This is not just true in the field of physics; it's also true in the field of mathematics, where David Hestenes discovered that "some things…[that] just can't be ignored" are being ignored nevertheless. In fact, when it turns out that things aren't adding up, like the enigma faced today in the form of quantum field theory's incompatibility with GR, then it's a pretty good indication that something that "just can't be ignored" probably is being ignored.

However, it's usually the investigators labeled "crackpots" who are motivated, for some reason or another, to go back to the basics to find what it is that has been ignored. Usually, this is so because only "crackpots" can afford to challenge long held beliefs. Non-crackpots, even tenured ones, must protect their careers, pensions and reputations and, thus, are not likely to go down into the basement and rummage through the old, dusty trunks of history, searching for clues as to what went wrong.

Instead, they keep on trying to build on the existing foundations, because they trust and believe that what they *know* isn't going to "do them in," contrary to the folk wisdom of the old farmer. If we are so sure that

GR is undeniably correct on some level – not only does it make accurate predictions, it is also very tight math.

then we are going to seek to incorporate it in our efforts to understand Nature. However, there's a possibility that, for some reason, the level on which "GR is undeniably correct," is not a physical level, but a mathematical level. In other words, it could be that it is an interpretation of physical concepts that works mathematically, but is physically wrong. We see this all the time in other cases, and we even acknowlege it in the gravitational area where, in the low limit, we interpret the physical behavior of mass in terms of a physical force formulated by Newton. When we need the accuracy of GR, however, Newton's physical interpretation of force between masses changes to Einstein's interpretation of geometry that results from the interaction between mass and spacetime. Then, when we get to the quantum level, neither of these physical concepts serves us, so we again employ mathematics to rescue us and come up with the Higgs field, or something else – actually, the race is on to see who can come with something first that can be verified.

What is actually happening, though, as us "crackpots" can easily see from the outside looking in, is that what is being verified is the mathematics, not the physical concepts. Physically, what we have verified is that light and energy are quantized, that the speed of radiation is constant relative to matter, that gravity is equivalent to acceleration, that distant galaxies are receding from our location in all directions, and that this universal expansion is not slowing down for sure, and may even be speeding up.

We can predict the behavior of subatomic particles with mathematical precision, if we measure certain quantities first, and if we limit the range of our calculations in just a certain way. However, we haven't verified the physical concepts involved in the nuclear model of the atom, we have only found a mathematical solution that enables us to interpret the observed physical behavior.

All this means that there is always the possibility that another mathematical approach to interpreting the same results would, if successful, lead to a different physical concept.

But, as you say:

There are certain steps in the evolution of science that are not optional – you can't make a gravity theory that doesn't in some sense incorporate GR at this point, any more than you can make one that ignores Newton on that level.

This is only true if you are building on all the existing foundations. If an error is discovered in the foundations, then some dismantling is inevitable. For instance, Einstein's theories are based on Maxwell's equations, which show that the law of conservation leads, not only to symmetry, but to electromagnetic waves that travel at the same speed in all directions, at the speed of light. There does not appear to be an error in these equations, yet the physical concept at the time included the idea of an all pervasive aether. Contrary to popular belief, Einstein didn't eliminate the aether concept, he just modified and renamed it. Today, the concept of a physical field is as indispensible to modern concepts of physics as the concept of the aether was in Maxwell's day. However, now we know that, although Maxwell's equations were correct, the physical interpretation of the meaning of the math was not. So, it's just as likely that the physical concept of the field is as incorrect as the physical concept of the aether was, but the mathematics works in either case. Therefore, it's true that

Anyone who claims that Einstein's analysis is all wrong is probably really a crackpot.

because it's obviously not wrong. That is, it's not mathematically wrong, but the interpretation of the mathematics may incorporate incorrect physical concepts that will not work except in special cases, such as when we see GR's spacetime concept unable to work at quantum scales, and QFT's field concepts unable to work at large scales. While the maths in both cases work fine within the prescribed limits, the two physical interpretations of these mathematical concepts are incompatible; one is background dependent, and the other is background independent: obviously there is something wrong!

Here's an idea, let's go down to the basement and rummage through the dusty trunks of history. Who's afraid of the dark? Us "crackpots" aren't, because we have nothing to lose.

(I can't end this without saying how pleasantly suprised I was to learn that you have considered three dimensions of time in your own work. I very much appreciate the invitation to discuss these things with you via email, too. I'll probably take you up on it.)

13. **D R Lunsford**
January 4, 2005

Doug –

Perhaps I misunderstood you. I see you accept the 4Dness of SR at least.

I certainly know from experience that your point about the behavior of the gatekeepers is true – I worked out and published an idea that reproduces GR as low-order limit, but, since it is crazy enough to regard the long range forces as somehow deriving from the same source, it was blacklisted from arxiv (CERN however put it up right away without complaint).

Nevertheless, my own opinion is that some things in science just can't be ignored or you aren't doing science, which is *not* a series of wacky revolutions. GR is undeniably correct on some level – not only does it make accurate predictions, it is also very tight math. There are certain steps in the evolution of science that are not optional – you can't make a gravity theory that doesn't in some sense incorporate GR at this point, any more than you can make one that ignores Newton on that level. Anyone who claims that Einstein's analysis is all wrong is probably really a crackpot.

(BTW my work has three time dimensions, and just as you say, mixes up matter and space and motion. This is not incompatible with GR, and in fact seems to give it an even firmer basis. On the level of GR, matter and physical space are decoupled the way source and radiation are in elementary EM. Feel free to send email if you want to discuss it or your own ideas.)

Arun said: *So, string theory embraces both General Relativity and not-General Relativity!!!! In other words, string theory says nothing definite.*

Plato said:*And about Arun's comment about GR. Phase transitions would be reduced holographcally from higher dimensions(the standard model would have been decribed from earlier states), would finally show up there?:)*

If one did not recognize earlier states of existence and just accepted the cosmological playground sight seen, it always existed in this form then:) That is, if we take the standard set by observation:)

I for one thought, topological considerations would have been formulated from earlier cosmic designs, but aparently this might have been subject to scrutiny, and thought out. Rejection of the soccer ball design as well?:)

I'll have to readjust accordingly. I'll be posting the reasons why on my own blog soon.

15. **Doug**
January 4, 2005

drl,

I know it's hard to believe that anything else could work, but the truth is there is another alternative. The reason GR works is because the speed of light is constant relative to matter and because gravity is an acceleration, not equivalent to an acceleration, mind you, but is a time rate change of motion. The question to be answered, then, is actually, "what is the nature of the gravitational motion?" not "what is the nature of the gravitational force?"

GR doesn't answer either question really, but instead eliminates the need for a force through an adjustment of the reference system mediated by covariance. Nevertheless, I'm afraid the discussion of GR is way off topic, which is "crackpotism." Hence, my point is not that GR or a 4D union of space and time is wrong, but that another point of view, especially one that not only works, but addresses the very foundations of our physics, cannot exist EXCEPT in the minds of "crackpots" by fiat.

Suppose that I claimed to have discovered that there exists, after all, an absolute frame of reference of motion, but I'm not a reputable physicist, just an honest investigator. What do you suppose the reaction of the non-crackpots would be? Would those who referee journals allow my findings to be published? Would those who teach at Universities take the time to listen to my arguments? Would those who advise philanthropists and public agencies brook my ideas?

The prevailing sense of the scientific enterprise is that at the core of its dynamics lies a merit-based ethics, but this is just not so. Discovering this is more traumatic than uncovering the deceit inherent in the alleged fact that the NY Times' real credo is not "All the news that's fit to print," but actually "Print all the news that fits," because scientific truth is so sancrosanct.

Nevertheless, it's a fact: regardless of merit, any concept far enough outside the accepted line of thinking will be labeled a "crackpot" idea by the guardians of the orthodox doctrine, and, of course, many people don't read beyond the label. Ironically, though, the really "crackpot" idea of string theory and its poly-dimensional approach and parallel universes of colliding branes, originating on the "inside" so-to-speak, has now emerged and overtaken orthodoxy, making the situation even more ludicrous.

Now, the completely ad hoc idea that space has 10 dimensions, and that seven of them are "compactified," and that the "strings" of gravity escape into a parallel universe, is embraced by Universities and published in thousands of journal articles and funded by public and private entities to the tune of untold millions of dollars.

However, if a voice of reason is raised, that points out that we live in a three-dimensional universe, where there are only three degrees of freedom observed, and that space has no properties of its own that can be observed, in spite of every effort to do so, except for the properties it has as an aspect of motion, and that it is more reasonable to assume, therefore, that time has three dimensions, and, with three dimensions of space, forms three dimensions of motion, that voice truly might as well be crying in the wilderness, for no one will hear it. If they do hear it, though, you can be sure that they will most likely just moan, and grunt, and mumble the word "crackpot."

16. **D R Lunsford**
January 3, 2005

Doug –

It's totally wrong-headed to think of the transition to 4D as a "correction". Rather, 3+1 is an approximation to bulletproof reality. I can well understand having a distaste for relativity, since it is usually very badly taught and written about (e.g. all the idiotic problems with pole vaulters in barns and the like). You'll have to get over any resistance to the idea before you can make real progress in any direction.

17. **Doug**
January 3, 2005

drl,

I assume that parts of your post are missing, but I think I get the gist of your point. I do not say that at high speeds the covariant technique does not produce the correct results. I only insist that the success of the procedure doesn't mean that the world is necessarily four dimensional.

For instance, I can get the same correction in a 3D world that includes *time* motion (the reciprocal of motion in space), as demonstrated in the correction accounting for the excess advance of the perihelion in the orbit of the planet Mercury. The effect of time motion is small at everyday speeds, but at high speeds, it accounts for the same descrepancy as your 4D approach.

The wonderful thing about it too is that it is the natural result of homogeniety and reciprocity!

January 3, 2005

Hi drl,

You wrote:

The world is really, really 4D on some level. It can't go back to being 3D – this is quite impossible in the light of experience. It can't be anyD unless (any-4) has a damn good explanation.

Of course, you realize that you just violated Peter's admonition not to respond to "crackpots" don't you?! LOL. Don't worry though, I'm not going to harrangue you with a myopic and stubborn insistance that living in ignorance in the age of enlightenment is better than embracing the "reality" of 4D consequences. If I were to do that, Peter might put me in his filter.

However, to be honest, your comments do cause me to wonder at the conviction that the world "can't go back to being 3D." Actually, the "world" has never stopped being 3D in the minds of some of us "crackpots." While the theories you non-crackpots have embraced have given you a way to understand the apparent "force" of gravity in terms of non-3D, both the crackpots and the non-crackpots still move in three dimensions, right?

You see, if you combine one dimension of space with one dimension of time, as one dimension of motion (ds/dt), something magical happens: you can move one-dimensionally in a three-dimensional world. And guess what happens if you combine two dimensions of space with two dimensions of time (ds/dt)^2? or even more innovatively, dare to combine three dimensions of space with three dimensions of time (ds/dt)^3?

Well, enough of that from this crackpot, I'm probably overstepping my bounds in a non-crackpot 4D world where such nonsense is unwelcome. Nevertheless, I want to go on record as testifying that assuming that four dimensions of spacetime is real, is not necessary to understand the 3D world of motion. The only thing that is necessary is that you understand motion: the only KNOWN relationship of space and time.

Regards,

Doug

Lubos said:

"But there are loads of backgrounds where string theory gives absolutely unique, quantitative, sharp, and theoretically crosschecked predictions for a given Universe, and these contexts of course always agree with GR at low energies.

If someone believes that string theory is mathematically vague, then he completely misunderstood everything about it. The "fictitious" new Universes predicted by string theory, especially those with a lot of supersymmetry, are completely rigid and sharply defined."

Lubos: have you nothing to say since I pointed out the fundamental error you made in your 4*ln(3) paper?! See the comment section of the Strominger Interview. Basically I point out that writting down ANY differential equation that takes derivatives against space and time, and deal with quantities about or below the Planck Scale, is fundamentally wrong, because at Planck Scale there is no longer continuous space and time.

No one was able to argue against the notion that derivatives against Planck Scale space and time is wrong. They could only defend for you by claiming that the math symbols in your equation (1) does not mean derivaties (which is laughable), or that you are not dealing with Planck Scale (how could it be a black hole if the mass scale involved is less than one Planck mass). Both are invain arguments.

