that people were excited about string theory (I had previously tried to read Schwarz' 1982 review on my own, without success). In particular, I remember Weinberg making one prediction: that the 1991 Nobel prize would go to one of the smart young string theorists. So S.W. has evidently made at least one manifestly wrong prediction.

Perhaps growing up means that you realize that the heroes of your youth have become pathetic old men. It is nevertheless tragic.

8. **D R Lunsford**
November 4, 2005

TL – W was basically completely wrong about gravity as well (although he did it perfectly in his book).

-drl

9. **woit**
November 4, 2005

Hi Thomas,

One of my colleagues this morning, after being shown the Weinberg article, commented that Weinberg must just be senile. Unfortunately I don't think that's what's going on. Weinberg wants to be part of whatever the hot topic in particle theory is, and the landscape is the hot topic these days. It's being driven mainly by younger people, not by seventy-year-olds, and you can't put their behavior down to senility.

10. **Ranger**
November 4, 2005

Is everyone getting the feeling that String Theory is the Enron of physics?

Wouldn't it be fun to do a documentary and ask Brian Greene, "Yes–those were some very pretty animations in your show, and yes, we might well live in ten or twenty or thirty dimensions, but what exactly do you mean? What are the laws of string theory? What are the postulates? Besides TV shows and tenure and millions of tax payer dollars, what are string theory's hopes and dreams? Finally, could you please draw the intersection of the seventeenth dimension with the twenty third dimension? I have no idea how to picture this, but I imagine it must be very beautiful. Please share. Einstein and Feyman and Farady and Dirac and Newton and Ohm and Ampere and Gauss shared their wisdom in simple equations, so could you please do the same? Thanks! And keep on rockin'!!!!"

11. **elmer fudd**
November 4, 2005

what is pathetic is being unable to even consider a paradigm shift. The history of science is littered with pathetic scientists of all ages who just could not let go of old ways of thinking.

The current situation seems to be littered with spectators who would rather consider distinguished older scientists, and the most creative younger ones, wrong rather than let go of their little box of intellectual familiarity.

12. **elmer fudd**
November 4, 2005

Isn't the classic scenario that older scientists cling to the theories of their own generation that they helped create? Now you're saying that older scientists want to jump on the bandwagon. Which is it?

13. **woit**
November 4, 2005

Hi Elmer,

Nothing against paradigm shifts myself, I actually think particle theory is in desperate need of one right now. But if the paradigm shift is to completely trash the intellectual traditions of physics in order to prop up a failed research program that some people have a lot invested in, count me out.

In this instance, Weinberg is both jumping on a bandwagon and clinging to a theory he helped create (the anthropic "prediction" of the CC is generally attributed to him).

String theory is no longer a cutting edge new idea only embraced by the young. It has been around since about 1970. Young Turks who first came up with it (Susskind, Schwarz, etc.) are now old enough to collect Social Security. Those who came of age at the time of the First Superstring Revolution (1984) are now deep into middle age and losing their hair (I know a lot about this, this was my generation). Younger people trying to make a career for themselves in recent years have to do so in the context of an ossified ideology older than they are. That they end up doing things to prop it up in order to get ahead is not particularly surprising.

14. **Ranger**
November 4, 2005

Whoah elmer.

The only thing people are saying is that science does science and religion does religion.

You can use a fork to dig a grave and eat your spaghetti with a shovel, but we're allowed to laugh.

As a young scientist my greatest fear is that the old guard is pulling up all the ladders of objectivity, logic, and reason, and surrounding their NSF funded castles with useful-idiot grad student guards who will shoot you on site if you ask questions such as, "how many millions of dollars has each new dimension cost the NSF?"

The first three dimensions came relatively inexpensively.

And the fourth dimension was a bargain too.

But now it seems that each new dimension costs billions.

And can we really use them?

Can I take my date there tonight?

If so, then rock on, as there aren't any good bands playing tonight.

15. **Aaron**
November 4, 2005

"Weinberg wants to be part of whatever the hot topic in particle theory is, and the landscape is the hot topic these days"

Actually, Weinberg's mostly working on cosmology these days. I really doubt Weinberg does much of anything because of fashion. As you note, he was making anthropic arguments before any of the stringy types jumped on the wagon.

16. **Kris Krogh**
November 4, 2005

Hi D R Lunsford,

"W was basically completely wrong about gravity as well (although he did it perfectly in his book)."

Could you elaborate? I'm familiar with the book, which I admire very much, but not the mistakes about gravity.

17. **Shantanu**
November 4, 2005

Peter , I believe this conference was held at Cambridge university in 2001
and was discussed in Physics world. Smolin also has contributed to this volume
(hep-th/0407213), so has Wilczek (hep-ph/0408167). some other contributions
for this conference on preprint archive are by Aguirre (astro-ph/0506519)

See http://space.mit.edu/home/tegmark/photos/science/anthrofest_010830.jpg
which I believe is a photo of this conference (although I see neither Weinberg nor Wilczek in the photo)

18. **woit**
November 4, 2005

Hi Shantanu,

Weinberg's article says his talk was on Sept. 2 of this year. There have been lots of "multiverse" conferences over the last few years, often sponsored by Templeton, at least a couple of them at Stanford.

19. **blank**
November 4, 2005

I'm not a big historian of science, so could somebody please tell me, are there any past instances of succesful paradigm shifts, driven not to kill off an old theory which cannot explain empirical data, but instead to save an existing theory which cannot explain empirical data? This would seem truly to be a paradigm shift among paradigm shifts.

20. **D R Lunsford**
November 4, 2005

KK – he claimed that the geometrical picture that makes gravity sensible, is unimportant. He then wrote a 500 page book that is thoroughly geometrical!

-drl

21. **Kris Krogh**

November 4, 2005

Hi DRL,

Point well taken. Meisner, Thorne and Wheeler have said the same. But maybe Weinberg's heart was really in the right place. I don't think it's unreasonable to look for alternatives to complicated geometries to explain gravity, particles, etc… That was the road to this string theory mess!

Here's an alternative to to general relativity which is quantum-mechanical rather than geometrical: http://arxiv.org/abs/astro-ph/9910325

22. **Jean-Paul**
November 4, 2005

The whole story is very weird. Within 1 week, I see Weinberg's article in Physics Today on Einstein's mistakes and then his own arXiv paper in which he essentially disintegrates as a physicists, quotes cardinal Schoenberg and cracks silly jokes. My suspicion was that he was getting senile, but then I felt embarassed by such disrespectful thoughts…
So let's simply forget about the whole incident, drop the curtain and remember Steven Weiberg at his best…

23. **Tony Smith**
November 4, 2005

Are there sociological pressures in the U. Texas physics department that might force Weinberg to conform or be ostracized ?
My view is that ostracism by one's "peers" (read fellow members of the U. Texas physics department, in the instant case) can be a powerful force inducing conformity of thought.
Consider, for example, "silent treatment" in military academies.
If Weinberg is stuck in such an environment, it is possible that even someone of his mental ability (evidenced for example by his excellent 1972 book Gravitation and Cosmology mentioned by DRL and his more recent 3-volume treatise on Quantum Theory of Fields) might be so "brainwashed".
If so, U. Texas should be ashamed of its physics department. Further, if the U. Texas physics department does have such an environment, it might even tarnish the highly favorable reputation now enjoyed by that university due to its currently successful football team.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

24. **Aaron**
November 4, 2005

"Are there sociological pressures in the U. Texas physics department that might force Weinberg to conform or be ostracized ?"

That may well be the funniest thing I've read in years.

And no, he's not senile. Just because you disagree with someone — and I'm against the anthropic principle — it doesn't make him nuts.

25. **D R Lunsford**
November 4, 2005

"smoking or not? Multi or uni verse? May I take your coat?"

-drl

26. **Moshe Rozali**
November 4, 2005

Aaron, That also brought a smile to my face, I'd like to see someone try giving Weinberg "the silent treatment"… also noteworthy, for earlier and more serious comments, is the fact that Weinberg's first paper on the subject is from 1987, so it is not clear who is jumping on which bandwagon.

The paper itself is really nice, as usual. I liked the clean separation between the anthropic principle (which is a tautology) and the "principle of mediocracy" which is much more problematic.

27. **Tung**
November 4, 2005

There's also an article by Weinberg in the latest issue of Physics Today, titled "Einstein's Mistakes".
http://www.physicstoday.org/vol-58/iss-11/p31.html

28. **D R Lunsford**
November 4, 2005

I should write out a detailed destruction of these (anhistorical) "arguments". "It is a pity that Einstein gave up on Kaluza-Klein.." etc. etc. And what about Pauli? Dirac? Everyone gave up on KK theory because it was demonstrably content-free.

-drl

29. **Quantum_Ranger**
November 5, 2005

Whatever stringtheory is?..it's not part of this Universe, no matter how wrong we are in our understanding of our Universe.

It's apparently quite clear that the only saving grace of the stringtheory era, is choosing the right 'get out clause'. Anthropic reasoning is quite obvious the only way out, as embarassing as it is, its the one and only way out.

Finding 'multi-universe' reasons to which they can catogorize a Universe, where they know they would be absolutely correct in stating that stringtheory would finally exist somewhere!..although not in this universe..there is a more than likely probability that it exists elswhere?

Saving grace future headline replacing the previous ST headline of wondering how they discovered stringtheory?>,.. (you know the one:where a monkey left some mathematical clue from the future, and it suddenly was discovered in the 20th century, explaining the discovery of ST-MTheory?)..HEADLINE:We had the correct theory..but it was in the wrong Universe!..oops!.. sorry wrong place and wrong time!

Even to mathematically show this to be 'almost' true..we would all have to pack our weekend overnight suitcase's, and visit the correct Universe to see for ourselves.

Problem?..why go to another Universe just to proof ST!

30. **MathPhys**
November 5, 2005

"Those who came of age at the time of the First Superstring Revolution (1984) are now deep into middle age and losing their hair (I know a lot about this, this was my generation)."

Speak for yourself, Peter!

November 5, 2005

I only have this to say: Weinberg is getting old now and he no longer say anything intelligent.

I could not bear to read on when reaching the end of the third paragraph, which he claimed never before was a symmetry principle involved. One who made such a statement should return whatever prize he was once rewarded for being intelligent.

I thought it's taught to every kindergarten kid who has learned any physics at all, that **Each one symmetry principle is ALWAYS associated with one corresponding conservation law**, and vise versa.

By Weinberg's extraordinary claim, he is suggesting there had been no conservation law proposed before Einstein. He must have forgot all the physics he leaerned. For example, what is the corresponding symmetry that caused Galileo to believe that an object shall continue to move at constant speed, if left free of inference of any external force? Weinberg should have known better.

Quantoken

33. **island**
November 5, 2005

I liked the clean separation between the anthropic principle (which is a tautology) and the "principle of mediocracy?? which is much more problematic.

Has anybody but me ever tried to actually answering the obvious and begged question of what good physical reason might exist for the implied "specialness", rather than to automatically assume that it's a circular reasoned tautology.

FYI: The principle of mediocrity only applies to banded spriral galaxies that are on the same evolutionary "plane" as us. SETI is wasting its time looking elsewhere.

34. **Nigel**
November 5, 2005

Feynman, Character of Physical Law, BBC 1965, page 57-8:

"It always bothers me that, according to the laws as we understand them today, it takes a computing machine an infinite number of logical operations to figure out what goes on in no matter how tiny a region of space, and no matter how tiny a region of time. How can all that be going on in that tiny space? Why should it take an infinite amount of logic to figure out what one tiny piece of space/time is going to do? So I have often made the hypothesis that ultimately physics will not require a mathematical statement, that in the end the machinery will be revealed, and the laws will turn out to be simple, like the chequer board with all its apparent complexities. But … it is not good to be too prejudiced about these things."

Earlier in the book he had reviewed the LeSage ether theory, concluding on p. 39 that it didn't do anything right as of 1964:

" 'Well,' you say, 'it was a good one, and I got rid of the mathematics for a while. Maybe I could invent a better one.' Maybe you can, because nobody knows the ultimate. But up to today [1964], from the time of Newton, no one has invented another theoretical description of the mathematical machinery behind this law which does not either say the same thing over again, or make the mathematics harder, or predict some wrong phenomena. So there is no model of the theory of gravitation today, other the mathematical form."

These lectures were given at Cornell in 1964, filmed and transmitted on BBC2 in Britain in 1965. It is a pity they are not available on DVD or on the internet. People like Weinberg could learn from them.

35. **Tony Smith**
November 5, 2005

1986 – Weinberg said "… In the last two years, theoretical physicists have become intensely excited over the idea that the ultimate constituents of nature … are … strings. … [each of]… these theories … has no free parameters in it … 'solve the string theory' … mean[s] to find out what these theories predict at much lower energies than 10^18 GeV …
The aim today is to try to find out whether the theory does in fact predict the standard model of the weak, electromagnetic, and strong interactions.
If it does then the second question is, what does it predict for those seventeen or more parameters of the standard model … the mass of the electron, the mass of the quarks, and so on?
If it does, then that's it. …". (from his 1986 Dirac Memorial Lecture)

1992 – Weinberg said "… Physicists will certainly keep trying to explain the constants of nature without resort to anthropic arguments. My own best guess is that we are going to find that in fact all of the constants (with one possible exception … the cosmological constant …) are fixed by symmetry principles of one sort or other and that the existence of some form of life will turn out not to require any very impressive fine-tuning of the laws of nature. …" (from his book Dreams of a Final Theory)

2005 – Weinberg said "… when the effort to extend the Standard Model to include gravity led to widespread interest in string theory, we expected to score the success or failure of this theory in the same way as for the Standard Model: String theory would be a success if its symmetry principles and consistency conditions led to a successful prediction of the free parameters of the Standard Model.
Now we may be at a new turning point, a radical change in what we accept as a legitimate foundation for a physical theory. …
Unless one can find a reason to reject all but a few of the string theory vacua, we will have to accept that much of what we had hoped to calculate are environmental parameters, like the distance of the earth from the sun, whose values we will never be able to deduce from first principles. … Theories based on anthropic calculation certainly represent a retreat from what we had hoped for: the calculation of all fundamental parameters from first principles….". (from his paper Living in the Multiverse at hep-th/0511037)

Why has Weinberg relaxed his standards for a well-founded physical theory from
"predict … parameters of the standard model" in 1986
to
anthropic principle only for the cosmological constant / vacuum energy in 1992
to
"much of what we had hoped to calculate are environmental parameters" in 2005 ?

If Aaron is correct that Weinberg is "not senile" and that he is not responding to sociological pressures, then:
What accounts for the deterioration in Weinberg's standards for a well-founded physical theory ?
Why does Weinberg not even mention the possibility that the "retreat" should be a retreat from string theory itself rather than a retreat from high standards for a well-founded physical theory ?

My only remaining guess is that, as Weinberg said in his 1986 Dirac Memorial Lecture, "Many of us are betting the most valuable thing we have, our time …" on string theory, and that Weinberg, having invested a lot of time in string theory, is, like some monetary investment losers, unwilling to cut his losses and move on.

Tony Smith

November 5, 2005

Kris Krogh,

Weinberg did an atempt to quantize gravity based in previous work by Feynman. Now we know that gravity is nonrenormalizable as a field theory.

Juan R.

Center for CANONICAL |SCIENCE)

38. **John Gonsowski**
November 5, 2005

Tony, yes it may be more that Weinberg has blinders on than a "brainwashing" but I guess it's the same thing really. It's not like the leaders in the field haven't come up with good ideas. You've mentioned Susskind and Smolin both having nice 27-dim M-theory related papers. Nobody seems to get excited even over their own good ideas. You seem more interested in SU(5) GUT than its creators. You've talked with Schreiber and Baez about Feynman lattices and exceptional algebras but the excitement doesn't seem to last past the conversation. People don't seem to get excited enough about their own good ideas to pursue them far enough. You would make for a nice refreshing Discover magazine article kind of for the same reasons the Penrose article was refreshing (even if it was not all correct).

39. **Nigel**
November 5, 2005

I read Weinberg's "Dreams of a Final Theory" when it came out, but can't remember a word from it. I think he had his day with "The First Three Minutes" in 1977. Dreams can easily turn into nightmares with science.

40. **MathPhys**
November 5, 2005

I heard that S Coleman used to say that the reason why "The First Three Minutes" sold so well is that people thought it was about sex.

41. **Kris Krogh**
November 5, 2005

Juan R.,

"Weinberg did an atempt to quantize gravity based in previous work by Feynman. Now we know that gravity is nonrenormalizable as a field theory."

Do we know that? I think it's only been shown for gravity theories exactly equivalent to general relativiity, as Weinberg's was. The Yilmaz theory is renormalizable, for example.

Feynman called renormalization a "dippy process." And he said he didn't know whether renormalizability is a valid test of a theory's correctness or not.

Ever look and look for something and can't find it — then it turns up in a place you didn't look because you "knew" it wasn't there?

42. **Chris W.**
November 5, 2005

There is a subtle but noticeably subversive tone in Weinberg's article. (Why not bet his own life on the multiverse?) Think of Shostakovich's work while Stalin was still alive. I'd say the man knows exactly what he is doing; he is hedging his bets, and gently pointing out that the foundation is hardly stable.

(Einstein said, "To punish me for my contempt for authority, fate made me an authority myself.")

43. **MathPhys**
November 5, 2005

My understanding from the comments of people like John Baez and Steve Carlip is that Yilmaz' theory is simply wrong.

Einstein's theory is a cultural phenomenon: A major, far reaching theory and a pillar of modern physics that was created single handedly by one man (unlike quantum mechanics), in the absence of any pressing experimental motivation (unlike both quantum mechanics and special relativity). It is elegant and deep, and has stood the test of time for almost 90 years now, during which time it remained a focal point of research.

44. **D R Lunsford**
November 6, 2005

MP,

Yilmaz may be wrong, but he's not "simply wrong". His motivation is legitimate but he's trying to solve his problem in the wrong context (analogous to, say, the contracted electron flying through the ether, of Lorentz).

-drl

45. **D R Lunsford**
November 6, 2005

Any comments from Glashow about this business?

-drl

46. **JP**
November 6, 2005

Of course, given the enormous number of consistent CFTs, as well as the large number of moduli in each, string theory will not have real predictive power until the dynamics that SELECTS the vacuum is understood.

47. **Adrian Heathcote**
November 6, 2005

Elmer F. above implicitly appealed to Kuhn and his Structure of Scientific Revolutions to say that W. is not being irrational (he's going with the paradigm shift despite being old) but that others here were (for not going with the paradigm shift despite being young).

I doubt that Kuhn had anything useful to say about irrational belief in science and his book is notably free of hard data. What arguments there are are pretty naive. Truth to say irrationality comes in a lot of shapes and forms and is probably by its nature hard to classify. Unlike rational belief it is inherently disordered.

But one form that the irrationality of old scientists *can* take is to want, before they die, to see that the current situation, whatever it is, is good—that we are on the right path. After all, they know that they won't get to see the final answer—but they want to assure themselves that their life's work was not wasted. So whatever is currently going on is *in the right direction*. And they are prone, in this stage, to retreating to philosophy, as though that might be where the answer really lies, rather than slaving away at the math to come up with something that really fits nature.

Einstein was a great figure IMO because he never gave up on the math—he was always trying to find what he (justifiably) thought was missing. Even when the orthodoxy was complacent.

Weinberg has done a lot of kicking of philosophers in the past (particularly in the NYRB) in my view with perfect justification. How ironic that he's now turned into one of them! "The problem my friends is that we had the wrong philosophy of physics: we expected experimental predictions. How naive! How Positivist of us!"

cheers

48. **Nigel**
November 6, 2005

Adrian,

Kuhn's "Structure of Scientific Revolutions" book, at least the edition I read (a red paperpack) has a preliminary page thanking Niels Bohr and the Copenhagen people for editing or whatever. Kuhn was having to err on the side of a defence of Bohr's Copenhagen Interpretation. Hence Kuhn saw the issue as one in which physicists like Planck, Einstein, and Schroedinger were old fools being irrational, while Bohr and Heisenberg were right. He then dug up those arm-waving bits of the history of phlogiston and caloric which fitted in with his prejudices.

You say "Einstein was a great figure IMO because he never gave up on the math—he was always trying to find what he (justifiably) thought was missing."

I agree, although as Feynman suggested in the November 1964 lectures on physical law, if the math is so complex it takes an infinite series of coupling terms to calculate the magnetism of the something as tiny as just an electron exactly, perhaps God is not a renormalised mathematician as such. The automatic assumption that nature is abstract mathematics because there is a mess of equations is just like the joke of the great biologist JBS Haldane who said God must be a lover of stars or beetles, because he made so many of them.

Not very anthropic!

49. **Adrian Heathcote**
November 6, 2005

Hi Nigel

Yes, I read that same red paperback! I agree with your remarks of course—its a pity so many people took that book as a reliable guide to the sciences. (Sociologists took it to mean that all scientists were irrational but themselves!)

Weinberg, ironically, was one of its greatest critics.

But on math: surely there is no problem in which the answer is: *less math*. More elegant, yes, more powerful, yes. Different, yes. But never less.

Less only makes the computations longer!

cheers

50. **Elmer Fudd**
November 6, 2005

Isn't it possible that there is a nested approximation within string theory that will predict the realities of our own universe close enough to build further machines, even as Newtonian physics exists as a useful approximation/limited case within relativity/quantum physics?

People seem to want "the final answer" to mean complete description of our own universe with its physical laws. Now that "the final answer" may turn out to be talking about something different, many are unable/unwilling to listen since it does not accord with their expectations.

If the Landscape shows that there are infinite universes, it is up to the sentient beings (in those universes that support their existence) to come up with versions of physics that work in their particular universe, as useful appoximations. Two different things- one speaks of the large picture, the other focuses on one small picture at a time.

51. **island**
November 6, 2005

There has never been logical proof the universe is infinite.

Relativity extends to a finite closed universe.

So who listens Einstein, his theory, or anybody else, further than they really want to…?

stars or beetles, because he made so many of them.

Not very anthropic!

Stars and beetles are entropy-efficient… only, they're not as efficeint as humans… "pound-for-pound".

How practical.

52. **Mr Jones**
November 6, 2005

Kuhn tried to understand aspects of (as Popper also did) how science works in practice, instead of prescribing how it ought to be done (as was common among philosophers of science up to that time roughly). What's so offensive about that? He got some of it right but not all, but then who gets everything right anyway?

53. **Kris Krogh**
November 6, 2005

MathPhys,

It's come to light in Einstein's collected papers he did have a pressing experimental motivation. First there is a previously unknown manuscript, coauthored with Besso, on his next-to-last gravity theory. There he calculates Mercury's precession and gets the wrong value. Then there are two letters on the final theory, to Lorentz and Planck, explaining he abandoned the previous one because it didn't fit Mercury's orbit. Why hasn't this been noted by the general relativity community?

The "elegance" of general relativity, reminds me of string theory hype. If it were really elegant, would it be necessary to say so? Shouldn't such a theory include quantum mechanics? Some say it's elegant because it's based entirely on general principles. Weinberg (bless his heart) says that isn't true, because Einstein arbitrarily assumed second-order partial differential equations.

Maybe general relativity stands the test of time because the only tests counted are the ones passed. Does it pass the test of the velocity curves of the stars in galaxies? Or the motions of the Pioneer space probes? A failure only means we've discovered "new physics," like strange dark matter and energy.

I agree Einstein's theory is a cultural phenomenon — but so are myths.

54. **Yraste**
November 6, 2005

W- "…we will have to accept that much of what we had hoped to calculate are environmental parameters, like the distance of the earth from the sun, whose values we will never be able to deduce from first principles."

-Did he forget Titus-Bode law which can be explained from first principles.

When the math gets too hard, then you are left with the philosophical option only.

55. **island**
November 6, 2005

I guess I crossed that line but I thought it was just a natural extension of einstein's theory, rather than one that I'd dreamt-up.

I'm sorry.

56. **D R Lunsford**
November 7, 2005

KK,

A theory need only include its “referents” in the observable world. If that theory is inherently macroscopic, then quantum mechanics is both 1) unnecessary and 2) impossile – you can’t arrange the experiment that nails down |psi>. That GR has no direct quantum statements is neither unexpected, nor troublesome.

GR is compelling because it deals with matter *even when Tmn = 0*. This is exactly analogous to light, even before the inverse square law.

-drl

57. **Not a Nobel Laureate**
November 7, 2005

What Weinberg neglected to mention is that that success of theoretical physics in the 20th century was due in no small part to rapid advanced in technology enabling physicists to generate a flood of experimental data

Theories were rapidly tested and those found wanting rejected.

58. **Nigel**
November 7, 2005

The “flood of experimental data” still exists and remains to be analysed, the mass ratio of muon to electron and other particles, and the coupling constants of electroweak to strong nuclear and gravitation.

Theories were not “rapidly tested and those found wanting rejected”.

Take the case of Gell-Mann’s quarks versus Zweig’s aces. Zweig wrote a more detailed paper and was suppressed by a big American journal while he was in Europe at CERN, while Gell-Mann in America from experience was shrewd enough to submit his briefer and less substantiated paper to a small European journal which printed it. (Let’s not get involved in the issue of Zweig never getting a Nobel prize, as Gell-Mann officially got it for symmetry work.)

Arthur C. Clarke once said that any sufficiently advanced technology is indistinguishable from magic. This is the fate of any revolutionary idea, which by definition (being revolutionary) is in conflict with preconceived ideas like string theory. It is very easy to weed out reality, to flush the baby away with the bath water. It is a different matter to take a heretical idea seriously. Everyone can see it is absurd and obviously wrong. I think this is why the Soviet’s having lost an enormous amount in WWII still managed to beat America into space with Sputnik. The mainstream is always too prejudiced in favour of yesterday’s methods to be really serious about science.

Kris Krogh,

Yes, Weinberg worked with a GR spin-two field. i wanted say that GR is nonrenormalizable as a field theory.

Effectively, there is not proof that other approaches to gravity cannot be renormalizable.

So far as i know Yilmaz theory has been proven to be incompatible with experimental data, including some Newtonian-like tests.

Feynman called renormalization a “dippy process.?? And he said he didn’t know whether renormalizability is a valid test of a theory’s correctness or not.

Well, i completely agree with Feynman and also with Dirac and Landau who expressed similar claims before. Moreover, the trick on renormalization is on infinite less infinite equal to any thing that i want, because mathematically the operation is not defined. In some sense renormalization has worked but ONLY in scattering experiments, where renormalizable terms do not modify the dynamics. It appears that renormalization does not work in recent test of QED in bound states in He atom.

It is often claimed by particle physicists that renormalization is rigorous, which is false since it has been only proven for scatering states with free fields doing lot of asumptions in the ‘proof’.

Precisely, i am working in a promising line of research where renormalization is not needed and the theory is defined also for bound states. My work is a further generalization of Fokker/Dirac/Wheeler/Feynman theory. A first version of a non-perturbative quantum gravity is already available at our center but we are doing consistency tests and consulting with external colleagues. Until 2006, we will not publish first results which would be -if our work is correct- a serious candidate to string or LQG approaches.

MathPhys Said,

Einstein’s theory is a cultural phenomenon: A major, far reaching theory and a pillar of modern physics that was created single handedly by one man (unlike quantum mechanics), in the absence of any pressing experimental motivation (unlike both quantum mechanics and special relativity). It is elegant and deep, and has stood the test of time for almost 90 years now, during which time it remained a focal point of research.

This is part of the mith around einstien he developed his theories alone. This is not true. I proved in sci.physics.research General relativity is mainly the work of four or five guys. Einstien was just one of them.

The only contribution of Einstein to GR was his proposal of substituting the scalar potential by a 10-component metric.

The geodesic equation of motion was proposed in an early paper of 1909 by Harry Bateman and the field equations of GR were obtained by Hilbert at least nine days before Einstein. See

http://canonicalscience.blogspot.com/2005/08/what-is-history-of-relativity-theory.html

for some aditional comments and historical analysis of recent data including Einstein-Hilbert correspondence. I am updating the page with a more extensive and rigorous version.

Nigel,

Even submiting his work on quarks, Gell-Mann's obtained a rejection form one of referees and practically was rejected for publication but finally he was able to convince editor for publication.

It is really interesting as string theorists were rejected by stablished colleagues four decades ago whereas now string theorists are the "stablishment" and reject any theory -even promising- if do not fit string theory preconceived ideas.

The difference is that in the past the criterion was 'mainly' fit of experimental data now it is a supposed mathematical elegance

DRL,

"GR is compelling because it deals with matter even when Tmn = 0."

Does Tmn = 0 refer to the instant of the Big Bang? Has it been proven there was such an instant, before which nothing existed?

63. **MathPhys**
November 7, 2005

Juan R,

Thank you for the correction. I actually tend to believe your version of history rather than the popular one. I'm not surprised at all to learn that there were priority disputes for both special and general relativity. Einstein was never an easy man, particularly in his youth, and from what I know of his character, I'm not so very surprised by what you say.

65. **Tung**
November 7, 2005

Juan R,

It is an interesting account of "actual" history that you are promoting. True, Einstein's contribution is not really understood by the public, but for a more accurate and more objective account of what he did, I think I would recommend the works by real historians of physics like John Stachel, Arthur Fine, John Earman, Don Howard etc. Some of them are the first to read Einstein's then unpublished manuscripts and letters, and seems to me to be more believable.

66. **Tony Smith**

Actually, IIRC, neither Gell-Mann nor Zweig were the first to invent/discover quarks.

Around 1960, Liu Yao-Yang invented the Ceng Zi (Quark) model of particle physics. He was working at the University of Science and Technology of China, which was then located at Beijing, when he invented the Ceng Zi model. He wrote a paper and submitted it to a Chinese journal. It was turned down because the editors thought the paper was not correct. After the quark model had been independently re-invented a few years later, with most of the credit going to Murray Gell-Mann, the editors apologized for rejecting the paper. The latest information I have is that Liu Yao-Yang was working at the University of Science and Technology of China, which is now at Anhui, in the fields of atomic and molecular physics, quantum field theory, and quantization of gravity.

Chris W. said:
"Over on Cosmic Variance, Sean Carroll reminds us to consider what **extraterrestrial intelligences** might have to say about the "anthropic?? principle."

He might as well ask what god would say on the topic, or what the hypothetical green men on mars would say.

I mean the whole thing is complete fictitious and hypothetical. How could you use something purely imaginary and hypothetical, instead of something based on solid evidence, to back up a scientific argument? We have not made contact with any alien and no one is able to ask an alien how it will answer the question regarding anthropic principle. So no one really knows how an alien will answer. Anything you say is then just your own personal opinion, not opinion by aliens.

Quantoken

72. **Adrian Heathcote**
November 8, 2005

Quantoken says: "So no one really knows how an alien will answer. Anything you say is then just your own personal opinion, not opinion by aliens."

I would have thought that the only thing they might insist on is a name change! ('Anthopos'—how terracentric!)

But seriously, surely the AP is just a way of eliminating theories that are so wide of the mark that they predict a universe in which life is impossible. Life exists, ergo such theories are false. String theorists seem to have taken it over as a way of putting back in by hand some of the predictive power that the theory itself has left out.You might just as well talk about a Planetary Principle: any theory which is so wide of the mark that it says that there are no planets can be ruled out from the beginning. *Anything* we know about our universe can be used as a filter on String theory models, or *any* theory.

BTW Tony: really interesting information on Liu Yao-Yang. Someone should write an article to give him his due.

A.H.

73. **Chris Oakley**
November 8, 2005

surely the AP is just a way of eliminating theories that are so wide of the mark that they predict a universe in which life is impossible. Life exists, ergo such theories are false.

I think that this is a good way of putting it. The AP is not worthless, but neither is it especially valuable. To expect a full dynamical theory just from this principle is crazy.

74. **Quantoken**
November 8, 2005

AH:
Too many people meantioned Liu Yao-Yang and his Ceng Zi model that a few words are worth saying. The so called Ceng Zi model was but vapourware. It was nothing scientific. The idea was a politically motivated one, inspired by the philosophy thought of then Chairman Mao, who held the belief that matter can always be divided no matter how small they become. It's the same intuitive belief since ancient times. For example, imagine you cut a stick in half, the remaining half is shorter, but you can cut it in half again, and you can repeat it infinite times and there is always a little bit left.

The Ceng Zi model believes, therefore, it must be divisible within the most fundamental particle known by then, proton and neutron. There were already experimental evidences that there are intrinsic states of protons and neutrons, implying that they have structures. But beyong suggesting that baryons are divisible into Ceng Zi's, the model says nothing specific about how the Ceng Zi should look like, how they interact. How many kinds there are, etc. Therefore it's nothing beyond just some philosophy ideas.

The problem with Sean Carroll, and other people in the same camp. Is that their "research" have been long detached from reality, that they probably believe that solid experimental data is not necessary and can be substituted by pure imagination in one's mind, and that such imagination can be used to establish or support a scientific argument.

I am not trying to argue for or against the AP. But hypothetical questions have no weight in making any argument. Sean already counted it as a fact that aliens exist and that in principle we could ask an alien. In reality, we simply do NOT know it as a fact whether aliens even exist or not. There is no evidence.

It must be point out that the AP is completely useless. That is, zero usefulness. AP does NOT eliminate any theory. Experimental evidences do. If you believe that AP helps to eliminate some theories, then you belong to the same camp of people who believe solid experimental evidences can be substituted by pure mind hypothesis. The fact of matter is experimental data is ultimately the only thing that can eliminate or establish a theory. **Data is the only judge in the court of science**. Principles, no matter how sounding, can not be used to make a judgement regarding a theory. You may have a theory which is at odd with the AP principle but fits the data, but the fact that your theory conflicts the AP only means that AP is probably wrong, not that your theory is wrong.

As far as experimental data is concerned, the AP is completely useless because it has no predictive power whatsoever. Anything we already know, by definition becomes part of the AP and be rationalized by the AP. But anything we do NOT already know, the AP leaves it wide open and anything could be possible. So the AP is unable to say a single thing about the unknwns that could be later checked against the facts. AP is as useless a princple as thereligious idea of rationalize everything by simply claiming "because God made it so."

The anthropic principle, when extended to become a biocentric principle is valid science that makes predictions about what aliens might say. Failure to look for evidence why the anthropic principle is valid, does not constitute a lack of evidence.

This is what I wrote in his thread concerning how it applies to his question about what aliens would say about the principle:

Space aliens would tell you that we humans are an arrogant bunch, and modern science is wrongly prejudiced against it for that reason, because the principle is actually biocentric in nature, extending to every banded spiral galaxy that is on the same evolutionary "plane?? as us, in terms of its implications that fall from the observation that we inhabit a preferred "place and time?? in the history of our universe. We're far from alone in that… is anybody awake?

Methinks that modern science is gonna be sorry that they didn't try to answer the begged question of what good physical reason exists for why the implied "specailness?? might be for-real, rather than to automatically assume that we are so detatched and insignifcant to the thermodynamic process that the principle is no more than a circular reasoned tautology, that's easily explained-away if we simply make a few leaps of speculative theoretical faith that aren't even close to being justified in origins science, which is dominated by empiricism.

Insignificance in not a valid argument either, when the principle is biocentric, due to the cumulative high-energy physics contributions that intelligent life is capable of making to the process, which is unmatched in terms of energy-efficiency, pound-for-pound, so to speak. Fred Hoyle proved that it only requires a few particles anually from each galaxy to account for expansion. What a coincidence NOT!

So this indicates that particle creation from negative vacuum energy holds the universe flat… What an anthropic coincidence! No, wait… my mistake, it's actually an anthropic prediction that theories which don't derive this are cluelessly screwed up about how the physics actually works!

In other words, space aliens will tell you that "Free-thinkers?? are every bit as arrogant as creationists for thinking that space aliens could be much more or less advanced technologically than us… although they might actually trust us to figure out why that might be for ourselves, assuming that we gave them a clear indication that we were finally actually getting a clue as to how the principle actually works… and applies.

"Data is the only judge in the court of science. Principles, no matter how sounding, can not be used to make a judgement regarding a theory." – Quantoken

What about the principles of Copenhagen quantum mechanics, like Bohr's beloved Correspondence and Complementarity? Or Einstein's principles? The maths of Bohr and Einstein is very elegant and of course consistent numerically with reality. What people argue is that there are other ways of getting the same results without using the same principles, at least regarding SR and Copenhagen principles.

It seems that Bohr and Einstein didn't notice that there were other ways of getting the same maths without using the same philosophy. FitzGerald, Lorentz and Larmor, had the testable formulae of SR. Einstein still didn't notice this when he gave his "Ether and Relativity" lecture at Leyden in 1920. His biographer Pais wrote that he (Pais) first gave Einstein the Poincare's relativity papers of 1904 in the early 1950s. Einstein asked Born to acknowledge Poincare's work. Pais says he (Pais) was angry with Born for praising Poincare too highly, since Poincare used 3 postulates and Einstein used only 2. The whole story makes me nauseous. The love of monk Ockham's razor is just absurd. You don't find biologists or chemists banning biological or chemical mechanisms as superfluous or unnecessary difficulties. The lack of mechanism for forces allows string theorists to claim they are copying the guessed principle philosophy of Bohr and Einstein.

79. **Tony Smith**
November 8, 2005

Quantoken said "… The so called Ceng Zi model was but vapourware. It was nothing scientific. The idea was a politically motivated one, inspired by the philosophy thought of then Chairman Mao …".

Since I have not personally read the paper that Liu Yao-Yang wrote around 1960, I cannot deal directly with Quantoken's assertion that the Ceng Zi model was "vapourware" and "nothing scientific". Perhaps some Chinese sources might respond to that part of Quantoken's criticism.

However, I can say that it should be quite irrelevant whether or not the Ceng Zi model was "politically motivated" or "inspired by the philosophy thought of then Chairman Mao". Further, given the political climate of China around 1960, it should not be surprising that ANY paper about ANYTHING might well be phrased in terms that are connected with "the philosophy thought of then Chairman Mao".

Not only is that part of Quantoken's criticism invalid, it is unfortunately typical of the attitudes of some Western European / American people about physics motivated by philosophical schools to which they do not ascribe.
For instance, it is interesting that the Nobel prize have yet to recognize Kobayashi and Maskawa even though it is experimentally clear that there are three generations of fermions. Perhaps that might be related to the facts that their work was closely related to that of the Nagoya group (they both got their Ph.D.'s at Nagoya) and that the fundamental philosophy of the Nagoya group was Dialectical Materialism. As Kent Staley says in his book "The Evidence for the Top Quark" (Cambridge 2004): "…

some japanese physicists felt strongly that Western physicists, especially in the United States, systematically ignored their work. …". Staley's book contains some details about the philosophical underpinnings of the physics ideas of the Nagoya group around the 1960s. I do not know much about the flow of ideas between China and Japan during that time period, but it might be an interesting bit of history.

Quantoken

Just some thoughts to try to clarify the idea of the AP.

The normal situation in science is to have T –>P, a theory making a prediction. Verifying the prediction increases the confidence that the theory may be true. The AP takes a range of theories/models and filters out those that are inconsistent with some known obvious fact (life exists). The AP leaves those theories/models that are consistent with the facts. It's perfectly true that a theory being consistent with some fact is not the same as a theory predicting that fact—the relation is much weaker. But filtering is not nothing either: Evolution is essentially a filtering process.

One could say that prediction is to forensic investigation as the AP is to a police line-up. (Or worse: to a line-up in which the person knows only what the suspect *didn't* look like!)

cheers

81. **island**
November 8, 2005

The constantly growing number of anthropic coincidences clearly indicates that the principle predicts that life only occurs fixed *near*-exactly between diametrically opposing runaway tendencies, like the near-flatness of the universe, or the balance between the relevant cumulative runaway tendencies that the earth has toward Milankovitch predicted glaciation… that gets offset by the innate tendency that humans have for warming the climate… etc, etc, etceteras… anthropic *Ecobalances*make a statement about uniform energy dissemination in a flat yet expanding universe.

Evobiologists could also make valid predictions from the AP if they weren't so knee-jerk conditioned and pre-prejudiced against any and all use of the principle because its religious abuse.

…cept for maybe the fringe like the templeton bunch.

November 8, 2005

Adrian H. said:
"The AP takes a range of theories/models and filters out those that are inconsistent with some known obvious fact (life exists). The AP leaves those theories/models that are consistent with the facts."

Wake up, **checking theories against observational facts is all science research is doing**. That's the day time job of all scientists. You do NOT need a middleman called AP to do such reality checks. People have been doing it for thousands of years without AP.

What other great usefulness of AP can you propose, other than your suggestion that without AP we will not be able to exam theory against known facts, or that we probably will not know for a fact that life exists if it were not for the AP? How absord!

On the same token of AP, we may also propose Hydrogen Principle or Oxygen Principle, Or Snake Oil principle. We know these things, hydrogen, oxygen, or snake oil, exists, so any correct theory must leads to the existence of these items. If a theory leads to the conclusion that snake oil does not exist, we know its wrong because snake oil exist, especially in the field of fundamental physics research. I would so propose that we rename Anthropic Principle as **"Snake Oil Principle"**, which may be more appropriate.

Quantoken

83. **island**

November 9, 2005

Hey Quantoken

woah, woah, woah!

I am not arguing for the AP by any stretch of the imagination. Essentially I am arguing on *your* side—but also trying to show what the AP is doing (the very little that it is doing!) In fact you are repeating my argument and pretending that it refutes what I said.

Perhaps I can suggest the principle of counting to ten before one hits the submit comment button.

cheers

85. **Juan R.**
November 9, 2005

Some authors have said that Weinberg was already anthropic decades ago. I think that is another exageration.

I do not really know those previous Weinberg works on cosmological constant and similar, if i am wrong please correct me.

I think that in the past, Weinberg used some kind of statistical methods for computing some average value for cosmological constant or similar. I think that his motivation would be obtain some, even approximated, value. Probably Weinberg's hope was to obtain the correct value from some future theory.

It appears that now is usually thought that those 'future theory' does not exist and all we can do is 'obtain' (so say) those anthropic values. I think that **now** Weinberg is anthropic therein Woit's title for this thread *Weinberg Goes Anthropic*

MathPhys, thanks! Works, manuscripts, and those are always subjected to certain personal interpretation (history is not one of exact sciences) but correspondence with Besso, Seelig, Hilbert, etc. proves that Einstein copied work of others and after do not cite them in his papers. For instance, in his correspondence to Hilbert said not the true and in his posterior 1915 (day 25) paper on GR, newer cited to Hilbert.

Also the history of string theory is completely distorted and that is the basis of popularity of people like Brian Greene, or Witten.

Tung, thanks by the advice. In the new extended version more authors are cited. Stachel coincides with me on that "*Einstein's proposal of the quanta of light was not revolutionary*" and that contributions to SR were pionnerized by Poincaré.

Regarding GR, in his broadly critized article on *Science* Stachel accused Hilbert of plagiarism. On a new article -more serious- now he argues that Hilbert had already obtained the correct GR Lagrangian…

Juan R.

I read your article on Einstein and found it very interesting. If the dates that you infer for who knew what when stand up then you've made a pretty strong case. The thing that I hadn't heard anything about was the relation with Hilbert and his work. Pretty damning!

It would be good to see a more polished version of this come out somewhere.

cheers

Krauss New York Times Essay

November 8, 2005
Categories: Uncategorized

Lawrence Krauss has an essay in today's New York Times about science, religion and string theory, covering much the same material discussed here in a recent posting. There are postings about this from Mark Trodden at Cosmic Variance and Lubos Motl on his blog. In comments at Cosmic Variance, Lubos tries to make the rather bizarre claim that the status of the theory of evolution is much the same as that of string theory. I don't notice any string theorists writing in there to tell him that he is full of it.

Meanwhile, in the real world, the Kansas Board of Education has voted to change the definition of science. Krauss has been very involved in this controversy in recent years, fighting the good fight against Intelligent Design and Creationism. I suspect he's all too aware of the danger posed by string theorists like Lubos intent on muddying the waters about the question of what is solid, testable science, and what isn't.

Update: Over at Cosmic Variance, see some of the reaction Krauss is getting to his criticisms of string theory.

Comments

1. **Ranger**
   November 8, 2005

   String theory is no different from religion, except that while religion finds many practical applications in civilized society, string theory has none.

   String theory is based on blind faith.

   And not only blind faith, but tenured snarkiness, taxes, and vast student loans.

   But nevertheless, the renaissance that takes us beyond postmodernism to truth's beauty will yet be.

2. **Quantoken**
   November 8, 2005

   Peter:

   There are something in parallel between the theory of evolution (TOE) and that of Super String Theory (SST). Both, in my opinion, are not falsifiable.

   But there is a huge difference. TOE is unfalsifiable because it is the result of pure logic. Just like mathmatics, you know 1+2=3 is absolutely correct, but you can't design an experiment to test to see if 1+2=3 is true or not. Because the possibility it's wrong simply do noit exist.

   TOE is pure logic. Natural Selection Rule and Survival of the Fittest. They come from logic and nothing more than logic. How could you refute that. How could you possibly design an experiment that could potentially defy logic. Fitness of a spiece is defined as the likelihood how it will survive. So of course a better fitting spiece has a better chance of surviving and spreading offsprings. It can not be falsified by any experiment, but it is correct by logic.

   On another hand, SST is un-falsifiable because it has no relevance whatsoever with the reality world. There is no connection whatsoever so there is no way any experiment can be proposed to prove or disprove it. So SST is at the completely opposite end, the wrong end, of un-falsifiability.

   Quantoken

3. **Eugene Stefanovich**
   November 8, 2005

   I think Krauss put his finger on a very important issue. I have a feeling that some parts of theoretical physics were hijacked by formal mathematicians who place mathematical "beauty" above sober observable reality. I am not even talking about strings. For better or for worse, this started 100 years ago with the invention of spacetime. This idea quickly became a favorite toy of mathematicians.
   Think about many different ways you can play with the spacetime: you can bend it, twist it, "foam" it, tear it apart. You can apply numerous branches of mathematics to it: differential geometry, topology, … What if you add some extra dimensions? Oh! The joy is endless! There is just one thing you cannot do with the spacetime. You cannot observe it!

   This seems to contradict one important lesson we learned from quantum mechanics. This lesson says: "never ask questions about something that you do not (can not) observe." If you want to get a verifiable answer from your theory, then specify the experimental conditions and the measuring apparatus. You can say: I have an electron gun at point A, a two-slit screen at point B, and a photographic plate at point C. Then the theory would correctly predict what is the image on the photographic plate. If you don't want to get into trouble, never ask which slit the electron passed through. This question has no counterpart in your experimental design.

   Now back to the spacetime. I don't think there is experimental apparatus that can measure spacetime curvature or topology, or whatever.
   All these "properties" are hidden, or maybe even non-existent.
   I think there should be a very very high threshold for introducing non-observable concepts in physics. Wouldn't it be much safer to limit the vocabulary of physics to things that we can directly observe: like electrons, photons, protons, their positions, momenta, spins, wave functions, etc.

   I see a tendency to move away from this basic stuff to some esoteric high-dimensional never-observable purely mathematical rather speculative things. Some may say that the logic of science led us there. I am not sure. I have a suspicion that pursuit of pure "mathematical beauty" played a part in misleading us there. Sorry for harsh words directed to mathematicians, but this tendency worries me a lot.

   Eugene.

4. **Luboš Motl**
   November 8, 2005

   Although it may sound strange, Quantoken is quite clearly closer to the truth than Peter Woit. The very evolutionary framework or the string theory framework are not falsifiable by a single experiment.

They're much more fundamental approaches to broad classes of questions that are supported by very general arguments – such as the billion-year-long history of Earth and life and/or the existence of gravity in the quantum world. In the case of string theory the arguments are much more mathematical in nature, but the basic reasons are very similar.

There is a belief system that is primary. It underlies another layer of insights which are viewed as technical details to be answered in the future. It is true about evolution much like about string theory.

Any particular experiment designed to falsify either evolution as such or string theory as such – before the exact vacuum etc. is localized – could only result in the modification of some subtle technical features of these theories. Only very unrealistic people claim that there exists a single experiment whose result would convince everyone in science that the whole Darwinian picture of species is wrong.

Something similar holds for string theory because we don't have the complete picture either: the absence of SUSY at the LHC won't kill string theory (although it may convince many to work on other problems) – and some people in fact claim today that SUSY is not a prediction of string theory.

Let me not go into details but string theory as such is a much more robust framework than SUSY at 1 TeV which is a mere quantitative technicality.

Peter's celebration of Krauss' anti-religious activity sounds like a prayer itself. Krauss may have obtained the right binary answer to the question whether creationism is wrong, but as far as his texts in the New York Times and elsewhere can indicate, his reasons are misguided. The reason why a theory in science is wrong is definitely not that the theory is too counter-intuitive for a layman or that it uses too complex maths or that the religious people may like the theory, and whoever thinks that these are the reasons that decide about the truth in science is confused about very basic features of the scientific method.

Also, I find Peter's suggestion that biology of the early life forms is more rigorous or more scientific or more well-established than theoretical high-energy physics to be rather absurd. We're continuing the same physics whose insights have been tested with the accuracy of 13 decimal places – the only difference is that we focus on harder questions that are also less accessible to cheap experiments.

At any rate, theoretical physics is more rigorous and reliable than biology – especially theoretical physics that follows from well tested frameworks. This includes the Bekenstein-Hawking entropy mentioned at Cosmic Variance and used as a non-trivial check of self-consistency of the theories of quantum gravity. Of course that the physicists are much more certain about the magnitude of the entropy of large black holes than the biologists can ever be sure about the hierarchy of very early life forms on Earth. If you disagree, Peter, are you just joking or are you serious?

5. **Luboš Motl**
   November 8, 2005

   I think that Eugene's example is excellent. There are simply people around who deny not only spacetime curvature – something that has been tested in several different types of experiments (they deny it because the theory behind it normally involves differential geometry that they hate) – but even the spacetime itself. They have problems with special relativity from 1905 whose 100th anniversary we just celebrated.

   Our colleagues like Lawrence Krauss and Peter Woit are qualitatively similar; the difference is merely quantitative. Maybe they don't deny the insights made by Einstein in 1905, but they almost definitely deny all insights in theoretical high energy physics made after 1975. Because they don't understand it and they don't want to understand it.

   Even if a majority of the population on Earth does not care about relativity, there are still people who care, and there is a subset of people who care about even more advanced questions, and so forth. What Peter Woit and Lawrence Krauss are doing is nothing else than a gigantic anti-scientific crusade. They want to destroy whole branches of science just because they personally find the questions and the concepts considered as solutions to be too difficult and too abstract.

6. **woit**
   November 8, 2005

   Hi Lubos,

   I was comparing string theory to the theory of evolution, not theoretical high energy physics to the theory of evolution. String theory is not equivalent to theoretical high energy physics, much as you wish that to be true.

   You're really out of your gourd to compare string theory and the theory of evolution. Sure, scientific theories are generally frameworks that can't be easily falsified by a single experimental result. But the framework of the theory of evolution does something the string theory framework can't do: it makes lots of testable predictions, ones that have been tested and come out as predicted. Wasting my time by arguing about this is against my personal religious convictions, as is responding to your foolish belief that people who have a problem with string theory just don't understand it.

7. **scott**
   November 8, 2005

   quantoken, I will repeat for you here a post I made on the Mark's thread over at cosmic variance.

   The theory that all organisms evolved is in no way the same postion as string theory. Microevolution, the prerequisite for the theories of speciation and common being general among all species, has actually been observed in the lab as well as selection pressures and other things. Corresponding things in string theory strings, compactified dimmensions, and susy have not been observed. Furthermore direct evidence that doesn't depend on the observation of microevolution exist.

   > In the following list of evidences, 30 major predictions of the hypothesis of common descent are enumerated and discussed. Under each point is a demonstration of how the prediction fares against actual biological testing. Each point lists a few examples of evolutionary confirmations followed by potential falsifications. Since one fundamental concept generates all of these predictions, most of them are interrelated. So that the logic will be easy to follow, related predictions are grouped into five separate subdivisions. Each subdivision has a paragraph or two introducing the main idea that unites the various predictions in that section. There are many in-text references given for each point. As will be seen, universal common descent makes many specific predictions about what should and what should not be observed in the biological world, and it has fared very well against empirically-obtained observations from the past 140+ years of intense scientific investigation.

   http://www.talkorigins.org/faqs/comdesc/

   String theory meanwhile has not been subjected to any tests.

   November 8, 2005

   If the LHC and colliders of the future fail to find evidence of the graviton, will Standard Modelers and Stringers still search for it?

9. **andy s.**
November 9, 2005

On TOE. Natural Selection and Survival of the Fittest exist obviously enough, but Darwin's insight is that these phenomena are the ONLY mechanisms behind the differentiation of species.

So it is falsifiable. If you proved that, say, species bifurcate because endoparasites diddle with their germ lines – for their own benefit, not their hosts, that would disprove Darwin by making Selection irrelevant.

(and don't laugh at the example; the endoparasites in your body get away with tons of weird shit we don't even know about).

10. **Eugene Stefanovich**
November 9, 2005

Lubos,

it is not correct to say that "spacetime curvature … has been tested in several different types of experiments." As far as I know, curvaturemeters have not been invented yet. What have been measured are observable effects with real physical systems, like planet Mercury, or light rays passing near the Sun, or binary pulsar systems. Spacetime curvature is a theoretical tool that our current model of gravity employs to explain these effects.
There is no theorem stating that GR is the only possible theory that can explain these effects.
Surely, GR is very beautiful mathematically. Surely, no other successful theory has been suggested yet. But I think we should better keep an open mind and try to avoid as much as possible those non-observable theoretical ingredients Krauss was talking about.

I think it is important to keep an open mind, because, in my opinion, quantum gravity project was a complete failure so far. In order to make it right, we should exercise discipline and logic, and try not to be distracted by beautiful, but physically empty, mathematical ideas.

I don't hate differential geometry or algebraic topology. To the contrary, I find them very enjoyable. I am just not sure what is their place in physics.

If (keeping the discipline of logic and an open mind) we rewind 100 years back and analyze foundations of special relativity, we may find that
4D Minkowski space-time unification does not follow from two Einstein's postulates (which are based on solid observations, of course) by straight logic. In fact, the idea of Minkowski spacetime is an additional postulate.

Moving some 20 years closer to our times we may discover that this idea is in a deep contradiction with basic quantum mechanics where position is an observable described by 3 Hermitian operators, and time is a numerical parameter. This just does not work well with the 4D spacetime unification. That's where the seeds of modern quantum gravity controversy were planted. In my humble opinion.

I am convinced that this controversy will not be solved until we make a deliberate choice between sober reality-based formalism of quantum mechanics where each component has a directly measurable counterpart in the real world and abstract non-observable (but mathematically so sweet!) postulate of the 4D spacetime unification.

Note that rejecting the 4D spacetime does not require us to reject the principle of relativity or the Poincare group properties of transformations between inertial observers. These two ideas have overwhelming support in experiments.

Eugene.

11. **wiseguy**
November 9, 2005

While I get some people are pissed at string theory, people outside the community (physicists in neighboring disciplines, like me) have I think a pretty accurate idea of what string theory is. It's a set of mathematical ideas, with some intriguing analogies, that a number of very smart people have worked on for more than twenty years.

Back in the day, string theory made some big claims. It still makes some big claims, but it tends to make them in the New York Times these days, and not in serious journals.

There are competitors to string theory. Even some of the great string theory gurus have taken up research into those areas.

Today, string theory is in trouble. It has provided no significant input into other areas of physics in a long time. All of its predictions are either trivial (fundamental Lorentz invariance, which may yet be hidden) or ambiguous (different versions say different things.) Sexy things like string cosmology may be "inspired" by string theory, but in practice are mostly statements in classical GR with a dose of field theory and a perhaps a nod to Hawking radiation.

Fields in trouble are not new for Science. Science will survive despite the occasional ideologue.

That's how we see it. IMO, Krauss should not be saying silly things about Intelligent Design and science. ID is, intellectually, somewhere up there with Dick Cheney's 2001 napkin theory of Iraq.

12. **Nigel**
November 9, 2005

"There are simply people around who deny not only spacetime curvature – something that has been tested in several different types of experiments (they deny it because the theory behind it normally involves differential geometry that they hate) – but even the spacetime itself. They have problems with special relativity from 1905 whose 100th anniversary we just celebrated." – Luboš Motl

Luboš, the spacetime curvature is physically required to keep Pi intact when the contraction term of GR reduces the radial distance around mass without affecting transverse distance, circumference. One way to account for this reduction of radius while circumference isn't reduced is to say spacetime is curved by the fourth dimension.

This is equivalent to radial pressure from the spacetime fabric virtual radiation, causing the contraction in the same way as the FitzGerald-Lorentz contraction in the direction of motion. I've shown how each contraction is related to the other, on my home page.

If you are going to worship Einstein religiously, relativity is going to forever remain stuck in either 1905 or 1915. How are you going to prove it is a theory so special that it can't be worked on any more? How are you going to defend it by saying it is so useful that nobody is allowed to use it? Differential geometry shouldn't be used to simply cover up ignorance, nor should any other mathematical tool.

13. **Arun**
November 9, 2005

Speaking of curvature meters – we measure the curvature of space-time in exactly the same way as we can measure the curvature of earth – by observing and measuring the non-parallelism of geodesics.

While there is no theorem that General Relativity is the only theory that can explain all the things we observe, there is the Parametrized Post Newtonian formalism, which is a systematic set of corrections to Newtonian gravity with a number of free parameters. Any theory of gravity sets values for these parameters; these parameters are obtainable by experiment or observation; and as I understand it, GR is the only theory left standing.

14. **Nigel**
November 9, 2005

Arun,

GR is not a scientific theory as Popper views such a thing, it is right because it ties up two empirical facts, Newtonian gravity (put in as the weak field/slow speed limit) and mass-energy conservation (the contraction term correction).

This is why GR is not a speculative Popper-type guessed theory. Einstein was not being arrogant when he said to a student in 1919 that it is right regardless of Eddington's experimental result. GR is not fallible provided the two inputs, Newtonian gravity plus the mathematical compensation for energy conservation, are correct.

Since the two 'arbitrary' inputs are empirical facts at least within the solar system, GR is logically correct on that basis alone. You don't need to test a mathematical prediction based entirely on empirically determined facts. Where Einstein ran into problems was in fiddling the basic field equation to give cosmological predictions, such as the cosmological constant fix to give a steady state universe. In addition there is the issue of whether gravity (thus the Newtonian G factor) is due to a mechanism like some kind of gauge boson pressure, which causes the contraction in gravitational fields, which is determined by the surrounding matter in the universe. Because rotational motion appears to be absolute with respect to the surrounding stars, ultimately there is empirical evidence for Mach's principle over relativism. GR is, as Einstein recognised in his 1920 Leyden university inaugural lecture "Ether and relativity", an absolute motion theory because it describes accelerations – which are and have always been absolute. Restricted or "special" relativity (SR) is incomplete. So much applauding is given to SR having only 2 postulates that people forget Einstein added a third postulate in GR in 1915, and GR is the universal theory.

As an analogy to GR, consider the heuristic interpretation of QFT, with virtual particles polarised around particle cores, forming a shielding veil which reduces the bare core charge by the 137 factor. In turning the maths of GR into a physical mechanism, you do the same thing, looking for a mechanism which fits the facts and then using the mechanism to make some testable predictions.

15. **Juan R.**
November 9, 2005

I completely agree Eugene!

Great physicists like Isaac Newton or R. Feynman understood perfectly the diference between physics ('science') and math. There is a current tendency in theoretical physics to use the pure mathematical formalism without a clear underlying physics.

Not only nobody has newer measured spacetime curvature. Even as i said in sci.physics.relativity and sci.physics.research time ago, in others theories as FTG or torsion gravity one verifies the same tests that GR with a **flat spacetime**.

Perhaps the most interesting of last days in this topic was my proof in spr of that in the nonrelativistic limit of GR, the metric of spacetime goes to (1 -1 -1 -1) and spacetime looks flat.

Some specialists like Carlip were rather sckeptic and initially did rather bold statements (as "your metric is wrong", when is a recomended metric) but finally Carlip agreed with me own proof that in the nonrelativistic limit one can obtain zero connections and still there is Newtonian-like gravity: a = -grad(phi).

Obviously curvature, R_ab, R, or \gamma^i_{ab}, etc. of spacetime is zero in that limit, but gravity is not.

If A is cause of B, then elimination of A may eliminate B…

My emphasis on this is because this is one of keys on why until now GR has been not unified with other forces and quantized: the geometric view of gravity has been the great failure of 20th century physics.

String theorists just hereditated this geometric view and the result has been… 40 years…

Baez on the Geometry of the Standard Model

November 8, 2005
Categories: Uncategorized

John Baez has a very interesting new paper on the arXiv this evening entitled Calabi-Yau Manifolds and the Standard Model. In it he points out that the standard model gauge group (which he carefully defines as SU(3)xSU(2)xU(1)/N, where N is a six-element subgroup that acts trivially on the standard model particles) is the subgroup of SU(5) that preserves a splitting of $\mathbf{C}^5$ into orthogonal 2 and 3 dimensional complex subspaces. Furthermore, if you think of SU(5) as a subgroup of SO(10), then the spinor representation of SO(10) on restriction to the standard model group has exactly the properties of a single generation of the standard model.

Baez would like to think of SO(10) as the frame rotations in the Riemannian geometry of a 10d manifold X. The SU(5) is then the holonomy subgroup picked out by a choice of Calabi-Yau complex structure on the manifold. One way to get such an X is as the product of $\mathbf{R}^4$ and a compact 6-manifold M^6, picking Calabi-Yau structures on both manifolds in the product. What is happening here is related to an old idea I wrote a paper about a very long time ago (see Nuclear Physics B, vol. 303, pgs. 329-342, from 1988). By picking an orthogonal complex structure on $\mathbf{R}^4$, one picks out a U(2) in SO(4) (the Euclideanized Lorentz group), and it is tempting to identify this with the electroweak U(2). This is one part of what is happening in Baez's construction. It's very hard though to see what to do with this within the standard gauge theory framework; this is true both for my old idea and for Baez's newer one. Maybe string theorists can come up with some way of implementing this idea of thinking of the standard model gauge group in terms of the Riemannian geometry of the target space of a string. If so I might even get interested in string theory…..

I don't immediately see from Baez's paper why the hypercharge assignments come out right. I need to sit down and work that out, but it's getting late this evening. There are some other issues his paper raises that I'd like to think about, and maybe I'll finally get around to doing some work to see whether what I've learned about spin geometry in recent years has any use in this context.

I also noticed today that Baez is advertising for students to come to UC Riverside to study Quantum Mathematics. I like the term, and for many students who really care about mathematics and fundamental physics, this would be worth thinking about.

Please, commenters who want to write about their favorite ideas about standard model geometry, try and stick to any aspects of this directly related to Baez's paper.

Comments

1. **Luboš Motl**
   November 8, 2005

   As far as I understand, John:

   * rediscovered that the Standard Model group is SU(3) x SU(2) x U(1) divided by a certain Z_6 group

   * rediscovered that 16 of spin(10) is a good representation for a single generation of quarks and leptons – i.e. rediscovered one reason behind grand unified theories

   * rediscovered that manifolds with SU(5) holonomy are called Calabi-Yau five-folds

   * wants to study, for a very incomprehensible reason, manifolds whose holonomy coincides with the Standard Model gauge group

   The last point seems completely crazy because holonomy is exactly the symmetry – a part of the tangential group – that is broken by the manifold's shape, while the gauge group of the Standard Model is a group that must be, on the contrary, completely unbroken.

   Comparing the dimensions 4+6 of the large and hidden dimensions in string theory with the (doubled – real) dimensions of the fundamental reps of SU(2) and SU(3) is pure numerology. The four dimensions of the space we know do not transform under the electroweak SU(2), and the six hidden dimensions do not transform under SU(3).

4. **Thomas Larsson**
   November 9, 2005

   There is one thing about GUTs that has bothered me for some time. We know that SU(5) is out because it predicts too fast proton decay, whereas SO(10) does not. However, it seems to me that two-step breaking, SO(10) -> SU(5) -> SU(3)xSU(2)xU(1) is also ruled out because of the SU(5) in the middle. Doesn't this mean that any kind of GUT where SU(5) plays an important role, apparently including John's, has trouble with proton decay?

   Alas, I have heard people talk about non-minimal SU(5), which apparently evades this problem.

5. **Quantoken**
   November 9, 2005

   John:

   I am not interested in discussing your paper, but in your description of QM in UCR, some dangling words really seem sexy:

   What exactly is the relationship between **number theory** and quantum mechanics? I have no idea. Can you explain? For example, is there anything particular that the inverse of the fine structure constant necessarily happen to be very close to the 26th odd prime number?:-)

6. **Robert**
November 9, 2005

The fact that the hypercharges work out has been checked already many years ago by people working on SO(10) GUTs.

I like the observation about 10=4+6 although I don't see an obvious way to turn it into something that resembles a model.

And note (besides Lubos' point about the holonomy being the part of the isometry that is broken which I think is valid) that the CY2 x CY3 is not what we have in nature: At least the large four dimensions are very likely to have full SO(3,1) holonomy as there seem to me arbitrary curvatures around. Of course one could make the approximation (or mumble something about 'groundstate' or whatever) that one should take 4D Minkowski space (or (A)dS if one worries about the cosmological constant) for the large dimensions but those in turn have too small a holonomy group.

7. **Urs**
November 9, 2005

> the holonomy being the part of the isometry that is broken which I think is valid

I you wanted to, you could argue that the standard model has only been tested in flat space. The proposed model would then presumeably predict deformations of the standard model group in strong gravitational fields.

I'd like to note that people interested in what they call 'geometric algebra' have played around with similar ideas (I'll look up concrete papers when I find the time).

In particular, note that if one wants to adopt the idea that the standard model particles arise as components of a spinor, one has to address the question what then happens to the 'usual' spinor degrees of these fermions.

The only natural answer to that which I am aware of is "Dirac-Kaehler" formalism. Assume the particles are not spinors, but "bispinors", i.e. inhomogeneous differential form, with the Dirac operator really being the Dirac/Kaehler/deRham operator d + del. The form bundle is Lamda M = S x bar S the product of two spinor bundles. One can interpret the left factor as the observed spinor degrees of freedom, while using the right factor to model families of fermions. That has been proposed several times.

I could remark that the Dirac operators arising in string theory actually are Dirac/Kaehler operators (on loop space). The reason this is usually not seen is chiral splitting of left- and rightmovers in WZW backgrounds.

8. **X**
November 9, 2005

Can this neat geometrical picture provide any insight into electroweak symmetry breaking? Or the existence of 3 generations of quarks and leptons?

9. **Tony Smith**
November 9, 2005

John Baez, in hep-th/0511086, says:
"… a G-manifold where G is the Standard Model gauge group is precisely a Calabi–Yau manifold of 10 real dimensions whose tangent spaces split into orthogonal 4- and 6-dimensional subspaces, each preserved by the complex structure and parallel transport. In particular, the product of Calabi–Yau manifolds of dimensions 4 and 6 gives such a G-manifold. Moreover, any such G-manifold is naturally a spin manifold, and Dirac spinors on this manifold transform in the representation of G corresponding to one generation of Standard Model fermions and their antiparticles. … For example, we can take M to be Euclidean R4 and K to be any 6-dimensional Calabi–Yau manifold. …[and then]… M x K is a G-manifold….".

Penrose and Rindler, in their book Spinors and Spacetime, v.2 (Cambridge 1986) say (at pages 307-308):
"… projective twistor space PT … has the structure of a complex projective 3-space CP3 … the points of CM# [compactified complexified Minkowski space] represent the lines of PT. Such a correspondence, in which the lines of a projective 3-space are represented as the points of a quadric in a projective 5-space, is known as the Klein representation …
Even more relevant to twistor theory was the observation by Sophus Lie in 1869 … that oriented spheres in (complex) Euclidean 3-space could be represented by lines in CP3, with (consistently oriented) contact between spheres represented by meeting lines in CP3. These spheres can be regarded as the intersections of light cones, of points in (complex) Minkowski space, with a constant time …".

Is it consistent with John Baez's physical model picture to use for Calabi–Yau manifolds of dimensions 4 and 6:

6-dimensional CP3 for a twistor picture of space-time
and
4-dimensional CP2 for the (10-6) dimensional space, related to SU(3) in the sense that CP2 = SU(3)/S(U(2)xU(1)) ?

Would the Klein correspondence allow you to use a conformal spacetime based on the 6-dimensional space of signature (2,4) upon which the Conformal Group SU(2,2) = Spin(2,4) acts ?

Could the CP2 then be related to the standard model groups in a way similar to that described by Batakis in his paper at Class. Quantum Grav. 3 (1986) L99-L105 in which the CP2 plays the role of the compact extra-dimensional space of a Kaluza-Klein model ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Thomas Larsson, in this same blog thread, said: "… We know that SU(5) is out because it predicts too fast proton decay …". Although that is clearly the conventional view as of now, there are alternative definitions of background so that the experimental results may be interpretable as consistent with proton lifetimes not so far from SU(5) predictions. See hep-ex/0008074 by Adarkar, Krishnaswamy, Menon, Sreekantan, Hayashi, Ito, Kawakami, Miyake, and Uchihori, entitled Experimental evidence for G.U.T. Proton Decay.

10. **Kasper Olsen**
November 9, 2005

Personally, I don't find Baez' paper that interesting,
– that the SM gauge group is not SU(3) x SU(2) x U(1), but rather this group divided by Z_6 has been observed **many** years ago, for example by H.B. Nielsen like 20 years ago (but it is anyhow, a rather trivial observation, since for most purposes we are just interested in the *Lie algebra*)
-as Lubos also observed, the inclusion of SU(5) in SO(10) has been known for ages – sure enough, SO(10) has some nice features, but if he's looking for beauty he could as well have chosen E_8 x (something), or whatever else that thas his SM group as subgroup. Spin(10) is the double cover of SO(10) (which is known for anybody who have heard about Clifford Algebras) and there is basically nothing new in noting, that the Dirac representation is single-valued in SU(5); this is basically just a

mathematical ‘accident’
– his comments about representations ‘on’ the exterior algebra Lambda(C^5) which he observes includes d-quarks, u-quarks etc. is also rather trivial since it is – as far as I can see – just another ‘accident’ related to how Clifford Algebras, Spin-groups and Exterior Algebras of C^n are related (or more precisely, representations of those)
– his comments about relating this to Calabi-Yau manifolds is also rather fictitious since his observation about the ‘real” SM group preserves the splitting of C^5 into a three- and a two-dimensional subspace is just another ‘accident’ related to the structure of Clifford Algebras, for which he — out of the blue — chose R^10 = C^5
– and in the same vain – the observation, that if M^4 and K^6 are Calabi-Yau manifolds, then M^4 x K^6 is a G-manifold (where G is *his* SM group) follows trivially as above. I guess he want’s it to be conneted to string theory (by choosing R^10 = C^5, i.e. the magic number 10 coming out of string theory), but actually it is not (at least not in any non-trivial way) . Sorry, I have to **agree** with Lubos, he is just playing with numbers 😉

Kasper

11. **Urs**
November 9, 2005

The paper I had in mind is this. Not that I have looked at it closely enough, but it does build (see the references) on the idea of embedding standard model particles into spinor reps. These people tend to use a slightly non-standard language when talking about spinors, but it’s mostly easy to sort it out.

I guess if you took these ideas and tried to embed them into something string-motivated in 4+6 dimension it would amount to trying to interpret the closed type II string’s RR states (the p-form fields) collectively as spinor bilinears (what is called ‘algebraic spinors in papers of the above sort’) with interpreting one spinor factor as the observed spin degree of freedoms and decomposing the other in terms of standard model particles of one generation.

I don’t know if that could work out to a sensible model. But it seems to be a natural way to try to implement the idea of realizing particles species as components of a spinor representation.

15. **John Gonsowski**
November 9, 2005

“the inclusion of SU(5) in SO(10) has been known for ages – sure enough, SO(10) has some nice features, but if he’s looking for beauty he could as well have chosen E_8 x (something)”

The idea of someone well know bringing up ideas prematurely pushed to the sidelines and suggesting nice new things to do with them is not so bad. Funny, I pretty much said the same thing a couple days ago in the Weinberg thread. I even mentioned SU(5) GUT and Baez but I had Baez mentioned in relation to the exceptional algebras… so yes why not start at E8, there’s those E6 orbifolded fermions just waiting to suck up the SO(10) bosons. For details of the algebraic glue see Tony Smith, that’s his forte.

16. **Kasper Olsen**
November 9, 2005

John – the fact, that Baez’ observation – that SU(5) is a subgroup of SO(10) – is quite old, does not in itself logically make it “bad” (or irrelevant, unjustified, or whatever). The thing is this – virtually all his assumptions are not substantiated in any way, and this is why he could have decided to consider E_8 or E_8 x E_8 or U(1)^496, or ….

And I don’t think he is suggesting any nice “new things” with this. Basically, he is only expressing well-known fact in terms of Clifford Algebras, which might seem fancy and ‘new’ to some people; talking about Clifford Algebras is roughly just the same as talking about Dirac matrices, which for obvious reasons are related to Spin-groups, as for example Spin(n) is a certain subgroup of Cl(n,0) – but I guess you know all this.. 😉

Best,

17. **Nick Warner**
November 9, 2005

While Lubos is sometimes not as diplomatic as one might like, this does not mean you should ignore his comments – which are essentially correct.

It may be useful to explain the last one in more detail because the Baez article makes an elementary mistake in the physics underlying compactifications from higher dimensions. Unbroken gauge groups *do not* come from holonomy, and generally the exact opposite is true. The point is that if a field transforms under the holonomy then it is responding to the curvature tensor of the compactifying manifold and as a result fields that transform under the holonomy group will have masses that are set by the compactification scale. This means that a compact manifold, no matter how big it is, will not give rise massless fields that transform under the holonomy group.