Now, about your "predictions" about a "given universe" or any "virtual new universes". Let me assure you that it takes me 20 minutes instead of 20 years to come up with a self consistent 13 dimentional self consistent theory about an alternative "given universe", outside this one we known, and I will make predictions. And certainly no one can prove me wrong because no one can observe the other universe in any way direct or indirect.

Physics deal with obsersations we can make in this universe, which is the only one known, as far as physics is concerned. Any study or even meantioning of alternative universes, which we can not provide observation evidence for, are NOT physics, but religion.

The whole landscape and alternative universe nonsense in ST seem to be pushing itself out of physics and towards the religion end, since to believe in something no evidence can be provided, faith in the deep of your soul may be the only way. Don't you see that in deed deep in your heart, you have that kind of faith towards ST? You want to curse every one who is infidel, right?

January 2, 2005

The interpretation of Newton's program of research, as a dictum to focus on forces, has led to the goal of describing nature in terms of a few interactions among a few particles. The standard model attempts to do that, but it leaves out a huge piece of the picture. It also must start with a large number of empirical observations, and, of course, it is completely at odds with recent cosmological observations.

The development of string theory started as an attempt to address the SM's many problems, and in fact received its biggest impetus when it seemed to offer a solution to the missing piece – gravity. If Supersymmetry and string theory can never succeed, what will happen to the SM? After all, it is an attempt to extend the SM, so what should young particle physicists replace string theory with? Should they abandon the SM altogether, concluding that "you just can't get there from here?" Or, alternatively, should they abandon the current interpretation of Newton's program of research as a dictum to focus on forces, and seek a new, innovative, intrepretation that might yield better results?

Would it be a crackpot idea to suggest that a alternative interpretation of Newton's program might be that we should focus on *motion* as prior to force, and thus examine the nature of space and time as two, reciprocal, aspects of motion? Might that simple idea offer some real prospects for describing nature in terms of a few types of motions, combinations of motions and relations between motions (forces)?

It's obvious that we live in a 3D universe, and we even see two types of 3D motion, the outward motion of the receding galaxies and the inward motion of gravity. The force aspects of these motions are interesting, but why not investigate these motions themselves? What are their characteristics? How do they originate? Can we simulate them someway without a 4D spacetime, but with just 3D motion?

These are some simple suggestions of a possible new line of inquiry that doesn't ingnore the successes of the SM, Peter, but does recognize that its limitations, as a means for describing nature in a satisfactory manner, call for some fresh ideas. Does that have to be a crackpot thought by definition?

28. **D R Lunsford**
January 2, 2005

One more comment to "X" and his claim that ST is a natural progression (?) from the idea of point sources – of course this is completely false: a natural progression would have been, say, an infinitely thin vibrating shell, retaining spherical symmetry. Of course such an idea is also laugable in the light of relativity – that it was taken seriously by the likes of Poincare and Lorentz just shows what a rare commodity is sound physical insight. I doubt that the latter can be taught, which is why the stringers defend their dysfunctional world so vehemently – abandoning their little shadow-cave would force them to come to terms with their lack of insight and to stop hiding behind Platonic ideals.

-drl

29. **D R Lunsford**
January 2, 2005

"X" wrote

Frankly, I don't understand why ST was not a natural progression (eg. Lunsfords belief that it was obviously 'horseshit' from the outset) from the standard model..

My *advisor* thought that ST was horseshit from the beginning. Given his pedigree (Weisskopf) and his achievement up to that time (it speaks for itself), I think I was well justified in agreeing with him for my *own* reasons, which were actually different than his but just as deeply felt.

ST is horseshit because it is postmodernly anhistorical and revisionist. Nothing in physics is ever revolutionary. Everything proceeds from past experience. Winding the clock back to before Democritus was a laughable idea that became pernicious. I thought it would die of its own accord. I'm totally amazed that anyone with half a brain takes it seriously for *any* reason (even if they are purely mathematical ones).

January 2, 2005

"X" wrote

*I don't suppose D.R. Lunsford will ever be banned despite his enormous arrogance in calling a *mathematical* physicist such as Witten a failure while paradoxically demonstrating his admiration for other predominantly *mathematical* physicists such as Dirac and Einstein."*

Well this is rather self-evident, and you are mistaken. Dirac and Einstein were **actually** physicists. Even their side work is crammed with interesting physics (e.g. Dirac's superconducting vacuum and large numbers hypothesis; Einstein's Brownian motion). Both Dirac and Einstein used math as the *means to the end* – physics – and did not set it up as the *end in itself*.

Of course you must have actually sought out and read the side work, to know this. Since there is no time for detours in the usual sausage grinder curriculum, the chances are slim that the typical student will ever know anything about this side work. Nevertheless it is great physics and was to me very suggestive. I don't think I would have been able to solve my particular problem in the unexpected way that actually came about, if not for Dirac's side work. So, I have a very personal attitude about it.

(Ban me? I had no idea I was so formidable.)

-drl

31. **Lubo? Motl**
January 2, 2005

No, I don't see any difference. The LQG team also claims that they have a theory of a fundamental interaction at the Planckian energies, while they ignore the Standard Model.

You can't really go beyond the electroweak scale without properly explaining the electroweak and lower scales, i.e. the Standard Model.

Other crackpots say, for example, that all matter is made of letters X and T. They show how proton is constructed – and their goal is not to describe the Standard Model either. Their goal is to construct a theory of particles.

32. **Peter**
January 2, 2005

Hi Lubos,

No, I certainly don't think LQG is crackpotism. The LQG people are not claiming to say anything about particle physics, their claims are restricted to quantum gravity. And they are doing this using a mathematical set-up (connections and loop holonomy variables) which is close to the mathematical set-up of gauge theory. They're definitely not doing what crackpot particle theorists do, claiming to have a theory of particle interactions that ignores the standard model and its mathematical structure.

33. **plato**
January 2, 2005

Don't be hard on your self Lubos. When one plays with certain models, you can get burned?:)

The basis of the argument could be an + or – thing, and things will oscillate all day long, and no ones happy with the shape of things.:)

34. **Lubo? Motl**
January 2, 2005

The criterion about taking the actual structure and the required math of the Standard Model seriously is of course very important.

Incidentally, Peter, do you agree that not just Wolfram, but also loop quantum gravity and many other directions squarely fall to your definition of crackpotism?

35. **Lubo? Motl**
January 2, 2005

Maybe I should not have written the post about MOND at all if it is misinterpreted.

It's a complete speculation of mine that in cosmological setups, new phenomena may arise.

But there are loads of backgrounds where string theory gives absolutely unique, quantitative, sharp, and theoretically crosschecked predictions for a given Universe, and these contexts of course always agree with GR at low energies.

If someone believes that string theory is mathematically vague, then he completely misunderstood everything about it. The "fictitious" new Universes predicted by string theory, especially those with a lot of supersymmetry, are completely rigid and sharply defined.

36. **Lubo? Motl**
January 2, 2005

I kind of agree with what Peter wrote, and it is comforting to see that he at least looks at the problems in this way. Sorry, I have not read any comments yet, it's just too much of it.

The definition of the past crackpots 30 years ago is much less of a controversy than the definition of crackpots today. I believe that in 2030 they will have a better and more unifiable idea who were the crackpots back in 2004.

The S-matrix, bootstrap approaches etc. were not quite scientifically sound, and it's a matter of historical coincidences that a related line of research has led to something useful and deep – string theory in this case.

But don't forget: the history is written by the winners. The bootstrap people were simply losers, at least in the 1970s, and it makes them much more vulnerable to an attack. A reasonable person will resist the temptation to attack them, especially because some of their ideas were vindicated by recent research in string theory.

I am happy that Peter realizes that most of his supporters are much clearer crackpots than the worst idealized string theorist he can imagine, even though he can't state this fact as clearly as I can (because his blog is partly driven by them). 😉 Crackpots can be annoying, but someone similar to crackpot can, in very special cases, propose a great idea. People have different approaches, and I am sure that Peter understands the huge difference between Lenny Susskind and the unsophisticated crackpots.

Lenny is a genius, in some sense, and this can't be obscured by a couple of talks that many of us find too vague.

37. **Quantoken**
January 2, 2005

Arun said:

"String theorists are not crackpots. The problem with string theory is exemplified by the exchange on sci.physics.strings, where it is said that one can IMAGINE that string theory and holography have their ways to induce corrections needed to explain the Pioneer anomaly and others, and a MOND-like alternative to dark matter. So, string theory embraces both General Relativity and not-General Relativity!!!! In other words, string theory says nothing definite."

String theory and holography could only "imagine" (i.e., wishful thinking) to have a way of explaining Pioneer anomaly. But I see no solid and unambiguous solutions of such published. On another hand, Generalized Universal Information Theory And Relativity naturally leads to prediction of abnormal "acceleration" like the Pioneer, and it gives the correct quantitative calculation.

I used quotation around "acceleration" because it is actually not an acceleration, but a relativity effect proposed by my theory. The two are equivalent just like gravity field and acceleration field are equivalent.

In a nutshell, the principle that the total quantum information in the universe being a finite and conserved quantity, necessarily leads to the conclusion that our spacetime do not extend to infinity. Our spacetime is curved to be enclosed. That's because flat and infinite spacetime would require infinite amount of quantum information to describe and decipher each individual spacetime coordinate point.

Keep in mind when spacetime is curved and enclosed, that does not just mean space. Time is curved, too!

Now, when Einstein developed his special relativity, he made one assumption which is correct in a flat and infinite spacetime, but which is wrong in our universe. Einstein recognize that in different inertial frames, clocks may tick in different speed, and spontaneous events at different locations in one reference frame may not look spontaneous in another reference frame.

However, Einstein did presume that in the same inertial frame, as long as there is no acceleration or gravity to cause the clocks to change, all clocks at all different locations would all tick at exactly the same pace when observed by the same observer. Such an assumption is only true when the spacetime is infinite.

In a curved spacetime, you can NOT have all clocks ticking in exact synch. Having such means the time is still flat and extends infinitely, while as the space is curved and finited. That's impossible. The time axis would necessarily be curved and enclosed too.

So that's the conconsion of QUITAR, there is a universal relativity that any observer will see a clock at a remote location will tick slightly slower than his own. The further away the other clock is placed, the more it is slowed. That slowing is in addition to any special relativity or general relativity time dilation effect. At the edge of the universe, it will be slowed to a complete halt.

The time dilation described by universal relativity is relative: A sees B's clock slower than A's own. But B also sees A's clock slower than B's own.

How do we know two clocks at different locations are ticking at the same pace or not? We may bring the two together to verify they tick at the same pace. But that doesn't tell us because it's position dependent, once you move the other clock away, it slows down again. You can bring them together once in a while to see if the slowness has accumulated, but in the process of bringing them together you have accelerated them and that destroys comparability of the two clock, because acceleration causes time dilation.

In similar reason like Einstein did, the only feasible way to verify whether two clocks at remote distance are ticking in sync or not, is to use light signal as beacon and see if the beacon arrives at the correct interval or not.

And that's what we actually do!!! We observed that the light beacon from remote stars indeed are arriving ever slower, depends on the distance. That, we call Hubble Redshift, has been observed.

You can explain the slowdown of light beacons as evidence that the remote light source is moving away, or you can explain it as a universal relativity effect that remote clocks simply tick slower. The two explanations are equivalent, just as gravity and acceleration are equivalent.

However, the Doppler explanation would have to presume the remote clock ticks at the same pace as ours. We do not have evidence for that. On another hand, remote clock slowing has been mandated by quantum information conservation, which is very reasonable and logical. So, indeed, Hubble Redshift is indeed the universal relativity caused time dilation effect.

The same can be used to explain the Pioneer Anormalcy. Since we presumed the clock on Pioneer would tick in sync., we instead explain the observed discrepancy as an anormality acceleration towards us, the observer. The amount of such "acceleration", based on my derivation, is

(4/PI)*C^2/(Radius of Universe)

Might this satisfy why astronomical valuations in Peter's eyes are not worth doing because of the magnitude of the orders of dollars associated?