In compactification one finds the low mass/massless fields in the sectors with trivial (generalized) holonomy, and as Lubos says, the holonomy group is precisely what is broken at the compactification scale.

18. **woit**
November 9, 2005

Nick,

Lubos's first four comments are just offensive and stupid. John was obviously not claiming to have discovered any of these well-known facts, he was just stating them. Today seems to be my day for pointing this out repeatedly, but I'll do this here again: you can't imagine how much damage Lubos has done to the cause of string theory by this kind of behavior. He's convinced large numbers of people that string theorists are arrogant, ill-informed fanatics. One reason for this is not just his behavior, but the fact that other string theorists seem to think it is all right to behave this way towards non-string theorists, just perhaps "not as diplomatic as one would like".

As for the last point, John wasn't making "an elementary mistake in the physics underlying compactifications from higher dimensions", since his only comment about the relation of the two mathematical propositions he states to physics was that "it would be nice to find a use for these results". He was pointing out a characterization of the standard model group that isn't hard to see but that I hadn't thought about before, as the subgroup of SO(10) preserving certain geometrical structures.

There are lots of problems with coming up with any sort of dynamics that make use of this, from the ones I pointed out about the U(2) piece, to the ones you and Lubos note If you try and do standard dynamics on a compactification. John isn't getting very far, but what he is addressing are two of the biggest problems the standard model leaves unanswered:

1. Why SU(3)xSU(2)xU(1)/N?

2. Why the certain specific representations of this group that occur in the standard model?

What he's saying is that if you start with 10 dimensional Riemannian geometry and certain specific geometrical structures, from the distinguished 10-d spinor rep you get an answer to 1. and 2. This just changes the problem to

Why 10 dimensions, and why these specific geometrical structures?

I'm not at all convinced it's much of an advance, but it seems to me more worth thinking about than what currently seems to be the preferred answer to questions 1. and 2.: "because of some horrifically complicated lowest energy state of some ill defined infinite dimensional minimization problem we know hardly anything about". At least it's different and has a bit of mathematical beauty.

19. **Kasper Olsen**
November 9, 2005

Dear Peter,
I agree with you, that 1. and 2. should be answered in a more 'fundamental' theory. But I don't actually think that Baez answered these questions. He starts with SO(10), but for no obvious reason, except that of course SO(10) has SU(5) as subgroup which has the SM group (= G) as subgroup. But of course SO(10) has many other subgroups which as well could be 'interesting' for the same reasons. The group G has the nice feature observed by Baez, that representations of Spin(10) restricted to G includes the fermion representations given by the exterior algebra *Lambda(C^5)*. But this fact seem (at least to me) to be implicitly included in the old grand unified SU(5) theories. I don't think this *really* answered the question #2 about the representations.

20. **woit**
November 9, 2005

Hi Kasper,

As I said, he leaves unanswered the question "Why 10 dimensions?" If you decide that 10 dimensions is fundamental and you want to do Riemannian geometry in it, you've got an SO(10) structure group.

For a mathematician, if you're doing geometry in an even number of dimensions, picking an almost complex structure is a very natural thing to do (i.e. you're identifying the tangent spaces with complex vector spaces). Doing this reduces the structure group to U(5). The Calabi-Yau structure that further reduces to SU(5) is a bit less of an obvious thing to do.

If your're working with SO(10) (or, better, its double cover, Spin(10)), the spin representation is a very special one, and you can build all other reps out of it (i.e. you can build all tensors out of spinors, not vice versa). The fact that this spinor rep gives you a generation of standard model particles is well-known. In general, for SO(2n), once you pick a complex structure and reduce to U(n), the spinor rep becomes the complex exterior algebra rep, up to a certain projective factor, one which is trivial if you just look at SU(n). So that's why John can explicitly construct his spinor rep as an exterior algebra.

21. **Kasper Olsen**
November 9, 2005

Dear Peter – It's of course correct what you are saying. If you just start by assuming D=10, then the structure group is SO(10), and since D is even, it reduces naturally to U(D/2)=U(5). And then – out of the blue – comes the assumption that the manifold should be a Calabi-Yau which is unique in the sense of having a SU(5) holonomy (while in string theory, as you know, a SU(n) holonomy comes from the requirement of the existence of a covariantly constant spinor). But here, the assumption is not justified – you could as well have chosen the manifold to be Kahler with first Chern class c_1 *different* from zero, and therefore not CY. But again, only with SU(5) holonomy here can the spinor representation be identified (up to isomorphisms) with the exterior algebra Lambda(C^5), which (roughly) is identified with a generation of fermions. How did that "explain" the #1 on your list — that our Standard Model gauge group *should* be exactly SU(3)xSU(2)xU(1)/Z_6? (Which has some nice geometrical features observed by Baez and many others) And how did the coincidence, that the fermions 'fit into' the exterior algebra here "explain" that our Standard Model fermions should transform as they do? (I.e. answer your question #2, except from the trivial observation, that the representation of Spin(10) decomposes as determined by the exterior algebra mentioned above). If I'm missing something here, please explain 😉

Best, Kasper

22. **somebody**
November 9, 2005

I'm simply amazed at all LM's ignorant stuff about holonomy groups and "symmetries". Holonomy groups are not symmetries and have absolutely nothing to do with isometries….jeez….

The only problem I see with JB's stuff is this: is there a manifold with holonomy that is not just *contained* in G, but actually *isomorphic* to it? I think the answer is no, so the actual holonomy group would be a subgroup of the standard group. And that is much less interesting. Still a stimulating paper though.

23. **woit**
November 9, 2005

Hi Kasper,

To me the not very well-motivated stuff is the extra structure needed to get from U(5) to the standard model group. This is the Calabi-Yau structure on the 10-manifold and the splitting of the tangent space into 2 and 3 d complex spaces. That the standard model particles fit precisely into an SO(10) spinor rep has always been perhaps the most appealing feature of SO(10) grand unification. This is just representation theory. Given any irreducible rep of G, you can ask how it decomposes into H irreducibles for H a subgroup of G. Here G=SO(10), H the standard model group. It's quite striking that the simplest SO(10) irreducible, the spinor, decomposes as precisely the sum of irreducibles that makes up a standard model generation.

24. **john baez**
November 9, 2005

Peter has tried his best to clarify certain issues, but I can't resist adding my two cents, since it's my paper…. 🙂

Thomas Larsson said:

> However, it seems to me that two-step breaking, SO(10) -> SU(5) -> SU(3)xSU(2)xU(1) is also ruled out because of the SU(5) in the middle. Doesn't this mean that any kind of GUT where SU(5) plays an important role, apparently including John's, has trouble with proton decay?

You raise an important question here, and I think we should talk about it. But for now, I just want to make something clear:

My paper *does not propose a grand unified theory*, or any sort of physical theory. It simply points out some facts relating the Standard Model and Calabi-Yau manifolds.

There's a reason I'm doing this. So far most approaches to deriving the Standard Model from a more "beautiful" or "unified" theory seem rather artificial. One reason is that the math of the Standard Model looks, to our eyes, ugly and arbitrary. To address this problem, I think some of us should play around the math of the Standard Model… until maybe we see that it's not so ugly and arbitrary after all!

In other words, some of us should try to connect the Standard Model to ideas that seem natural and inevitable. (Other people should explore other ideas, including the "landscape" scenario which has the Standard Model as a completely undistinguished inhabitant of a vast panoply of theories.)

Connecting the details of the Standard Model to truly beautiful mathematics is a tough challenge. Georgi and Glashow's SU(5) and SO(10) grand unified theories make a promising start. So does Alain Connes' ideas on the Higgs boson. So does Victor Kac's work on the exceptional Lie superalgebra E(3,8). So does work on the heterotic Standard Model and the recent attempt to get the minimal supersymmetric Standard Model from the heterotic string. Various people who post here have also done their bit, with greater or lesser success.

I think all these efforts are praiseworthy, even if it turns out that none of them are "the right theory".

Indeed, some of this work, like Victor Kac's work and my own little paper, does not even propose a theory of physics! It still might come in handy.

We need to explore. We need to play around. We need to stop being so grandiose that we think we're gonna write a paper that proposes The Theory of Everything and gets it right the first time.

Robert wrote:

> the CY2 x CY3 is not what we have in nature: : At least the large four dimensions are very likely to have full SO(3,1) holonomy as there seem to me arbitrary curvatures around.

Right: had I been proposing a theory, I would not have proposed one in which the visible 4 dimensions of spacetime are modelled by a Calabi-Yau manifold.

The connection on the Calabi-Yau 2-fold (=CY2) in my paper is clearly related to the electroweak force, not gravity.

Kaspar Olsen writes:

> […] the Baez article makes an elementary mistake in the physics underlying compactifications from higher dimensions. Unbroken gauge groups *do not* come from holonomy, and generally the exact opposite is true.

Since I wasn't proposing a physical theory, I was not in the position to make this elementary mistake. You may have thought I was proposing something like a Kaluza-Klein theory, or perhaps planning to use my CY2 x CY3 as a string theory background. I wasn't. I was doing exactly what I said I was doing in the first sentence of the paper. I wrote:

> The purpose of this note is to point out a curious relation
> between the mathematics of the Standard Model and the geometry of Calabi–Yau manifolds.

No more, no less.

A Polynomial Quantum Algorithm for Approximating the Jones Polynomial

Dorit Aharonov, Vaughan Jones, Zeph Landau
26 pages

"The Jones polynmial, discovered in 1984, is an important knot invariant in topology, which is intimately connected to Topological Quantum Field Theory (TQFT). The works of Freedman, Kitaev, Larsen and Wang provide an efficient simulation of TQFT by a quantum computer, and vice versa. These results implicitly imply the existence of an efficient quantum algorithm … Unfortunately, this important algorithm was never explicitly formulated. Moreover, the results of Freedman et. al are heavily based on deep knowledge of TQFT, which makes the algorithm essentially inaccessible for computer scientists.
We provide an explicit and simple polynomial algorithm to approximate the Jones polynomial …Our algorithm does not use TQFT at all. By the results of Freedman et. al, our algorithm solves a BQP complete problem.
The algorithm we provide exhibits a structure which we hope is generalizable to other quantum algorithmic problems…"

Quantoken writes:

> What exactly is the relationship between number theory and quantum mechanics? I have no idea. Can you explain?

There are lots of relationships. I think it would be quite a digression to explain them here, but I've begun explaining some in various issues of This Week's Finds, especially week199, week216, week217 and week218.

I'm just getting started – in part because I'm just getting started on learning number theory. The really interesting ideas on the border of quantum mechanics and number theory, like the Langlands program, the relation between zeta zeroes and quantum chaos, and Connes' work on the Riemann hypothesis, are pretty darn deep.

Every week I spend a few hours studying this stuff in the UCR coffee shop with James Dolan. Right now we're trying to understand the Taniyama-Shimura hypothesis. As a start, we're trying to see why automorphic forms that are eigenvectors of Hecke operators give Dirichlet series with Euler product expansions. It's great fun!!!

29. **Kasper Olsen**
November 9, 2005

Peter – it's correct what you are saying. But I'll have to ask again: 1) how did the coincidence between the standard model group H and the SU(5) holonomy explain that the interesting group is actually H? – it seems this is what you claimed had been answered.(Except from the obvious thing that you get a splitting of T(M) as C^2 x C^3?) 2) And how did the representation of H in G=SO(10) actually explain why the standard model fermions are in certain representations? Apart from the fact, that SO(10) potentially could be a good grand unified theory group since the standard model fermions fit into representation of SO(10), which has been known for decades…

Actually I think John himself answered above: he is just observing some 'nice' mathematical 'coincidences' between the standard model group H and the Calabi-Yau geometry. And this is of course completely legitimate.

You can always find thousands of reasons for 'why' our SM gauge group should be exactly H, when you actually know what it is. You can also find millions of reasons for why our spacetime seem to have 3+1 dimensions. 4 is an interesting number – there are for example the exotic R^4's – on which you have an uncountable number of differentiable structures. And actually, we should look at not R^4, but rather R^{3,1}. But, that's also interesting; the Clifford Algebra Cl(3,1) is isomorphic to H(2), and the Spin group Spin(3,1) is even more beautiful….

John – no reason to worry; I don't mind you confused me with Nick
😉

Best, Kasper

30. **woit**
November 9, 2005

Hi Kasper,

I should leave this to John, especially since I'm having trouble explaining this, but here's a last stab at this:

Given 10d, John is not explaining "why H", he's showing that "why H" is equivalent to "why certain specific geometrical structures. He has just reformulated the problem, not solved it.

The important point about SO(10) representations is that you get precisely the standard model multiplet, no more no less, from choosing a single SO(10) irreducible, the most basic one, the spinor. That choice is very simple and compelling, whereas the standard model multiplet looks complicated. This idea isn't John's.

31. **john baez**
November 10, 2005

I could spend all night commenting on comments that criticize me for not achieving grandiose goals that I never claimed to achieve, but I won't.

I'll just say this: particle physicists are a touchy bunch! Give 'em a 4-page paper with two propositions and a corollary – I save the word "theorem" for things that are hard to prove – and they'll complain you *didn't explain why the universe must be the way it is*.

Reminds me of the guy on sci.physics who's been viciously attacking me for… *not being the next Einstein!* Hard to argue with that. But there's some kind of "I've gotta save the world today or it ain't worth getting out of bed" attitude going on here, and I don' t like it.

Anyway, back to physics:

Everyone always says how the Georgi-Glashow SU(5) theory predicts too high a rate of proton decay, and that kills it. This is one reason my paper is not about the SU(5) theory: it uses some math from the SU(5) theory, but it's really just about G-manifolds where G is the Standard Model gauge group.

However: I am ashamed to admit, but I must admit here, that I've never carefully gone through the calculation that predicts the rate of proton decay in the SU(5) theory. This is bad, because it's dangerous to take the conventional wisdom on faith: the conventional wisdom tends to leave out the assumptions behind the results. For example: compare how many people know the conclusions of the Coleman-Mandula theorem to how many people remember its assumptions!

So, I should strap myself to a chair and work through this calculation. I should also see exactly how supersymmetry helps. I should see how flipped SU(5) changes things. And, I should see how things are different for SO(10). I know what people say about this stuff. But, I should check it for myself.

Unfortunately, I always seem to have something more fun to do.

In case anyone here is even worse at this stuff than me, I recommend the Wikipedia articles on the Georgi-Glashow SU(5) GUT and other grand unified theories including SO(10), the Pati-Salam model and flipped SU(5). They don't compute proton decay, but they're really not bad for starters!

For more detail while keeping things pretty easy, there's chapter VII of Zee's book *Quantum Field Theory in a Nutshell*.

For even more detail, I recommend Ross' *Grand Unification* and Mohapatra's *Unification and Supersymmetry: The Frontiers of Quark-Lepton Physics*.

These old review articles are also good:

D. V. Nanopoulos, Tales of the GUT age, in Grand Unified Theories and Related Topics, proceedings of the 4th Kyoto Summer Institute, World Scientific, Singapore, 1981.

P. Ramond, Grand unification, in Grand Unified Theories and Related Topics, proceedings of the 4th Kyoto Summer Institute, World Scientific, Singapore, 1981.

But, given how fundamental the topic is, I'm surprised there are not more books on grand unified theories – books that cover every popular theory in excruciating detail, computing the proton lifetime and the running of coupling constants in each one, etcetera.

Maybe I'm overlooking some?

32. **John Gonsowski**
November 10, 2005

"virtually all his assumptions are not substantiated in any way, and this is why he could have decided to consider E_8 or E_8 x E_8 or U(1)^496, or …And I don't think he is suggesting any nice "new things?? with this. Basically, he is only expressing well-known fact in terms of Clifford Algebras"

Yes I know a Clifford Algebra bivector when I see one so that's not the new I was thinking of. It's kind of as you've been discussing, just looking at spacetime geometry and standard model bosons and having this be a potential area for "new". Also as you've been discussing, if you want spacetime geometry, SO(10) is kind of on the short list of known places to look and Baez is not suggesting it's the only place to look. Smith by the way has Clifford Algebra reasons for starting with a single E8.

33. **john baez**
November 10, 2005

Kasper Olson writes:

> […] the inclusion of SU(5) in SO(10) has been known for ages – sure enough, SO(10) has some nice features, but if he's looking for beauty he could as well have chosen E_8 x (something), or whatever else that [has the] SM group as subgroup.

Of course for my "G-manifold" idea one wants a nice small orthogonal group O(n) containing the given group G, to get some reasonably simple description of Riemannian n-manifolds whose holonomy group lies in G. When G is the Standard Model gauge group, O(10) is the smallest one that will work. So, I consider 10-dimensional G-manifolds. And, as you know, I prove a couple of things about them: 1) they're 10d Calabi-Yau manifolds whose tangent spaces split invariantly into 4d and 6d parts, and 2) spinors on them form one generation of the Standard Model fermions.

But speaking of E8….

My most recent spell of thinking about this stuff was last summer, when I was stuck in the Beijing Friendship Hotel. My wife was attending an international congress on the history of science. Whenever I got sick of talks on that subject – held in small, miserably hot and stuffy rooms – I went back to my nicely air-conditioned hotel room, took a shower, turned on the BBC news, and worked on finding patterns relating the Standard Model to the octonions and exceptional Lie groups. It was especially fun because I hadn't brought any notes with me, so I had to rework everything from scratch. Endless hours of amusement!

I found some neat stuff which I will develop further when I have more time, and eventually write up. The quickest bit to describe was this thing about G-manifolds, so that's what I wrote up first. Exceptional groups will make their appearance later.

34. **Quantoken**
November 10, 2005

John:

I'd be interested in knowing what you come up with, after you strip yourself to a chair and calculate the proton decay lifetime.

Mean while, I am making this observation from what I know. All particle decaying phenomena has a decay life time spanning a great range of order of magnitude, from as short as femto second to as long as billions of years. However the longest decay lifetime observed do not exceed a norminal value times the age of the universe scale. We have not seen anything that decays at a time scale like say a thousand times the age of the universe, or a million times, or 10^10 times. **A few billion years seems to be an upper limit**.

Any one know a counter example that the decay lifetime is actually observed to be significantly higher than a norminal multiply of the age of the universe? Please let it be known if such counter example exist. If not, then there is a reason why it can go from femto second to billions of years, a dynamic span of more than 40 orders of manitude. But it doesn't go beyond that. I have a perfect reasonable explanation why that is the case. But I shall refrain from discussing it here.

Quantoken

35. **Passby**
November 10, 2005

Quite interesting topic and discussions, although I don't understand what your guys talked about!

36. **a**
November 10, 2005

Just to quickly answer the question above: there are no 10-dimensional CY manifolds with the standard group as holonomy group. Once you reduce as far as that, you have to go right down to SU2 x SU3. There is an obvious 12-dimensional non-CY manifold with a holonomy group very much like the standard group [namely SU5/G] but I'm not sure what the exact holonomy group is after you factor out the center of SU5. I guess it's ok.

37. **Quantum_Ranger**
November 10, 2005

Did not Ed Witten:http://arxiv.org/abs/hep-th/0211269

http://arxiv.org/abs/hep-th/0304079

get pretty close to moving the 'proton-decay' goalposts?

One major problem of a precise proton-decay rate, is that you first have to have a precise "vacuum".

I do recall that Witten tried his best a number of years ago, and I recall that I could only conclude that the/our PROTON must have its decay mode from another Universe, this is to say that the appearence of the standard model 'proton', must have decayed into that fundemental state "prior" to it appearing at the finite Vacuum in the early Universe.

This other "Universe" may for all intensive purpose be contained at Blackhole singularity 'terminal' junction, as the primordial/first particle in certain cosmological bounce models, aka Turok?

38. **Haelfix**
November 10, 2005

As far as model building in this scenario, I really don't think it would buy you much. You can't deform the CY2 or CY3 at all obviously since you would break the all fundamental gauge group.

Perhaps it might be useful *somehow* to analyze various subtelties of gauge theory using CY machinery, but that seems to me to be somewhat backward. We tend to know more about gauge theory than we do about CYs, and obviously those two specific calabi Yaus picked out aren't terribly illuminating on the general case.

Maybe im missing something.

39. **Tony Smith**
November 10, 2005

"a" says "… there are no 10-dimensional CY manifolds with the standard group as holonomy group. Once you reduce as far as that, you have to go right down to SU2 x SU3. …".

Arthur L. Besse (pseudonym for a group) says as author of the book Einstein Manifolds (Springer 1987) at page 284: "… Hol(g) = U(m) for the canonical Kahler metric on the complex projective space CPm. …".

Green, Schwarz, and Witten, in v. 2 of Superstring Theory (Cambridge 1987) say at page 440: "… a metric of SU(N) holonomy is the same thing as a Ricci-flat metric. This … is our first taste of he fact that in finding states of unbroken supersymmetry we actually are finding vacuum states that obey the equations of motion of string field theory. …".

So, if the superstring theory requirement of unbroken supersymmetry were removed, could John Baez find the 10-dimensional standard model holonomy model that his paper describes ?

If the unbroken supersymmetry requirement of Ricci flatness were removed, could holonomy U(3)xU(2) (which includes the standard model) be achieved by using 6-dimensional twistor-and-conformal-related CP3 along with 4-dimensional CP2 ?

Dear All

This discussion raises an interesting question about when one should pay attention to numerical coincidences. I get a large number of e-mails claiming to have solve the mysteries of the universe based upon numerology. For my own part I have stared for hours at tables of counts of rational curves in Calabi-Yau manifolds in the hope of relating them to characters of Lie Algebras and thereby see interesting dualities. I did this with the odd success until a colleague told me that he just found his complete eight-digit birthday in a particular divisor set ….

So here is the question: When is numerology pointless and when is it valuable? (There are lots of examples of the latter…. so I am not asking for a catalog.) When do we say "enough!"? There are some obvious criteria for when it is useful:
(i) When the number of numerical coincidences is outrageously large
(ii) When there is a conjectured underlying mechanism for which one is trying to gather evidence
(iii) When the setting suggests many possible mechanisms and the task is to find the correct one ….
(iv) When your numerology satisfies (i), (ii) or (iii) and does not have an elementary explanation that is already well understood.
Conversely, numerology is probably pointless if you satisfy none of the conditions above.

Put more practically, Physicists and Mathematicians have lots of demands on their time and if you are going to attract their attention you have to get beyond the "crank-mail filter" which means that your numerical coincidence better have more than a few matching numbers.

So we come to my earlier post. John's article (from my perspective and, I think, Lubos') fails to meet (i), (ii) and (iv). One might hope that it meets (iii), and the burden of my original post was to examine this possibility in more detail, and expalin why it actually fails (iii). That is, based upon standard approaches and mechanisms of compactification the expressed hope behind the numerology cannot work. Given this, it is especially important to postulate, even very vaguely or roughly, some new proposed mechanism by which the numerology could be given meaning. To hide behind statements like

"Since I wasn't proposing a physical theory, I was not in the position to make this elementary mistake."

simply makes me (and probably most other physicists) move the idea to the pile of amusing but insubstantial numerical coincidences that arrive in the mail each week. It is possible that this approach will indeed cause me to throw out the solution to life, the universe and everything, but the practical fact is that we all have to make judgements of what will be profitable to pursue and for me John's paper does not cross this threshhold.

More constructively, it might be useful to have a discussion on what kinds of conjectures and what kind of evidence is needed in order to engage the average theorist more deeply ….. The criteria will have some interesting universal properties, and probably a number of really quirky individualistic ones …. I suspect that the ones I have given above are pretty universal (but that might just be the arrogance of a particle physicist….)

41. **Michael**
November 10, 2005

Hi Nick,

nice post. I would like to add one 'negative' criterion: If the mechanism suggested by numerology is obviously not operating in nature, it shouldn't be taken seriously.

In the present example, quoting Lubos, the "four dimensions of the space we know do not transform under the electroweak SU(2), and the six hidden dimensions do not transform under SU(3)." This seems good enough to dismiss John's idea as not relevant to physics, doesn't it?

42. **DMS**
November 10, 2005

Nick,

What you say is interesting and thoughtful. It is a matter of personal taste what one works on, of course.

However, there is a LOT of string-inspired "numerology" (think "realistic brane models")that is out there, that do not explain ANYTHING about the physics beyond the standard model(and in my opinion, never will). So for *some string theorists* to be going it bullying and insulting anyone coming up with any idea that is not completely string-inspired is a bit rich.

Peter,

Seems like you had a busy day yesterday 🙂 Thanks to the arrogant attitude of some(I think they believe they are the next Pauli; well, they are, minus the contribution to physics), I and others I know have changed our attitude from:

"(Ok, some)String theorists are arrogant, but they may have a point."
to
"(Ok, some)String theorists are arrogant and **liars**, who thrive on delibrately distorting other people's work, likeley because they have nothing useful to say."

It is amusing to note that Clifford was upset about Krauss' opinions. Many physicists I know have a **much worse opinion** of the field(unfair, in my opinion).

DMS

43. **Kasper Olsen**
November 10, 2005

Dear John,

I guess we can all agree that the standard model is not the *final* story – it is basically just a low-energy effective field theory. So, some of its mathematical 'coincidences' might be important and some might not. Therefore, as long as you do not have a more 'fundamental' theory, I doubt you will be able to tell which of these coincidences are important and which are not.

Best, Kasper

44. **X**
November 10, 2005

Modern physics seems to be mostly about piling up beautiful symmetries; with the symmetry breaking required to match the real world as an ugly and arbitrary and an afterthought – this is my subjective impression. Is there some framework in which symmetry breaking is more elegant?

45. **Chris Oakley**
November 10, 2005

Hi X,

I completely agree. I remember asking "Is there anything better than the Higgs mechanism?" when studying QFT for the first time in 1980/1981 in Cambridge, UK. The lecturer – Peter Goddard, now running the IAS – answered with a forceful "No". He could justifiably give the same answer today. Whilst I can see the attraction of spending most of one's time doing classical field theory – it is easier and more elegant, after all – ultimately *quantum* field theory is the thing that actually counts and I have no doubt that more focus here would quickly lead to constructs greatly superior to the Higgs mechanism.

John, I am unsure it is related to your paper, but if you are going towards using GUT SU(5) or SO(10) groups without running up to GUT scale as traditional, it could be worth to bring into attention my unpublished note on extracting GUT angles from Z0 decay only. It is at

http://dftuz.unizar.es/~rivero/research/gut.pdf

(Referee told that it could do a good footnote to a more important paper. I am a writer of footnotes, you see)

49. **andy.s**
November 10, 2005

Summing up all the contributions, it looks as it John B's first comment in the thread was right on the money.

It took a lot of effort, but it was worth it.

50. **woit**
November 10, 2005

Nick,

John's idea isn't really numerology, more just a geometrical characterization of the standard model group. The only real numerology is the standard model multiplet as SO(10) spinor, which isn't his idea.

From the way you refer to Lubos, I take it you don't see much wrong with his behavior. Suit yourself. But do read DMS's comment. I don't think you or most string theorists have a clue how much damage Lubos and Susskind together are doing to how string theory is now viewed by other physicists.

JB wrote: a writes:

Just to quickly answer the question above: there are no 10-dimensional CY manifolds with the standard group as holonomy group. Once you reduce as far as that, you have to go right down to SU(2) x SU(3).

Well, that would be a bit sad. Could you point me towards a proof?

OK let me back off a moment and say that I was talking about the simply connected case. Back to that in a minute. S[U2 x U3] is a subgroup of U2 x U3, so we [as you know] are talking about a *Riemannian product* of Kaehler manifolds. But for a product of two manifolds to be Ricci-flat, each one separately has to be Ricci-flat. Hence the holonomy group has to be contained in SU2 x SU3. Somehow writing it out like this makes it look trivial, but there is something highly non-trivial going on here; see Besse's book.
All this is in the simply connected case. In the more general case you might, by cleverly taking a Riemannian quotient that affects both factors non-trivially, get a holonomy group which is a *disconnected* group which sort of interpolates between SU2 x SU3 and the standard group. That might be interesting but it still wouldn't be the standard group itself of course.
Let me conclude by saying that although I have no clue as to how your idea can be used, at least I opened the paper and looked at it; which is more than I can say about the dry technical exercises which, particularly over the last couple of years, have clogged the arxiv. And several of the responses in this thread made my jaw drop after the manner of one of the skeletons in "Corpse Bride". I do hope that people won't be discouraged from posting papers like yours. God knows, we don't exactly have an oversupply of interesting papers these days……

52. **Ruadhan**
November 10, 2005

I think Nick's question is answered by the minimum description length criterion. Essentially, the log probability that a particular conjecture, C, which happens to explain some data, D, is just a coincidence, is given (more or less) by the amount of information needed to specify the conjecture (the complexity of the conjecture) minus the amount of information needed to specify the data. To apply this in practice you need a way to "encode" conjectures, or rather, you need to make a list of all conjectures, and then the complexity of a conjecture is the log of its position in the list. (Be careful, though – you can't simply choose an ordering which puts your conjecture at the top; you need to choose a way of generating the list which doesn't require much information to specify).

I've never seen anybody apply this procedure to the problem of classifying physical theories, but I think it would be a great idea for somebody who isn't me to work on. It's exactly the kind of procedure that will tell us how surprised we should be that this apparently simple group mod that one looks like the standard model. It's numerology done properly, so to speak.

53. **Tony Smith**
November 10, 2005

"a' refers to Besse's book and says "… In the more general case …[than]… the simply connected case. you might, by cleverly taking a Riemannian quotient that affects both factors non-trivially, get a holonomy group which is a *disconnected* group which sort of interpolates between SU2 x SU3 and the standard group. …".

However, Besse says at pages 323-324:
"… 11.21 Theorem. Let M be a compact Kahlerian manifold with vanishing real first Chern class. Then M admits as a finite holomorphic covering the product of a complex torus by a simply-connected Kahlerian manifold, again with vanishing real first Chern class.
…
Theorem 11.21 allows us to restrict the study of the compact Kahlerian manifolds with vanishing real first Chern class to the study of simply-connected ones. …".

In light of that, it may not be feasible for John to evade "a"'s statement that "… there are no 10-dimensional CY manifolds with the standard group as holonomy group. Once you reduce as far as that, you have to go right down to SU(2) x SU(3). …", unless somehow by using noncompact things Besse's Theorem 11.21 might be evaded.

However, please do NOT take this as being critical of John for having written the subject paper. It is, as "a" says, a truly "interesting paper" and such things are indeed all too rare nowadays.
To me, even if John's paper's construction does not apply to Ricci-flat Kahler manifolds, it is doubtless applicable to some non-Ricci-Flat Kahler manifolds,
and
since Ricci-flatness is means (in string theory context) unbroken supersymmetry,
maybe the lesson to be learned from John's paper is that the standard model, and probably nature itself, does not like currently fashionable string supersymmetry (no matter how attached to it some physicists may be).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

54. **Quantum_Ranger**
November 11, 2005

Supersymmetry?

Surely Riemannian Geometry is the crux of General Relativity?.. Relativity is Observer dependant? ..Stringtheory needs a continuious string field background as stated by TS above 'ricci-flatness'? is exactly what you get when observers are removed, an observer is nothing more than a curveture imposed by the presence of an 'observer' being that observers are composed of tangable matter?

Baez paper is really a very complex "Hand-Wavy" investigation into discrete notions of continued or, broken dimensions that energy and fields exist within.

In fact, it is really the bases of how matter and energy are contructed and manupulated, using the techniques of "seperation" or "extended" continuations of inquiry?

55. **Quantum_Ranger**
November 11, 2005

Should have stipulated:Reductionism v Separation
as the standard definition:continuous = Reductionism
"a continued decomposition" from a prefered or real location.

56. **Urs**
November 11, 2005

> since Ricci-flatness is means (in string theory context) unbroken supersymmetry,

That's just the simplest case. When for instance (p-form-)fluxes are turned on susy no longer comes with plain Ricci-flatness in general.

Heuristically this is because further fields have further energy-density which back-reacts on the geometry by its gravitational field.

More technically it is because the susy one is talking about here is the existence of a spinor which is constant with respect to a given covariant derivative. That covariant derivative receives contributions from essentially all of the background fields. For instance Kalb-Ramond flux gives rise to a torsion term, etc.

57. **MathPhys**
November 11, 2005

Agressive behaviour has always been part of the theoretical high energy physics scene in the US. Motl's behaviour is silly and childish. He's so predictible, that by now he's boring.

58. **Tony Smith**
November 11, 2005

Urs says that "Ricci-flatness is means (in string theory context) unbroken supersymmetry" is "just the simplest case. When for instance (p-form-)fluxes are turned on susy no longer comes with plain Ricci-flatness in general. Heuristically this is because further fields have further energy-density which back-reacts on the geometry by its gravitational field. …".

Then, could John's construction be seen as indicating
that "simplest case" Ricci-flat Calabi-Yau superstring theory may be physically unrealistic
and
that perhaps realistic string theory models should be based on non-Calabi-Yau, non-Ricci-flat, Kahler manifolds for 6+4=10 dimensional string "background" (maybe even including my favorite pair , CP3 and CP2) ?

If so, might that mean that the "landscape" based on Calabi-Yau manifolds may have a flawed basis, and that work like John's might be a good way to search for a physically realistic string theory model ?

Tony Smith

59. **Urs**
November 11, 2005

> could John's construction be seen as indicating
> that 'simplest case' Ricci-flat Calabi-Yau superstring theory may be physically unrealistic

Isn't that essentially asking if any spacetime which is not a manifold of S(U(2)xU(3))-holonomy may be physically unrealistic? Sure it may. But unless you find some mechanism why spacetime should have S(U(2)xU(3)) holonomy it's hard to see a relation between one and the other.

> might that mean that the 'landscape' based on Calabi-Yau manifolds may have a flawed basis

The landscape arises precisely due to the freedom of turning on all sorts of discrete values for these fluxes.

But I am no expert on landscape issues, so that's all I am going to say on that point.

There is little point, I think, in trying to see any relations between standard string phenomenology and an approach that tries to find particles in spinor reps.

In ordinary string phenomenology, the fermions arise from the R-NS and the NS-R sector of the string. This means that they are really just spacetime spinors. Now, if you identify the components of that spinor with particles, you are left with something like scalars, no?

That's why I said above that – if you wanted to identitfy spacetime spinor components with spinning particles, you'd need to supply another set of ordinary spinor degrees of freedom. For instance by using "bispinors" or whatever you'd call them.

That's just a very vague observation. It is not new, but has been investigated in papers like the one I mentioned above. Being totally untrained in phenomenology, I cannot judge the viability of such ideas. All I can do is make the general observavtion that such bilinears in spacetime spinors appear in the string's spectrum, too. Namely in the RR sector, where they are known as RR p-form fields.

Make of that what you wish.

61. **Nick Warner**
November 12, 2005

Peter,

From my comments about Lubos you can only reasonably infer that I consider him to be "somewhat undiplomatic". I have no wish to be drawn into a more personal discussion. The purpose of my posts was try to explain, more diplomatically, some of the substance underlying Lubos' post and why his particular post here, but *not* his mode of expression, probably represents the views of many people who work on physics from higher dimensions.

I read DMS's comment. It is hard to determine whether his comments were directed at me or Lubos (perhaps this ambiguity was your point, Peter). At any rate, I agree that there is a lot of nonsense under the "string inspired" banner. Indeed, the worst of it is actually fundamentally inconsistent with string theory. However, this is beside the point here. Holding me responsible for the excesses of the "string inspired" is comparable to holding me (a US resident) responsible for George Bush's supreme court nominations ….. . While you may be justified in disliking the messenger and his other messages, one should keep focussed on the actual content of a particular post within a thread. In this instance the subtantial content of Lubos' post is correct, but the way he chose to express it was not.

62. **woit**
November 12, 2005

Hi Nick,

Yes, my point was that the way in which you choose to describe and deal with Lubos's comments here gives the strong impression that you think his behavior is acceptable (if "undiplomatic'), and this will influence people and cause them to draw conclusions you're not going to be happy with.

I understand that there was a substantive point in what Lubos wrote that may have been worth discussing. There also were substantive points in his comment (his claims that John thought he had discovered all sorts of well-known facts), that were stupid, dishonest and offensive, not just undiplomatic.

November 13, 2005

Luboš Motl of Harvard University once wrote something that was sensible: '… quantum mechanics is perhaps the deepest idea we know. It is once again a deformation of a conceptually simpler picture of classical physics.' – http://motls.blogspot.com/2005/07/measuring-depth-of-ideas.html

I can't understand why he seems to think string theory fits into this. String theory is not a deformation of conceptually simpler ideas, it is a real mess with no empirical basis at all. I wish he would grasp that you need to go back and review the evidence, discard obsolete speculations (ST), before making progress.

I know that Motl's being paid some grant by Uncle Sam or whoever to pontificate on crank ST, or he wouldn't be under such pressure. He complains about Baez rediscovering things, but this is what happens in real science! Darwin rediscovered the evolution theory of Anaximander while Copernicus rediscovered the solar system of Aristarchus. Cranks who deny rediscoveries are just creationists believing in an earth-centred world. You have to feel sorry for Motl.

65. **Juan R.**
November 14, 2005

Nigel,

In *some sense* i agree with Motl at this point.

String theory 'born' (of course after its failure on strong-force) from a very simple idea: a string vibrating could offer us a two-spin vibration mode resembling the hypotetical graviton.

Since then string theorists unable to understand gravity (or any other part of real science) have claimed that string theory was "important", "fundamental" or even "elegant". Since 40 years ago, the topic had been modified, radicalized, and today 'string' theory is a 'deformation' of conceptually simpler ideas.

Today, there is not simplicity, there is not elegance, there is not empirical basis, there is not fundamental point of view, there is not unified theory. Is there nothing? Well i think that ego remain and this is the reason that string theorists -specially smart ones -are unable to recognize that they have failed 🙂

In fact, today there is not theory or 'strings'. Now, the conceptually simple idea of reducing 'all' (of course, this was always an exageration from arrogant people as Schwartz or Greene) to a simple vibrating string in 4 dimensions is abandoned.

Now, one finds 11D that reduce to 10D in weak coupling limit, those 10 contain 16 'inner' dimensions in that unelegant mixture of bosonic and fermionic stuff, all aderezed with zero mass and none connection with real particles. The breaking into 4×6 is done by hand, it is not well defined, etc.

The initial single parameter transformed into a mixture of more than 10000 parameters in the best of cases. It is true that initially the posibility for reducing the near 20 of standard model to 1 was really good, but if my math is correct 10000 >> 20 and the situation now is worse.

The theory of everything turned into the theory of nothing.

From the posibility for understand 'all' of our universe they are passing to the unability for understand even one of multiple (posibly infinite) predicted 'universes'.

What is more, from the elegant reduction of dozens and dozens of different particles to a single item. Now there are p-branes (0, 1, 2, 3, 4, 5, 6, 7, 8, and 9). All the theory (so say) offering towers and towers and towers of unobserved effects.

From

> NO, the standard model is incorrect. There is not pointlike objects on Nature. The basic item of nature is a small unidimensional object

Now some of them are claiming

> NO, string theory is incorrect. There is not real unidimensional object on Nature. The basic item of nature is a small pointlike object: the D0-brane

Etc, Etc.

Well i could agree that was a 'distorsion'. One very very great 🙂

Juan R.

Non Abelian gauge symmetries induced by the unobservability of extra-dimensions in a Kaluza-Klein approach (gr-qc/0511100)

Latest Freed-Hopkins-Teleman

November 10, 2005
Categories: Uncategorized

A wonderful long-promised paper by Dan Freed, Mike Hopkins and Constantin Teleman entitled Loop Groups and Twisted K-theory II has just appeared. They have advertised it in the past under various names such as "K-theory, Loop Groups and Dirac Families", but their latest way of organizing their work seems to be to relabel the two-year old Twisted K-theory and Loop Group Representations (which recently has been updated, improved and expanded with new material) as "Loop Groups and Twisted K-theory III". Working backwards it seems, they now advertise a "Loop Groups and Twisted K-theory I" as still to appear, hopefully in less than two years.

I don't mean to give them a hard time about this. They are doing wonderful work, continually refining and improving on their results, and the paper is worth the wait. At the moment I don't have time to do them justice by explaining much about their results or the conjectural relations that I see to quantum field theory, but I wrote a little bit about this a while back in another context. In the future I'll try and find time to write some more entries about this material.

Also related to this is a new paper of Michael Atiyah and Graeme Segal called Twisted K-theory and cohomology which discusses the relation of twisted K-theory to twisted and untwisted cohomology.

Teleman has also recently made available on his web-site a preliminary version of notes from his fascinating talk at the algebraic geometry conference in Seattle this past summer, entitled Loop Groups, G-bundles on curves. He starts off with some philosophy he claims comes from lessons learned in working with moduli of bundles:

(i) K-theory is better than cohomology
(ii) Stacks are better than spaces
(iii) Symmetry

The first and third points I'm well aware of, and he has convinced me to spend some more time learning about stacks by his next point, which I hope may clarify some issues that confused me when I was writing my notes on Quantum Field Theory and Representation Theory. According to Teleman, the fundamental K-homology class of a classifying stack BG gives a notion of "integration over BG" in K-theory that corresponds precisely to that of taking the G-invariants of a representation. This idea has been a fundamental motivation for me for quite a while. It seems to me that one fundamental question about the path integral formulation of the standard model is "why are we looking at the space of connections and trying to integrate over it?" The K-theory philosophy gives a potential answer to this: we're looking at the space of connections because it is the classifying space of the gauge group, and we're integrating over it because we want to be able to pick out the invariant piece of a gauge group representation. I'll try and write up more about this later, especially if learning some more about stacks ends up really clarifying things for me as I hope.

On a somewhat different topic, Teleman recently gave a very interesting talk at Santa Barbara entitled The Structure of 2D Semi-simple Field Theories.

Comments

1. **Anonymous**
   November 11, 2005

   we're looking at the space of connections because it is the classifying space of the gauge group, and we're integrating over it because we want to be able to pick out the invariant piece of a gauge group representation.

   Hmm. I, for one, would like to see you elaborate on this. I know you wrote some of this up in your notes on the arXiv, but it's nice to see it written up in words. I would like a summary of the idea in "physics language." As I understand it you want to recast the ill-defined path integral formalism as some sort of sophisticated (and currently not well-understood) representation theory. Is that the gist of it? It sounds like this might make QFT more rigorous but it doesn't seem that it would have calculational advantages. What do you think would be the physics applications if your program worked?

2. **AJ**
   November 11, 2005

   What do you think would be the physics applications if your program worked?

   Peter, I'm sure, will provide his own answer, but let me pipe up anyways. Providing a definition of the path integral in terms of the algebraic topology of a stack would almost certainly allow us to introduce new computational tools into quantum field theory. Algebraic topologists have a fascinating collection of Really Powerful Computational Gadgetry, and I for one, would love to see what they can do to QFT. It'd be nice, for instance, to compute correlation functions using simplicial resolutions.

   There would probably also be conceptual advantages. Right now, the status of the path integral is a bit murky. We write down some classical action, and then we define the path integral measure in a rather ad hoc fashion, choosing some regularization. But our computations are supposed to be independent of our choice of regularization. It would be nice to interpret this by saying that each regularization is a different way of representing a fundamental class.

   Or, less trivially, it would be nice to explain anomalies as obstructions to the existence of a fundamental class, just like we think of the Stieffel-Whitney class as an obstruction to the existence of an orientation. This would provide a very clean explanation for the fact that they tend to be measured by characteristic classes.

3. **Anonymous**
   November 11, 2005

   AJ, what you say sounds very nice, but it's unclear to me how one would ever hope to compute correlation functions using algebraic topology. Probably this is because of my elementary understanding of algebraic topology. In what sort of calculation does one really capture the sort of local information we are after in QFT correlators? I'd like some example of an algebraic topology calculation where one gets back a continuous function. (I can see that a calculation might for instance tell one about a DeRham class, but one still has to figure out what is the functional form of the form, yes?) It seems to me that the question of computing correlators where perturbation theory does not apply is currently formulated as a difficult analysis problem (solving some infinite coupled set of Schwinger-Dyson equations, subject to certain constraints), and I don't see how the proposed approach would do any better than reformulating it as a different difficult analysis problem.

4. **woit**
   November 11, 2005

   Hi Anonymous,

   Let me start with an analogy. You can write down the Schrodinger equation for an atom, even a simple one like the hydrogen atom, but then you have a difficult PDE to try and solve. Without exploiting the rotational symmetry group and what you know about its representations (i.e. using angular momentum operators and corresponding decompositions of states), it's hard to get anywhere, but if you exploit what you know about representations of SU(2), all sorts of calculations become possible. Perhaps if we understood better how to reformulate certain QFTs from the ground up in terms of representation theory, we would get all sorts of new insights and possible calculational methods. Maybe some of these would involve the kind of algebraic topology AJ mentions (the Teleman idea I described directly relates representation theory and algebraic topology: you study the representation ring by looking at the K-theory of the classifying space). If you're an incurable optimist, you might hope these new insights will give you a new idea about how to solve one of the big problems of particle theory: e.g. how is electroweak symmetry broken? how do you unify gravity and the standard model?

This is in some sense just a fancy way of saying something well-known: as Weinberg in his latest article points out, physics in the 20th century made progress by finding symmetries and exploiting them. He thinks this idea is played out and we need to change paradigms and abandon it. I don't. I think physicists need to understand that "exploiting symmetry" = representation theory, and mathematicians know a vast amount about representation theory that physicists have never absorbed. Before abandoning hope like Weinberg, people should try and understand this kind of mathematics and see what can be done with it.

The Freed-Hopkins-Teleman stuff is relevant to 2d QFT, but precisely 2d chiral gauge theories, which are the 2d analog of the standard model in 4d. My specific hope is that if you properly sort out the 2d story, you'll get a new idea about how to approach things in 4d. From a more physical point of view, my claim would be that, at a non-perturbative level, chiral gauge theories are still extremely ill-understood. Sure, we know how to use BRST to get a consistent perturbation expansion and to cancel anomalies, but we don't know much about what happens non-perturbatively. There are all sorts of problems with the BRST formalism (Gribov ambiguities just for a start), my hope is that the FHT kind of stuff will allow a reformulation of BRST that makes more sense non-perturbatively, and might expose some new and interesting structure we can use to do real physics.

Anyway, at the moment, this is all a pipe-dream, but I see quite a few reasons to believe that it is a promising direction to pursue.

5. **Lubos Motl**
November 11, 2005

The fact that K-theory is "better" than homology to classify possible cycles (on which D-branes can be wrapped) has been known to the string theory community since 1998.

http://arxiv.org/abs/hep-th/9810188

I placed "better"in quotation marks because there is of course no universal adjective "better". Some things may be described by homology, some things may be described by K-theory, and only more specific statements are meaningful.

Also, the D-brane people have been using stacks, sheaves, and other things for quite some time.

Nevertheless, I am happy to see that some mathematical insights ignited by string theory have become so powerful that even Peter Woit was forced to notice and admit the reality.

6. **woit**
November 11, 2005

Despite what certain string theorists think, K-theory and sheaves have been around since the 1950s, stacks since around 1970. It's just absurd to claim that they are "mathematical insights ignited by string theory". Atiyah has been promoting the idea that K-theory is sometimes more fundamental than cohomology since the early 1960s.

7. **AJ**
November 11, 2005

AJ, what you say sounds very nice, but it's unclear to me how one would ever hope to compute correlation functions using algebraic topology. […] I'd like some example of an algebraic topology calculation where one gets back a continuous function

Short answer: Use a _really_ big space, something that bears the same resemblance to the space of connections as a sphere does to the smallest complex computing its cohomology. Let me be clear: I don't believe the tools exist yet to treat spaces this huge. But I think there's good reason to hope that they could be developed within the context of homotopical algebra, and I believe that algebraic topologists have been taking steps in the right direction. The elliptic cohomology theories, for instance, give us formal power series, instead of just elements of a finite-dimensional vector space.

Moreover, I do expect that, if we could reinterpret path integrals in this fashion, a lot of the usual gadgetry from algebraic topology would carry over, giving us new methods of computing. Maybe we'd run afoul of conservation of trouble, and computations would still be next to impossible. I don't know. But it's amusing to speculate.

I should probably emphasize that this what I'm talking about here is even more pie-in-the-sky than Peter's suggestion, which (if I understand him correctly) could be crudely characterized as "develop an analogue of geometric quantization which works for the group of gauge transformations". I'm focusing more on the connection between fundamental classes and integration; he's looking more at the representation theory side. What he's suggesting is probably actually a more promising idea — certainly closer to being not-a-fantasy. My only complaint is that I don't know how we're supposed to think about regularization and renormalization in that context. There should be some conceptual explanation for the fact that the choice of regularization doesn't matter in well-defined theories.

8. **Lubos Motl**
November 11, 2005

Dear Peter, I am not talking about K-theory being universally more fundamental than homology because, as I've indicated, this statement is meaningless. I am talking about a very specific example where homology played (and plays) a role, which are wrapped D-branes. Apologies to Prof. Atiyah, but some general statements that a legitimate object is universally more interesting than another legitimate – and very natural – object have no testable meaning.

String theory is the only known context in which the question "is K-theory more faithful or fundamental than homology" can have a well-defined meaning.

9. **woit**
November 11, 2005

Lubos,

"String theory is the only known context in which the question "is K-theory more faithful or fundamental than homology?? can have a well-defined meaning."

Your delusional mania that things only make sense in the context of string theory is getting weirder and weirder, suggesting organic brain damage. If you want to know why Teleman is saying this, read his papers, he has well-defined technical reasons for what he says, reasons which have zero to do with string theory. Similarly, Atiyah back in the early sixties had very good reasons for what he was saying (hint: there's this thing called the Atiyah-Singer index theorem….)

10. **Anonymous**
November 11, 2005

Perhaps by “only known context”, Lubos means “only context known to Lubos”.

11. **Anonymous**
November 11, 2005

So all this talk about using representation theory to define a path integral seems to raise the question: what about scalar field theory? If there’s no gauge group, shouldn’t the representation theory all be trivial? And yet we have no nice mathematically satisfying definition of the path integral for, say, phi^4 theory. I must be missing your point.

12. **woit**
November 11, 2005

I’m not conjecturing that all QFTs can be understood in terms of representation theory, just the fundamental one that has to do with the real world (i.e. the standard model or some extension of it). In 4d, you can rigorously define phi^4 theory, but all evidence is that you end up with a trivial theory in the continuum limit. Which may explain why you don’t see elementary scalars. Actually I think there are things you can say about scalar field theory using representation theory, but they’re pretty minimal (just as in QM for any Hamiltonian you can invoke the Heisenberg algebra, but things get more interesting when there are other symmetries around).

13. **Moshe Rozali**
November 11, 2005

Point that confuses me about this, in topological field theories usually the space of physical states tends to be finite dimensional and the number of observables quite small compared to that of a generic QFT. In generic QFT there are new issues to do with renormalization that are crucial in its understanding (e.g. the difference between asymptotically free and trivial theories will only show up then). Is the statement that some infinite dimensional version of K-theory useful for understanding generic field theories, with all their infinities?

14. **woit**
November 11, 2005

Hi Moshe,

In the kind of 2d QFT that I think Freed-Hopkins-Teleman is relevant to (basically a chiral fermion coupled to a gauge theory), there’s only a finite dim space of observables and it’s topological, when you’re looking at the gauge invariant sector. But the constructions are infinite-dimensional and involve the infinite dimensional gauge group, and infinite dimensional space of connections. Freed-Hopkins-Teleman are working in infinite dimensions. But the end result is a finite dim piece they describe in terms of finite-dimensional K-theory. The only renormalization sort of trickery involved here is the standard sort that gives the anomaly, i.e. you only need normal-ordering to get rid of infinities.

I certainly don’t know much about how to do things in 4d, where you do have to face coupling constant renormalization and infinite dimensional spaces of gauge invariant observables. I don’t believe that this kind of abstract mathematics will give insight into renormalization. Rather the opposite: that what physicists have learned about renormalization will be needed to understand exactly when it even makes sense to talk about things like representations of gauge groups in 3 or 4d, and what kinds of constructions of these actually can work.

Again, I don’t think of these ideas as a general tool that will be applicable to generic QFTs. Rather, I’d hope they will pick out a very specific QFT or set of QFTs, one’s which are very simple in representational-theoretic terms (just as certain special QM systems are special in purely involving representation theory, e.g. the quantization of a co-adjoint orbit in the compact Lie group case.) A.J. is right to say what I’m trying to understand is how to do geometric quantization in certain special infinite dim cases. In my pipe-dream this class of special cases will include the standard model. Anyway, the 2d case is something with a lot of beautiful mathematical structure, so it’s well worth sorting out for its own sake and to see what it teaches you.

November 11, 2005

Thanks Peter, one of the things that I liked about the topological string on twistor space story is the (probably well known) fact that the sheaf cohomology of the appropriate twistor space is infinite dimensional and gives you the fields of N=4 SYM, that is pretty.

16. **Urs**
November 13, 2005

> what I’´’m trying to understand is how to do geometric quantization in certain special infinite dim cases

BTW, the question recently raised by John Baez on the String Coffee Table seems to be closely related to the desire to understand a field theoretic analog of geometric quantization, I think.

There the question was, in a way, if we can understand something defined by a symplectic 2-form on an infinite-dimensional space in terms of a 2+n form on a finite dimensional space.

In particular, for 2D QFT it seems that it should be possible to re-express geometric quantization in terms of bundles over loop space in terms of gerbes over target space. Maybe, somehow, sort of … 🙂

Polyakovfest

November 11, 2005
Categories: Uncategorized

Last weekend Princeton held a Special Symposium in honor of Alexander Polyakov's 60th birthday. Witten talked about his recent work on Langlands duality. He'll also be speaking about this next week at Rutgers and December 1 and 2 up in Boston.

I hear from someone who attended the symposium that Gross gave a talk with title officially still TBA, but for which he said he'd use the title "Strings and Instantons", since that is what all of Polyakov's titles are. His theme was irresponsibility and he recalled around 1990 having dissuaded Polyakov from going to Santa Barbara and spending his time on the beach, getting him to come to Princeton instead. Of course Gross himself then soon left Princeton for Santa Barbara. Gross also said that, unlike his usual practice, he would end his talk on time since he didn't have much to say due to being busy with the events of the past year.

On a completely unrelated topic, Fermilab recently held a celebration of the tenth anniversary of the discovery of the top quark, and the talks are on-line. Also on-line at Fermilab are some on-going lectures by Chris Quigg on The Electroweak Theory and Higgs Physics.

   November 11, 2005

   Any chance that Atiyah will be present at Gross talk?

   It sound like Gross is expecting some tricky questioning, thus the reason given for the lack of available 'Time' at the upcoming talk, tells me Gross is aware of how interuptions of speaker's can be grossly mis-interpreted.

2. **Thomas Larsson**
   November 12, 2005

   Belavin's talk is probably about hep-th/0510214. Pokrovsky's article about Polyakov's contributions to condensed matter in the same e-print explains why I consider Polyakov to be one of the greatest physicists alive (Einstein, Dirac and Feynman are all dead).

   Jackiw's talk is probably about hep-th/0511065. This is what I'm currently reading.

3. **Amazon.com**
   November 12, 2005

   A book about this blog finally appeared here.

4. **Chris Oakley**
   November 12, 2005

   Re: the above, I found a list of treatments for autism:

   Nutritional Therapies
   Hyperbaric Oxygen Treatment
   Fibroblast Growth Factor 2
   Live Cell and Stem Cell Therapy
   Anti-fungal Treatment
   Antibiotic Therapy
   Naltrexone (NTX) Treatment
   Intensive Educational Therapies
   Detoxification for Heavy Metals
   Craniosacral Therapy

   Would any of these work on String Theorists, I wonder? One could could start the experiments on Landscapers (the useless ones, that is – not the ones who re-design your garden).

5. **Dr. Ranger McCoy**
   November 12, 2005

   does string theory have any laws or postulates?

6. **Alejandro Rivero**
   November 12, 2005

   While Chris Quigg is based on hep-ph/0204104, its companion paper 0404228 is a must.

7. **Juan R.**
   November 14, 2005

   Chris Oakley,

   A 10^120 volts electro-shock therapy?

   Perhaps one could then observe supersimmetric strings…

   I sincerely doubt that works with Landscapers. At least we would search them between the multiple universes first.

   Dr. Ranger McCoy

Of course!!

God is a string theorist. If God is not one then he is not so smart.

String theorists are smartest people of this universe. Landscape corolary: and of the rest of infinite others.

String theory explains more than everything

If anyone is against string theory, then kill her/him (academically, of course).

String theory is not defined, therefore you can define string theory as you want

Remember if you are a string theorist, you are smart. Corolary: this also apply if your contribution to science was zero

Any rival theory, if good, is part of string theory if not, then it is another example of how smart you are

Publish papers claiming contrary things. For example, in a paper string theory is unitary in other it is not and in other paper it is a mixture of two last ones. Then string theory always win. Corolary: you are more smart still

Energy spectra is bounded due to dualities. But 'smart spectra' is unbounded. You can always become more smart still

Rival people is so 'stupid' that when they say a thing they are not saying it, then you can claim that they are saying a different thing they really said. Corolary: if they claim that you are an ignorant, then that mean that they are saying that you are smart. Remember (1/R) => R

If string theory is incompatible with Standard model, the problem is with Standard Model. It is ugly

If string theory is incompatible with experiments, the problem is with the experiment. It was incorrect, or done to a very low energy. Corollary: by each time that energy level to observe effects is sited to more higgher level, smart level is also

If string theory is incompatible with scientific model model, the problem is with scientific model. It is so 'old' and string theory so new and revolutionary…

If string theory is incompatible with string theory, then there is not problem

If string theory is unelegant, then change the definition of elegant

If string theory is nonscientific, then change the definition of scientific

Name 'theory' to any thing that you can think or imagine even if you cannot write anything about it. Example: M-theory. Corollary: in private sure to young impresionable students that M-theory does not exist by the motive of being more smart when you write it by the first time

Public is…

If you are wrong, do not worry, wait to next duality

Maintain the name string theory by marketing purposes

This list is time-dependant, author-dependant, and context depdendant

Superstrings at Princeton

November 14, 2005
Categories: Uncategorized

Yesterday, Princeton University, as part of an effort to bring physics to a wide audience during the centennial of Einstein's great work of 1905, sponsored a performance of Superstrings. This event featured a lecture by Oxford physicist Brian Foster as well as a performance by violinist Jack Liebeck, and it was one in a series of such events that have taken place around the world.

I've always wondered what non-physicists come away thinking after being exposed to things like this. There's not much real scientific content, lots of wonderful music that has no real connection to the physics at issue, and many impressive analogies that could easily confuse listeners as to what the point of the analogy is. This time, one can see some of the effect the event had by reading an article about it in the Daily Princetonian.

The report recounts how the performers explained superstring theory:

"The concept of superstrings can be illustrated with a demonstration of quantum cookery," Foster said, as Liebeck helped him into an apron. A mesh colander modeled the universe with very fine holes corresponding to fluctuations in the space-time continuum. Foster poured flour through the holes, exemplifying how point-like particles cannot be contained in the universe, making a "delicious mess" on the floor of the stage.

Foster proposed circumventing this problem by making the particles long, rather than point-like, a concept known as particle supersymmetry.

To complete the analogy, Foster introduced uncooked pasta in three different varieties, one for each generation of matter, which he nicknamed "quantum pasta" or "superpasta." Although composed of the same ground-up grain as the flour, these "particles" avoided the problem of the point-like particles, staying contained within the colander.

Besides convincing at least some of the audience that supersymmetry is the idea of using uncooked spaghetti instead of flour, Foster did admit there was no evidence for any of this: "Superstrings may be purely philosophical and may have no measurable contributions to our universe". It might have been more helpful if he'd mentioned that "purely philosophical" here really means "wrong".

Some other facts about physics that the reporter learned yesterday are that:

gravity distorts the smoothness of Einstein's continuum, a problem he attempted to resolve through quantum mechanics.

There are *three "generations" of matter — the quark, lepton and boson.*

Superstring theory will resolve *the large discrepancies in the masses of these elementary particles.*

All in all, it seems to me that these performances are not helping the public understanding of science, but rather signficantly setting it back. I'm sure that those bloggers who are highly concerned about the public understanding of science in general, and string theory in particular, will want to address this issue and demand the immediate cessation of events like this.

Comments

1. **MathPhys**
   November 14, 2005

   This remind me of Brian Greene's last Nova on strings. Educated laymen told me that (unlike his book) they found it shallow and boring. Simplifying things beyond a certain point, coupled with absence of real punchline, gives the impression that string theorists have money and time on their hands, but it doesn't help the cause. I think the public wants to see solid results, like "There was this very big puzzle, now it's solved".

2. **blank**
   November 14, 2005

   Mission Accomplished!

   The less the public actually understands, the better.

   I wonder if Big Ed attended the performance?

3. **cvj**
   November 14, 2005

   Hi Peter,

   I note that the article that you pointed us to ends with the following:

   > "Superstrings may be purely philosophical and may have no measurable contributions to our universe,?? Foster said. However, their existence could be proved if they are large enough to create new, detectible particles when they collide.
   >
   > "If supersymmetry exists, the subatomic particles physicists found over the past 50 years are like various notes that can be played on superstrings,?? the final slide read, as Foster and Liebeck performed a duet believed to have been played by Einstein.

   About his other analogies, I can't comment. I don't fully understand them!

   But he does seem to allow for (and clearly point out) the possibililty that the enterprise may come to naught. Is that not significant? The extracts in your post don't mention these lines. I'm puzzled about that. Please help me.

   Cheers,

   -cvj

4. **woit**
   November 14, 2005

   Hi Clifford,

   I don't think it's difficult to understand what the analogies were trying to explain (perturbative superstrings better behaved than perturbative quantization of GR as a QFT in the ultraviolet), or that they were unlikely to actually transmit any information about this and would instead just confuse people.

   In my posting I did quote Foster's line that "Superstrings may be purely philosophical and may have no measurable contributions to our universe", and commented that this is highly misleading and gives people the wrong idea about what science is. If superstring theory ends up involving "no measurable contributions to our universe", it's not "purely philosophical", it's wrong.

   The last line that you quote is something the reporter says that she copied off the final slide, it would be interesting to hear in her words what she thought it meant. I actually think it is again quite misleading: as you're well aware, the existence of supersymmetry does not imply the existence of superstrings (although I'll readily agree it would be some evidence that superstring theory might be on the right track).

   So I take it you have no problem with this kind of performance and think it should be encouraged?

   Peter

   This discussion is now taking place in parallel here and at CV, which doesn't seem like a great idea. I never know how to handle this. If you want to continue it, pick one of the two places, your choice, and one of us can put a pointer at the other place to the continuation of the discussion.

5. **cvj**
   November 14, 2005

   Whoops, I see a flaw in the last sentence…. susy does not imply strings, of course. that is certainly wrong.

   Cheers,

   -cvj

6. **Alejandro Rivero**
   November 14, 2005

   Well, if SUSY gets to imply QCD, then as QCD implies strings…

7. **cvj**
   November 14, 2005

   Sorry Peter. I replied to your last question over on cosmic variance, since when I posted the comment above (correcting my earlier remark), your comment had not yet appeared here. It seems that we posted here at precisely the same time.

   Anyway, my mistake…just was not sure where you were looking!

   Cheers,

   -cvj

8. **woit**
   November 14, 2005

   Hi Clifford,

   That's fine, comments crossing each other in cyberspace seems to be part of the joys of blogging. If there's more of this particular discussion, I think it will be over at Cosmic Variance.

9. **Tony Smith**
   November 14, 2005

   As I read the Daily Princetonian article about "… "Superstrings," a lecture and concert event with Oxford physics professor Brian Foster, violinist Jack Liebeck and pianist Charles Own, … was sponsored by the physics department as part of the World Year of Physics, I am, as a graduate of Princeton (AB 63 mathematics), ashamed and embarrassed.
   A silver lining in the black cloud is that it validates my decision to change majors from physics to math.

10. **Dr. Ranger McCoy**
    November 14, 2005

    Hello!

    I attended Princeton and worked with Professor John Archibald Wheeler.

    It was there that moving dimensions theory was born.

    But because it has a Postualte, is based in logic and reason, and does not use cooking utensils, moving dimenisons theory is banned. But you can google it's postulate which unifies relativity and quantum mechanics.

11. **Dr. Ranger McCoy**
    November 15, 2005

    Actually moving dimensions theory isn't banned–I just haven't submitted it to any journals.

Not too long ago one of the faculty of the physics department here was retiring and throwing out all of his journals, saying it was all “useless rubbish” these days.

Are there too many physicists just publishing bs to get tenure and government grants these days?

12. **Plato**
    November 17, 2005

    Now I understand your kitchen analogy over at Cosmic Variance. 🙂

13. **Plato**
    November 17, 2005

    While you had deleted such comments before, I would hope you will reconsider.

    If the analogies stand for anything then it had by nature as Jacque noted, taken us to a certain point. Now it becomes complicated. Yes for me very much so.

    But as you read on, you must consider how Susskind or others like Wolfgang, or yourself, might have inflicted the evilness of what is “inhernetly right” with observations of the physics involved.

    Do you understand that in context of Krauss’s article, while there is great divergence from it, we might have inflicted our own makeup in this bashing? I am trying to make this point clear.

    I’ll save this entry

    Thanks

Lawrence Krauss at Cosmic Variance

November 14, 2005

More Swampiness

November 14, 2005
Categories: Swampland

Jacques Distler has a new posting about the Swampland, based on hearing a talk by Cumrun Vafa and discussions with him in Eugene, Oregon. Vafa seems to have made clear to Jacques that what he had in mind was just what he wrote about in his paper, investigating qualitative issues such as what gauge groups could arise in string theory. Jacques notes correctly that if string theory is ever to make contact with experiment, it has to have detailed, quantitative things to say. Vafa didn't think that such things were currently addressable, an attitude Jacques found perhaps overly cautious, although it just sounds to me realistic.

Jacques enlarges Vafa's swampland question to make it include the obvious crucial problem for string theory: given some arbitrary choice of the 120 or so parameters of the MSSM, can you get this out of the string theory framework? He makes much of the fact that current constructions of flux vacua are parametrized by sets that are not continuous, but discrete, although of such a huge if not infinite number that it is unclear whether this is of any practical significance.

Jacques and many others seem to be of the opinion that the thing theorists should now be doing is studying the details and physical implications of these huge numbers of flux vacua. Besides the fact that this is a horribly complex and ugly business, without the slightest indication from physics that it is a promising thing to do, it seems to me to be something inherently doomed to failure. Without knowing what the non-perturbative formulation of the theory actually is, the reliability of the perturbative string approximation one is using is unclear, with wishful thinking the only reason to believe that the real world will correspond to a region where the approximation is sufficiently reliable. Furthermore, these flux vacua constructions have been accurately described by Susskind as "Rube Goldberg mechanisms", and it seems to me likely that one can get just about whatever one wants by further complicating the mechanism. This is the completely conventional way wrong scientific ideas often fail: the simplest version of the idea doesn't work, so people keep trying to fix it by adding more and more ugliness and complexity. Sooner or later the whole thing collapses or fades into deserved obscurity when people finally give up hope of getting anything out of it.

To make the whole question of calculating anything in this framework even worse (something hard to imagine), it seems that there is an inherent theoretical problem with the computational complexity of the question of figuring out which flux vacua correspond to specified observable quantities. Frederik Denef mentioned this in some of his recent talks and Michael Douglas will be giving a talk about this on Wednesday at the KITP, entitled "Computational Complexity of the Landscape". I guess perhaps the new line about all this will be that string theory is the TOE, but it can be rigorously shown that one can't ever actually calculate anything with the theory.

Update: The Douglas talk is now on-line. As far as I can tell he has now given up on the idea of doing statistics of vacua, and is instead concentrating on the problem of whether you can show that, given one of the known flux vacua constructions, some flux vacua give you what you want, e.g. a cosmological constant of the right magnitude. Given how poorly string theory on these flux vacua is actually understood, I don't see that he can even formulate a calculation that makes any sense. But he doesn't actually calculate anything, engaging instead in a long meta-discussion about computability. Kind of a weird performance. Gross seems to have been in the audience, but not spoken up. I hope he hasn't given up.

   November 15, 2005

   If they run into computational complexity issues, then that's probably the end of the story. They definitely need a new brilliant idea.

2. **Who**
   November 15, 2005

   MathPhys Says:
   November 15th, 2005 at 7:46 am
   If they run into computational complexity issues, then that's probably the end of the story. They definitely need a new brilliant idea.

   Here's a new idea Ma.Ph., I don't know whether it is brilliant.
   It approaches TOE (joining gravity and particle physics) by deriving features of the Standard Model from beefed-up spin-networks (the LQG states of geometry) so that a quantum description of the geometry includes a description of matter (various numbers of different kinds of fermions)

   I don't know any source for this except a set of slides from the recent Loops '05 conference. If you want to check it out, start reading at around slide #35 in this bunch of transparencies for Smolin's talk

   [url]http://loops05.aei.mpg.de/index_files/PDF_Files/smolin.ppt[/url]

   The abstract has links to both the slides and the recorded talk (video).
   [url]http://loops05.aei.mpg.de/index_files/abstract_smolin.html[/url]

   If you want to watch the video allow a quarter of an hour or so for it to download:
   [url]http://loops05.aei.mpg.de/index_files/Video/smolin.wmv[/url]

   the (so far speculative) model being described here draws on work by Bilson-Thompson
   http://arxiv.org/abs/hep-ph/0503213
   A topological model of composite preons
   ===============
   so whether or not the specifically stringy approaches are bogged and need a new idea (as you suggest) that could be true but string IS NOT THE ONLY PROMISING APPROACH TO JOINING GRAVITY WITH PARTICLE PHYSICS, and this seems to be a new idea in the Loop approach—-in case you or anyone might be interested.

3. **Chris W.**
   November 15, 2005

   Who,

   For a different take on this, still involving spin foams, see hep-th/0403137 and other papers by the same author.

4. **Quantoken**
   November 15, 2005

“Computational Complexity of the Landscape” is an utter understatement of the problem, which makes it sound like a technicality issue of computer science. It is NOT. 10^500 vacuas is a HUGE HUGE HUGE number that few super string theorists even have enough brain cells to comprehend how big the number actually is. To put it in procpsective the univerve has roughly 10^80 various particles and it’s Hawking entropy is roughly 10^120, far shy from the 10^500. You can construct a quantum computer using the whole energy of a gogoplex of universes, and still has not even been able start to enumerate even just a small fraction of the 10^500 vacuas. For all practical purposes and intents, it’s an intractable math problem. Computer science is not the limit, physics is.

Put the computability issue aside, **what makes any one to believe there is ONE, and ONLY ONE vacua, and no more, out of that total of 10^500, that happen to match up to the Standard Model**? There may be more than one “correct answser”. There may be a dozen. Actually there could be much more.

An arbitrary vacua, or any arbitrary theory of any sort, has approximately 1 in 10^12 random chance of matching a particular numerical result to a discrepancy of no more than one part in 10^12 disprepancy, purely by random chance. If we consider one part in 10^12 as a reasonable precision requirement before we consider the experimental result as a matching one, then in average we have one “correct” vacua out of every 10^12 of them.

In all 10^500, lots of them, about 10^488 of them, will be deemed to be “correct” in providing the correct parameters to the Standard Model. When a theory gives 10^488 equally good and “accurate” descriptions of the nature, it is as good as useless.

Quantoken

5. **Scott Aaronson**
   November 15, 2005

   Quantoken: “You can construct a quantum computer using the whole energy of a gogoplex of universes, and still has not even been able start to enumerate even just a small fraction of the 10^500 vacuas. For all practical purposes and intents, it’s an intractable math problem. Computer science is not the limit, physics is.”

   No, that’s not really true. Supposing there were 10^500 vacua, it wouldn’t follow that you’d have to enumerate all of them to find out whether there exists a vacuum with desired properties. Maybe there’s a much faster method. Granted, we *believe* there’s no general way to speed up combinatorial search by more than a small amount; even quantum computers are known to yield exponential speedups only for a few highly-structured problems (such as factoring and discrete logarithm). Right now, there doesn’t seem to be a good reason to think that the problem of (say) finding a minimum-energy vacuum given a collection of scalar fields has the requisite structure. But you need computer science to tell you that. 🙂

6. **Dr. Ranger McCoy**
   November 16, 2005

   Does anyone see the corruption and celine of Wall Street pension plans, Hollywood, and culture tied directly to the decline of Physics?

   Elite groups of snarky insiders have replaced truth and beauty with trash and bureaucracy, all to benefit themselvs at the expense of the public.

   But less people trust Wall Street. Less people are going to see movies. And less people are believing the string theory hype.

   A renaissance is around the corner.

Templeton on ID

November 16, 2005
Categories: Uncategorized

I've criticized the Templeton Foundation in the past for their endless attempts to blur the line between science and religion, supporting some of the most dubious research in cosmology and physics. To be fair to them, at least they are not promoting Intelligent Design, something they make clear in a statement released on Monday. The statement challenges a front-page Wall Street Journal story that referred to Templeton as a supporter of ID. Evidently one of the main pieces of evidence that the Wall Street Journal gave for this was Templeton's support of IDer Guillermo Gonzalez as part of their Cosmology and Fine-Tuning Research Program.