Delivered by David Politzer on December 8, 2004 in Stockholm

There is a very active field of theoretical research which seeks to go beyond the Standard Model. Success in these endeavors would mean explaining the apparently arbitrary aspects of the Standard Model; success would mean bringing an account of gravity into the picture; and success would mean illuminating the previously mentioned issues in astrophysics. **However, we now face a very serious problem in advancing the experimental frontier, a problem which few people like to discuss**. It seems to me that ever since Leeuwenhoek, advances in the resolving power of our "microscopes" have come with similar investments of capital and manpower. I.e., an increase by an order of magnitude in the one required an increase by roughly an order of magnitude of the other — at least once we average over fits and starts and brilliant insights. The last big machine planned and canceled in the U.S. was to cost about $10 billion. (That's .) That would have allowed us to reach distances small enough to study the interactions of weak bosons directly. The realm of the conjectured "unification" of the forces of the Standard model, the realm of their possible unification with gravity, and the basic physics of String Theory, the most widely pursued approach to a physics more fundamental than the Standard Model, are all more than a dozen orders of magnitude further away. However, is simply not available for this line of research (or anything else for that matter).

And about Arun's comment about GR. Phase transitions would be reduced holographcally from higher dimensions(the standard model would have been decribed from earlier states), would finally show up there?:)

39. **Peter**
January 2, 2005

Hi Arun,

Actually there was nothing in this posting about string theory. In general string theorists are trying to reproduce the Standard Model, or even use string theory to solve QCD, so they're not crackpots by the criterion I was talking about.

The one part of the recent string theory enterprise that has definitely veered towards crackpot territory is the whole "Landscape" business.

40. **Peter**
January 2, 2005

Thanks for the link to the Politzer Nobel lecture. I'll update that posting to include it.

By the way, I've been closing the comment sections for posts that are more than a couple weeks old. Unfortunately this is necessary to keep the problem of "comment spam" under control.

41.
January 2, 2005

Mathematica makes errors on simple problems? I use Mathematica at times, and if that is really true…

Can you give some examples I can check for myself?

42. **Arun**
January 2, 2005

Using Peter's definition of crackpot, it is only because of crackpots that European sailors broke the confines of the Western Atlantic and Mediterranean.

It is crackpotism if Columbus continues to insist that he has found a passage to India.

String theorists are not crackpots. The problem with string theory is exemplified by the exchange on sci.physics.strings, where it is said that one can imagine that string theory and holography have their ways to induce corrections needed to explain the Pioneer anomaly and others, and a MOND-like alternative to dark matter. So, string theory embraces both General Relativity and not-General Relativity!!!! In other words, string theory says nothing definite.

43. **as**

January 1, 2005

This should have been a comment on the post “Nobel Lecture”, but it looks like it’s not possible to comment on that post.

David Politzer has put his Nobel lecture on his website at
http://www.theory.caltech.edu/people/politzer/

44. **plato**
January 1, 2005

I thought the least I can do is help to lead you in the direction of Penrose and the picture I gave you.

Remember Smolin was quite clear here about the three roads to quantum gravity, that I wonder how this road would seem more comfortable to you then the other two?:)I will wait and see what materializes I guess.

45. **plato**
January 1, 2005

Peter said,*“As long as you stick to this particular variety of speculation, you’ll have no trouble getting all sorts of silliness published. I don’t think this is progress”*

….was in response to Serenus and Brane theory models.

I would think that the brane models would set up new mathematical structures for consideration? If such cyclical natures was to assume an idea about the existance of this universe, then fundamental positions had to be assumed as well? In regards, to building the mathe structures that you want to deal with?

You then assume, that if it has always existed that the ability to formulate such structures would be relevant to the mathe you want to use?

You would have to forgive my ignorance on such technical matters, that I wonder if I should be warying or not, by speculatives opinions coming forth from all areas?:)

Just pretend I am the public, and remember what you are saying.

Already one clarification on the subject of this post, and a reference now to quantum gravity. I think as time goes on, the distilliation of what you want to say, should be mathematically voiced!

This would stand in support of what all of you demand. A position from which you speak in regards to the math you use and speak about the abstract world you deal in.

I would like to see how this world is represented by and what you people speak of, can be married to the real world we live in:)I characterize my self as plato and am well aware of my illusions which I can create and models I can play with.:)

I took a fundamental position of the post presented on crackpotism, and ciphered the demands placed, and was going to deal with the issues of the standard model and how these materialize, but as one realizes, many here who want to hold to a set way of speaking are all over the map.:)

Unbeknownst to you Peter you selected one of three roads to quantum gravity by Roger Penrose?:)

So indeed it can be quite fun to live by the rules that people would like to institute, but do not live by, and maybe then characterize it, as a freeflowing quorum of ideas?:) Non! Qui!:)

46. **Doug**
January 1, 2005

I’ve mentioned before that Hawking characterizes the standard model as “ugly and ad hoc,” and if it were not for the fact that he sits in Newton’s chair, and enjoys enormous prestige in the world of theoretical physics, he would certainly be labeled as a “crackpot.” Peter’s use of the standard model as the criteria for filtering out the serious investigator from the crackpot in the particle physics field is the natural reaction of those whose career and skills are centered on it. The derisive nature of the term is a measure of disdain for distractions, especially annoying, repetitious, and incoherent ones.

However, it’s all too easy to yield to the temptation to use the label as a defense against any dissent, regardless of the merits of the case of the dissenter, which then tends to convert one’s position to dogma, which, ironically, is a characteristic of “crackpotism.” However, once the inevitable flood of anomalies begins to mount against existing theory, no one engaged in “normal” science, can realistically evaluate all the inventive theories that pop up in response. So, the division into camps of innovative “liberals” vs. dogmatic “conservatives” is inevitable, and the use of the excusionary term “crackpot” is just the “defender of the faith” using the natural advantage of his position on the high ground.

Obviously, then, this constant struggle, especially in these days of electronically enhanced communications, has nothing to do with science. If those in either camp have something useful in the way of new insight or problem-solving approaches, they should take their ideas to those who are anxious to entertain them: students and experimenters. The students are anxious because the defenders of multiple points of view helps them to learn, and the experimenters are anxious because they have problems to solve.

The established community of theorists, on the other hand, are the last whom the innovators ought to seek to convince because they have no reason to be receptive to innovation that threatens their domains, and clearly every reason not to be. So, if you have a theory that suggests an experiment that Adam Reiss can reasonably use to test the nature of dark energy, by all means write to him. Indeed, he has publically invited all that might have an idea for an experiment. But don’t send your idea to Sean Carroll because he is not going to be receptive, even though he too publically acknowledged that “we need all the help we can get,” (see the Science Friday archives).

“All the help we can get,” in addressing the problem of dark energy, is to be understood in terms of the standard model of particle physics and the consensus model of cosmology. To suggest to Sean that the 4D “fabric” of space-time is not real, or to Peter that the quantum field fluctuations don’t exist, that they are, in reality, merely ad-hoc expedients employed to solve the problems of earlier generations, is going to inevitably get you labeled a crackpot. No matter how convinced you are of the merits of your innovation, and no matter how strongly they insist that they would entertain logically derived and “observationally supported” arguments, if only they existed, the truth is that they will not! (see Ivor Catt’s experience for a good example in a less complex field.)

It’s not a question of bad guys vs good guys, or smart guys vs dumb guys, or the foolish vs the wise, as much as the adherents to the different camps would like to believe that is in order to boost their egos as innovators or as defenders of the truth. Nope, it’s just a matter of social economics, the only science that might benefit from the study of the phenomenon.

47. **Daniel Doro Ferrante**
January 1, 2005

Wow! Amazing how can such simple a post generate so much noisy! (Sorry Peter, i don?t mean to diminish you, your post, your thoughts, etc… it?s just that i don?t remember seeing this kind of "heat" around here for quite some time now… >8-)

Also, there?s so much stuff here to talk about that i could probably go on and on for quite some time… but, if you guys excuse me, it?s still New Year?s day (here where i am) and i don?t want to miss my family?s cookout! >;-)

To begin with, let me say something which is a lot more pragmatic but, to my understanding, seem to reasonate with the "overall feeling" buried in some of the comments here: "This beautiful idea of freedom and democracy of ideas and thoughts only works on very restricted geographical regions of this planet of ours!" And, if any of you need an example of this, get a plane to anywhere below the equator; i?m sure it?ll be an enlightening experience. (An old joke comes to mind: "Democracy is when i say and you do; Dictatorship is when you say and i do." >;-)

As for Penrose?s comments on the precision of GR, there?s a very nice paper on the arXivs, which also happens to be on The Living Reviews of Relativity, that should help to clarify this issue: .

The new term added to my lexico: "psychoceramics"! Outstanding! >:-)

As for the more serious matter, one thing that is key to all of this meta-discussion but was introduced late into it, is FASHION. Or, as Peter put it, "orthodoxy". I agree wholeheartedly with the idea behind this comment by Peter: "Fashion cannot, and shoud not, lead anything, let alone science!" Unfortunately, because we all happen to be human beings, there?s always a "personal" touch on everything we do. From Newton vs Leibnitz to Clifford vs Boltzmann, science (as any other human endeavor) has been filled with "ego fights". As is usual with most animals, this can easily be translated into "mine is bigger than yours". Even a man like Newton could profit from some (not to say ?lots?) ideas from other folks, like Leibnitz for instance. Ditto for Boltzmann.

But, as we move higher in the "food chain of thought/academia", it becomes increasingly more difficult for us to learn from other people, to take responsibilitie for our mistakes… it becomes harder for us to keep our cool, to be humble.

[Un]Fortunately, or not, (for me, personally) i have participated and been involved in several discussions of the sthereotype "Strings vs Rest of the World". I have heard quite a few people that i respect say quite a lot of things that are just [mathematically/physically] wrong: I know it, they know it. However, no one does anything to change the pattern… (I?m sure that both Freud and Yung would have a LOT to say about patterns and their repetitions. >;-)

There?s a LOT of stuff to be done in physics, in math, in chemistry, in biology, in computer science, etc, etc, etc… in science in general! Using fashion to limit the highway of ideas is simply unfair.

Nowadays, in our posy-industrial society, called "Informatin Society" (not the band: ! >;-), our media/press plays a very crucial role. So, when one of us, physicists and/or mathematician, goes "out there" and writes a book selling an idea… Do you see my point, or should i spell it out?!

Good ideas do not need advertising…

As for Mathematica, the software, PLEASE: "Do NOT feel overwhelmed by it; it is quite crappy!" Do you want to talk about symbolic math…?! Try going back a bit in time and searching for "algebar" (or one of its GPLed versions). Maybe even "derive"! Those were very good indeed; they cared about the algorithms behind them. Mathematica chokes (or gives you the WRONG answer) even on quite simple problems… and this happens basically because they "cranking software" was really crappy! The one thing that it can really do well is plotting and PS graphs! Did you know, or did you ever wondered, why was Mathematica completely rewritten in this past couple of versions?!!!

This is just the begining, the tip of the iceberg… On top of this, the argument that someone smart enough to "create" Mathematica (BTW, Wolfram did not do that alone; there was a huge crew behind him) can be smart enough in some other area; this is called "argument of authority" and, as the name suggests, has very little reasoning behind it. If you really want to argue pro/con Wolfram, i suggest you ready some of his work, maybe from the 80s.

As for me, i do think that he is a quite smart person, i also think that his cellular automata are good for quite a number of things. What i don?t like is the fact that, after you read his bible-book, you have a sense that everything in the Universe has been understood BUT you have no evidence for it. 😉

48. **Quantoken**
January 1, 2005

Steve Wolfram's ideas are interesting but I do not know enough of it to make judgements. But a guy who created Mathematica shurely could not possibly be a complete idiot and there may be some thing in his "new science".

What do you think of Seth Lloyd's "computational universe", Peter:
http://www.edge.org/3rd_culture/lloyd2/lloyd2_index.html

49. **Peter**
January 1, 2005

Hi Robert,

Glad to hear that was a joke, I was worried about you for a minute there.

Actually Wolfram is a perfect example of my particle theory crackpotism criterion. From what I remember his chapter on particle theory pretty much completely ignores the standard model, while claiming that properties of particles can be understood using his ideas about cellular automata (and providing no evidence of this). This is crackpotism in a pretty unadulterated form.

50. **Quantoken**
January 1, 2005

Peter said:

"I should clarify something. My remarks about identifying crackpotism were specifically restricted to the subject of particle physics, where a huge amount of experimental data and a very successful theory exist. Other subjects, e.g. quantum gravity, are a whole different story, and I didn't intend to say anything about the much more difficult question of how to identify crackpotism in that area."