So, if you're interested in seeking funding from Templeton, you'd be aligning yourself with an organization controlled by right-wingers that wants to bring religion into science, but they're not IDers. If you decide to go for it, it looks like Dec. 1 is the day when fq(x), a Templeton funded program run by highly reputable physicists, will announce how to apply for money from them. If you just want to extract money from Templeton for something completely flaky, I'd suggest considering another new program they are funding, Science and Theology Advanced Research Series (STARS), devoted to research "on the ways science, in light of philosophical and religious reflection, points towards the nature, character and meaning of ultimate reality." It appears that, if you play your cards right, you can get a free winter break in Cancun, as well as grants of \$20,000 in walking around money and multiples of \$100,000 to look into this ultimate reality thing.

Comments

1. **Wolfgang**
   November 16, 2005

   Peter,

   > So, if you're interested in seeking funding from Templeton, you'd be aligning yourself with an organization controlled by right-wingers

   would this be (currently) also true of every researcher who seeks government funding in the US ? The last time I checked the US government was "controlled by right-wingers".

2. **woit**
   November 16, 2005

   Wolfgang,

   Very good point. Even worse, I think the US these days is "controlled by right-wingers who want to bring religion into science". At least the Templeton people don't go around starting wars.

3. **Fabien Besnard**
   November 16, 2005

   They say they don't promote ID… But just look at that .

   Staune is in the board of advisors of the Templeton Foundation .

   He is the director of the UIP (université interdisciplinaire de Paris) which received funding from the Templeton foundation. On their website they promote a little documentary I've seen on the french tv which was clearly anti-darwinian (apart from being utterly stupid). So they don't promote ID, they promote anti-darwinism and let others do the dirty work…

4. **Geoff**
   November 16, 2005

   Why the air of ridicule?
   It's a private foundation
   They don't claim to be a source for basic science funding
   Issues of "this ultimate reality thing" actually matter to people, even scientists.

5. **woit**
   November 16, 2005

   My main concern about Templeton is about having a very well-funded foundation trying to inject religion and pseudo-science into science, especially into theoretical physics. The anthropic landscape pseudo-science is already a big problem for theoretical physics, and the fact that it is being promoted and funded by Templeton is part of the story.

   There's a nearly infinite amount of idiocy about religion, science, "ultimate reality" out there and in general I'm not about to waste my time discussing it here, unless it happens to come into contact with mainstream theoretical physics research, which is unfortunately what is happening with Templeton recently.

6. **Dr. Ranger McCoy**
   November 16, 2005

   Is String Theory intelligent design?

   Or unitelligent design?

   For the tax payers who fund the indecipherable smorasborg of snarky, condescending crap, it would appear to the latter.

7. **DMS**
   November 16, 2005

   The situation is some areas of physics is beginning to be a lot like the situation in economics(see **Peddling Prosperity** by **Paul Krugman**). The funding (and media prominence) given to supply-siders (called **charlatans and cranks** by Greg Mankiw), who are basically frauds(unlike conservative economists) dwarfs the money from fed. govt. sources in economics.

Looks like we will see something similar happening in parts of physics that areas that they want to control/shape public perceptions for religious or ideological reasons(cosmology and ID). Their share of the overall funding is only going to get higher thanks to the reckless economic policies currently being pursued.

Obviously, they have been very successful in economics: most think tax cuts, especially for the rich, are the cure for all economics problems. One shudders to think what will happen if they have similar success with cosmology and evolutionary biology. It is sad that there will be physicists, perhaps even some prominent ones judging by recent events, who will gladly take this Faustian bargain.

DMS

8. **Tony Smith**
November 16, 2005

The Templeton statement described by Peter said in part:
"… the Templeton Foundation refuses in its programs to blacklist scholars based on their ideological positions. … Blacklisting is ethically inappropriate in academic contexts. The Foundation believes that proper academic adjudication of important and controversial issues is not by censorship but rather by open scholarly debate and consideration of positions and arguments on the merits or lack thereof. Research scholarship does not proceed by processes of censorship and inhibition of debate. …".

As one who is blacklisted from posting on the Cornell arXiv, I am happy to see that there exists an influential institution that opposes blacklisting.

Tony Smith

November 16, 2005

The statement from the Templeton Foundation is perhaps worth reading to the end in order to understand why such unwarranted
"confusion" could have arisen in the mind of the WSJ reporter:

Indeed, it should clearly be recognized that some perspectives that scholars associated with the ID movement have brought to scholarly attention involve matters of very considerable public importance. ID scholars have been prominent critics of the abuse of evolutionary biology today by prominent philosophical interpreters arguing for modern science to be considered as if it provided a clear coherent scientific foundation for philosophical atheism. (Which it most certainly is not: such grandstanding does science a grave disservice in the United States). They also have most unfashionably, but importantly, brought to attention the catastrophic abuse of evolutionary biology by Nazi intellectuals in the 1930's and 1940's in support of racist "master race?? eugenics, leading clearly and directly to the justification of genocide against the Jews.
If this is not an endorsement of ID what exactly is it? Darwinism uncheked leads to either nazism or "philosophical atheism"!? Ho-oh! Which could be worse, I wonder? My guess is that the ID guys and the Templetons are here to prevent such "abuses" to which science is so "prone" and unwilling to denounce… (Give me a break!)

10. **James**
November 17, 2005

Re-read their statement carefully. It is not an endorsement of ID. It says that some of the ID proponents' critiques of the abuse of evolutionary biology have merit. It does *not* say that their proposals to correct the abuses have merit.
This evaluation seems quite accurate: the combination of philosophical reductionism (never questioned) and evolutionary biology *is* used as a foundation for atheism. The place to address this abuse is not evolutionary biology, as we all agree; but instead is the philosophical assumptions used to interpret it. We never bother to teach our kids anything about philosophical questions, we just let them absorb the Zeitgeist. Kids need at least a little introduction to the big questions.
So let's fill that gaping hole and introduce them to the debates about meaning. Just not in science class, even though evolutionary biology makes a great example for discussing a couple of the important concepts.

11. **John Gonsowski**
November 17, 2005

Templeton does not seem any worse than the Quantum Mind 2003 conference that Roger Penrose and the University of Arizona co-hosted. There were things like Hindu cosmology and Jungian Psychology at that conference as well as physics. It was fun watching Henry Stapp show up and do a little debate with one of the Hindu cosmologists who quite enjoyed it and her family took pictures afterwards. The world could use more of that. I don't think Penrose and the U of A are particularly right wing. Here's a nice Henry Stapp quote:

"Pauli`s idea of a regulative principle lying beyond the mind-matter distinction is intertwined with the Jungian concepts of archetypes and synchronicity. Synchronicity refers to the occurrence of representations of archetypes in meaningful coincidences that defy causal explanation … behind the process of nature that we already know and understand there lies another, which acausally weaves meaning into the fabric of nature."

12. **Joao Leao**
November 17, 2005

To James:

I hate to nitpick but the sentence refers *"some perspectives that scholars associated with the ID movement have brought to scholarly attention"* leaving open whether what they (Templeton) applaud is part of the ID dogma or of the ID critique of Evolution, which is already telling. In either case putting atheism and genocide in the same basket (=abuses of Evolution!) seems quite OK for Templeton . Is this what you teach your kids? It sounds much less like a big question than an already-made-up answer…

To John:
I am not sure whether Templeton funded the Quantum Mind conference or the "Toward A Science of Consciousness" conferences in Tucson, but I doubt they did since they don't take credit for it in their Web pages. But I don't think that these are quite the same thing! Unlike Jung, Pauli, Penrose or Stapp, who may have dabbled in mystical speculation on the side, Templeton has a lot of money and an agenda which is not so benevolent or amusing, namely the eradication of secular humanism.

13. **John Gonsowski**
November 18, 2005

Actually to me secular humanism seems at best silly and at worst spiritually draining, kind of like creationism seems at best silly and at worst scientifically draining. One of Peter's links mentions CTNS and the "about us" for CTNS sounds quite fine in a Tucson conference kind of way:

"CTNS is an international non-profit organization dedicated to research, teaching and public service. The central scientific focus of CTNS is on developments in physics, cosmology, evolutionary biology, and genetics, with additional topics in the neurosciences, the environmental sciences, and mathematics. With regard to the theological task, CTNS engages in both Christian and multi-religious reflection. The Christian theological agenda focuses on the various doctrinal loci of systematic theology. The multi-religious agenda attends primarily to theological issues arising from the engagement between the sciences and religious traditions such as Islam, Hinduism, Judaism, Buddhism, Confucianism, Taoism, and indigenous spiritualities. This engagement is best reflected in the work done in the Science and The Spiritual Quest Program (SSQ). "

CTNS seems partnered with the Vatican Observatory which is run by the Jesuits who are quite liberal overall. The Jesuits also operate telescopes at the University of Arizona. I not only don't see a problem, it actually sounds interesting though as a disclaimer I should mention I'm Catholic.

14. **Nigel**
November 18, 2005

Tony:

The Templeton statement on 'blacklisting' is meaningless. Open debate sounds very nice, and was promised also by Britain's Prime Minister who stated we were going to war to defend liberty.

When people wanted to raise the issue of liberty in Iraq during the last Labour Party conference, the Government used its power over the police to have an old member held under the 'Prevention of Terrorism Act' to prevent free speech. He was lucky compared to the guy who was repeatedly shot in the back until dead 'by accident'.

Templeton will have to turn similarly paranoid when it runs into the real world. The whole point of 'blacklisting' seems to be accusing people of terrorism or being unethical, without foundation.

They will simply take the moral high ground like religion, Tony, and when you start asking questions or providing ideas they'll fabricate some irrelevant excuse to suppress you, saying you're a cowboy.

15. **Nigel**
November 18, 2005

Hitting the delete key is not just a string theorist or religious problem, either, as Quantoken says:

'Peter is one of those few scientists "in the circle" who is able to speak out about something wrong with the state of theoretical physics research nowadays. For that I admire him. But while he sees problems with the establishment theories. I am a bit take back that he is NOT willing to look at some alternative approaches and make some judgement.'

http://quantoken.blogspot.com/2005/03/dont-become-scientist.html

(Of course, if Peter does look at alternatives, he steps outside of the circle. Quantoken's GUITAR is a bit like Eddington's claim to have predicted the ratio of proton/electron mass from a quadratic containing 10 and 137, without explanation. Eddington defended himself saying modern physics is based on guessed equations!)

16. **Joao Leao**
November 18, 2005

To John:
Catholic, huh? It figures. The Catholic Church has had a less inimical attitude towards science than the fundamentalist protetstant hordes, at least since that pesky Giordano Bruno affair, and such. Yes, and you are right, jesuits have even, on occasion, made significant scientific contributions, say, as in Boscovitch, Lemaitre or Pat Heelan. Yet these were pursued as part of genuine scientific inquiry goals, not as a "theological task" or "a spiritual quest program" as your CTNS (Catholic TempletoNS?) puts it. Unlike the good brothers, these novel "spiritual sponsors" are about getting scientists to peddle religion for money. Considering the latest financial drainage that Catholic Church is currently attending to, I would estimate the prospects of the CTNS in this crowding field at worst, as you would put it,… silly!

My disclaimer: I find all religions equally objectionable and uncalled for in what concerns scientific matters. Now let us get back to the One True Church of String Theory!

17. **island**
November 18, 2005

Eddington defended himself saying modern physics is based on guessed equations

Dirac did a much better job defending large numbers, and he was thoroughly convinced that nature provided these numbers in a meaningful manner that theory should explain.

He had the same kind of belief about higher structuring in nature that Einstein had.

It's a good thing that we got so much smarter than them… so fast.

18. **Stan**
November 19, 2005

Have a look at this statement from the Discovery Institute. Note the following sentence:

"The Institute does not favor requiring that students learn about the scientific theory of intelligent design."

A new tactic, perhaps?

19. **island**
November 19, 2005

That's only for high school students, not higher-education.

The DI has never endorsed teaching ID in high school, because they don't think that they can win a First Amendment challenge, and they are afraid that losing would have the effect of legally ruling Intelligent Design a form of religious creationism, and greatly diminish any possibility of the movement ever achieving its goals set forth in their "Wedge" strategy.

The ding-bats that *were*on the Dover school board had to revise their original statement to meet the state educational guidelines to include Darwin's "alleged" feelings about the random nature of speciation in order that they had some basis by which to challenge his theory.

Kansas went to Oz with Dorthy… surely, they're in violation of the constitution and every federal educational guideline in existence.

20. **Bryan**
November 20, 2005

"The Institute does not favor requiring that students learn about the scientific theory of intelligent design.??

A new tactic, perhaps? -Stan

Stan, this whole thing is just weird to us in Britain. As a Catholic I see no contradiction between ID and evolution. ID was taught in religious education classes and evolution in biology. It must be a thing peculiar to America that there are rows on this. Brother John, a monk, taught us evolution as integrated in biology. I think he glossed over the differences between ID and evolution by an analogy to modern physics where wave theory and particle theory were taught on alternate days, and the two are not really contradictory, but complementary! Thus, you use ID when thinking religiously, but evolution when thinking scientifically. America only has problems because the religious fanatics try to corrupt biology.

21. **Bryan**
November 20, 2005

String theory fanatics only get into trouble because they try to brainwash the whole of physics before they have any empirical evdence they are right. If string theory was a small backwater of crackpotism, people like Peter would leave it alone. Religions only become dangerous when they try to destroy scientific integrity.

22. **island**
November 20, 2005

Religious fanatics are the only ones that recognize goal oriented design in nature, while ideologically motivated evobiologists anti-fanatically knee-jerk react to deny that any such evidence is even possible, citing multiverses and uncertainty as their chaotic anti-gods of choice.

Ya'll are gonna love me for this, but I see ID as necessary for it's anti-political relevance, since honesty in science has absolutely nothing to do with the debate whatsoever.

One of the most respected members of the evolutionary biologists community, Lynn Margullis, called these anti-fanatics "neo-dawinian bullies"… which illuminates that this is no normal dispute among peers. That was a direct shot at the exact form of "anti-fanaticism" that runs rampant throughout the field and comes about as a reactionary response to the constant barrage of BS from creationists fanatics that would wrongly hold up evidence for design in nature as evidence for intelligent design.

Lynn said what she said as the honored guest speaker at the last evolutionary conference.

… or could this be an IDist…?

The problem with neo-Darwinism is that Random changes in DNA alone do not lead to speciation…

> The problem with neo-Darwinism is that Random changes in DNA alone do not lead to speciation. It was like confessing a murder when I discovered I was not a neo-Darwinist. I am definitely a Darwinist though. I think we are missing important information about the origins of variation. I differ from the **neo-Darwinian bullies** on this point.
> -Lynn Margulis
>
> The only watchmaker in nature is the blind forces of physics, albeit deployed in a very special way.
> -Richard Dawkins
>
> Not just any universe would be one in which Darwinian evolution would work. For example, if a tiny reduction in the early cosmic expansion speed would have made everything recollapse within a fraction of a second while a tiny increase would quickly have yielded a universe far too dilute for stars to form, then such changes would have been disastrous to Evolution's prospects.
> -John Leslie

Don't be so sure any of them on the side of science.

23. **CWB**
November 25, 2005

Ah, yes random mutations alone do not cause spectiation. I don't think anyone claims that – there are such things as natural selection and genetic drift.
I don't think anyone is saying that there is no design in nature, that would be stupid, the arguement is that there is no reason to believe the unsupported IDist position that some vast hyper-intelligent being created life.

24. **Alexander Hellemans**
November 25, 2005

To CWB:

What do you mean by "design in nature?" Is that not the ID position? There are even weaker ID forms, derived from Teilhard de Chardin's idea that evolution is a fact, but it is directed, and was always directed towards the appearance of man. This form of ID has recently raised its head in France, with the help of the Universite Interdisciplinaire de Paris (wich is funded by the Templeton Foundation).

25. **John Gonsowski**
November 25, 2005

The idea of Teilhard de Chardin (a Jesuit) has a modern home in the person of Alexander Wendt.

http://en.wikipedia.org/wiki/Alexander_Wendt

It is also consistent with the transaction models of Andrew Gray, Tony Smith and Chris King where the probabilities for the transactions are for worldlines extending far into the future.

26. **island**
November 27, 2005

Ah, yes random mutations alone do not cause spectiation. I don't think anyone claims that

No, that's false.

What do you mean by "design in nature?" Is that not the ID position?

Yes… idists hold up evidence for design in nature as evidence for intelligent design, which it cannot be without direct proof, and that's all that needs to be said in order to rebut the point, since design can be perpetually inherent to the energy of the universe.

http://www.anthropic-principle.ORG

Design in nature usually gets twisted around by neodarwininans to refer to patterns that fall accidently from what is assumed to be a random process and they reach to unprovable theoretical speculation in order to support this **belief**… so they're equally religious in this respect, since this is origins science that we're talking about… not speculative cutting-edge theory 101. Empiricism rules this debate, and so crackpot theories about multiverses and whatnot are not valid arguments against the implications for "specialness" that Brandon Carter, Robert Dicke and Fred Hoyle found in the constants of nature.

Neodarwinians aren't scientists… they are ideologically motivated antifanatics.

27. **CWB**
November 27, 2005

By design in nature I mean patterns – not design as in something that was created by any sort of intelligent being. For instance evolution is a process by which things can be "designed" – in a sense but design, or the presence of patterns does not neccesarily mean an intelligent designer.

And Island, where do you get this assertion:

> Ah, yes random mutations alone do not cause spectiation. I don't think anyone claims that
>
> No, that's false.

Perhapes you have some obscure little reference but I've never heard biologist advance the position that evolution is only the mutation of genes and nothing more. To me it seems like your asserting biologists have abandoned natural selection.

28. **CWB**
November 27, 2005

No I do not accept the idea of "evolution with direction", by design I mean pattern and form.

29. **island**

November 28, 2005

You mean… no, you refuse to recognize evidence for evolution with direction.

Are you a string theorist?… cause they don't much care about evidence either.

30. **island**
November 28, 2005

And Island, where do you get this assertion:

Ah, yes random mutations alone do not cause spectiation. I don't think anyone claims that

> No, that's false.

Well, it you'd read what was written you'd know, since it was a credited direct quote of a statement made by Lynn Margulis when she was the honored guest speaker at the last evolutionary conference… this past summer.

Not that it's any big secret, you can also find it in books and about a million other places:

http://www.biology-online.org/2/14_gene_pool.htm
Mutations are random occurrences which change the genome of an organism. They greatly increase genetic diversity, where advantageous mutations are favoured by natural selection and disadvantageous ones are phased out.

31. **CWB**
November 28, 2005

> Mutations are random occurrences which change the genome of an organism. They greatly increase genetic diversity, where advantageous mutations are favoured by natural selection and disadvantageous ones are phased out.

Well that's basically what I'm saying. There you have natural selection acting on populations in which genetic mutations have created advantages and disadvantages. Neo-Darwinian Evolution was just the marriage of genetics with the old natural selection based theory of evolution. Genetics provided a framework in which to understand how characteristics can be inherited and how new features in organisms can arise. This is the first time I've ever heard a non-Creationist claim that evolutionary biologists think that biological diversity is a result of the purely random process of genetic mutation. That's a very standard creationist claim – they totally disregard the more or less deterministic process of natural selection.

As for evolution with direction, that's the stance of many biologists who are also religious but I don't think that would be something you'd want to include in a formal scientific theory. I think your claims of ideology on the part of biologists is unwarrented.

No, I am not a string theorist.

32. **island**
November 28, 2005

Well that's basically what I'm saying.

And I made no creationist claims, but, like Lynn, I believe that we are missing important guiding information about the origins of variation. Lynn's approach is symbiosis, which she's had enough success with to get her the medal of science, (which is commonly called the U.S. Nobel Prize), for her 'outstanding contributions to the understanding of living cells, their structure, and their evolution, as well as for her extraordinary abilities as a teacher and communicator of science to the public'.

Her son's approach, (Dorion Sagan), as well as mine, (independently derived), is that we are driven to higher orders and enabled by the second law of thermodynamics, but mine includes an entropic interpretation of the weak anthropic principle via the life-practical environment in an expanding universe that has an increasing negative pressure component. In case you don't know it, and independent derivation serves as hard supporting evidence.

http://www.taipeitimes.com/News/edit/archives/2004/09/30/2003204990

http://www.intothecool.com/

James Kay was instrumenatal in the above, arrived at in conjuntion with Eric Schneider before he, (very unfortunately), died at a young age, and Dorion Sagan stepped-in.

"Many" biologists are also religious"…

No, actually, a very small minority may be, but "for some reason" evobiologist like to pretend that this is not the case. Why is that?… like I don't already know.

I cannot tell you how many times that I've been called a creationist by evolutionary biologists at the mere mention of the anthropic principle, and I'm an atheist, but this clearly defines the preconceived prejudice that runs rampant throughout the field.

There is no denying this fact to me as I have too much personal experience with evolutionary biologists to believe that you aren't in willful denial of these facts, and Lynn does not call them **Neo-Darwinian bullies** because she is having a normal dispute with her peers. Lynn's statement was clearly a direct shot at exactly the kind of antifanaticism that I speak of.

It's not entirely their fault, because creationists constantly provoke them, but that does not justify the willfully ignorant nihilistic "devil's advocate" approach to the manner that they will interpret evidence. Rather, they refuse to recognize said evidence while citing speculative and unproven cutting-edge theory in order to *explain-away* any implied significance.

In point of supporting fact, there is a big movement in the field right now to quit using mechanistic terminology to describe mechanistic function and systems in nature in order that they can **hide from this evidence.**

But of course they deny this, since it's strictly a matter of interpretation, they can simply rationalize their way to the denial of my interpretation. Denial is very big with them, as they remove the layers of the onion until they can claim that there's nothing there.

These people are not honest scientists, and are led by the mentality of liberal extremists like H. Allen Orr, so do not be fooled by the fact that they are technically "in the right"… where the ID debate is concerned, because evidence for "design in nature" does not and cannot prove that there is an intelligent agent involved without **direct** proof, so hiding from the evidence is completely un-necessary and only hurts their position while furthering their lack of credibility.

I know the game too well… it's about downplaying the significance while selectively ignoring any and all evidence that runs contrary to their motivations.

I don't buy your denial… from experience.

33. **John Gonsowski**
November 28, 2005

Island, multiverses with transactions looking far into the future is actually an arguement for your "specialness". A single particle going one way instead of another to avoid annihilation is a form of intelligence and looking into the future. Extend that to a large spacetime scale and one could get your "specialness".

34. **island**
November 28, 2005

Keep talking like that and Peter's gonna send us packin!… 😉

… but he also doesn't like us to discuss our pet theories here, so please click on my name and goto my website and see about half-way down why I think that multiverses aren't necessary, because I don't believe that anybody ever proved Einstein to be wrong in the first place.

This article and the three that are attatched to it that were made to the spr group also illustrates the point:

http://www.lns.cornell.edu/spr/2005-06/msg0069755.html

The ball is not in Einstein's court… in other words, and the significance of the implications of the anthropic principle increases by orders of magnitude if the universe if finite and bound.

35. **CWB**
November 28, 2005

But what do you want here? You want biologists to throw away the theory of evolution for what exactly, Intelligent Design? Do you want them to include "guidance by a superior being" as part of biological evolution?
I don't understand what you're upset about.

36. **CWB**
November 28, 2005

I don't see how Intelligent Design is useful science, actually I don't see how it's science period.

Also, I am not a biologist.

37. **island**
November 28, 2005

I want them to fight the battle on the right front, which is the ludicrous distance that you have to go in order to attain scientific plausibility for something like alien intervention, which is the actual "science" IDists hide behind.

Distance to plausibility kills it as a comparible and viable theory, and there is no valid reason to fight the battle based on the denial of evidence for goal oriented design in nature, so it won't be a matter for interpretation, which, you would likely lose in court, unless you can prove what the motivations behind it were… even though that's not a valid arguement as far science is concerned.

My understanding is that the physics derives that punctuated equilibrium is analogous to a *near* static flat universe, whereas a big bang convolves characteristics forward in the same manner and by the exact same mechanism, so why would I want to be foolish enough to throw the "writing-on-the-wall" theory of evolution away?

38. **island**
November 28, 2005

As far as I can tell… The TOE… is the ToE.

39. **Tony Smith**
November 28, 2005

With respect to discussion of how IDers and Evolutionists etc stand on the issue of whether speciation can be fully explained by random mutations, what about epigenetic inheritance, such as described by Gail Vines in an article at http://www.ifgene.org/vines.htm ?

Could such epigenetic inheritance be embraced by Evolutionists as just another scientific process that supplements random mutation ?

Could such epigenetic inheritance be embraced by IDers as a way that a purposeful design could influence evolution ?

Could such epigenetic inheritance be a common ground embraced by both Evolutionists and IDers, so that they could "just get along" with each other ,
or do they hate each other so much that they don' t ever want to see any common ground ?

There is a wikipedia article at http://en.wikipedia.org/wiki/Epigenetic_inheritance
but please bear in mind that some wiki contributors have axes to grind, and it is not always useful to take a wiki article on a controversial subject at face value without looking closely (in great detail) at the history of that article.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

40. **CWB**
November 28, 2005

I think the fight against ID is based mostly on the fact that it's creationism in disguise and that it doesn't have any hard science behind any of it.
Now, you're upset that biologists don't accept goal-oriented design in nature? I think this is more of a philisophical position than one that has any real applications to biology.

41. **CWB**
November 28, 2005

> With respect to discussion of how IDers and Evolutionists etc stand on the issue of whether speciation can be fully explained by random mutations

Why do people keep leaving out natural selection and genetic drift? Those are extremely important to evolutionary development, genetic mutation isn't everything you know.

42. **CWB**
November 28, 2005

> Could such epigenetic inheritance be a common ground embraced by both Evolutionists and IDers, so that they could "just get along" with each other

No, IDers won't be happy until Evolution is vanquished. Take a look at the "Wedge Document", the goal of the ID proposed by the Discovery Institute is to be used to discredit science and allow supernatural (particularly Christian/Biblical) explanations to be used in scientific theories. They really don't give a damn about advancing human knowledge or solving scientific problems.

43. **woit**
November 28, 2005

I'm closing this thread, since I'd rather people carry on the Evolution/ID debate elsewhere. There are many, many much more appropriate places for this. This was a posting about Templeton, its policies and funding of theoretical physics, not about evolution vs. ID.

Seed Magazine On-line

November 16, 2005

   November 19, 2005

   One of the most notorious physics blogs is Peter Woit's Not Even Wrong—the first site this summer to discuss the gravity wave experiment. Although Woit has been critiquing string theory since 2000, he had difficulty finding an audience for his ideas: Journals rejected him, theorists attacked his credentials as an untenured mathematician, and a book he was writing on the subject was "too radical?? for publishers. In 2004, he launched Not Even Wrong and engaged string theorists with pithy and scientifically rigorous posts. A young Harvard string theorist named Lubos Motl was one of the first to defend his intellectual territory on Woit's and others' blogs, often peppering his comments with invective, and eventually starting his own blog "as a balance against Peter Woit.?? With traffic and links to his site expanding, Not Even Wrong carved out a unique space for Woit's criticism that broke through previously impenetrable walls, and helped his ideas gain credibility. "People have told me that they have changed their career plans because of my criticisms,?? Woit told us, adding, "They used to think I was crazy. Now I think they're warming to me.?? –
   http://www.seedmagazine.com/news/2005/10/a_new_force.php

   What made Peter think Lubos Motl and other string theorists are 'warming'? Getting overheated would be be more honest!

Jim Simons in the New York Times

November 19, 2005
Categories: Uncategorized

There's an article (unfortunately not available for free) in today's New York Times based on an interview with the normally publicity-shy mathematician Jim Simons of Chern-Simons fame. Simons runs the incredibly successful hedge fund Renaissance Technologies, and I've written something about this earlier. The New York Times article describe his mathematical career as follows: "A former crypt analyst – a code breaker, that is – he did important work in mathematics that helped lay the foundation for string theory."

Comments

1. **Cameron Peters**
   November 19, 2005

   Off topic, but did you see the mention of your blog in the latest issue of Science?

2. **woit**
   November 19, 2005

   Hi Cameron,

   No, I hadn't seen it. Thanks for pointing it out. For anyone interested, it's at the bottom of:

   https://science.sciencemag.org/content/310/5751/1099.5

3. **Tony Smith**
   November 19, 2005

   The science web page cited by Peter also mentions John Baez, saying:
   "… For nearly 3 years, mathematical physicist John Baez of the University of California, Riverside, has discoursed on books and papers that catch his interest …".

   In fact, John has been writing "This Week's Finds" since 1993. His first entry can be found at http://math.ucr.edu/home/baez/week1.html

   Could the description of the time period between 19 January 1993 and now as "nearly 3 years" be indicative of the lack of mental discipline that has crept into science reporting during the superstring era?

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

4. **Chris W.**
   November 19, 2005

   Maybe that was supposed to be "nearly 13 years", ie, a copy-editing oversight rather than sloppy reporting and fact-checking.

5. **Tony Smith**
   November 19, 2005

   Chris, you say, about the science web page description of John Baez's This Week's Finds that says it has been written by John "… For nearly 3 years …",
   that
   "… Maybe that was supposed to be "nearly 13 years??, ie, a copy-editing oversight rather than sloppy reporting and fact-checking. …".

   Are you suggesting that the reporter/writer wrote "nearly 13 years" and that a copy-editor changed it to "nearly 3 years" ?
   If so, it would appear to me that such copy-editing, which changes correct writing to incorrect publication, is far worse than a mere "oversight".
   It might even indicate that editors, seeing a 13-year time frame, are so ignorant, lazy, and stupid that they just cannot believe that something similar to a blog could have possibly existed in the far distant past beyond 3 years ago, and that they are so confident of their wrong concept (no blog-type stuff in such distant past) that they are too arrogant and lazy to even look at John's web site to which the article itself refers.
   If so, such editors would, in my view, be much like what I regard as typical superstring theorists.

   In the alternative, if the reporter/writer did initially write "nearly 3 years", then maybe the editors would be guilty of no more than oversight (due, probably, to a mixture of laziness and ignorance with a little stupidity thrown in). However, the reporter/writer would then indeed be guilty of what you describe as "sloppy reporting and fact-checking", to say the least.

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

6. **Nigel**
   November 20, 2005

   The arrogance of untestable string theory makes the whole of physics look like a time-wasting fantasy, so why should editors waste time checking the details?

7. **anon**
   November 20, 2005

   Let's face it. Science journalism at present is attrocious. Often, 90% of an article consists of a press release from a university, full of disingenous exaggerations. I also particularly dislike the cliche story trying to portray a particular scientists as an amazing individual that young ones should admire and emulate. Well, I've know a lot of Physicists, having a Phd in physics myself, and very few were worthy of my admiration as human beings. I love physics, but physicists I could happily do without. Paul Farmers they are not.

A Particle Theorist's Perspective on String Theory

November 19, 2005
Categories: Uncategorized

There's a new posting over at Cosmic Variance by JoAnne Hewett of SLAC about string theory, entitled A Particle Physicist's Perspective. It gives a good idea of what I believe most non-string-theorist particle physicists think about string theory.

She does express some very controversial views, ones that are widely held in the physics community, but rarely publicly expressed:

I find the arrogance of some string theorists astounding, even by physicist's standards. Some truly believe that all non-stringy theorists are inferior scientists. It's all over their letters of recommendation for each other, and I've actually had some of them tell me this to my face.

and she describes string theorists as holding the arrogant belief that

String theory is so important that it must be practised at the expense of all other theory. There are two manifestations of this: string theorists have been hired into faculty positions at a disproportionally high level not necessarily commensurate with ability in all cases, and the younger string theorists are usually not well educated in particle physics. Some literally have a hard time naming the fundamental particles of nature. Both of these manifestations are worrying for the long-term future of our field.

I suspect that some of Hewett's strong feelings about this come from being at Stanford, where the theoretical physics group is made up mostly of members of the looniest wing of the string theory enterprise. The logo of the new web-site of the Institute for Theoretical Physics there is a representation of the multiverse, and Stanford is probably the major center for landscapeology in the world (and perhaps in the multiverse).

My alma mater, Princeton, is rather different in that landscapeology is not popular, but the particle theory groups both at the university and at the Institute have only hired string theorists for the last twenty years, displaying the kind of attitude that Hewett finds disturbing.

While most string theorists demonstrate no more than the usual theoretical physicist's helping of arrogance, it has certainly been my experience that some of them display a degree of arrogance that is pretty astounding. This includes some of the earliest and most prominent string theory bloggers, where the phenomenon is pretty much off-scale. When it comes to purely intellectual arrogance and confidence in one's own beliefs, I'm no paragon of humility, but I don't take the attitude that people who disagree with me are idiots who don't know what they are talking about, an attitude I've encountered amazingly often from more than one string theorist.

Comments

1. **Bryan**
   November 19, 2005

   I think it is very sad that people like JoAnne Hewett are queuing up to put kick string theorists' because of their arrogance.

   There have already been abuses of string theorists leak into the media, like http://www.theonion.com/content/node/41454

   It's a good thing the media think this is just a storm in a teacup.

2. **Plato**
   November 19, 2005

   > I'm no paragon of humility, but I don't take the attitude that people who disagree with me are idiots

   Thanks Peter 🙂

3. **JoAnne**
   November 19, 2005

   Bryan,

   Hmmm….I'm not quite sure what a `put kick' is, but am going to assume it is similar to a punt kick in American football. So, no, if you read my post, you will see that I am most certainly not lining up to punt kick string theory. I most emphatically said that I believe the enterprise is worth pursuing. It's all a matter of balance.

4. **Bryan**
   November 19, 2005

   Hi JoAnne,

   Do you just think Lubos Motl should be kicked, then? 😉

5. **D R Lunsford**
   November 19, 2005

   How's this for irony – the server that hosts the HETG at Harvard, loaded with stringers, is named "democritus" 🙂

   -drl

6. **Aaron**
   November 19, 2005

   Princeton has made many offers to non-string theorists.

7. **Bryan**
   November 19, 2005

   D. R. Lunsford, mind your step! Motl will probably investigate you and find you're major paper http://cdsweb.cern.ch/search.py?recid=688763&ln=en stems to NASA astronaut training, http://www.hq.nasa.gov/office/pao/History/alsj/DRLunsford.html so you are just a nerd with a chip on your shoulder about string theory!

8. **Eli Rabett**
November 19, 2005

Any field such as sting theory starts from a few places. How much of the arrogance is a reflection of those who founded the field, which was picked up by their students?

BTW, I think there was a confusion betweeen the American term punt (something) as in be ready to abandon or leave, and the English term "put the boot in", ie kick someone when they are lying on the ground, as in rugby. Both may be appropriate

9. **Nigel**
November 19, 2005

Bryan, in replying to Lunsford, should write 'your major paper' not 'you're'. It's a shame that there's no automatic grammar check/correction on blogs.

Eli, surely you mean 'string' not 'sting' theory, although in England a 'sting' is slang for a rip-off or overpriced commodity, so it is certainly right to call string theory a sting theory! 🙂

10. **Rafael**
November 19, 2005

I saw a talk given by Robert Laughlin which was very interesting. Mostly it was about emergent properties but he did talk a bit about his criticisms of string theory. Especially, not being able to make any predictions which can be measured. I think he was sad (or angry) that theoretical physics has gone off the rails. I guess that would be a condensed matter theorist's perspective?

11. **Eli Rabett**
November 19, 2005

The best laid puns of mice and men, oft go awry. Thank you Nigel.

12. **D R Lunsford**

Wow, they actually *credited* me on the ALSJ? For revising a transcript? Hey! This is easy!

-drl

13. **dan**
November 19, 2005

So what kind of non-stringy particle physics research directions are being pursued these days? By non-stringy I mean fundamental particle physics that (1) do not involve string theory, (2) do not invovle SUSY, (3) do not involve higher-dimensions?

Incidentally, how do particle physics explain the transformation of kind of fundamental particle, the electron/position, into another, such as photons? Do they recourse to string theory or are there non-stringy ways of explaining this?

curious
Dan

14. **Thomas Larsson**
November 20, 2005

Incidentally, how do particle physics explain the transformation of kind of fundamental particle, the electron/position, into another, such as photons? Do they recourse to string theory or are there non-stringy ways of explaining this?

Hopefully particle physicists don't explain the transformation of a single electron into a photon at all, since it does not happen. The transformation of one electron + one positron into two photons is explained by a theory called QED. Believe it or not, but it does not involve string theory, and it makes some predictions in reasonable agreement with experiments (to ten decimal places or so).

15. **Aaron**
November 20, 2005

So what kind of non-stringy particle physics research directions are being pursued these days? By non-stringy I mean fundamental particle physics that (1) do not involve string theory, (2) do not invovle SUSY, (3) do not involve higher-dimensions?

That's a very odd definition of 'stringy'. I'm sure the vast legions of phenomenologists who work on those subjects would be surprised that they're doing 'stringy' stuff. Some might even object rather vociferously.

Anyways, there's stuff involving little higgs models, dark matter, baryogenesis, neutrino masses, some GUT stuff (although most of that is supersymmetric), lattice stuff and probably plenty more that's not coming to mind.

BTW — in case it wasn't clear from context above, I meant that Princeton has made job offers in the past to high energy theorists who were not string theorists.

16. **D R Lunsford**
November 20, 2005

TL,

I think his point was, does anyone work on something you can't find in a Michio Kaku book..

And as for his comment about matter/antimatter, I think he meant – is there a mechanism for this beyond just positing the interaction? And the answer is – not one that is generally accepted.

-drl

17. **andy s.**
November 20, 2005

Dan: Loop Quantum Gravity addresses many of the same issues are String Theory. Google Lee Smolin or the Perimeter Institute.

18. **Aaron**
November 20, 2005

And as for his comment about matter/antimatter, I think he meant – is there a mechanism for this beyond just positing the interaction? And the answer is – not one that is generally accepted.

It's called gauge invariance.

19. **D R Lunsford**
November 20, 2005

Yep, that's the old posit right there Aaron.

-drl

20. **Aaron**
November 20, 2005

Positing gauge invariance is far from positing an interaction. I invite you to write down a quantum theory of a massless vector (we do want electromagnetism, right?) without gauge invariance.

21. **D R Lunsford**
November 20, 2005

This isn't the place to discuss it. As it happens a post on SPR will soon address it, so go there (gauge invariance determines the interaction, and for 4d they are practically synonymous).

-drl

22. **Who**
November 20, 2005

Dan asked
"dan Says:
November 19th, 2005 at 9:57 pm
So what kind of non-stringy particle physics research directions are being pursued these days?"

to expand on an earlier comment
"andy.s says
November 20th, 2005 at 1:50 am
Dan: Loop Quantum Gravity addresses many of the same issues are String Theory. Google Lee Smolin or the Perimeter Institute."

you might like to watch this 40 minute video of a recent Smolin talk, and download the set of slides that goes with it.
http://loops05.aei.mpg.de/index_files/abstract_smolin.html

in this talk Smolin tries out a certain a particle physics scheme in the context of Loop QG. the quantum state of the gravitational field is given by a kind of graph called a "spin network" and families of particles (electrons, quarks, etc.) are are built into the gravitational field as kinds of links in the graph. the "preon" model which he uses is due to Bilson-Thompson and it reproduces some features of the standard model.

there must be several cases of non-string QG research which strives to unify particle physics with quantum gravity, by a variety of authors, but I can't think of a survey paper specifically about this. andy.s suggestion to use search engines is a good one. This talk, that smolin gave last month (10 October) is at least something like what you were asking about, to start you off.

the effort is bound to look preliminary and insubstantial compared with string

23. **Dr. Ranger McCoy**

http://physicsmathforums.com/showthread.php?t=56

Tied Up & Strung Out: Hollywood String Theory Movie!!! Looking For Extras!!!
FOR IMMEDIATE RELEASE:

ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

"As contemporary physics is about money, hype, mythology, and chicks," Ed Witten explained from his offices at the Princeton Institute for Advanced Study, "The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy."

Brian Greene, the famous String Theorist who will be played by David "the truth is out there" Duchovney, explained the plot: "String theory's muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone, and I win the Nobel prize for showing that M-Theory is in fact the dark matter it has been searching for."

Greene continues: "At first my character is reluctant to stop theorizing and start postulating, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he's doing in my soul, and he explains that the answer is contained in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. And he shows me God in all her greater glory, as he points out that we can make more money in Hollywood than writing coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler. I am quickly converted, and I agree to turn my back on String Theory's hoax and save Jessica Alba."

But it's not that easy, as standing in Greene's way is Michio "king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this" Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the "ironic" pretense his salary, benefits, and all-expense paid trips depend on. "WE MUST HOLD BACK THE YOUNG SCIENTISTS WITH OUR NON-THEORIES!! WE MUST FILL THE ACADEMY WITH THE POMO DARK MATTER THAT IS STRING THEORY TO KEEP OUR UNIVERSE FROM FLYING APART, OUR PYRAMID SCHEMES FROM TOPPLING, AND OUR PERPETUAL-MOTION NSF MONEY MACHINE FROM STOPPING!!" Kaku argues as he delivers a flying back-kick, "There can be ony ONE! I WILL be String Theory's GODFATHER as referenced on my web page!! I have better hair!"

But Greene fights back as he signs his seventeenth book deal to make the hand-waving incoherence of String Theory accessible to the South Park generation, senior citizens, and starving chirldren around the world. "Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket)," Greene shouts. "It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!!"

"Time travel is also theoretically impossible, but there's a helluva lot more money for us in flushing physics down a wormhole. Nobody knows what the #&#%&$ M stands for in M theory ya hand-waving, TV-hogging crank!!! Get it?? Ha Ha Ha! We're laughing at the public! We're the insider pomo hipsters! Get with the gangsta-wanksta-pranksta CRANKSTER bling-bling program!!"

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We'll all just have to wait!

But in the meantime, how do you think it will play out?

Will theories with postulates ever be allowed in physics again? Or will the well-funded, tenured pomo String Theory / M-Theory (Maffia-Theory) Priests send their armies of desperate, snarky postdocs and starving graduate students forth to displace and destroy all common sense, logic, reason, and physics in the academy? It must be so–for the greater good of physics, the individual physicist, and thus physics, must be sacrificed.

24. **WL**
November 20, 2005

As usual, things are turned upside down. The supreme form of arrogance is not the one of experts, but of fools who claim to know better than the experts.

25. **secret milkshake**
November 20, 2005

I know lumo a bit. It's not the Strings – he is like this on any subject. He cannot help it.

26. **Quantum_Ranger**
November 20, 2005

Peter, the interesting thing is that the 'new' webpages here:
http://www.stanford.edu/group/sitp/
specifically the bottom copyrighted macromedia image at the bottom,
have been extracted from the website of here:
http://www.perimeterinstitute.ca/activities/scientific/seminarseries/index.php

look closer at the bottom starcluster image, there are Aztec and Toltec "gods" embedded into the image?

!!..the Perimiter webpages had the inca/toltec statues embedded into the starcluster picture sometime ago, this was tackled here:
http://www.physicsforums.com/showthread.php?t=48248

reply#3

The institutes appear to be having a "bat-ball" exchange, the Cosmic-String theorists at Stanford are obviously having fun with the symbolic inclusion of theory of the "Gods"?

I twould be interesting to find out when the 'new' stanford webpages became active, as the smae Aztec/Toltec images from perimiter were present Oct04?..they are no longer there today, but the reason for their removal must have a significance at Stanford webpages?

27. **Juan R.**
November 20, 2005

Arrogance could be supported if string theorists really were smart people, but unfortunately only one or two of them are really good. The rest is a group of…

This is the reason that people working in other areas -biophysics, quantum measurements theory, arrow of time, quantum gravity, complexity and chaos, etc.- often do jokes (even denigrating) with string theorists.

One of lasts, i know was a joke from F. Dyson (the Nobel winner) who argued against Brian Greene (that 'SMART' string theorist 🙂 regarding several conceptual issues on the quantum measurement problem the last year.

Dyson had studied the problem with some deep, whereas Brian Greene only speculated (his true speciality) that string theory would revolutionate our current views…

Dyson words were crystal clear:

> He rejects without any serious discussion

This is the best (mean) definition of string theorists activity i know

…Without any serious discussion…

Juan R.

Center for CANONICAL |SCIENCE)

28. **secret milkshake**
November 20, 2005

To Juan: Freeman Dyson was left out of Nobel for QED, actually. What he got was Templeton.

29. **dan**
November 20, 2005

Now that someone meontioned “preons”, are strings (D0 branes) are said to be “fundamental” and make up other fundamental particles, including gravitons, photons, etc cetera.

according to string theory, do strings make up quarks, or do strings make up preons, which then make quarks?

incidentally, if the project of spin networks giving rise to preons seems to work, then LQG would be relevant to particle physics, right?

30. **D R Lunsford**
November 20, 2005

Juan,

This is the impression I get – that stringers are not very bright.

-drl

31. **Adrian Heathcote**
November 20, 2005

Dr Ranger McCoy

Someone’s got to say it. Bravo! Author!

I might mention that a famous winner of the Templeton (whom you mention) once said that the way to understand mathematics was to stare at the page for a long time until it looked about right.

(Forget about doing those pesky exercises!)

I’m amazed that physics has fallen into this hole. It’s like the malaise in the humanities has spread like an ink-stain outwards.

A.H.

32. **Who**
November 20, 2005

dan, I think you draw the right conclusion but put it a bit strongly
“… if the project of spin networks giving rise to preons seems to work, then LQG would be relevant to particle physics, right?”

In his talk that I gave the link for, Smolin was drawing on this Bilson-Thompson preon paper
http://arxiv.org/abs/hep-ph/0503213
A topological model of composite preons
you might enjoy this paper and get something from it

you must judge for yourself how far along is Smolin’s project of relating spin network to these twisted-ribbon preons of B-T.
it strikes me as very tentative but in Smolin’s Loops ’05 talk
http://loops05.aei.mpg.de/index_files/abstract_smolin.html
he is saying that networks are a hospitable place to find these braided triplets of preons as links, and putting them in the picture could address several problems efficiently.
Best if you listen to smolin’s talk and look over the slides yourself

I see that both Bilson-Thompson and Renate Loll (CDT) are now at Perimeter. Also Xiao-Gang Wen. B-T just gave a talk on preons a few days ago and Loll and Wen were giving a workshop this weekend.

the talks and/or slides of some of these are available on line at
http://streamer.perimeterinstitute.ca:81/mediasite/viewer/

select “Seminar Series” and go to page 14 to find the Bilson-Thompson preon talk, if you are interested.

to find the Loll and Wen workshop scroll the menu down to
“Emergence of Spacetime Workshop” and click that

anyway it sounds too definite to say non-string QG relevant to particle physics but there certainly are connections being explored and it is not too hard to keep track of the various initiatives people are pursuing

glad you are interested

33. **dan**
November 21, 2005

hi who,
well i would love to see QG within my lifetime, as one of the final frontiers of science. his talk spoke of fermions, what about interger spin bosons, such as higgs, photons, and gravitons?

as for string theory, does string theory predict preons? does string theorists predict an inner structor of quarks much in the same way as preons do?

i am curious in lqg how is GR dynamics to be recorded, by gravitons, or by the large-scale behavior of spin foams?

34. **We Pretty**
November 21, 2005

Hi,

scientists are in general more interested in facts than attitutes of other people. But as a representative of the public I think that the way string theorists trumpet their theory as a solution to everything is cheating. I suppose that if you ask a random person what is quantum theory, if he or she knows anything about it, he or she will usually say that it is something that explains the atoms and inderminancy and stuff. If you currently ask a random person what is string theory, if he or she knows anything about it, he or she will usually say that it is some new theory that explains everything.

To help to change string theorists and especially young physicists but also the public attitude towards string theory, you should add section of string theory to the physics FAQ (though strictly speaking it does not belong there). In the beginning of the FAQ about physics in general Q: "What is a prediction" ? Q: "What is a nontrivial prediction" (A: "A prediction that differs from the currently accepted theories such that if the predicted thing does not happen then the theory that makes the prediction is false"). In string theory sections Q: "Does ST make non-trivial predictions ?" A: "No". Q: "Does string theory make predictions ?" A: "No" (I suppose). Or make this information otherwise available.

There are also other issues that would be of interest like how long string theory has predicted nothing, are there any other theories and stuff. I know also that there are positive side in string theory, cool mathematics and such.

Whatever landscapes and multiverses and extra dimensions sound cool. It sounds also very cool that the universe is 2 or 4 everything between dimensional.

We Pretty

35. **Tony Smith**
November 21, 2005

The arrogant narrowmindedness of superstring theorists may not be unprecedented.

According to an Opinion article by Gregory Benford (not only a scifi writer, but also a professor of physics at UC Irvine) in Physics Today (November 2005 at pages 48-49):
"… In the late 1940s, George Gamow, Ralph Alpher, and Robert Herman worked out element formation and the entire scenario that led to the now-famous 3-K background radiation. Yet the steady-state model held sway, and their work had faded from view by the mid-1950s. …
Rather than testing the Gamow-Alpher-Herman model, cosmologists spent more than a decade falsifying steady state's predictions. No one followed on the nucleosynthesis path, let alone thought of observations. …
To outsiders, such events might seem a scandal. … We didn't treat both models fairly, and lost more than a decade before discovering the truth. … what were the scandal's roots? …
Alpher and Herman … said they suspected a cultural bias was at work: "It is possible, but regrettable, that Gamow's fun-loving and irrepressible approach to physics led some scientists not to take seriously his work. …" … Gamov, Alpher, and Herman committed a minor social sin: They weren't in the club. …
Are there similar scandals in our own era? …
Despite 30 years of their drum-beating, the string theorists never suspected that the dark energy could comprise the majority of the energy density of out universe. …
When a bug of this size hits your conceptual windshield, it makes a big splash. The dark energy scandal is that the bug was the size of an eagle.
String theory is an idea that functions as … no predictions, yet widespread acceptance.
Theorists can fall in love with mathematical beauty. Philosophical elegance, which steady state had, is even more glamorous. Gamow, Alpher, and Herman had to fight steady state's shiny splendor, which blinded our field.
What causes such scandals?
… An unspoken timidity lurks in the close-focus grant-approval process – small steps are rewarded as more reliable than conceptual leaps. Possibilities beyond our current conceptual horizons get little attention. In academia, we maximize publicaton numbers rather than originality. This approach also gets us through the incremental mindset of review committees, which are seldom noted for their leaps of insight. ….
Do we suffer from anxiety over imagination?
Rigor is reassuring, but it should come at the end of that powerful chain that starts with intuition and proceeds to experimental checks – not at the beginning. To set our work in motion, we reason mostly by analogy, not by rigorous deduction. Imagination is not incremental.
Yet among reviewers, "speculation" is a work mostly deployed as a pejorative. We should not allow it to be. …".

I think that the lesson here is that there should be some sort of reasonable evaluaton mechanism for nonstandard physics models (not just mine). However, since I am more familiar with my work than with the work of others, I will state that I wrote a paper calculating the Dark Energy : Dark Matter : Ordinary Matter ratios and got results pretty close to the WMAP observations. When I submitted the paper to the Cornell arXiv in 2004, it was rejected (probably due to me being personally blacklisted by them). I then posted a similar paper to the CERN EXT preprint series as CERN CDS preprint EXT-2004-013, where it was accepted and is still available. However, later in 2004 (October 2004) the CERN Scientific Information Policy Board (SIPB) closed the CERN CDS EXT preprint series. A speculative opinion of mine is that EXT was closed due to pressure from the Cornell arXiv to prevent work blacklisted by them from seeing the light of day.

Just as the steady state model, in Benford's words, "… could not explain helium formation …", (afaik) superstring theorists have yet to explain the Dark Energy : Dark Matter : Ordinary Matter ratios observed by WMAP.

Tony Smith

November 21, 2005

I just accidentally deleted this entry, and had to restore the whole blog database from a version of early this morning. This happened partly due to my own carelessness, partly due to the bad user interface of WordPress, and partly due to the fact that I've had to spend a lot of time deleting repeated attempts by people to post long discussions of their own completely off-topic ideas about physics.

Please stop doing this, it is getting really, really, annoying, wasting my time, and now causing damage. This is not a forum for you to go on about your favorite ideas about physics that have nothing to do with the topic of the posting. Do that elsewhere. From now on, I'll be taking steps to shut off access to this weblog from anyone who repeatedly tries to post such material.

37. **Matti Pitkanen**
November 21, 2005

Dear Peter,

you definitely cannot argue that my comment relating to Tony's posting was a long discussion about off topic idea. It was precisely about the immense arrogance of super string theorists and about its tragic consequences: I am not talking about myself here but about the development of the theoretical physics as a whole.

It seems that superstring theorists are not the only ones to be blamed of extraordinary arrogance and willingness to censorship. This is a disease plaguing the entire comunity. This blog could be much more than it is by allowing open discussion of new ideas (in my own case not only new ideas but extensive life work) rather only allowing boring repetition of the well-known failures of string theory.

With Best Regards,
Matti Pitkanen

38. **woit**
November 21, 2005

Matti,

Your comment was not deleted by me intentionally, it was accidentally deleted when I accidentally deleted the whole posting. The latest backup of the blog database was made automatically early in the morning after Tony's comment and before yours. I had to restore from that backup and your comment was lost.

I was not about to delete your posting, but the problem is when you, Tony and others start discussing your own ideas, many others then want to join in with their own pet theories, and the comment section rapidly degenerates into a long string of comments by people promoting their own ideas (many of which make no sense). This leaves me with the job of trying to moderate such a forum. I don't have the time or energy for it and I resent having to do it, especially when it causes me to accidentally damage things here (e.g. by irretrievably deleting your comment). If you have a copy of your comment, you're welcome to resubmit it.

39. **D R Lunsford**
November 21, 2005

I'm personally a little sick of your whining about the status of your damn blog. Your own work in this field is pretty thin, but you've carved out a niche for yourself by calling a spade a spade. If you can't handle the heat, get out of the damn kitchen. And if you need some computer help, drop me a line, I'm pretty damn good at it after 20 odd years without a career in physics, that I worked very hard to secure from an early age. I don't "lose things".

-drl

40. **Who**
November 21, 2005

The topic is Joanne's forthright expression of a perception that is shared by others—–about string hubris.

I think the arrogance or pretention she speaks of is based on a (questionable) fundamental premise which Joanne herself repeats.
In other words, Joanne's own assumption is part of the problem.

In her original blog, Joanne pays tribute to a dubious cliché (which is at the root of string complacency). I don't object to her conclusion that string is worth studying. i object to her premise, which people seem to repeate unquestioningly:

"…string theory worth studying? I would answer yes, for two reasons. One has already been given, namely, that **string theory is currently our best idea about how to quantize gravity.**"

Why can't people say yes string theory is worth developing **even though it is not** necessarily the best idea for quantizing gravity that has been proposed?
And why not say yes we should support string research, among other approaches **even though it is not** necessarily the most promising avenue being explored?

I think the claim that it is the "best" or most promising is not to be taken for granted but is, in fact, controversial. There is legitimate difference of expert opinion. The only string theorist I recall acknowledging this is Andy Strominger. I hear people like Steve Shenker and David Gross use phrases like "our one best hope" like an article of faith or a party line—but the Strominger attitude i heard is that it aint so clear: String is worth studying but it's not clear that it is the best and there may be other avenues worth exploring as well.

41. **Who**
November 22, 2005

I think complaining about Peter losing some comments is off topic.
It is fine for him to occasionally lose stuff, most of what we write is not for the ages—-and it keeps the threads shorter and easier to read.

for better or worse, in this thread the topic is Joanne Hewett having the guts to say "arrogant"—-and she is a nice person too. so we better talk about that while we have the chance and not get off quarreling about minor blog mishaps

42. **plato**
November 22, 2005

I think complaining about Peter losing some comments is off topic.

I second that. I keep getting my posts deleted repeatly you think I am going to whine about?:) Non!

I just wonder though about the fervor with which a group view on anti- can become, could be affected by a lone person who might disagree, with what you people go on about string/M theory.

Peter you took a stand.

While it is not totally comprehensible to me, I do try to understand the models that are being adopted? And see them, as models.

Do you think Lee's comments arise just in cosmic varaince?

http://cosmicvariance.com/2005/11/14/our-first-guest-blogger-lawrence-krauss/#comment-7514

43. **Aaron**
November 22, 2005

Why can't people say yes string theory is worth developing even though it is not necessarily the best idea for quantizing gravity that has been proposed?

Maybe people have actually looked at what's out there and actually think that string theory is the best game in town?

Just a thought.

44. **Matti Pitkanen**
November 22, 2005

Peter,

I am glad to hear that this was an accident. And I want to emphasize that we were not going to discuss about details of our theories. Unfortunately I do not have the copy of posting. The ingenious definition of Who for what is off topic allows unlimited censorship without complaints. Congratulations!

Matti

45. **Nigel**
November 22, 2005

'…others then want to join in with their own pet theories, and the comment section rapidly degenerates into a long string of comments by people promoting their own ideas (many of which make no sense). …'

Sorry for causing problems by being arrogant. My arrogance is just copied from the string theorists who lead physics, which JoAnne Hewitt writes about. If they're arrogant, others follow.

BTW, some people want to have a go at stringing other people's stuff together, to sort out what makes sense.

46. **Juan R.**
November 22, 2005

Well, i will 'repeat' my post (since i think that was on-topic and, moreover, i do not speak on my own theories here)

secret milkshake

YES!! What great mistake!! Thanks by correction. Since Dyson unified the 'different' QED of the époque (and even people as Feynman was initially unable to see that Tomonaga or Schwinger, were just other 'pictures'), do you know why do not received the Nobel? Perhaps the lack of PhD?

dan

Since there is not still formulation for M-theory, nobody can reply you now. However, some brane theorists as Banks claim that D0-branes (which are NOT strings; a string is a 1-brane) are "fundamental" blocks of nature. It has been already proven, for example, that supersimmetric gravitons can be derived from 'excitations' of D0-branes.

For me, the most 'beatiful' result from M(atrix) theory is that fundamental building blocks are again pointlike particles. Probably the four decades 'stringy' excursion around extended object (and the popularization of how 'stupid' poinlike particle were) will finalize again in that the pointlike behaviour of particle physics was sufficient, when divergences and some other mistakes are corrected.

D R Lunsford

I personally think that one can find clever people in any field (scientific or not). Due to my multidisciplinary interest, I found genial papers on math, particle physics, quantum gravity, ecology, irreversible thermodynamics, electromagnetism, chemical dynamics, philosophy, etc.

However, I agree with you that current 'hidden' law saying that *the most brilliant guys of the planet are string theorists*, is a pure assumption without sound basis. Simply by reading published literature on string theory and comparing it, one already detects that. In my opinion, there is not a single Feynman on the current string theory community and this is the reason that physics has not advanced.

Moreover i think that the comparative of Witten with Einstein (or even with Newton!!) is, I believe, one of multiple distorted outcomes of the heavy stringy marketing.

We Pretty

> But as a representative of the public I think that the way string theorists trumpet their theory as a solution to everything is cheating. I suppose that if you ask a random person what is quantum theory, if he or she knows anything about it, he or she will usually say that it is something that explains the atoms and inderminancy and stuff. If you currently ask a random person what is string theory, if he or she knows anything about it, he or she will usually say that it is some new theory that explains everything.

A scientist is one who solves problems via generating scientific knowledge (i.e. acquiring knowledge via scientific method). String theory would be fantastic and string theorists become heroes if string theory was a scientific solution to only a 10% of the claimed in media. Unfortunately, it is all pure marketing. String theory is not a theory of physics, it is not a theory of science, it is an excellent piece of marketing, just that. I completely agree with Woit here. The only success of string theory has been on mass media.

Many people think that string theory does not predictions about nature. I partially agree. However, string theory claims that universe IS 10-D AND supersymmetric. Our observed universe is 4D and non-supersimmetric, therefore there is 'some' that string theorists are ignoring… just the scientific method!

Juan R.

47. **Juan R.**
November 22, 2005

Who

Could you explain why you think

> that string theory is currently our best idea about how to quantize gravity

?

During my travel on 'quantum gravity lands' i have known many people who believe 'that' because other people also believe 'that'.

I have even heard that the 'best' argument for studying string theory is because Witten believes on it!!!

If you really sustain you are writting here, could you write your real name too?

Is not part of the typical arrogance of string theorists to begin their talks on string 'theory' (so say) claiming that string theory is the ONLY possibility for quantizing gravity?

Where is the paper, book, talk, etc. where this was supposedly proven? Or is just another piece of the propaganda?

Juan R.

Center for CANONICAL |SCIENCE)

48. **Who**
November 22, 2005

Juan R you totally misunderstand me. Please carefully read JoAnne Hewett orig. blog
http://cosmicvariance.com/2005/11/18/a-particle-physicists-perspective/

Notice where she says

> string theory worth studying? I would answer yes, for two reasons. One has already been given, namely, that string theory is currently our best idea about how to quantize gravity. We obviously need to explore that link further, no matter how tenuous.

I am pointing to where she says "best idea" as if it were taken for granted and not controversial. Well-informed people can differ, but she does not not indicate this. It is something that even nice intelligent sensible people like JoAnne PARROT. This item of unquestioned dogma is a large part of the problem.

Suppose JoAnne had said this:

> string theory worth studying? I would answer yes, for two reasons. String theory is one of several promising ideas about how to quantize gravity. We obviously need to explore that link further, no matter how tenuous.

then the conclusion (worth further support) would remain the same but the grounds for what she objects to—the privileged sense of entitlement—would be removed.

If people could make that simple substitution, I think it would be a real step towards solving the problem she is talking about.

BTW think we should acknowledge who JoAnne is and what she puts on the line. correct me if I am mistaken but i think she is a type of nice levelheaded young scientist that people in the research establishment pick to be on advisory boards and to organize panels and committees and workshops. She is someone you trust to be constructive and have a sense of humor and be normal according to the highest standards. I've worked with people in an NASE/NRC study and I respect them and their careers are partly political and based on people-skills that some of the rest of us lack. And I have to say that I think JoAnne has something to RISK

49. **Aaron**
November 22, 2005

It is something that even nice intelligent sensible people like JoAnne PARROT.

Not to speak for JoAnne or anything, but I hope you realize that you're being rather insulting here. How do you know that anybody is 'parrot'ing anything?

And this idea you have that there is this string mafia who seek out to destroy the careers of those who oppose string theory is just silly. Lots and lots and lots of people criticize string theory.

50. **Bee**
November 22, 2005

Folks, today there is probably no particle physicist more tired by stringers than I am. If I have to listen to one more heterotic twisted whatever type string talk with compactification on manifolds that I don't know how to pronounce w/ or w/o flux or any connection to the real world, I am sure my head is going to implode.

However, I don't think string theory is such a stupid thing to do. It's just not plausible to me what it should have to do with nature and I find it is time that stringers admit they are mathematicians.

String theory has some beauty on its own, there are for sure many points worth investigating and the properties of the theory are amazing. Just why that is physics, I can't see. Maybe it would help, if any of the guys giving these headache-causing talks would at least TRY to explain why the physics community should be interested in that topic.

Also, string theory in the US is definitly completely over-funded, whereas there is lack of funding in equally or more important fields – that's for sure.

How come the NSF hasn't yet noted that?

51. **woit**
November 22, 2005

Hi Bee,

The problem with your suggestion that "stringers admit that they are mathematicians" is that, on the whole, the math community doesn't agree and doesn't want them.

52. **Aaron**
November 22, 2005

We're inspirational to the mathematicians. They like us. We give them things to prove.

53. **secret milkshake**
November 23, 2005

Bee: their attitudes are awful, not the field. The fluff – not the stuff.

54. **JC**
November 23, 2005

Peter,

Is there any particular reason why the math community doesn't really want string theorists?

55. **woit**
November 23, 2005

JC,
Would you want Leonard Susskind ranting about the anthropic landscape in your department?

Mathematicians are interested in some parts of string theory, e.g. conformal field theory, mirror symmetry, topological strings, etc. These are pretty well-defined ideas that have led to very non-trivial conjectures about interesting mathematical objects. Some people working on these things are happily working in math departments. Other parts of string theory, where no one knows precisely what the object under study even is (e.g. M-theory), or where there's no new insight into interesting mathematics (e.g. most of the work on the landscape or string cosmology) aren't things mathematicians want much to do with.

56. **Juan R.**
November 24, 2005

Ok **Who**! I agree

Juan R.

All Sorts of Links

November 22, 2005
Categories: Uncategorized

Here's a collection of things I've run across recently that may be of interest:

The Tevatron is doing quite well, with sizable increases in luminosity in recent months. There are some articles telling about this in Fermilab Today, and you can get up to date information about how things are going here. At the moment they're doing better than their "design" projection, which is meant to be quite optimistic.

On December 1 there will be a live 12 hour webcast called Beyond Einstein, which will feature many different groups and individuals talking about physics.

December 1 will also be the opening of the 23rd Solvay conference in Brussels. These conferences have a very illustrious history. This year the topic is The Quantum Structure of Space and Time, and most of the invited participants will be string theorists. Of the 60 participants there seems to be exactly one physicist from the LQG camp, Abhay Ashtekar. There will also be an event for the public, with talks by string theorists Brian Greene and Robbert Dijkgraaf, and a debate featuring five string theorists and Gerard 't Hooft.

Witten has been giving talks about his new work on gauge theory and geometric Langlands. Notes from a talk at Penn last month are on-line, and video from a talk at Rutgers last week should soon appear.

A conference was held earlier this month at Queen Mary College in London entitled From Twistors to Amplitudes, with many interesting talks on using twistor techniques to study gauge theory amplitudes.

There's a new site called Mixed States which does a good job of aggregating blog entries about physics.

There are all sorts of links relevant to research in number theory at the Number Theory Web.

Robert Wald has an article on teaching general relativity. Until I taught our graduate differential geometry course I hadn't realized just how tricky the definition of a tangent vector can be. Most of the difficulty with teaching GR has to do with the large amount of sophisticated geometry needed.

This is one of the funnier things I've read in a while. It seems that, like all non-string theorists, internet con artists are really stupid.

Update: Two recent talks by Alain Connes at the KITP in Santa Barbara are now online. One is entitled Non-Commutative Geometry and Space-Time, the other, discussing his ideas about the Riemann hypothesis, is called Noncommutative Motives, Thermodynamics, and the Spectral Realization of Zeros of Zeta.

Comments

1. **Tax Payers Revolt**
   November 22, 2005

   http://physicsmathforums.com/showthread.php?t=56

   I think the taxpayers aare getting tired of funding String Theory.

   Perhaps Hollywood is better suited?

   Tied Up & Strung Out: Hollywood String Theory Movie!!! Looking For Extras!!!
   FOR IMMEDIATE RELEASE:

   ALL TIED UP & STRUNG ALONG, a movie about String Theorists and their expansive theories which extend human ignorance, pomposity, and frailty into higher dimensions, is set to start filming this fall. Jessica Alba, John Cleese, Eugene Levie, Jackie Chan, and David Duchovney of X-files fame have all signed on to the $700 million Hollywood project, which is still cheaper than String Theory itself, and will likely displace less physicists from the academy.

   "As contemporary physics is about money, hype, mythology, and chicks," Ed Witten explained from his offices at the Princeton Institute for Advanced Study, "The next logical step was Hollywood, although I thought Burt Reynolds should play me instead of Eugene Levy."

   Brian Greene, the famous String Theorist who will be played by David "the truth is out there" Duchovney, explained the plot: "String theory's muddled, contorted theories that lack postulates, laws, and experimentally-verified equations have Einstein spinning so fast in his grave that it creates a black hole. In order to save the world, we String Theorists have to stop reformulating String Theory faster than the speed of light. We are called upon to stop violating the conservation of energy by mining higher dimensions to publish more BS than can accounted for with the Big Bang alone, and I win the Nobel prize for showing that M-Theory is in fact the dark matter it has been searching for."

   Greene continues: "At first my character is reluctant to stop theorizing and start postulating, but when my love interest Jessica Alba is sucked into the black hole, I search my soul and find Paul Davies there, played by John Cleese. I ask him what he's doing in my soul, and he explains that the answer is contained in the mind of God, which only he is privy too, but for a small fee, some tax and tuition dollars, a couple grants here and there, and an all-expense-paid book tour with stops in Zurich and Honolulu, he can let me in on it. And he shows me God in all her greater glory, as he points out that we can make more money in Hollywood than writing coffee-table books that recycle Einstein, Bohr, Dirac, Feynman, and Wheeler. I am quickly converted, and I agree to turn my back on String Theory's hoax and save Jessica Alba."

   But it's not that easy, as standing in Greene's way is Michio "king of pop-theory-hipster-irony-the-theory-of-everything-or-anything-made-you-read-this" Kaku, played by Jackie Chan. Kaku beats the crap out of Greene for alomst blowing the "ironic" pretense his salary, benefits, and all-expense paid trips depend on. "WE MUST HOLD BACK THE YOUNG SCIENTISTS WITH OUR NON-THEORIES!! WE MUST FILL THE ACADEMY WITH THE POMO DARK MATTER THAT IS STRING THEORY TO KEEP OUR UNIVERSE FROM FLYING APART, OUR PYRAMID SCHEMES FROM TOPPLING, AND OUR PERPETUAL-MOTION NSF MONEY MACHINE FROM STOPPING!!" Kaku argues as he delivers a flying back-kick, "There can be ony ONE! I WILL be String Theory's GODFATHER as referenced on my web page!! I have better hair!"

   But Greene fights back as he signs his seventeenth book deal to make the hand-waving incoherence of String Theory accessible to the South Park generation, senior citizens, and starving chirldren around the world. "Kaku! Kaku! (pronounced Ka-Kaw! Ka-Kaw! like Owen Wilson did in Bottle Rocket)," Greene shouts. "It is theoretically impossible to build a coffee tables strong enough to support any more coffee-table physics books!!!"

   "Time travel is also theoretically impossible, but there's a helluva lot more money for us in flushing physics down a wormhole. Nobody knows what the #&#%&$ M stands for in M theory ya hand-waving, TV-hogging crank!!! Get it?? Ha Ha Ha! We're laughing at the public! We're the insider pomo hipsters! Get with the gangsta-wanksta-pranksta CRANKSTER bling-bling program!!"

How does it all end? Does physics go bankrupt funding theories that have expanded our ignorance from four dimensions into ten, twenty, and thirty dimensions? Do tax payers revolt? Do young physicists overthrow the hand-waving, contortionist bullies and revive physics with a classical renaissance favoring logic, reason, and Truth over meaningless mathematical abstractions? Does Moving Dimensions Theory (MDT) prevail with its simple postulate? We'll all just have to wait!

But in the meantime, how do you think it will play out?

Will theories with postulates ever be allowed in physics again? Or will the well-funded, tenured pomo String Theory / M-Theory (Maffia-Theory) Priests send their armies of desperate, snarky postdocs and starving graduate students forth to displace and destroy all common sense, logic, reason, and physics in the academy? It must be so–for the greater good of physics, the individual physicist, and thus physics, must be sacrificed.

MDT's postulate: THE FOURTH DIMENSION IS EXPANDING AT A RATE OF C RELATIVE TO THE THREE SPATIAL DIMENSIONS IN QUANTIZED UNITS OF THE PLANCK LENGTH, GIVING RISE TO TIME AND ALL CLASSICAL, QUANTUM MECHANICAL, AND RELATIVISTIC PHENOMENA.

http://physicsmathforums.com/showthread.php?t=56

2. **andy.s**
   November 22, 2005

   How many times are you going to post this spoof.?
   It was only funny the first time.

3. **AJ**
   November 22, 2005

   It was only funny the first time.

   I'm not sure I'd go that far…

4. **Jason**
   November 22, 2005

   How many times are they going to publish the string theory spoof?

   How many more coffee table books?

   How many more films?

   How many more conferences?

   How many more millions of dollars to further the postmodern hoax that is string theory?

   How many more hoaxters are going to receive tenure for doing absolutely nothing positive for physics?

   How does it feel to be famous, to be revered, and yet,

   not one iota
   of your thought
   matters
   because it ain't true.

   what does it profit a man
   to gain the world
   and lose his soul?

   so c'mon!

   let us in on it!

5. **Jason**
   November 22, 2005

   I think it's hilarious. Especially with the pictures:

   http://physicsmathforums.com/showthread.php?t=56

6. **David Corfield**
   November 22, 2005

   Peter wrote: "Until I taught our graduate differential geometry course I hadn't realized just how tricky the definition of a tangent vector can be."

   Much simpler than equivalence classes of paths, derivations, or whatever, is synthetic differential geometry's idea of a tangent vector as a map from an infinitesimal object into the manifold.

   Urs Schreiber discusses SDG and gives references here.

7. **Elmer Fudd**
   November 22, 2005

   apparently assistant professors at haavard aren't too bright either.

8. **Shantanu**
   November 22, 2005

Peter , Jim Hartle is another non-string theorist whose name appears in the participants of teh quantum structure of space-time conference.

9. **woit**
November 22, 2005

Shantanu,

I didn't mean to imply that all except Ashtekar were string theorists, just that Ashtekar is the only LQGer. Besides Hartle, there are also various cosmologists (Linde, Steinhardt, etc.), and various other non-string theorists (Wilczek), or even historians (Peter Galison).

10. **Shantanu**
November 22, 2005

yes you are right. sorry I misundertood your article.
hope the video of the talks are archived

11. **Nigel**
November 22, 2005

Thanks Peter for the link to Robert Wald's paper. I like his emphasis on Einstein's great discovery in GR, p3:

'Gravity isn't a force at all, but rather a change in spacetime structure that allows inertial observers to accelerate relative to each other.'

Well done Robert Wald! That is accurate, and emphasises the spacetime fabric of general relativity. General relativity is better tested than string theory. Students should be allowed to know that there is FAR MORE evidence for a spacetime fabric than there is for string theory 😉

12. **andy.s**
November 22, 2005

Mega-dittoes on Robert Wald. I didn't realize until reading the paper that a lot of my hangups in understanding GR are due to my attachment to the Sophmore level Linear Algebra concept of a vector.

Maybe I should do some re-reading. Got nothing else to do while my spacetime fabric is at the cleaners.

13. **ks**
November 23, 2005

The definition of a tangent vector becomes tricky only in context of modern DG because algebraic techniques are introduced right from the start. The concept itself is nothing that one can't explain a high school student or even an ancient mathematician of a Pythagorean academia in a pure geometric terms without coordinates or algabraic clutter. With little additional investment of very basic topology it goes as follows:

Start with a sphere S (in arbitrary dimensions > 0) . Draw a line L from the center of S to a point p on S. The hyperplane H orthogonal to L with p in H is the *tangent space* of S in p. The points q!=p on H are called *tangent vectors*.

This concept can now be applied to smooth surfaces. First we need a definition of smoothness: let F be a surface of dim n and p a point on F. F is *smooth* in p if p is a point in an open set of S (not a boundary point) and n-dim spheres S1, S2 exist which suffices the requirements that p is the only common point of S1, S2 and F (no cusps). F is smooth iff it is smooth in each point (it is left to the reader to proof that choosing a certain pair of S1 and S2 is no loss of generality).

In particular a non-intersecting sphere S(p) exists in each point p on a smooth surface F. The tangent bundle is the set of tangent spaces of such spheres in the points p of F.

14. **ks**
November 23, 2005

One thing is missing in the little discussion above. The n-spheres S1 and S2 should be "parallel" i.e. embeddable in an n+1 dim space. Otherwise the tangent-spaces in their common point p would be different.

15. **Anonymous**
November 23, 2005

I took a one-quarter GR class from Bob Wald and didn't think it was so great. As he mentions in those notes, it was almost all spent on mathematical background. If I remember correctly, he only got to the Schwarzschild solution on the last day of class. Rather than cutting out material, perhaps he could save time if he didn't write everything out longhand on the blackboard and spend a great deal of time formulating every sentence in the most precise way possible. People are capable of getting all of the details from his book without him spelling it all out on the blackboard, after all. I felt that his class involved very little physics, so for those of us with a solid mathematical background it was largely a waste of time.

Do people really get to grad school at Columbia without knowing what a tangent vector is? This was covered in my first year of undergraduate mathematics (an analysis course, where we learned about calculus on manifolds and differential forms). Granted, not everyone has such a class so early, but surely most well-educated undergrads in mathematics learn some basic things about differential manifolds?

16. **woit**
November 23, 2005

Certainly most grad students at Columbia have seen some geometry and know what a tangent vector is. My comment was from the point of view of teaching this material in a graduate level math class where you want to be able to rigorously prove things. The issue here is how to define a tangent vector intrinsically, not assuming your manifold is embedded in Euclidean space. There are at least three kinds of different definitions you can use:

1. tangent vector = derivation
which is one the algebraic geometers love because it can be expressed algebraically.

2. tangent vector = equivalence class of curves

3. tangent vector = something that transforms correctly under change of coordinates.

Each of these definitions works, and can ultimately be shown to be equivalent. When preparing this material, I was just surprised to realize that rigorously showing this is not completely trivial.

17. **Anonymous**
November 23, 2005

"The issue here is how to define a tangent vector intrinsically, not assuming your manifold is embedded in Euclidean space. There are at least three kinds of different definitions you can use"

Sure. We saw each of these definitions, and proved their equivalence, in that undergrad class I was talking about. And they came up again in at least one other undergrad class I took. So I would have expected graduate students in math to be familiar with this already.

18. **woit**
November 23, 2005

This was covered as one part of the first couple weeks of foundational material in the class, it wasn't a big part of the course. Graduate classes often go over some of the same material as in undergrad classes, just much faster. Some undergraduate geometry classes don't really do much intrinsic geometry, so some of our graduate students probably hadn't seen some of this before.

19. **Walt**
November 25, 2005

It's not *that* unusual for an undergraduate math major to never have seen differential geometry, particularly at a smaller school. Most will have heard about tangent vectors from a differential equations course or just because the idea is in the air, but it's not unusual to not see it formally.

I think the place where starting with manifolds embedded in R^n really pays off is in tensor calculus. Picturing the tangent bundle as the manifold with little vectors attached to it isn't that hard, but general tensors are sufficiently abstract that the extrinsic point-of-view helps ease the pain.

20. **Florifulgurator**
November 29, 2005

Isn´t one of the most basic things you learn in math phys class that COORDINATES ARE OF NO PHYSICAL SIGNIFICANCE?
But then it looks physicists (and many diff geometers too) don´t want to do linear algebra without coordinates.
A field is a Christoffel symbol. A tensor is a monstrosity with indices. Wrrrrrrrrrrr. 90% of your IQ wasted! I´ve seen eminent minds fail at the calculus product rule while doing "tensor" calculus. No wonder without abstract tensor product.

Them Christoffel symbols and index notation have their place in computations with concrete coordinates. In general expositions they are more than a superfluous nuisance. O microsoftified math!

21. **woit**
November 29, 2005

Funny thing is I've known several physicists who have told me what a revelation it is to realize that you can think about these things in a coordinate-invariant way. I've also known mathematicians who have told me it was a revelation to realize they could actually make a choice of coordinates and use them to do calculations.

Seems to me, what one should aim for is understanding what you are trying to calculate in a coordinate invariant way, but also being able when necessary to know how to choose appropriate coordinates and work with them.

22. **Florifulgurator**
December 7, 2005

A veeery subtle reason for avoiding coordinates/bases where possible: TO MAKE CLEAR WHERE THEY ARE NEEDED. This point is way above almost all math/phys writ I encountered.
Indeed you sometimes need bases in abstract linear algebra. Example: Compute the adjoint of
[tex]T\bigotimes\bigwedge T \longmapsto\bigwedge T[/tex],
[tex]t\otimes a \mapsto t\wedge a[/tex]
This might occur in computations with (co)differential.
——————-
One more pearl of my wisdoms thrown into this fine black hole:AVOID DIRECTIONAL COVARIANT DERIVATIVES where possible. Otherwise, you will one day get stuck at a Laplacian.Exercise: Formulate the product rule for the induced cov. derivative on the tensor product of vector bundles without using a directional derivative. (Hint: Use the flat map permuting the factors).
=============
Sigh. Last century one of the final drops into my bucket was when I caught myself translating Lichnerowicz & Tachibana stuff (P Petersen, Riem.Geom, Springer GTM 171, Ch. 7.5) into my own calculus. Shortly after I gave up on serious math…
—————-
One of my DaDaistic dreams is writing a book titled THE CALCULUS OF PHYSICS, based on Th. Frankel´s book "The Geometry of Physics", putting most of his writ into a large appendix titled "Computational Reference"

Slate on Krauss

November 23, 2005
Categories: Uncategorized

Slate today has an article entitled [Theory of Anything?]() about Lawrence Krauss's [recent book]() and the controversy over string theory. The article begins by describing Krauss as having "a reputation for shooting down pseudoscience." and goes on to say:

Yet in his latest book, Hiding in the Mirror, Krauss turns on his own—by taking on string theory, the leading edge of theoretical physics. Krauss is probably right that string theory is a threat to science, but his book proves he's too late to stop it.

The article ends with the following summary:

Hiding in the Mirror does a much better job of explaining string theory than discrediting it. Krauss knows he's right, but every time he comes close to the kill he stops to make nice with his colleagues. Last year, Krauss told a New York Times reporter that string theory was "a colossal failure." Now he writes that the Times quoted him "out of context." In spite of himself, he has internalized the postmodern jargon. Goodbye, Department of Physics. Hello, String Studies.

Update: Lubos Motl [deals with the Slate article]() with the all-too-familiar favorite tactic of many string theorists when faced with criticism of the theory: don't respond to the argument being made, but instead attack the intelligence and competence of the person making the argument. After all, they're not a string theorist, so how bright can they be? In this case Lubos informs us that "Boutin's intelligence resembles that of dogs", while repeating his favorite claim that the status of string theory is much like that of the theory of evolution.

1. **Dr. Ranger McCoy**
   November 23, 2005

   String theory is starting to get on my nerves.

   I see hundreds of sheep getting tens of millions of dollars to polay pomo pattycake games with tax dollars, while physicists, poets, and philosophers, who rely on logic, reason, truth, and beauty, are exiled.

   I am shooting a documentrary entitled "Call the Bluff."

   I am looking to interview any string theorist, pomo artist, pomo Wall Street analyst, or pomo politician on video so as to get them to explain why think it's cool to steal tax and tuition dollars as well as pensions for their arrogant friends.

   The same kind of people who're stealing your pensions on Wall Street are furthering String Theory.

   They are anti-theory.
   Anti-truth.
   Anti-beauty.

   Pro-money for their rizty homes.
   Pro-tenure for their friends.
   Pro-BS as long as it keeps paying.

   It is time for a Renaissance.

   Let theories with postulates, truth, and beauty take the forefront of physics.

   November 23, 2005

   Beyond the standard model, is there any theory confirmed with experiment? No, we should conclude that all those theories aren't scientific theories?

4. **woit**
   November 23, 2005

   Jose,

   The problem with string theory is not that its predictions aren't confirmed, the problem is that it doesn't make any predictions.

   In the initial stages of working on a very speculative idea, it's not surprising if you can't yet figure out how to get predictions out of it. But after more than twenty years work, with no progress towards predictions, you start to get suspicious that they aren't possible. And much string theory research is now based on the idea that the theory can't inherently predict things, which seriously raises the question of whether it is scientific.

5. **Tony Smith**
   November 23, 2005

   It seems to me that this modification of part of Rudyard Kipling's "The Gods of the Copybook Headings" gives an optimistic (from my point of view) vision of the future of SuperString Theory:

As I pass through my incarnations
in every age and race,
I make my proper protestations
to the Gods of the String Theory Place.
Peering at reverent Stringers
I watch them flourish and fall.

And the Gods of Experiment Results,
I notice, outlast them all.
We were living in trees when they met us.
They showed us each in turn.
That water would certainly wet us,
as Fire would certainly burn:
They denied that Wishes were Horses;
they denied that a Pig had Wings.

So we worshiped the Gods of String Theory
Who promised these beautiful things.
But, though we had plenty of Strings,
there was nothing our Strings could predict,
And the Gods of Experment said:
'That means that String Theory is sick.'

Then the Gods of String Theory tumbled,
and their smooth-tounged wizards withdrew,
And the hearts of the meanest were humbled
and began to belive it was true
That All is not Gold that Glitters,
and Two and Two make Four—
And the Gods of Experiment Results
limped up to explain it once more:
As surely as Water will wet us,
as surely as Fire will burn,
The Gods of Experiment Results
with inevitable truth will return!

   November 23, 2005

   Just found that Peter's name has been listed after P. W. Anderson, Sheldon Glashow, L. Krauss as "Prominent critics" on string theory in Wiki's "string theory" item.

   See:
   http://en.wikipedia.org/wiki/String_theory#endnote_critics

7. **secret milkshake**
   November 23, 2005

   1) There is the dark energy and dark mass we don't know anything about. It will be hard to cook up a grand unification scheme until the bulk ingredients are found.

   2) Maleable frameworks with lots of internal adjustable parameters are unhelpful. It is like Freudist psychoanalysis – you cannot prove them wrong. Invoking extra 7 unobservable dimensions having whatever-you-want properties seems like lotsa degrees of wiggle freedom to me.

   The particle zoo was there when the gauge theories were developed and one was able to predict the pattern of interactions and the properties of unknown particles – even as the numbers were hard to extract.

   String theorists keep adjusting their framework to the observable world – weeding out the alternatives that would not produce it – but apart from their requirement for SUSY and predictions about black holes, not much is realy coming out. Their swamp is big and deep and maybe they will never landscape (or dredge) it into a productive field.

8. **MathPhys**
   November 23, 2005

   They should have included G 't Hooft amongst string theory's prominent critics, for he certainly is (prominent and a critic!).

9. **Dr. Ranger McCoy**
   November 23, 2005

   M-theory is in fact the dark matter it has been searching for.

   The dark energy can be accounted for by the mysterious drive that compels young grad students to devote their lives to bs, by studying string theory.

   Oh wait–meaningless, indecipherable bs is the best way to get tenure.

10. **Aaron**
    November 24, 2005

    't Hooft taught a [course]() on string theory. You can find some of his views on the last page.

    Like most people, string theorists included, I think you'll find that he has more nuanced views than "string theory bad" or "string theory good".

11. **We Pretty**
November 24, 2005

What I as a representative of the public find wrong in string theory is the status that it has. Here is a comparison of some features between string theory and other theories
(CDT, LQG, Christianity):

String theory is cool (extra dimensions etc).
Applies also to Causal Dynamical Triangulations (2 and 4 and between dimensions), loop quantum gravity and Christianity (eternal life, heaven).

String theory does not yet make testable predictions.
Applies also to Causal Dynamical Triangulations, loop quantum gravity and Christianity.

String theory has been trumpeted as the theory of everything for a long time but is not yet scientific theory.
Applies also to Christianity.

String theory is known by the public as a theory that tries to explain everything.
Applies to Christianity

String theory is generally believed by the public to explain everything.
So is Christianity by large proportion of the public

12. **Ugo**
November 24, 2005

I think the problem String Theory, and to a certain extent Quantum Gravity Theory have is that they aren't born out of necessity.
For instance special relativity, general relativity, quantum physics, quantum field theory even qcd and electroweak theory were all born out of necessity to explain physical phenomena which couldn't be explained within the framework of the accept theories of the time.
They were doing catch-up to experimental results and that is the way work theoretical physics should proceed.
Not the other way around.
I mean, the lack of any kind of observable phenomena at the planck scale for the foreseable future (maybe one-two centuries) will make string theory, quantum gravity and a host of other "speculative" theories completely irrelevant.
Were they even in mesure of giving testable predictions there wouldn't be any type of realisable experiment to test those predictions.
Today, high energy theoretical physicsts are just playing with toy theories, they aren't doing physics.
Anyway wouldn't it be great if once the LHC is online, the experiments demonstrate that the higgs boson doesn't exist ?
Theretical physicists abandoning string theory and going back to the "drawing board" to come up with a good physical theory ?
Yep, we need experimental data to advance theoretical physics.

13. **Jose**
November 24, 2005

In XIX century Boltzmann introduces statistichal mechanics and the hypothesis of atoms to explain at a deeper level thermodynamics. He was strongly criticized, for example by Mach, because atoms were abstractions no forced by facts. Match thought that Boltzmann was not doing physics.

The same can be said about many other theories (quarks, Yang-Mills theories,…).

I think that explorations in theoretical physics shouldn't be confined by experiment. Experiments will decide what is the better theory but there is not a logical path from facts to theories.

With respect to string theory I think is a possibility and we shouln't discard it.

14. **Wolfgang**
November 24, 2005

> String theory is generally believed by the public to explain
> everything.
> So is Christianity by large proportion of the public

Would Lubos Motl be the Jerry Falwell of string theory in your analogy?

15. **Juan R.**
November 24, 2005

And do not forget others string theory's prominent critics, Feynman was one!

Jose. There is a **big** difference between string 'theory' and Boltzmann kinetic theory. The idea of atoms was rather 'popular' between physicists and chemists, and the theory was mainly testable even if atoms were not detected. Once atoms were experimentally found, Boltzmann theory was completely accepted.

The first step of string 'theory' would be offer us testable predictions and after, only after, we could search the strings. However, and this *may be you unknow* string theory has failed in all tests done until now.

As explained by Woit in his American Scientist's article *Is string theory even wrong?* string theory is probably the hypothesis/theory with the biggest discrepancy with experimental data (10[sup]55[/sup]).

> This is perhaps the most incorrect experimental prediction ever made by any physical theory that anyone has taken seriously.

Moreover, string 'theory' have appeared -during 3 decades- totally incompatible with observed data. For example, particle spectrum derived on string theory are massless supersimmetric states, laboratory data says that states are non-supersimmetric and with nonzero mass.

Do not forget that even the initial idea of an unidimensional object on 10D has failed and TODAY people is working with others things (such as D0-branes, which are pointlike objects) in 11D.

In the past, was claimed that string theory was a theory of physics with posibility for quantizing gravity, explaining the Standard Model, solving the measurement problem of QM, the divergences of R-QFT, and the singularities of GR (e.g. Big Bang). And all of this based in a single parameter!

Reality **TODAY** is as follow:

– The theory cannot predict anything, even statistically, due to the infinite Landscape trouble!

– The theory does not quantize gravity. In fact, it is already recognized by string theorists that string theory failed and then launched M-theory, that is not formulated still and nobody know what is.

– The theory can only deal with supersimmetric masless states, which are not the states of the Standard Model. Nothing of the sucesfull Standard model has been explained and/or derived from first principles.

– The theory does not solve the measurement problem of QM. In fact ideas proposed by people as Witten has been durely critized by specialists on quantum measurement as 'nonsense'.

– String theory does not cure the divergences of R-QFT. In fact, there exist not single paper, lecture, or book where was proven that string theory is NOT divergent, just a partial theorem and some conjetures. In fact, some authors think that string theory is as divergent (therefore unuseful) as covariant quantum gravity.

– Cosmological models based in string and brane theory have failed. A. Linde and other cosmologists proven as 5D-brane models was theoretically inconsisten and violating many experimentla data.

– From the initial single parameter on 10D we obtain a theory with more than 10000 unknown parameters when one compactificates to 4Dx6D!

– Etc.

Once string theory was a marvellous hipothesis but become a pure nonsense. Today many string theorists (or even some particle physicists as Weinberg) openly admit that theory is not predictive.

Juan R.

November 25, 2005

Been saying this for years and years. Common sense tells us that in order to qualify as a scientific theory, job one is that it must make objectively falsifiable predictions. Ufology makes none, so it's not science. String theory makes none either. In what meaningful way does ufology differ from string theory?

The big question that comes to mind: how long? How long will the public and the government (via tax breaks for educational instutitions, including NSF and DOE grants to private institutions like Stanford) continue to pay the proponents of a belief system like string theory which persistently fails to produce any objcetively falsifiable predictions?

20 years? 30 years? 50 years? 100 years? 200 years? 500 years? At what point do we decide string theory is a fancier more mathematically sophisticated version of alchemy or phlogiston?

How long do we continue to shovel money and time and energy, most importantly the intellectual abilities of some of our brightest young scientists, into a scheme that yields not a single testable prediction?

This proves a painful question to ask, since we all know the gummint spends precious little money on basic research — and the amount continues to plummet yearly. Plenty of gummint cash for "faith-based" initiatives nowadays, but none for basic research. It's to weep. But string theory just provides more ammo for those who want us to spend less. When no-neck members of the great unwashed talk about shutting down the NIS, string theory is the poster boy for that position.

Let's ask another question — would you object if the government suddenly started funding scientology? How about if all the brightest young scientists started to take lucrative tenure positions at major universities teaching scientiology? Would you have a problem with that?

If so, why don't you have a problem with the same situation going on for string theory? How does string theory differ from scientilogy in any signiifcant way? Both use impenetrable jargon…both systematically fail to make objectively falsifiable predictions about observed reality…both have churned away for many decades without generating any meaningful new areas of knowledge. Nobody ever built a new kind of power plant or invented a new kind of transistor based on the alleged "science" in scientology…but then again, nobody built a new kind of power plant or invented a new kind of transistor based on the alleged "science" in string theory either. The only thing the string theorists lack is an e-meter.

What makes this especially significant is the fact that the field effect transistor was a direct result of some of the earliest work done in quantum emchanics. Abstruse and arcane they might be, but quantum mechanics and special relativity both generated a cornucopia of practical real-world technologies from LEDs to transistors to nuclear power. Which practical new real-world technologies have arisen from string theory? Can you name one?
Just one?

After 30-plus years of work on string theory, there ought to be at least _one_ new technology coming out of all this intellectual ferment. When there isn't, I start to smell a Unarius saucer cult.

String theory and Intelligent Design are twins separated at birth. Both fail Occam's Razor. When I ask ID proponents, "Show me a single disease you can cure using ID theory that can't be cured using standard Darwinian molecular biology," they fall silent. When I demand of ID proponents, "Which new vaccines has ID theory allowed us to create that we couldn't create with the standard Darwinian model of evolution?" the response is…zero. Nada. Dick. Diddly. Zip. Zero. Squat. Bupkiss. The ID proponent stands there with his mouth opening and closing, like a guppy in a fish tank.

So let's hear it, string theorists — which new device can you build using string theory that you can't build using the standard electroweak model? Power plant? Computer? Sensor? Detector? Anything? Show me one device. Just one. Let us see it. Put it here on the table.

Put up or shut up. I'm tired of the 50-dollar words and the incoherent equations. Show me the hard objectively falsifiable evidence or shut up, sit down, and stop wasting my time.

The real tragedy of the superstring fiasco is that we're living in an incredibly anti-intellectual era. Arguably it's the New Medievalism. Rational skeptical thinking is getting rolled back on every front, from the denial of global warming to the denial of Darwin to the redefinition of "torture" into something (anything) less offensive… Yes, kiddies, we're rocketing back into the year 1100, and it's not pretty. What with the catastrophic drop in the funding of basic research and the wholesale destruction of skeptical critical thnking and the ever-growing public disdain for evidence and logic, America's in serious trouble. 23% of the Americna public *still* believe Saddam used chemical weaopns on our troops in Iraq.

And the big tragedy is that string theory adds fuel to the fire. String theory (so-called) gives the irrational 51% of American society (who think God created human beings in their present form and American forces found WMDs in Iraq and Saddam parachuted out of one of the 757s just before it hit the twin towers on 9/11) all the ammunition they need to _further_ remove logic and observed facts from American society. After all, the ID(iots) can argue, if ID makes no objectively falsifiable predictions, well, no matter: neither does string theory…and string theory is accepted at major U.S. universities, isn't it?

Somtimes I pinch myself and say, "What the hell happened to this country?" 40 years ago we were building particle accelerators and sending men to the moon. Now, we waste our time arguing about vacuous twaddle like ID and string theory. What next, angels dancing on the head of a pin? Will we get into a civil war about tridentine transubstantiation? Has an epidemic of highly infectious brain parasites over the last 40 years destroyed the population's frontal lobes? Why is anyone even spending time arguing about unbelievable tripe like ID or string theory or whether waterboarding is torture?

I feel like Ripley in the sequel to Alien, when she looked at the corporate officers and asked, "Did IQs drop sharply while I was away?"

20. **Juan R.**
November 25, 2005

Christine Dantas,

I agree with you that we are far from claim that quantum gravity is unobservable at usual scales. Similar errors were done in the past by particle physicists, first regarding relativistic quantum effects in chemistry (Dirac wrong quote claiming that relativistic effects would be unobservable in chemistry, today there exists relativstic quantum chemistry) and recently regarding parity violating effects.

Of course PV effects are very small for a single particle, but due to 'acumulative' effects can be observed in certain molecules thanks to modern high-precision spectroscopy. Weinberg's explicit claim that QM + electrostatic CB potential was sufficient for **all** chemistry purposes turned wrong, today there exists a electroweak quantum chemistry.

Quantum gravity, *a priori*, lives on the Planck scale. But has anyone shown that 'acumulative' effects in a molecule cannot be detected, for instance?

However, i would add a note on your comment.

Since there is not complete and satisfactory theory of quantum gravity, what is people 'proving' on astrophysical tests?

We would agree that they are only 'testing' partial truths, hypothesis, ideas. For example, if finally 'spacetime foam-like' contributions to energy spectra in future acellerators are detected, then one 'prediction' of LQG would be verified, but that does not automatically mean that full LQG was correct.

Juan R.

Center for CANONICAL |SCIENCE)

21. **Juan R.**
November 25, 2005

mclaren,

there is no comparison of string theory with alchemy or phlogiston. Alchemy (preparative alchemy) was based in experimental work and worked! It was basis of early medicine (iatrochemistry) of Paracelso, etc, etc.

Regarding phlogiston theory, it also worked, in fact explained many experimental data: chemical reactions, odor, color, etc.

Just a day plogiston theory was unable to explain combustion. well combustion was explained, but at expenses of negative masses. Then was subsituted by Lavosier theory.

Being wrong phlogiston theory could still be used today in a basic course of chemistry.

Eugenio Portela, 1999, Historia de la Ciencia y de la Técnica, 33-La Química ilustrada, ediciones Akal S.A. Madrid pag 19.

Somewhat as initial Dirac theory, being wrong (as explained in many quantum field theory textbooks), is still used in elementary courses on relativistic quantum mechanics.

Juan R.

22. **CWB**
November 25, 2005

How did Alchemy work? Who has ever turned lead into gold?

23. **Zelah**
November 25, 2005

CWB,Juan R means that Alchemy was success because it LEAD TO CHEMISTRY. At the moment in time, it is unclear if String Theory will lead to new theories. It seems to have lead only to improving old ones.

Juan R, if relativistic effects are being noticed in chemistry, then is this not in some sense an quantum gravitation effect? Especially as you support looking at Quantum Gravity using Flat connectives and putting the physics in gauge effects?

An amateur mathematician.

24. **Arun**
November 25, 2005

CWB,
Turning lead into gold was only one of the objectives of alchemy. A good recent book is
Distilling knowledge : alchemy, chemistry, and the scientific revolution / Bruce T. Moran.

The publisher’s blurb is

> The traditional grand narrative of the scientific revolution styles it as a decisive rejection of magic and mysticism in favor of rationality and empiricism. This engaging study of early modern science insists there was no such sharp break. Historian Moran traces the gradual evolution of alchemy to chemistry through a wide array of texts from the 15th through 18th centuries, including classical alchemical treatises, handbooks of practical alchemy, early chemistry textbooks and the writings of Newton and Boyle, both of whom considered alchemy a perfectly legitimate scientific discipline. He finds in alchemical thought intriguing precursors of modern ideas about the particulate nature of matter, the biochemical paradigm of life and disease, and Newtonian gravity. Moreover, he considers alchemy, which boasted a vast amount of lore on everything from metallurgy to medicine and was practiced not just by adepts but by doctors, artisans and housewives, to have been an important catalyst in the development of the scientific mindset; while alchemical theories may have been wrong, alchemical practice schooled society at large in everyday habits of observation and experimentation. Conveying a wealth of historical detail in an accessible, jargon-free style, Moran provides a fascinating corrective to simplistic notions of the origins of modern science.

25. **Juan R.**
November 25, 2005

Sorry to say this CWB, but your two questions are irrelevant. I clearly emphasized “preparative alchemy”. And YES! in the 20th century physicists were able to convert lead atoms into gold atoms via a nuclear reaction.

Zelah,

About if quantum gravity is observable or not a current energies, Penrose believes that mind may be based in some quantum gravity effect amplified by chaotic processes in human neocortex structure. I personally doubt, but nobody can afirm that still.

Yes relativistic effects are noticed in chemistry but are NOT gravitatory ones! For instance, chemical difference between AgH and AuH, the famous lanthanide contraction, optical properties for 5d band –> Fermi level in metallic gold, etc.

My emphasis on this topic was simply for illustrating that in the past physicists (even smart ones as Dirac, Weinberg, etc) said *this is unobservable this sin unimportant for chemistry* and now we **can measure** effects in the laboratory.

Can anybody claim that quantum gravity effects will be unobserved in physics, chemistry, or biology laboratories? Can someone really assure us that quantum gravity effects are observable only with a particle accellerator of Jupiter size?

Since this is going out-topic i will nothing more about this. Simply remark that string theory is **not** testable in many ways (due to ill-defined formalism, due to Landscape, due to lacking detailed models, etc.) and in others is **clearly incompatible with experimental data**.

Juan R.

26. **Lubos Motl**
November 25, 2005

If you’re interested in 15 reasons why Paul Boutin is a complete ignorant, read

http://motls.blogspot.com/2005/11/ignorance-of-paul-boutin.html

27. **Juan R.**
November 25, 2005

After read and re-read Paul Boutin Slate article i can resume it:

MISINFORMED.

Next some details.

> String theory, which stretches back to the late 1960s, has become in the last 20 years the field of choice for up-and-coming physics researchers.

Due to presure! Many young people interested in fundamental science is doing a PhD in string theory because other doors are closed to them. In fact, several graduate students confirm this to me personally! Today i think that two great topics are condensed matter and biophysics. ‘Stringy’ is only followed by 10^3 people or similar.

> Many of them hope it will deliver a “Theory of Everything”—the key to a few elegant equations that explain the workings of the entire universe, from quarks to galaxies.

In the past this was pure speculation, after turned into marketing point and now is pure nonsense. It is curious that nobody explain NOW why believe that string theory is a TOE. You can personally reply me on sci.physics.strings:

String theory is not a TOE. Juan R. (21 oct)

> Elegance is a term theorists apply to formulas, like E=mc2, which are simple and symmetrical yet have great scope and power. The concept has become so associated with string theory that Nova’s three-hour 2003 series on the topic was titled The Elegant Universe (you can watch the whole thing online for free here).
>
> Yet a demonstration of string theory’s mathematical elegance was conspicuously absent from Nova’s special effects and on-location shoots. No one explained any of the math onscreen. That’s because compared to E=mc2, string theory equations look like spaghetti. And unfortunately for the aspirations of its proponents, the ideas are just as hard to explain in words.

The BIG problem is that there is NOT elegance in string theory, i.e. mathematical simplicity, basic postulates, and explanation of phenomena. There are not postulates on string theory, there are a mathematical goulash and *ad hoc* procedures, and none experimental prediction or even ‘postdiction’.

> Einstein dismissed this probabilistic model of the universe with his famous quip, “God does not play dice.” But just as Einstein’s own theories were vindicated by real-world tests, he had to adjust his worldview when experimental results matched quantum’s crazy predictions over and over again.

Einstein NEWER accepted experimental results and was guided by pure mental experiments the rest of his life. For example, some biographers remarked as Einstein simply ignored the good concordancy of relativistic quantum mechanics to data.

> Step 3: String theory (1969-present). String theory proposes a solution that reconciles relativity and quantum mechanics.

This is flagrantly wrong. String theory reconciles nothing.

> To get there, it requires two radical changes in our view of the universe. The first is easy: What we’ve presumed are subatomic particles are actually tiny vibrating strings of energy, each 100 billion billion times smaller than the protons at the nucleus of an atom.

Even asuming as true that strings are ‘vibrating energy’. The idea of strings is already very outdated. All popular recent advances -for example computation of BH entropy- are based in BRANE theory. Modern views point to the abandon of the string (really superstring) as fundamental. In fact, the only version known of M-theory is a theory of **poinlike particles** (D0-branes).

> That’s easy to accept. But for the math to work, there also must be more physical dimensions to reality than the three of space and one of time that we can perceive. The most popular string models require 10 or 11 dimensions.

But for explaining world we look, we may do 10 –> 4×6 and then all initial ‘elegance’, hyphotetical predictive posibility, etc. is lost.

> What we perceive as solid matter is mathematically explainable as the three-dimensional manifestation of “strings” of elementary particles vibrating and dancing through multiple dimensions of reality, like shadows on a wall. In theory, these extra dimensions surround us and contain myriad parallel universes. Nova’s “The Elegant Universe” used Matrix-like computer animation to convincingly visualize these hidden dimensions.

Nothing of this paragraph has been even minimally proven. In fact, it is proven just the contrary, none of string theory spectra is compatible with Standard Model. Using computer animation i can prove that universe is 0 D and that earth is really flat. I can prove anything with a computer package 🙂

> Unlike relativity and quantum mechanics, it can’t be tested. That is, no one has been able to devise a feasible experiment for which string theory predicts measurable results any different from what the current wisdom already says would happen.

Typical marketing! String theory has been tested during decades and changed due to failures. Begin from failure on strong force (before QCD) and finalizing by most recent claims that dark matter was cosmic strings…

Do not forget that string theory has been succesive changed due to experimental failure.

For example, the first post-strong-force version was bosonic and due to violation of *experimental* LI, string theorists passed from 4D to a new 26D version, then this is again *experimentally incorrect* and ad hoc corrected via KK, but then the new version of string theory predicted tachions, since they are *experimentally* unobserbed, the theory was again modified via ad hoc supersimmetry, and the new theory was again inconsistentet, and etc. String theory newer worked. Now, since string theory is again considered to be not 100% compatible with GR, it has been proposed the *new* M-theory that nobody know that is.

> The string theorists blithely create mathematical models positing that the universe we observe is just one of an infinite number of possible universes that coexist in dimensions we can’t perceive. And there’s no way to prove them wrong in our lifetime.

But then ‘the 101’ says that a hypotesis cannot be tested is not a scientific hypotesis!

> That's not a Theory of Everything, it's a Theory of Anything, sold with whizzy PBS special effects.
>
> Last year, Krauss told a New York Times reporter that string theory was "a colossal failure." Now he writes that the Times quoted him "out of context."

String theory pressure again?

Juan R. Says:

Since there is not complete and satisfactory theory of quantum gravity, what is people 'proving' on astrophysical tests?

We would agree that they are only 'testing' partial truths, hypothesis, ideas.

Yes, it would be illogical to test something that one does not know what it is. Some quantum gravity approaches suggest the existence of effects that could be verified in principle. Therefore some limits are being searched for using astrophysical signals: gamma ray bursts, ultra high energy cosmic rays, the microwave background radiation, etc. One of the main effects being investigated is Lorentz violation. There are already quantitative limits to this. More information can be found in, e.g., Mattingly´s review. I have posted a partial list of papers in my blog that I think is a reasonably good entry to the relevant (astrophysical) literature on this matter. The bottom line is that these are not really tests of quantum gravity, we are just probing Nature the best we can. This is better than nothing.

29. **John Gonsowski**
November 25, 2005

The best way for string theory to pick up a bunch of predictions would of course be to actually include the Standard Model in the theory. I could see them having a good connection to the Standard Model and still having a bunch unneeded extra stuff but that would be an improvement on no Standard Model. What does the all-intelligent Lubos have to say on connecting to the Standard Model? He told me this back in 2001:

"Yes, there are hundreds papers about realistic heterotic string models;this is a very well known issue. Throughout the 80s and the early 90s, everyone believed that there was a single realistic stringy way to descibe our world: E8 x E8 heterotic string theory on a Calabi-Yau space where the Standard Model is embedded into one of those E8s. For instance, you can start with an E6 subgroup of E8 – a good Grand Unified Theory that automatically gives you correct representations of fermions etc. if you start from string theory. Today we have some new implementations of the real world into string theory: Horava-Witten on Calabi-Yau, M-theory on G2 manifolds, F-theory on Calabi-Yau four-folds, brane worlds where the Standard Model lives on branes etc. but heterotic strings are still the most classical example."

I personally think they should have declared more of a victory with that E6 GUT and then keep the new ideas (branes, M-theory, F-theory) as related as possible to that GUT.

Lubos also had this to say about a good E6 GUT related M-theory:
"People are excited about the possibility that the 26-dimensional bosonic string is connected in one way or another with supersymmetric string theories (see also papers by Englert et al.). But I repeat that no convincing arguments have been found – excitement is one thing, evidence is another; at least 95% of string theorists (especially the leaders) agree with this claim of mine. From this point of view, those three names you mention consistute none. Physics – and string theory especially – is not a free arena for your fantasy. It has very tough rules and things that are not justified do not become part of it. Once again, all such things are just idiosyncratic speculations. Concerning nonperturbative behavior of the bosonic string, many more renowned names than those you mentioned – namely Lenny Susskind and Gary Horowitz – suggested various solutions (a 27-dimensional Bosonic M-theory in this case) but it is fair to say that their proposal has not been accepted by the community and there are serious reasons."

The serious reason is probably the bosonic part of Bosonic M-theory but if you have the E6 GUT (with fermions) then why is bosonic such a problem? It's not like there are actually any supersymmetric particles around that need an explanation.

30. **Bryan**
November 26, 2005

The supersymmetric partners in the vacuum are part of the aether of string theory. You can't disprove aether very easily…

31. **Juan R.**
November 26, 2005

Christine Dantas Says,

> Yes, it would be illogical to test something that one does not know what it is. Some quantum gravity approaches suggest the existence of effects that could be verified in principle. Therefore some limits are being searched for using astrophysical signals: gamma ray bursts, ultra high energy cosmic rays, the microwave background radiation, etc. One of the main effects being investigated is Lorentz violation. There are already quantitative limits to this. More information can be found in, e.g., Mattingly´s review. I have posted a partial list of papers in my blog that I think is a reasonably good entry to the relevant (astrophysical) literature on this matter. The bottom line is that these are not really tests of quantum gravity, we are just probing Nature the best we can. This is better than nothing.

I completely agree that many quantum gravity approaches suggest the existence of effects that could be verified in principle. Take for example Lorentz violation.

I do not know details of the history of LQG approach, but from reviews i obtained the idea that violation of Lorentz invariance is an early claim of that approach. Moreover, it appears that recently they found some links with double spacial and other ideas. Then if one tests Lorentz violation at 2007 via verification of LQG formula

E^2 = p^2 + m^2 + f(L_p)

are we verifying LQG?

Well the reply may be NO.

The obtaining of the formula may a lucky 'coincidence' (just as Dirac predicted antiparticles using his hole theory which is wrong according to R-QFT where E is > 0).

LQG may be still wrong. Remember that after of many decades still nobody has found the correct classical limit of LQG. Therefore, the theory cannot be correct even if just the part used for computation of Lorentz violating terms appears correct.

Situation is similar to Gerber gravity; it predicts the same perihelion anomaly for Mercury that GR and, however, is an incorrect theory.

Now take string 'theory'. Of course, there is not theory, just mathematical time-dependent gulash of ugly formulas with inconsistent ideas. In the past, Lorentz was claimed to be exact and then people introduced extradimensions and other stuff. After LQG was durely critized by string theorists because was not purely Lorentz invariant.

See for example

http://en.wikipedia.org/wiki/Lorentz_invariance_in_loop_quantum_gravity

Curiously, now string theorists admit that string theory is not the *last word* and are searching a M-theory.

😉 just M(atrix) theory is NOT Lorentz invariant in general. From Banks

> Full Lorentz invariance is not obvious and will arise, if at all, only in the large N limit. It also follows from this that Matrix Theory is not background independent.

Therefore one can chose 'stringy' formulations where Lorentz invariance is fundamental and other where it is not, but derived in certain limits.

Scenario A

Imagine that one finds violation of Lorentz invariance in a future experiment, string theorists will say:

> Yes we predict that via M-theory. This is the first quantum gravity prediction of M-theory verified. LQG, if correct, may be a part of M-theory

Scenario B

Finally no violation of Lorentz invariance is measured. Then string theorists will say:

> Yes string theory predicts that since decades ago since Lorentz invariance is one of basic 'simmetries' of the theory. During last decades we critize LQG, now it is experimentally found that LQG is incorrect, string theory is the only way to quantize gravity

String M-theory, as a whole, is a theory of nothing, but taking some parts of the formalisms developed during 3 or 4 decades, one can make a theory of anything.

Personally, i believe that Lorentz invariance is approximated and we can test it (In fact, it appears that recent cosmic ray observations suggest the possibility for a preferred rest frame. No?).

> don't respond to the argument being made, but instead attack the intelligence and competence of the person making the argument.

Sounds familiar
http://iso42.blogspot.com/2005/11/lubos-motl.html

33. **joe**
November 26, 2005

Peter,

With which of lubos's statements do you take issue?

34. **secret milkshake**
November 27, 2005

Slate should have hired actual physicist to pen the Krauss review. Boutin does not have the understanding – he parrots what he thinks he got from the book and he is confused about basics. It is a lot like Rush Limbaugh explaining Bjorn Lomborg to the popular audience. Add Motl to the mix and you get a troll-fest.

35. **Jim Wills**
November 27, 2005

As the author of a novel whoes protagonist concludes there will never be a coherent theory of quantum gravity, I find all of this interesting.

36. **dog**
November 28, 2005

It is funny when Motl says "Boutin's intelligence resembles that of dogs"

Did he not recently sign his posts as "Lumo leashed" ?

37. **ark**
November 28, 2005

Those who criticize string theory for not producing results simply forgot the fact that it did produce conformal field theories known in condensed matter physics and fully supported experimentally. It produced Gromov-Witten invariants-extremely useful in algebraic geometry. It produced mirror symmery traces of which can be seen experimentally already. It affected theory of exactly integrable systems used in many practical applications, etc. etc The fact that some people do not like extra dimensions cannot be considered as fundamental flaw of string theory since even simplest models of classical mechanics are multidimensional. The problems with string theory originate from the fact that it is based on the Regge theory which itself is not well founded. No string theory texbook mentions this fact. No texbook also mentions about the fact that for each parent Regge trajectory there is a countable infinity of daughter trajectories which actually never were observed….Instead for each parent trajectory one sees just a few daughters…Why this is so….? Or how string theory can reconsile itself with the Froissart theorem (providing some known bounds on the total crossections) in the case of a graviton? I would like string theoreticians to think about this…and the rest who are critics of string theory too…

38. **Thomas Larsson**
November 29, 2005

Those who criticize string theory for not producing results simply forgot the fact that it did produce conformal field theories known in condensed matter physics and fully supported experimentally.

Nobody has denied that CFT is the correct theory of 2D critical phenomena; this has been verified beyond reasonable doubt, and I have argued on several occasions that BPZ deserve a Nobel prize for this discovery. However, this does not mean that string theory is the correct theory of QG in 4D. There is little doubt that string theory and its cousins are the correct way to describe 2D things – strings in spacetime (obviously), membranes in space, 2D gravity, 2D phase transitions. This is valuable, because 2D systems can be readily manufactured in the laboratory, but it is also a limitation, since systems in 3D and 4D are physically more interesting.

In fact, my own critique of string theory follows closely the LQG critique voiced by Nicolai-Peeters-Zamaklar in hep-th/0501114. In section 6.1 they essentially argue that

1. The free bosonic string is 2D gravity coupled to scalar fields, and as such it is a useful toy model for 4D gravity coupled to matter.

2. The constraint algebra generically (except for D=26) acquires an anomaly, but the theory is nevertheless consistent for D less than 26.

3. By analogy, the constraint algebra of quantum gravity in 4D, which in covariant formulations is the spacetime diffeomorphism algebra, should generically acquire an anomaly.

4. No such diff anomalies in 4D appear in LQG, which hence is probably wrong.

I have twisted their argument a little, but only very little, in order to make the punchline:

5. No diff anomalies in 4D appear in string theory neither, which hence is probably wrong, too.

The idea to treat 4D gravity in analogy with 2D gravity is not new; it was proposed by Roman Jackiw and collaborators, see e.g. hep-th/9501016, gr-qc/9511048. What gives myself a competitive advantage is that I know the generalization of the Virasoro algebra to higher dimensions and its representations. It seems clear that if anomalies arise in 4D gravity, which they must in analogy with the 2D case, it is a good idea to know how to construct such anomalies. Otherwise is like trying to do string theory without knowing about the central charge.

39. **ark**
November 29, 2005

The existing string/brane theory is not going to succeed even if the swampland problem is resolved. This is so because of the Froissart bound (theorem) mentioned earlier. I completely agree with items 1 and 3. Moreover, I am about ro submit paper where items 1 and 3 are fully developed …

40. **Thomas Larsson**
November 29, 2005

Moreover, I am about ro submit paper where items 1 and 3 are fully developed …

You may wish to study the literature, lest you rediscover something which is already known.

41. **ark**
November 29, 2005

This is precicely what I've said in my 1st message: some things are either intentionally or unintentionally deleted from the string-theoretic textbooks. New generations of interested young people begin their study of string theories without proper historical background believing that foundations are corect and only the roof needs some repair.

42. **andy**

The Slate site seems to be down. Presumably it will be fixed soon.

44. **Anonymous**
December 1, 2005

http://www.techcentralstation.com/120105C.html

Leonard Susskind in 1970 'got stuck in an elevator with Murray Gell-Mann' who ridiculed Susskind's string theory: 'Gell-Mann responded with loud, derisive laughter.'

'… Some scientists regard string theory as an unjustified and over-hyped speculation. Peter Woit, who teaches mathematics at Columbia University, has a blog and upcoming book criticizing string theory as "Not Even Wrong." Moreover, contrary to longstanding hopes, string theory has not provided a concise formula — something like Einstein's E=mc2 — giving a deep mathematical explanation for why the cosmos is as it is. Instead, string theory increasingly has seemed compatible with diverse universes. That's something celebrated by Susskind but disturbing to some of his fellow string theorists; and to critics such as Woit, it's a sign the theory makes no sense.'

Two Conferences

November 26, 2005
Categories: Uncategorized

Two recent interesting conferences that have some materials available on-line:

Last week the Perimeter Institute held a workshop on Emergence of Spacetime. Some of the talks are available at the Perimeter streaming video site (scroll to the bottom of the list for the Emergence of Spacetime workshop). The first day talks which are available online cover a very wide variety of points of view, including Petr Horava on string theory, Renate Loll on causal dynamical triangulations and Seth Lloyd on “Computing the Universe”.

Earlier this month there was a program in Lisbon on Algebraic Geometry and Topological Strings. The program included mini-courses by Jim Bryan, Marcos Marino, Albrecht Klemm and Rahul Pandharipande.

Comments

1. **Who**
November 26, 2005

   that link doesnt get to it either
at least this should work to get the program of the workshop, with its schedule of talks:
http://perimeterinstitute.ca/activities/scientific/PI-WORK-5/schedule.php

   to download the slides and recording you probably do have to
go thru the steps Peter mentioned, scrolling down the menu and all.

2. **Chris W.**
November 26, 2005

   Xiao-Gang Wen has collected the papers most closely related to the ideas presented at the PI workshop on this page.

   I just finished watching the presentations by Markopoulou and Seth Lloyd. The latter summarizes his quant-ph/0501135, which was submitted to *Science*, and also touches upon the subject matter of quant-ph/0505064.

   In case you haven’t read much of or about Lloyd’s work, it can be very briefly summarized as follows:

   He starts by setting the problem (after an introduction by Lee Smolin). Forget trying to arrive at a quantum theory of gravity by quantizing the classical theory in some fashion. Instead, make a guess at a quantum theory that (one hopes) captures essential features of general relativity (as geometrodynamics!), and see how much headway can be made. So what’s the quantum theory? It’s a system consisting of simple two-way quantum gates — two inputs and two outputs. Feed an output of one gate into an input of another, constructing a simplicial lattice *and a causal order*. As in causal set theory one relies on the fact that the causal order determines the metric structure of spacetime up to a conformal factor. Getting this to work with two-way gates constrains the dimensionality of the spacetime to 4. (Lloyd spent some time on this in his talk.) The structure of system — the quantum computation — contains more information however, and this makes it possible to formulate an analog of spacetime’s energy-momentum content as well as a Regge-calculus-like construction and reproduce Einstein’s field equation.

   Of course there is fine print. In particular he makes the point that the computational universality of even such a simple system is a problem — his version of the string theory landscape, as it were. (He mentioned this; I’m not just throwing it in.) It can simulate too much; we would like to identify a principle that constrains the simulation to something closely approximating the Standard Model in a classical spacetime governed by $G_{\mu\nu} = 8\pi T_{\mu\nu}$.

   Markopoulou’s talk complements Lloyd’s in some respects, and she makes the connection explicitly; she also employs ideas from quantum information theory, with emphasis on the ramifications of coarse-graining procedures applied to a quantum computational “pre-geometry”.* Furthermore there are strong connections between spin networks as employed in LQG and string-nets as employed by Wen and, more generally, several points of contact with condensed matter models of fundamental physics, which is what led the organizers to invite Xiao-Gang Wen and G. E. Volovik to this workshop.

   ——————————
   * Remember John Wheeler’s “pregeometry as the calculus of propositions” in Chapter 44 of *Gravitation*?

   Also compare with the ideas outlined in physics/0505040.

3. **Wolfgang**
November 27, 2005

   Chris W.,

   interesting post about an interesting idea. Other people (e.g. Finkelstein) have made similar proposals and the difficulty is always to get GR in a classical continuum limit. Lloyd tries to use Regge calculus to do this, but the devil is in the details as you have noticed. In particular the details of the ‘microscopic elements’ of the quantum network; There sems to be an infinite number of possibilities how such an element could look like.
But perhaps we are lucky and the ‘simplest element’ can reproduce our world (and nothing more).

4. **Fabien Besnard**
November 28, 2005

   CDT is a very interesting theory also. However there is something that puzzles me. You are in a 4 d world, but you can show that at short scale it is 2 dimensional. Now you use 4 d building blocks to prove this. But suppose you were living at the 2 d scale : you would never think of using 4 d building blocks, you would use 2 d blocks instead. But now I think I remember from a paper of Loll et al that if you use 2 d blocks you get degenerate geometries, and anyway you don’t get 4 d at large scale. I think this is problem. You should be allowed to use 2 d building blocks if the short scale effective dimension is really 2. It’s a bit like supposing you have an acid solution and finding that the pH is 8. Now it’s an effective dimension, and maybe this is why I’m mistaken. Does Loll address this question in the conference ? I watched the loops 2005 one but unfortunately the sound was too bad in the part where she talked about this dimension issue.

5. **Wolfgang**
November 28, 2005

Fabien,

the fractal dimension of 2d euclidean dynamical triangulation is 4
or very close to it. It seems to work in both directions.
At this point I would emphasize "it seems".

6. **Who**
November 28, 2005

Fabien, to respond without being able to give more than my own interpretation:

I think one has to make a sharp mental distinction between the simplex dimension (a feature of the regularization) and the quantum observable which is the observed dimensionality at a given scale.

I think the simplex dimension is a combinatorial formality that helps to determine the network in which the blocks are assembled and how to shuffle and permute their interconnections, and the form of the Lagrangian.

the simplex dimension has no direct tie to the resulting spacetime dimension—–indeed prior to 1998, when they used plain DT, they found that when they used 2D and 3D simplices the resulting dimensionality was usually wrong. It would either be unbounded—essentially infinite—or too small. the resulting dimension was always too big (much too big) or too small.

in 1998 they started doing CDT and by 2003 they had found that in the case of using 2D and 3D simplexes the resulting expectation value of the largescale dimensionality was CORRECT. Actually the pathological behavior of too large or too small dimensionality can occur, but it has vanishing probability.

It took several years to do the computer simulations for the 2D and 3D case, so only in 2004 they got around to the 4D case.

I think in the CDT approach they do not pretend that the simplexes actually exist—they are just a combinatorial formalism that provides a framework for the dynamics and a regularization for the path integral.
When the model is compared to physical scale my understanding is that it is assumed the size of the simplexes is much smaller than planck length, the idea is that the size of the simplexes should go ideally to zero.
So I think of these simplexes as an imaginary formality, for performing the random Monte Carlo moves that implement the spacetime dynamics and for computing the path integral and expectation values of various things. I try to detach the idea of the simplex dimension from my expectations about the real spacetime dimension observed at various scales.

The result is that although I find your questions intriguing I nevertheless disagree when you say: "You should be allowed to use 2D building blocks if the short scale effective dimension is really 2."

You could be right though. I can't speak with any assurance and what you are pointing to does seem paradoxical. No time right now to try to shorten or clarify this post so have to leave it confused. maybe someone else can clarify.

7. **steven jones**
November 28, 2005

I'm visiting Duke this week, and they have this talk:

String Theory Seminar

2:45pm, 120 Physics Building (DUKE)

Katrin Wendland (University of North Carolina, Chapel Hill)

"Z_4 orbifold limits of K3 and a family of smooth quartic K3s: A
nonclassical duality"

Smells like bullshit to me… but perhaps someone can explain what the title means?

8. **woit**
November 28, 2005

Steven,

Not clear why you think Wendland's talk is any more "bullshit" than any other. She works on conformal field theories with target space a complex surface (i.e. 2 complex dimensions, 4 real dimensions). A K3 is such a surface, they come in families.

I think it's hard to make the case this is interesting for physicists. It seems to me to be the kind of thing many physicists have in mind when they say it belongs in math departments, not physics departments. Wendland does work in a math department, so physicists can't complain. There's a lot of interesting math involved here: conformal field theory and algebraic geometry. I don't know any particular reason to be interested in the specific geometry and models she is studying, presumably experts in this are could tell you more of the motivation.

9. **Chris W.**
November 28, 2005

New paper (25 Nov 2005) by Lauscher and Reuter reviewing their recent work and the similiarity of its conclusions to those of the recent work in CDT:

Asymptotic Safety in Quantum Einstein Gravity: nonperturbative renormalizability and fractal spacetime structure (hep-th/0511260)

10. **Fabien Besnard**
November 29, 2005

Wolfang :

>the fractal dimension of 2d euclidean dynamical triangulation is 4

This is very interesting. Can you tell me in which paper do they speak about this ? I could not find it. It is strange that such a consistency result is not more emphasized.

Who :

>So I think of these simplexes as an imaginary formality

Yes, this is precisely why it is important to prove it. In fact you seem to think about an even more stringent consistency condition : that the building blocks topology (and in particular dimension) have no importance whatsoever. I don't think that something that strong could be true, but maybe I'm wrong.

11. **Wolfgang**
November 29, 2005

Fabien,

http://xxx.lanl.gov/abs/hep-th/9806241

Already in the abstract they state that:

"the intrinsic Hausdorff dimension of usual 2d Euclidean quantum gravity is four, and not two. However, certain aspects of quantum space-time remain two-dimensional, exemplified by the fact that its so-called spectral dimension is equal to two"

The paper discusses the relationship between 2d Euclidean and Lorentzian dynamical triangulation and may shed some light on your question.

12. **Fabien Besnard**
November 29, 2005

Thanks a lot, Wolfgang. It seems a very interesting and important result, although I still don't understand why the spectral dimension would remain equal to two. I'll have to read and see.

13. **Chris W.**
November 29, 2005

By the way —

From hep-th/0505113; Ambjorn, Jurkiewicz, Loll; June 2005 (abstract):

> We measure the spectral dimension of universes emerging from nonperturbative quantum gravity, defined through state sums of causal triangulated geometries. While four-dimensional on large scales, the quantum universe appears two-dimensional at short distances. We conclude that quantum gravity may be "self-renormalizing" at the Planck scale, by virtue of a mechanism of dynamical dimensional reduction.

Compare with gr-qc/9310026; G. 't Hooft; October 1993 (abstract):

> The requirement that physical phenomena associated with gravitational collapse should be duly reconciled with the postulates of quantum mechanics implies that at a Planckian scale our world is not 3+1 dimensional. Rather, the observable degrees of freedom can best be described as if they were Boolean variables defined on a two-dimensional lattice, evolving with time. This observation, deduced from not much more than unitarity, entropy and counting arguments, implies severe restrictions on possible models of quantum gravity. Using cellular automata as an example it is argued that this dimensional reduction implies more constraints than the freedom we have in constructing models. This is the main reason why so-far no completely consistent mathematical models of quantum black holes have been found.
> Essay dedicated to Abdus Salam.

14. **Matti Pitkanen**
November 29, 2005

I think that I have good reasons to hope that this comment might not be classified as off topic but still I have unpleasant feeling in my gut(;-).

The effective 2-dimensionality is an interesting phenomenon which appears also in TGD framework. Apart from vacuum functional which carries information about 3-surface or equivalently about corresponding 4-surface analogous to Bohr orbit (exponent of Kahler function in the configuration space of 3-surfaces, the "world of classical worlds"), the quantum state carries only information about certain rather special 2-dimensional sub-manifols of 3-surface having interpretation as partons.

These partonic 2-surfaces represent cross sections of 3-D lightlike causal horizons of 4-surface meaning that partons are analogs of shock waves. It is not difficult to guess that a generalization of super-conformal invariance so that it applies to metrically 2-dimensional but topologically 3-dimensional lightlike causal horizons is involved. This superconformal invariance is present only for 4-dimensional space-time surfaces so that the theory predicts space-time dimension correctly from the requirement of generalized super-conformal invariance alone.

Matti

Off-topic, but did anyone else see Brian Greene on The Colbert Report last night?

Brian's heart just didn't seem in it. He trotted out the usual talking points though anyway. I really wish that string theorists wouldn't always immediately think in terms of strings when addressing unification. Don't they see a need to introduce the problem first and then say why strings are nice? From the interview you didn't get really any idea of why quantum theory and gravity were so hard to put together. Brian just said that there's this great theory out there called Superstring theory that may be the final theory that describes everything. I would've far preferred Brian giving a physical basis for why unifying gravity and quantum mechanics is so hard. And not one based on non-singular, stringy Feynman diagrams, please. (I realize that Colbert's Q&A sessions can be a bit daunting, but that's all the more reason to really figure out what it is you want to say beforehand.)

Case in point: I attended a talk by Seth Lloyd this week where he described a very conceptual approach to quantum gravity. His springboard was the GPS system. Satellites with clocks all tracking one another and mapping out spacetime. That kind of explanation could capture the imagination of the public much more than non-singular Feyman diagrams or extra dimensions.

To string theorists, I say, please step back a little bit when addressing the public before launching into your talking points.

16. **Anonymous**
November 30, 2005

god, ali, string theorists like that should be strung up…

17. **woit**
November 30, 2005

Anonymous,

Please stop with the content-free abuse of string theorists, both ones who are my colleagues and ones who aren't. It has been justifiably pointed out to me recently that there's sometimes a Motlesque tone to many of the comments here, which is not a good thing. Leave the personal abuse tactic to Lubos and colleagues since it's often the only argument they have.

18. **Who**
November 30, 2005

" Leave the personal abuse tactic to Lubos …"
Amen to that. Self-defeating.

BTW of course like everyone else, I would imagine, I have have the highest respect for Frank Wilczek, but I was disappointed by parts of his article with Tegmark and others

http://arxiv.org/astro-ph/0511774

"Dimensionless constants, cosmology and other dark matters"

the reasoning involving the "prior" probability distribution on the vector of 31 dimensionless constants seemed nebulous or fishy.
the assumption of a particular eternal multibubble inflation to give a prior. Bayesian reasoning can be a very good thing but unexamined foundations here could be rotten.
wonder if anyone else felt worried by this paper

however nothing adhominem—only highest respect for Wilczek and his fellow authors.

19. **anon**
November 30, 2005

"Case in point: I attended a talk by Seth Lloyd this week where he described a very conceptual approach to quantum gravity."

Seth Lloyd's "theory of quantum
gravity" has much less predictive value than String Theory, and very little original content (it consists mainly of the ancient Regge ideas). For all his faults, Lubos has given a very intelligent assessment of Lloyd's extremely naive, wishful thinking ideas about quantum gravity. It's sad that some of the people (not Woit or Wolfgang) commenting in this blog seem to think that Lloyd's ideas are a respectable alternative to string theory or even a serious foundation for a theory of quantum gravity. I'm afraid that those highly gullible people are guilty of judging a book by its cover, in this case judging Lloyd by the fact that he works at MIT.

Even within quantum computing, Lloyd's contributions have been minimal. (if you disagree, please tell me what they are). If somebody asked me who is the quantum computation counterpart of Michio Kaku, I would say Seth Loyd. Lately, Seth has decided to make a foray into quantum gravity, and he is way out of his depth.

20. **Andreas**
November 30, 2005

What I do not understand about Lloyd's approach is that at some point he ad hoc introduces a continuous manifold in which he embeds his QC-graph. What is the motivation for this and "where" does the manifold come from? It does not seem to be a truly "emerging spacetime" concept.

21. **Chris W.**
December 1, 2005

anon,

It might help others in assessing Lubos Motl's comments if you could point to some approaches to quantum gravity — other than string theory of course — that he has *not* dismissed as a naive product of wishful thinking and half-baked speculation, or a reasonably well developed but conclusive failure. "String theory is the only game in town and everything else is a waste of time, talent, and research funding" doesn't cut it.

After watching his antics for more than a year and a half I find it difficult to care about anything Motl says anymore. If I want a usefully critical perspective on any idea I happen to find interesting there are plenty of other places I can find it.

22. **Wolfgang**
December 1, 2005

anon,

the proposal of Seth Lloyd is an interesting idea, just 'some details' need to be worked out; as in the story of Pauli who claimed that he can paint like Tizian once he has worked out 'some details'.
By the way there are many other great ideas which just need 'some details' be worked out (LQG, causal sets, etc.)

With superstring theory it is almost the other way around. A lot of details have been worked out and it all looks very promising.
I am just not convinced it is such a great idea 😎

But what do I know…

23. **Wolfgang**
December 1, 2005

By the way, there is a fresh paper related to this discussion:
"Spin networks, quantum automata and link invariants"
http://xxx.lanl.gov/abs/gr-qc/0511161

24. **Chris W.**

December 1, 2005

The aforementioned paper is one of several included in the proceedings of QG05 (September ’05). The list of participants is impressive, and many of the abstracts are very interesting and relevant to this post.

25. **Brett**
December 1, 2005

I happened to be in Seth Lloyd’s first ever quantum computing class, and in the last lecture, he presented some of his first ideas about quantum gravity. To me, they seemed hopelessly naive, built almost entirely on dimensional analysis (something that is not necessarily useful in nonperturbative GR, which was what he wanted to talk about). His ideas have gotten a little more sophisticated since then, but they are still quite unimpressive.

26. **Shantanu**
December 1, 2005

Peter (and others) what do you people think about Finkstein’s aproach to
quantum gravity based on plexors ? sometime back I remember reading
on usenet that his work (though heroic) has received very little attention.
I don’t recall it discussed even once here or on cosmicvariance

27. **Quantum_Ranger**
December 1, 2005

As good as the talk by Lloyd was, PI emergence of spacetime, I was not surprised that during this talk he admitted he was at the same “car-salesman” seminar as detailed here:

http://www.physicsforums.com/showthread.php?t=89240

in the early eighties!

This San Francisco seminar series of the early eighties, has really a lot of explinations for the emergence of String Theory and Anthropic Rationale.

28. **Matti Pitkanen**
December 2, 2005

Personally I cannot take seriously the discretization of space-time continuum. A much more elegant manner to introduce
dicreteness at the basic level consistent with basic ideas fo algebraic geometry emerges if one accepts all number fields, also p-adic number fields and their extensions as building blocks of physics.
This more or less forces the view that real and various p-adic physics (possibly representing physical correlates for intention and cognition) are obtained by analytical continuation from rational physics both at classical spacetime level and quantum level.

A possible application is the definition of fermionic determinant playing fundamental role in QFT:s and also in TGD and being plagued by divergences. The idea is that the restriction to rational eigenvalues of the appropriate Dirac operator could make the determinant finite. Entire hierarchy of determinants corresponding to various algebraic extensions of rationals emerges perhaps defining a hierarchy of finite Dirac determinants. This hierarchy would not be a calculational trick in TGD Universe but represent an actual physical hierarchy having natural identification in many-sheeted space-time of TGD Universe.

Matti Pitkanen

Sciencegate

December 2, 2005
Categories: Uncategorized

The editors at Seed magazine have started a new blog about science called sciencegate, which contains a wide variety of interesting material. One of the recent postings is called Strung Out on the Couch; it's by Joshua Roebke and not exactly complimentary about string theory. Here's his analogy for the current situation of string theory:

Think of it this way, a precocious little genius, who everyone has been touting would do great things in the world, finally grows up. Now imagine he's 30 years old, living at home having not accomplished much, and his mom keeps going on about how great he is and is still going to be. You'd probably just want to tell him to grow up and make something of all that potential instead of just talking about how he's going to get off the couch.

Before Lubos and others start the usual personal attack on any string theory critic as not knowing anything about the subject, it's worth pointing out that Roebke spent several years as a graduate student working on string cosmology before leaving academia.

Comments

1. **ks**
   December 2, 2005

   Sciencegate – sounds like a big scandal these days…

2. **A.**
   December 2, 2005

   Boy, who is this Joshua Roebke? Please present list of his publications, otherwise its difficult to judge from his repetitive and, I may add, boring piece whether he came to these conclusions himself after working hard many years in " string cosmology", or he is just this blog's big fan and read a couple of articles in new york times and such. As far as I checked arxiv.org produced no records of Joshua Roebke.

   I am in no way trying to "personally attack" you, but , in my opinion, unless you Joshua Roebke have actually wokred in the area on the level to produce something more or less deserving attention of the community, your comments have zero value. Who are you to comment on string theory?

   What is it with you people? Why everyone thinks starting his own blog is a good idea? Everyone is confident that his thoughts are the correct ones, "everyone else is stupid, I am smart"
   Dont start a blog, there are more than enough blogs, Peter doing his job quite well already. Just go home , or better go to your office, sit there from 8am to 8pm, and work on a problem. Maybe you will feel better.

3. **Ralph**
   December 2, 2005

   Apparently stringists can produce any number of possible universes from their theories, except it seems, the one we live in.

   I think it is time to formulate this as a scientific hypothesis "the anti-string hypothesis":

   Our universe is uniquely determined, by the inability of string theory to approximate it.

4. **woit**
   December 2, 2005

   "who is this Joshua Roebke?"

   Well, first of all "A.", who are you? Don't you think it's kind of disgraceful behavior to attack others from behind the cloak of anonymity?

   It's funny how predictable string theory partisans are these days. When Roebke wrote to tell me about the Seed blog and what he'd written for it, I wrote back to tell him I'd be happy to mention it here, but I could confidently predict his professional competence would be immediately attacked by Lubos and various others of his ilk. If you actually had any arguments to answer the ones Roebke is making, you'd be making those and not instead attacking his fitness to make those arguments. But go right ahead and behave like this, by doing so you and others are doing a great job of convincing ever increasing numbers of people that you are both intellectually and morally bankrupt.

   If he's in the mood I suppose Roebke can defend himself. I have met him and can tell you that his understanding of string theory appears to be consistent with what you would expect given his background, that of a good physics Ph.D. student who did research for a while in the subject, but ultimately decided to do something else. Your criterion that no one can criticize string theory unless they have written papers on the subject is that of a member of a cult convinced that only the opinions of true believers are of any value. By now lots of smart people have gone through the experience of spending years of their lives learning about string theory, finally reaching the point of realizing that the theory hasn't lived up to its promise, and that devoting the rest of one's life to working on it might not be such a great idea.

5. **secret milkshake**

Loop Quantum Gravity is teh suck!!1! It is for the losers and the nerds.

Kool kids do teh strings. They might have lots of vacua but they also have lots of funding money and womens LOLOL. Also they use kool words liek heteroteric so they are the real daddy. And they have simetries in hodgy-podgy mirrors too!!

9. **Christine Dantas**
December 2, 2005

Dear A.:

You say:

What is it with you people? Why everyone thinks starting his own blog is a good idea? Everyone is confident that his thoughts are the correct ones, "everyone else is stupid, I am smart"
Dont start a blog, there are more than enough blogs, Peter doing his job quite well already. Just go home , or better go to your office, sit there from 8am to 8pm, and work on a problem. Maybe you will feel better.

Internet is just like that: you will find a broad spectrum of material, from garbage to excellent. The same is valid for blogs of course. I have started my own blog even though I know several of them, from garbage to excellent. At the same time, I never thought that "everyone else is stupid, I am smart". Maybe a lot of people think like that, but I am sure many do not.

I am not here to defend one approach to quantum gravity or another (much less the people involved), nor to say that I have a good blog. I am interested in all of the ideas towards a quantum theory of gravity as long as they seem sufficiently sound or look interesting enough to me. That is my blog. Yet, I do work from 8am to 8pm, or even more, and that involves several responsabilities as well as my own personal projects. So having a blog is not incompatible with doing hard work. This is valid for many people, as much as it is not valid for many others.

There is a little more I would like to comment on blogs. We are living in an epoch were ideas on quantum gravity are being constructed. It is a formidable problem. I see this as a very exciting period in the history of physics, and the various discussions I read daily in the (good) blogs are, to my opinion, very illustrative of our times. So these blogs are useful, and in some sense will serve as unique testimonies of our struggle towards quantum gravity.

Now, concerning the problem of who should be considered competent to "judge" a given approach. It seems clear to me that "judgement" is a strong word and an inappropriate one in science, except from the point of view that nature is always the final judge, since it is obviously nature what we want to probe, describe and ultimately explain.

Intelligent and constructive criticism is what is necessary in order to make progress. But this is hard to find. String theory in particular does not "help", and it is a good example in that sense. It requires years and years of very hard work in order to gain some knowledge of its basics. So, it seems inevitable you must be an expert to say something technically valuable considering the huge amount of mathematical material involved.

At the same time it is an obviously tricky or paradoxical situation, specially when one finds out that apparently there are no predictions of the "theory". So, considering this state of affairs, it seems natural that one needs not to be an expert to have the strong impression that it might be "not even wrong".

I must say I share this overall impression, although I am not saying I have a final position on this. I am not competent enough to offer a reasonable or more technical criticism on this matter, so I stop here to go for my daily hard work.

A final, perhaps also obvious thing: technique or knowledge is nothing without wisdom, but that is another story.

10. **Aaron**
December 3, 2005

I am in no way trying to "personally attack" you, but , in my opinion, unless you Joshua Roebke have actually wokred in the area on the level to produce something more or less deserving attention of the community, your comments have zero value. Who are you to comment on string theory?

Is this a parody? I hope so….

The difference between string theory and ID, BTW, is that string theorists dream of making positive statements. IDers never will.

11. **Adrian Heathcote**
December 3, 2005

I think the problems with String Theory go way back to the beginnings of Quantum Mechanics or Quantum Field Theory. There was a misconception as to what was needed to bring them together with General Relativity.

The fundamental difference between QM and GR is that, in the former, observables are operators (or at least are the results of operators acting on states to yield eigenstates). In GR they are pretty much just functions—functions of many variables, but still just functions, just as in classical physics. Getting a unification means, at the very least, having a mathematical formalism that represents the observables in one single way. But then, going backwards, it would be possible to recast QM in that same formalism, but just neglecting gravity. We would then have the revised mathematical structure for QM with the measurement problem—just what so many now want.

But I think this got fudged way back at the beginning. The Copenhagen interpretation effectively hid the interesting features of QM, and masked the important mathematical structures: the state space K of pure and non-pure states, the self-adjoint operators and their awkward formal properties. (Just how much of what is true of bounded operators really carries over to the unbounded case?)

These things got buried. And quantum field theory seemed to adopt a purely heuristic attitude to QM. It took the little bits that it liked—Heisenberg Uncertainty, transition probabilities, the Planck length—and downplayed the rest. You could read what particle physisit's wrote and think for all the world the universe was still basically Newtonian. And as time has gone on this cavalier attitude to QM seems only to have gotten worse.

String Theory is just the culmination of a long period of not getting the fundamental problem and sweeping the real difficulties under the rug. The renormalisation problem was the real clue that something had gone very wrong at a basic level. The calculational sucess of QED just allowed the sleepers to stay asleep.

Now we have a very elaborate mathematical structure that has no contact with reality. But given the history this was bound to happen. Physists started out fudging the conceptual issues and caring only about the calculations—the irony is that we have no more calculations to care about, but we have a whole lot of bad concepts.

Just my 2 cents.

12. **Adrian Heathcote**
December 3, 2005

Sorry, that should have said:

”We would then have the revised mathematical structure for QM without the measurement problem—just what so many now want.”

13. **Christine Dantas**
December 3, 2005

Anonymous Says:

Is this kind of crackpotism, which does make tested and testable predictions by the way, would be easy to write off as crazy.

I think there is a perceptible difference between “crackpotism” and “theory under construction”. Baez index list on the former is a good reference to unmask potential crackpots; scientific method on the latter is usually enough, and the result is progress or refutation.

A “grey zone” however is always possible and that is where the danger lies. This is specially symptomatic when theorizing about nature at regimes where experimentation is very difficult or observation relatively inaccessible. So you have a “theory under construction” that cannot be adequately or promptly investigated under the conventional rules of the scientific method. One may even end up with a mathematically consistent formulation, but in what sense it is satisfying? One may think it is “beautiful”. One may think is the only proposal for a given problem. So this is the grey zone because it is all under the umbrella of personal taste.

I had the curious experience a few years ago of giving a talk on the basics of braneworld scenarios to a mixed audience of astrophysicists ranging from specialists on gravitational waves, CMBR, high energy, extragalactic, galactic and stellar astrophysics. This is a much harder audience than a general public audience, because these people are well versed in the scientific method. They deal with very, very hard problems, and even problems that may need new physics. Although I did my best and they enjoyed the talk, most of them thought there was something quite disturbing on the overall idea. I am sure this is symptomatic of the grey zone.

As I see it, the only obvious way out is to work as hard as possible on the problem of identifying possible observable effects of a given quantum gravity proposal as it is being constructed and look for these effects, otherwise one is hopelessly stuck in the grey zone, sometimes without even being aware of it.

14. **Arun**
December 3, 2005

In reply to Michael at 7:14 PM, just what constitutes a research program in ID? There would be scientists receptive to ID if there existed any sch thing. ID is intellectually sterile. String theory is far from sterile, its problem is that its productions don’t yet make contact with the real world.

15. **Arun**
December 3, 2005

Peter, I think you did Joshua Roebke a disservice by not including the lines just previous to what you quoted.

> Don’t get me wrong. I actually love string theory and think it’s light years ahead of other theories. I follow the papers, and excitedly read them in earnest. I just think perspective and critique are necessary for progress.

16. **Quantoken**
December 3, 2005

Joshua Roebke said:
“I actually love string theory and think it’s light years ahead of other theories.”
Oh sure, how could you not be light years ahead of others, if you started several decades before other theories were first proposed, and you have several orders of magnitude more researchers working on the fields, and many times more public funding invested in supporting you. Surely you are light years ahead of other approaches. But it doesn’t make you look good. What matters is are you on the right direction? **You are on the wrong approach**. So the further light years you go forward in your dead end, the further away you are from the ultimate answer!!! Look at the 10^500 landscapes figure. You may be light years ahead but you have another 10^500 light years to cross in your front. Mean while the theory that is on the correct approach doesn’t need to go a light year: It only needs to reach the moon.

17. **ks**
December 3, 2005

I think there is a perceptible difference between “crackpotism” and “theory under construction”.