I do not think you can clearly separate particle physics from other areas of fundamental physics theory research. They are interweaved so tightly nowadays, especially in the view that a theory that unified GR and QM will necessarily deal with both the microscopic particle world and the macroscopic cosmological world.

Roger Penrose has his own share of crackpotism. One of his claim that impressed me very much is that he claimed often that GR has been verified to be correct up to 12 decimal places. One would thought that means to find any discrepancy between the GR and the nature one has to look beyond the 13th decimal place after the decimal point. What he actually meant is in the binary pulsar observation data by Taylor, who got a Nobel Prize for it, has to be accurate up to 12 decimal places to show any GR effect at all. If the accuracy of the observational data is less than 12 decimal places, then the GR effect portion would be too weak to be seen and be buried in statistical noise.

So the 12 decimal places claim actually put the Taylor data into credibility question. The raw data of individual pulsar pulse period is in no way accurate at all: they vary by as much as a few percentage. Only though statistical average of bizillions of data can you achieve better accuracy. The question to ask is did Taylor's statistical model really provide that 12 digits accuracy through statistical average?

Back in the 70's there wasn't even a 32 bits computer CPUs yet, so the computers can't even represent a number up to 12 decimal places. I checked the Fortran computer code of the original software Taylor used, there wasn't even any data types of double precision floating points defined in Fortran language at that time. Even on a 32 bits PC today, double precision floats, which takes 64 bits, gives you just 19 decimal places accuracy.

That puts Penrose in the rank of Sr. Eddington, who claimed his observational data from 1919 solar eclipse, obtained using a portable 4 inch telescope he brought to South America, confirmed the GR prediction of 0.75″ star light bending near the Sun's surface. In reality, neither the optical resolution of his 4 inch telescopy, or the exposure film, or the disturbance of atmosphere "seeing", would have allowed any credible measurement of that tiny bending.

When looking at experimental data, you have got to take a grain of salt. There are too much of an urge to bend the data to fit what one believes in, for various none-scientific reasons. And too little effort spent on verifying the credibility of experimental data. The "12 decimal places" of the Penrose kind is a good example.

51. **RT**
January 1, 2005

"Wolfram a great man comparable to Newton? I know that's what he thinks and tells everyone, but really…."

I was joking, honest (cf 'Mathematical Humour'). An attempt to introduce a note of levity into a debate that seems only too ready to lurch into the realms of acrimony. As an engineer/applied physicist, I found Penrose's book to be enlightening, entertaining and educational in equal measures. For what it's worth, many of my professional colleagues regard all theoretical physicists as crackpots, and my interest in their world as a signature of senescence.

52. **Peter**
January 1, 2005

Wolfram a great man comparable to Newton? I know that's what he thinks and tells everyone, but really….

I'm still not quite up to writing about Penrose, but, no, he's not a crackpot. He takes the standard model quite seriously, has an interesting discussion of it, and is properly skeptical about it just where it deserves skepticism (the Higgs mechanism). His speculative ideas about twistors have already had interesting implications for the standard model (in finding solutions to the Yang-Mills equations, recent "twistor-string" formulation of perturbative N=4 super Yang-Mills) and it is quite possible that more will be found.

I should clarify something. My remarks about identifying crackpotism were specifically restricted to the subject of particle physics, where a huge amount of experimental data and a very successful theory exist. Other subjects, e.g. quantum gravity, are a whole different story, and I didn't intend to say anything about the much more difficult question of how to identify crackpotism in that area.

53. **RT**
January 1, 2005

I look forward to finding out whether Sir Roger qualifies as a crackpot or not; the criteria Peter lays out seem a little stringent. And, almost without exception, great men, from Newton the alchemist to Wolfram the WANKOS, exhibited a touch of the balmpot at some point.

54. **Peter**
January 1, 2005

Hi Serenus,

I don't think that what has happened is that speculation is now encouraged, whereas it wasn't earlier. If you try and get something published that goes against orthodoxy (as an example, let's say you have an idea about how to make sense of theories with anomalous gauge symmetries), you'll still have a lot of trouble with referees. All that is new is that certain outlandish speculative ideas (e.g. brane-worlds) are now part of the orthodoxy, heavily funded by the NSF and promoted by prominent theorists. As long as you stick to this particular variety of speculation, you'll have no trouble getting all sorts of silliness published. I don't think this is progress.

What's wrong with brane-world scenarios is that they are ugly and don't actually predict or explain anything. The fact that you can work on them and have a successful career, while if you work on something less orthodox you'll have a lot of trouble, is at the root of a lot of the problems of the field.

Peter

55. **Quantoken**
January 1, 2005

Peter:

Don't you realize that crackpotism is a relativistic term? You call the string camp crackpotism, and they call you crackpotism. The string camp call the LQG cracks and so does LQG call the string camp. So who deserves to be the ultimate judge on this matter? Everybody? Nobody?

It's a relativistic term. Please do not abuse its usage. I would not use that term to criticize string theory, LQG or any theory in exploration. Certainly there do exist true crackpotisms, like perpetual motions kind of thing. Those stuff challenges well established theories and experimental evidences and are crackpots.

On the other hand, in the field of searching for a theory that unified both GR and QM, there has not been a single winner yet. There simply hasn't been any established theory in this area. So people from different camps really can not call each other crackpots.

Before a clear winner is well established and well confirmed by experiments, every potential theory could potentially be right and equally potentially be wrong. The only rule is the theory must be able to arrive at known limits and agree with known and established theories, GR and QM.

GUITAR does give the GR and QM limit and does not violate any of the established theories. It makes clear predictions that can be verified or ruled out by future experiments, predictions that is completely reachable in technology in near future. It explains a lot of things including CMB and Hubble Red Shift, and it even explains the origin of the uncertainty principle, all in a very natural way. My theory could still be wrong at the end of day but it is definitely not crackpot.

Quantoken

56. **Serenus**
January 1, 2005

"Famous professors from the best research institutions in the world go on about the properties of the universe being determined by colliding branes, or by an anthropically determined point in a multiverse, or any number of similar ideas."

There was a time, not so long ago, when the top journals routinely rejected papers for being "speculative". In effect, dull technical papers were preferred over anything that might look imaginative and interesting. Do you really want to return to the bad old days, Peter? I thought you only objected to the *overselling* of new ideas, but it seems that I may have been mistaken. What exactly is so awful about brane-world scenarios, as long as nobody pretends that there is observational evidence favoring them?

57. **JC**
January 1, 2005

I always thought that looking at crackpot "freakshows" was similar to activities like watching a car wreck and/or high speed police chases live on television. It's a bit like the equivalent of intellectual "junk food" for the brain, and a cheap way of indulging in a schadenfreund guilty pleasure in seeing the silly depths some folks are willing to lower themselves to.

58. **Peter**
December 31, 2004

Marko, thanks for the new vocabulary word!

About "Out of This World": if I thought that my review of it was likely to cause its author to immediately write another similar one, I certainly would have thought twice before doing it.

59. **Marko**
December 31, 2004

I believe the term used nowadays is "psychoceramics".

60.
December 31, 2004

Peter, look in the mirror. You are the one posting entries on books reviews for infinitely silly books such as "Out of this World". Why don't you take your own advice and just ignore it?

61. **Peter**
December 31, 2004

I wish people would start taking my advice, which I'll repeat here:

"The first line of defense against people who you think are not making any sense is to just ignore them. Do not give in to the temptation to point out to them that they are not making sense, because all this will accomplish is to clutter things up as they respond to your response to them."

62.
December 31, 2004

I don't suppose D.R. Lunsford will ever be banned despite his enormous arrogance in calling a *mathematical* physicist such as Witten a failure while paradoxically demonstrating his admiration for other predominantly *mathematical* physicists such as Dirac and Einstein. Those who have developed ingenious physical apparatus for experiments are not on his list, and then he has the gall to predict the decline of "western science" (whatever that is) because of its preoccupation with mathematical toys? Frankly, I don't understand why ST was not a natural progression (eg. Lunsfords belief that it was obviously 'horseshit' from the outset) from the standard model (see below)

Quantum Field Theory in a Nutshell
by A. Zee

"It struck me as limiting that even after 75 years, the whole subject of quantum field theory rooted in this harmonic paradigm, to use a dreadfully pretentious word. We have not been able to get away from the basic notions of oscillations and wave packets. Indeed, string theory, the heir to quantum field theory, is still firmly founded on this harmonic paradigm. Surely, a brilliant young physicist, perhaps a reader of this book, will take us beyond"

63.
December 31, 2004

"Do not give in to the temptation to point out to them they are not making sense…all this will accomplish is to clutter things up as they respond to your response to them"

I totally agree Peter. They crave attention, good or bad. I am afraid I am guilty of having responded a couple of times this week, for which I apologise. As much as I like vigorous scientific debate, it is clear that you simply can't have any with a crackpot at all–they are only interested in "their theory" and condemn just about everything else. I would say the difference between a real scientist/physicist and a crackpot is that the real scientist does not really believe their own ideas but treats them with a kind of playful irrelevance, and are the first to try and find fault with their own ideas. If it is right or is promising, great, if not them move onto something else. I think it is ok to work on strange stuff if you keep this sober attitude. You are trying things out a lot of the time and seeing where they might lead…if anywhere. I would hope that most string theorists have this attitude, and I think most of them do (the best ones anyway).

Much of theoretical physics and mathematical physics is like an advanced form of play for the human mind I think, but if you get completely obsessed with an idea and start ignoring all feedback and interaction the potential for self delusion is really vast.

The crackpot is charactersied by being totally obsessed with his ideas or one idea no matter how absurd, and absolutely nothing can convince them otherwise. They simply don't understand how science works. Rather than work on some small problem their theories are always "revolutionary" and everyone else is wrong or has missed the point. It must be some sort of psychological condition characterised by delusions of grandeur (I have the ultimate final theory) plus paranoia (the physics establishment wants to censor me and my ideas). Theoretical physics seems to attract them.

64. **JC**
December 31, 2004

Peter,

After the 1960's, how common were the hardcore analytic S-Matrix bootstrap guys like Fritjof Capra, who did not really pay attention to the Veneziano string stuff?

When I was bored one afternoon, I decided to go through several old journals searching for analytic S-Matrix bootstrap papers during the 1970's and 80's. The one thing I noticed was that there were less and less equations in those bootstrap papers as time went on. Many of Geoff Chew's later papers seem to be devoid of equations, especially in his "topological" bootstrap stuff from the late 1970's and early 1980's. At that point Chew could possibly be certified as a genuine "crackpot".

More Science Fiction

January 2, 2005
Categories: Book Reviews

It seems that every week there's a new book out about branes, M-theory, the multiverse, etc. by someone who doesn't really seem to understand the difference between science and science fiction. This week's example is Michio Kaku's Parallel Worlds: A journey through creation, higher dimensions and the future of the cosmos.

My impressions of the book come from a few minutes spent flipping through it in the bookstore, so maybe I missed something. The only reference I saw to the lack of any experimental evidence for anything he is writing about was where he noted that we'll need to travel faster than the speed of light to get to these parallel universes. So, we just have to wait for the development of warp drives. While references to experimental evidence were lacking, there were plenty of references to various science fiction novels.

I recently ran across a review of one of Kaku's very similar other books, called "Hyperspace". My favorite line in the review was near the end:

"Hopefully some time-traveler will go back and prevent this book from ever being published!"

Comments

1. **plato**
   January 4, 2005

   If one had to sum up Gr, how would you do it?

   Never mind about the lesser degrees of intelligences and references to angels and all kinds of things. You follow the history, it leads you where?:)

   As a laymen, I would have had to think about this very hard and assume it was about gravity, but of course once you meet this idea, all of a sudden you wonder what is being emitted? Taylor and Hulse have graduated the ideas for us in those elliptical paths that Mercury orbited to the discoveries of …..?:)

   So you move from this point to learn, what the historical forbears have revealled in their journies and come to meet Wheeler and Kip Thorne. Webber, and his alumininum bars and you understand that detection systems, are now being developed and have been employed.

   If you do not keep abreast of this continuing developement then of course one would become dismayed, about the new direction GR has gone?:)Numerical Relativity?

   So in weak field manifestations, you had to know that early cosmolgical consideration would have already included the standard model, and look to incorporate gravity into a whole view of the cosmo from planck epoch to now.