Unfortunately cargo-kult-science according to Feynman does anything right, is a true slave of scientific ritual and jargon but is nevertheless not science. This reminds me somehow to the old catholic problem off finding a true saint or a real representative of god obtaining all the priviliges of god including the permission to kill. Both science and religion are hunted by their own double or shadow.

It is interesting that you find the difference “perceptible”. Ususally strong differences do not follow from something as subjective as perception in particular the perception of strange social behaviour but from a certain axiomatic or precise and objective diagnosis. Misusing authority is therefore not so much an accident in evaluating competing researchers work but has to be expected. On the other hand the theory of social systems provides a self-referential answer presupposing a running science business: viable is what gives rise to connectivity. As an addition of my own I would guess that connectivity is not only a conservative mechanism of affiliation in modern societies but can be understood more dynamically like trading commodities on a stock-market.

Peter, explain how someone can make a cheerful comment 😉

23. **A. nonymous**
December 3, 2005

I think Joshua's article takes approximately the right tone towards string theory. It is not yet certain that srting theory will never be able to make a prediction, although there are some signs that this might be the case. The real problems for physics are the position that string theory has taken in the common view of theoretical physics as the only option available and the fact that young theorists don't really have any career options apart from string theory or condensed matter, while faculty positions are increasingly being occupied by string theorists at the expense of other legitimate research programs.

There is, of course, a separate problem with the string theorists themselves, namely that they are arrogant and narcissistic, to the degree that they dismiss all non-string theorists as idiots and all non-string theory physics as irrelevant. String theory shows practically all the signs of groupthink, namely:
1. Illusion of invulnerability
2. Unquestioned belief in the inherent morality of the group
3. Collective rationalization of group's decisions
4. Shared stereotypes of outgroup, particularly opponents
5. Self-censorship; members withhold criticisms
6. Illusion of unanimity (see false consensus effect)
7. Direct pressure on dissenters to conform
8. Self-appointed "mindguards" protect the group from negative information

Lubos would no doubt be pleased to know that he is a "mindguard".

On the subject of intelligent design, it might be instructive to see how A's comment looks from that point of view:

I am in no way trying to "personally attack" you, but , in my opinion, unless you have actually wokred [sic] *in the area on the level to produce something more or less deserving attention of the community, your comments have zero value. Who are you to comment on intelligent design?*

ID = (100 – IQ)/IQ

A negative ID is a sure sign that IQ

27. **Jose**
December 4, 2005

String theory predicts the BH entropy formula, string theory predicts a 10-dimensional space-time, string theory predicts how particles interact at [tex]10^19[/tex] GeV. STRING THEORY MAKES PREDICTIONS. The difficult task is going from [tex]10^19[/tex] GeV to the actual energy that can be reached in experiments.

In any case, if string theory is a wrong physical theory, string theory has given a great amount of mathematical results, and it is a respectable endeavour of the human mind.

28. **woit**
December 4, 2005

Jose,

1. It would take too long to go into the exact status of black hole entropy calculations in string theory, but there is no solid "prediction" for physical black holes, at best an argument that you get the semi-classical limit that you expect for any thing that deserves to be called a quantum version of gravity.

2. String theory doesn't predict 10d spacetime (have you heard of M-theory?). And if it did, there's the problem that we only see four dimensions.

3. String theory doesn't predict how particles interact at the Planck scale (have you heard about M-theory?).

STRING THEORY MAKES NO PREDICTIONS. NONE WHATSOEVER, NADA, ZIP.

29. **Juan R.**
December 4, 2005

Jose Said,

> String theory predicts the BH entropy formula, string theory predicts a 10-dimensional space-time, string theory predicts how particles interact at 10^19 GeV. STRING THEORY MAKES PREDICTIONS. The difficult task is going from 10^19 GeV to the actual energy that can be reached in experiments.

String theory does **not predict** BH formula because i) compactification is done *by hand*, ii) string theory 'BH' are highly idealized objects are not general relativity BH, iii) etc.

String theory does **not predict** a 10D spacetime. The 10D spacetime is introduced *by hand*, with a strange 'compactification' of the rest 16D. Not forget that supersimmetry is not correct at low energies. Not forget that all 10D are equivalent and for comparison with observed 4D universe, 6D may be differentiated by hand. Not forget that a new dimension is hidden in the perturbative regime. Not forget that still nobody know if 11D is the correct dimensionality for M-theory, etc.

The 'prediction' (of course there is **not prediction** because topology and geometry of background spacetime and others features are choosed by hand) of interactions at 10^19 GeV are just scattering amplitudes with the wrong large distance limit. There is not dynamics, there is not adequate classical limits (GR causality structure is broken when taken classical limit of gravitons), etc.

Etc,

Etc,

> In any case, if string theory is a wrong physical theory, string theory has given a great amount of mathematical results, and it is a respectable endeavour of the human mind.

Many other theories give mathematical results. Moreover, the real impact of **string theory** on math is easily sumarized:

epsilon, when epsilon –> 0.

I, at least, am able to distinguish between math and physics. For example between NC geometry (math) and M(atrix) theory (physics).

30. **God**
December 4, 2005

Woit, religion makes more predictions than string theory!

Religion predicts a day of judgement! Religion predicts sinners will go to hell. This is perfectly testable: die and you'll see… Religion predicts all kinds of things that you can test if you are desperate enough…

String theory merely predicts 10^500 universes, a landscape of universes, that there could be any number of branes, and so forth.

I think you've got to start saying that string theory is not 'as bad as religion', but rather that religion is a lot more scientific than strings. Be honest!

31. **Wolfgang**
December 4, 2005

Peter,

> STRING THEORY MAKES NO PREDICTIONS.

a standard argument (I guess E. Witten is the author) is that string theory predicts supersymmetry [*]. Of course, we do not know at which energy scale we may see it…
My question to you is this:
Assume that the LHC (or ILC) will provide strong empirical evidence, e.g. for a MSSM or NMSSM model.
What would be your reaction?

[*] Lubos became quite angry when I stated once that string theory 'assumes' supersymmetry in order to be consistent; It is the same IMHO, string theory/M-theory requires supersymmetry at some energy level to be consistent, at least at our current understanding.

32. **anon**
December 4, 2005

Wolfgang,

Where you say 'string theory predicts supersymmetry' you are really saying that Witten and others developed string theory so that it would do this. It is an ad hoc 'prediction', like epicycles.

Lubos gets angry all the time, you should know. Being a string theorist, he has a good excuse, because the news keeps getting worse.

If and when empirical evidence is found for strings, that will be the time for it to be taken seriously. The whole problem is that it is being taken seriously by the world now, when there is no evidence.

33. **woit**
December 4, 2005

Wolfgang,

It doesn't really make sense to "predict supersymmetry" if you then say it may be broken at arbitrarily high scale and be indistinguishable from no supersymmetry. The real question is whether it is broken at LHC energies and can thus do one of the main things it is supposed to, solve the hierarchy problem. My guess is that the LHC won't see supersymmetry and I'll be surprised if it does, especially if it sees some random MSSM spectrum. If this does happen, that's certainly some encouragement for the ideas that have led people to work on string theory, although far from solid evidence for string theory.

34. **Wolfgang**
December 4, 2005

anon,

I am not very interesting in the syntax or semantics of the word 'predict'.
Also I do not care if Lubos is angry (but he is sometimes entertaining when he is).
But I would like to hear Peter's opinion, since he is a strong critic of string theory (like many here), but seems to really know QFT and particle physics. And my question is simple and straightforward:
How would you react if the LHC (or ILC) provides strong evidence for supersymmetry?

I would see this as strong evidence that superstring/M- theory is at least on the right track.

35. **Wolfgang**
December 4, 2005

Peter,

ooops, seems that posts have crossed here.
Thank you for the response.
When you say

> If this does happen, that's certainly some encouragement for the ideas that have led people to work on string theory

I interpret this as you saying "with strong evidence for supersymmetry I would eventually change my opinion on superstring theory" ?

36. **woit**
December 4, 2005

Wolfgang,

Our comments crossed. I'd agree that supersymmetry at the LHC would be some sort of evidence that superstring/M-theory might be on the right track, although I wouldn't go so far as to call it "strong evidence".

It would also depend a lot on exactly what was seen and what sort of hints this gave about the mechanism for supersymmetry breaking.

37. **Chris W.**

December 5, 2005

> I am not very interest[ed] in the syntax or semantics of the word 'predict'.

That's unfortunate. I think the semantics of this word is badly in need of review under the current circumstances.

It used to mean something very much like this:

An experimentalist finds a way to reproduce a particular effect, which they characterize with one or more measurements. That is, they identify those features of the experimental situation that must be controlled to bring about the same effect (within certain error margins) in multiple runs of the experiment.

The experimentalist then says to a theoretician: "I can reproduce this effect, but I can't explain it. Can you tell me why the effect occurs in this situation, ie, given the features I have identified, and also calculate the results I have measured using the features of the experimental setup as inputs to the calculation?"

Now, I would assert that the theoretician's job is to do this, and do it with a *minimum* of auxiliary assumptions, ie, in addition to the theory (the explanation) being tested. Any auxiliary assumptions that are made should be *independently* verifiable by the experimentalist, so they cannot be freely used to fit the prediction to the result.

It appears to me that string theory in its current form must make extensive use of auxiliary assumptions that can't be independently tested in order to make anything like a definite prediction of any given physical effect. Of course one could say, "well, I'm sorry if you don't like it that world is this complicated, but this appears to follow from the basic principles of the theory. The world can be as complicated as it likes; we can't dictate the structure of physical reality for our methodological and epistemological convenience."

I would assert that in fact we *must* "dictate the structure of physical reality for our methodological and epistemological convenience". In doing so we may find that those dictates are repeatedly violated, but nonetheless our theories must be as restrictive and unambiguous in their predictions as we can make them. If one thinks the world can be arbitrarily complicated then one might as well abandon any attempt at testable explanation, and simply accept the *prima facie* complexity of the observed world, along with whatever interpretive mythology one finds most comfortable.

It is not noted often enough that the deep symmetries of the physical world, and moreover, the decomposability of physical systems into largely independent parts, have great epistemologic as well as aethestic significance.* In a world like that of the astrologer, in which physical influences of arbitrary form and magnitude can be propagated over arbitrary distances at arbitrary speeds, one can hardly imagine any effective dialogue between experimentalists and theoreticians, or even among observers trying to reach intersubjective agreement about what they perceive. We have not been merely discovering what the physical world is like for the last several centuries; we have also been gradually discovering how it is possible for us to know the world at all. The anthropic principle offers an answer to this question that is perhaps suggestive but ultimately scientifically vacuous. There is yet reason to believe we can do better.

38. **Christine Dantas**
December 5, 2005

According to Amelino-Camelia et al. (gr-qc/0501053), "string theory may predict many new low-energy effects, but it can also be easily tuned to avoid all of them."

I have just highlighted their paper today in my blog page (see their very nice fig.5).

39. **Colin Rosenthal**
December 5, 2005

That is a somewhat unusual usage of the word "predict".

40. **anon**
December 5, 2005

"string theory may predict many new low-energy effects, but it can also be easily tuned to avoid all of them"

What beautiful flexibility! Those who love string theory will be enchanted. Lubos will be delighted. Why bother testing string theory when it is so vague any result is consistent with it?

41. **Christine Dantas**
December 5, 2005

Amelino-Camelia et al. also write (page 11 of that same paper):

"The low-energy physics of String theory, as presently understood, could be very rich, with the presence of new fields and the possibility of a variety of new effects. This may provide the basis for a large phenomenological effort, even though one should keep in mind that **the new effects are not genuine 'predictions' of String theory**: String theory could make room for these effects but it could equally well suppress them all. **It appears at present not possible to falsify String theory on the basis of low-energy phenomenology** , but it would nonetheless be very exciting if any of the new effects that String theory may host was actually found."

So it is clear enough that the motivation that Amelino-Camelia et al. focuses on is the search for new low-energy physical effects per se. They clearly state that string theory does not actually predict them, nor can be falsified by them, it just can accommodate them if one wishes.

I really look forward to a technical, non-passionate (if possible) opinion of string theorists and non-string theorists on this matter (specially on Amelino-Camelia et al.´s paper). If considered off-topic, please apologize and feel free to redirect to my blog page.

42. **Juan R.**
December 5, 2005

Wolfgang Said

> Lubos became quite angry when I stated once that string theory 'assumes' supersymmetry in order to be consistent.

Since string theorists like to claim that string theory does predictions, a brief historical review of 'predictions' would be interesting…

String theory began from his **first failure** on explaining strong force on a 4D world (and substituted by QCD), then predicted **wrong** Lorentz symmetry when extended and for correcting this **wrong prediction** 22 additional dimensions were introduced by hand.

Then, **wrong** dimensionality was predicted and for correcting this **wrong prediction** KK was introduced by hand.

Then, tachionic modes were obtained and this **violated again** experimental data, and for correcting this novel **wrong prediction** supersimmetry was introduced by hand.

Of course, string theory continued doing **wrong predictions** and evolutioned until the modern M-theory nobody know that is!

However, supersimmetry is a fascinating example of how string theory is wrong.

String-superstring theory predicts either

superimmetric non-tachionic world

or

non-superimmetric tachionic world.

Curiously our observed universe (at least at low energies) is

both non-superimmetric and non-tachionic.

Therein the extended criticism in relevant literature that string theory predicts **nothing of this world**.

If one follows scientific method (string theorists do not) then one may develop a first theory for:

– 4D Standard gravity and

– Compatible with non-superimmetric and non-tachionic known Standard Model.

At future HLC-data is supersimmetry found?

No problem, to generalize above theory adding supersimmetry to HIGH energies (NOT at all energies).

At future 'cosmic-acellerator' are hidden dimensions found?

No problem, to generalize above theory adding more dimensions to HIGH energies (NOT at all energies).

The 40 years failure of string theory is because string theorists want say how universe may be.

Science is about we can observe, NOT about we want observe and complete ignorance we really observe.

Juan R.

43. **Alejandro Rivero**
December 5, 2005

Juan, we have actually found [supersymmetry 🙂] Perhaps Lubos is right after all.

44. **Juan R.**
December 5, 2005

Alejandro Rivero,

Since i said is crystal clear, it appears that after all Lubos is again wrong 🙂

If anyone want help to Lubos in his research, then may try to find a well-defined mathematical limit where superstring actions turn, at least, **non-supersimmetric**, all looks 4D at large distances, and masses are non zero.

Juan R.

Center for CANONICAL |SCIENCE)

45. **dan**
December 5, 2005

is m-theory, are strings supposed to make up quarks (and electrons) directly, or do they make up preons which then make up quarks?

46. **dan**
December 5, 2005

lubos has claimed m/string theory predicts BH entropy, but LQG does not. apparently john baez claims LQG does predict BH entropy. what is the status of BH entropy in LQG (and BI-like CDT) gravity?

47. **Juan R.**
December 5, 2005

dan,

see Lee Smolin said. Question 4 of page 60 of arXiv:hep-th/0303185 v2 11 Apr 2003.

BH entropy is 'solved' on LQG, whereas only partial results and many open questions remain on the string side.

I do not follow this topic in detail now (i discovered that string theory is a waste of time) , but some few years ago, string theorists were working with certain idealized states that they 'believe' that *could* explain GR black holes.

Yes! almost all in string theory are beliefs and conjetures…

See also section 6.3

> The results in string theory do not concern, precisely, black holes, as they are found in a limit in which the gravitational constant is turned off.

Since LQG arises directly from quantization of GR field equations, the BH studied are more close to GR (Schwarzschild) BH.

Juan R.

Center for CANONICAL |SCIENCE)

48. **Chris Oakley**
December 5, 2005

I would like to draw everyone's attention to the prefix "pre" in the word "predict". It means "before". In other words, it describes a situation where you guess it is going to happen before it actually happens. Examples of this are:

1. Maxwell guessed that it would be possible to observe a displacement current before anyone actually did. It was therefore a "prediction".

2. On the basis of observed patterns of quantum numbers for baryons, Gell Mann "predicted" a baryon of strangeness -3 and mass of about 1680 MeV. In 1964, a particle fitting this description was observed. A fine prediction.

One can, of course, predict things which turn out to be wrong. But there are also things which never were predictions in the first place. For example:

1. Special relativity does not "predict" four dimensions. Four dimensions are assumed at the outset.

2. Superstring theory does not "predict" gravity. General relativity – a tested theory of gravity – is one of the inputs (although it is not clear that one can get it back).

3. Superstring theory does not "predict" supersymmetry. Supersymmetry is assumed at the outset.

I am happy to answer any further questions that anyone might have about the usage of this word.

49. **Jose**
December 5, 2005

"Superstring theory does not "predict" gravity. General relativity – a tested theory of gravity – is one of the inputs (although it is not clear that one can get it back)."

This is not true Chris if we suppose that particles are strings then we are led to the existence of massless spin 2 particles, that is gravitons, without more assumptions.

50. **A. nonymous**
December 5, 2005

Jose is more or less right, but one could also say that there is a selection bias; mathematical formalisms in which Einstein's equations appear are going to be selected and studied more intensely than those which don't 'predict gravity'. Thus, the fact that the currently most intensively studied theory has the field equations inside it is not particularly surprising.

The question at hand – whether string theory has earned the attention it has received – is to be decided by asking what predictions it has made which were not simply the reasons for paying attention to it in the first place. The result seems to be that string theory has produced dualities, AdS/CFT and so on, which are interesting, but which don't actually qualify as experimental predictions.

It seems likely to me that in the distant future, string theory will occupy a position in relation to gauge theories similar to that presently occupied by group theory in relation to quantum mechanics. That is, it will be regarded as an invaluable tool, although it is really a branch of pure mathematics which on its own makes no statement about nature.

51. **Aaron Bergman**
December 6, 2005

what is the status of BH entropy in LQG (and BI-like CDT) gravity?

There is some debate on this point. There has been a calculation done that obtains a number proportional to the area with an unfixed constant of proportionality. I don't think there's a real sense that this calculation was done in LQG; it's done in a sort-of hybrid formalism.

From my reading of the calculation, I think that the proportionality to the area is something assumed by the particular formalism used. In other words, I don't think it is true to say that black hole entropy has been derived to be proportional to the area in LQG. Others disagree.

I discussed this a bit with Lee Smolin here — scroll down a bit.

I discussed this a bit with John Baez here.

I know of no discussion of black hole entropy in CDT.

52. **Chris Oakley**
December 6, 2005

I do not understand why, when talking about String Theory, I always have to choose the optimistic version, whereas when talking about most other scientific theories, I am allowed to tell it like it is.

If we have to select, among the various candidate String theories, the ones that contain Einstein's equations, then Einstein's equations are not a "prediction" of String theory.

Please explain why it is more complicated than this.

Although I find it hard to believe that ST will ever be a useful tool in doing anything other than duping funding agencies, I do at least agree about group theory – indeed, if you can be bothered to look through the archives of this blog, you will find me advocating teaching the theory of continuous groups to physics undergraduates. Also, in my own attempts to understand QFT – e.g. here, I try to give group theory as central a role as I can.

53. **Thomas Larsson**
December 6, 2005

Wolfgang,

Assume that the LHC (or ILC) will provide strong empirical evidence, e.g. for a MSSM or NMSSM model.
What would be your reaction?

I think one should formulate the answer symmetrically.

Low-energy SUSY would not prove string theory, and absense of low-energy SUSY would not disprove it.

Low-energy SUSY would be a strong argument in favor of string theory, and absense of low-energy SUSY would be a strong argument against it.

Do you agree?

I have an analogous question about LQG, which somebody (Christine perhaps) may be able to answer. LQG apparently predicts (or may predict) Lorentz violation. If this is observed in Auger or GLAST (or whatever the relevant experiments are called), it would be a great triumph for LQG. But is it a real, falsifiable prediction, in the sense that no Lorentz violation at Auger or GLAST would disprove LQG?

54. **Christine Dantas**
December 6, 2005

Thomas Larsson Says:

I have an analogous question about LQG, which somebody (Christine perhaps) may be able to answer. LQG apparently predicts (or may predict) Lorentz violation. If this is observed in Auger or GLAST (or whatever the relevant experiments are called), it would be a great triumph for LQG. But is it a real, falsifiable prediction, in the sense that no Lorentz violation at Auger or GLAST would disprove LQG?

According to Lee Smolin, there are two scenarios that specify how lorentz invariance is treated in LQG, see: "An invitation to Loop Quantum Gravity" (hep-th/0408048; section 5, "The near term experimental situation"). From a reading of this material, it is not really clear that LQG offers clean-cut, distinguishable low-energy physical predictions at the moment, exactly because of these 2 possible scenarios. But that is my understanding.

I think Smolin offers a somewhat optimistic view, which is not something particularly bad, I even share it. That is acceptable if you are not stuck by it and are able to contrast it with, e.g., Amelino-Camelia et al.'s (gr-qc/0501053) more direct words expressing that the main difficulty is:

"*the fact that **the techniques for obtaining the classical limit of the theory have not yet been developed**. Since our phenomenology will usually be structured as a search of corrections to the classical effects, this is a very serious issue. However, several authors [16, 17, 18, 19], guided by the intuition from working with some candidate quasiclassical states, made analyses that led to the expectation that Lorentz symmetry should be broken in Loop Quantum Gravity, and as a result the Maxwell and Dirac equations should include extra terms of higher derivatives. But clearly these violations from Lorentz symmetry still cannot be viewed as a "prediction" of Loop Quantum Gravity because of the heuristic nature of the underlying arguments, and indeed there are some authors (see, e.g. Ref. [20]) who have presented arguments in favour of exact Lorentz symmetry for Loop Quantum Gravity."*

Two more papers I find relevant are:

* "Falsifiable predictions from semiclassical quantum gravity" (by Lee Smolin, hep-th/0501091).

* "On Loop Quantum Gravity Phenomenology and the Issue of Lorentz Invariance (by Martin Bojowald et al., gr-qc/0411101).

I have a somewhat biased view that LQG is — or will eventually be — a falsifiable approach/theory, and the current problems of LQG concerning the issue of predictability are of a very different nature as those already pointed out in the case of string theory. That is my biased view but I am attempting to broaden my understanding of this matter of course.

The overall conclusion I have at the moment is that **LQG phenomenology is a very, very incipient one, but a possible one**. I have a much more pessimistic view concerning ST, since, as already stated, *"string theory may predict many new low-energy effects, but it can also be easily tuned to avoid all of them"*. I do not think that is the case for LQG, but I may be in error of course.

55. **Juan R.**
December 6, 2005

Ed Witten often has said in open forums and media that string theory pre-dicts gravity.

Of course, this is a nonsense and then Witten openly admits that that really with that phrase is that he means a **post-diction** because

> the experiment was done before the theory.

Naturally, an 'uniportant' detail for stringys!

Source: Interview with John Horgan on the in-famous book *The End of science*.

Note1: i obtained the Spanish version (pag 97), perhaps the english quote is not exactly equal.

Note2: perhaps i would remember readers as Jose that only 'gravity' contained in superstring theory is a perturbative spin-2 (masless) graviton over a flat classical spacetime. String states are masless and, therefore, even a basic description of e-e gravitational scattering is absent.

Of course, a spin-2 perturbation over a flat background is NOT general relativity.

How many times, will string theory be mistified until it was abandoned as a complete failure?

Juan R.

Center for CANONICAL |SCIENCE)

56. **Juan R.**
December 6, 2005

Christine Dantas, it appears that LQG already offers expressions for alpha coefficient and some bounds for beta, but I have not clear still is at what extension the proporcionality constant (L_p) is fixed on LQG.

Moreover, not forget that still nobody has proven that LQG was the correct classical limit. Why would we speculate about future AUGER, GLAST, etc. predictions being unable to explain current data (classical gravity)?

Even if tomorrow LQG offers corrects values for possible Lorentz violations, will continue to be an incorrect theory if anybody does not prove that when h–> 0, LQG –> GR or similar.

The same about 'stringys', very anxious waiting indications of supersimmetry at HLC without worry that string theory has not the correct low energy limit?

Is this science?

Juan R.

Center for CANONICAL |SCIENCE)

57. **Christine Dantas**
December 6, 2005

Juan R. Says:

> I have not clear still is at what extension the proporcionality constant (L_p) is fixed on LQG.

I would like to know that too. I have a lot of information yet to process. Could someone answer that?

> Even if tomorrow LQG offers corrects values for possible Lorentz violations, will continue to be an incorrect theory if anybody does not prove that when h–> 0, LQG –> GR or similar.

Undoubtedly yes. I have never thought otherwise.

> Is this science?

According to Frank Wolfs' text,

> The scientific method is the process by which scientists, collectively and over time, endeavor to construct an accurate (that is, reliable, consistent and non-arbitrary) representation of the world.

So the answer would be yes if we believe we are in the process of construction without forgetting the 3 magic words: reliable, consistent and non-arbitrary. However, of course this is not all. Let us review some concepts. He continues:

> In physics and other science disciplines, the words "hypothesis," "model," "theory" and "law" have different connotations in relation to the stage of acceptance or knowledge about a group of phenomena.
>
> *1. An **hypothesis** is a limited statement regarding cause and effect in specific situations; it also refers to **our state of knowledge before experimental work has been performed and perhaps even before new phenomena have been predicted.***
>
> *2. The word **model** is reserved for situations when it is known that the hypothesis has at least limited validity.*
>
> *3. A **scientific theory or law** represents an hypothesis, or a group of related hypotheses, which has been confirmed through repeated experimental tests.*

So it is my opinion that ST and LQG are both hypotheses for sure (at least in the sense highlighted above). I am optimistic that LQG can evolve towards item 3, because item 2 seems within its reach, if not already. I am not sure about string theory and other approaches, but one obvious thing that none of them can be seen as theories.

Christine

58. **Aaron Bergman**
December 6, 2005

If we have to select, among the various candidate String theories, the ones that contain Einstein's equations, then Einstein's equations are not a "prediction" of String theory.

We don't have to do so. It's very hard to write down a string theory that doesn't contain gravity. Sometimes it's even annoying. Much of the excitement about the twistor string, for example, was tempered when it turned out that it was computing amplitudes in conformal supergravity rather than ordinary super Yang-Mills.

59. **Juan R.**
December 8, 2005

Aaron Bergman Said;

> We don't have to do so. It's very hard to write down a string theory that doesn't contain gravity. Sometimes it's even annoying. Much of the excitement about the twistor string, for example, was tempered when it turned out that it was computing amplitudes in conformal supergravity rather than ordinary super Yang-Mills.

Any inexpert reader would be convinced that string theory works except by a 'small' detail you forgot.

As explained above on reply to Jose, the "gravity" contained in string 'theory' is not the gravity contained on general relativity not Newtonian gravity

Juan R.

Center for CANONICAL |SCIENCE)

December 8, 2005

Christine Dantas,

In science a hypotesis is a premise can be falsified via laboratory. The hypothesis, beyond any distance reachable by present or future telescopes stars are pink cubes is not scientific since is not testable. It would a metaphysical hypotesis.

Therefore string theory is not a scientific hypotesis since it is not (in rigor) testable; in fact, some leading string theorists openly call it a kind of church (i can obtain this cite).

A priori, i think that LQG may be a scientific hypotesis. However, my emphasis on the classical limit of LQG was not superfitial.

The failure for finding the limit is not due to thecnical difficulties. I mean that the classical limit obtained is not compatible with correct classical limit and this is the basis of the general criticism to LQG: it has not the correct classical limit.

Therefore, as one scientist, i consider 'stupid' the construction of detailed models and predictions for that "we will observe at HLC" when TODAY we cannot explain already know and explained by general relativity, for example Mercury perihelion or binary pulsar data.

That is, first to develop a candidate to quantum gravity with the correct classical limit and then **only then** predict it will be observed at HLC. Do not follow this basic scientific methodology is, in my opinion, a waste of time.

Juan R.

Center for CANONICAL |SCIENCE)

61. **Christine Dantas**
December 8, 2005

Juan R. Says:

> A priori, i think that LQG may be a scientific hypotesis. However, my emphasis on the classical limit of LQG was not superfitial.

Yes, I agree with you. I do not consider it (the classical limit of LQG) a minor problem, on the contrary. It is a very serious one of course.

Best wishes
Christine

LatexRender

December 3, 2005
Categories: Uncategorized

I've just added LatexRender support to this weblog, using Steve Mayer's WordPress plugin. In principle you should now be able to add formulas in TeX in the comments by putting the TeX in between and (without the space).

Here's an example of the output:

\displaystyle{\int_{-\infty}^{\infty} e^{-x^2}dx=\sqrt{\pi}}

I fear this will undoubtedly require some further debugging, but no time for that right now.

Update: This is now long out of date. I've replaced LatexRender with MathJax support. The opening and closing delimiters for tex math are now '\$' and for displayed math are "\$\$".

    Peter and everybody else: any similar software for use at blogger.cóm?

    Best, Kasper

29. **Who**
    December 5, 2005

    Chris Beasley has posted a new Beasley-Witten paper
    in case anyone is interested
    http://arxiv.org/abs/hep-th/0512039
    New Instanton Effects in String Theory

    I assume some other blogs mentioned it but am having trouble
    opening them, so can't be sure. Is it news that Edward Witten
    has coauthored a stringy paper? Don't recall many such from him
    recently.

30. **D R Lunsford**
    December 7, 2005

Another supremely uninteresting paper without a millisecond expended on physical thought. To witness a genius like Witten produce this effluvia is analogous to watching some hypothetical Beethoven scribble down advertising jingles for an orchestra of detuned kazoos.

Not only is there no physics, but the paper's English style is as deadly monotonous as VCR clock-setting instructions.

-drl

31. **God**
December 7, 2005

Lunsford, I notice that Woit comes in for criticism on Wikipedia for being needlessly kind to Witten: http://en.wikipedia.org/wiki/Peter_Woit

32. **woit**
December 7, 2005

Ugh,
It's pretty annoying to see the Wikipedia entry containing Witten-bashing and descriptions of my research I don't really agree with. Too busy right now, but I'll have to see if I can get this changed.

33. **logopetria**
December 7, 2005

I've had a go at making a few (minor) improvements. Here's a snapshot of the page as I left it:
http://en.wikipedia.org/w/index.php?title=Peter_Woit&oldid=30491221

Took out the Witten-bashing, deleted the stuff about your research that was, I guess, unrepresentative, and replaced it with a couple of sentences from a post at this site. Hope that's OK. Can't claim that I've made the page better, but I hope I've made it less bad.

34. **God**
December 7, 2005

Logopetria,

Good, but you deleted the bits saying:

'He argues that from the path integrals approach to quantum field theory, Euclidean four dimensional space makes the most sense, and Unitary group U(2) is a proper subset of Special Orthogonal group SO(4). Using a spin representation Spin(2n), U(2) gives the quantum numbers of a Standard Model generation of leptons. For a generation of quarks, the 'vacuum' vector transforms under Unitary group U(1) with charge 4/3, which makes the overall average U(1) charge of a generation of leptons and quarks zero.'

(that just summarises the ideas arrived at in hep-th/0206135) and

'Witten, however, has his own share of crackpotism as the inventor of the mainstream string theory, 'M-theory', in 1995: 'String theory has the remarkable property of predicting gravity.' (Witten, April 1996 Physics Today.) Peter Woit avoids an outright condemnation of Witten.'

then you inserted a link to 'The Holy Grail of Physics', http://www.math.columbia.edu/~woit/wordpress/?p=3 which is a mud-wrestling argument between Woit and professor Srednicki!

Roadmap for Fermilab

December 6, 2005
Categories: Uncategorized

Over at Quantum Diaries, Rob Gardner has an interesting report on a lunchtime informal brown bag talk given yesterday by Pier Oddone, the director of Fermilab.

He includes some telegraphic comments about prospects for financing future accelerators (the ILC and upgrades to the LHC):

Scenarios are complex to me! What will CERN and Asia do? Looking at 8B for ILC? How to share the cost? CERN is in debt till 2010! And, note that LHC will need to be upgraded, and will cost 1.5B or so. Can CERN chip in 1B + other Europe 1B? Can we then claim 50% from abroad (ask for 4B)? But what if the ILC RDR comes back at 12B?

Comments

   December 7, 2005

   Peter,

   Do any String theorists have access to your kitchen?

   One can't be too careful …

5. **Quantoken**
   December 7, 2005

   Sure they have access to Peter's kitchen. Through extra dimentions!!! Kaku, the guy who always brag about extra dimentions, has no problem access the TV screen in my family room, no matter what channel I switch to. I guess he has plenty of extra dimentions to use 🙂

The Cosmic Landscape

December 7, 2005
Categories: Book Reviews

Susskind's new book, The Cosmic Landscape: String Theory and the Illusion of Intelligent Design is now out. It's basically a lengthy version for the general public of the argument that he has been, with some success, trying to sell to the physics community for the last few years. In short, the argument is that the compatibility of string theory with an essentially infinite variety of different physics is not a bad thing (because it can't predict anything), but a good thing (because it allows an anthropic argument for the small size of the cosmological constant).

Susskind devotes quite a lot of space to attacking the argument that the string theory picture of unification is "elegant", instead promoting the idea that the properties of the universe come from some more or less random very complicated "Rube Goldberg" construction of a vacuum, one whose nature is just constrained by the anthropic principle. He asks:

But is String Theory beautiful? Does String Theory live up to the standards of elegance and uniqueness that physicists demand? Are its equations few and simple? And, most important, are the Laws of Physics implied by String Theory unique?

He answers these questions by first making fun of the supposed mathematical elegance of the theory:

Elegance requires that the number of defining equations be small. Five is better than ten, and one is better than five. On this score, one might facetiously say that String Theory is the ultimate epitome of elegance. With all the years that String Theory has been studied, no one has ever found even a single defining equation! The number at present count is zero. We know neither what the fundamental equations of the theory are nor even if it has any.

He goes on to argue that the laws of physics implied by string theory have turned out to be highly non-unique:

During the 1990s the number of possibilities grew exponentially. String theorists watched with horror as a stupendous Landscape opened up with so many valleys that almost anything can be found somewhere in it.

The theory also exhibited a nasty tendency to produce Rube Goldberg machines. In searching the Landscape for the Standard Model, the constructions became unpleasantly complicated. More and more "moving parts" had to be introduced to account for all the requirements, and by now it seems that no realistic model would pass muster with the American Society of Engineers — not for elegance in any case.

From this he draws the following bizarre conclusion:

Judged by the ordinary criteria of uniqueness and elegance, String Theory has gone from being Beauty to being the Beast. And yet the more I think about this unfortunate history, the more reason I think there is to believe that String Theory is the answer.

He remarks with surprise that no one has drawn the obvious conclusion that these arguments just imply that string theory is wrong:

What I have never heard is criticism based on the unfortunate inelegance or the lack of uniqueness of String Theory. Either of these tendencies might be thrown back at the string theorists as evidence that their own hopes for the theory are misguided. Perhaps part of the reason that the enemies haven't pounced is that string theorists have kept their Achilles heel under wraps until fairly recently. I suspect that now that it is becoming public, partly through my own writings and lectures, the kibitzers on the sidelines will be grinning and loudly announcing, "Ha, ha, we knew it all along. String Theory is dead."

adding a footnote to this paragraph in proof:

This remark was written in the spring of 1994, but by the time I completed writing 'The Cosmic Landscape' a year later, the vultures had descended in force.

He seems to have forgotten about at least one particular vulture, who back in 2003, tried to make this point at the question session after one of his colloquium talks.

Susskind's argument that string theory's compatibility with just about anything is actually an advantage is based on the fact that this makes a place for Weinberg's 1987 anthropic principle argument for the size of the cosmological constant (which from what I've seen gets it wrong by at least one to two orders of magnitude if you only vary the CC, more if you vary other parameters). He addresses criticism of the anthropic principle as unscientific by denouncing the field of philosophy of science, and the criterion of falsifiability in particular:

Frankly, I would have preferred to avoid the kind of philosophical discourse that the Anthropic Principle excites. But the pontification, by the "Popperazi," about what is and what is not science has become so furious in news reports and Internet blogs that I feel I have to address it.

He then goes on to quote from something he wrote for a debate with Smolin at the Edge web-site. For the bizarre story of how this debate came about, including the rejection by the arXiv of a submitted "paper" by Susskind about this, see here. He begins with:

Throughout my long experience as a scientist I have heard unfalsifiability hurled at so many important ideas that I am inclined to think that no idea can have great merit unless it has drawn this criticism. I'll give some examples:

The examples he gives are:

1. Behaviorist psychologists like B. F. Skinner who argued that statements about emotions were unscientific. Here I think Susskind is confusing positivism (the philosophy that science should just deal with directly observable quantities), with falsifiability, which is different. A theory may be based on quantities that are not directly observable, and still make falsifiable predictions about experimentally observable quantities. In any case, physics is supposed to be a much "harder" science than that part of psychology dealing with human emotions, and it is pretty strange for a physicist to be arguing that what he is doing really is science using this as an example.

2. The theory of quarks. Again, Susskind completely confuses positivistic objections (that if quarks are not directly observable you shouldn't talk about them), with falsifiability. While quark theory was problematic until 1973 since there was no workable dynamics, it was taken seriously because it made some very impressive, highly falsifiable predictions. The best known example is the quark theory prediction of the mass, spin and charge of the Omega-Minus particle. If string theory had made some predictions like this, few people would be criticizing it.

3. The theory of inflation. Susskind claims that after Guth first came up with this in 1980, it was attacked as unfalsifiable. I don't recall ever having heard such a criticism, although it was always clear and remains true to this day that experimentally distinguishing between the predictions of different mechanisms for inflation is difficult. From what I remember, there was actually a lot more optimism in the early 80s about this than now, since people were pretty enthusiastic about GUT models, and there seemed to be a good chance that one of the scalar fields in a simple GUT model would do the trick. Susskind writes: "It took 20 years to do the experiments that confirmed inflation." As far as I know people were calculating the effects of inflation on the CMB and starting to design experiments to see them within a few years after Guth's work. I don't see the relevance of the fact that it took a while to get a sufficiently sensitive experiment working.

4. The theory of evolution. Susskind joins other string theorists like Lubos Motl and an anonymous Cambridge referee I dealt with in believing that the status of string theory is much like that of the theory of evolution. He seems to believe that fossil evidence is irrelevant to testing Darwin, writing:

And it took more 100 years or more for to decisively test Darwin (some would even say that it has yet to be tested).

I'll leave it to a professional biologist like P. Z. Myers to argue this point with him, but it seems to me both nutty and irresponsible, given the ongoing battles over the teaching of evolution (which Susskind is getting himself involved with in the very subtitle of this book).

After attacking falsifiability as a criterion for a scientific theory, Susskind does admit that a theory has to make some predictions, even if they're not the sort that could falsify the theory. He acknowledges difficulty in coming up with any predictions:

Is there any way to explain in which of these anthropically acceptable vacuums we live? Obviously, the Anthropic Principle cannot help us predict which one we live in — any of these vacuums is acceptable.

This conclusion is frustrating. It leaves the theory open to the criticism that it has no predictive power, something that scientists are very sensitive about.

He discusses the idea of using statistical arguments, acknowledging that there are severe problems with this due to the "measure problem" of not being able to compare sizes of infinite sets, as well as the problem of not knowing what a priori probability to assign to any given vacuum state. Finally he does try and come up with some suggestions of how the theory might be tested, they are:

1. Evidence in the CMB that our universe was formed by bubble nucleation:

If we are very, very lucky, the largest lumps in the CMB might date to a time just before the usual Inflation got started — in other words, just as the universe was settling onto the inflationary ledge…

If we are that lucky, then the Inflation did not go on long enough to wipe out evidence for the curvature of space… If our pocket universe was born in a bubble nucleation event, the universe must be negatively curved.

At the level of accuracy that the curvature of space has been measured, there is no indication of such curvature. This idea may fail because standard Inflation probably has been going on for a long time when the largest visible lumps were formed.

So, this is both very unlikely to be something we can observe, and even if we did it would only tell us that the universe was born in a nucleation event, still giving us just about zero information about the supposed landscape and none whatsoever about string theory.

2. Cosmic superstrings. Here Susskind is referring to claims by Polchinski and others that amidst the infinity of possible physics due to string theory, one can cook up special cases where certain kinds of superstrings of astronomical dimensions exist and have properties precisely such that we wouldn't have seen them yet, but could see their effects in gravitational wave experiments like Advanced LIGO. As far as I've ever been able to tell, these are contrived constructions, with no reason at all that the vacuum state of the real world should be such as to support them. These are highly non-falsifiable "predictions" of string theory. No string theorist is going to give up on string theory just because Advanced LIGO doesn't see these effects.

3. High energy physics. Susskind talks about the LHC and the question of whether the fine-tuning problem of the Higgs mass will be resolved by supersymmetry or is anthropic. He acknowledges that, based on Landscape arguments:

My original guess was that supersymmetry was not favored, and I said so in print. But I have changed my mind — twice — and probably not for the last time.

This isn't much of a argument for predictivity on this issue, but I guess his point is that sufficient study of the Landscape might somehow resolve this question, although all the evidence so far is that this is not possible.

The bottom line here is that Susskind is unable to come up with any remotely plausible way of ever getting any scientific predictions out of the string theory landscape framework, and yet he thinks it is a good idea to write a popular book designed to sell it to the public. He makes clear that he is doing this because he sees himself at war with that part of the theoretical physics community which still believes in the idea of continuing to try and do what theoretical physicists have always done: find a more mathematically beautiful, more compelling, more predictive theory than the one we have now. In one chapter he surveys the state of the ongoing political battle for the hearts and minds of his fellow theorists. He crows (with some justification) that Weinberg agrees with him, saying physicists have to give up the paradigm of how to do physics they pursued during the last century, that Witten is facing defeat and getting depressed, that Joe Polchinski says there's no alternative, that the entire Stanford theoretical physics group are his allies, that 't Hooft won't rule out anthropic explanations, that Maldacena believes in the Landscape, that Michael Douglas is on his side, that cosmologists Linde, Vilenkin, Rees and Tegmark are in his camp, and that Alan Guth is at least a fence sitter. One of the few active opponents that he sees left on the scene is David Gross, whose reasons for opposition he describes as "more ideological than scientific." He sees Gross as dead meat: "the field of physics is littered with the corpses of stubborn old men who didn't know when to give up."

In coming weeks, it will be interesting to see how the physics community deals with the challenge presented by Susskind's publicity campaign for changing how theoretical physics is done. So far the initial signs are depressing. Michael Duff's review in Physics World just more or less respectfully repeats Susskind's argument, not challenging it in any way. In a review of the Duff review, Clifford Johnson answers the question of whether this sort of thing is still science with "I have not yet made up my own mind whether it sits well with me or not…" He makes a distinction between postdiction and prediction that I don't quite agree with (if Susskind's framework accurately postdicted even a few of the known Standard Model parameters, I'd be a believer). He takes the usual stance favored by most sensible string theorists who want to keep working on the theory that they don't understand the theory well enough yet to know whether they are stuck with the Landscape or not. Finally he thinks there's a chance that maybe the structure of the Landscape is such that once one anthropically fixed the CC and some other constants, the remaining set of vacua would actually predict something. I don't see the slightest evidence for this, but it's the argument many are now using to justify exploring the Landscape and surrounding swampland instead of giving up on string theory and trying to find a better idea.

Update: I should have mentioned a recent well thought out review of Susskind's book at Tech Central Station by Kenneth Silber. It's quite sensible and worth reading if you're following this story. Another review of the book has just appeared, this one by George Ellis at Nature. Ellis is much more critical of Susskind than Duff was, realizing that the crucial issue is that Susskind has no evidence for his claims, and writing in his final paragraph:

Physicists indulging in this kind of speculation sometimes denigrate philosophers of science, but they themselves do not yet have rigorous criteria to offer for proof of physical existence. This is what is needed to make this area solid science, rather than speculation. Until then, the multiverse situation seems to fit St Paul's description: "Faith is the substance of things hoped for, the evidence of things not seen." In this case, it is faith that enormous extrapolations from tested physics are correct; hope that correct hints as to the way things really are have been identified from all the possibilities, and that the present marginal evidence to the contrary will go away.

One peculiar thing about Ellis's review is that he accuses Susskind of ignoring the fact that there is no experimental evidence for negative curvature of the sort one might get if the universe was formed by bubble nucleation. In Susskind's defense, he does address this point, saying it is very unlikely we can see this negative curvature since inflation is likely to have gone on long enough to make it unmeasurably small.

Comments

1. **Chris W.**
December 7, 2005

   One hardly knows what to say. I find myself wondering whether this isn't some kind of setup, with Susskind accusing dozens of people—some years from now—of allowing themselves to get sucked in by what was, in the end, just a ruse.

   Also, I sense an ironic twist in many of Weinberg's comments on this subject that suggest he isn't buying. He has merely made a modest investment which he would be happy to lose. (He hasn't actually done much work on the Landscape himself, right?)

   Great post, Peter.

   Peter

   A great article, and for my money you are spot on in your critisisms of Susskind's claims about falsifiability. Susskind seems to not have a clue about these things. And it's interesting that he didn't mention the one theory that has repeatedly faced claims of unfalsifiability, namely Freud's theory of dreams and repression. And he doesn't mention it because it would upset this silly idea that a theory could be perfectly good yet unfalsifiable.

   (Why do referees do such a poor job? they block the good and interesting, and let through confused stuff like this. The world's going to hell in a handbasket.)

9. **Jose**
December 8, 2005

   It seems to me that the book of Susskind is the best allegation against string theory!.

10. **Chris Oakley**
December 8, 2005

    Why do referees do such a poor job? They block the good and interesting, and let through confused stuff like this.

    This may have something to do with the fact that LS has a prestigious job at a prestigious university.

    The same comment I made about Weinberg also applies here: if one is in a position of influence then one is duty bound to try to encourage people to do one's subject rather than to try to scare them off. Telling people that String theory is nonsense but still the only idea in particle physics worthy of study is not going to make anyone want to sign up.
    Of course, there *are* alternatives to String theory, but the String-theory-dominated research establishment does its utmost to make sure that these particular suckers never get an even break. In the long run, though, if leaders like Susskind and Weinberg convince taxpayers that theoretical particle physics is not worth funding, then who are the

real suckers?

11. **Juan R.**
December 8, 2005

Peter Woit said,

> Susskind's new book, The Cosmic Landscape: String Theory and the Illusion of Intelligent Design is now out. It's basically a lengthy version for the general public of the argument that he has been, with some success, trying to sell to the physics community for the last few years. In short, the argument is that the compatibility of string theory with an essentially infinite variety of different physics is not a bad thing (because it can't predict anything), but a good thing (because it allows an anthropic argument for the small size of the cosmological constant).

That is, we can choose between two options:

– **Theory A**. The theory predicts many things with great precision. By "predict" i mean that one knows the result of an experiment before it was done. For instance, one known approximation to theory A is the pair standard model more general relativity, even if both are incompatible, since both provide excellent result on the very big and the very small! Of course the true theory A may be internally compatible. String theorists often misunderstand the word "predict" and use it instead of "post-dict". By "post-dict" i mean that one may know first the experiment and then *modify*/*adapt* the theory to the obtained value. Since we may know first the experimental outcome, of course, the practical utility of this kind of theories is zero. The theory cannot scientifically explain the cosmological constant.

– **String 'theory'**. Or its M unknown generalization! *The 'theory' predicts nothing of this world and is incompatible with physics we observe in laboratory*. Since string 'theory' is not useful, people of the real world continue using well-tested scientific theories. For example, astronomers continue using general relativity on the prediction/explanation of phenomena. Chemists continue using quantum mechanics of particles on the computation of reaction constants, biologists continue using thermodynamics to understand metabolism, etc. Using antrophic principle, string theorists can 'explain' the cosmological constant. The antrophic principle basically says that cosmological constant has value we measure because if has other value life would be imposible and we would not measure it! Of course, this is not a scientific explanation. At the best, it is phylosophical one, but of no real utility on science.

Therefore, the option opened by string theory reduces to either scientifically understand/predict/explain a 'billion' of things or scientifically understand/predict/explain nothing and just phylosophically explain ONE single thing.

Of course, the phylosophical antrophic principle can be used with theory A!

Since my position is well-known i add no more comments!

Nice, but depressing review.

It is quite pathetic to see some of the arguments used by Susskind, like comparing string theory to QCD, in terms of falsifiability. Whom does he think he is fooling with this blatant lie?

I am afraid the post-War (generally very favourable) perception of the public of physics(and physicists in general), not just string theorists, will be severely damaged. This will not be without consequences.

It is quite amusing to see the kid glove treatment of Susskind by other string theorists and contrast it with the reaction to Krauss; he obviously touched a nerve. The irony is that Susskind's book(right from the title onwards) is more damaging to the field than Krauss'. I suppose, intellectual dishonesty is in all fields, but the extent of it in string theory may be unrivalled.

I was quite surprised to note the many eminent physicists who are behind this anthropic nonsense, or at least not outright rejecting it. I was under the impression that it was merely a fringe in the community. No longer, it seems…

I think you are discussing two different issues.

1) The anthropic issue. Here you seem too negative: experiments still have something important to say. If LHC will find that the Higgs mass hierarchy problem is solved in some "natural" way, anthropic interpretations will be mostly abandoned. If LHC will find nothing, anthropic intrpretations will be a good alternative to harakiri.

2) The string issue. Here it is easy to guess the impact of LHC results: whatever LHC will find (nothing? supersymmetry? extra dimensions?) will be used to argue in favor of string theory, and you are doing a good work to make the situation more healthy.

Dear. Dr. Woit,

I've been an admiring lurker for quite some time*, but this review prompted me to contribute. Superbly written, and I am always deeply appreciative of scientists who can not only think clearly, but also communicate their thoughts with equal parts clarity and cogency to a lay audience (in physics, at least). I suppose the depressing starkness with which Susskind's bereft position is revealed is also due, in no small part, to his efforts to reach a broad audience as well.

I've no doubt Dr. Susskind is my intellectual superior, as are most, if not all of the String "theorists", but all the powers of all the greatest physicists joined together will never conjure experimental verification out of thin air, and for the assay and its fruits, logic is simply no substitute in the realm of skeptical inquiry. Now that we've seen a preeminent physicist's attempt to herald a new paradigm shift, by eschewing testability altogether in the name of "progress", I fear for the integrity of the natural sciences in general, and physics in particular. I'd laugh it off in happier times, but particularly the ID "theorists'" faith-based pollution and perversion of the public scientific discourse has revealed how truly vulnerable the edifice of skeptical inquiry, built as it has been, brick-by-torturous-brick since the Renaissance, can be battered by the rams of fundamentalist faith and dogmatic philosphizing on nothing. It's painful to see science assaulted from without, but positively excruciating to see it eat at itself from within.

Despite the sometimes overly-pejorative nature of the conversation here (which it seems you've recently taken more assertive steps to limit, which I appreciate), I'm glad people like you are willing to stick their necks out and protest this corruption of the scientific method. I hope the message gets through someday.

*I chose my handle to preempt any insults hurled my way by Dr. Motl, should he deign to swat at a biognat such as myself if something I might ever say touches a nerve.

15. **woit**
    December 8, 2005

    a,

    All I was doing here was reporting on what Susskind is saying, he's the one bringing claiming that string theory both allows and requires anthropic arguments, and that, perversely, this is a good thing.

16. **Chris Oakley**
    December 8, 2005

    I chose my handle to preempt any insults hurled my way by Dr. Motl, should he deign to swat at a biognat such as myself if something I might ever say touches a nerve.

    No-one is going to take you seriously in this forum until you have been savaged by Lubos Motl. Look on it as a rite of passage.

17. **Brett**
    December 8, 2005

    While I disagree with Susskind's ideas about anthropic reasoning, I have to say that I find Smolin's arguments on the subject equally unconvincing. Smolin's (and everyone else's) main example of how the anthropic principle is used is Weinberg's examination of the cosmological constant. Smolin's seems to mistake the fundamentally inductive character of this argument. The deductive stage is unambiguous, that because there are galaxies, the cosmological constant must be small. But this tells us nothing about why it is small. Part of the purpose of science is to determine causes for what is observed, and what Weinberg wanted to argue was that the size of the cosmological constant could provide evidence that the cause of that smallness was purely anthropic. While I do not consider his evidence to be all that strong, the problem is a numerical, not philosophical one.

    I believe that Susskind is correct that bringing heavy philosophy into things is simply misleading, and Popper's ideas, in particular, do not really match with how many real scientists have always done science. Popper rejected almost entirely the notion of positive evidence, which is really one of the cornerstones of the scientific method. Falsifiability is fundamentally a deductive criterion; we can deduce which theories are false, but not which are true. The earliest modern philosophers of science, Descartes and Bacon, ridiculed the deductive reasoning of the scholastics. Scholastic reasoning assumed known (and theological) causes and tried to work of predictions from that. There was no apparatus for determining any new causes. But finding new causes was exactly what a scientist like Newton had to do. This is a fundamentally inductive process, and it is based, ultimately, on the intuitive Bayesian fact that an observation of a cause's effects makes that cause more likely. This kind of framework allows anthropic causes, and so there is no a priori reason to reject them as unscientific.

18. **Dumb Biologist**
    December 8, 2005

    I think if you simply substitute "testability" for "falsifiability", many these pernicious philisopical issues simply vanish. Science, simply put, involves putting ideas to the test experimentally. Perhaps there are scientifically relevant concepts which cannot be falsified by any means available to mortals, but we become comfortable (or only ought to, anyway) with such assertions only after the most vigorous experimental assault. That's how science keeps itself honest. Surely scientists utilize everything from induction to deduction to dumb luck in the process of discovery, but the process becomes rather suspect when the very meaning of "discovery" is subverted, and at the end of the day one no longer feels beholden to nature to demonstrate the predictive power of one's ideas. Perhaps we invent hypotheses, but we verify the accuracy of those hypotheses and build theoretical frameworks through observation. THAT is the scientific method.

    If what I have read in the "popular science media" about String "theory", it is right to say it's not a theory at all, but a hypothetical model. There's nothing wrong with hypothetical models, but mistaking or conflating such a thing, no matter how rigorous or ambitions, with the TESTED predictive power of a true theoretical framework is irresponsible. Look no further than the "controversy" over Intelligent Design to see why respecting the meaning of words like "theory" is vitally important.

    And yet: Because of its purported beauty and profundity, what started as hope does seem, at least in the minds of some, to have become a kind of faith among some physicists. String Theory simply must be true, because of all its wonderful symmetries, and so forth. Ergo, if it cannot be falsified (or worse, even tested), the need for anything remotely resembling experimental verification is shown to be superfluous, quaint, even obstructive. Such is the "progress" we've achieved with deductive reasoning, it would seem. Perhaps the sciences are coming full circle to mere philosphy once again. It's especially rich when the very definition of science, speciously derided as some "Popperian dogma", is being deliberately reworked to defend a so-called theory that apparently can't predict anything (or rather, predicts everything?). The scientific method isn't just any philosophy we can discard when no longer fashionable (like postmodernism). At least, I hope it isn't, because we've tried promulgating "truth" after bouts of deep thought, and that program of "discovery" has rather failed to deliver.

19. **Dumb Biologist**
    December 8, 2005

    Oh, and apologies for some of my typos and other poor writing. I failed to see the preview unfolding below the entry field (first time posting on a blog and all…simple use of the scroll bar would have revealed the Preview), and hence didn't proof-read my posts very well. I'll may just shut up now, but, anyway, thanks again Dr. Woit for your contributions to a worthy subject of debate.

20. **Chris W.**
    December 8, 2005

    From Leonard Susskind, in his email exchange with Lee Smolin published on Edge.org:

    > Good scientific methodology is not an abstract set of rules dictated by philosophers. It is conditioned by, and determined by, the science itself and the scientists who create the science. What may have constituted scientific proof for a particle physicist of the 1960's—namely the detection of an isolated particle—is inappropriate for a modern quark physicist who can never hope to remove and isolate a quark. Let's not put the cart before the horse. Science is the horse that pulls the cart of philosophy.

    A quote from Popper, via this page:

    > "We all take our philosophies whether or not we are aware of this fact, and our philosophies are not worth very much. But the impact of our philosophies upon our actions, our lives, is often devastating. This makes it necessary to try to improve our philosophies by criticism. This is the only apology for continued existence of philosophy which I am able to offer." (from *Objective Knowledge*)

(I don't think this transcription is completely accurate, but it's very close to the original. I remember the passage well from my own reading of *Objective Knowledge*.)

21. **Christine Dantas**
December 8, 2005

As a somewhat newcomer to the subject of quantum gravity, and an astrophysicist by formation, I find this all exceedingly interesting. Congratulations to Dr. Woit for making this very relevant and timely debate possible.

I would like to take the opportunity, if not considered a diversion, and quote the following paragraph from Barrow & Tipler – The Anthropic Cosmological Principle, page 275:

> At present there is no theoretical understanding of why just three dimensions have expanded to a large size if the others are indeed confined to minute extent. However, the Anthropic arguments we gave concerning the special properties of three-dimensional space and four-dimensional space-time show that there would be a Weak Anthropic explanation for this observation also; but, for all we know, it may also be a consequence of the unique topological properties that four-dimensional manifolds have recently been found to possess. The fact that only they admit more than one distinct differentiable structure may well turn out to have something to do with the fact that observable space-time has four dimensions.

Is that view compatible or incompatible with the current anthropic landscape issue? In any case, how can this really be useful?

Thank you,
Christine

22. **Clark Goble**
December 8, 2005

Good post, although I'd quibble with your discussion of logical positivism. Logical positivism, at least none of the figures I've read, would say science can "just deal with directly observable quantities." Rather logical positivism was more trying to take the typical science of the day and move it towards philosophical problems. That is, if it can't be verified empirically, it is meaningless. That tendency goes back well into the 19th century. In America we have figures like C. S. Peirce espousing a theory fairly similar, for instance. All would admit theoretical entities, although they'd say our justification for theoretical entities comes from this verification principle.

Once could adopt *both* a verification principle and a principle of falsification. Peirce does this, for instance, although many more argued that one could verify directly through empirical knowledge.

Logical positivism does start diving kinds of science when we get into psychology, history and related disciplines. But with a few caveats, I think one could be a logical positivist and not have trouble with most physics.

Where the logical positivists part ways is with people who tend to espouse a coherency theory of truth. The positivists were very much tied up into a correspondence theory of truth.

23. **Quantum_Ranger**
December 8, 2005

The clarity of your post peter, portrays a just confusion with respect to Susskind's "state of mind".

It is by no coincedence that the 'boom and bust' mentality of the 80's, was perfectly matched with stringtheory's creation and evolution.

The sober thinking these days, albeit with hindsight, needs the guiding voice and eye's such as you attain in your varied writings.

I do not think it is all doom'n'gloom though, but it is apperaing more and more that there is a lot of "dis-information" contained within the Anthropic Landscape, by fact of his positional stance, Susskind rule's supreme, over the scientific kingdom that is apparently untouchable as well as unaccountable?..if one takes the vacuum background as literally de-facto?

24. **Chris W.**
December 8, 2005

Christine,

Regarding the significance of the special features of 4-dimensional manifolds, see the excerpt from a paper by Hendryk Pfeiffer quoted in this comment on an earlier post on this blog.

There is much of interest in this post and many of the ensuing comments.

25. **Who**
December 8, 2005

when Susskind's views on the String Landscape are discussed, together with Anthropic, and related, reasoning, I think you miss half the argument if you dont mention this article by Smolin (which upset Susskind quite a bit when Lee sent him a copy)

http://arxiv.org/abs/hep-th/0407213
Scientific alternatives to the anthropic principle
Lee Smolin
Contribution to "Universe or Multiverse", ed. by Bernard Carr et. al., to be published by Cambridge University Press.

"It is explained in detail why the Anthropic Principle (AP) cannot yield any falsifiable predictions, and therefore cannot be a part of science. Cases which have been claimed as successful predictions from the AP are shown to be not that. Either they are uncontroversial applications of selection principles in one universe (as in Dicke's argument), or the predictions made do not actually logically depend on any assumption about life or intelligence, but instead depend only on arguments from observed facts (as in the case of arguments by Hoyle and Weinberg). …
…
We show however that it is still possible to make falsifiable predictions from theories of multiverses, if the ensemble predicted has certain properties specified here. An example of such a falsifiable multiverse theory is cosmological natural selection. It is reviewed here and it is argued that the theory remains unfalsified. But it is very vulnerable to falsification by current observations, which shows that it is a scientific theory.
The consequences for recent discussions of the AP in the context of string theory are discussed."

Chris W.,

In your link "http://www.math.columbia.edu/~woit/wordpress/?p=206#comment-3795" in a previous post, check out the talk of one of the authors (Prakash Panangaden) of the paper you linked to gr-qc/0407094. The last page of the talk is hilarious.

28. **island**
December 11, 2005

Lenny doesn't realize it, but he is advocating a natural design theory if he's using the landscape to rationalize away the significance of the fact that *the appearance of [intelligent] design is undeniable*… because it isn't just an "appearance" if multiverses don't exist to lose the significance in.

He isn't just correct about that, he's…

NOT EVEN RIGHT

29. **Chris W.**
December 11, 2005

The same talk is available as a PDF file.

— — — — — — — — —
It seems that a number of computer scientists studying distributed systems have formulated theories of what might be called *asynchronous causality*, and some have noted the potential value of connecting these ideas with Lorentzian geometry. In Panangaden's recent papers with his collaborator Keye Martin this point of view has been well developed.

Also see Discrete Quantum Causal Dynamics (gr-qc/0109053).

[By the way, asynchronous processor designs have been the subject of a growing R & D effort in the computer industry for the last several years. (Sun Microsystems' effort has been led by Ivan Sutherland.) Synchronous clocking of highly integrated digital circuits is threatening to become non-viable in the fairly near future, for performance and power consumption reasons as well as the sheer difficulty of implementation at very high clock rates.]

(* professor of CS at McGill)

30. **island**
December 12, 2005

Finally, he thinks there's a chance that maybe the structure of the Landscape is such that once one anthropically fixed the CC and some other constants, the remaining set of vacua would actually predict something. I don't see the slightest evidence for this

Universes with other exaples of the commonly speculated forms of life, like; Silicon based life, Nitrogen and Phosphorus based life. Chlorine or Sulfur based life, where differently tuned constants produces a different set of eco-balances, and a different ratio in the cosmic abundance of any of the mentioned elements to carbon, of 10 to 1 in their favor, rather than the other way round like it is in our universe… for examples of how far your imagination can run if…

… if ours is an anthropic universe that undergoes an evolutionary-like leap/bang to a higher order of symmetry and efficiency, in terms of more uniform form of energy-disseminating capability…

…but that's not going to happen in the one that exists this go-round, and there certainly isn't the slightest bit of evidence that a "pocket" of naturally selected near-identical bubble-universes in a "would-be" multiverse, would or should be preferred over an evolving biocentric universe, for which there is pre-existing observed justification for all the way down to your ancestors, the apes.

David Gross Admits String Theory is in Trouble

December 9, 2005
Categories: Uncategorized

The latest issue of New Scientist has an article entitled [Nobel Laureate Admits String Theory is in Trouble](). It describes remarks by David Gross at the recent Solvay conference in Brussels, mentioned [here]() earlier.

Gross described the current state of string theory as "We don't know what we are talking about", and also admitted:

"Many of us believed that string theory was a very dramatic break with our previous notions of quantum theory," he said. "But now we learn that string theory, well, is not that much of a break."

He said the field was in "a period of utter confusion", and compared the current situation to that at in 1911, at the time of the first Solvay conference, when no one had any idea what was causing radioactivity.

"They were missing something absolutely fundamental," he said. "We are missing perhaps something as profound as they were back then."

The same issue of New Scientist also has an editorial on the subject entitled [Physics' greatest endeavour is grinding to a halt](), which ends as follows:

For decades, string theorists have been excused from testing their ideas against experimental results. When astronomers discovered the accelerating expansion of the universe, which string theory fails to account for, many string theorists took shelter in a remarkable excuse: that their equations describe all possible universes and should not be tied to matching data in just one of them.

But when the theory does not match the one data set we have, is it science? There is a joke circulating on physics blogs: that we can, after all, call our universe unique. Why? Because it is the only one that string theory cannot describe. Should we laugh or cry?

There is a growing feeling that string theory has run into the sand. Gross thinks we are missing something fundamental. We need a leap in understanding, though where it will come from is not clear. Many of the greatest minds in physics were there at last week's conference, and none had an answer.

We are approaching the end of Einstein's centennial year – a celebration of physics. While some lesser-known areas of the subject are flourishing, the search for a theory of everything is in a sorry state. Unless string theory gets a radical shake-up, gifted but frustrated minds will begin to drift into other areas of science. And if that is what makes biology the subject of the century, it will be depressing reason indeed.

Update: Lubos Motl has some [comments]() on this. He compares the current devastation of string theory to the effects of hurricane Katrina and me to an Islamic extremist, while arguing against the terrible danger to physics if all this leads to study of a "diversity of approaches" other than string theory.

Update: Gross now [claims]() his words were misinterpreted.

Comments

1. **blank**
   December 9, 2005

   Ouch!

   Now is Lubos going to tell us that Gross has s**t for brains?

2. **Who**
   December 9, 2005

   for me the big question is whether David Gross acknowledged the existence of other interesting approaches to quantum spacetime or quantum gravity that might reasonably be pursued.

   there has been a consistent tendency for string leaders to say things "our one best hope" and "the only consistent quantum theory of gravity". Steve Shenker used that phrase at an embarrassing moment in Strings '05 when someone in the audience asked why study string theory and the panel members didn't have a ready answer.

   It is a kind of monopoly delusion—-of being God's chosen research program—-which is maintained by repetition, like a creed. The only time I heard any string notable break from it was in what Andy S said during the same discussion. He outright said there were other interesting approaches that you could reasonably investigate. No sneer or any hint of condescension. Apparently it takes courage and honesty to say that.

   For me the question is if David Gross went that far. If his message was merely "Oh my we are the only game in town and look how confused we are!!! This must be an exciting historical moment, like 1911, when relativity and quantum mechanics were waiting in the wings."
   If his message was merely that, then it lacked integrity.

   But if he said "we are confused right now and there are alternatives—we aren't sure of being the one right approach", then I would put that on par with the Andy S statement at Strings '05. It is the kind of healthy realism that leadership has to show before things can start getting better.

   December 9, 2005

   a propos "physics greatest endeavor" grinding to a halt, I seem to remember that in past years Michael Peskin's Topcite Review of previous year has been out by around September.

   but if you look here
   http://www.slac.stanford.edu/library/topcites/
   you see that it promises 4 items of information for 2004 but has delivered only two, not including Peskin's review

   —-quote—
   2004 Edition

(The 2004 edition covers all HEP papers from January 1, 2004 and December 31, 2004. The following articles are available for this edition.)

Review of top cited HEP articles 2004
List of top cited HEP articles in 2004
List of all-time top cited HEP articles (as of 12/31/2004)
List of top cited articles from the E-print archives 2004

—-endquote—

only the two bolded items appear to be actually available

Is Michael Peskin going to write the review this year, in fact, or is he reluctant to continue performing that ceremonial function?

has the annual Rose Bowl of cite-ranking become so embarrassing to string theorists that the Stanford librarians have tactfully decided to let the practice lapse?

4. **Doug**
   December 9, 2005

   It would be really interesting to know what Gell Mann, t'Hooft, Atiyah, Weinberg and the rest had to say. Does someone know of any plans to make the proceedings available?

5. **woit**
   December 9, 2005

   Who,

   I doubt it's the Stanford librarians deciding this, but suspect that, given the discouraging situation of virtually no new ideas in particle theory to report, Peskin has been avoiding the task of sitting down to write up the kind of thing he's done in past years. Maybe he'll get to it at some point, maybe he'll give up on it for good.

6. **Christine Dantas**
   December 9, 2005

   Is it really a consensus in the string theory community that this enormous so-called landscape of vacua is in fact an unavoidable result from the "theory"? Or there are people that do not really accept this result as a final word and attempt to find other possibilities (within the "theory", I mean)?

   Now one more thing concerning this apparent dead-end for string theory. This question is ashamedly basic and possibly a nonsense, but I will ask anyway.

   – This landscape thing. Has anyone thought about some "meta"(?)-variational principle or something analogous so that a unique vacuum could be selected from such "principle"? I have not the slightest idea if that makes any sense, but I appreciate any comments on this.

   Christine

7. **Aaron Bergman**
   December 9, 2005

   Is it really a consensus in the string theory community that this enormous so-called landscape of vacua is in fact an unavoidable result from the "theory"?

   Yes and no. There seem to definitely be an infinite number of vacua — toroidal compactifications at various radii, for example. The new idea is the production of vacua that have no massless scalars. These are all AdS vacua. The techniques involved in the production of these vacua aren't completely rigorous, but persuasive.

   Because they're AdS, none of these vacua are realistic. One needs to lift them to de Sitter vacua with a positive cosmological constant. This step is much more sketchy.

   Even when you accept all that, one has to ask how many vacua are there that have a reasonable matter content. For any useful definition of reasonable, that's a difficult question. It has been joked by various string theorists that people have extrapolated the existence of a huge number of realistic vacua when string theory hasn't yet produced a single one.

   One scenario for predicitivity of string theory is that there turns out to be very few vacua consistent with current observations. If we can pin down the precise vacuum that we live in, then the theory becomes predictive.

   Lots of people have thought about selection mechanisms for vacua, but — in that we don't actually understand string theory — it's all pretty speculative.

8. **A. nonymous**
   December 9, 2005

   I think the variational principle involved is that the background should be a (meta-)stable vacuum. This will ensue that you have a discrete set of candidate backgrounds. The problem is that, although there are discrete vacua, there are a very large number of them. You need some principle which selects a good element from a very large and discrete set, and those kinds of principles are much harder to come by than principles which let you choose a special element from a continuous set.

9. **Who**
   December 9, 2005

   christine, before people start discussing the "landscape" I want to make one point of information about the 23rd Solvay CONFERENCE. It was myopically organized, to a disappointing extent I think. Ostensibly, the conference was about research areas where the non-string quantum gravity community has been especially successful recently —and by contrast little of significance has been happening in string.

   When this was realized, it may well have left a residue of embarrassment—-either in David Gross himself or in some of the others. It would have been a better conference had it been less parochial. I will illustrate how 23rd Solvay shot itself in the foot.

   To see the program follow links at:

   http://tena4.vub.ac.be/23Solvay/qsst/

   The subject was the
   QUANTUM STRUCTURE OF SPACE AND TIME

broken down into several main foci of discussion
each with a "rapporteur" and a panel. I will list the rapporteur
for each of several main topics:

A. singularities (Gibbons)
B. mathematical structures (Dijkgraaf)
C. emergent spacetime (Seiberg)
D. cosmology (Polchinski)

the page I mentioned has links to lecture notes for three of the four rapporteur talks—-A. C. and D. Gibbons, Seiberg, Polchinski
I was impressed by how insubstantial these lecture notes were, and how much they missed by way of active research and recent results in these areas

In each of these three cases, significant advances are being made outside string, to which the rapporteur does not refer.

A. in the case of singularities the removal of the black hole and cosmological singularities in the Loop context, by Martin Bojowald and others should have been highlighted (in any but a narrowly string-centered context) and apparently was not even mentioned

C. as for emergent spacetime, that has been exactly the point of recent work by Loll and others—the emergence of a 4D spacetime in Causal Dynamical Triangulations. In fact it was surprising that Loll was not on hand.

D. as for cosmology, I assume this means Quantum Cosmology since the overall subject of the conference was the quantum structure of space and time. Abhay Ashtekar, who was at 23rd Solvay, could well have pointed out the rapid growth in activity in Loop Quantum Cosmology, with connections beginning to be made with observational astronomy. But quite possibily he would not have done so in public, since the organization made it awkward. Ashtekar was not included on the cosmology panel. In fact there was no LQC representation on the cosmology panel at all! It consisted of Banks, Guth, Kachru, Kallosh, Linde, Steinhardt, Weinberg! I see that not as a recipe for quantum cosmology discussion, but instead for speculative talk about eternal inflation, bubbles, multiverses, and the landscape.

maybe some discouraging noises in the Solvay wake is due to unwise organization, I'm thinking.

10. **Not a Nobel Laureate**
December 10, 2005

Radioactivity was an experimental observation that no one knew how to explain in 1911.

What experimental data requires a string theory explanation?

Physics is still an experimental science.

Deduction by pure reason is the domain of meta-physics or, in the case of strings, Ubian pata-physics.

December 10, 2005

Would that we could do experiments that probe quantum gravity.

What would we learn? I don't think anyone can realistically formulate what you would measure.

Sometimes I'm amazed at how bright people such as you can defend these labyrinthine thought constructions. No successful theory of anything was ever so complicated. On the contrary, the good theories like Dirac and GR are simple and involve a bare minimum of structure. Isn't it just intuitively obvious that when things get so complicated, it's time to try something else? Even if you choked some kind of answer, even a wrong one, from such a theory, who would be happy?

Thank you all for the instructive comments on my landscape question an to "Who" for the important comments on the 23rd Solvay conference.

All the best,
Christine

15. **FP**
December 10, 2005

> we could do experiments that probe quantum gravity

Let's assume that somebody can show that the Pioneer anomaly is real and
measure it exactly.
How would this help string theorists? (And how would this help LQG?)
As far as I know "the only consistent theory of quantum gravity" cannot estimate
deviations from Newton's potential.

16. **Not a Nobel Laureate**

December 10, 2005

NNL: Physics is still an experimental science.

AB: Would that we could do experiments that probe quantum gravity.

NNL: Since we can't then what's the point of constructing theories that can't be falsified, be they stringy or loopy.

17. **Aaron Bergman**
December 10, 2005

Since we can't then what's the point of constructing theories that can't be falsified, be they stringy or loopy.

Because they might be right? I don't know about loopiness, but we've also learned a lot of things about susy gauge theories and mathematics from the study of string theory, too.

18. **Anonymous**
December 10, 2005

Peter,

Lubos Motl is a clown, and a rather pathetic one at that. That much is obvious to anyone who's had a glance at his blog. What I don't understand is why you are so concerned about his silly tirades and opinions (e.g., the update to this post). If he has'nt anything substantiative to say, why not just let him rot in this own dimensions?

Just curious.

-Anon.

19. **woit**
December 10, 2005

Anonymous,

Sometimes I think Lubos's antics are just hilarious, and don't want anyone needing entertainment to miss them, thus the update to the post. OK, this is not very high-minded behavior on my part, I admit it.

20. **Anonymous**
December 10, 2005

I thought I would share this link demonstrating that even if the older members of the string community are becoming more pessimistic about the current incarnation of string theory, younger people certainly aren't. The website:
http://www.interactions.org
Has an article written by a grad student describing the field to a lay person:
"String theory a very exciting prospect for physicists"
http://www.theithacajournal.com/apps/pbcs.dll/article?AID=/20051207/LIFESTYLE18/512070307/1025

21. **D R Lunsford**
December 10, 2005

In the day, we usually had (or taught ourselves) a course in theoretical physics (Sommerfeld, Landau, etc.) which included not only QM and relativity, but things like hydrodynamics, elasticity, kinetic theory of gases, optics, etc. etc. I doubt this student has much acquaintence with these things, and therefore he is not in a position to know what he's missing with ST.

-drl

22. **Aaron Bergman**
December 10, 2005

younger people certainly aren't

Like older people, there's a wide array of opinions among younger people.

23. **Chris Oakley**
December 10, 2005

Another interesting point you might have heard about is that string theory predicts that there are really ten dimensions — the three big spatial ones and time, which we are used to, and six more tiny dimensions.

This is a bit like saying, "I'm a qualified brain surgeon: all I need to do is to get into medical school and study for seven years"

24. **Not a Nobel Laureate**
December 10, 2005

NNL: Since we can't then what's the point of constructing theories that can't be falsified, be they stringy or loopy.

AB: Because they might be right?

NNL: The odds of finding the right theory be it string or loopy or something entirely different in the space of all possible theories is vanishingly small – the history of pure reason is the history of dead ends.

If some people want to pursue this fine – they should, but it is inappropriate that it should come to dominate theoretical HEP.

AB: I don't know about loopiness, but we've also learned a lot of things about susy gauge theories

NNL: Great. Now what's the experiment evidence for SUSY?

AB: and mathematics from the study of string theory, too.

NNL: That's also great. And it reinforces why strings belong in the math dept not the physics dept – until they can predict some physical phenomena.

25. **Aaron Bergman**
December 10, 2005

The odds of finding the right theory be it string or loopy or something entirely different in the space of all possible theories is vanishingly small – the history of pure reason is the history of dead ends.

Like GR?

If some people want to pursue this fine – they should, but it is inappropriate that it should come to dominate theoretical HEP.

It doesn't. There are more posts on hep-ph than on hep-th. String theory, for better or worse, just gets most of the press. In the future, there's going to be even more of a trend towards hep-ph jobs. You can see that happening right now.

Great. Now what's the experiment evidence for SUSY?

SUSY for years was impressive in that it provided a dark matter candidate, unified the couplings and made things more natural. It's not looking as pretty as it once did these days, but we'll see in a few years.

That's also great. And it reinforces why strings belong in the math dept not the physics dept – until they can predict some physical phenomena.

Who cares what department it's in?

26. **Not a Nobel Laureate**
December 10, 2005

NNL: The odds of finding the right theory be it string or loopy or something entirely different in the space of all possible theories is vanishingly small – the history of pure reason is the history of dead ends.

AB: Like GR?

NNL: Thanks. I was expecting this reply.

1. The validityof inertial and gravitational mass as physical concepts and the WEP were already established by experiment – although Einstein states that he was unaware of the Eotvos experiement until later.

The concept of strings is not established experimentally.

2. Even if we allow that you're right, GR is atypical of the way the progress in physics is usually made:

Technical advance in instrumentation -> observation of new and unexplained phenomena -> candidate theories -> new predictions -> experimental tests.

27. **dan**
December 11, 2005

before we write off string theory shouldn't we wait for LHC to come online?

I think SUSY ans SUSY-m-theory are important research programs for *physics* in that they help
1- encourage investments into particle accelerators, including LHC
2- tell experimentalists what sort of particles to look for (Higgs, extra dimensions, SUSY-particles)

if LHC does find SUSY-particles such as the neutralino, such a finding would strongly support the string theory research program.

as difficult as the landscape problem presents, m-theory may be worth pursuing if LHC finds evidence of SUSY particles and/or higher dimensions.

if LHC does not find SUSY-particles or extra dimensions, i would agree with Woit we should more aggressirvely pursue other research programs, including LQG.

28. **Chris W.**
December 11, 2005

(Taking off from NNL's comment —)

Both special relativity (SR) and general relativity (GR) are atypical, inasmuch as they were motivated in Einstein's mind by *facts about certain relations of existing theories to well-established experimental observations and to each other*.

In the case of GR the relevant fact was the apparent equivalence of gravitational and inertial mass, which was relied upon but not explained in the formulation and application of Newton's theory of gravitation. The significance of this fact was amplified for Einstein by Ernst Mach's acute analysis of the difficulties that universal gravitation created for any effort to give operational meaning to the idea of inertial motion.

In the case of SR the relevant fact was the equivalence of the currents induced in a wire (eg, in the form of a coil) when (1) the wire was held stationary relative to the laboratory and a magnet was moved near it, and when (2) the magnet was held stationary and the wire was moved such that the relative velocity of wire and magnet was the same in the two situations. The measured and calculated currents (in Maxwell's electrodynamics) were known to be the same in the two situations, but the description of the two situations in Maxwell's theory as it was understood at the time differed markedly. The significance of this fact was amplified in Einstein's mind by the *apparent theoretical possibility*—given Newtonian kinematics—of overtaking an electromagnetic wave and rendering its oscillation stationary in the observer's frame of reference.

Other physicists of the time could have responded to both of these concerns this way: "Well, *so what?* What observation is being contradicted here? I don't see any real difficulty, certainly not one that justifies reconsidering the foundations of our science, or the assumptions behind our current investigations into the properties of the luminiferous aether."

The point in the case of SR is that the theoretical issue restated here was as much or more of a preoccupation for Einstein than any of the specific observational oddities that were perplexing his contemporaries. They were concerned with specific discrepancies between theoretical expectations and observation. He was concerned with what he saw as a *deficiency in explanatory power in situations where no specific discrepancy between calculated consequences and corresponding observations was at issue*.

His genius lay in the fact that he had latched onto genuine problems within the overall theoretical framework of classical physics that had not been clearly seen before, proceeded to resolve them, and in so doing showed that observational anomalies already known could be understood and resolved.

This echoes our current predicament in essential respects. The fact that string theory in its early formulations did not follow directly from supporting observations is beside the point. (We should be so lucky…) We *do* have fundamental inconsistencies within the overall structure of late 20th century theoretical physics, and we do have observations and experimentally determined quantities which play a fundamental role in our theories but which have no deeper explanation. Our problem, as it was for Einstein, is to understand these difficulties, see how they can be resolved, and see how the resolution can be tested, ie, how it manifests itself in the world we now observe or might observe if we are sufficiently clever.

There is no guarantee that this can be done in a way that doesn't amount to an epistemological capitulation, an abandonment of essential methodology of science—that we find things out by having ideas and trying very hard to see where they might fail as well as where they succeed. To do this we must have ideas that are *not* designed at the outset to be immunized against empirical failure. Such immunization must itself be regarded as a failure; this point is what this weblog has become largely about. Einstein had a profound faith that one could adopt this attitude and yet not be hopelessly stymied in understanding the world.

29. **D R Lunsford**
December 11, 2005

Chris W makes excellent points, and just to emphasize, GR was no more (or less) a product of "pure reason" than was the Dirac equation, and it fit in nicely with the historical development in its time, no matter how surprising the form*. Antimatter and horizons are concepts that *emerged* from the two formalisms – they were not inputs. In contrast, string theory *puts in by hand* an assumed form of matter. To make an analogy, one cannot derive the Dirac equation from the existence of antimatter, because the Klein-Gordon equation also leads to the same idea. String theory is always trying to derive what we already know with an assumed form of matter, which is backward – the traditional way is to model what we don't know as competently as possible and see what new ideas emerge, which inevitably correspond to real facts.

(markus: that is an intriguing idea 🙂

30. **Aaron Bergman**
December 11, 2005

The program of quantum gravity — not just string theory — is certainly an act of hubris. That nobody has made it very far in twenty-five years is humbling. The hope of everyone in string theory, for years, was that it would uniquely predict our world. At best, in now seems more likely that string theory has a huge multitude of vacua, and the best hope of obtaining predictions would be to overconstrain the particular vacuum we live in or discover some way to probe the universal aspects of the space of vacua.

I don't know if that's possible. One can argue aesthetics all night, but string theory's still the only idea out there that has derived a black hole entropy. Until we've got some experimental data, we're stuck with our hubris. It's either that or go work on something with the prospect for data — which a lot of people are doing these days.

31. **FP**
December 11, 2005

Aaron,

> Until we've got some experimental data, we're stuck with our hubris.

I have asked this question before. How would experimental data help you (or any other string theorist) ?

E.g. If the Pioneer anomaly is real and we could measure it exactly,
how would this help with superstrings (or LQG) ?
You cannot calculate corrections to the Newton potential and thus you cannot decide if the Pioneer anomaly confirms or falsifies string theory.

I am just using this as an example, the same would be true for any other (gravitation) experiment.
What if Gravity probe B data show a small (or large?!) deviation from GR? How would a superstring theorist react to such news?

32. **Arun**
December 11, 2005

Chris W., thank you!

FP, if the Pioneer anomaly is real, and cannot be accomodated in Einstein's GR or similar geometric idea, then the idea of gravity as the effect of the geometry of space-time may be overthrown. Who knows what will happen to blackholes and their entropy? The idea of space-time fluctuations at the Planck scale, etc., may be discarded and so on. The correct classical theory of gravity is an essential ingredient to a theory of quantum gravity and thereby to string theory as well. For instance, whatever the corrected theory of gravity turns out to be, it had better show up in the string theory derivation of the consistency condition on the background space-time that looks like Einstein's equations.

33. **Aaron Bergman**
December 11, 2005

I have asked this question before. How would experimental data help you (or any other string theorist) ?

It depends on the type of the experiment. If one could (unlikely) directly probe high energy quantum gravity, that would be immensely useful.

Low energy things, on the other hand, are much more difficult to exploit. The cosmological constant, for example, is a bit of low energy experimental data that has drived people to ~~despair~~ anthropic explanations.

Nonetheless, it's still better than nothing. And the more stuff we have, the more likely it is that someone might be able to guess some unifying theory.

34. **FP**
December 11, 2005

Arun,

> The correct classical theory of gravity is an essential ingredient to a theory of quantum gravity and thereby to string theory as well

I always understood it the other way around. The quantum theory of strings, or
M-theory if you will, contains necessarily a theory of gravitation and there is no freedom to begin with different ingredients …

35. **theon**
December 13, 2005

Did anybody question whether we really have to quantize gravity?
If not, then a lot of the current problems need no answer.

36. **Aaron Bergman**
December 13, 2005

Did anybody question whether we really have to quantize gravity?

Yes. It's very hard to write down anything that makes sense that way. Jacques talked a bit about it here.

37. **CapitalistImperialistPig**
December 13, 2005

Question especially for Peter and Aaron (or anyone else who knows): I have been hearing for many years some variation on "we don't really know what String Theory (or sometimes M-Theory) is." Clearly string theorists know how to compute a lot of things, so what do they mean by that? If it's not the theory of these little string like things, why not?

Is some key conceptual or dynamical piece still missing? If so, isn't it likely that discovering it might simplify landscape, swamp, etc.?

38. **woit**
December 14, 2005

CIP,

Basically what is understood is "perturbative string theory", which is conjectured to be a series expansion of some underlying "non-perturbative string theory, AKA M-theory". Many string theorists certainly hope that when M-theory is finally understood, it will solve the problems currently plaguing string theory. But some things are known about M-theory, and what is known gives no evidence at all for this to be true.

39. **Aaron Bergman**
December 14, 2005

If it's not the theory of these little string like things, why not?

Damned if I know.

Really, it's not at all clear that we understand what the fundamental degrees of freedom actually are in string theory. We have control over a few things like AdS/CFT and a perturbation expansion, but beyond that, it's a lot of patchwork approximations.

It'd be cool if understanding all this stuff got rid of the multitude of vacua — Tom Banks has argued that many of the approximations break down for subtle reasons having to with asymptotics in cosmology — but it's hard to say that it's likely.

You ask if some key conceptual piece is still missing. I think, even after who knows how many 'revolutions', we still understand next to nothing. The anthropic and string phenomenology types get a lot of the press, but there's still a whole bunch of us who would prefer to understand just what string theory is before trying something as audacious as applying it to the real world.

Of course, that's hard, so I'm just working on trying to understand what a quiver gauge theory on a D-brane is….

40. **Who**
December 14, 2005

Theo asked a good question.

Did anybody question whether we really have to quantize gravity?

there is a thread at PF about this question, in case anyone has ideas about why it could be useful to quantize gravity.

http://www.physicsforums.com/showthread.php?p=856677#post856677

41. **Wolfgang**
December 14, 2005

> Did anybody question whether we really have to quantize gravity?
Yes of course. And the answer is, yes we do have to quantize gravity,
as explained e.g. by Jacques Distler (the part about): http://golem.ph.utexas.edu/~distler/blog/archives/000639.html

Princeton Center for Theoretical Physics

December 9, 2005
Categories: Uncategorized

Princeton University has just announced the formation of a new Princeton Center for Theoretical Physics, to be led by Curtis Callan (who was my thesis advisor).

Interestingly, the concept of this new center seems to be to move away from Princeton's traditional emphasis on particle theory (and more recently, string theory) as the central topic of theoretical physics, in favor of a much broader concept, bringing "together faculty, postdoctoral fellows and students from science departments across campus to study topics ranging from the Big Bang to quantum computing to evolution."

In recent years Callan has been spending much of his time working on biology, and the idea seems to be for the center to encourage this sort of work by theoretical physicists in other disciplines. Callan says:

"A motivation for the center is the growing realization that some very exciting challenges in theoretical science arise when we ask what theoretical physics can do to help comprehend the new phenomena and enormous amounts of high-quality data that other disciplines are now producing."

"In discussions among a group of faculty over the last year, we came to the conclusion that Princeton is remarkably well-placed to foster such developments: It is a leader in theoretical physics and it has an unusual number of faculty in other departments — including chemistry, engineering, molecular biology and genomics — who are trained in theoretical physics," he said. "The purpose of the center is to create a framework in which these people can work together to expand the boundaries of theoretical science."

The associate director will be cosmologist Paul Steinhardt, and the other faculty associated with the center include condensed matter theorists Ravindra Bhatt and Shivaji Sondhi, string theorist Igor Klebanov, astrophysicist David Spergel, biophysicist William Bialek, and materials scientist Salvatore Torquato. The center will open in the fall of 2006 with thematic programs in cosmology and quantum computation starting in 2007.

Across town at the IAS they're not branching out into other subjects but sticking to pure string theory, recently announcing that next year's Prospects in Theoretical Physics summer program will be devoted to training graduate students and postdocs in string theory.

Comments

   December 9, 2005

   They're putting the thing *inside* Jadwin?

   That's not very nice.

2. **anon**
   December 9, 2005

   Will they recruit Lubos to research climate change? 🙂

3. **secret milkshake**
   December 9, 2005

   Only if they desired to bring about a precipitous change in research climate there… (Seriously, I do think that LuMo should start doing something with his Misanthropic Principle.)

4. **Dave Bacon**
   December 9, 2005

   Woot! Quantum computing! This coming from theoretical physics? Woot!

5. **andy**
   December 9, 2005

   What if the chemists already have their own theorists?

6. **secret milkshake**
   December 10, 2005

   Chemistry theorists: Only theorists that work in physics-related part of chemistry (in applications like such as material science or NMR spectroscopy) are realy helpful. Chemistry is run by experimentalists – because they know about chemicals and theorists do not. Study of any real problem very quickly gets out hand from the theory standpoint. You can use physicist insights to explain something after observing it but problems in chemistry and biology (and generaly in any complex system) are pretty impossible to deal with from first priciples.

7. **anon**
   December 10, 2005

   Maybe Princeton will find an application of SuperString Theory to Chemistry!

8. **biophysics**
   December 10, 2005

   secret milkshake – you are definitely correct that complex systems are pretty impossible to deal with from first principles in the sense that it's pretty useless to write down a Hamiltonian and then expect to describe the rich dynamics. But I think the programme (in biophysics as I understand and practise it at least) is more toward phenomenological model building to start with and then go back and see if the models point toward some kind of overarching framework. In particular (again for me) it will be interesting to see whether good quantitative models in biophysics will fulfill the promise of research into self-organisation, etc. A lot of beautiful mathematics from nonlinear dynamics seems not to have lived up to its hype vis a vis applications to physics but perhaps the search for new physics in biology will be the place where they shine. In fact I'm guessing that is what Princeton is betting on (of course as my pseudonym indicates I'm betting my career on this as well 🙂).

9. **Richard**
December 10, 2005

I would definitely welcome more involvement by physicists (and mathematicians) with biology, especially regarding molecular biology. Having been born with a flakey immune system, and done a lot of reading about the immune system, I realize how amazingly complex it is (probably more complex than the brain) and how difficult it is to model its dynamics with its very large array of cell types with complex functions, feed forward and feed backwards chemical signaling via a large number of cytokine types, and genetic variations. Understanding the immune system is a highly nontrivial problem that needs very bright people. And a related and worthwhile pursuit would be attempting to understand the relation and interaction between the immune system and evolution. This is something I've never noticed anyone discussing, but I think it could be fascinating.

10. **Chris W.**
December 10, 2005

Richard,

From the May 2005 addendum to the biography of **Gerald Edelman** on NobelPrize.org:

> Dr. Edelman has made significant research contributions in biophysics, protein chemistry, immunology, cell biology, and neurobiology. His early studies on the structure and diversity of antibodies led to the Nobel Prize for Physiology or Medicine in 1972. He then began research into the mechanisms involved in the regulation of primary cellular processes, particularly the control of cell growth and the development of multicellular organisms. He has focused on cell-cell interactions in early embryonic development and in the formation and function of the nervous system. These studies led to the discovery of cell adhesion molecules (CAMs), which have been found to guide the fundamental processes by which an animal achieves its shape and form, and by which nervous systems are built. *One of the most significant insights provided by this work is that the precursor gene for the neural cell adhesion molecule gave rise in evolution to the entire molecular system of adaptive immunity.*
>
> Most recently, he and his colleagues have been studying the fundamental cellular processes of transcription and translation in eukaryotic cells. They have developed a method to construct synthetic promoters and have also been able to enhance translation efficiency by constructing internal ribosomal entry sites of a modular composition. These findings have rich implications for the fields of genomics and proteomics.
>
> Dr. Edelman has formulated a detailed theory to explain the development and organization of higher brain functions in terms of a process known as neuronal group selection. This theory was presented in his 1987 volume *Neural Darwinism*, a widely known work. Dr. Edelman's continuing work in theoretical neuroscience includes designing new kinds of machines, called recognition automata, that are capable of carrying out tests of the self-consistency of the theory of neuronal group selection and promise to shed new light on the fundamental workings of the human brain. A new, biologically based theory of consciousness extending the theory of neuronal group selection is presented in his 1989 volume *The Remembered Present*. A subsequent book, *Bright Air, Brilliant Fire*, published in 1992, continues to explore the implications of neuronal group selection and neural evolution for a modern understanding of the mind and the brain. His book published with Giulio Tononi, entitled *A Universe of Consciousness: How Matter Becomes Imagination*, presents exciting new data on the neural correlates of conscious experience. In his latest book, published this year, entitled *Wider than the Sky: The Phenomenal Gift of Consciousness*, Dr. Edelman offers a model of the biology of consciousness.

December 11, 2005

The Princeton NEWS read,

> This is an exciting venture for the University that we believe will be immediately recognized as a site where some of the most important theoretical work around the world is being done

This sound a bit to "Santa Fe Institute". We still are waiting for some useful science from there!

Or maybe sound a bit to "string theory is the last formulation of nature. Everything will be understood from string theory."

I am seeing that by "interdisciplinary" methodology Princeton means

joint many people in a single room and wait

As proved by "Santa Fe Institute" and explained next this does not work for obtaining "new physics".

biophysics said,

> secret milkshake – you are definitely correct that complex systems are pretty impossible to deal with from first principles in the sense that it's pretty useless to write down a Hamiltonian and then expect to describe the rich dynamics.

This is a myth! There is not Lagrangian or Hamiltonian description! this is one of billion of scientific reasons that string theory always was a wrong approach to theory of everything (see "String theory is not a TOE" in sci.physics.strings).

The literature on the topic is huge and i cannot cite here, but see below some basic works and references cited therein.

I am talking of real science. NOBODY studies electron transfer in biological systems, for instance, using a Hamiltonian approach. In fact, **standard** approaches as Redfield-like or Lindblad-like one are not based in Hamiltonian approaches.

Lindblad approach is axiomatic and NOT derived from Hamiltonian dynamics. I have updated a xml page [http://www.canonicalscience.com/en/researchzone/time.xml] with last tendencies on the topic. Since it is not accesible to old browsers i add next some relavant literature cited.

Prigogine, Ilya. The End of Certainty: Time, Chaos, and the New Laws of Nature; The Free Press: New York, 1997.

Wang, G. M; Sevick, E. M; Mittag, E; Searles, D. J; Evans, D. J. Phys. Rev. Lett. 2002, 89(5), 050601/1–050601/4.

González-Álvarez, Juan R. Has thermodynamics been violated in the quantum domain? In press.

Zwanzig, Robert. Nonequilibrium statistical mechanics; Oxford University Press, Inc: New York, 2001.

Eu, Byung Chan. Nonequilibrium Statistical Mechanics, ensemble method; Kluver Academic Publishers: Dordrecht, 1998. In Fundamental theories of physics; van der Merwe, Alwyn (Ed.); vol 93.

In Chan monograph *is clearly explained that Hamiltonian/Lagrangian equations are not sufficient* and a new equation (Eu equation) explaining experimental data (that Schrödinger or classical Hamiltonian cannot explain) is postulated as a complement to “old” physics.

Eu equation (10.14) has the formal structure

drho/dt = (H + B) rho

H is Hamiltonian dynamics.

B is a new dynamics!

This expliting is formally similar to Prigogine one (see eq 7.19 on http://nobelprize.org/chemistry/laureates/1977/prigogine-lecture.pdf) but experimentally more useful and theoretically sound that early Prigogine approach.

That is NEW exciting physics!

String theory is garbage (Note: some particle-string theorists are attempting to expand string theory via that new physics. See arXiv:hep-th/9406016) But their approach is tecnically wrong and lof ot advanced math proves that contains lot of wrong stuff, even if eq (45) ‘looks’ as Eu approach. Equation 37 was incorrectly copied!

biophysics said,

> perhaps the search for new physics in biology will be the place where they shine.

Precisely, on my study of biological systems via Keizer modelling (eggs metabolism, membrane fluctuation currents in Ca^2+ transport in muscle membranes, etc.) i obtained one of first formulations of nanothermodynamics [*].

New physics, experimentally verifiable and contradicting some last wrong papers on PRL and PRE!

Juan R.

December 11, 2005

Chris,

> One of the most significant insights provided by this work is that the precursor gene for the neural cell adhesion molecule gave rise in evolution to the entire molecular system of adaptive immunity.

If so, this is very interesting! Thanks!

While walking in the snowy woods with my dog today, I was thinking about related issues. There does seem to be some tight relationships between the nervous system and the immune system. The brain (especially the hypothalamus) is highly responsive to cytokines emitted by immune cells, and we have even discovered neural receptors on immune cells. One of the most difficult problems in immunology has been the self/non-self issue; that is, how do immune cells distinguish between tissue which is myself and that which is not myself. We only partially understand how the immune system is self-regulated so that it is aggressive enough to disable invaders but controlled enough so that it doesn’t begin attacking ourselves or overwhelming us with inflammation. [All of this breaks down with autoimmune diseases, of course, such as Lupus. And ironically, some people with immune deficiencies also have autoimmune diseases.] At any rate, it occurred to me that there could be (at least weakly) analogous issues with the brain. There must be a problem of self/non-self there, and at the actual neuronal system level, not just a philosophical issue. Well, my brain started spinning even further, and began to wonder how fundamental physics could be approached from a kind of self/non-self viewpoint. Is there any analogy there to what I’ve been talking about with biological systems? A quiet walk in the woods with your dog is conducive to free association! Now, back to math.

Resistance to our factoring machines is futile!

Wilczek Goes Anthropic

December 12, 2005
Categories: Uncategorized

A few weeks ago one Nobel prize winner put out an article promoting the idea of adopting anthropic reasoning as a new paradigm of how to do theoretical physics. More recently another Nobelist, Frank Wilczek, has to some degree followed suit. Wilczek is one of four authors on a new paper entitled Dimensionless constants, cosmology and other dark matters which first appeared on the arXiv November 29th, then in a slightly revised version on December 8. The other authors are Tegmark, Aguirre and Rees, with Tegmark's name appearing first indicating it's more his work than that of his co-authors.

I wasn't sure quite what to make of this paper when it first came out, especially how much it reflected Wilczek's own point of view on anthropism. Last Friday I attended talks by Wilczek and Tegmark at the 6th Northeast String Cosmology Meeting organized by the Institute for Strings, Cosmology and Astroparticle Physics here at Columbia.

Wilczek's talk was entitled "Enlightenment, Knowledge, Ignorance, Temptation". He explained that these corresponded to categorizing parameters of physical theories according to whether life depended on them or not and whether we have a good idea for what determines them or not. Choosing the two possible answers to these two questions gives four cases:

Enlightenment: Parameters that life depends on, and we think we have a good idea about what determines them. Here his example was the proton mass, very small on the Planck scale, but we think we know why: logarithmic running of coupling constants.

Knowledge: Parameters that life doesn't depend on, and we think we have a good idea about what determines them. One example he gave was strong CP violation, which is irrelevant to life, but very small, perhaps because of axions.

Ignorance: Parameters that life doesn't depend on, and we don't have a good idea about what determines them. This includes most of the standard model parameters, as well as just about all parameters in theories that go beyond the standard model.

Temptation: Parameters that life depends on, and we don't have a good idea about what determines them. The examples he gave were the electron and up and down quark masses.

He said that his talk would concentrate on "Temptation", the temptation being that of using anthropic argumentation. He noted that David Gross believes this is a dangerous opiate, causing people to just give up instead of really solving problems. The one anti-anthropic point he made was to put up a graphic showing agreement of the lattice QCD spectrum calculations with experiment, saying the lesson was that sometimes real calculations turned out to be possible even though people had at times doubted this. So one should try and "limit the damage", not go wild and use anthropics inappropriately, trying to save as much beautiful physics as one can even when anthropic reasoning is forced on us.

The rest of his talk though showed a significant amount of enthusiasm for the new anthropism. He referred to people like his co-author Rees who have been promoting the anthropic point of view for years as "unhonored prophets". Given the paucity of experimental data relevant to explaining where things like standard model parameters come from, he said that at least anthropics gives lots of new questions so one has something to do when one gets up each day which might be fruitful. He attacked the idea of using "pure thought", without consulting the physical world, saying this hasn't worked, not 20 years ago, not now, not in the future. I presume he had string theory in mind when he said this, noting out loud that it might annoy some people in the room.

The main idea about anthropics he was trying to push is that anthropic calculations were "just conditional probability", making much of the equation

$f(\mathbf{p})=f_{prior}(\mathbf{p})f_{selec}(\mathbf{p})$

for the probability of observing some particular value **p** of parameters, given some underlying theory in which they are only determined probabilistically by some probability distribution $f_{prior}(\mathbf{p})$. The second factor $f_{selec}(\mathbf{p})$ is supposed to represent "selection effects", and it is here that anthropic calculations supposedly have their role. In the paper the authors argue that "Including selection effects is no more optional than the correct use of logic". The standard way physics has traditionally been done, one hopes that the underlying theory determines **p** (i.e. $f_{prior}(\mathbf{p})$ is a delta-function), making selection effects irrelevant in this context. The authors attack this point of view, writing:

to elevate this hope into an assumption would, ironically, be to push the anthropic principle to a hedonistic extreme, suggesting that nature must be devised so as to make mathematical physicists happy.

At no point in his or Tegmark's talks, or anywhere in their paper, do they address the central problem with the anthopic principle, that there's a huge issue about whether you can get falsifiable predictions out of it, and thus whether you're really doing science. In this context, the nature of the problem is that if $f_{prior}(\mathbf{p})$ is not peaked somewhere but is flat (or more or less flat), then everything just depends on $f_{selec}(\mathbf{p})$, but if you calculate it anthropically, all you are doing is seeing what you can conclude from known laws of physics and the fact that we exist. In the end what will come out of this kind of calculation is some probability distribution that better be non-zero for the values of the parameters we observe, otherwise you've done the calculation wrong.

There is a particular sort of physical model one can hope to falsify this way. If one assumes our universe is a randomly chosen point in a "multiverse" of possibilities, and looks at an observable that is supposed to have a more or less flat probability distribution in the ensemble given by the multiverse, then one can argue that we should be at some region of parameter space containing the bulk of the probability in the anthropically determined $f_{selec}(\mathbf{p})$, not far out in some tail where the probability distribution is vanishingly small. There are plenty of examples of this already. The proton lifetime is absurdly long compared to bounds from anthropic constraints, so any model of a multiverse that doesn't have some structure built into it to generically sufficiently suppress proton decay is ruled out. This includes the string theory landscape, so one of the many mysteries of the whole anthropic landscape story is why its proponents don't take their own arguments seriously and admit that their model has been falsified already. It also applies to Tegmark's favorite idea, that of the existence of a Level IV multiverse of all possible mathematical structures, an idea he also promotes in the paper with Wilczek.

Wilczek also discussed one particular axion cosmology model in which $f_{prior}(\mathbf{p})$ can be calculated. In these models one has the relation
$$\xi_c\sim f_a^4\sin ^2\frac{\theta_0}{2}$$
for the axion dark matter density in terms of the Peccei-Quinn symmetry breaking scale and the misalignment angle of the axion field at the Peccei-Quinn symmetry breaking phase transition. To make this agree with the observed dark matter density, if one assumes the misalignment angle is some random angle then the Peccei-Quinn scale has to be about 10^{12}GeV. If one wants to make the Peccei-Quinn scale the GUT or Planck scale, one has to find some reason for the misalignment angle to be very small. The proposal here is that this happens for anthropic reasons, since if the angle were not small it would cause an amount of dark matter incompatible with our existence. For these small angles the above formula implies that the probability distribution for the dark matter density caused by such axions satisfies
$$f_{\text{prior}}(\xi)\sim \frac{1}{\sqrt \xi}$$

The Tegmark et. al. paper contains an elaborate calculation of f_{selec} for the dark matter density, involving all sorts of "anthropic" considerations which goes on for eleven pages or so and involves a bafflingly long list of considerations about galaxy, star and planet formation, as well as many possible dangers that could have disrupted the evolution of life, such as disruption of the Oort cloud of comets. I'll freely admit to not having taken the time to follow this argument. The end result for f_{selec} as a function of $\sqrt\xi$ is a probability distribution with the measured dark energy corresponding to something close to the peak.

I'm not sure exactly what conclusions one can or should draw from this calculation. So many different facts about our specific universe are being folded into this that it's not clear to me that there isn't some circular reasoning going on. This is a general problem with "anthropic" arguments: if you assume that life couldn't exist if the universe was much different than it is, you smuggle all sorts of information about the way the world is into your "anthropic" calculation, after which it is not too surprising that it "predicts" the universe has more or less the properties you observe.

What we really care about in these arguments is whether they can be used to extract any information whatsoever about f_{prior}, the physics we are trying to get at. In this axion cosmology case we have a prediction for this distribution and the calculation shows this is consistent with the observed dark energy density, but as far as I can tell, all sorts of other quite different distributions would work too. So, I'm still confused about exactly what this calculation has told us about the underlying axion cosmology physics that it is supposed to address, other than that it is not obviously completely inconsistent.

Tegmark's talk at Columbia was titled "Measuring and Predicting Cosmological Parameters". The "measuring part" was a summary of some of the impressive experimental evidence for the standard cosmological model. The "predicting" part was pretty much pure promotion of anthropism, including a long section on reasons why the electroweak symmetry breaking scale is anthropic and some comments making fun of David Gross ("even he couldn't predict the distance from the earth to the sun. Laughter…"). The only actual "predictions" mentioned were the results about the axion cosmology model mentioned above and described in detail in the Tegmark et. al paper, as well as the well-known Weinberg anthropic "prediction" for the cosmological constant.

All in all, I found these two talks and the Tegmark et. al. paper pretty disturbing. They seem to me to be part of a highly ideological effort to sell the Anthropic Principle as science. The paper devotes two pages to a detailed list of standard model parameters, and makes various statements about the probability distribution function on this large number of parameters, even though it has nothing to say about almost all of them, and I think there's a strong argument that the anthropic program inherently will never have anything useful to say about most of these parameters. Many of Wilczek's remarks were more modest, but the paper he has signed his name to is highly immodest in its claims for anthropism. Together with Weinberg and Susskind's anthropic campaigns, it seems to me that more and more theorists are going to join this bandwagon. Neither Wilczek nor Tegmark are string theorists (and Wilczek is clearly somewhat skeptical about the whole idea), but there seems to be an unholy alliance brewing between them and Susskind and his followers. The only prominent person in the field standing up to this publicly is David Gross, and it is very worrying to see how little support he is getting.

Update: A preprint by Frank Wilczek corresponding to his talk last week entitled Enlightenment, Knowledge, Ignorance, Temptation has appeared. It is a contribution to the same conference as the one Weinberg contributed Living in the Multiverse to, I gather in honor of Martin Rees. Wilczek's preprint announces a "new zeitgeist", that anthropic arguments are in the ascendancy. One quite strange thing in the preprint is that he suggests an anthropic explanation for the long proton lifetime in terms of doing anthropic calculations involving future observers.

He does say there are drawbacks to the new order (a loss of precision and of targets to calculate), but on the whole he seems to embrace the new anthropic paradigm rather whole-heartedly, seeing it as a lesson in humility for those who had the hubris to believe it was possible to understand more about the universe through "pure thought."

Update: Two of the authors of the paper discussed here (Aguirre and Tegmark) wrote in with some comments that are well worth reading (as well as those from Smolin and others about his own proposal). Aguirre points to an interesting paper of his On making predictions in a multiverse (see also an earlier paper with Tegmark), which addresses some of the conceptual issues that were bothering me about this sort of calculation. It points out many of the problems with this kind of calculation, and I don't really share the author's optimism that they can be overcome.

Lee Smolin mentioned to me a somewhat related workshop that was held this past summer at the Perimeter Institute, on the topic of Evolving Laws, especially "do the laws of nature evolve in time?" Audio of the discussions at the workshop is available

Comments

   December 12, 2005

   God, I'm so sick of this crap. And people wonder why I do math these days….

   The proton lifetime, by the way, has been often mentioned by people against anthropic reasoning. It is not alone in Wilczek's "ignorance" category. The existence of such parameters is one of the reason that Nima would like to claim that only superrenormalizable couplings are anthropically selected. It's also was some of the motivation for his "friendly landscape" paper.

   Remember, BTW, the vote in Toronto. Most people don't go for this stuff.

2. **Anonymous**
   December 12, 2005

   The anthropic arguments remind me of the ones you will encounter from people into bible codes. Typically, they have found some code, and then the calculate the probability that a book like the bible would at random produce this code. Of course, it turns out to be really small, thus "proving" divine intervention. The point is of course that they have singled out precisely the code they already found, and in any random string of letters, they might very well not have found this particular code, but they probably would have found another code, which they then would have argued was of divine origin.
   So the anthropic people have found the code that is life in the universe, and in particular the kind of life that exists here on Earth. And it seems really unlikely to them, implying not a divine origin of the universe, but an almost infinite amount of existing universes. But life, and sometimes really bizarre forms of life, are known to flourish in the most unlikely conditions here on Earth. Why not in another kind of universe? All needed is some process of replication, variation, and some kind of selection, maybe plus minus some conditions on the mutation rate, et cetera. Have the anthropic people been able to produce anything towards a proof that no kind of life is possible in some hypothetical universe? If they did, they'd at least have a methodology.
   Finally, why single out life? Why not single out the Iraq war or the act of seeing a squirrel? Or why not concern oneself with universes in which it is possible to go out and drink beer?

3. **JE**
   December 12, 2005

   It may be worth mentioning that besides a Nobelist, Wilczek is editor in chief of Elsevier's Annals of Physics. Let's just hope that his anthropic leanings do not permeate the journal's content.

   December 12, 2005

   Apart from the points Peter mentions against anthropic reasoning I see two others. The first : anthropic reasoning necessarily begins this way : there is intelligent life–> there is life –> there is carbon chemistry. After this, one can make so-called predictions which I think are just very indirect measurements of some observables which remind me (in the best case) of the very clever way Einstein measured avogadro number thanks to the fact that the sky is blue. To call this sort of thing a 'prediction' one has to be confident in the chain of implications I mentioned above, which is very weak indeed since it is based mainly on our lack of imagination and on our very poor understanding on what is intelligence. One also has to assume the existence of a multiplicity of uninhabited universes and use the indifference principle, which is well known to lead to crazy conclusions on some occasions. For instance, suppose I am struck with sudden amnesia about who I am. I could argue that I am chinese by using this principle. However looking around me would soon provide me with clues that I'm in fact french. I feel that it's the same with anthropic argument. That is, you assume the standard model+GR is the end of the story, you vary parameters as if they were independent, knowing it will give crazy results if they happen not to be so etc… Perhaps this is the only thing to do when you give up any hope of finding a more precise theory. Except that 'giving up' is not precisely the right attitude for a scientist, I think.

December 12, 2005

Everyone is tired (in cosmology at least) of talking about the anthropic principle. Everytime it comes up everyone rolls their eyes and mutters something about philosophy and that its 'boring'.

When approaching a problem as a working scientist, I see no valid reason to think of fprior as anything other than a delta function. If I can't calculate something, I then assume its either b/c im stupid or b/c I have insufficient information about the system, such that it might naively appear that fprior is smeared out into a nontrivial ensemble.

Historically the amounts of time a physics problem did not involve a fprior delta function and instead was something else is vanishingly small compared to the times that there is a pure deterministic or selection effect at play.

So it seems to me, from a historical perspective, this is just another example of people jumping the gun and giving up too early.

And perhaps its really not so surprising is it? We are implicitly making an intellectual leap of tens of orders of magnitude between observable physics and intellectual gaming, does it astonish anyone then that there is a understanding gap, such that you could seperate unknowns away into the prior distributions?

6. **FP**
December 12, 2005

It would be interesting if anthropic reasoning could predict something we do not yet know. E.g. the exact Higgs mass.
As long as anthropics only 'predict' what we know already, the whole philosophy is not very convincing.

7. **Wolfgang**
December 12, 2005

Does anybody want to comment on this paper?
http://xxx.lanl.gov/abs/physics/0512062

From the abstract: "I make some comments about brane world scenarios and their potential to strengthen the Fermi Paradox."

In the text: "My solution to the Fermi paradox is compatible with the
speculations that some UFO's could be true alien spacecrafts."

8. **Alejandro Rivero**
December 12, 2005

The classification Wilczek does is a good idea in order to distinghish anthropicism from empiricism. To me, antropic reasonment is a trick to introduce empirical measurements (under the disguise of "life normal conditions") inside the theory.

I join Gross' objections; any ad-hoc theory is an opiate if it is not perceived as ad-hoc, and it can cause retirement from the fight. Mattews' pill killing Barrow. I was not surprised by Weinberg take on anthropicism; his book promotes Effective Field Theory, which is a lesser narcotic but with similar effects. I am not sure about Wilczek, even after reading your report.

9. **woit**
December 12, 2005

Please, Wolfgang and others, no space aliens and UFOs here. The anthropic stuff is bad enough.

10. **weichi**
December 12, 2005

Aaron,

Which crap are you sick of? Peter's crap? The anthropic crap? Wilczek's crap?

11. **Aaron Bergman**
December 12, 2005

Anthropic "just so" stories.

12. **Wolfgang**
December 12, 2005

Peter,

OK. But I think this type of paper (about the 'subanthropic principle') is the logical next step in the line of anthropic reasoning.
By the way, when will Frank Tipler and the 'Physics of Immortality' re-appear?

13. **Jason Douglas Brown**
December 12, 2005

It's disappointing that so many otherwise smart people are caving into this landscape rubbish. For one it will not ever yield one prediction whatsoever. The only real hope string theory or its new incarnation as the yet to be discovered M-theory is for it to have enough symmetry to find a unique vacuum. I am very partial to many of the ideas and discovers surrounding string theory but if I came across it now I'd think twice before putting in all the effort.

I think the reason for all this landscape crap is that string theorists have yet to make the next big discovery in superstrings. They say one comes along every ten years or so. Since AdS CFT not much has happened from a fundamental standpoint. It seems to me that string theory is foundering because we're reached an impass. String/M-theory will not move forward until the next major piece of the puzzle has been discovered. The next major step is to create a consistent second quantized covariant version of string/m-theory. String theory in the 60's gave way to QCD. Perhaps the current string theory/M-atrix theories will give way to a local field theory with enough symmetry to give a single unique true vacuum state. Or perhaps not. It really gives me the willies when some of the most intelligent men who've walked the earth invoke anthropic arguments in the context of some supposed string landscape.

14. **AJ**
December 12, 2005

JDB,

Field theories with lots of symmetry tend to have more vacua, not fewer. Very crudely, more symmetry equals more representations.

15. **Michael**
December 12, 2005

I don't understand Wilczek's categories. He claims to know that life doesn't depend on the smallness of CP? How could he possibly know this? Does it get any more pathetic than this? I am sad to see Wilczek go in this direction.

16. **Quantoken**
December 12, 2005

Jason, what makes you think that once Super String Theory is able to find a unique vacuum and make predictions, things will be OK, then? You guys have worked on the crackpot theory for too long and forget that a science theory not only needs to make predictions, but more important, make **CORRECT** predictions. The day that super string theory makes predictions will also be the day that the idea is dead. Because there is only one in 10^500 chance your "unique vacuum" will actually match the reality world. The world is 3+1 dimensions! There has been nothing suggesting anything different from that fact.

It will take a truely wrong time before super string theory will eventually be able to make a prediction at all. The **real tragedy** is by then you will realize how wrong you guys were and what a waste of time and effort it had been, to dwindle on a crackpot idea for so long, just because it was a paid day time job to research crackpots.

17. **Wolfgang**
December 12, 2005

Off topic:
Lubos just posted about Riemann's hypothesis and
states that "a proof may possibly follow from string theory".

18. **secret milkshake**
December 12, 2005

I have greatest respect for Wilczek but I don't understand where he is going with this. This material would be acceptable as a speculative afterthought chapter in a popular book or as a dinner discussion.

There was a discussion on anthropic stuff between Dyson and Gould (the biologist) many years ago and it went like this:
Dyson: "The numerical coincidences are striking. All the fine balancing in QED, for example. Universe must had expected our arrival – I have this hope, I feel this way."
Gould: "If you look on astrophysics models from the early 20th century, you can see now that the models were completely wrong. But then (as now) their authors were saying – 'what an incredible coincidence, if this aether behaved a bit different and comets were less populous, we would would not be here, no life possible, so these parameters must have been pre-arranged!' So there seems to be a strange alure to fall back on anthropism whenever we lack a real understanding."

19. **Kris Krogh**
December 12, 2005

milkshake,

I had an Earth Science teacher who gushed about how amazing the world is. If the oxygen content of the atmosphere were sligthly different, we couldn't exist. The world is perfectly tuned to our existence. Somehow it never occurred to him life existed here before oxygen.

20. **Quantoken**
December 12, 2005

Some how it never occured to any one that instead of the world being perfectly tuned for our existence, it is actually the case that instead our existence is ferfectly tuned for this world, not the other way around, just like the case of oxygen on earth.

21. **Adrian Heathcote**
December 12, 2005

Peter

Your point about the circularity of Anthropic reasoning is dead right I think. People complain about philosophy—but this is *bad* philosophy, bad logic. Interestingly I don't know of a single professional philosopher who has backed this idea.

And as for explaining anthropic reasoning using conditional probability—that is truly a risky business. There are more abuses of conditional probability out there than all of us have had hot dinners.

cheers

22. **Chris W.**
December 12, 2005

Speaking of the conversation between Freeman Dyson and Stephen Jay Gould, and the gushings of Kris Krogh earth science teacher, NPR's *Speaking of Faith* is starting a two-part series on Albert Einstein this week (tonight on some NPR stations). Guests include Freeman Dyson and Paul Davies. The latter is described as an astrobiologist.

As I write this, Dyson is saying that "nature is much more than a set of equations"—more like the rain forest surrounding a mountain peak than the pristine sterility of the peak itself. This immediately followed a turn of the discussion to Einstein's break with his contemporaries on quantum mechanics.

(For what it's worth, Dyson is on record as saying that he finds the complexity and diversity of nature more interesting than any prospect for the unification of its laws.)

23. **Not a Nobel Laureate**
December 12, 2005

Anthropic "Principle"?

One thing that is certainly unbounded is human hubris.

24. **Chris W.**
December 12, 2005

Even if one suspects that the existence of life could teach us something important about fundamental physics, it seems to me that the formulation of the Anthropic Principle as a selection effect is a woefully inadequate way to approach the problem. Given what we have learned about the basis of heredity and evolutionary change, why not ask a question like this:

Life depends for its continued existence on the fact that the laws of physics allow metastable configurations of matter, and also on the possibility of such configurations repairing and reproducing themselves, albeit with variations (errors) that produce changes of form and patterns of behavior in successive generations. To what extent does the allowed existence of such systems, *understood computationally*, constrain or dictate the laws of physics?

This problem formulation is reminiscent of questions about fundamental limits of computation, which have received [considerable attention] from workers in quantum computation and others. Of course it is by no means unexplored territory, and would require the input of some novel ideas to throw any additional light on our current problems. I don't know whether this is possible, but the current approach seems only marginally better than numerology. In fact, the main motivation for it, aside from the simple logic of selection effects, seems to be that it allows string theorists, particle physicists, and astrophysicists to continue applying familiar concepts, techniques, and arguments in this new context, unsatisfying though the results may be. That's easier than a deep reconsideration of fundamental assumptions and the development of fundamentally new ideas.

25. **Christine Dantas**
December 12, 2005

Talking about predictions (that is a strong word these days!), I am doing a survey on what quantum gravity models predict (again, the ugly word) on the GZK cutoff. I could not find (up to now, but still investigating) not even one single string theory paper solely dedicated to this problem. On the other hand, I did find at least 2 LQG papers on it (from the same authors, though):

> Alfaro, J., and Palma, G.A., "Loop quantum gravity effects on the high energy cosmic ray spectrum", hep-th/0501116.
>
> Alfaro, J., and Palma, G., "Loop quantum gravity and ultra high energy cosmic rays", Phys. Rev. D, 67, 083003, (2003). hep-th/0208193.

For those who want to know more about this issue, just go to my blog page. In there, I list today several references of interest on this matter.

What does the Anthropic Principle say about the GZK cutoff? Does the cutoff exist because we are here to observe it? Or does the cutoff not exist because we are here to not observe it? (note: I am being sarcastic here. The AP never convinced me as a valid scientific approach. It really bores me).

Best wishes
Christine

26. **Jenny Attiyeh**
December 12, 2005

Hi all,
As the blog post I'm responding to is now archived, I thought I'd weasel in on this one… I will be interviewing Lisa Randall shortly on her "Warped Passages" for my podcast program on authors, academics and intellectuals, and I'm eager for your input!
In the spirit of open-source research, I'm looking for good questions to ask her that are appropriate for an intelligent but mainstream (ie. non-scientific) audience. Please do pitch in, and of course I will credit you (and your blog) when I ask her your question(s)!
If you'd like to take a look at ThoughtCast, please go to http://www.thoughtcast.org, and thank you!
— Jenny

27. **ksh95**
December 12, 2005

Life depends for its continued existence on the fact that the laws of physics allow metastable configurations of matter
Here's something else that bothers me about the AP and similar arguments. Who says that the above is true (stable matter, carbon based life, etc). It seem to me that simple complexity may be a neccessary and sufficient condition for life….Can complexity arise in quark-gluon plasma. How about gravitational based complexity in a universe where big G is much much larger….
If life is more diverse than our carbon based examples appear, Quantokens point becomes very relevent…*.instead of the world being perfectly tuned for our existence, it is actually the case that instead our existence is ferfectly tuned for this world*…Here, the anthropic principal is even less "predictive" than before.
The point being that all of this is a never-ending discussion, built on likelyhoods, I-believe-thats, it-could-be-possilbe-thats, and what-ifs.

We would do well to remember that congress only funds nuclear missiles, semiconductors, space craft, and productivity enhancements.

28. **Kea**
December 12, 2005

Well, I guess, on the bright side: at least they're *starting* to think about logic.

29. **Dissident**
December 12, 2005

Some of us began suspecting that all's not well with Wilczek already after reading his review of "The Road to Reality". Post-Nobel stress syndrome, maybe?

30. **Michael Bacon**
December 12, 2005

Peter,

Your right that Tegmark's favorite idea – the existence of a Level IV multiverse of all possible mathematical structures – is subject to the same problems. What do you think generally about a Level III multiverse like that supposed to be underlying the physical computations performed by quantum computers?

31. **woit**
December 12, 2005

Michael,

I'm not really very fond of many worlds interpretations of QM, and not sure exactly what Tegmark has in mind here. The formulation you give "underlying the physical computations performed by quantum computers" doesn't seem to me to necessarily correspond to anything except QM itself, and I don't see the necessity of bringing the multiverse into discussions of QM.

Jenny,

An interesting question for Randall might be to ask her what she thinks about the whole "Anthropic Principle" controversy, discussed in several blog entries here recently, including this one. No need to credit me or the blog with this question.

32. **Chris W.**
December 12, 2005

[Jenny: The following might prompt some questions for Lisa. It reinforces my suspicion that higher-dimensional theories lead into a quagmire not unlike the multiverse and anthropic arguments.]

New paper on arXiv.org:

Extra symmetry in the field equations in 5D with spatial spherical symmetry (gr-qc/0512067)

> [ABSTRACT] We point out that the field equations in 5D, with spatial spherical symmetry, possess an extra symmetry that leaves them invariant. This symmetry corresponds to certain simultaneous interchange of coordinates and metric coefficients. As a consequence a single solution in 5D can generate very different scenarios in 4D, ranging from static configurations to cosmological situations. A new perspective emanates from our work. Namely, that different astrophysical and cosmological scenarios in 4D might correspond to the same physics in 5D. We present explicit examples that illustrate this point of view.

From the text:

> All these theories face the same challenge, namely the prediction of observable effects from the extra dimensions [8]. The success of this mission depends on the "correct" identification of the physical or observable space-time metric from the multidimensional one. This is not a trivial task in higher-dimensional cosmologies, like braneworld and STM, where the extra dimension is noncompact. In this scenario all the coordinates are alike, in the sense that the metric tensor is allowed to depend explicitly on the extra coordinate, usually called fifth coordinate.
> In this regard, the crucial question is: given an arbitrary 5-dimensional metric, that depends on all five coordinates, how do we decide which one is the "extra" coordinate? The answer to this question seems to be far from obvious. Even in the simple case of spherical symmetry, in ordinary three space, there are various possible options leading to different scenarios in 4D.

33. **Lee Smolin**
December 12, 2005

To Christine Dantas: What LQG implies for the GZK cutoff depends on whether the symmetry of the ground state shows broken Lorentz invariance or deformed Poincare invariance. The former is what Alfaro and Palma and other authors assume through their choice of an ansatz for the ground state. But there is increasing evidence (but no proof so far) for the latter conclusion. There is proof that Poincare invariance is deformed but not broken in 2+1 dimensional quantum gravity coupled to matter and there are heuristic arguments such as hep-th/0501091. If the ground state has deformed Poincare symmetry the expectation is that GZK threshold does not differ measurably from that of ordinary Lorentz invariant theories, as shown in several papers, including gr-qc/0312089, astro-ph/0008107 and gr-qc/0312124.

I agree its strange there are no papers making the obvious point that as string theory is constructed to be Poincare invariant it predicts that ordinary special relativity should hold to arbitrarily small distances. This would appear to be the only testsible predictions string theory is capable of making. The reason is perhaps that they would prefer to keep open the option of finding a consistent string vacuum with any symmetry that is observed experimentally.

Thanks,

Lee

34. **Michael Bacon**
December 12, 2005

Peter,

Thanks for the response. I'll take not corresponding to "anything except QM itself" as a compliment.

I guess then that you would not agree with Deutsch and others that the quantum theory of computation is the clearest and simplest language and mathmatical formilism for setting out quantum theory itself?

35. **Aaron Bergman**
December 12, 2005

I agree its strange there are no papers making the obvious point that as string theory is constructed to be Poincare invariant it predicts that ordinary special relativity should hold to arbitrarily small distances.

It's easy to break Lorentz invariance by turning on a background field.

36. **woit**
December 12, 2005

Michael,

Sorry, but I've never spent much time reading about or thinking about the quantum theory of computation (or is it the theory of quantum computation?), so I don't really have any views about it.

My views about quantum mechanics are different than some people's. I think the basic formalism itself, embodied in the path integral and in the idea of describing the world in terms of a Hilbert space, with self-adjoint operators as observables, is something closely connected to representation theory, and extremely mathematically deep. Sure, the interpretational issues that arise as one tries to understand how classical behavior emerges from the quantum formalism are very tricky, but that's no reason to search for a replacement for the QM formalism itself. There may be interesting issues arising from quantum computing, I'm just not very well informed about them.

37. **Michael Bacon**
December 12, 2005

Peter,

Thanks again. I agree that there is no reason to search for a replacement for the QM formalism itself.

38. **JC**
December 12, 2005

Peter,

(slightly offtopic)

Do you know of any references which try to put path integrals on a more mathematical rigorous footing, in the field theory context without going to the euclideanized version of the path integral?

39. **Jenny Attiyeh**
December 13, 2005

Thanks for the suggested questions — I really appreciate it. Also, I read an article about how this blog is quite a lightening rod. Hooray!!
-Jenny

40. **Aaron Bergman**
December 13, 2005

I guess then that you would not agree with Deutsch and others that the quantum theory of computation is the clearest and simplest language and mathmatical formilism for setting out quantum theory itself?

The clearest and simplest language for setting out quantum theory is quantum theory. Quantum computing is just an application of quantum theory.

Do you know of any references which try to put path integrals on a more mathematical rigorous footing, in the field theory context without going to the euclideanized version of the path integral?

Ugh. I suppose there's Glimm and Jaffe, but the impression I get from afar is that constructive field theory has been a spectacularly unsuccessful endeavor.

For the last, I suppose you could ask Lisa about how she fell off a mountain a few times, but it looks like that's actually fairly widely covered. You could ask her how she feels about top-down vs. bottom-up approaches to physics. You could ask what she feels might happen when the LHC turns on in a few years.

I actually think the middle one might be the most interesting.

41. **Adrian Heathcote**
December 13, 2005

There is a talk on this at KITP site by Graeme Segal of Oxford. You can watch the entire thing (and there are not so many interruptions in this one).

Cheers

42. **Chris Oakley**
December 13, 2005

Jenny,

I do not think that you should be interviewing String theorists, or apologists for String theory at all. The public are not completely stupid and the more exposure the String theorists get the more the public will realise that their hugely speculative idea has very little chance of connecting with reality. Those who are content to pursue ideas simply because they find them mathematically intriguing, and who show little or no interest in finding experimental verification, should not be held up as examples of application of the scientific method.

Find some genuine scientists. Molecular biology, for example, is an exciting area now – I am sure that you will find much more interesting material here.

43. **Lee Smolin**
December 13, 2005

Aaron says, "It's easy to break Lorentz invariance by turning on a background field."

In standard field theories, like Maxwell, it costs energy to break Lorentz or translation invariance, which is why for these theories the vacuum is the only Poincare invariant state. Are there explicit examples in string theory where it doesn't cost energy to break Poincare invariance of the uncompactified dimensions? Also, are there consistent string vacua with deformed Poincare invariance? With Magueijo we began to investigate this and found partial results in hep-th/0401087.

Lee

”Well there is at least Nick Bostrom who apparently is writing a paper with Tegmark. Incidentally, Bostrom also support the simulation argument which according to me is subject to the very same kind of logical problems that anthropic reasoning.”

I can’t read French but I trust you to be right about this one.

Hadn’t heard of Nick Bostrum previously but having looked at some of his stuff I feel no better about the AP.

BTW a sure sign that someone is talking unmitigated nonsense with the AP is when they say such things as ”the cosmological constant’s value is *caused* by the existence of humans.” This is the most foolish abuse of the concept of causation I know. There should actually be a law against it.

47. **JKG**
December 13, 2005

Hi,

I just want to understand something about anthropic reasoning. Suppose I find that the probability of finding value of X close to what we observe is 99%. So what? Suppose I find that the probability of finding value of X close to what we observe is 10^{-100}%. Then what?

Is it that beneath this kind of reasoning is the metaphysical assumption that our universe is probable? If so how to justified this assumption?

48. **Aaron Bergman**
December 13, 2005

Those who are content to pursue ideas simply because they find them mathematically intriguing, and who show little or no interest in finding experimental verification, should not be held up as examples of application of the scientific method.

And what exactly makes you think that Lisa Randall fits this description?

Are there explicit examples in string theory where it doesn’t cost energy to break Poincare invariance of the uncompactified dimensions?

I was thinking of the D-branes with a Moyal product which is a limit of a background with a B-field.

Also, are there consistent string vacua with deformed Poincare invariance?

Not that I know of. Some people have thought about q-deformed de Sitter symmetries, though.

49. **Chris Oakley**
December 13, 2005

52. **Arun**
December 13, 2005

Yes, Aaron, since we have little hope of saying "correct" and "incorrect" about people's work, we are reduced to classifying the people, sort of like what happens in any humanities department. The level of objectivity that characterized particle physics is being eroded.

53. **Who**
December 13, 2005

Arun:…**since we have little hope of saying "correct" and "incorrect" about people's work, we are reduced to… level of objectivity … is being eroded.**

maybe there is a ray of hope regarding falsifiability. judging by what Smolin said earlier, string ideas were constructed to have thorough Poincaré invariance, naturally, and so in 2008 if GLAST finds some energy dependence of the speed of gammarays, that will falsify string. I presume that string can then be discarded as physics for that reason, if for no other.

conversely there are several non-string approaches to quantum gravity which do naturally and unavoidably predict energy dependence of the speed of photons—I think Smolin-style LQG does, for one. If GLAST does NOT find energy dependence in arrival time of gammaray burst photons that would seem to me like a good reason to discard Smolin-type LQG and any other QG approach with that feature.

By the way this does not affect CDT as far as I know.

I looked at the Stanford GLAST website recently and it appeared that it was still on schedule for a launch in 2007. Perhaps someone will wish to correct me, but that does seem to introduce a little "correct" and "incorrect" into the picture—which Arun found lacking.

54. **island**
December 13, 2005

Anthropic "Principle"?
One thing that is certainly unbounded is human hubris.

I think that it's equally arrogant to think that we can detatch ourselves from nature to presume that we can remove ourselves from the natural process to conclude that nature doesn't specially produce intelligent life for the thermodynamic contributions that intelligence enables. As soon as you do that, then you realize how stupid that it is to think that we humans could be alone in that effort if there's a real thermodynamic need for it.

Especially when there is writing-on-the-wall evidence that the leap from apes to humans enabled us to take advantage of energy sources that we would not be able to tap into otherwise. Etceteras and so on, the list of stuff that humans do in this effort is about as endless as the growing list of anthropic coincidences.

And then start looking from there… ASK the questions, don't *automatically* knee-jerk react with lame representations that are designed to ignore the full implications of the principle.

Some how it never occured to any one that instead of the world being perfectly tuned for our existence, it is actually the case that instead our existence is ferfectly tuned for this world, not the other way around, just like the case of oxygen on earth.

That means that we're a part of the local ecobalance, and you're right, so don't assume that we're any different than squirrils that bury nuts when we warm the climate, this counterbalances the *cumulative* accelerating runaway tendency toward glaciation that is predicted by Milankovitch models, which have been verified spectrographically from ice core samples taken in Greenland.

This balance between cumulative runaway tendencies, the greenhouse effect, vs the tendency toward glaciation… is yet another anthropic coincidence for which we are *innately* contributing players… go figure?

Deal with it, you don't have a choice, so don't be so arrogant as to presume that we can fool mother nature, the tug-o-war between "big business" and the "green movement" self-regulates the process, not the biggest brains in science, who *would* have us stagnate and die. Deal with it, we're not detatched from the process, we're specaially required 'fungi' that design "fairy-rings" per our inherent predisposition so do so. Nothing more… NOR LESS CONNECTED.

Bostrom introduced the Self Sampling Assumption in an attempted extension of the Copernican Principle into the time domain, but it has been proven that this is of no real-world significance to cosmology, because theories of everything that have constrained prarameters guarantee the emergence of man in a world in which man is known to exist. And that's where the ill-considered idea from skeptics comes from, they then conclude that "just so" isn't a significant factor, because that's a given or we simply aren't going to be here. I say that it is ill-considered reasoning because this line of thinking fails to take into account the fact that "just so" falls between cumulatively runaway tendencies.

The anthropic principle fell from only one of these weirdly balanced coincidences, the vast number of these life-permitting "ecobalanced" conditions that have been discovered since that time serve to compound the significance exponentially by orders of magnitude with each additional coincidence that is discovered. So it isn't even close to rational to offer up, multiverse-like "what if" scenarios about other forms of life and conditions that MIGHT exist elsewhere.

One thing that string theory teaches is that you can lose touch with real physics in imaginary universes, so be very careful when you project beyond what is observed to "what-if" things are different elsewhere in the universe scenarios, because you're appealing to religion when you do that. Just because we don't know something isn't an excuse to assume whatever you want.

Nick Bostrom's ideas are interesting and relevant where apparently chaotic, (subtly determined?), scenarios are applicable, but he fails to take into account the fact that an anthropic explanation for the fine-tuning of the universal constants is supposed to be embedded into humans by the universal scale mechanism that enables or requires human existence. That justifies the selection effect, in this case, because anthropic bias is supposed to be an innate characteristic of the universe.

He correctly notes that there can be areas of low entropy, (which are necessary to life), within the greater whole of our entropic, expanding universe, but he failed to equate the predominant entropic prejudice of our universe to the anthropic bias, as supported by conventional Big Bang Theory and The Standard Model of Particle Physics.

The anthropic principle notes that "Anthropic Bias" is, by definition, the natural expression for universal scale favoritism toward humans.

The principle becomes a powerful form of support for our best theories if we are thermodynamically connected to the process and there is no way to set yourself apart from this because the underlying direction of all action in a big bang induced expanding universe is ultimately entropic, per conventional Big Bang Theory as supported by the latest confirmed observational evidence.

Barring quantum fantasies… any occurrence within the system is, therefore, a result of the tuning of the constants that were set at t=10^-43. This includes humans in all their glory, and the weak entropic anthropic argument would support this via the fact that it is observationally proven that the human is comparitively one of nature's more preferred methods for efficiently dissipating energy at a regulated but increasing rate.

Dicke got his coincidence from Dirac's Large Numbers Hypothesis, but Dirac's cosmological model was wrong… gravity falling off with expansion. It is logical to think that repairing Dirac's cosmolgy would necessarily complete and clarify the anthropic principle, while removing the tautologous nature of it. Oh that's right we've accepted assumptions that take us beyond all that, no wonder Einstein died believing what he couldn't prove, rather than to accept that crap.

If you stick to the observed universe like the AP is telling you to do, then you can only derive that a multiverse is for dreamers, and so are infinities, uncertainty, absolute cosmic singularities… etc. idealizations. We have to distinguish between an idealized vacuum and the lowest actual energy state, which is non-zero.

It's equally arrogant to assume that there isn't some good reason for the anthropic principle in one universe as it is to intentionally bury OBVIOUS significance, (as Lenny pointed out), in many imagined universes.

Quit pretending that you don't see the writing on the wall.

At least Lenny has the guts to admit that the "appearance" of purpose in nature is real.

Deal with it.

55. **Michael Bacon**
December 13, 2005

It's far too skeptical to say that when you project beyond what is observed you're appealing to religion. What we know about the world is far greater than what we observe. More interesting is the idea that if GLAST finds some energy depedence of the speed of gammarays, that will falsify string theory. If not, non-string approaches like Smolin-style LQGs, which can accomodate energy dependence, are faced with a similar situation. I was wondering what folks thought of that?

56. **island**
December 13, 2005

It's far too skeptical to say that when you project beyond what is observed you're appealing to religion.

That's true. I worded it improperly and should have said that the anthropic principle is telling us that we shouldn't project beyond what is observed to assume that idealizations can actually exist… or you're appealing to religion.

57. **Michael Bacon**
December 13, 2005

Not sure what you mean by "assume" and "idealizations". Nevertheless, regardless of the meanings, there is much beyond what is observed that actually exists.

58. **Chris W.**
December 14, 2005

Hey, look at the papers linked by 'Dissident' in his comment on Cosmic Variance ("Where the dark matter is"). Many of you are aware of the recent work of Lauscher and Reuter (latest in hep-th/0511260). Reuter, et al, are arguing for observable manifestations of renormalization effects in QG at galactic and larger scales. Along with the connections of the same work to recent results in CDT, I find all this very encouraging. It seems to me that Wilczek of all people should be paying close attention to this stuff instead of wasting his time with the Multiverse and AP.

59. **Chris W.**
December 14, 2005

PS (credit where credit is due): I believe Aaron Bergman has been closely following work in CDT as well as the papers of Lauscher and Reuter. Any comments, Aaron?

60. **Aaron Bergman**
December 14, 2005

I haven't been following very closely — I have my own research, after all. I read a bit on CDT, and while it's intriguing, it's still feels very preliminary and somewhat *ad hoc* to me. A lot of people believe that any such UV fixed point is going to be extremely sensitive to the matter content in the theory, so it's not clear what significance a pure GR calculation would have. In that, as best I know, this is the first time anyone's every found something that's not horribly crumpled up, I'll be paying attention to where it's going. It'd be nice to see some black hole stuff with it.

I haven't looked at the Reuter stuff myself, but Jacques has, and it seems pretty persuasive to me.

61. **island**
December 14, 2005

…there is much beyond what is observed that actually exists

Like what, goblins? or did I stumble through a side door into the church of infinities?

I'll leave a tip in the plate when they pass it around, the point that I made was that the observational evidence indicates that you'd have to fix Dirac's Cosmology to see if it repairs his Large Numbers Hypothesis before you can make that claim, since we are talking about the affect that an entropic anthropic cosmological principle would have on this model.

A failure to look for evidence is popular where the AP is concerned, but that's all starting to change now that the string theorists have started abusing it to support their belief system, like creationists do.

Better lose the lame arguments that are designed to downplay its significance though, because they won't fly, they just make you appear as antifanatics who don't care what the actual science is.

62. **Christine Dantas**
December 14, 2005

It is not clear to me whether the framework below can be implemented in string theory. If this could be so, then will string theory accommodate Lorentz violation as well? Does it depend on how far string theory reproduces the standard model?

This is taken from Mattingly's review (gr-qc/0502097):

> The most conservative approach for a framework in which to test Lorentz violation from quantum gravity is that of effective field theory (EFT). Both the standard model and relativity can be considered EFT's and the EFT framework can easily incorporate Lorentz violation via the introduction of extra tensors. Furthermore, in many systems where the fundamental degrees of freedom are qualitatively different than the low energy degrees of freedom, EFT applies and give correct results up to some high energy scale. Hence following the usual guideline of starting with known physics, EFT is an obvious place to start looking for Lorentz violation.

And:

> "(…)the first place to look from an EFT perspective is all possible renormalizable Lorentz violating terms that can be added to the standard model. In [Ref] Colladay and Kostelecky derived just such a theory in flat space – the so-called (minimal) Standard Model Extension (mSME).

[Ref] Colladay, D., and Kosteleck´y, V.A., "Lorentz-violating extension of the standard model", Phys. Rev. D, 58, 1160

Thank you,
Christine

63. **Brett**
December 14, 2005

Christine-

The original motivation for developing the standard model extension came from string theory! Alan Kostelecky was an expert in string field theory, and he and Stuart Samuel wrote several papers in which they found minima of the string potential with odd properties. Perhaps the oddest property was that some of the minima had spontaneous Lorentz violation. (I think it turns out that none of the Lorentz-violating minima are actually the global vaucua of the theories, though, unfortunately).

Moving to effective field theory was motivated in large part by the fact that there are no realistic string theories. (There are no sufficiently realistic quantum gravity theories of any type.) But, knowing that string theory or some other high-scale physics could break Lorentz violation, it was immediately natural to consider how this could be encoded in an effective field theory. Having an effective field theory of Lorentz violation allows us to translate empirical verifications of relativity into bounds on specific coefficients, and these effective field theory bounds should not be sensitive to the underlying physics that gives rise to the Lorentz violation.

The effective field theory has now been developed for both quantum field theory and GR. The GR part is very interesting, because it apparently does not allow for explicit Lorentz symmetry breaking; any Lorentz violation must be spontaneously induced. There are a few other conditions on what form the Lorentz violation can take, but there's still a lot of very simple questions whose answers are unknown.

64. **Who**
December 14, 2005

about falsifiability, something interesting came up in QG recently

there is this different but related question which is sometimes asked string thinkers
What would make you give up string theory?
It was e.g. asked in the Panel Discussion at Toronto Strings '05 and Steve Shenker replied "You're not supposed to be asking that!"
From string theorists I've never seen a serious answer.

but Laurent Freidel recently gave a serious answer to that as regards LQG—he works on the spinfoam approach—in his invited talk at October Loops'05.

spinfoam is a kind of path integral, or sum over histories, treatment of spacetime. Freidel has introduced matter in the 3D case and shown that an effective QFT appears as the zero-gravity limit. he gets feynman diagrams and vertex amplitudes out of the spinfoams in the limit as newton's G goes to zero.

he was reporting on the first steps of an effort to extend this to 4D.
the requirement of getting the right effective QFT as a flat limit, of getting the correct feynman diagrams out of the spinfoam, should according to him determine a unique spinfoam QG model. IF IT DOES NOT he says, then he would stop researching spinfoam QG.

There is a video of Laurent Freidel talk at Loops '05. I downloaded it earlier and just watched it again. I was impressed—there is a kind of "falsifiability" here. It is not so much empirical (except that feynman diagram vertex amplitudes are supported empirically) as theoretical consistency. but he is obviously serious about it. for people who think like that and expect that, it is an exciting time in spinfoam.

something has worked in the 3D case and they are starting to check it and if it does not work in 4D that means, for them, that spinfoam goes on the scrap heap. but if it does work then it passes a kind of test.

see if you can download the Freidel talk from the Loops05 site. I think they may have taken the videos offline because I can't download it now.

the relevant preprint is
http://arxiv.org/hep-th/0512113
and references therein

65. **Christine**
December 14, 2005

Dear Brett,

Thank you for your comment.

Best wishes
Christine

66. **Who**
December 14, 2005

Wilczek posted this today
http://arxiv.org/abs/hep-ph/0512187
Enlightenment, Knowledge, Ignorance, Temptation

Frank Wilczek
10 pages, 5 figures. Summary talk at "Expectations of a Final Theory", Trinity College, Cambridge, September 2005
"I discuss the historical and conceptual roots of reasoning about the parameters of fundamental physics and cosmology based on selection effects. I argue concretely that such reasoning can and should be combined with arguments based on symmetry and dynamics; it supplements them, but does not replace them."

67. **Chris W.**
December 14, 2005

I just read through Wilczek's preprint. It is beautifully written; whatever one may think of the ultimate fate of these notions one could hardly ask for a better introduction. String theory and its current travails plays only a supporting role in it.

Some thoughts occurred to me after I finished it:

The so-called anthropic coincidences are derivable and interesting only because so much is governed by dynamical laws. We could hardly argue that a certain small set of parameters must be close to their measured values for life to exist unless those parameters were embedded in a theoretical structure that is largely unique, precisely formulated and testable, and broadly applicable. That is, if the structure of the world, and its changes from one moment to the next, were completely arbitrary then the notion of selection effects would have no meaning; we couldn't sensibly reason about them. So the possible need to invoke cosmological selection effects, unless we approach it in a glib and superficial way, should force us to think deeply about the nature and basis of physical laws, as well as their relationship to the possibility of discovering them.*

For these reasons I am deeply suspicious of assertions that are tantamount to saying that in the multiverse *all physical laws are possible*. This implies that the dynamical laws that we have formulated and successfully tested are in fact purely accidental—just aspects of one "point" in the multiverse—so that the very basis for analyzing the anthropic coincidences threatens to collapse. Everything about the observed universe becomes a selection effect, and we are forced to conclude that the laws, the fundamental constants, and the existence of life are one big arbitrarily selected package.

(Of course I'm setting aside the fact that defining life, and identifying the features of the observed universe upon which life really depends, is still a fairly dicey enterprise.)