   Yes, the early uinverse and the symmetries involved of course in question:)

   Rest assured that we are talking about the cosmological discernation of the geometry thats leads us to consider, other things(topological considerations), and how quickly this is dimissed?

   I have heard Peter speak about the ideas of Reimann and the fruitless direction this has gone and am equally dismayed at how this could not have been estimated from a geometical standpoint not to have questioned the quantum mechanical discription of the small world[quantum geometry](it's incapatibilty GR) with the quantum world becoming very large?

   So again, it is a easy enough assumption to realize that the model in question changes what we view of the spacetime fabric, and becomes it? It then asks about light and if this is included, how would you ever get to what Smolin would have wanted in the Glast determinations as the final deal?

   This is what I have surmised, and I could be wrong:)

   This is a easy enough assumption about energy sources(gamma ray bursts) and the information that is release? Some would be very happy with the ideas of the compton scattering(glast determinations) that has gone on, to help us determine this information, as well as what will be revealled to LIGO and the SETI computers users, being utilized?

   This goes to Gerard Hooft's question of how much information could ever be assembled at such levels, that strings would have implied, that he would have been quite happy I am sure, with the way in which the SETI user screens are being utilized.

   I hope my asseessment has been correct and am open to any corrections.

2. **serenus zeitblom**
   January 4, 2005

   Were you referring to the s.p.r thread on whether Special Relativity is diffeomorphism invariant?

   Indeed I was. The thread title was "symmetries of GR" or something like that. One of the many things I found amusing at that time was LM's insistence that Carlip and I "wanted" general covariance to become meaningless. I guess we two are just a pair of terrorists who should be dealt with by the US army.

   I think Bertrand Russell's ABC of Relativity is a prime example of a bad popular book.

   Well, it's a very old book that probably reflects the majority view of the subject at that time. Nowadays we think about relativity very differently, but most popularizers, together with those who depend on them for an education, are stuck in 1920. In many cases this is just laziness — people writing books about string theory aren't really interested in telling you about the foundations of GR, so they just copy all the old junk about angels pulling up elevators etc, so that they can quickly get on to what really interests them.

3. **plato**
   January 4, 2005

   After consideration, I think I am in need of a exorcism?:)

   New post should turn up later, in real time:)

Cynicism can run from higher dimensional existance, to manifest as real emotive qualities called, human action, or words?

So if I attack cynicism from the right angle, I should be able to convince?:)Good thing, we have standards from which to proceed.

4. **D R Lunsford**
January 4, 2005

All the text below was Anderson, not I, notwithstanding software post mangling.

-drl

5. **D R Lunsford**
January 4, 2005

PW Anderson writes this morning in the Times, in response to the question "What do you believe but cannot prove?" –

Is string theory a futile exercise as physics, as I believe it to be? It is an interesting mathematical specialty and has produced and will produce mathematics useful in other contexts, but it seems no more vital as mathematics than other areas of very abstract or specialized math, and doesn't on that basis justify the incredible amount of effort expended on it.

My belief is based on the fact that string theory is the first science in hundreds of years to be pursued in pre-Baconian fashion, without any adequate experimental guidance. It proposes that Nature is the way we would like it to be rather than the way we see it to be; and it is improbable that Nature thinks the same way we do.

The sad thing is that, as several young would-be theorists have explained to me, it is so highly developed that it is a full-time job just to keep up with it. That means that other avenues are not being explored by the bright, imaginative young people, and that alternative career paths are blocked.

6. **Arun**
January 4, 2005

S.Z.,

Were you referring to the s.p.r thread on whether Special Relativity is diffeomorphism invariant?

—-

I think Bertrand Russell's ABC of Relativity is a prime example of a bad popular book.

-Arun

7. **Dolomite**
January 4, 2005

I've never seen any of his popular books, but I once made the mistake of buying one of Kaku's graduate level textbooks on String theory. The table of contents looked quite impressive, but the body of the book turned out to be a smorgasborg of equations from the various original papers, but with the symbols changed around in a failed attempt at making the different chapters look consistent, in the process removing much of the logical connective tissue and adding in typos. All in all negative value added. I've regarded him as a charlatan ever since.

8. **serenus zeitblom**
January 3, 2005

The usual response to criticisms of popular books is: what harm do they do? The answer was provided to me back in October 2003 when Lubos Motl very unwisely got into an argument with — of all people — Steve Carlip about the foundations of general relativity. It soon became painfully clear that LM had never taken a formal course in GR and had, in fact, derived all he knew about GR from reading popular books. The whole fiasco ended with Steve Carlip having to remind LM that it is actually quite Ok to use polar coordinates in special relativity! The problem of course is that popularizers tend to hand down basic misunderstandings from one generation to the next, so the account of GR you get in most of these books corresponds to Einstein's understanding circa 1912 when he was professor in Prague….

9. **Dave Bacon**
January 3, 2005

I saw Michio Kaku on Tech-TV (before it merged with G4) a few years ago. He talked about quantum computers. He said that the beauty of quantum computers was that they could efficiently multiply numbers. I almost went and burned his field theory book on the spot.

10. **D R Lunsford**
January 3, 2005

I like Kaku's field theory book, and he seems like a normal, straigtforward person in interviews (that is, not another carnival barker). Maybe he writes these books just to make money. Maybe his grad students write them for him for a cut. Certainly his "real" book is not full of hyperbole and sensationalism.

11. **quantoken**
January 3, 2005

Peter said:
"It seems that every week there's a new book out about branes, M-theory, the multiverse, etc. by someone who doesn't really seem to understand the difference between science and science fiction. This week's example is Michio Kaku's Parallel Worlds: A journey through creation, higher dimensions and the future of the cosmos."

Peter, looks like you are the one who does not understand the difference between science and science fiction. When you see a book in a book store, you should be able to clearly make a determination if this is a science book or a science fiction book, based on its content, not what the author claimed to be.

If I am a book author, I surely want to write a science fiction book and some how make it look scientific. Science fiction books sell better, especially those disguist as science books.

Any talk about things not happening in THIS universe, are pure fictions or religions, not science. Because science deals exclusively with this universe only, which is the only thing accessible by observation. So next time some one meantioning multiverse or alternative universe, you should automatically know it is not about science but fiction.

Now Lubos, are you really going to accept my criticism against the fatal error in your paper, and not even try to say a word to defend yourself? Admit defeat! You take derivatives against continuous space and time at Planck Scale where continuous space time simply do not exist. So the rest of your paper looked nice mathematically but are simply rubbish.

Quantoken

12. **Peter**
January 3, 2005

Sure, the book does go on about CMB, COBE, WMAP. But as you know well, the experimental CMB results don't provide any evidence for strings, branes, M-theory, the multiverse etc.

I didn't look closely enough to see whether Kaku explicitly acknowledges this. If he doesn't, his inclusion of reference to these experiments is just intentionally misleading.

13. **Lubos Motl**
January 3, 2005

I thought that this book spent a lot of time with experimental cosmology, such as WMAP, COBE, and others. Was I really wrong?

14. **Peter**
January 3, 2005

Hi Eleggua,

My comments about "Parallel Worlds" not explaining anything were directed at the idea of different universes being part of the same "multiverse", not at the many-worlds interpretation of QM.

I don't have anything much to say about interpretational issues in QM. These are something I've never found relevant to questions that do interest me. I am a big believer in Occam's razor, and it is not an argument against quantum fields. QFT is by far the most conceptually simple and compact theory that covers all the different things we know about how elementary particles behave.

15. **plato**
January 3, 2005

Correction: *Denmark*, should read **Vienna** in previous post.

16. **plato**
January 3, 2005

I really do not know what Peter means when he only has a slight look at what is being exposed to him from others opinions?:)I am to assume he read them?

No less then what I can give him and then to say, that if the brain as a muscle was not exercised, one would not have understood the comments made immediately by Michio Kaku about his artistic expression of the vision from the bridge and speaking about the gold fish:)

Imagine the surface of water and looking at it from two different perspectives:)

Not that I am a defender of the faith, but for sake of the abstract developement of the brain to move in the higher dimensions, he would have missed the obvious.

If the brain was further developed, one could also have distilled the understanding that part of crackpotism was not to have encourage discussion or respond, so I develope knowing full well, that resignation is always much easier, then being truely honest about how one could have become so cynical, no less then the psychological developement, of others.

Hmm…where to now?:)

To poster below me.

What was developed in Denmark(quantum entanglement) was a materialization of the points Penrose highlighted as a question.

THis is part of Smolins developmental attitude, as well as strings graviton graviton intersectional ideas that have yet to be developed.

Lubos might see the significance of the work he spoke on earlier in regards to gravitational lensing and clumping in the early universe:)

17. **Eleggua**
January 3, 2005

Hi Peter,

Now that I have had a look inside the book at my local bookstore, I see what you mean.

However, I am interested in your statement:

'The problem with "Parallel Worlds" is not that they aren't observable, but that they don't actually explain anything.'

Now, I am interested in what you think about the field of quantum computers.. In particular the statement by David Deutsch in Fabric of Reality that how do you explain the working of a quantum computer without parallel universes?
Of course, you can say that it is just Quantum parallelism, but I have never seen a DETAILED explaination of what Quantum parallelism would be for Quantum computers outside the Many-World scenario! (I would be very interested in references for such a thing!)

Anyway if you believe in the Many World scenario, surely it EXPLAINS away all of the problems in QM regarding measurement in a natural way?

I understand that Occam's razor could be used against it, but I believe Occam's razor can be used against Quantum Fluctuations in QFT as well!

Thanks in advance for any reply

18. **Peter**
January 2, 2005

Hi Jesse,
I wasn't trying to promote anything about that review other than the snide line about time travel. I couldn't care less about whether Kaku is a "materialist", dialectical or otherwise.

Hi Eleggua,

The book definitely contains large sections of material about branes, strings, M-theory, etc. The part about many-worlds seemed to me to be a small fraction of the material I saw there.

No, I'm not really a positivist. If a simple theory that successfully explains a lot of observed phenomena is based on some unobservable objects, I'm happy to believe in them. The problem with "Parallel Worlds" is not that they aren't observable, but that they don't actually explain anything.

Peter

19. **Jesse M.**
January 2, 2005

Some of the statements in that guy's review sound pretty crockpot-ish themselves. For example:

[However, it is all too easy to cook up theories that produce "predictions" that you already know the answers to, and then pretend the theory is thus a great success! Cosmologists are always doing this (e.g., with the Big Bang theory); indeed it seems to be their basic modus operandi.]

Or how about this:

And as presented by Kaku, string theory is essentially idealist besides. Pythagoras and Plato would have loved it; it is one of those theories that claims that matter and energy are composed entirely of "geometry". Although Kaku does not mention it in this book, these "strings of vibrating hyperspace" are assumed in the theory to be strictly one-dimensional, that is to say, geometric objects, not physical objects. He does constantly say in the book that the whole goal is to reduce physics to a geometrical theory. No real materialist can possibly acquiesce in the idea that the world is truly composed of geometric, rather than physical objects. All geometric concepts, such as points, lines and circles, are abstracted from physical objects in the real world, such as tiny things like dust motes, rows of things like pencil lines on paper (which are really composed of numerous graphite particles), etc. But points, lines, and other geometric "objects" do not literally "exist" in the world, and the world is certainly not "made" out of them!

The idea that the basic elements of reality should conform to preconceived ideas about what "physical objects" are supposed to look like is an idea Feynman disparaged in chapter 2 of *The Character of Physical Law* ('The Relation of Mathematics to Physics'), and it sounds pretty close to #17 on John Baez's crackpot index:

10 points for arguing that while a current well-established theory predicts phenomena correctly, it doesn't explain "why" they occur, or fails to provide a "mechanism".

20. **Eleggua**
January 2, 2005

As far as I can tell, Michio Kaku's book is NOT about String Theory, or Branes, instead it is about the many worlds hypothesis and theories about cosmology similar to Max Tegmark – see http://www.hep.upenn.edu/~max/.

Now, I understand that the Many World hypothesis is not strictly testable, but are your views about science really as positivistic as you are making out in this post? I mean Science has many concepts which are not observable like information/energy/action but have proven useful in the past!!!

Thanks for your reply in advance Eleggua.

21. **Peter**
January 2, 2005

You can't really blame the publishers on this one. These books are written either by people with serious academic credentials, or by science writers quoting such people. The problem is not that publishers are passing off science fiction as science, but that scientists are doing it.

22. **JC**
January 2, 2005

For many book publishers, isn't revenue maximization the main goal of their enterprise? Whether something is correct in factual and/or scientific terms, seems to be a secondary concern for many publishers. This is possibly one of the reason why there zillions of books on subjects like UFOs, astrology, ESP, political ideologies, etc …

The only time they seem to be concerned about getting things factually correct, is when there's the potential of a libel or slander lawsuit.

Anderson and Others at the Edge

January 4, 2005
Categories: Uncategorized

Several people wrote in this morning to tell me about Phil Anderson's comments about string theory that appeared in the New York Times today. These originally come from John Brockman's "Edge" web-site where he has gathered responses from more than a hundred scientists and others to the question "What do you believe is true even though you cannot prove it?".

Beside's Anderson's answer, also interesting is Paul Steinhardt's. Steinhardt refers to the currently fashionable use of the anthropic principle as "an act of desperation" and "millennial madness", notes that the Weinberg anthropic "prediction" of the cosmological constant gives the wrong value, and even acknowledges that string theory may just be wrong. For sheer weirdness, as usual these days, Lenny Susskind is hard to beat. Brockman doesn't seem to have located any string theorists who believe string theory but can't prove it. Since it can't be proved, I guess even they don't believe it anymore.

Phil Anderson has always been somewhat of an intellectual hero for me. He's really the person who discovered the Higgs mechanism, among many other things. Despite a reputation for being a curmudgeon, at one point he was quite kind to me. At some sort of social event at Princeton to mark students passing their generals, he came up to me and told me that he had graded my solid state physics exam. He complimented me on one problem in particular, one I had got wrong. I had realized something was wrong with my solution of that problem, noting on my exam that the result I was getting couldn't be right and explaining why. He told me that this had impressed him, that one should always know what the result of a calculation should look like before attempting it.

1. **Chris Oakley**
   January 6, 2005

   Ah yes, I remember this: T & V rishons, or whatever they're called. The sub-structure of quarks and leptons. Maybe when someone constructs a satisfactory relativistic theory of bound states we'll be able to see whether we can test Harari's ideas beyond the mere counting of quantum numbers.

2. **Chris W.**
   January 6, 2005

   See Haim Harari's response.

3. **plato**
   January 6, 2005

   I guess if we are to take you Peter at your word, about where we should spend our money, then such avenues of exploration are then unsuitable?

   A lot of people are picking up on Steinhardt, but lets say we discover something in regards to Planck, how would this effect areas of quantum geometry?

4. **Peter**
   January 5, 2005

   I don't think mathematical physicists doing string theory have gotten any funding that would otherwise go to molecular biologists.

   There's also no evidence that the overhyping of string theory, M-theory, branes, etc. in recent years has lead to any funding for new accelerators. The only thing that has gotten extra funding because of this are the grants going directly to those theorists doing the overhyped work.

5. **Anonymous**
   January 5, 2005

   Freeman Dyson's answer was the coolest.

6. **James**
   January 5, 2005

   Curious layman has two questions

   1. How can you attract large scale funding from either public or private sources without all the nonsensical hype(eg. wormholes, etc). In otherwords, you came clean and stated the impact on everyday life would likely be much smaller than even GR plus you have to pick up a huge bill from the cost of a collider. How do you sell that?

   2. RE: needless complexity of the mathematics. I read where the mathematician Rota stated that developments in knot theory and braids would probably be necessary to solve a lot of problems in *both* physics and biology (eg. protein folding). It has always seemed to me that mathematicians have played a minor role in molecular biology. Could it be that the umbrella of 'String Theory' is a clever backdoor for mathematical physicists to secure significant funds in an attempt to elbow into the turf of molecular biologists?

7. **plato**
   January 5, 2005

   Reading the developement of someone else's thesis is interesting approach to encourage further thought developement?

   That we know full well model comprehension can stimulate other areas, and is always worth looking at for execising the brain's further possibilties:)

   It is vital that such developement understand the evolution of geometrical design(roads to to higher dimensions) to include topological considerations, as part of the developing framework?

   The one common thread relating the twentieth century higher-dimensional models of the previous section is Klein's compactification paradigm. Standard Kaluza-Klein, supergravity, and superstring theories all explain our seemingly (3+1)-dimensional world via compact topologies for extra dimensions. However, one the sidelines there have been concurrent models that do not make use of Klein's idea; models that either make no assumptions about the size of extra dimensions or hypothesize that they have macroscopic extent. Up until very recently, such models were outside of the mainstream because of a fairly strong prejudice in favor of compactification. **But there**

has been a notable change of heart in the community at large, and there is currently a huge amount of interest in models that involve large extra dimensions, which we will now proceed to describe

I know what people think in general about these proposals, but I highlight the question here* above.

8. **Chris Oakley**
January 5, 2005

"In the case of special relativity, the reason why causality implies vanishing commutators at spacelike separation can be found in any textbook"

Not really. The best you can find is the notion that currents comprised of bilinear products of fields commuting for spacelike intervals implies commutation or anticommutation of the fields. It is just *assumed* that commuting currents mean causal separation.

The problem, AFAIC, is *what* currents? Physical states are of positive energy & so the same thing should apply to non-local convolutions of the currents formed by filtering out the positive energy parts. However these do *not* in general commute for spacelike intervals, even when the correct spin/statistics connection obtains.

Causality is in any case about the flow of information. What exactly one means by "information" is hard to define at the quantum level and what one sees in the text books – when they bother to address the matter at all – is (to my mind) far too glib.

9.
January 5, 2005

There are some interesting things here, but I've always thought Edge was one of the (untentionally) funniest sites on the Internet. Something about giving people enough rope to make fools of themselves.

10. **D R Lunsford**
January 5, 2005

Thomas,

C is independent of causality, micro or macro! That is, homogeneity and isotropy of space and time produce a light cone structure – whether or not the world is causal (how it *uses* that structure) is not determined at that level.

11. **ksh95**
January 5, 2005

Aperion wrote:

…and then, in the real future perhaps, trumpet the accuracy of the few that turned out to be correct. Is this not really pretty silly?

Relax, not everything in life needs to fit into some perfectly rigid framework. Sometimes, it's ok for things to be just fun or entertaining. It's not like the edge is PRL.

BTW

I can't stand all this talk about Occam's razor??? Nature feels no obligation to follow our wishy-washy, sorta-kinda, maybe-sometimes statements, and neither do I.

I propose a new scientific guiding principal. We'll call it Ksh95's Razor.

He who is guided by imprecise, unrigorous, folksy wisdom is an idiot.

12. **Thomas Larsson**
January 5, 2005

In the case of special relativity, the reason why causality implies vanishing commutators at spacelike separation can be found in any textbook, which can explain it much better than me. In general-covariant theories, 3+1 decomposition and the very notion of spacelikeness is problematic, as has recently been emphasized by Savvidou. Her (and Isham's) History Projection Operator formalism is philosophically close to what I suggest. However, she does not explicitly introduce an observer and can hence not formulate observer-dependent anomalies.

However, I tend to understand locality more intuitively. The problem with fundamental, non-local objects is that we cannot transmit information faster than the speed of light (or so I believe). So one endpoint of the string does not know what the other is doing, but only what is was doing a string-length/c ago. This is OK for real-world strings made up of atoms, but it just seems to be wrong for fundamental strings. The same argument applies to non-local observers. One part of a macroscopic, real-world detector does not know what the other is doing in this instant, but that is OK because it is made out of point-like quarks, gluons and electrons, which should be regarded as the irreducible observers.

It might be possible to transmit information faster than light over Planck-scale distances, so microscopic strings might (just might) be consistent with macrocausality. However, the by far simplest way to prevent superluminal signals over macroscopic distances is to forbid superluminal signals over microscopic distances.

13. **Chris Oakley**
January 5, 2005

Thomas,

I am thinking about this problem too. One could argue that the observed spin-statistics connection is excellent evidence for microcausality but personally I am still a little puzzled as to why (anti-)commuting operators for spacelike intervals should necessarily be the expression of the latter.

14. **Thomas Larsson**
January 5, 2005

Chris W ,

It might also help to ask what could physically motivate the transition (at the classical level) from point particles to 2-dimensional objects tracing out worldsheets in *spacetime?*

There are strong physical motivations for **no** transition from point particles to 1D strings (or higher-dimensional branes): locality and causality. These properties, which are fundamental consequences of special relativity, are automatic in point particle QFT by construction. You don't need to be Einstein to realize that there might be problems with locality in a theory of non-local objects – evidently it's enough if you are Gross (though apparently it took him 20 years to take this problem seriously).

One should distinguish between microcausality and macrocausality, where the border between micro and macro is perhaps at 1 fm. Macrocausality is firmly established and will not yield, but microcausality can of course never be tested – you can only push the demarcation line. However, just because microcausality cannot be experimentally tested does not mean that it is violated. QFT is microcausal, and that suffices for macrocausality. From this perspective, the idea of cosmic strings is really outlandish – how can you apply the cluster decomposition principle to a fundamental cosmic string?

I am convinced that the answer lies elsewhere. In QM, observation is a complicated, non-local process, and as such it is in conflict with the spirit of locality and (special) relativity. To make observation into a local process, one needs to assign it to a definite event in spacetime, and to treat the observer's trajectory as a material object to be quantized together with the fields. This is clearly a very small fix to the logical structure of QFT, and it does not really involve any new physics, but it has a profound consequence: new types of gauge and diff anomalies arise, which cannot be seen in conventional QFT because the cocycles are functionals of the observer's trajectory.

This does not rule out any new physics, of course, although observations do not seem to indicate anything beyond the SM and GR. But no matter what happens in future experiments, the insight that we need to localize the process of observation and that this leads to new anomalies can not be undone.

15. **Chris Oakley**
January 5, 2005

    Excuse me for pointing out the obvious, but if one applied the Principle of Parsimony, aka Occam's Razor, consistently, one would never have arrived at String theory in the first place.

16. **Apeiron**
January 5, 2005

    btw – bad spelling intentional

17. **Apeiron**
January 5, 2005

    I'm leaving this post – as admittedly a low investment observer.
    Observations:

    -Typical Question –

    Peter:- String theroy is so terrible – Lubos Motl is an idiot!

    Lubos:- Peter is not even qualified to understand why my superior knowledge is vodka-stle-eastern-european-vodka correct.

18. **Chris W.**
January 4, 2005

    Chris O,

    Given my characterization of string/M-theory as a theory generator, Occam's razor is more properly applied to the theories (models*) it generates. The question then becomes, what physical principles can we invoke to select among the generated theories?

    Consider general relativity. Its formulation in terms of Riemannian geometry inspired the consideration of numerous alternatives using more or less the same mathematical framework. The latter could be looked upon as a meta-theory from which one could draw many candidate physical theories for describing gravitation, some claiming to incorporate other physical fields in some kind of unification. However, the physical ideas underlying GR result in a remarkably restrictive sieve for choosing among alternatives; indeed, in the end it is hard to come up with viable alternatives.

    At least, this was the case before quantum gravity came on the scene, with GR regarded as a low energy effective theory. The question now becomes (in the QG context), what physical principles can help us select among the mess of alternatives offered by the string/M-theory meta-theoretical framework? After two decades of investigation we still don't know. It might help to at least state the problem in this way.

    It might also help to ask what could *physically* motivate the transition (at the classical level) from point particles to 2-dimensional objects tracing out worldsheets in spacetime? (Taking "physics as geometry" to the next level doesn't cut it, in my opinion; more on that later.) The original motivation in hadron physics seems completely irrelevant now. What should (or could) replace it? The mathematical discoveries that enthralled Witten and others in the early 80s strike me as things calling for an explanation—for deep physical insight—not just a mathematical treasure hunt.** Of course this is especially difficult when the original physical motivation is so obscure, and the mathematical territory is so vast and intriguing in its own right.

    —
    * BTW, I've always had some discomfort with the term *model*, regarding it as something of a weasel word.

    (** Peter's recollection of his encounter with Philip Anderson is relevant here.)

19. **Peter**
January 4, 2005

    Sorry Danny, but I'm a big believer in minimizing the amount of trouble software brings into your life by sticking to the defaults when they are something you can live with, and this default is something I can live with.