————————
[* Note that, in some sense, all living things must discover something about physical laws, through evolution as well in the adaptive behavior of individuals, in order to effectively negotiate their environments and survive long enough to reproduce.]

68. **Chris W.**
December 14, 2005

By the way, Sean Carroll's latest post on Cosmic Variance nicely complements this discussion.

69. **Michael Bacon**
December 14, 2005

If spinfoam does work in 4D it adds evidence that it fits the quantum formalism and that the math surrounding the sum over histories approach is appropriate in the circumstances. I'm curious how the information representing the physical objects constituting the spinfoam, whatever its ultimate appearance, commute with their nearest neighbors. Perhaps quantum computation theory has something to add in this regard.

70. **Arun**
December 16, 2005

Which fundamental physical parameters, when changed to within a factor of 2, would make carbon-based life impossible?

71. **Arun**
December 16, 2005

Further question – would the "Standard Model" with a single generation of leptons and quarks instead of three (hence the scare quotes) be as consistent as the Standard Model? Would such a universe with such physics support life? While one generation instead of three would change details of the big bang and nucleosynthesis and so on, presumably a carbon atom doesn't change all that much; planets and chemistry might still be possible? If the answer is yes, then doesn't that put paid to the anthropic principle? i.e., if the anthropic principle can't distinguish between one generation and three, then it isn't of much use, is it?

72. **Max Tegmark**
December 17, 2005

Hi Mark,

I recently discovered your blog entry about our paper, and found it both interesting and amusing. Next time you spot me at a meeting, please stop by and say hello during a coffee break, as it would be fun to discuss these issues.

My opinion is that this anthropic debate is so spirited and long-lived because the two sides are largely talking past each other, addressing different questions. In this spirit, I think it would help of we both state clearly what points we're trying to make. The essence of what you write seems to be "the anthropic principle is unscientific and I don't like it" -how would you phrase your core points, and what precisely do you mean by "the anthropic principle"?
Specifically, how would you classify your critique?
a) The calculations in our paper are uninteresting and a waste of time.
b) Our paper contains incorrect statements.
If it's (a), then I respect your viewpoint and merely disagree with it.
If it's (b), then which specific statements to you object to?

This may surprise you, but I don't like using the phrase "anthropic principle", because there are many different definitions of
it floating around, all of which I believe to be either tautological or false. The question that I'm personally interested is how to confront a mathematical theory of physics (given by some Lagrangian or whatever) with observation, which I think you agree involves computing its predictions with selection effects taken into account.
For example, what does the pre-inflationary axion model predict, and is it ruled out? A key goal of our paper was to addresses these questions.

Cheers,
😉

73. **Who**

December 17, 2005

Dear Max,
I thought it was a serious flaw in your paper that it failed to address Smolin's cosmological natural selection proposal (CNS) and the accompanying arguments presented in

Scientific Alternatives to the Anthropic Principle
http://arxiv.org/abs/hep-th/0407213

—exerpt from abstract—
…We show however that it is still possible to make falsifiable predictions from theories of multiverses, if the ensemble predicted has certain properties specified here. An example of such a falsifiable multiverse theory is cosmological natural selection. It is reviewed here and it is argued that the theory remains unfalsified. But it is very vulnerable to falsification by current observations, which shows that it is a scientific theory. ,,,
—endquote—

Since the CNS proposal is the simplest and most directly testable multiverse model, and it has not yet been refuted by observation as far as I know. I think it is incumbent on you to describe CNS and to say why you think it can be ruled out. Or explain why it is not testable by current astronomical observations, if you believe it is not.

It might further the discussion if you did this.

Cheers 😉

74. **woit**
December 17, 2005

Hi Max,

Thanks a lot for taking the time to write here, I'd certainly enjoy talking to you in person about these issues sometime. Here are some comments, I hope they address the questions you asked.

First, some context. My background is in mathematics and particle physics, not cosmology, and what motivates me is the idea of trying to find an improvement of the standard model, using new mathematical ideas. I think Wilczek would classify me as the sort who is trying to get somewhere by "pure thought", something which he doesn't believe will ever work. I'd claim that, given the lack of any new helpful experimental input, particle theorists don't really have any choice at the moment except to go this admittedly much more difficult route. I've never found string theory a particularly appealing idea for unification (although it gives interesting insights into strongly coupled gauge theories and has led to some important new mathematics), and think the way it has completely dominated mathematically-minded particle theory for the last twenty years has been a disaster for the subject. By now it should be clear that it is simply a highly speculative idea that failed, and the field desperately needs to acknowledge this and move on to trying other things. The whole string theory landscape program, especially in its "anthropic" version, seems to me to be a retreat from the very idea of doing science, motivated by a refusal to admit failure. For more about this, read my recent review here of Susskind's new book.

Like just about any particle theorist, I've spent some time looking at what is going on in cosmology and hoping it will provide some new insights into how to get beyond the standard model. So far it seems to me cosmology has provided some interesting hints, but unfortunately they're no more than hints. We're agreed that what needs to be done here is to find ways of confronting our mathematical models with the real world. When dealing with models that involve a statistical ensemble of universes and observables that are only probabilistically determined, sure, one has to take into account selection effects.

The scientific part of my critique of your paper was not that I thought any of it was incorrect. The major part of it, your anthropic calculation of the selection effect for the dark energy density was more complicated than I have the time or interest to follow. You end up with a probability distribution for the dark energy, with the observed value near the peak. What was unclear to me was exactly what conclusions you are claiming can be drawn from this. Ignoring the axion cosmology prior, it seems you're just claiming that there's an anthropic window in the dark energy density, and observations show we're in the middle of it.

But, as a particle physicist, what I really want to know is what is left over when you remove the selection effect. Exactly what does your calculation says about the axion cosmology model? Have you provided any new evidence for it other than that it's not obviously inconsistent? Can you rule out a flat dark energy density prior in favor of the axion cosmology one? Your paper didn't seem to seriously address these kind of questions, or the more general question of when you can expect to get genuine, falsifiable predictions out of this kind of calculation.

That's the scientific critique, there's also a more general critique, one I made in my posting. Especially the early part of your paper seemed to me a heavily ideological push for the idea of anthropic determination of the standard model parameters, without anything to really back this up. Given the on-going disaster in particle theory these days due to the string theory landscape, I think this is really unhelpful.

Anyway, thanks again for writing in. If you'd like to write something more than a short comment in response, I'd be more than happy to put it up as a new posting, so people would be more likely to see it and comment on it if they wish.

Peter

75. **Aaron Bergman**
December 17, 2005

For my part, I think probabilistic arguments across multiverses are nonsensical. Otherwise, I don't see a satisfactory response to the doomsday argument. So, you can file me under (a).

76. **Who**
December 17, 2005

Peter to Max: "If you'd like to write something more than a short comment in response, I'd be more than happy to put it up as a new posting, so people would be more likely to see it and comment on it if they wish."

That would be great! Please consider doing this, Max!

77. **Max Tegmark**
December 18, 2005

Hi Peter,

Thanks for your thoughful response. I'm glad to hear that you didn't feel any of it was incorrect.

I agree that it will be interesting of one can make stronger statements about the axion model – as described in the paper, this will require improved astrophysics calculations that I hope somebody will make. You described the early part of the paper as a heavily ideological push for the idea of anthropic determination of the standard model parameters. The intent was rather to push for an open mindset on the issue, since we frankly don't know how many parameters will ultimately be computable from others.

Regarding the CNS-critigue by "Who": The pre-inflationary axion model is a complete physical theory, whereas Smolin's "Cosmological natural selection" is not (we lack a mathematical description of how black holes spawn universes; see also http://arxiv.org/abs/hep-th/0407266). Moreover, my guess is that the hypothesis is ruled out by the low observed fluctuation level (~1/10^5), since raising it would lead to more black holes.

Finally and most importantly, I'm glad that many of you disagree with my views! As argued in http://arxiv.org/abs/physics/0510188, I think that diversity in the physics community is more useful than an ideological monoculture, since it motivates physicists to tackle unsolved problems with a wide variety of approaches.

😉

78. **Who**
December 18, 2005

Hi Max,
personally I view your "low observed fluctuation level" not as a fundamental physical constant but more of an ad hoc *result*. It could be symptomatic of more basic parameters established prior to the beginning of expansion. But this is largely a matter of preference. It is personal opinion on your part (as you say) and equally on mine!

I would have expected you to mention CNS in your paper and to say why, in your opinion, it is probably ruled out. This would have given others a convenient opportunity to argue that it has not yet been ruled out.

There have been quite a few papers in the past year relating to the question of how black holes might spawn universes. Much of the work (QG modeling black hole collapse) was by people who reported in the Friday (14 October) session of Loops '05. The main topic was LQC, but the same people work on quantum models of gravitational collapse and, for what it's worth, the bounce mathematics has turned out to look rather similar in both cases.

You say "we lack a mathematical description" and cite a 2004 paper by Leonard Susskind responding to Smolin, but, as I say, there has been quite a bit of mathematical description since then. I also do not believe Susskind's rebuttal stands unchallenged.

Be that as it may, my point is that the CNS idea has not been disposed of and should have been discussed. If you think it is not falsifiable, or that it has already been falsified, then you should at least give your reasons.

In case you would like to look up the past year's QG papers modeling gravitational collapse and bounce, I will post some arxiv numbers later. Some of the relevant authors, if you want to look up their recent work yourself, would be Abhay Ashtekar, Martin Bojowald, Viqar Husain, Oliver Winkler, Leonardo Modesto, Parampreet Singh.

To be fair, one should note that Smolin's CNS proposal is testable without reference to any specific mathematical description of black hole collapse and bounce. The CNS conjecture is that some reproductive/evolutionary mechanism has fine-tuned the constants for black hole production. CNS challenges us to find even one fundamental constant (hope you will pardon me if I decline to view your "low observed fluctuation level" as a fundamental constant) which if it were better tuned would result in substantially greater black hole abundance.
That is something one can use to test—and possibly falsify—CNS, even before one has a complete mathematical theory of the conjunction of black hole and big bang events.

Thanks,
😉

79. **Lee Smolin**
December 18, 2005

Dear Max and Who

Thanks for mentioning the CNS proposal. The issue of the level of delta rho/rho-the fluctuation level-was discussed in detail and resolved in the first paper published on the model, Did the universe evolve?, Classical and Quantum Gravity 9 (1992) 173-191, summarized in Life of the Cosmos, ps 309-10.

Given that this was the first theory based on the "landscape*" I would hope that people would look at the literature before dismissing it.

The point is that in simple one field inflation models the fluctuation level is proportional to the inflaton self-coupling constant. However the number of e-foldings in inflation is related to (if I recall right) the inverse of the square root of the inflaton self-coupling. The result is that the cost of raising the self-coupling to produce primordial black holes or make more galaxies is that there are fewer e-foldings in inflation and the resulting universe is exponentially smaller. The result is that CNS predicts that the self-coupling should be as small as possible consisent with some steady level of black hole production. i.e. many more black holes are produced by a slow, but steady rate of black hole production in an exponentially larger universe than by a burst of primordial black hole production in an exponentially smaller universe.

This seems to characterize our universe where most black holes are made as supernova remnants. It also leads to a prediction, which is that inflation is governed by one parameter and not by a complicated potential with more than one parameter in which the fluctuation amplitude and number of e-foldings would be independent. So were there any evidence for an inflaton potential governed by more than one parameter the theory would be ruled out. I made this prediction in 1992 and so far it has held up.

I can endorse WHO's comments: recently we have very good detailed support from the quantum theory of gravity that black hole and cosmological sinigularities bounce. There is not yet a detailed description of the parameters mutate in a bounce, but this is certainly plausible given current views of the "landscape".

Max, if these were your main objection to CNS, would you now agree that the theory is viable?

I would go further, CNS is the only landscape theory proposed so far that makes falsifiable predictions, Should this not make it the leading candidate for an explanation of the choices of parameters in the case that the landscape is real?

Thanks,

Lee

*and indeed the origin of the term, which comes from "fitness landscape".

80. **Anthony Aguirre**

December 19, 2005

Hi Lee,

This is a nice argument, but does not terribly ease my misgivings about CNS, which are approximately 5-fold.

First, the initial field value will also come in to the number of e-foldings, and (absent a concrete model) that may or may not be correlated with the inflaton coupling.

Second, other things could lead to ultra-numerous black holes, e.g. a very high baryon/photon ratio. This physics should be unrelated to inflation, and variable by tuning the coupling constants. Or, we could introduce tilt into the perturbation spectrum to create scads of primordial black holes. Or is there a size requirement?

Third, I've never been clear on the 'number of black holes': per unit what? If per unit photon (or dark matter particle), we can easily maximize this by increasing the baryon (or dark matter) to photon ratio. If per unit volume, this is of course time-dependent. And in all cases we must worry about infinite universes (note that a universe starting out finite does not mean that it cannot spawn an infinite universe either, as in open inflation). These are more-or-less the same semi-intractible issues eternal inflation has to deal with.

Fourth, CNS still requires, even if we accept the nascent models for creating baby universes from black holes, some way of passing-down constants with small variations.

Last, CNS does not answer the question of why the universe supports life, unless black holes are alive. It merely transforms the question into 'why does a high black-hole formation rate correlate with life?'. An alternative that *would* explain things, I would say, were if advanced civilzations were responsible for creating the baby universes. But that it pretty science-fictiony and I suspect you would rather avoid going down that path.

Thus I would be very pleased if CNS could be made to work and create strongly-peaked probability distribution for the observed parameters. (Note, in regard to our recent paper that CNS is not, as I see it, an alternative to the scenario we present, but a special case of the 'multiverse' explanation in which p_prior is strongly peaked around certain parameter values related to black hole formation. Unless axions are involved in black holes, I'm not sure it would impact the argument). But it seems to me that there are even more missing pieces, and about as many very difficult problems of principle to deal with, than in the eternal inflation scenario.

cheers,

Anthony

81. **Anthony Aguirre**
December 19, 2005

Hi All,

An interesting discussion, and I agree with Max that it is good for parties with very different viewpoints to discuss this in a way that is "not talking past each other", i.e. making assumptions about what the other parties are actually saying. Those interested in a more detailed (and, I think, not particularly pro-'anthropic') discussion of what responses one might take to having non-unique constants, by one or two of the authors of the paper under discussion, might enjoy hep-th/0409072 or astro-ph/050651.

Anthony

82. **Chris W.**
December 19, 2005

Anthony,

Was that was supposed to be astro-ph/0506519 ("On making predictions in a multiverse: conundrums, dangers, and coincidences")?

83. **woit**
December 19, 2005

Anthony,

Thanks for your very interesting comments. I'm sure the paper Chris mentions is the one you had in mind. It looks like it goes into much greater detail in addressing the kinds of questions that your more recent paper raised in my mind. I'll add something to the main posting pointing to it.

84. **Aaron Bergman**
December 19, 2005

I'll ask my usual question for people who make arguments along these lines? Is the human race going to end soon? Or, if you don't like the Doomsday argument, then there's Olum's argument that we should be in some star spanning civilization.

I just don't see how the notion of probability makes any sense in these situations and, even if it did, what we gain from thinking about it.

85. **Lee Smolin**
December 19, 2005

Hi Antony,

Thanks for your criticisms. Briefly, CNS works well for the parameters of the standard model of particle physics, and I don't think this can be disregarded. Every variation of those parameters for which definite conclusions could be reached, the conclusion was that the number of black holes made decreased. The case is not as strong for some of the cosmological parameters. I don't take these as important as we don't which if any cosmological parameters are determined by parameters of a theory. But there are some answers to your points, which I'll repeat and then address:

"… the initial field value will also come in to the number of e-foldings, and (absent a concrete model) that may or may not be correlated with the inflaton coupling…."

Fine, but the mechanism that determines the initial field may be independent of the inflaton coupling to leading order, if so then this decouples, i.e. for any initial field value my argument works.

What about "… a very high baryon/photon ratio…?"

If I recall correctly, this affects nucleosynthesis, and many other things, as this is a cold or tepid big bang. Ill check.

"…Or, we could introduce tilt into the perturbation spectrum to create scads of primordial black holes.."

The question again is what the consequences are for other processes, Ill think about this.

"…I've never been clear on the 'number of black holes': per unit what?"

The answer is per unit bounce, which means per unit black hole in the previous universe.

"Fourth, CNS still requires, even if we accept the nascent models for creating baby universes from black holes, some way of passing-down constants with small variations…."

Granted. This remains to be filled in. But still it is possible to deduce falsifiable predictions. This is not surprising, Darwin could make predictions in spite of being ignorant of DNA and its replication.

"…Last, CNS does not answer the question of why the universe supports life, unless black holes are alive. It merely transforms the question into 'why does a high black-hole formation rate correlate with life?'…"

There is a clear correlation. You only get a lot of black hole production in universes with many massive stars. You only get many massive stars when the initial mass function (IMF) is power law out to many solar masses rather than exponentially damped. While this is incompletely understood, there is evidence the high end of the IMF is power-law because there are processes which efficiently cool giant molecular clouds (GMC's) and because the GMC's are well shielded from star light. Both the cooling and shielding involve carbon and oxygen. (This is described in some detail in Life of the Cosmos). Hence the chemical complexity life requires may exist because it is needed for a universe to efficiently produce stars massive enough to leave black hole remnants.

"…An alternative that *would* explain things, I would say, were if advanced civilzations were responsible for creating the baby universes. But that it pretty science-fictiony and I suspect you would rather avoid going down that path…."

I don't. But Harrison (of Harrison-Zeldovich) has written a paper which goes down that path, as has Louis Crane.

I hope this helps,

Thanks,

Lee

86. **ksh95**
December 20, 2005

"…Darwin could make predictions in spite of being ignorant of DNA and its replication…"

Darwin had evidence that during a "species-bounce" a chicken would not mutate into a donkey. The important word here is small. Without small changes one is left with a random mess.

"…CNS does not answer the question of why the universe supports life…"

Why should CNS (or any theory for that matter) answer *that* question. An equally valid question could be: why does ksh95 like soup?

87. **Anthony Aguirre**
December 20, 2005

Chris W.:

That is indeed the article; sorry about the typo.

Lee:

This is probably a discussion that we should have over a nice meal sometime, and hopefully I can make it out to PI soon to do so. I would love to understand how CNS could work, and would be happy to be convinced. Perhaps my biggest stumbling block now, as I think about it, is the invocation of inflation. If inflation is involved, then it is easy for inflation to be future eternal, and if this were possible for *any* set of constants, then universes involving eternal inflation, which spawn infinitely many black holes, would immediately dominate the ensemble, and we are back where we started. If you have a good idea for allowing inflation while precluding the possibility of eternal inflation, that would be wonderful (as much as I enjoy thinking about eternal inflation, I would not mourn it's passing, I have to say 😉 But, for example, in the case with possible multiple vacua, I see no way to avoid it from occuring at least for some parameter values — and I think evolution would find a way to exploit this mechanism for infinite reproduction!

cheers,

Anthony

88. **Moshe**
December 21, 2005

Peter, since this discussion is going in your territory, I am curious what is your opinion of cosmological natural selection as an alternative to anthropic reasoning. Feel free to ignore this if you haven't looked at it in sufficient detail.

Happy holidays!

best,

Moshe

89. **woit**
December 21, 2005

Hi Moshe,

I haven't looked at CNS in enough detail to have an intelligent comment on it. The crucial question for anything like this is whether it generates testable predictions. Here

Smolin claims it does, and his discussion here with Aguirre looked like it could be very illuminating, but I haven't taken the time to really understand the arguments on both sides (life is short, and it's exam period here these days…)

In general, what I really care about and am willing to invest time in trying to carefully understand, are new physical ideas that explain something about particle theory, or new mathematical ideas that might somehow be useful in better understanding particle theory. This means there are a lot of topics in cosmology and quantum gravity that I've never studied in a really serious way, CNS is one of them.

90. **Lee Smolin**
December 21, 2005

Hi,

To Antony on eternal inflation. I understand the arguments that go from inflation to eternal inflation but I find myself unconvinced of them, especially in the context in which inflation would arise in a small region to the future of the bounce of a black hole singularity. I would trust inflation in general much more if we had solved the cosmological constant problems. The cosmological constant problem arises not in a fundamental theory but only at the effective field theory level and, as pointed out by Dreyer in hep-th/0409048 there may be a physical mechanism such as proposed by he or Volovick which dynamically adjusts the vacuum non-perturbatively close to zero, in which case there is no inflation. Of course then I would lose the argument I made, but there is no problem in principle as the horizon problem is already solved by the fact that the universe arises from a bounce.

On the other hand, WE KNOW that there are many black holes-perhaps as many as 10^19 in our Hubble volume. And we have good theoretical evidence that black hole singularities bounce. So only one element is missing for the CNS scenario-that the changes in vacuum resulting results in small changes in standard model parameters.

For the time being we must assume this-although it is possible this assumption may be tested soon. But once we do we get quite a bit.

My impression, if I can say so, is that many cosmologists undervalue the positive successes of CNS. It EXPLAINS otherwise mysterious features of our universe such as the setting of the parameters to make carbon and oxygen abundent-not because of life but because of their role in cooling GMC's. It also EXPLAINS the hierarchy problem and the scale of the weak interactions-because these can also be understood to be tuned to extremize black hole production. Further, it EXPLAINS two otherwise improbable features of glaxies: why the IMF for star formation is power law and why disk galaxies maintain a steady rate of massive star formation.

Moreover CNS makes a few real predictions: that the upper mass limit of neutron stars is less than 1.6 solar masses and that inflation is governed by one parameter. Made in 1992 these predictions could easily have been falsified but they have stood up.

CNS makes these genuine explanations and predictions without having to invoke the AP, whereas eternal inflation requires invoking strongly the AP just to be plausible.

It seems to me CNS has a much longer list of successes than eternal inflation. which so far as I can tell explains NOTHING about the particle physics standard model parameters and which makes no fallsifiable predictions.

There are always many theories with attractive features, my understanding of how science is supposed to work is we are to pick out of the list of otherewise attractive theories those few that genuinly explain and predict over those that don't.

The problems I set out to solve were 1) why the neutron is a bit heavier than the proton, 2) why their difference is comparable to the electron mass, 3) the value of the fermi constant, 4) the value of the strange quark mass, 4) the hierarchy problem. These are real problems which have been around for decades. So far as I know, CNS is the only explanation proposed so far that is both genuinly explanatory and genuinly falsifiable in terms of ongoing observations.

If you ask me to discount all this because of a highly speculative theory of the very early universe that explains nothing and makes no falsifiable predictions, that may easily dissapear when the cosmological constant problem is solved, I am afraid I don't think this is consistent with the methodology of science as I understand it. I understand reasonable people may differ, and I have the greatest respect for you, Max and other cosmologists, but I must admit also I am puzzled by your apparent judgements of what is more and less reliable in present theory.

Also, to Michael Bacon: Methods from quantum computation are being used to solve the problem you mention, which is how distinct particle states emerge from a spin foam. See D. W. Kribs, F. Markopoulou, Geometry from quantum particles, gr-qc/0510052.

Thanks,

Lee

91. **Moshe**
December 21, 2005

Thanks Peter, and good luck with finalizing the semester.

92. **Who**
December 21, 2005

in his preceding post Lee Smolin says

The problems I set out to solve were 1) why the neutron is a bit heavier than the proton, 2) why their difference is comparable to the electron mass, 3) the value of the fermi constant, 4) the value of the strange quark mass, 4) the hierarchy problem. These are real problems which have been around for decades. So far as I know, CNS is the only explanation proposed so far that is both genuinly explanatory and genuinely falsifiable in terms of ongoing observations.

[MY COMMENT] this is a key paragraph and I want to connect the dots and see what I understand and what I dont. Maybe get some help explicating, if possible. The above connects with page 31 of the paper (Scientific Alternatives to the AP, hep-th/0407213). Here is an exerpt from Smolin's paper:

The crucial conditions necessary for forming many black holes as the result of massive star formation are,

1. There should be at least a few light stable nuclei, up to helium at least, so that gravitational collapse leads to long lived, stable stars.

2. Carbon and oxygen nuclei should be stable, so that giant molecular clouds formand cool efficiently, giving rise to the efficient formation of stars massive enough to give rise to black holes.

3. The number of massive stars is increased by feedback processes by which massive star formation catalyzes more massive star formation. This is called "selfpropagated star formation, and there is good evidence that it makes a significant contribution to the number of massive stars produced. This requires a separation of time scales between the time scale required for star formation and the lifetime of the massive stars. This requires, among other things, that nucleosynthesis should not proceed too far, so that the universe is dominated by long lived hydrogen burning stars.

4. Feedback processes involved in star formation also require that supernovas should eject enough energy and material to catalyze formation of massive stars, but not so much that there are not many supernova remnants over the upper mass limit for stable neutron stars.

5. The parameters governing nuclear physics should be tuned, as much as possible consistent with the forgoing, so that the upper mass limit of neutron stars is as low as possible.

The study of conditions 1) to 4) leads to the conclusion that the number of black holes produced in galaxies will be decreased by any of the following changes in the low energy parameters:

• A reversal of the sign of Δm = m_neutron – m_proton.

• A small increase in Δm (compared to m_neutron will destabilize helium and carbon.

• An increase in m_electron of order m_electron itself, will destabilize helium and carbon.

• An increase in m_neutrino …, will destabilize helium and carbon.

• A small increase in α will destabilize all nuclei.

• A small decrease in α_strong, the strong coupling constant, will destabilize all nuclei.

• An increase or decrease in G_Fermi of order unity will decrease the energy output of supernovas. One sign will lead to a universe dominated by helium.

[my comment: not sure the Delta and alpha are going to print. Some of the above seems readily understandable. Some, not. In one case where I failed to understand, I shortened the quote by elision. Refer to the original. Would be glad if anyone volunteered to clarify, instead of my having to, even the more self-evident points here.]

93. **Frank Wilczek**
December 26, 2005

Hi,

I'd like to encourage readers interested in my views on these subjects to read to original papers, which are rather more nuanced and substantial than the summaries presented here. Thanks, and happy holidays.

94. **woit**
December 26, 2005

I'd like to second Wilczek's encouragement to all to read the original papers discussed here. In this posting, as in just about all others, what you are getting here is not an accurate, objective summary of a talk, article or book, but my own commentary on one or more specific aspects, written under the assumption that readers will read the original source for themselves.

In addition, in cases like this particular one, it should be taken into account that my commentary is very much not objective, but highly colored by certain specific concerns which the regular readers of this blog should be well aware of.

95. **Who**
December 26, 2005

Hello Frank Wilczek,
I'm a long-time fan of your writings—like the combination of ideas and style.

Here I am responding directly to the Tegmark et al paper
http://arxiv.org/abs/astro-ph/0511774
"Dimensionless constants…"
of which you are co-author.

What disturbs me about this paper is that it does not include a discussion of Smolin CNS, as described in
http://arxiv.org/abs/hep-th/0407213
"Scientific alternatives to the anthropic principle"

Would you please explain why the CNS hypothesis does not merit consideration when one discusses the explanation or non-explanation of basic dimensionless constants? Has CNS, in your view, already been falsified by observation?

96. **woit**
December 26, 2005

Who,

I probably shouldn't try and answer for Wilczek, who I gather from his comment is not particularly happy with my summary of parts of his papers and talk, but there's an obvious answer to your question. His paper with Tegmark is not a review of the various attempts to get scientific predictions out of anthropic arguments. It not only doesn't mention Smolin's CNS hypothesis, but it also doesn't discuss the far more popular string theory anthropic landscape program being pursued by many string theorists. The paper is specifically about the dark matter density, looking at axion cosmology and WIMPs as hypotheses for the origin of dark matter, as well as relevant anthropic selection effects. Given what they are trying to do in that paper, I don't see any particular reason the authors should be addressing the CNS hypothesis there.

97. **Who**
December 26, 2005

Peter,

let me be a bit more specific about where I think the omission occurred and then either you or Wilczek can judge if my objection is valid. In the Tegmark et al paper, on page 1, in the introduction section1B, quote:

—quote from Tegmark et al—

B. The origin of the dimensionless numbers

So why do we observe these 31 parameters to have the particular values listed in Table1? Interest in that question has grown with the gradual realization that some of these parameters appear fine-tuned for life, in the sense that small relative changes to their values would result in dramatic qualitative changes that could preclude intelligent life, and hence the very possibility of reflective observation. As discussed extensively elsewhere [9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22], there are four common responses to this realization:

1. **Fluke: Any apparent fine-tuning is a fluke and is best ignored.**

2. **Multiverse: These parameters vary across an ensemble of physically realized and (for all practical purposes) parallel universes, and we find ourselves in one where life is possible.**

3. **Design: Our universe is somehow created or simulated with parameters chosen to allow life.**

4. **Fecundity: There is no fine-tuning, because intelligent life of some form will emerge under extremely varied circumstances.**

Options 1, 2, and 4 tend to be preferred by physicists, with recent developments in inflation and high-energy theory giving new popularity to option 2.

Like relativity theory and quantum mechanics, the theory deepening our understanding of the nature of physical reality. First of all, inflation is generically eternal [25, 26, 27, 28, 29, 30, 31], so that even though inflation has ended in the part of space that we inhabit, it still continues elsewhere and will ultimately produce…

…More dramatically, a common feature of much string theory related model building is that there is a "landscape" of solutions, corresponding to spacetime configurations involving different values of both seemingly continuous parameters (Table 1) and discrete parameters…

—endquote—

Peter, you say an obvious answer to why CNS was not mentioned is that
" **His [Wilczek's] paper with Tegmark is not a review of the various attempts to get scientific predictions out of anthropic arguments.**" But I would reply that CNS is *not* an attempt to get scientific predictions out of anthropic arguments. The theory has no anthropic character at all—it doesnt refer to life or consciousness, or depend logically on their existence.

However the paper does review 4 possible ways of reacting to the "realization that some…parameters appear fine-tuned for life."

I believe that until or unless CNS is refuted it should be included among the possible responses, and that it does not fit neatly into any one of the four listed by the paper. I suppose that according to the CNS view it can be considered a **fluke** that conscious life can arise where evolution has tuned the constants for abundant black holes. And that in this view there is a single **universe** capable of branching where, as in the case of a stellar mass black hole, gravitational collapse leads to a bounce. So it is perhaps closest to responses 1 and 2—but not adequately represented by either!

98. **Aaron Bergman**
December 26, 2005

CNS is subsumed in #2.

Hope this helps!

99. **Anthony Aguirre**
December 26, 2005

To "who":

I agree with Aaron Bergman that CNS is subsumed in 'multiverse', (and this is why I did not think it required separate listing either in the present paper or my earlier one with a similar list) though I also agree with you that, as I noted before, there is an aspect of 'fluke; that the conditions for life must coincide with the conditions for black-hole formation (or else life all lives in rare universes and we are back to anthropics to explain why we do not observe the most common type of universe).

Lee:

For me, and I think for many, the argument goes:

1) observations imply inflation.
2) Inflation implies at least the possibility of eternal inflation.

breaking eather link would be extremely interesting. Breaking the first, by creating a viable alternative to inflation for explaining the CMB fluctuations, etc., would obviously be interesting, but has not, in my opinion, been even nearly done, with all due respect to the cyclic and VSL folks.

Breaking the second link, which you suggest, would also be interesting and I would be happy to entertain such a possibility — I just do not see how to do it. You may be right that somehow eternal inflation will 'go away' if we understand vacuum energy, but I'm not sure how this could happen without inflation itself going away.

There are some, I think, who entusiastically embrace the eternal inflation picture. But I think many others others, like myself, find it interesting that observations seem imply it, perhaps despite our wishes.

cheers,

Anthony

100. **Dissident**
December 27, 2005

Anthony, what about Luminet's "hall of mirrors"?

http://arxiv.org/abs/physics/0509171

101. **Lee Smolin**
December 27, 2005

Dear Anthony,

Thanks, I am aware of this point of view but I haven't found the literature completely convincing. Perhaps you could tell me the paper where the argument "inflation implies eternal inflation" is most clearly and convincingly presented, and I'll study it.

Worry about the realness of the vacuum energy is not the only issue I've had with this argument. Another is how well defined are the frameworks in which calculations are done. Some are very heuristic, others depend on assumptions about the interpretation of the wave function of the universe and measures on infinite numbers of universes that don't seem to make sense when scruitinized.

Another kind of worry is that extending from inflation to internal inflation requires believing that the mechanism is reliable at scales presently outside our horizon that were formerly way below the Planck scale. If there is a universal planck scale cut off, as in DSR, it could alter the physics presently outside of our horizon. In fact, there are apparent anomalies in the CMB spectra near present Hubble scales-both the low power and the axis of evil. If real they support the idea that Planck scale effects have a non-trivial effect on inflation, which would change things outside our present horizon.

On the other hand, we know our universe produces large numbers of astrophsyical black holes, a fact that depends on features of star formation and galactic dynamics that do not seem otherwise necessary.

Thanks,

Lee

ps to Who, thanks for pressing the argument.

102. **Anonymous**
December 27, 2005

I tried to get a response over at CV and none so far, so I might as well point it out here: there's a new paper from Reza Mansouri, http://arxiv.org/abs/astro-ph/0512605, which claims that properly accounting for inhomogeneities in the universe eliminates the need for dark energy or a cosmological constant to explain the data. It looks reasonable to me and much more convincing than the Kolb stuff earlier this year. Any thoughts? This is somewhat off-topic, but on the other hand if this sort of reasoning is shown to be correct I think much of the reason for supporting anthropic arguments will go away fairly quickly.

103. **Anthony Aguirre**
December 27, 2005

Hi Lee,

Absolutely agree that many of the arguments for eternal 'stochastic' inflation (driven by quantum fluctuations) are somewhat unrigorous, even at the level of effective field theory in curved spacetime. I find them reasonably compelling but consider it possible that there is something fundamentally wrong with them. The argument for eternal inflation with multiple minima, however, seems extremely strong to me — the spacetime can be described more-or-less exactly, and a very straightforward computation implies that the (physical) inflating volume increases when spatial sections are chosen so as to make the background spacetime homogeneous. One must only accept the Coleman-De Luccia picture of the decay of the false vaccum for this to be true for at least some multiple-well potentials.

Now, the questions of how *generic* eternal inflation is, is I think an interesting one: are there non-fine-tuned inflation models that explain the observations and are not eternal? I don't know of any decent study on this question (and may well undertake one myself). In the context of CNS, however, even the *possibility* of eternal inflation is very dangerous, however, because unless eternal inflation is *forbidden* by the 'meta' laws that govern which types of inflation are possible in the landscape of possibilities, it must only be realized once to 'take over' the ensemble by creating an infinite number of black holes out of one. The only escape from this, it would seem, would be to have other channels to create infinitely many black holes from one 'parent' — but then you would be in the same extremely thorny boat of comparing infinities that eternal inflation is already in; further, which type of universe would come out 'winning' in this competition between infinities would seem quite independent of mundania such as the IMF…

One interesting way that EI might be essentially wrong is if the QFT in curved spacetime description is essentially wrong, for example for 'holographic' reasons (see the recent Banks paper). In this view, all of the zillions of 'other universes' are just refigurings of the same degrees of freedom inside the horizon (this realizes, in some sense, a version of the 'hall of mirrors' mentioned by 'dissident' above.) I find this view very hard to understand, but perhaps it is right and would change the way we think about EI, perhaps in a way less troubling (to me at least) in regard to CNS.

cheers,

Anthony

104. **Chronos**
December 28, 2005

Would it be fair to say that the Anthropic Principle rules out the impossible, but is not predictive beyond that?

105. **Shantanu**
December 30, 2005

To
Anthony and others,
what do you think about Penrose 's objections to inflation?
I have not seen a good counter-argument to them.

Yet More Assorted Links

December 14, 2005
Categories: Uncategorized

Various and assorted things that may be of interest:

Joshua Roebke at Seed has accumulated opinions about the landscape from various physicists. No real surprises; Witten wins the award for most non-committal:

I just don't have anything incisive to say. I hope we will learn more.

There's a mailing list called philphys devoted to "philosophical and foundational problems of modern physics."

The web-site for the ICFA Seminar held in Korea a couple months ago has several interesting presentations on-line, including one by John Ellis, and several about future plans at various accelerator laboratories world-wide.

There was a conference recently in Geneva celebrating the 100th anniversary of the birth of E.C.G. Stueckelberg. Some anecdotes about Stueckelberg are here.

There is a bit of a controversy about another E.C.G., Sudarshan, who some (including himself) feel should have been part of this year's Nobel prize in physics. Stories about this here, here, and here.

Some talks given at the recent conference at OSU on Strings and the Real World are on-line. See if you can find anything in them about the real world.

According to this article, string theory is now being marketed to the 6-11 year-old age group, appearing as test questions in the Flashcard Fishing game on the GoGo TV game system.

Barry Mazur has an article about category theory entitled When is one thing equal to some other thing?.

Penn State mathematician Adrian Ocneanu has designed a sculpture representing an interesting four dimensional figure, the Octacube.

Update: Sean Carroll has a new preprint out entitled Is Our Universe Natural?, and some commentary about it at Cosmic Variance. Unlike certain Nobel prize winners, Sean recognizes that before throwing in the trash the paradigm of how to do theoretical physics that has had such success for many centuries, one should at least have a shred of scientific evidence for one's proposed alternative. He explains what the problems are with the one supposedly successful "prediction" of the anthropic principle, that of Weinberg for the cosmological constant, noting that it makes three assumptions, and :

The first of these is a guess, the second is likely to be fantastically wrong in the context of eternal inflation, and the last only makes sense if all of the other parameters are held fixed, which is not how we expect the multiverse to work.

Even with these dubious assumptions, the "prediction" one gets is off by more than an order of magnitude.

Comments

1. **Kea**
   December 14, 2005

   Thank you for the very beautiful article by Barry Mazur.

2. **D R Lunsford**
   December 14, 2005

   It's high time Stueckelberg got his due. There is a beautiful article here about Stueckelberg's 1934 paper:

   http://arxiv.org/abs/physics/9903023

   Stueckelberg was, like Pauli, a student of Sommerfeld. I'd still recommend Sommerfeld's 6-volume course any day, even alongside Landau. (Sommerfeld's teacher was Klein. This was a lusty vein of physics and mathematics.)

   More on the Sudarshan issue :

   A report in Frontline about the whole issue
   Sudarshan's Letter

4. **Tony Smith**
   December 15, 2005

   Peter, you say "… Penn State mathematician Adrian Ocneanu has designed a sculpture representing an interesting four dimensional figure, the Octacube. …".

   When I went to the link you gave to
   http://www.science.psu.edu/alert/Math10-2005.htm
   I found material including the following:

   "… The subject of the projection is a regular 4-dimensional solid of intermediate complexity, which Ocneanu calls an "octacube." It has 24 vertices, 96 edges, and 96 triangular faces, which enclose 24 three-dimensional "rooms."
   …
   No good rendering of any 4-dimensional object existed anywhere in the world before the Octacube, either in solid or virtual form, according to Adrian Ocneanu, the Penn State professor of mathematics who designed the sculpture.

…
The sculpture represents a three dimensional map of the surface of a four dimensional regular solid. Adrian Ocneanu developed and copyrighted the map, called windowed radial stereographic projection. … Linear edges of the solid become circles in the projection. …".

I am appalled by those statements, and I wish that I could attribute them solely to Penn State PR bureaucrats, because Ocneanu has done interesting mathemematics, such as work on von Neumann algebra factors.

First:
The "octacube" is nothing new. It has been around in mathematics for decades, and it already has a well-accepted name (the 24-cell).

Second:
"Good renderings" of the 24-cell have been in existence for a long time. In 1932, Hilbert and Cohn-Vossen wrote the book Anschauliche Geometrie, which has a nice rendering of a 24-cell that is figure 172 in the English translation, which is entitled Geomety and the Imagination (Chelsea 1952). There have been so many other renderings over the past decades that I will not attempt to list them here.

Third:
Radial stereographic projection of the 24-cell is nothing new either. For a very nice description with beautiful illustrations, see the web page of Frans Marcelis at http://home.wanadoo.nl/f.marcelis/24-cell.htm
If you go to the PSU web page cited above, you can see an image whose caption reads "Dr. Ocneanu, pictured at the inauguration of the Octacube, sharing his first apparition of the octacube as a wire model.". If you look at the "apparition", you will see that it looks almost identical to the work of Frans Marcelis.

I think it is disgusting that the PSU people are trying to rename the 24-cell and claim priority on renderings and projections thereof.

The sculpture itself is quite beautiful and is a good visualization tool. It is a shame to degrade such a nice work of art by associating it with attempts to rewrite history and rename the 24-cell.

December 15, 2005

I read about this "controversy" of who between Stueckelberg and Feynman first came up with the now famous diagrammatic perturbative approach to doing QED calculations about 2 years ago, when I was in my second year of undergraduate studies at Melbourne University. Some of the anecdotes related to this matter that were brought to my attention shocked me, especially Feynman's comment after his CERN lecture. If the story is true and Stueckelberg did actually work things out well before Feynman did, then we wonder why Feynman, who reportedly was aware of Stueckelberg's works before he was awarded the Nobel Prize, did not say anything explicitly about it. But maybe more facts need to surface for a consistent picture to emerge… Funnily, I remember being rather angered on hearing the story, more so because I respect Feynman a lot, and such a behaviour of his would be condemnable. Then I forgot about it, until I bought a copy of Schwinger's "Selected papers in QED", and found no paper by Stueckelberg. Now, if Schwinger knew that Feynman did something morally wrong, as the remark during the phone call would suggest, then why did he not say anything about it in this book? Maybe Stueckelberg did not write any paper about his approach, so would this be reason why Schwinger did not include any of Stueckelberg's papers? I wonder if these questions are legitimate…

6. **Tony Smith**
December 15, 2005

Crease and Mann say in their book The Second Creation (revised edition, Rutgers 1996) (page 143) that Stueckelberg "… in the army, was almost totally isolated from physics. Nonetheless, he apparently wrote up a lengthy paper – in English, for once – that outlined a complete and correct description of the renormalization procedure for quantum electrodynamics. Sometime in 1942 or 1943, he apparently mailed it to the Physical Review. It was rejected. "They said it was not a paper, it was a program, an outline, a proposal," Stueckelberg remembered. … Stueckelberg was not a bitter man. … We asked if he had the manuscript, which would help him establish priority. "I never cared much about that question," he replied. "I don't know what happened to the original copy. I lost it, it completely disappeared. …".

7. **secret milkshake**
December 15, 2005

It is normal that several people have the same key insight but it matters what they do with it.

I take it that Feynman was just being very nice to Stueckelberg, mentioning him (for getting on the right path before anybody else). F was always bending backward to aknowledge people like Jehle, Wheeler and Bethe from whom he got the helpful ideas – S. was not a source of F inspiration but he deserved the honorable mention. Also, had Tomonaga not published in wartime Japan, he would hardly get more credit then Stueckelberg.

8. **D R Lunsford**
December 15, 2005

Stueckelberg had a German name and tried to get a paper published in the pre-eminent American physics journal. In 1943. Before D-Day.

Read the paper I linked. Weisskopf states:

Already in 1934 […] it seemed that a systematic theory be developed in which these infinities [divergent radiative corrections] are circumvented. At that time nobody attempted formulate such a theory […].There was one tragic exception and that was Ernst C.G. Stueckelberg. He wrote several important papers in 1934-38 putting forward a manifestly formulation of field theory. This could have been a perfect basis for developing of renormalization. Later on, he actually carried out a complete renormalization procedure in papers with D. Rivier, independently of the efforts of other authors. Unfortunately, writings and his talks were rather obscure,and it was difficult to understand them or to make use of his methods. He came frequently to Zurich in the years 1934-6, when I working with Pauli, but we could not follow his way of presentation. Had Pauli and I myself been capable of grasping his might well have calculated the Lamb shift and the correction the magnetic moment of the electron at the time.

There is little to argue about. There is no doubt at all that Stueckelberg had the whole program down.

9. **sunderpeeche**

December 15, 2005

Many Nobel Prizes are controversial
Anthony Hewish (pulsar) – no prize to Jocelyn Bell
Ken Wilson (RG) – many people (incl Wilson) feel Leo Kadanoff + Michael Fisher should have shared prize
prize for (integer) Quantum Hall Effect ….
prize for MRI ….
no prize John Bahcall solar neutrino
no prize Lise Meitner etc discovery nuclear fission (because of WW2 + bomb)
The list will not end anytime soon

10. **Dissident**
December 15, 2005

Could somebody please remind me why we attach such significance to a prize awarded by a bunch of Swedes, apparently expecting the choice of recipients to reflect superior competence? Because of all the outstanding contributions to physics made by the Swedish Cook…?

(I can hear somebody in the backrows shouting "Klein!". Sorry, no. Klein was a mathematician – and as the story goes, Alfred Nobel explicitly excluded mathematics from the list of awardable subjects because he was after the same lady as Klein, whom he knew would have been a strong contender for the prize. Hardly an auspicious start.)

11. **sunderpeeche**
December 15, 2005

Nobody knows how the prizes attracted such prestige, even from the early years. As for Nobel and mathematicians and ladies, there is much hogwash on the subject. Don't believe most (all?) of it. Nobody really knows either.

12. **Tony Smith**
December 15, 2005

DRL mentions the paper at http://arxiv.org/abs/physics/9903023 which (in addition to the very interesting part quoted by DRL) also states:
"… Stueckelberg came to the University of Zurich in 1933 … Stueckelberg was … Privatdozent at the University of Zurich with professor Gregor Wentzel …".

Crease and Mann, in their book The Second Creation cited above by me, quoted Stueckelberg as saying, about his 1942 or 1943 submission to the Physical Review:
"Afterward, I was told that our friend and teacher, Gregor Wentzel – he was the expert [referee] – he got my paper."

So, to me it appears that Stueckelberg's 1942 or 1943 paper was not rejected by American Physical Review due to wartime hostility against Stueckelberg (who after all was in the army of neutral Switzerland),
but was in fact torpedoed by his former teacher Wentzel.

I also find it interesting that Stueckelberg's submission to the Physical Review in New York could have been floating around in the USA physics community (as a rejected but possibly interesting program) after its submission in 1942 or 1943, well in advance of the 1948 Shelter Island conference at which Feynman and Schwinger both presented their approaches to QED.

According to the paper physics/9903023 cited by DRL
"… The main innovation of the 1934 paper [by Stueckelberg] is the introduction of a new perturbative scheme yielding manifestly relativistic expressions for the matrix elements. This is achieved by performing a four-dimensional Fourier transformation of the wave-function, thus eliminating space and time variables … Stueckelberg's procedure is thus the first departure from the "older (Dirac) form of the perturbation
theory … The approach proposed by Stueckelberg is far more powerful, but was not adopted by others at the time. …".
As DRL has indicated, Weisskopf felt that Stueckelberg's 1934 ideas would enable calculation of "the Lamb shift and the correction of the magnetic moment".
In my opinion, it is almost certain that Stueckelberg's 1934 key ideas would be set out in his 1942 or 1943 submission to the Physical Review.

As to the time of Feynman soving the QED problem, in 1941 (according to Mehra's Feynman biography The Beat of a Different Drum (Oxford 1994)) Feynman had the inspiration from Dirac's paper of using the Lagrangian method, which led to Feynman's 1942 Ph.D. thesis. As to that thesis, Mehra says "… Feynman mentioned that "the problem of the form that relativistic quantum mechanics, and the Dirac equation, take from this point of view, remains unsolved. …". So, Feynman's Shelter Island relativistic QED solution was developed after his 1942 Ph.D. thesis.

Therefore, it seems to me that Feynman's solution of the relativistic QED problem was probably achieved during the time when Stueckelberg's 1942 or 1943 paper could have been circulating in the USA physics community as a manuscript rejected by the Physical Review,
and it is probable that Stueckleberg's rejected manuscript did in fact contain the key to solving the relativistic QED problem.

Tony Smith

13. **robert**
December 15, 2005

Like Stuekelberg, Sudarshan can claim to be multiply mis-used, as he was, with Marshak, pre-empted in the announcement of V-A by Feynman (again) and Gell-Mann, under slightly questionable circumstances. This too caused considerable rancour and unpleasantness, which MGM, for once, did his best to minimise. Marshak's 'Conceptual foundations of modern particle physics' makes very scant reference to F-G in its discussion of this topic.

14. **JE**
December 15, 2005

"Alfred Nobel explicitly excluded mathematics from the list of awardable subjects because he was after the same lady as Klein…"

Fairly speaking, it seems Mittag-Leffler was the contender A. Nobel had in mind when he decided against a Nobel prize in math. Mittag-Leffler was Swedish, unlike Klein, who was German.

15. **Chris Oakley**
December 15, 2005

I am looking at the paper about Stueckelberg linked by Danny(http://arxiv.org/abs/physics/9903023), and am amazed that I was never aware of it – 4D Fourier transforms, power series expansion in the coupling constant – all the stuff I was playing with 20 years ago, and 50 years after Stueckelberg first dreamed it up. I am also surprised that none of the referees for my papers picked it up either. Maybe they too were unaware of his work. If it is leading where I think it is leading, then, yes, you can do manifestly covariant perturbation theory, and you can get agreement with tree Feynman graphs, but you still get infinities exploding all over the place from second order upwards. IIRC Stueckelberg's solution was to start assigning meaning to meaningless quantities (infinity minus infinity) – as everyone in the subject but me seems to be happy to do. A better solution, though, is just to choose equations of motion where the infinities do not appear in the first place. I am going to find out more, and will update the QFT part of my web site once I have studied his work properly.

16. **Dissident**
December 15, 2005

JE, Klein really was a Swede (the common misunderstanding about him being German is probably due to the German-sounding family name). See e.g. http://www-groups.dcs.st-and.ac.uk/~history/Mathematicians/Klein_Oskar.html
(just happens to be the first link that comes up on Google).

Yes, I've seen the mittag-Leffler version of the Nobel story, too. Admittedly, the dates make more sense in that version. But who knows…

17. **JE**
December 15, 2005

Dissident – You're right, for chronological reasons I thought you were referring to Felix Klein (who was contemporary with Nobel).

18. **Brett**
December 15, 2005

The story about Nobel not giving a prize in mathematics because of competition for some lady's affections is a many-times debunked urban myth. (Nobel never married, but he had a regular girlfriend for many years, and she was never involved with any mathematicians.)

If you actually read the terms of Nobel's will, the reason there is no mathematics prize is self-eveident. Math just doesn't fit into the framework; Nobel wanted to reward much more applied and immediate research than the committees that have actually presented the awards. In fact, the committees consistently violate the rules Nobel set down. (At least one of the prizes–chemistry, I believe–is specifically supposed to be for discoveries made in the last year, for example.)

19. **Dissident**
December 15, 2005

Oh, come on Brett! So he had this one girlfriend – and never ever laid eyes on another woman? And he was smart enough to come up with dynamite and build a business empire – but not to write terms for the prize excluding mathematics for socially acceptable reasons?

20. **Dissident**
December 15, 2005

JE: yes, having now checked the dates, I see Oskar Klein was 2 years old when Alfred Nobel died, so I think we can safely debunk his having had any role in the story at least!

21. **fh**
December 15, 2005

There is a moral here. It is not important who first dreams up the idea, it is important who first contributes it.
That is, it is important to formulate this ideas in a language that makes them accessible to non-geniuses (or in Stückelbergs case to the co-geniuses of the time like Pauli and Weisskopf). To get the ideas "out there".

22. **Chris W.**
December 15, 2005

Since this post mentions a miscellaneous collection of things, I thought I would throw in something a bit out of left field, from today's Wall Street Journal:

> **A Hedge-Fund Titan's Millions Stir Up Research Into Autism**
>
> In their quest for answers, the Simonses aren't just another family seeking comfort. Audrey's father, world-class mathematician James H. Simons, runs Renaissance Technologies Corp., one of the world's most successful hedge funds. With little notice, the family's charitable foundation has in the past two years committed $38 million to find the causes of autism. The money manager says he and his wife will spend $100 million more in what is rapidly becoming the largest private investment in the field.

23. **Chris Oakley**
December 16, 2005

fh,

In the case of Stückelberg, the HEP community seems to have retained the chaff (his work on renormalization) while throwing out the wheat (his covariant perturbation theory). There really ought to be more of a clue about the latter in mainstream QFT literature. I am in the Bodleian (Oxford U) today to chase up the references, and when I am finished I will hopefully be able to say something about his work on my web site, at least.

24. **Juan R.**
December 16, 2005

Well, i do not know personally to Sudarshan but know his interesting work on Kaon systems and his generalized quantum mechancis presented at Solvay conference of last 97. My colleague Gonzalo Ordonez at Texas always said that Sudarshan was a "very good profesor" there, at the Prigogine Institute.

Also i may say that i am :-0 by the history of Feynman and Stückelberg.

For anyone interested in the politics beyond the Nobel Prize can read fascinating and extensively documented (The author, who had access to the Nobel archives, spent 20 years researching) book by recognized historian Robert Marc Friedman: Politics of Excellence: Behind the Nobel Prize in Science.

Available at amazon

An interesting review (from Kauffman) was published in the top journal [Angew. Chem. Int. Ed. 2003, 42(11), 1194].

An excerpt:

> the archives show that from their inception the awards have reflected the changing priorities, arrogance, racism, hostility, sexism, inconsistencies, politics, ambitions, open and hidden agendas, biases, rivalries, vanities, pettiness, prejudices, and narrow personal, scientific, and cultural self-interests of comittee members who evaluate nominations. He concludes that the process is nowhere nearly as impartial or objective as generally believed

Juan R.

Center for CANONICAL |SCIENCE)

25. **sunderpeeche**
December 16, 2005

Alfred Nobel invented dynamite, built a successful business empire (and never married, had a girlfriend etc). It is also a documented fact that his will took EVERYONE by surprise. It was hastily written and the terms of the prizes were vague (but it did say "work in the previous year" for physics, chemistry, medicine not just chemistry). It took 3 years (I think) for the lawyers to sort it out. Also the academicians usurped the prizes for themselves. So for example Thomas Edison never won a prize even though his technological contributions to society were many and profound. In fact it is unusual that Guglielmo Marconi was awarded a prize for the wireless.

Many NPs have been controversial since the early days.
All the stuff about Kein, Mittag-Leffler etc is urban legend.

26. **Chris Oakley**
December 16, 2005

Hi Danny,

Thanks again for the tip about Stueckelberg. I managed to get copies of his papers. The 1934 one seems to be key, but my German was not up to reading it properly, so I mainly relied on the pre-digested version supplied by Lacki, Ruegg and Telegdi.
The QFT pages on my web site now take account of his work.

<my personal view>
I am gobsmacked. There he was with a much better way of doing things than Feynman (Gell Mann apparently even referred to Feynman diagrams as "Stueckelberg diagrams") and yet he seems to have spent much of his time messing around with renormalization.

Did he not realise that minimal substitution is just *a guess based on classical field theory* and that there is no physical principle that requires it – ??? Tamper with the field equations just a little and the need to renormalize goes away.

</my personal view>

27. **D R Lunsford**
December 16, 2005

Chris, excellent, I'd be happy to translate the whole paper and perhaps you could fill me in on what I'm missing 🙂 Just mail a scanned copy.

-drl

28. **D R Lunsford**
December 16, 2005

Chris, I'd have to say miminal coupling is the trace of conformality, but we could discuss it later perhaps.

-drl

29. **Chris Oakley**
December 16, 2005

Hi Danny,

Thanks for that. A translation would certainly help, although maybe one of Lacki, Ruegg and Telegdi has already done it.
Remind me of your e-mail address & will send scans (19 small journal pages, BTW).
BTW: What about follow-ups on this work? Was it just that he never bothered to to get stuff published?

30. **Tony Smith**
December 16, 2005

As to later publications by, or about the work of, Stueckelberg:
According to The Second Creation by Crease and Mann:
Stueckelberg "… … struggled to carry out the program rejected by the Physical Review. By the end of the war, in 1945, he seems to have done it. … he wrote up bits and pieces of his ideas. Eventually they were presented in a complete form in a chapter of the thesis of one of his students, Dominique Rivier. … HPA 22, no. 3 (1949):265 …".
HPA refers to Helvitica Physica Acta. According to an ICTP Trieste web page it may no longer be published, but have been superseded by Annales Henri Poincare.

Crease and Mann say: "… by then [1949 when Rivier's thesis was published] Schwinger had come out with his program, and Stueckelberg, who had the ideas first, published afterward …".
I guess that the idea that publication, and only publication, establishes priority is the (in my opinion flimsy and unjust) basis for denying Stueckelberg a prominent place in the history of physics.

If a world-wide physics e-print archive had existed back in the 1930s and 1940s, maybe it would have allowed Stueckelberg's priority to have been recognized by the physics establishment. However, if such an archive had blacklisted Stueckelberg, then maybe it would not have been helpful to him.

31. **Chris Oakley**
December 16, 2005

Hi Tony,

Thanks for that information. What bothers me is not Stueckelberg publishing after Schwinger so much as Stueckelberg not publishing certain things *at all*. I am not sure when Helv Phys Acta became Ann Henri Poincare, but either way I am sure that I will be able to find the reference you give, which I will check. I am sure that Stueckelberg would always have been able to publish in *this* journal, being the local boy, even if the likes of Ann Phys and Phys Rev were reluctant …

32. **JC**
December 16, 2005

Chris Oakley,

Did you look up the citation indices for Stueckelberg's 1934 paper and/or it's english translation? It would be interesting to see what other papers cited it before Schwinger, Feynman, etc …

33. **D R Lunsford**
December 16, 2005

CO: antimatter33 -@- yahoo -.- com

Thanks in advance.

-drl

34. **Chris Oakley**
December 17, 2005

Danny … thanks.

JC,

This article http://arxiv.org/abs/physics/9903023 tells the story of Stueckelberg's covariant perturbation theory (BTW: Peter, why can't I seem to get <a> … to work any more? Am I doing something wrong?)
Although I have not checked in any citation index, it looks as though, citation-wise, Stueckelberg's 1934 Ann. Phys. article did not do much better than my (independent) re-creation of some of the arguments more than fifty years later … I know for a fact that one can take the arguments much further than he does in this paper, and I would very surprised if he or someone else had not done so. But I will have to check. The Lacki/Ruegg/Telegdi paper sounded fairly convincing, though.

35. **Juan R.**
December 17, 2005

Chris Oakley,

probably you are already addressed this, but let me note that Gell-Mann may be not a neutral source regarding Feynman contributions, due to heavy rivalry between both and Gell-Mann public accusations of 'plagiarism'.

Any case your discussion is very interesting since i unknow this part of history of physics: Stueckelberg vs Feynman.

Juan R.

Center for CANONICAL |SCIENCE)

36. **Chris Oakley**
December 17, 2005

Hi Juan,

I agree about the Feynman/Gell-Mann rivalry.

Bjorken and Drell, vol. 1 talks about "Stückelberg-Feynman positron theory", giving references Helv. Phys. Acta **14**, 32L, 588 (1941) for Stückelberg and Phys. Rev. **76** 749, 769 (1949) for Feynman. I have not yet studied the Stückelberg paper, but I am guessing that he does not use the covariant perturbation theory he worked out in 1934 here.

37. **Chris Oakley**
December 21, 2005

Following on from the above, and after a day ferretting around various Cambridge libraries, it seems that Lacki/Ruegg/Telegdi have done a fine job in assessing the impact of Stueckelberg's Covariant Perturbation theory. The only cites of his 1934 paper between 1945 and 2002 are the Weisskopf review article in *Physics Today* (1981) and a list of all his publications to date at the start of Helv. Phys. Acta **38** in 1965 when they were celebrating his 60th birthday.
I do not think that he followed up on it much at all.

Susskind Interview at New Scientist

December 15, 2005
Categories: Uncategorized

There's an interview with Susskind in the latest issue of New Scientist by Amanda Gefter, entitled Is String Theory in Trouble? Susskind makes many of the same points as in his recent book The Cosmic Landscape: mixing up positivism and falsifiability, attacking those who ask for falsifiable predictions as "Popperazi", and saying that the best he can come up with as a prediction from his ideas is the very long-shot that the negative curvature of space due to its origin in bubble nucleation has not been made vanishingly small by inflation.

There's a discussion forum about the article on the New Scientist site that people might want to contribute to.

Update: Ken Silber writes in to point out that William Dembski, one of the most prominent Intelligent Design ideologues, has now latched on to the string theory controversy as evidence that mainstream science is no better than ID. Dembski has both comments on Susskind and comments on David Gross's admission that string theory is in trouble.

I've been pointing out to string theory partisans for a while that they need to publicly confront Susskind and his followers over their abandonment of the scientific method, otherwise they will have no argument against Intelligent Design. Susskind is making all this much worse with his dismissive comments about the falsifiability of evolutionary theory, as well as the following from the New Scientist interview:

If, for some unforeseen reason, the landscape turns out to be inconsistent – maybe for mathematical reasons, or because it disagrees with observation – I am pretty sure that physicists will go on searching for natural explanations of the world. But I have to say that if that happens, as things stand now we will be in a very awkward position. Without any explanation of nature's fine-tunings we will be hard pressed to answer the ID critics. One might argue that the hope that a mathematically unique solution will emerge is as faith-based as ID.

Update: Susskind is fast becoming the darling of the IDers. A new posting on the web-site "Intelligent Design the Future" run by the Discovery Institute links to a review by IDer and nuclear physicist David Heddle entitled Susskind's Sophie's Choice.

Heddle concludes:

Susskind has presented the physics community with what is, for some (not this writer), a Sophie's Choice: a hidious, complictated, unfalsifiable String-Theory Landscape, or Intelligent Design.

Susskind rocks.

Comments

   December 15, 2005

   So New Scientist has this moderated "discussion forum" with an invitation to post and highly visible links leading to it both from here and from Cosmic Variance. As I write this there are 127 views, a handful of negative comments in the Cosmic Variance thread – and 0 (that's zero) posted comments in the "discussion forum". Shall we guess that they are waiting for a few positive responses for balance? 😉

2. **Tony Smith**
   December 16, 2005

   In the New Scientist interview, Susskind says: "… Even most of the hard-core adherents to the uniqueness view admit that it looks bad. …".

   If Susskind is restricting his universe of "adherents" to superstringers, then indeed the difficulty of superstring theory in predicting anything does make it look bad for uniqueness emerging from superstring theory.

   However, the fact that the basic structure of gravity plus the minimal non-supersymmetric standard model is so good at explaining experimental results, even though it is a remarkably restrictive and predictive structure that permits only SU(3) color, SU(2) weak, and U(1) electomagnetic forces along with gravity, and permits only 3 generations of leptons and quarks with clearly defined charges and helicity,
   seems to me to be an indicator that nature IS probably aligned with a unique model,
   even though it is becoming increasingly clear that superstring theory will not be the way to get to it.

   Just because there is now no widely accepted unique model that specifies all the observed force strengths, particle masses, etc, does not mean that such a model does not exist (it might even turn out to be a lot like my currently-much-ignored model).

   In short, it seems to me that, although Susskind's remark that things look bad for the uniqueness view does apply to superstring theory,
   it does not apply to other approaches based on gravity plus the standard model.

   That, in turn, indicates to me that physics would be advanced if some of the army of people and flood of funding now being spent on superstrings were to be applied to such other approaches.
   Failure of the physics community to make such changes indicates to me a failure of imagination, and fear of trying to think creatively and deeply about gravity plus the standard model, on the part of the people in the now-dominant superstring community.
   Perhaps the leaders of the superstring community actually fear the possibility that an unconventional approach might be successful, because it would disrupt the current rigid sociopolitical "pecking order" of the present superstring establishment.

   December 16, 2005

   "We can hope to get an answer from string theory and we can hope to get some information from cosmology." Surely Susskind is a bit misled here in his beliefs. A possible answer would naturally come from (observational) cosmology and hopefully some information from string theory (which is, so far as the theory presents itself, rather unlikely)!

4. **secret milkshake**

"Ask not what you can do in Physics – ask what you can do to it."

5. **Christine Dantas**
December 16, 2005

If the criteria for publishing in a high-impact journal, e.g., the Physical Review Letters, is taken at face value, for instance (see the guidelines in their site):

> "(…) The paper must satisfy criteria of validity, importance, and broad interest. The work must be sound, free of detectable error, and presented in reasonable detail. (…) Papers advancing new theoretical views on fundamental principles or theories must contain **convincing arguments** that the new predictions and interpretations are distinguishable from existing knowledge, at least in principle, and do not contradict established experimental results. (…)"

(my boldface) then how anything related to the anthropic reasoning or the landscape issue can be possibly accepted there? I didin´t search to see. But of course, it seems clear that it depends on how "convincing" your arguments are.

6. **Juan R.**
December 16, 2005

String theory always was in trouble. Is cosmological constant explained via graviton mass?

The problem of string theory is NOT that it 'predicts' multiple universes and, therefore, one may use previous knowledge for fixing undetermined parameters of the theory (more than 10000 in some models of compactification 10D –> 4Dx6D). The serious problem of string theory is that none of those 'billions' of possible universes coincides with real universe we observe on Nature. For example, string theory works with supersymmetric massless states, whereas our observed universe is non-supersymmetric and non-massless. Imagine that we observe supersymmetric at next HLC data. It does not mean that string theory is correct, because any plausible theory of supersymmetry (if finally observed) may reduce to the experimentally verified non- supersymmetric theory we name the Standard Model, somewhat as general relativity reduces to special one when gravitation vanishes. Simply we may admit string theory is incompatible with all data we know. In fact, there is a joke circulating by the Internet saying that the best definition of observable universe is "that string theory cannot explain".

What was the main motivation for string theory in the past? Simple: that "*it predicts gravity*". Well again this is not correct, the 'gravity' contained in string theory is **not** Newtonian gravity **not** relativistic gravity.

Newtonian gravity describes direct interactions between non-massless particles, but current string theory spectra are massless states and there are not electrons or protons defined. Precisely, since the graviton is massless, it can be defined in string theory. However, if finally the graviton has some mass as some theorists recently argue [see for example Class. Quantum Grav. 20 No 6 (2003) L67-L73 or recent 2004 talk by Vainshtein here] then string theory could not explain it.

What is more, the relativistic gravity contained in string theory is a 2-spin graviton over a flat background metric. That is not general relativity, as explained in textbooks on matter, and the reason that all of us know that 10D string theory -even if some day was internally consistent and compatible with experimental data- would be improved by its background-independent 11D generalization currently called M-theory.

Many other criticism on why string theory is not good enough is addressed in moderated newsgroup sci.physics.strings in the Oct 21 post "String theory is not a TOE"

Juan R.

7. **Dissident**
December 16, 2005

Juan: http://arxiv.org/abs/hep-th/0512177

The problem isn't that string theory can't produce something that looks like our universe. It's that it can produce just about anything you want, so it doesn't predict anything.

8. **Juan R.**
December 16, 2005

Christine Dantas,

perhaps this link to recent work published in PRL by string theorists Karch and Randall, may be interesting.

I do not read the letter, but it appears that they are doing 'convincing' arguments 🙂 seeing i am finding on the net

> They believe the way our universe started and then diluted as it expanded what they call the relaxation principle favored formation of three– and seven–dimensional realities. The one we happen to experience has three dimensions.
>
> The only assumptions were that it started with a generally smooth configuration, with numerous structures called membranes, or "branes" that existed in various spatial dimensions from one to nine, all of them large and none curled up.
>
> Other realities, either three– or seven–dimensional, could be hidden from our perception in the universe, Karch said.
>
> "There are regions that feel 3D. There are regions that feel 5D. There are regions that feel 9D. These extra dimensions are infinitely large. We just happen to be in a place that feels 3D to us," he said.
>
> "We know there are people in our three–brane existence. In this case we will assume there are people somewhere nearby in a seven–brane existence. The people in the three–brane would have a far more interesting world, with more complex structures," Karch said. With gravity diminishing rapidly with distance, a seven–dimensional existence would not have planets with stable orbits around their sun, Karch said.
>
> "I am not precisely sure what a universe with such a short–range gravity would look like, mostly because it is always difficult to imagine how life would develop under completely different circumstances," he said. "But in any case, planetary systems as we know them wouldn´t form. The possibility of stable orbits is what makes the three–dimensional world more interesting."

AMEN

I only wait that Kaku can someday built a multidimensional teletransporter and all those ‘stringy guys’ can travel to other parallel universe full of nine-branes.

9. **Juan R.**
December 16, 2005

Dissident,

thanks by the link to the recent preprint. But please note that does not invalidate i said. Perhaps, i would resume and emphasize i said:

1) String theory **cannot** predict.

2) There is **not** model in string theory compatible with the experimentally verified non-supersymmetric and non-massless **Standard model** of particle physics.

3) The ‘gravity’ contained in string theory is **not** Newtonian gravity and is **not** compatible with relativistic (general relativity) gravity.

4) brane, stwing, or M theories does **not** solve the problems opened by string theory.

Juan R.

Center for CANONICAL |SCIENCE)

10. **Dissident**
December 16, 2005

Juan: Agree about (1). About (2): the MSSM is an extension of the SM compatible with current experimental data. The LHC may be able to rule it out, but that’s yet to come. About (3): any quantum theory of gravity will deviate from the classical theory at some point (or what would be the point of quantizing it?). Agree about (4).

11. **Jean-Paul**
December 16, 2005

I think that there is a large social/psychological component of the recent anthropic endorsements. There are made by senior, very accomplished physicists who are at the end of their productive lives (or like Polchinski ready for early retirement at 55) and want to ride away into the sunset with “this is the end, my friend” — nothing left to do, we solved all important problems, we won’t miss anything. It is very sad that among younger generation, only Lubos dares to scream foul play…. while the more distinguished people like Vafa and Witten who are clearly opposed to this nonsense hide their heads in the sand instead of energizing their junior colleagues…

12. **Ken Silber**
December 16, 2005

William Dembski has now latched on to Susskind’s landscape-intelligent design dichotomy.

http://www.uncommondescent.com/index.php/archives/583#more-583

But shouldn’t life evolve easily in a “fine tuned” universe?

13. **woit**
December 16, 2005

Hi Ken,

Thanks for pointing that out. Dembski has definitely latched on to string theory, also see:

http://www.uncommondescent.com/index.php/archives/570

14. **Who**
December 16, 2005

Peter quoted Susskind as follows:
Without any explanation of nature’s fine-tunings we will be hard pressed to answer the ID critics. One might argue that the hope that a mathematically unique solution will emerge is as faith-based as ID.

this “hope” is a straw-man. the mainstream scientific enterprise exhibits confidence in the gradual INCREMENTAL explanation of nature—not in the appearance of a complete “mathematically unique solution” explaining everything once and for all. Moreover this confidence is not analogous to religious faith, but has been born out by gradual progress over the course of several centuries and many generations. It is the fruit of long experience.

At least for physicists, the string venture may have been a mistake, and its present quandary should not be interpreted as a portent of anything. One cannot draw wider conclusions from the confused frustration of this one theoretical initiative—-it does not mean anything as regards intelligent design, or the determination of several dozen fundamental numbers, or the cause of the big bang or the fate of science. If string thinking fails to explain the current list of basic numbers, it simply means that a large bunch of theoreticians were misled, perhaps self-deluded, for several decades—this is no reason to start imagining a “sea-change” in the “zeitgeist” (that is portentous over-dramatizing). String is just a hiccup in the history of science.

Susskind’s phrase “without any explanation of nature’s fine-tunings” is also a straw man—at least a rhetorical exaggeration. We have explanation for SOME of nature’s fine tunings, and can reasonably expect to get more. I mean real physical explanation, not anthropic selection from a postulated ensemble based on stringy conjecture.

the the Old Guard show is increasingly embarrassing, I’m disappointed with Wilczek—expected better.

15. **David Heddle**
December 16, 2005

That’s “Heddle” not “Weddle”.

16. **Juan R.**
December 16, 2005

Dissident said,

> Juan: Agree about (1). About (2): the MSSM is an extension of the SM compatible with current experimental data. The LHC may be able to rule it out, but that's yet to come. About (3): any quantum theory of gravity will deviate from the classical theory at some point (or what would be the point of quantizing it?). Agree about (4).

Thanks by your comment. Unfortunately i was not able to express my thinking correctly and i may correct one thing.

Of course, any quantum theory will deviate from the classical one (in the contrary case its quantization would be irrelevant) but i was not saying that. i was saying that the classical limit of superstring theory is not general relativity. I mean that gravity contained in strings and superstrings is a quantum spin-2 (graviton) in a flat classical background defining causality structure (e.g. S-matrix). The classical limit looks as a classical gravitational 'field' propagating on a flat background. But general relativity is not that (in general), and this is the reason that superstring theorists are now anxiously searching a background free generalization called M-theory. Precisely the perturbation formalism around a flat spacetime metric structure has been always the criticism of loop theoreticians to string/superstring theories.

In fact, i think that it is a common misconception the claim that general relativity is equivalent to a theory for a spin-2 field **on** a Minkowski background.

[tex]g^{ik} = \eta^{ik} + h^{ik}[/tex]

I think that this error was perpetuated in literature 'thanks to' Misner, Thorne, Wheeler 1977 popular book and by some popular authors as Feynman or Weinberg.

The equivalence between full general relativity and a [tex]h^{ik}[/tex] field theory is valid only in the weak regime, in fact, Deser [Gen. Rel. Grav. 1970, 1, 9.] proved the equivalence between the 'geometric' and the ' tensor field' view only to third order in the tensor field recurrence series. But this did that some authors claimed that the two views are fully equivalent to any order when are not. In fact, there is crucial differences in the strong gravity regime between both approaches.

Juan R.

December 16, 2005

I've always thought it was only a matter of time until the IDers latched on to Susskind. In fact I'm surprised it took them so long. He actually had to go so far as to publish a popular book with "intelligent design" written on the cover to get their attention.