20. **D R Lunsford**
January 4, 2005

    Oak –

    How right you are! In fact KK theory is the ultimate theory generator. If you can make bowling balls generally covariant, you can strike up a theory of unified bowling ball gravity in your spare time. Then you can refer your theory to a moving frame. Of course, in the end you'll still never make a 7-10 split.

XXXXXXXXX/

21. **D R Lunsford**
January 4, 2005

Peter – aside – could you please change the font color to "black"? For some reason the MT people think charcoal grey is a nice default color for text.

Here's how:

22. **Apeiron**
January 4, 2005

I read the entire Edge comment group. Nearly all the postings involve saying something like:

"I personally believe that X is true, and I think that in the future, X will be universally believed to be true by people like me."

This is really quite a meaningless statement, and in fact may involve a serious misunderstanding of the nature of truth or potentially the conception of future and past.

I suspect the point of the exercise is to make unsubstantiated claims and then, in the real future perhaps, trumpet the accuracy of the few that turned out to be correct. Is this not really pretty silly?

23. **Chris Oakley**
January 4, 2005

Chris W,

The paradigm shift therefore is away from Occam's Razor towards something much more bizarre. I would never go there, as I view the activity as opening a Pandora's box. How many other "theory generators" besides M-theory could one dream up, I wonder? In any case, what satisfaction is there to be derived from explaining simple things in a complex way?

24. **Levi**
January 4, 2005

The response from Steve Giddings is also interesting. He thinks he knows what went wrong with Hawking's original argument about information loss in black holes. An excerpt:

"We base our argument on a principle we call the locality bound. This is a criterion for when physical degrees of freedom can be independent (in technical language, described by vanishing of commutators of corresponding operators). Roughly, a degree of freedom corresponding to a particle at position x with momentum p and another at y with momentum q will be independent only if the separation x-y is large enough that they are outside of a black hole that would form from their mutual energy. I believe this is the beginning of a general criterion (which will ultimately (be) more precisely formulated) for when locality breaks down in physics."

I don't know what to make of this idea.

p.s.: Sorry this comment is a bit off-topic.

25. **Chris W.**
January 4, 2005

At least one respondent, Keith Devlin, started by examining the problematic notion of *proof* itself. In practice, proof means (for many people) something like social or cultural acceptance—an idea is proven when it becomes widely discussed and applied, or commonly used as a jumping-off point for further investigations. Here "proven" is a shorthand for "proven to be of value"—interesting and useful at least, and at most, integral to how one understands the world.

Personally, I think that in the empirical sciences we should limit our use of the term to the sense in which mathematicians and logicians use it—ie, as showing that a conclusion follows logically from given premises. As Devlin discussed, this notion of proof is problematic enough by itself. I see no need to muddy the waters by talking about "proving" Newtonian mechanics or any other empirical generalization. It is enough to know that a theory is a conjecture that has been rigorously and broadly tested, and has stood up well to all (or most) of the tests. That fact alone makes the theory interesting, and in most cases useful as well.

So, the attention should be focused on tests—how can we know when a theory is wrong? Many people mistrust string theory because it apparently offers so many ways to avoid confronting this question. However, I get the sense that for many string theorists the question is irrelevant. They regard string theory (and M-theory) as a fabulously rich meta-framework from which one can derive a huge variety of interesting models, and modeling is what physics is really about. At least some of the models should be testable, but there is no reason why the meta-framework should be; its purpose is to spawn models.* All one can ask is that some of the models show some promise of producing successful physical predictions. In short, string/M-theory is not a physical theory in the conventional sense; it's a meta-theory and theory generator. Is a theory generator what we really need?

—-
* Of course, the meta-framework is such that the models are linked by a web of deep mathematical ideas and relations, which makes them interesting even to people who only care about solving mathematical problems.

26. **Apeiron**
January 4, 2005

If Susskind really doesn't understand why probability theory works [given certain very basic assumptions about the underlying processes involved] then it's not surprising he thinks that his impressionistic landscape stories and graphics are a real achievement.

27. **Peter**
January 4, 2005

Anderson has always had some degree of resentment about the way particle physics often views itself as the most important subfield of physics. He was far from the only one who felt that the cost of the SSC was crowding out funding for other subjects. I remember arguing at the time with various such physicists and mathematicians that if the SSC were canceled they certainly weren't going to see any of the money, which turned out to be right.

28. **DMS**
January 4, 2005

I have mixed emotions when it comes to Phil Anderson.

I agree that his contributions have been notable (actually, Schwinger also had a bit role when it comes to Higgs mechanism).

As an ex-particle theorist, I find it hard to accept that he advised the Congressmen to cancel the SSC and said that “particle physics is no more fundamental than any other branch of physics, \emph{ in any way whasoever}”(I don’t think his testimony was pivotal: budget considerations and lack of political support in the new administration killed it). My opinion is similar to Weinberg as he stated in “Dreams of Final Theory” on the subject: it is about the convergence of arrows of explanation.

But he is correct that reductionism is not everything. I think he may agree that “many-body physics”, be it relativistic as in QFT or NR as in condensed matter physics, is.

29. **plato**
January 4, 2005

Just so people understand this was a selective process (the many names that are presented) by which one will choose what to accept into their world or not?

I think Nicholas Humphrey deserves a lot of credit for thinking of the question, **“WHAT DO YOU BELIEVE IS TRUE EVEN THOUGH YOU CANNOT PROVE IT?”**🙂

If the rational, is to accept matter distinctions as the most relevant, then such thought manifestations have no other basis then the brain:)

Rest easy then:)

What is a Brane?

January 6, 2005
Categories: Uncategorized

Greg Moore has written an article for the latest Notices of the AMS entitled “WHAT IS… a Brane?”. He begins by noting that “The term ‘brane’ has come to mean many things to many people” and one of the difficulties of the subject is that one has to figure out from context what sort of brane someone is talking about.

For the case of branes of dimension greater than one, in general no one knows how to consistently quantize such objects. See Warren Siegel’s research summary for comments about this. He notes that now that M-theory shows that non-perturbatively strings are membranes in 11d, one doesn’t have a finite quantum theory of gravity, since membranes are infinite even in perturbation theory. All one has is an effective low-energy supergravity theory, which is what one had before one got involved with string theory. While at Siegel’s web-site, check out his latest parody paper called “The Everything of Theory”, which includes the following lines:

“The real problem with string theory is that there is no alternative. However, the reason there is no alternative is that no one ever bothers to look for one; in fact, there is a strong resistance to even considering looking for one. Consequently, practically all theoretical high energy physics (and even most of phenomenology) is now string theory. Thus, string theory is not so much the Theory of Everything (since it explains nothing), but rather the “Everything of Theory”, since it now encompasses all of theory. This era in string research is strongly reminiscent of the Dutch tulip trade just before the Tulip Crash of 1637. ”

I, for one, am missing the joke here…

For some new hyping of a different kind of brane, see the latest Nature, which has a piece on Nima Arkani-Hamed. Equal time is given to LQG, with a similar piece on Martin Bojowald.

Update: Lubos Motl has a long posting about branes and M-theory, which explains many things. As usual though, he insists that the full dynamics of the branes in M-theory is completely determined and unique even though he doesn’t know what it is in any phenomenolgically realistic background. To get a finite quantum theory of gravity that has anything to do with the real world out of M-theory, you need to show that you can get well-defined, finite results for the dynamics of these branes in the case of four large dimensions, the rest small. As far as I can see any claim to have this now is purely wishful thinking.

   January 11, 2005

   I think you’ll find that if you talk privately to many string theorists, they are very unhappy with the present state of the field. A common opinion would be that the standard picture of a 10/11 d string/M-theory TOE has been incredibly overhyped and now looks unlikely. But they’re not sure what else to work on. One of the few intellectually alive sub-fields of particle theory is that of trying to really understand QCD via its supposed string dual. A lot of people are working on that, keeping quiet about their doubts about the TOE. Siegel is one of the few not keeping so quiet (he has tenure, for one thing…).

2. January 11, 2005

   I read much of Siegel’s webpages and I’m surprised he seems to be able to hold contradictory opinions in the same webpage! In his “serious” pages, he is a proponent of string theory and he describes his work on it but in his parodies, he becomes very critical of string theory.

3. **Peter**
   January 7, 2005

   Well if some of the features of the physics look like they come from a vibrating string, it’s perfectly reasonable to try to model strong interactions with a quantum string. It just doesn’t work, or at least not in anything like the simplest such way of “quantizing a string”.

   I’d heard that lots of people had suggested a fourth quark with the right quantum numbers around 1964, but never that Zweig was one of them. The idea only became really compelling in 1970 with the GIM mechanism.

4. **D R Lunsford**
   January 7, 2005

   Peter – you mention Glashow and his 4th quark. Remember that George Zweig had his model of “aces”, which were really just 4 quarks at the outset.

   -drl

5. **D R Lunsford**
   January 7, 2005

   Peter –

   It looks like Siegel is carrying on the parton and Veneziano dual-resonance ideas in his own way, with modern tools. So he’s sort of going back to before gauge theory and s.s.b.!

   One thing I never understood – it seems that string theory got started because the dynamics of these models looked like that of a vibrating string. Why did they make the leap of faith to say that it really *is* a string??

   -drl

6. **Peter**
   January 7, 2005

   DMS: Sure, if when particles collide at the LHC, energy starts disappearing into extra dimensions, that would be a big deal. It also would be a big deal if these collisions caused the archangel Michael to appear at the collision point. These both seem about equally likely to me.

   Glashow and others had good arguments for a fourth quark. This was a simple extension of the three quark model that made the whole thing simpler and more elegant.

The extra dimension stuff is nothing at all like that.

ksh95: Yes p-branes for p>1 are described by a non-renormalizable sigma-model. Look at your favorite way of quantizing the string, increase the dimension of the world-sheet above 2 and see what happens.

Danny: I don't really understand exactly what Siegel has in mind, but he is clearly more interested in finding a 4d string that would help one understand QCD, rather than a 10d string that would explain gravity.

7. **DMS**
January 7, 2005

Getting to the article, I think I would agree with Nima that *IF* brane concept turns out to be correct, it will indeed be the biggest thing in science in 300 years. Don't you think?

Of course, I don't think it will be found, but who knows…

Maybe, it will be like the charm episode in particle physics, when Glashow made a bet that charm would be found with an estimate of the mass, and he won the bet(If my memory serves me right, it was based on the GIM mechanism based one-loop calculation of the K0-K0bar mixing.). But my understanding is that no one believed his prediction (unlike the case now where anyone who "matters" believes in it).

January 7, 2005

Whoa, whoa, whoa,

You're telling me that branes give infinite results, even in perturbation theory?

What's this about? Are they doing S-matrix calculations or something else?

I'll ask around, but in the meantime if some one could kindly explain the present state of affairs I'd be much ablidged.

9. **Thomas Larsson**
January 7, 2005

A Brane New World always reminds me of a Swedish dotcom company, by Huxley's original name A Brand New World. It defaulted a couple of years ago, after burning more venture capital than Boo.com.

As they say on the stock market: never try to catch a falling knife. No matter how much the string stock falls, there is always 100% left to the bottom.

10. **plato**
January 6, 2005

sorry Peter it won't happen again

11. **D R Lunsford**
January 6, 2005

Peter –

I read thru all of Siegel's comments and it seems that he regards the useful part of ST as a phenomenological expression of some kind of theory in which X can be regarded as a bound state of Y andZ, Y and Z can be regarded as bound states of X and W, W can be regarded.. etc. etc. IIRC, ST had its origin in a naive nuclear model in which nucleons were literally banded together, one wrote a Lagrangian for the bands with their tension etc. etc. Is this a correct summary?

12. **Peter**
January 6, 2005

This has really gotten out of hand. I'm quite annoyed that people are ignoring my request to not post multiple off-topic comments and not to respond to those who do. This is damaging something that belongs to me and I'm about to start deleting all such comments. Please do not continually submit multiple comments attempting to turn this into a forum for discussion of your private interests. This is extremely rude and I'm not going to put up with it any more.

13. **plato**
January 6, 2005

Okay don't let it happen again.:)

Alan Sokal saids:A lot of the blame for this state of affairs rests, I think, with the scientists. The teaching of mathematics and science is often authoritarian

Now who are you going to believe and quote, when you've cried wolf?

The more one adds, the crazier it gets:)

14. **plato's assitant**
January 6, 2005

I'm sorry Plato.

As you guys guessed, Plato's assitant doesn't exist.