18. **woit**
December 16, 2005

David,

Sorry about that. It's fixed now.

19. **woit**
December 16, 2005

Juan,

Please stop posting so many comments that don't have anything to do with the topic of the posting. In this case, if people want to discuss the interview with Susskind, that's great, but the question of the technical problems of string theory as a theory of gravity is off-topic here.

20. **Hans de Vries**
December 16, 2005

Of all contradictions I've never come upon a greater contradiction as this one:
–
Firstly:

The idea that constants of nature, reproducible in 15 digits, going to 16 digits (Frequency Comb work) are represented by 500+ hole clonable Calabi Yau pretzels. (16 digits means an object the size of the earth accurately reproduced with single atom precision)
–
Secondly:

That these Calabi Yau spaces live at Planck's length in a wildly bubbling space-time chaos at Planck's temperature of 1.417 10^32 degrees…

–
Total chaos meets total perfection….

–
Regards, Hans

21. **Eric Dennis**
December 16, 2005

It's important to keep in mind that rejecting anthropic reasoning in the context of the landscape and string theory does not imply a rejection of anthropic reasoning as such. Given apparently fine-tuned aspects of nature, anthropicism is certainly a legitimate sort of explanation if the necessary ensemble emerges naturally. The problem is just when anthropic reasoning becomes the *pervasive* explanatory mechanism of a theory, leaving it without any distinguishing quantitative predictions.

In the context of a healthier theory, I don't see the problem with e.g. the anthropic prediction for bounds on the CC, which I think Peter has criticized (but perhaps I misunderstood his intent). Indeed I think an unwillingness to accept this kind of limited anthropism is rooted in the same epistemic error of the IDers. Limited anthropism recognizes that Nature is just the way She is — She isn't designed so that our theories will be pretty and convenient and maximally deductive — just like She isn't designed so that Jesus could die for our sins. She just plain isn't designed.

22. **Peter**
December 16, 2005

No time for a long answer, but here's a short one:

A legitimate scientific theory has to make strong enough predictions that you can rationally decide whether there is good evidence for it by looking at the world. The string theory anthropic landscape doesn't do this now and there's no good reason to believe it ever can, so it's not science.

One can come up with legitimate scientific theories in which certain quantities are only probabilistically determined, e.g. because they are "environmental", depending on the history of the universe and one doesn't accurately know the initial state. It's certainly possible the CC is such a quantity, but there are lots of problems with the Weinberg "prediction" of it, including:

1. It comes out an order of magnitude or so too high.

2. It's done by taking known values of other similar cosmological parameters, fixing them and just varying the CC. Looking at the joint distribution for several variables, the CC is way, way smaller than one expects.

There's also a conceptual problem that bothers me with this specific piece of anthropic reasoning. The assumed a priori probability distribution for the CC is taken to be flat. Such a "theory" of the CC says about it exactly the same thing as my favorite theory: "Hell, I have no idea what determines the CC, so, a priori any value is equally likely." There's something funny about a "theory" that makes exactly the same "predictions" as deciding that anything is equally likely since you have no idea what is going on.

23. **michaeld**
December 16, 2005

Susskind's comments strike me as very strange.

"But I have to say that if that happens, as things stand now we will be in a very awkward position. Without any explanation of nature's fine-tunings we will be hard pressed to answer the ID critics."

It sounds as if he thinks physicists should be opposing ID just for the sake of it. To me, the reason to oppose ID is that the (scientific) arguments for ID are completely ridiculous. If that ever changed… if it happened that there were strong scientfic arguments for ID, then why should physicists be influenced by this and alter their theories simply for the sake of remaining in opposition to ID?

24. **anon**
December 17, 2005

Michael,

the reason to oppose something just for the sake of it is to blend into the mob. Susskind months ago was quoted on the issue of the reality of the casimir force as saying the problem should be solved simply by banning physicists from using the word "real".

It is just fashionable to sneer at laymen and reality by coming up with speculative 11 dimensional super duper theories which are so value that there are 10^500 different dynamical interpretations, and which predict nothing, and are untestable. Different versions of string theory produce different predictions naturally, so there is no clear prediction to be tested by experiment. That is in fashion.

String theorists have no grasp of science, and think the reason ID is a scientific failure is because it is unpopular in science, and the reason string theory is a success is that it is popular in the media.

String theory is lucid. Everyone knows what it claims: everything is string. They also know it is popular, so you get the herd instinct … so many people can't all be wrong, that sort of thing.

String theorists can't afford to use scientific criteria or they'd sink.

25. **Juan R.**
December 17, 2005

Peter Woit,

I am sorry, often i write in a random manner and click the submit bottom too easily. Please receive my congratulations about your blog. Let me write some few comments about New Scientist interview *Is string theory in trouble?*

i)
The first i want say is that recent Landscape trouble has emphasized the problems of string theory. I have noted in many magazines, media and talks this 2005 the emphasis to claim that string theory is in trouble. It appears that all was fantastic in previous years but we know that is not true: as said above **String theory always was in trouble** and i think that people may know this. Therefore, i would personally rename New Scientist title to *Is today string theory more in trouble that yesterday* or similar one.

ii)
I leave criticism to inflation for other thread.

iii)
About cosmological constant, we already discuss about anthropic reasoning and Weinberg last preprint (or would say last nonsense?) here. One of arguments of anthropic symphatizers is that experimental value for the cosmological constant cannot be explained by usual Standard Model more GR, therefore our best option -they claim- is Landscape. However, that is not true and this is reason i cited above some works where the cosmological constant is computed scientifically from hypotesis of a small mass for the graviton. I repeat again, by no means the Landscape argument is the only possible way to explain cosmological constant. In fact, Landscape way is not a scientific explanation, just metaphysics one.

iv)
About Steven Weinberg recently comment that Landscape is one of the great changes in fundamental science because changes the nature of science itself. I think that Weinberg has definitively lost the North. Landscape is just a return to so-called magic era before modern science born. The only "radical" that i can see is "to call that science", when we could call it "proto-science", "meta-science", "no-science" or similar. Weinberg attitude is so stupid (and i am sorry by the word) as if your cat does not look like a dog and then Weinberg argues that one may change the traditional definition of dog! If string theory does not fit science requirements, then call to string theory "no-science" or "meta-science" but never change the traditional mean of the word "science" for fitting string requirements.

v)
About last Susskind comment

> it seems increasingly likely that the constants of nature are more like the temperature of the Earth – properties of our local environment that vary from place to place. Like the temperature, many of the constants have to be just so if intelligent life is to exist. So we live where life is possible.

I believe it is an excellent way to illustrate anthropic nonsense.

Simply compare replies to scientific questions how "estimate the temperature here", "compute the temperature when", "draw the temperature profile for" using equations and the model-data from scientific literature [see Thermodynamics of Atmospheres and Oceans basic monograph] with **fact** anthropic theorists cannot compute anything and their "explanation" looks like

> the temperature have to be just so if intelligent life is to exist.

It is more, what if there is not life? Curiously the scientific models presented in above monograph can be applied (changing parameters of course, for example to flow radiation received from Sun due to different distance, etc.) to other planets where is not life. See Chapter 14.

vi)
Let me finalize saying that Susskind comment

> No more than when physicists discovered that the radii of planetary orbits were not determined by some elegant mathematical equation, or by Kepler's idea of nested Platonic solid.

Is not accurate since it appears that radii is determined. I have seen scientific models on that.

> There is a philosophical objection called Popperism that people raise against the landscape idea. Popperism [after the philosopher Karl Popper] is the assertion that a scientific hypothesis has to be falsifiable, otherwise it's just metaphysics. Other worlds, alternative universes, things we can't see because they are beyond horizons, are in principle unfalsifiable and therefore metaphysical – that's the objection. But the belief that the universe beyond our causal horizon is homogeneous is just as speculative and just as susceptible to the Popperazzi.

Of course! but Susskind perhaps forgets that serious scientists carefully invented the term *observable universe* for referring to the part of the universe accessible to our current telescopes. No serious scientists claim what there exists beyond is today observable: perhaps pink stars? Nobody knows.

Susskind reply to question "Is it possible to test the landscape idea through observation?"

> So the landscape, at least in principle, is testable.

is, of course, incorrect.

Juan R.

Center for CANONICAL |SCIENCE)

26. **ks**
December 18, 2005

Michael says: *It sounds as if he thinks physicists should be opposing ID just for the sake of it.*

But it is striking that some of Susskinds arguments are mimicking the structure of the conventional ID/creationist ones.

From the Susskind interview:

At first, string theorists thought there were about a million solutions [for string vacua]. Thinking about Weinberg's argument and about the non-zero cosmological constant, I used to go around asking my mathematician friends: are you sure it's only a million? They all assured me it was the best bet.

But a million is not enough for anthropic explanations – the chances of one of the universes being suitable for life are still too small.

Religion is not the only way of reasoning that creates "gap gods" these days.

Susskind's book "The Cosmic Landscape" is reviewed by George Ellis in Nature (8 December 2005, pages 739-740. The review is titled

"Physics ain't what it used to be".

In that review, Ellis says: "… The particular multiverse version proposed by Susskind, however, has the great virtue of being testable in one respect.
It is supposed to have started out by quantum tunnelling, resulting in a spatially homogeneous and isotropic universe with negative spatial curvature, and hence with a total density parameter OMEGA_o less than 1.
The best observationally determined value for this parameter, taking all data into account,
is OMEGA_o = 1.02 plus or minus 0.02.
Taken at face value, this seems to contradict the proposed theory. … These data are not discussed in the book – a symptom of some present-day cosmology, where faith in theory tends to trump evidence.
Presumably the hope is that this observational result will go away …".

December 19, 2005

[Re: String theory] About Steven Weinberg's recent comment that the Landscape is one of the great changes in fundamental science because it changes the nature of science itself:
I think that Weinberg has definitely lost his bearings. This is just a return to the so-called magic era before modern science was born.
The only "radical" that I see is calling it science, when we should be calling it "proto-science", "meta-science", "no-science" or similar.
Weinberg's attitude is so stupid (and I am sorry to use this word) that if your cat does not look like a dog then Weinberg would argue that one needs to change the traditional definition of "dog"!
If string theory does not fit the requirements of science, then we should call string theory "no-science" or "meta-science". But we should never change the traditional meaning of the word "science" just to accommodate string theory.

Sorry, Juan R. I don't normally go around correcting people's English, but what you say here is so sensible that I felt compelled to do so in this case.

30. **Juan R.**
December 19, 2005

Absolutely no problem with that!

Anyone is free for correcting all my failures from English to math.

December 19, 2005

Peter,

OK, I think we agree on the underlying issue then — the potential legitimacy of some kind of anthropic argument in the context of some independently confirmed theoretical framework. Your point about what happens for the specific case of the CC when you look at the joint distribution given other variables sounds reasonable (if that's in fact the case — I'm not familiar with the nitty gritty here).

But I don't understand your other objections. It's a bound obtained by imposing some galactic nucleation constraint, right? The "prediction" is just that the bound is satisfied, not that it's the most informative conceivable bound. About the flatness of the priors, I guess there's the question (like there always is when choosing priors) about what variable (CC or CC^2 or…) is the right one to have a flat prior distribution on. But aside from that standard Bayesian conundrum, the point of the argument is that we want to impose as little prior information as possible. We're admitting that we have no clue what are all the causal factors in the "environmental" determination of the CC. But at least we might resolve the discrepancy of it's (order of) order of magnitude.

It's inevitable that some physical processes are gonna be just too complicated to calculate, with whatever theory we settle on. If the hypothetical historical dynamics that determined the CC is one such process, que sera.

32. **woit**
December 19, 2005

Eric,

I have no problem with the idea that maybe the CC is something "environmental", depending on the history of the universe, in a way such that we'll never be able to calculate it. What I object to is people running around saying they have a "prediction" of it, based on nothing more than the fact that if it were 100 times bigger, all else being equal, galaxies wouldn't form. Even worse, people go on about this being a "successful prediction", write popular books about how great it is, and use it as an excuse to successfully push a research program which is pure pseudo-science.

33. **Eric Dennis**
December 20, 2005

I agree with that.

34. **Juan R.**
December 22, 2005

How much nonsense does one find in the anthropic idea?

Perhaps reply was in a simple example.

Look the Moon, why is it there?

Scientific reply: It is there (effect) because it is the result of the motion guided by gravity force (cause). We can predict the Moon position at some future instant *t* via mechanics.

Antrophic reply: It is there (effect) because we are looking it ("cause") here. We can**NOT** predict the Moon position at some future instant *t*.

Of course, some questions cannot be today solved from science, but then the (honest) scientist admits that does not know the reply. The rest is meta-science, religion, philosophy, etc.

Interview With Alain Connes

December 17, 2005
Categories: Uncategorized

Someone wrote in to tell me about a very interesting interview with Alain Connes, conducted at the IPM in Teheran at the time of the Workshop on Non-Commutative Geometry held there this past September.

As always, Connes has quite a few provocative things to say, including some harsh criticisms of the way string theory research is conducted (this in spite of the fact that the Institute hosting him is dominated by string theorists):

The only thing I resent in string theory is that they put in the mind of people that it is the only theory that can give the answer or they are very close to the answer. That I resent. For people who have enough background it is fine since they know all the problems that block the road like the cosmological constant, the supersymmetry breaking, etc., etc.. But if you take people who are beginners in physics programs and brainwash them from the very start it is really not fair. Young physicists should be completely free, but it is very hard with the actual system.

Connes also has many interesting comments about non-commutative geometry and about his own career, including the fact that he went off in the direction he did because he was put off by the arrogance of the algebraic geometers at the IHES. He also has a lot to say about the importance of having a system like the French CNRS system that allows talented young researchers to develop a long-term research program without too much pressure to achieve quick results. He is quite scornful about the US university system, which he sees as emphasizing money and subjecting young people to huge pressures to work in well-established areas instead of trying to do something new and ambitious.

The interview also contains quite a few amusing stories. In one of them Connes tells about a well-known string theorist who walked out of his talk at Chicago because he wasn't very interested, but two years later was paying rapt attention to the same talk when Connes gave it at Oxford. When Connes asked him about this, the physicist told him that the difference was that in the meantime he had heard that Witten had been seen reading Connes's book in the library at Princeton.

On a completely different topic, there's a nice review article by Edward Frenkel on the Langlands program and conformal field theory. Witten has new ideas about this subject and how it is related to S-duality in four-dimensional gauge theory. I hear he has been working on a paper on the subject since this summer, and that it should appear imminently.

Comments

1. **Aaron Bergman**
   December 17, 2005

   The paper on Langlands is by Kapustin and Witten and should hopefully appear soon, but I don't know when.

2. **QWERTY**

   YOUR LINKS ARE TEH DED!!1!

   I WANT TO READ THE INTERVIEW WITH ALAIN CONNES AND I CANNOT. I AM DESPARATE TO LEARN ALL ABOUT NON-COMMUTITIVE FROBENIUS ALGEBRAS AND HOW TO VISUALIZE ASOCIATED COBORDISMS IN 2D QFT, AND ALSO GENERALLY DRAW ALEPH-ONE INSPIRATIONS FROM HIS WISE FRENCH WORDS AND REFINED YET SARDONIC DEMEANOR.

   PLEASE ADVISE.

3. **Adrian Heathcote**
   December 17, 2005

   I've been a great admirer of Connes for some years. I think he has great intellectual honesty and courage—and judging by his KITP talks a good sense of humour. (And speaking of the KITP talks he took on that audience (trial by interruption!) and won.)

4. **Thomas Larsson**
   December 18, 2005

   What caught my eye in Frenkel's lecture was the statement on the top of page 27:

   "Before we get to that, we want to comment on why is it that we only consider curves and not higher dimensional varieties. The point is that while function fields on curves are very similar to number fields, the fields of functions on higher dimensional varieties have a very different structure. […] At the moment no one knows how to formulate an analogue of the Langlands correspondence for the field of functions on an algebraic variety of dimension greater than one, and finding such a formulation is a very important open problem."

   Since geometric Langlands is evidently closely related to the affine and Virasoro algebras, perhaps their higher-dimensional analogues have something to do with a higher-dimensional Langlands. Or perhaps not.

6. **Tony Smith**
   December 18, 2005

   In the IPM interview at http://www.ipm.ac.ir/IPM/news/connes-interview.pdf Connes said:

   "… The true question is whether or not string theory has anything to do with reality … That key question begins by supersymmetry; whether or not nature is supersymmetric … If one would already have found 3 or 4 super partners by now, then I would believe they would find the others but in reality they haven't found any and because of that I'm very skeptical. … The supersymmetric standard model is an horrible thing … with more than a hundred free parameters and an ugly mechanism to

break that “beautiful” unseen supersymmetry! …
I think it’s very important to construct other competing models which are not necessarily based on supersymmetry. I think it is crucial for the development of physics that there are people who are courageous enough not to follow the main dogma, heretics that develop a different model.
…
From my point of view the actual system in the US really discourages people who are truly original thinkers … The US are successful mostly because they import very bright scientists from abroad. For instance they have imported all of the Russian mathematicians at some point.
…
I believe that the most successful systems so far were these big institutes in the Soviet union, like the Landau institute, the Steklov institute, etc. Money did not play any role there, the job was just to talk about science.
…
the way the young people … in the US … get their position on the market creates “feudalities” namely a few fields well implanted in key universities which reproduce themselves leaving no room for new fields. … Beginners have little choice but to find an adviser that is sociologically well implanted … so that at a later stage he or she will be able to write the relevant recommendation letters and get a position for the student … all these letters look alike in their emphatic style. The result is that there are very few subjects which are emphasized and keep producing students and of course this does not create the right conditions for new fields to emerge. …”.

Since I am a patriotic citizen of the USA, I wish that I could disagree with Connes, but as one who works on heretical non-supersymmetric physics models and has been blacklisted by the Cornell arXiv, I cannot.

Tony Smith
http://wwww.valdostamuseum.org/hamsmith/

7. **Chris Oakley**
December 18, 2005

Tony,

Although I could never possibly agree with Connes’ attitudes towards QFT, I think that his analysis of the research machine, especially in the U.S., is right on the button. In view of this, if you are being blackballed by the ArXiv you should should regard it as flattery of the most sincere kind.

8. **Doug**
December 18, 2005

I would like to know who the top 10 “heretics” are. It appears that Danny and Tony are considered “heretics,” but would they make the top 10 list? What is the difference between “crackpots” and “heretics?” If mainstream string theory is “not even wrong.” then is it heretical?

9. **anon**
December 18, 2005

Doug, string theorists are crackpots. Real scientists are always heretics to religious dogma which has no evidence.

All those who believe in the mainstream because it is fashionable are crackpots. Dawkins states you have to be open minded in science, but not so much so that your brains fall out completely

10. **Anonymous**
December 18, 2005

QWERY IS THE BEST COMMETNAR EVAR LOLLERSKATES

But seriously, I think there is an important issue here regarding the US university system, and it’s much more important than your typical string theory complaints, Peter. Or perhaps your usual string theory complaints are just a specific instance of a broader problem. And that problem is that young people have to sustain a high rate of publications. As soon as one reaches the point that they begin publishing, one has little freedom to spend a long time delving into a hard problem. If one wishes to work on very difficult problems, one needs lots of publishable intermediate results. Also, one should be sure to publish things mainstream enough to help one get jobs.

This isn’t a completely terrible situation; academics, even young ones, still have considerable freedom, and some sort of politics and job pressures are unavoidable. But I think the culture could change in some beneficial ways.

Of course, it doesn’t help that a lot of the much-touted less mainstream ideas have blatantly obvious problems, so that nearly everyone outside the mainstream is crackpot or borderline crackpot.

11. **woit**
December 18, 2005

Hi Anonymous,

Thanks for your comment. I do think the problem of young scientists being forced by the job market to stick to research with a quick payoff is a significant part of the problem with string theory (and have written about this in various places, including my first public critique of string theory, from about 5 years ago). Particle physics is suffering more than most subjects from this because it is a victim of its own success: the standard model is too successful and it is very hard to see how to get beyond it. Progress in this field will probably require a major conceptual leap in a new direction, not just small incremental advances, and the way the US academic system is organized makes it much harder for a young theorist to try and do this without committing professional suicide.

The physics community needs to acknowledge this problem and start thinking about ways to deal with it. But one reason I’ve focused on the issue of getting people to acknowledge the failure of string theory based unification is that as long as the perception is that string theory is a viable idea making progress towards its goals, people are unlikely to agree that this kind of action needs to be taken.

While making it easier for young people to work on more ambitious research programs would help, that by itself probably won’t do the trick. A French string theorist friend correctly points out to me that young theorists in France with its CNRS system, and in some other similar European systems, haven’t done much better than those in the US in terms of coming up with something new.

It’s very difficult to figure out how to properly structure a reward system to encourage the kind of difficult, long term speculative work in new directions that particle physics needs. But I believe before this can be addressed, first the physics community has to realize how big a problem this is, and that some dramatic changes in traditional ways of doing business are needed.

12. **Steve**
December 18, 2005

I do not wish to go into philosophy or ethics, but I think another problem causing young people to rush into string theory is the desire to "show off" how smart they are; and reading Alain Connes' interview was such a comfort;

"I think in mathematics it is extremely important to be persistent. The point is not being brighter or faster. Forget it! What is important is to never abandon a problem"

— He is truely a great human being.

13. **Anonymous**
December 18, 2005

Peter wrote

Particle physics is suffering more than most subjects from this because it is a victim of its own success: … Progress in this field will probably require a major conceptual leap in a new direction, not just small incremental advances

Err, yes and no? I'm not quite sure what you mean by "progress in this field," but the LHC is almost certainly going to move particle physics forward in a big way. If it finds supersymmetry then maybe we can start paring down the huge space of SUSY models to something workable. If it finds new strongly coupled physics then the whole focus of the field will shift, I think. And with any luck, the whole industry of extra dimensional models will vanish (except to whatever extent they prove to be useful as duals). I think a lot of nonsense is going to get swept away in the next decade.

On the other hand, certain problems like quantum gravity almost certainly *do* need a major conceptual leap (as I'm sure most string theorists would agree). Other problems, like a better nonperturbative understanding of gauge theories, might actually be amenable to incremental progress, if people were to really focus on them. There are a lot of tools around, after all. On the other hand, a lot of them aren't trendy at the moment, so such work can be risky for young people.

It's very difficult to figure out how to properly structure a reward system to encourage the kind of difficult, long term speculative work in new directions that particle physics needs.

Agreed. To think out loud a bit: we certainly don't want to encourage just *any* speculative work. At this point I think various "alternative" ideas in quantum gravity (*cough*Reuter*cough) have *far more* partisans than they deserve, for instance. Truly promising new approaches are rare, and while it might be hard to know if they will be successful, it's pretty easy to see that many ideas will be *un*successful. So I think a few high-paying prestigious postdoc fellowships for people outside the mainstream could make a huge difference, *provided* that they were selected by well-respected and intelligent people who could filter out only the very best candidates, and that it could somehow be ensured that if these people's ideas didn't pan out that it does not mean the end of their career. It seems like the Clay Institute's fellowships in mathematics might be the analogue of the sort of thing I have in mind. But generally I get the impression that independence is more highly valued in mathematics than in physics.

14. **Tony Smith**
December 18, 2005

Peter Woit said "… young theorists in France with its CNRS system, and in some other similar European systems, haven't done much better than those in the US in terms of coming up with something new …".

Connes said "… the most successful systems so far were these big institutes in the Soviet Union, like the Landau institute, the Steklov institute, etc. Money did not play any role there, the job was just to talk about science. …".

Maybe both of the above statements might be correct. Two points then come to mind:

1 – Perhaps "big" is an important word, and a critical mass size is necessary for such institutions to be successful.
That is, maybe the "big institutes in the Soviet Union" were so large that the (probably small) percentage of useful creative innovators gave a reasonably large number of useful creative innovators, with the larger number of relatively unproductive people being tolerated as inevitable overhead,
while
the French CNRS and other similar European systems might be too small to produce a reasonably large number of useful creative innovators.

2 – Perhaps the French/European systems might be overemphasizing USA-type "efficiency", and concentrating too much on the idea of Anonymous that the process should "filter out only the very best candidates". If Anonymous's "filtering" were to be done by "well-respected and intelligent people" who are determined to be so by their status in the physics community, then it seems to me that in the case of the present-day USA physics community, no candidates outside superstring theory (90%) and LQG (10%) would be chosen.

Since the USSR is gone, there are no contemporary examples to support or refute 1.

As to 2, it seems to me that the demographics of North American institutes such as IAS, KITP, Perimeter, etc., are consistent with 2.

Tony Smith

15. **secret milkshake**
December 18, 2005

Since I had some exposure to the science establishment in Eastern Europe in late 80s, I can say it was not a model how science should be done. Please note how many people in USSR went into physics and math – and how little came out of it.

16. **Adrian Heathcote**
December 18, 2005

When I first heard of Non-Commutative geometry I enthusiastically told my wife about it, explaining as much as I understood. She thought for a minute and then said, 'No'.

So I had a T-shirt made up for her, in Soviet-style lettering (she's Russian): "Just say 'Non' to Non-Commutative Geometry". When she wears it out she is often asked what it means!

I have a feeling that Connes would like the joke.

17. **Tony Smith**
December 18, 2005

secret milkshake said ".. Please note how many people in USSR went into physics and math – and how little came out of it. …".

I do take note of "how many people in USSR went into physics and math", which is the point that maybe "big" is important,
but
I disagreee that "little came out of it".
For just a few examples:
the proof of the Bieberbach conjecture was validated in the USSR;
the geometry of Lie groups (for example the works of Boris Rosenfeld);
translation from Chinese of the work of L. K. Hua on geometry of classical domains;
works on singularity theory;
works on von Neumann algebras;
invention of supersonic cavitation torpedoes;
early work on nonlinear dynamics (Joe Ford, a founding father of the nonlinear chaos group at Georgia Tech, used to remark that in the early days some of his most productive contacts were with people in Novosibirsk) ;
… etc … the list is far too long to continue here.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

18. **Anonymous**
December 18, 2005

Tony Smith says:

If Anonymous's "filtering" were to be done by "well-respected and intelligent people" who are determined to be so by their status in the physics community, then it seems to me that in the case of the present-day USA physics community, no candidates outside superstring theory (90%) and LQG (10%) would be chosen.

And the alternative is — what? Funding every person who claims to have an interesting new idea? Clearly not. Most such people are just no good.

Also, please note that most of the theoretical physics community does not do string theory or LQG. Even in high-energy physics, string theory is only about half of the community.

secret milkshake said:

Please note how many people in USSR went into physics and math – and how little came out of it.

In high-energy physics: Gribov, Polyakov, Shifman, Vainshtein, Zakharov…. Others as well. A large fraction of important work on gauge theories from the 70s and 80s came from the USSR. (Another large fraction came from 't Hooft.)

19. **Tony Smith**
December 19, 2005

About filtering people in theoretical physics, Anonymous said "… Funding every person who claims to have an interesting new idea? Clearly not. Most such people are just no good. …".

Aside from being unable to restrain myself from remarking that "most people are no damn good" was a line by Lex Luthor (Gene Hackman) in the original Christopher Reeve movie Superman,

I will note that I have heard that with respect to NSF grants the most innovative and productive grants were NOT for proposals that received "excellent" overall ratings, but they came from proposals that:

received "fair" overall ratings resulting from a mix of "poor" and "excellent" reviews.

In other words,
successful innovation usually comes from controversial proposals that are strongly opposed by many "well-respected and intelligent people".

Anonymous and I might be able to agree that, in a system composed of reviewers who were NOT substantially universally biased (for example, toward superstring theory as the "only game in town"), a proposal that received "poor" from ALL reviewers should be rejected. (Unfortunately, I believe that the present system in the USA is in fact so biased.)

I would advocate approval of proposals with a mix of "excellent" and "poor".

I am not sure from the posted comments (and I have no other basis for knowing the views of an anonymous commenter such as Anonymous) whether Anonymous would insist on all "excellent" ratings for approval.

I do agree (as should be evident from my comment) with Anonymous that the USSR system produced a lot of high-quality results.

20. **garrett**
December 19, 2005

I can provide one data point regarding what it was like to be a young physicist in the US who wanted to work on fundamental problems:

In 1995, as a physics graduate student at UCSD, I found a soliton solution to the Maxwell-Dirac equations that no one — especially me — knew what to do with. I was working in nonlinear science at the time, but my real motivation has always been to understand and figure out the universe — it's the best puzzle around. I showed my work to the department chair, Roger Dashen (a great guy), and he liked what I'd done enough to take me on as an advisee. (And it didn't hurt that I was a straight A student) During this same time, string theory was growing in popularity and there was a strong push to move in this direction. I took a nascent string course, as well as read up on my own — but… I just couldn't buy it. There were too many wild assumptions, and in the end they bought you nothing. Using QED to calculate the results of experiments to twelve decimal places — THAT is good physics. But I was in the minority. And when Roger tragically died, I had nowhere to turn for a high energy physics advisor. I finished up my dissertation in nonlinear science under my previous advisor, and hit the dilemma. I wanted to work in GR and QFT — they have always interested me the most. But I had nobody to introduce me to opportunities in either field, and the main community was going for strings in a big way.

However, I had been lucky enough to have another wild option. My graduate fellowship had paid me on top of the money I earned as a TA, and I'd invested that in stocks while the market was booming. So I had a nice little nest egg built up — enough to last five years or so at my graduate student spending level. And, thanks to the net, I figured I could work anywhere, on the physics I wanted. So I wandered a bit, and settled in the most beautiful place I could find — Maui. I've been finding my own way ever since, working on what I want, and publishing only when I've thought I figured out something significantly cool. Well, after five years, and less than stellar stock market performance, the money ran out. So I've had to find money making projects to work on here and there while dedicating most of my time to working on physics — traveling down one theoretical path after another.

It's been a hard road to walk alone. I spend way too much time wading through arxiv articles that I can't know are bunk until I've invested time to figure that out myself. (I wish other people didn't have publishing pressure — it results in garbage.) And, in my own work, I've had to be very conservative and careful, since the only person checking my ideas and giving me feedback is me. But I've had the opportunity to work on what I want, and enjoyed it immensely. Now, much to my own surprise, I found that some of what I've been working on meshes amazingly well with recent work in quantum gravity. It was the type of thing that seemed too much of a coincidence to ignore, so I wrote it up. This, to me, may present a good opportunity. Because I miss hanging out with other physicists — I used to be a very social guy back in grad school, and I miss the active interchange of ideas. And now, as string theory appears to be collapsing under the weight of it's own broken promises, this seems a good time for me to come back and interact with other people working on alternative approaches to fundamental questions in physics.

So… young American physicists who want to work on fundamental questions in physics will do it themselves, because they want to, any way they can.

21. **D R Lunsford**
December 19, 2005

Gratuitous aside for Doug:

I am neither distressed by my absence from arXiv, nor would I want it any other way.

Esteemed Adrian Heathcote:

“I’ve been a great admirer of Connes for some years. I think he has great intellectual honesty and courage”

Yes, for a Frenchman to be scornful in Tehran about the U.S. University System(?) is the height of bravery indeed.

29. **Dissident**
December 19, 2005

Maybe on that particular occasion he was merely being honest, Attila…

30. **sbar**
December 20, 2005

The soviet system that produced these great scientific institutes also sent millions to their death in the Gulag .Let’s not forget them . Let’s not forget the Mendelian geneticists who perished in the Kolyma because they disagreed with Lysenko. Let’s not forget that 30 years after Stalin’s death Sakharov was still under surveillance and in exile in Gorky.
There is nothing to praise in such a system..

31. **Dissident**
December 21, 2005

sbar, while I certtainly sympathize with Connes on much he says, I tend to agree with you about the old Soviet way of doing science. When you look at the list of weel-known Soviet physicists, the vast majority seem to have come of age during the first decades of the revolution, pre-WWII, before all of Russian society was reshaped by it. What came out of those great Soviet institutes after 1960 or so?

32. **Zelah**
December 21, 2005

To Dissident,

You are correct that in terms of economics, the Russian institutes failed miserably, but post 1960’s Science?

You should do some homework son.

To help you along here are 3 in mathematics:
Perelman, Efim I Zelmanov, Vladimir Gershonovich Drinfeld.

The reason for the sucess of Soviet education is the ironies of ironies. Unlike Anglo Saxon failed one size fits all education systems, the Soviets let COMPETITION RIP!!!

That is the main point, students had to compete on a regular basis starting from 5 years old if they were to advance!

An amateur mathematician

33. **Dissident**
December 21, 2005

Ahem, I did write “Soviet physicists”, not “Soviet mathematicians”.

34. **Not a Nobel Laureate**
December 21, 2005

“Yes, for a Frenchman to be scornful in Tehran about the U.S. University System(?) is the height of bravery indeed.”

— Attila Smith

“There is no national science just as there is no national multiplication table; what is national is no longer science. ”

36. **Juan R.**
December 22, 2005

Connes said

> […] the most successful systems so far were these big institutes in the Soviet Union, like the Landau institute, the Steklov institute, etc. Money did not play any role there, the job was just to talk about science. […]

Today, my Russian colleagues would not say the same. See for instance the current policy of the High Certifying Commission (Russia) on foreign electronic journals here.

In fact, I know that Alexander Shagaev suffered hard personal pressure from some rival Russian scientists some months ago. Georgiy Vasilievich Lisichkin editor-in-chief of the Journal of Russian Chemical Society said us in public that the reviewer of the journal would be anonymous because was known tragic cases of murder of reviewers by scientific mafias at Russia!

Moreover, i find interesting the attitude of Connes regarding alternative approaches to NC geometry. In fact, Connes has been traditionally very hard with non-standard analysis and popularized his definition of infinitesimal via limits of non-compact operators (which i believe is totally inconsistent).

Is Connes critizing string theory attitude but following a 'similar' one regarding his own geometric approach?

It is a query, not an affirmation…

Juan R.

Raoul Bott 1923-2005

December 22, 2005
Categories: Favorite Old Posts, Obituaries

I was deeply saddened to hear this morning that Raoul Bott died a couple days ago, on December 20th, in San Diego, of cancer. Bott was one of the greatest mathematicians of the twentieth century; for some details about his life see the commemorative web-site set up by the Harvard math department. The article by Loring Tu gives an excellent outline of Bott's mathematical career and accomplishments.

I first encountered Bott when I attended his graduate course on differential geometry at Harvard. The course was over my head since I was an undergraduate, and the fact that it met at 9am (or was it even 8:30?) didn't help at all since I was sometimes not awake that early. But the course was extremely inspirational, giving a beautiful and revelatory view of geometry in terms of Lie groups, Lie algebras, connections and curvature. I hope someday someone who has a complete set of notes from that course will write them up. I never took Bott's course on algebraic topology, but learned much of the subject from the book Differential Forms in Algebraic Topology, which was a write up of the course notes done with Loring Tu. Bott's point of view on algebraic topology is a perfect one for physicists interested in the subject, starting very concretely with manifolds, deRham cohomology and Poincare duality, and only later getting to more abstract material. Later on in the 1980s when I spent another year at Harvard, one of the most rewarding experiences of that year was sitting in on an advanced course on the index theorem (especially the heat equation proof) that Bott was teaching.

During my undergraduate years I lived at Dunster House, and my last year there was livened up by Bott's presence, when he took up the position of "Master" of Dunster House, living there with his wife and often interacting with the undergraduates. Bott was an extremely warm and friendly person, a truly wonderful human being and a pleasure to be around. He gave the outward appearance sometimes of not being all that swift, demanding that one explain things to him slowly and in as simple terms as possible. His greatest mathematical achievements came not from any ability to quickly master difficult formalisms, but from a talent for seeing deeply into a problem, getting at its very core and finding new ways of understanding what was going on in the simplest terms possible. Many of his results have given new insights into mathematics at the deepest levels that we currently are able to understand.

Some of Bott's earliest work involved dramatic new applications of Morse theory, especially his discovery and proof of Bott periodicity, an unexpected fundamental new fact about topology that lies at the foundation of topological K-theory. Bott was intimately involved with Clifford algebras and spinors from early on, and his extremely important paper with Atiyah and Shapiro shows how crucial these are for understanding K-theory. While the proof of the general index theorem is due to Atiyah and Singer, Bott periodicity and the central role of the Dirac operator made clear by the Atiyah-Bott-Shapiro work are critical parts of the story. Bott also worked out with Atiyah an amazingly powerful fixed point theorem that also fits into the index theory story.

Despite being nominally a topologist, Bott had a big influence on representation theory, with his Borel-Weil-Bott theorem showing how to extend the Borel-Weil theorem to understand the way in which irreducible representations can occur not just as holomorphic sections of line bundles, but also in higher cohomology. He worked out the Dirac operator version of this result, an early check of the index theorem, and he was among the first to promote the idea that the notion of geometric quantization is best understood in terms of the index theorem and integration in equivariant K-theory.

His work with Atiyah on the moduli space of flat connections on a Riemann surface opened up a whole new field of mathematics, one whose implications are still not fully understood, especially the connections with quantum field theory. Over the years Bott took a great interest in physics and in communicating with physicists. He often gave lectures at physics conferences, and it was at one of these that Witten first learned about Morse theory, leading directly to his extremely influential work on supersymmetry and Morse theory. The fact that advanced age and ill-health reduced Bott's mathematical activity in recent years has been a huge blow to the whole subject of the interaction of mathematics and physics.

Most of Bott's papers have appeared in a four-volume set of his collected works, together with some commentary on them by him and by other mathematicians. Reading through these volumes has been a significant part of my mathematical education and I heartily recommend them to everyone interested in mathematics and physics. Bott was an exceptionally lucid thinker and thus a very clear expositor. His death marks a great loss on many levels for both mathematics and physics.

Update: Other blog entries about Bott can be found here, here, and here.

   December 22, 2005

   Oh, this is sad. 20-plus years ago when I was trying to be a theoretical physicist I attended some of his seminars. Your description of him fits perfectly with my memories of a large, genial, barrel-chested man, not obviously fast in movement or thought but clearly having truly great insight. Amusingly Atiyah attempted to disrupt things by playing the irritating schoolkid ("Please sir! Please sir!"). They could have been a nice comedy double act, though it wouldn't have been worth the crushing loss to mathematics if they had changed careers.

2. **john baez**
   December 22, 2005

   I took a course on differential geometry with Bott when I was a grad student at MIT. It was great! He was explaining, and trying to simplify, Witten's work on supersymmetry and Morse theory.

   He always had a benign twinkle in his eye. I remember him starting one sentence with the phrase "Before I was such a bigshot…" – and the whole class cracking up in laughter.

   I also remember him saying "So, if thinking doesn't let us solve the problem, what should we do? *Superthink!*" This was sometime around 1985, when mathematicians were just getting into supersymmetry, so it suited the spirit of the times.

   Like Dirac, Bott started out as an electrical engineer. He said that he worked his way to algebraic topology through Kirchoff's laws, which are a nice introduction to the ideas behind deRham cohomology and Hodge theory. My friend Robert Kotiuga, who is an electrical engineer at Boston University, talked to Bott about this and got really fired up about it – he's written a lot about electromagnetism and algebraic topology. Just another of the many people influenced by Bott….

   December 22, 2005

   Thanks for posting this Peter. It's good to pass along bits of personal history. I went ahead and ordered his book (sounds like it might help improve my poor knowledge of algebraic topology) — you should consider becoming an Amazon Associate so you can get a small percentage from books you link to. Sadly, Bott won't get his share either, but it sounds like he lead a good life.

6. **Lee Smolin**
   December 23, 2005

   This is very sad news. If I can add a reminiscence, Raoul Bott showed a great deal of generosity to me and other physics students who found a warm environment where he would give freely of his time to talk about physics and math. After he expressed interest in the singularity theorems in GR, another student, he and I met regularly to work our way through the key chapters of Hawking and Ellis's book. He required that every formula be translated into index free notation and insisted we gain an intuitive understanding of each term in each equation before moving on. I don't know if he got anything from it but it was an education to me.

   I learned from his example that one could do good science in an atmosphere that was as intellectually probing as it was warm and light hearted. At the end I felt sufficiently grateful to him that I arranged to receive my Ph.D. from him in the graduation ceremony at Dunster House, where he was master.

7. **MathPhys**
   December 23, 2005

   I met him only one time, when I attended one of his lectures. He was indeed a very warm man, very communicative. He talked about Morse theory.

8. **Andrew Sutter**
   December 27, 2005

   Very sad news about a warm and generous man. I confess to a pang of jealousy that I was in Dunster House a couple of years too soon to experience him as house master. Instead, I met him when I was a clueless freshman taking linear algebra. I was too young and ignorant to fully appreciate my luck at being plopped into the one section taught that year by tenured faculty: Shlomo Sternberg in the first semester, and Raoul Bott in the second.

   It was springtime, and my attention wandered. I tried to fake it through much of the final exam. My blue book came back with one comment written exuberantly across many of my answers: "SALAD!" Decades later, this is still the phrase I hear in my head — with its author's accent and enthusiasm — whenever I'm editing my most awkward prose.

Atiyah and Witten in Nature

December 22, 2005
Categories: Uncategorized

This week's issue of Nature has short articles by Atiyah and Witten, both addressing the issue of the current state of string theory.

Atiyah's piece is an interesting review of Lawrence Krauss's new book Hiding in the Mirror entitled Pulling the strings, and it concentrates on what Krauss has to say about the relation of mathematics and physics. Krauss ends his book quoting the mathematician Hermann Weyl as choosing beauty over truth, remarking that physicists don't have this luxury. Atiyah points out the story of Weyl's work on gauge theory, which Weyl published over Einstein's strong argument that it was physically wrong. The idea was just so beautiful that Weyl felt there had to be something to it, an opinion that turned out to be amply justified as the concept of a gauge theory has turned out to be among the most fundamental ideas in theoretical physics.

Witten's piece is entitled Unravelling string theory and it tells the story of how he got interested in string theory and offers a defense of its continued study despite the lack of progress during the past 21 years in using it to come up with a unified theory. His defense consists of three points:

1. It appears to be a consistent generalization of QFT, and is worth study on that grounds alone.

2. It incorporates general relativity and provides a "rough draft" of particle physics.

3. Research on string theory has led to all sorts of spin-offs: insights into confinement, black-holes, mathematics.

Those are certainly the strongest arguments for working on string theory, but I find it disappointing that Witten chooses to ignore much of what has been happening in string theory over the last few years. He addresses only by indirect allusion the whole issue of the landscape and the strong possibility that the string theory framework for unification is inherently incapable of predicting anything. Witten would do particle theory a huge favor by at least acknowledging that if the string theory landscape really exists, it is not, as many seem to think, a new paradigm for how to pursue theoretical physics, but instead the end of hopes for this idea about how to achieve unification.

   December 22, 2005

   I have a question for you, Dr. Woit, if you don't mind:

   What's so great about beauty? It seems one clear distinction between your assessment of strings, and that of, say, Witten, is the opinion regarding its purported "beauty". Obviously Witten and those who share his belief find their perception of the beauty of strings so compelling they've devoted their professional lives to it. You don't their aesthetic judgement on the matter.

   Either way, I have to wonder if the beauty criterion has produced as many red herrings as it has fruitful research programs, given that "beauty" is, in the end, in the eye of the beholder (with many philosophers arguing as only they can about its significance).

   I don't remember the precise wording, but Feynman asserted essentially that "beauty" pales next to experimental verification. I tend to agree, only because I distrust the aesthetic judgements of others, as well as my own, when it comes to describing what is vs. what I'd like reality to be. I wouldn't want to deny anyone the pleasure of deriving human pleasure from the perceived elegance or gorgeousness of theoretical models any more than I'd want to tell them their joy in experience art or music is worthless. However, it seems to me, in science, evidence trumps everything and anything else, precisely because good experimental data is not generated as a matter of oppinion.

   If the theory does it's job the way a scientific theory should, whether it strikes some as beautiful and others hideous is completely irrelevant. Isn't it?

2. **Juan R.**
   December 22, 2005

   Some comments on Witten's *defense of its continued study despite the lack of progress during the past 21 years in using it to come up with a unified theory*:

   1. Witten says "It appears". Yes, i agree, only that…

   Is Witten ignoring that there are others more interesting, consistent and realistic ways for generalizing standard QFT: via direct curved spacetime, nonlinear, NC-QFT, TFD (generalized vectors on doubled space), time-symmetric AAAD (Hoyle/Narlikar), via Gelfand triplets (Brussels School), etc.

   2. String theory does not incorporates general relativity. This is one of more dishonest claims of string theorists i know. In fact, the supposed background-independent version is not a string theory and is called M-theory. M-theory is not formulated and nobody know what is, if it really exists. M is for mistery…

   3. The comment that string theory provides a "rough draft" of particle physics can be easily replied via Woit's appeal to Pauli

   > one is reminded of another quote from Pauli. Annoyed by Heisenberg's claims that modulo some details he had a wonderful uniffied theory (he didn't), Pauli sent his friends a postcard containing a blank rectangle and the text "This is to
   > show the world I can paint like Titian. Only technical details are missing."

   4. Research on string theory has led to all sorts of spin-offs: insights into confinement, black-holes, mathematics.

   Yes, but like lot of other disciplines with minor publicity in mass media. Or has only string theory provided advances? For example, i estimate the impact of string theory on math less than 1%. The real impact of string theory on disciplines as chemistry, biology, or geology for instance, is 0%.

   Bad numbers for the so-named TOE; really bad numbers for the theory that, in words of Brian Greene, was revolutioning our views…

   Juan R.

3. **woit**
   December 22, 2005

Dumb Biologist,

One problem with beauty is that it is not precisely defined, so one has to be very careful about what exactly is being claimed to be beautiful, and what isn't. In Witten's article, note that he isn't actually claiming that string theory is beautiful. I've written extensively elsewhere about string theory and what about it is or isn't beautiful, so won't here.

By "beauty", theorists often mean the property of getting a huge amount of explanatory power out of a very small number of assumptions, or if you like, a simple equation or equations. Most people agree that the Dirac equation is "beautiful" for this reason. This is the sort of thing many theorists are hoping to find again. They haven't found this in string theory, since no one knows what the equations are. Experimental evidence is of course ultimately the arbiter of what is true and what isn't, and it can also often provide hints to theorists about what directions to be looking in. Beauty is another source of hints, especially important when experimental guidance is lacking. Atiyah's example of gauge theory is an excellent one of an idea that was so beautiful there had to be something right about it. But in its initial form, the idea wasn't quite right, input from another direction (QM) was needed to get it right.

4. **Dumb Biologist**
   December 22, 2005

   OK.

   Being myself a mathematical unsophisticate (with none of the virtue of earnest purity that word might imply), it's clearly a property of mathematically deep theoretical frameworks that is lost on me, but for the qualitative features you describe. Semantics may be as much the issue as any other, I suppose. "Beauty" here seems more-or-less interchangeable with notions like "elegance", "economy"… To the extent that this more specialized use of "beauty" is understood with broad consensus, then the problem could very well be, as you say, not one of naive reliance upon beauty as a "hint", but rather its misidentification or abandonment.

   Again, the beauty, as defined, of the Dirac equation is over my head, and perhaps I ought to do my best to understand the basics more (buy Penrose's book?) before I get too suspicious. Because I know I'm no genius, I've never trusted my own impressions enough to have ever said to myself, in my work, "that's just so darn beautiful it's GOT to be…" I suppose that allows me to always be pleasantly surprised when I'm right, though perhaps it also means I lack "common sense". I guess I've always been far more impressed with, say, the accuracy to so-many decimal places of QED and GR than any other feature those theories posess…probably because I'm too dumb to understand those other features well enough. But, because even the brightest among us can be misled, it seems, by personal biases, it's always seemed best to toss aesthetics if it looks too much like intellectual baggage.

   If one cannot observe, even in principle, my (perhaps ignorant) suspicion turns to alarm, and what little trust I have goes out the window. I find it difficult to resist the urge to dismiss considerations of "every possible universe" that lies beyond our horizon out of hand, no matter how beautiful the theory that describes them might be. If the theory tells us nothing specific about our own universe (or vacuum, or whatever), my dismissive reflex turns to a sense of betrayal of the scientific method.

5. **Dumb Biologist**
   December 22, 2005

   I must say, after re-reading Witten's essay, in light of the notion of beauty meaning "getting a huge amount of explanatory power out of a very small number of assumptions, or if you like, a simple equation or equations", he certainly seems to be saying ST is beautiful, in not-so-many words. Witten says String Theory "leads in a remarkably simple way to a reasonable rough draft of particle physics unified with gravity", and that it "has proved to be remarkably rich, more so than even the enthusiasts tend to realize", citing the insights it provides to quark confinement, BH entropy, and so forth. He outright asserts that its equations are profitable (so to speak), in this physically "beatiful" fashion, since that they give back more than what is put in. This seems, allegedly, to be congruent with what is said of the Dirac equation (which looks simple enough, I suppose, though it's been a long time since I've had to contend with diffy-q's and matrices), as it explains electron spin, magnetic moment, charge quantization, (where earlier work had to incorporate those properties "by hand"), predicts the existence of positrons, as well as agrees with all the experimental data of the day.

   I can't help but interpret Witten's words as an endorsement of String Theory's "beauty", and that this beauty is the very reason why it is to be taken seriously. Perhaps I'm just reading it all wrong.

   Again, its distant relation to empirical inquiry seems not to bother.

6. **woit**
   December 22, 2005

   I think Witten is being extremely careful in what he says, trying to find the absolute best argument he can make for string theory, without going too far and saying something that can't be supported. I don't think he is saying string theory is too beautiful to not be true, largely because he is saying we don't yet know what string theory is. He is marshaling evidence for the idea that there is something beautiful going on, but we don't yet know what it is. Until he actually knows what string theory is, he can't claim that it is beautiful, and I think he is being careful not to do this in his article.

   You're quite right to be suspicious of arguments based on universes we can't observe, but this has nothing to do with questions about beauty. Susskind forcefully makes the point that the string theory landscape picture of the multiverse is a quite ugly one. He doesn't say you should believe because it is beautiful, quite the opposite.

7. **Chris W.**
   December 22, 2005

   D. B.,

   I think the use of the word "beauty" in science is confusing precisely because the meaning summarized by Peter—"getting a huge amount of explanatory power out of a very small number of assumptions"—does not play much of a role in discussions of aesthetics in other fields (with the possible exception of music, given an appropriate recasting of "explanatory"). When non-scientists see the word used they naturally tend to think of the uses of it that are familiar to them, in connection with the visual arts, architecture, music, etc. Those uses tend to emphasize subjective responses of appreciative non-specialists to works of art.

   The best analogy in biology to the deep principles of physics are the deep structural principles of biology, and of course the principles of evolutionary biology. (Needless to say many of these principles have important connections to physics.) These principles place the staggering body of detailed empirical knowledge in biology in an intellectual framework without which much of that empirical knowledge would be far less significant, ie, far less worth knowing.

   Of course one might be inclined to say the same of various mythologies. The problem with myths is that, considered objectively and critically, they don't stand up to close scrutiny as explanations. Seeking after beauty in physics only becomes pernicious if it is used to argue for the irrelevance of testability and empirical verification in science. The existence of this potential should not be turned around and used to argue that theoretical beauty (in the sense given above) is itself irrelevant. We not only want but *need* more than an enormous catalog of verified but largely disconnected facts.

   In short, great theories (and for that matter, great engineering) elicit a kind of objective relief that a cacophony of disconnected and apparently contradictory facts (or problems) can be reconciled and understood in a unified, lucid, and robust way. To a scientist *that* is beautiful. Mathematical formulation can be be tremendously helpful, and sometime essential, in achieving this relief, although without key informal insights into the relevant problems formalization may simply augment the confusion.

That said, I think we are still in the process of figuring out what beauty in scientific theories *ought* to mean. The word is merely a label for a quality we are struggling to identify and articulate with ever increasing depth and clarity. That quality is best conveyed by lucid explanations of well-chosen examples, and the fertile insights they have provided.

8. **Dumb Biologist**
December 22, 2005

Oy. I must simply give up and say beauty gives me a migraine, especially when I try to contemplate what it ought to mean. I guess I'll never be comfortable with it, and must leave substantive discussion of the matter to those wiser and smarter than myself.

I guess it's a small comfort that I've got comparisons with objective reality to compensate for my philistine lack of aesthetic sense or interest. And no, I don't mean that sarcastically.

9. **pax**
December 22, 2005

Justifiying millions of (brilliant) man hours based on beauty alone is definitely questionable. After all, the very notion of beauty is most likely a result of evolution. The human mind has been selected to differentiate between ugly and beautiful as a survival mechanism. Harsh, dry desert terrain – ugly. Waterfall and greenery – beautiful. To now say that the key to understanding the way the world is put together lies in concepts like beauty and its younger sibling symmetry is, at the very least, a circular argument.

10. **Chris W.**
December 23, 2005

D. B.,

There is another issue here, I think. "Comparisons with objective reality" in physics have probably been more problematic* in physics than in biology for much of the last hundred years, if not before. Theories in physics set the very terms of the discussion to a much greater extent; they tell us what we can expect to observe, and how to go about observing it, which may require tremendous effort and technical skill. Many (most?) physicists' conception of beauty in a theory is also associated with its consistency, clarity, and comprehensiveness when used in this role.

Trying to follow the Baconian ideal and observe the world without preconceptions or prejudices—whatever you see in the microscope or the telescope,* as it were—is hopeless. You always have to assume something and have some problem in mind; the question is what these presuppositions are, how one would know if a given assumption or problem formulation was leading one astray, and what presuppositions are absolutely central to the enterprise. It obviously helps to have several alternatives in play, which may cut up the alleged objective reality in different ways. Some of these alternatives may be more or less "ugly"—unappealing on logical, philosophical, or "aesthetic" as well as empirical grounds—while still contributing something valuable to critical discussion of a problem. (Consider the case of MOND.)

(I should point out that philosophers of science have discussed this issue at great length, starting in the first third of the 20th century.)

(* Actually, I wonder if this is really the case, that is, if biological observation is really so unguided by theoretical presuppositions.)

11. **Anonymous**
December 23, 2005

pax: you have to consider that people are not just making that argument from out of the blue. look at it more as a historical obervatoin: physical theories have an uncanny tendency to be beautiful/symmetrical.

12. **anon**
December 23, 2005

Dumb biologist:

The Feynman quote on the benefits of beauty versus those of experiment is:

'You can recognise truth by its beauty and simplicity. … The inexperienced, and crackpots, and people like that, make guesses that are simple, but you can immediately see that they are wrong, so that does not count. … We have to find a new view of the world that has to agree with everything that is known, but disagree in its predictions somewhere, otherwise it is not interesting. And in that disagreement it must agree with nature.' (Character of Physical Law, 1965, p171.)

13. **sunderpeeche**
December 23, 2005

Dumb biologist:
Chris W gave you an excellent reply. ("The best analogy in biology to the deep principles of physics are the deep structural principles of biology, …") — this is right on the money. Think of the DNA double helix (coupled with what I believe is called the "Standard Dogma" in biology), how much it has explained based on a few simple ideas. That is beauty. The double helix is an icon of popular culture now — it is on the cover of Dec issue Scientific American and many other places.

14. **Juan R.**
December 23, 2005

i find really interesting the discussion about the supposed beauty of the Dirac equation addressed above.

Of course, beauty is a subjetive concept and whereas some theoreticians as Kaku claim that the Dirac equation is specially beatiful, others theoreticians such as the own Dirac (i already cited his words several times in this blog) or myself think that the equation is NOT beatiful.

Since string theorists like a wrong concept of 'beauty' and are rather unrigorous in her/his academic discussions, it is not so strange the *three decades stringy failure for finding a consistent theory of nature*.

Still more interesting is that nobody here has still expressed that she/he really understand by "Dirac equation":

– The original Dirac wavefunction, which is wrong and was ABANDONATED in modern quantum field theory by a Schrödinger equation for funtionals.

– The modern Dirac operator identity appearing in QED, which is not fundamental since does not apply to two-electron systems (in fact, still nobody know what is the full two-electron equation). I would note that also Dirac rejected the modern QED view in his last publications.

– Dirac-like equation obtained on string-brane theory when [tex]D_{10}[/tex] is splinted into “compact” and “non-compact” dimensions [tex]D_{6}\psi_{n} = m_{n} \psi_{n}[/tex].

I see also some incongruencies about the supposed ‘predictions’ of the original Dirac equation. For example, it is simply untrue that Dirac equation predicted the correct magnetic moment for electron and the prediction of antiparticles would be discussed because the concept of antiparticle on the original Dirac-hole theory is NOT the antiparticle of the modern QED.

For a simple review of the original Dirac equation and its obvious flaws see pages 13-14 of Weinberg manual.

Juan R.

15. **Dumb Biologist**
December 23, 2005

Well, there’s a lot of public discussion these days about the beauty of Darwin’s insight, as the very simple program of random variation coupled with selective pressure is all that is needed to explain the complexity and diversity of life. (Of course modern evolutionary theory incorporates other mechanisms like genetic drift, takes into account that mutation isn’t always completely random, etc., but those necessary additions to the theoretical framework in no way diminish the importance of Darwin’s proposed mechanism of natural selection).

Logically, evolution is a slam dunk, there’s no denying. I can’t think of a single good argument against the notion that, given a population of replicating, mutating entities in a dynamic environment, evolution simply MUST happen. Its inevitability does seem to make experimentation to empirically demonstrate the point essentially superfluous. What else could possibly happen? I certainly can appreciate the perception of beauty in a concept so simple, yet so powerful and, probably, _necessary_.

Then I look at the ID debate, and any confidence I might have had in the reliability of human perception crumbles. Platonic solids and epicycles have beguiled the minds of many a brilliant thinker in the past. Who knows what today’s equivalent might turn out to be. Of course, without some initial bias, sensible scientific investigation is impossible; and indeed most of those biases are entirely justified. But by the example humanity has provided time and again, it seems ultimate reliance upon anything but the well-tested hypothesis will yield rapidly diminishing marginal returns, and eventually complete detachment from reality.

December 23, 2005

Dear Anonymous: (Out of the blue guy…)

Has it occured to you that you regard the physical theory as beautiful
simply because your thoughts, aesthetic sensibility and yourself are a to some extent a product of that construct ?

It’s like saying “This candy is sweet because it tastes of sugar…”

17. **Shantanu**
December 25, 2005

Peter, one interesting thing in Witten’s article is that he makes no mention of LQG or CDT (when he talks of critics of string theory) but does mention twistor theory, non-commutative geometry .

18. **woit**
December 25, 2005

Shantanu,

Witten says something like “when critics of string theory have good ideas, they tend to be absorbed as part of string theory”. His failure to mention LQG and CDT could be interpreted as meaning he doesn’t think they are very good ideas. I found that sentence of his kind of strange: he seems to be claiming for instance that black hole entropy and twistor theory have been absorbed as part of string theory, which is a somewhat peculiar way to phrase the situation of the relation between these subjects.

19. **Samuel Prime**
December 26, 2005

The string theory bashing here is amazing. Why is this? Are such feelings directed towards researchers of string theory (and what they say) or towards the theory itself? (Or both?) They sound like a hint of jealousy.

Okay, so there is competition going on. What’s the deal about that? Physics has always had competition in its endeavor to find the truth (or the most successful theory to date). From what i have read by Witten he has been more careful than how some seem to portray him. He frequently speaks in tentative terms like “if string theory is correct”. And why would he bother to mention the problems with string theory if he’s that biased? He does mention them, but those who want to bad mouth him and string theory choose not to be fair.

Instead of engaging in negative interpretations of Witten’s not mentioning LQG, isn’t it best to settle the matter by asking Witten himself via a friendly e-mail (how he feels about LQG)? On a couple of occasions I have asked him some questions and Ed politely answered me to clear a speculation of mine. The reason Witten mentions noncommutative geometry is because he used it in some of his papers. And perhaps he doesn’t refer to LQG is because he’s either not convinced of it or does not see the need to use it. Do we do the same for LQG researchers when they don’t use string theory?

20. **D R Lunsford**
December 26, 2005

Homo biologicus non sapiens,

Beauty involves economy, in all cases. The Dirac equation
[tex]
\begin{eqnarray*}
(\gamma^{\mu}\partial_{\mu} + im)\phi & = & 0\end{eqnarray*}

[/tex]

is very economical. Another way of saying it is

P psi = M psi

the mass is the eigenvalue of the momentum. This equation is really the generalization of E = m to moving electrons. It explains not only the otherwise incomprehensible phenomenon of spin, but also gives a direct statement about the electron's magnetic moment. To top it off, this little equation implies the existence of a new kind of matter, that was hitherto unsuspected. Not bad for 8 symbols.

21. **Chris W.**
December 26, 2005

Follow-up on "Theories in physics set the very terms of the discussion to a much greater extent; they tell us what we can expect to observe, and how to go about observing it" (in my comment on 12/23): See this recently posted preprint:

Observables in effective gravity (hep-th/0512200)
Authors: Steven B. Giddings, Donald Marolf, James B. Hartle

This paper indicates the extent to which the above statement has been realized in quantum field theory and general relativity, and how its significance is further magnified in quantum gravity. The theme is pervasive in the vast literature on these subjects.

22. **woit**
December 27, 2005

Samuel Prime,

"why would he bother to mention the problems with string theory if he's that biased?"

I don't think Witten actually does mention any of the serious problems with string theory, other than that we're not quite sure what the theory actually is. By now there is strong evidence of problems with string theory as a framework for unification, and Witten doesn't address these, instead just making the positive case for continued research into the theory. He's within his rights to do so in this kind of short essay, but a serious examination of the problems with string theory is not what he is doing.

You'll not find coming from me personal attacks on leading researchers in string theory. I think there are serious scientific problems with the theory, which I've repeatedly explained in detail, as well as problems with how research into the subject has been conducted. Discussing these issues is not a personal attack on anyone. As for jealousy, I have immense amounts of respect for both Atiyah and Witten, for their talents, their hard work and their incredible accomplishments. Sure I wish I could have accomplished a fraction of what they have, but I'm well aware I'm just not as smart and hard-working as they are.

About string theorists in general, I don't envy them at all their current situation, and, on the contrary am quite happy with my professional life, as well as with my decision many years ago to not go into research in string theory.

23. **Samuel Prime**
December 27, 2005

Peter, but Witten does mention the serious problems with string theory. For example in his expository article "Reflections on the fate of spacetime" (which is available on his homepage) he states the good news with string theory, and then later asks "what is the bad news?" And he proceeds to discuss them—the first of which he calls "glaringly unsatisfactory" (see page 26, Ibid). He says clearly the concepts are unclear and the principles underlying string theory unknown or not yet understood. Later on in the article (page 28) he says "We are far from cing to grips fully with this paradigm, and one can scarcely now imagine how it will all turn out." These are a lot more than saying we are not sure what the theory is, but points to problems with it—and certainly leaves the reader (or me, at least) with the impression that it could all turn out wrong (not that it is "not even wrong"—which is actually unclear at this point). (Unless you say that you have a disproof of string theory!)

By the way, and respectfully, I do not think anyone is in a position to say what Witten is not doing. He may be doing privately what we don't know from his work publically. No one knew Wiles was working on Fermat's Last Theorem when he was; many mathematicians like to work on some things and keep them to themselves.

It's okay with me that there are serious problems with string theory. They could reflect that ultimately it is the wrong, but ingenious, approach. Or that there is still a lot of work ahead; work which might point to a different direction to something closer to the truth.

Anyway, in the end, string theory could be wrong in describing nature (or could be right), but whatever the outcome it has left its mark on the history of Physics it seems to me (having been around a couple decades or more). Let's remember that quantum theory didn't come to us on a silver platter.

24. **biophysicist**
January 5, 2006

Dumb biologist,

I think if you stop worrying about popular ideas of what beauty is and focus on the beauty we as scientists find in the remarkable simplicity and necessity of Darwin's law of natural selection, then you'll appreciate the physicist's view of beauty as well. It seems to me that the only difference (right now at least, this could of course change) between beauty in purely biological theory and physical theory is the presence of symmetry principles in the latter. But the psychological satisfaction in the Dirac equation and Darwin's natural selection are what I at least mean by beauty (both are beautiful in unique ways though, since the former is conjectured and the latter, as DB points out, just seems inevitable – but remember it still took a human being to point out what we take for granted as inevitable, that's why it is still beautiful!).

Trackback Censorship

December 23, 2005
Categories: Uncategorized

Over the last month or so I've sent repeated requests to the arXiv to have trackbacks posted for several of my weblog postings. The first of these requests, back in early November, was answered positively by "mjf", and the trackback (to a paper by Nekrasov) soon appeared. Since then I have sent repeated requests to the arXiv that they list trackbacks to my postings about papers by Weinberg, Baez, Freed-Hopkins-Teleman, and Tegmark et. al.. I've received no response whatsoever to these requests, including to requests that they inform me of what the arXiv policy on trackbacks is and why my postings don't seem to qualify.

Of the four postings involved, two of them (about the papers of Baez and Tegmark et. al.) led to discussions here involving some of the authors of the papers themselves, and I think seeing this discussion could be valuable to people interested in those two papers. I can think of no legitimate reason why trackbacks to those postings should not be allowed. The posting about Freed-Hopkins-Teleman was intended to point physicists to some very interesting new work in mathematics; I also believe some people might find that valuable. Finally, the posting about Weinberg's article was perhaps more controversial, but I believe it raises legitimate issues that the particle theory community needs to allow public discussion of, and censorship of this is inappropriate.

I've looked a few times at the list of recent trackbacks to see if I can figure out from that what the arXiv policy about this is. Today's list of trackbacks from the period December 20-23 has 6 listings, one from cs.unm.edu and five from golem.ph.utexas.edu. As far as I can tell, at least as far as particle theory is concerned, the arXiv trackback system is being run mainly for the benefit of the owner of golem.ph.utexas.edu, who sits on the arXiv advisory board, and may or may not have something to do with the censoring of trackbacks to my postings. Of course I have no way of actually knowing what is going on here or who is responsible. This situation seems to me to raise questions which the arXiv advisory board needs to address, and I am simultaneously contacting them about this.

Update: I still don't know exactly what is going on at the arXiv, but from what I've heard so far, it is clear that the problem is not a technical or administrative one, so I'm removing the question mark that used to be there in the title of this posting.

Time now to ignore this for a while and start celebrating the holiday with family and friends. Happy holidays to all!

Update: Still no word from the arXiv. Commenter Jose notes that trackbacks to comments at physcomments.org do generally appear on the arXiv. There are instructions at physcomments.org that say:

If and only if a blog annotation starts with an identification paragraph "A Comment by …", and its subject line starts with the preprint it is commenting about, then it is submited to the ArXiV for consideration. Note that currently the ArXiV reserves its right to reject the trackback ping.

Evidently Alejandro, who runs physcomments.org, has been successful in not only communicating with the arXiv, but getting them to post his trackbacks. He comments here that "It is only via Distler that it has been finally incorporated, and it is partial, experimental etc." From this I take it that the key to getting arXiv trackbacks posted is, as commenter Chris Oakley suggests, to not have pissed off Jacques Distler, something I seem to have done long ago with my criticisms of string theory.

I'm more and more convinced that what is going on here is all due to the simple fact that Distler doesn't like me. I was surprised and saddened to note that in his recent posting about Raoul Bott, he links to other postings about Bott by Sean Carroll (who credits my blog as where he learned of Bott's death) and Lubos Motl, but not mine. I also didn't realize that Distler was a couple years behind me at Dunster House, an experience that perhaps he has yet to get over.

Update: While I was writing the above, Alejandro submitted a comment noting that, after initial problems getting his trackbacks accepted "now it seems I am allowed to send trackbacks. Of course, one never knows when this permission can change again."

Comments

   December 23, 2005

   "Do not ascribe to conspiracy that which can be explained by incompetence" — Napoleon Bonaparte

2. **woit**
   December 23, 2005

   Sunderpeeche,

   Good advice in general. And I should make clear I have absolutely no idea how these issues are handled at the arXiv. All I know is that repeated polite requests to arXiv administrators over the past month and a half have been met with no response of any kind whatsoever. I'm having trouble at this point ascribing this to incompetence.

3. **Chris Oakley**
   December 23, 2005

   (Obviously the notion that you might have p***ed off Jacques Distler can be ruled out from the start)

4. **Dumb Biologist**
   December 23, 2005

   Seem's a safe bet whoever's responsible thinks you're a crank, and your views on physics don't merit inclusion in collegial discourse.

   If that's the case, it's kind of sad that there's presently no way to prove them right or wrong, there probably never will be, and you'll just have to accept their opinion on the matter.

   If this is the sorry state of affairs, it ought to give anyone pause before excluding degreed academics from the discussion, as it is itself a symptom of a major problem in a field that purports to be science, but maybe they don't see it that way.

5. **andy**
   December 23, 2005

   I'll point out at this juncture that you seem to censor your blog here. I posted a comment that I thought was germane and you deleted it. I point this out in as friendly a way possible. I'm a big fan of what you're doing here.

6. **ksh95**
December 23, 2005

Peter,

Please let us know how things turn out. I sincerly hope there is a legitimate explaination for this.
It is almost unthinkable to me that anyone on the arXiv advisory board would exibit such juvenile tantrum-like censorship.
I really hope this is not the case.

7. **woit**
December 23, 2005

Hi Andy,

Some form of censorship is necessary, both here and at the arXiv. I don't remember what your comment was that I deleted, but I do delete a lot of comments that seem to me off-topic. Glad to hear you remain a fan despite it all! How stringent I am about this depends on lots of random factors, including how much time I have to look at comments and decide what to do with them, whether I'm in a good or bad mood, etc. The difference with the arXiv case is that I take full responsibility for what I'm doing and will respond with an explanation to anyone who politely asks why I have deleted a comment.

Right now I don't even know that I am being censored since I've been unable to get anyone at the arXiv to respond and tell me what they are doing with requests that I submit. For all I know, my requests are sitting in a queue of things to be dealt with by some overworked arXiv staff member. No way to tell as long as no one there is willing to contact me and let me know what is going on.

ksh95,

I have heard from one advisory board member who promises to look into what is going on and get back to me. Of course, with the holidays now starting it may be a while before relevant people are back at work and willing to deal with this. The bad timing is my fault.

8. **Dumb Biologist**
December 23, 2005

Glad you got in touch with someone.

You might hear back it was an anti-spam snafu. That might even be the real reason.

9. **Anonymous**
December 23, 2005

I'm amused by the thought that "Dumb Biologist" is Paul Ginsparg in disguise.

10. **Dumb Biologist**
December 24, 2005

Ouch, poor Paul Ginsparg. No, absolutely not; I am quite what I say I am.

I will say minds of his caliber, and the knowledge they bring to bear on the increasingly relevant physical and computational problems important to a richer understanding of life science are precisely what the field can always use more of. It's interesting to see he's teaching a physics course on biological applications (which I doubt I'd survive). That's to be applauded.

11. **Quantum_Ranger**
December 24, 2005

Having a number of posts deleted is no big deal,(having encountered this myself) you have to maintain a selective balance of the subject being blogged. The "control" factor for reasons that are "total" and to a specific site namely Peter Woit's?..can only be guessed as someone "up there" does not like what you do?

Up there , being those whose, powers that be, far exceed their authority on the subject?.. they obviously have no knowledge about the subjects in question, or do they wish to promote any correspondance forthwith.

12. **secret milkshake**
December 24, 2005

Peter,

Say, you were an editor of a rather important journal like arXiv and you got lots of trackback request from somebody with extreme view and polemic bend towards a major fashionable enterprize that monopolized high energy theoretical physics – how would you react?

Being born in east-Eurepean contry (LUMO!) I know how ideological establishment works – but these things do not make much difference in the long run. In few years time, there will be new unexplained data from CERN and most of what is happening in the theoretical physics in the last few years will be mercifully forgotten.

"The Nature will come out the way she is – it does not matter how famous you are, how beatiful the theory is – if it is wrong, it is wrong. It's all there is to it."

Either way, I think you are wasting too much time and energy on things that are much like politics – in few years, somebody else will deploy troups and who cares? Stick close to people that do the actual experimental work.

13. **Juan R.**
December 24, 2005

Welcomed to real life… and science,

Perhaps you would contact with

archivefreedom

explaining your case.

A public criticism to ArXiv censure by Nobel winner Brian Josephson was recently published on Nature journal and is openly available here.

Juan R.

Center for CANONICAL |SCIENCE)

14. **FP**
December 24, 2005

Maybe it is a problem that arXiv has a quasi-monopoly as pre-print storage?
Some competition is always healthy, but apparently nobody outside Cornell wants to do the job.

15. **Tony Smith**
December 24, 2005

secret milkshake said "… In few years time, there will be new unexplained data from CERN and most of what is happening in the theoretical physics in the last few years will be mercifully forgotten.
… I think you are wasting too much time and energy on things that are much like politics …".

As to "new unexplained data from CERN" LHC, for all we know any new LHC data may NOT be "unexplained" by the Standard Model.
Indeed, Fermilab has produced a lot of data over the past decades and ALL of it can be "explained" in terms of the Standard Model.
So, maybe it is not only possible, but actually likely, that LHC might find a Higgs around 100 – 150 GeV, with everything else very similar to Fermilab data, extended to somewhat higher energies and luminosities.

That being the case, theoretical physics should not sit on its thumbs for the next few years, but (in my opinion) should look closely at constructing models that include the Standard Model, without supersymmetry or other exotic extensions.

The way to do that is to actively work NOW on theoretical physics, and one way (of the many ways that should be pursued) would be to look at the K-theory math that might lead to a deeper understanding of Quantum Field Theory as suggested by Peter in his blog at http://www.math.columbia.edu/~woit/wordpress/?p=292 about "Latest Freed-Hopkins-Teleman". Unfortunately, as Peter indicates, arXiv seems to have censored Peter's K-theory ideas.