15. **plato**
January 6, 2005

Plato's Assistant,

It is unfortunate that you have refused to keep yourself confined to the club, (url listed on my name), that we will have to suspend you until further notice.:)

Brane and Brain, are not the same thing.:)

As to understanding the gist of my resources, you might find such accumulation of the data very interesting, and why, any attempts to devalue, is only a rejection of the reality that has been moved into this century:)

Cater to Peter's request, if you dare 🙂

16. **D R Lunsford**
January 6, 2005

Apparently, there really was a Tulip Crash:

http://slate.msn.com/id/2103985/

Most amusing is the noted battle of "Wittstock":

http://www.fact-index.com/b/ba/battle_of_wittstock.html

Obviously this was the first real-world test of flower power. (King Jiminy Hendrix of the Duchy of Fender prevailed over Count Rey Josef und die Fische. After the victory, a great celebration of music, a free "concerto grosso" was held at Maximilan Yasgar's fuedal estate. This was the first appearence of the band then known as Jefferson Bargepole with Grace Slick, a stimulating teenager from San Francisco di Zitterbewegung.)

17. **Chris W.**
January 6, 2005

This must be the Bogdanoffs' secret. Thousands of students could save themselves the expense and risk of buying term papers and phony theses with only a minimal decline in the quality of the work they submit.

18. **D R Lunsford**
January 6, 2005

Peter –

A few simple mods of the Postmodernism Generator should do fine! Just throw in a few classic formulas pulled from Dirac or Messiah, and make the obligatory reference to the CMB, and a postscripted estimate of the cosmological constant, references to Witten, etc. Making up references would be fun!

January 6, 2005

It's Brane New World?

Branes reside in the hidden dimensions, known as "the bulk." While matter and light stick to the branes, gravity traverses both branes and bulk. The hidden dimensions cannot be seen because only gravity can go there.

Maybe the tulip trade is reminscent and inferred by Veltman and Hooft, as a realization of a cosmological principle that can be mapped holographically, even if Hooft is overwhelmed?

Finally, we describe the embedding of branes in the 5d bulk using the phase space geometric methods developed here. In this language the boundary conditions at the branes can be described as a 1d curve in the phase space. We discuss the naturalness of tuning the brane potential to stabilize the brane world system.

You just have to adjust your views to the bulk is all?:)

Complex Structures on the Six-sphere

January 9, 2005
Categories: Uncategorized

A preprint by Andrei Marshakov and Antti Niemi appeared on hep-th this evening making a remarkable claim. According to this preprint, a few weeks before passing away recently at the age of 93, Shiing-Shen Chern completed a preprint entitled "On the Non-existence of a Complex Structure on the Six Sphere".

Whether or not a given manifold defined using real coordinates can be given the structure of a complex manifold is often a difficult problem. For the case of a d-dimensional sphere, clearly you can't do this in odd dimensions, but for even dimensions, you certainly can for the case d=2. For the cases d=4 and d=8 or more, there is a topological obstruction to even finding an "almost complex structure". In other words, you can't find a continous choice for each point on the sphere of what it means to multiply elements of the tangent space by the square root of minus one. The case d=6 is special: you can use the octonions to construct an almost complex structure, but this complex structure is not "integrable", it doesn't come from any local choice of complex coordinates. One of the most famous open problems in geometry has long been the following: is there another almost complex structure on the six-sphere that is actually integrable?

It has long been conjectured that there is no such integrable almost complex structure, but no one has ever been able to prove this. Chern's preprint contains a purported proof, but Marshakov and Niemi devote only a paragraph to the non-trivial part of his argument. From their preprint you can't tell whether Chern has a valid argument.

I've heard via e-mail from a knowledgeable authority on the subject who points out that there are serious flaws in the manuscript that was privately circulated. His opinion is that Chern's argument actually does prove something interesting, but not the full result Chern claims, so the conjecture about the non-existence of a complex structure on the six-sphere remains open.

Comments

1. **Peter**
   January 11, 2005

   The section of the paper on "Chern's Last Theorem" is almost entirely devoted to explaining well-known facts about G_2/SU(3)=S^6, including the well-known fact that the almost complex structure you get from the octonions is not integrable. I'm pretty sure all of this material goes back to Elie Cartan in the early part of the last century. The new argument due to Chern is only dealt with in the last paragraph of the section (I said it was only one paragraph, not one sentence. String theorists have a weird inability to quote me correctly…). It's the argument in this last paragraph that is new, but also has a hole in it.

2. **DMS**
   January 11, 2005

   Peter,

   You have captured what I tried to say. And in the process you have given me a glimpse of the complexities and subtleties of (dis-)proving statements in mathematics. Thanks!

3. **Lubos Motl**
   January 11, 2005

   It is not true that there is just one sentence dedicated to Chern's proof in Marshakov et al. Look at their conclusions – and you will see that they say that "we have explained his proof in detail". I also think that there's a lot of it over there.

4. **Peter**
   January 11, 2005

   I think what you mean by "physicist's proof" is something along the lines of what a mathematician would call an outline of a proof, with some steps in the outline possibly justified by appeal to a physical argument that such a step has to somehow work out correctly.

   There certainly are some reasonably good examples of this kind of thing. One would be Witten's work on supersymmetry and Morse theory. There he outlined an argument relating Morse theory, Hodge theory and index theory, using at crucial points expectations of what should happen based on semi-classical approximation techniques in quantum mechanics.

   But the Ricci-flow case is very different. Based on personal experience, I can tell you that claims by some physicists that the RG provides a "physicist's proof" of geometrization have convinced some mathematicians that said physicists are arrogant idiots. In this subject you can't assume that metrics are well-behaved, since they aren't. Singularities develop when you follow the Ricci flow, and understanding what happens then is what the whole subject is about. There is no "physical" argument for ignoring this phenemenon. If there were it would imply an infinite number of untrue mathematical theorems.

5. **DMS**
   January 11, 2005

   Someone wrote:
   "If it's wrong for a mathematician, it must also be wrong for the physicist."

   Of course that is obvious: don't need a Harvard education to see that.

   The question was: is there a strong physical reason for one to believe a particular statement to be true. Of course, such physical reasons may turn out to be wrong. Alternatively, the statement may be correct, but may require newer mathematics to demonstrate that rigorously (like Dirac delta functions —> distribution theory).

   "A difference between a physicist's proof and a mathematician's proof can only exist in physics where the physicists know what they mean and mathematicians are slower."

   Well, the recent proof of Thurston geometrization conjecture relied on Hamilton's Ricci flows, reminiscent of RG.
   http://www.math.columbia.edu/~woit/blog/archives/000077.html
   A physicist would be happy if he could show it for "well-behaved metrics", not a ("slow") mathematician.

6. **plato**

January 11, 2005

It's important that we can see where you are both focused instead of having the ramble of content that deters from appropriate discussion.

So we now have you both fixed in the appropriate direction, so that you can philosphically:) discuss the idea being expounded at the forefront of our knowledge base.

Is one, going to reject the mathematics of another? On what grounds? Physics?:)

7. **Lubo? Motl**
January 11, 2005

Impressive guy (Chern), even it it's not right.

Someone asked whether the proof is valid as a "physicist's proof". That's a ludicrous question. A difference between a physicist's proof and a mathematician's proof can only exist in physics where the physicists know what they mean and mathematicians are slower.

In mathematics, for example in discussions about the existence of a complex structure, the physicist's proof and a mathematician's proof is the same thing. If it's wrong for a mathematician, it must also be wrong for the physicist.

8. **plato**
January 10, 2005

At planck scale with topological considerations, no determination can ever be foolproof, as it is conjectured math already based, unless, you willingly admit and move into abstract spaces, detached from reality:)

But its still fun to conjecture?

9. **Peter**
January 10, 2005

The Marshakov-Niemi paper just gives an outline of Chern's argument, it doesn't in any sense provide a "physicist's proof".

10. **DMS**
January 10, 2005

What about Marshakov-Niemmi paper itself? Is it valid as a "physicist's proof"?

That is, even if Chern was wrong, it may be that someone is going to prove it rigorously, so it is basically correct (like a lot of QFT proofs).

11. **Matti Pitkanen**
January 10, 2005

The claim that S^6 does not possess complex structure is very interesting from TGD point of view. Since I cannot expect that anyone sees the trouble of getting bored of what follows I demonstrate my deep ignorance by representing my question immediately:

Does the possible existence of complex structure in S^6 imply the existence of Kaehler structure?

In the following I try to the physical meaning of Chern's last theorem emerges in TGD Universe.

1. Number theoretical dynamics for space-time surfaces

The motivation for my question comes from what I believe but cannot yet quite prove(;-). I have been working hardly to concretize my belief that the classical dynamics of space-times identified as 4-dimensional surfaces in 8-D imbedding space M^4xCP_2 can be expressed purely number theoretically. I have gone through several variants of the hypothesis and thought to describe one option since it seems most promising at this moment and also relates very closely to the Chern's last theorem.

The first guess was that tangent spaces of H and M^4 could be given octonionic resp. quaternionic structures. The Minkowskian signature however forces to modify the approach by replacing these structures by their hyper counter parts obtained by multiplying imaginary units by commuting sqrt(-1).

[This structure is not identical with the commutative algebra structure that I called hyper-complex structure and talked about in an earlier email containing several mistakes.]

Clearly a number theoretic analog for the transition from Riemannian to pseudo-Riemannian geometry is in question. M^4 resp. M^8 could be seen as a sub-space of complexified quaternions resp. octonions. This space does not form field nor algebra but this can be tolerated: for instance, the overall important notion of hyper-prime makes sense. For instance, in the quaternionic case the interpretation would be as four-momenta satisfying automatically the stringy mass formula M^4=p. Light-like hyper numbers having no inverse correspond to massless 4- or 8-momenta and hyper-units to Lorentz boosts in analogy with pslash/m in the case of Dirac equation. The notion of pole of analytic function is replaced with lightlike 3-surface, etc…

2. Number theoretical variant of spontaneous compactification as M^8M^4xCP_2 duality?

Since HO/HQ power series with real coefficients give end result in HO/HQ, the notion of HO/HQ manifold with hyper transition functions between coordinate charts makes sense. HO analyticity is not plagued by the complications due to non-commutativity and non-associativity. The reason is that this notion results also if product is Abelianized by assuming that different HO imaginary units multiply to zero.

The problem is that M^4xCP_2 very probably does not allow HO structure.

Here comes in rescue the old idea is that four-surfaces in M^8 define four-surfaces in M^4xCP_2 in a natural manner and vice versa assuming that field equations are satisfied. This duality would be a number-theoretical counterpart of spontaneous compactificatition. It would have nothing to do with dynamics but would be one item in the list of dualities relevant to TGD.

3. Justification for the number theoretical spontaneous compactification

The justification for the hypothesis comes from following observation. The space of quaternionic sub-spaces of octonions with a priori fixed complex structure (containing a fixed octonionic imaginary unit) is CP_2. Same applies in the hyper case.

This means that if one has a four-surface X^4 in M^8==HO with a hyper-quaternionic tangent space and a fixed complex structure, it defines a surface in M^4xCP_2. The

M^4 coordinates of a given point are obtained by a canonical projection from M^8 to M^4 and CP_2 coordinates as parameters characterizing the HQ tangent space at given point.

One can assume that the local complex structure depends on space-time point and thus characterized by a map

f: X^4–>S^6.

It is here where S^6 pops up in TGD framework.

4. Foliations of HO=M^8 and M^4xCP_2 by space time surfaces maps g: OH–>SU(3) satisfying integrability conditions.

For a given map f: HO –> S^6 defining a local preferred imaginary unit M^8-M^4xCP_2 duality allows to construct a foliation of HO/M^4xCP_2 by HQ space-time surfaces in terms of maps

g: HO–> SU(3)

satisfying certain integrability conditions guaranteing that the distribution of hyper-quaternionic planes integrates to a foliation by 4-surfaces.

The reason is that the bundle projection SU(3)–>CP_2 defines the local tangent plane at each point of SU(3). The foliation defines a four-parameter family of 4-surfaces in M^4xCP_2. The dual of this foliation defines a 4-parameter family HQ space-time surfaces.

5. Hyper-octonion analytic functions OH–>OH as a solution to the integrability conditions?

HO analytic functions HO–> HO with real Taylor coefficients provide a physically motivated ansatz, which might satisfy the integrability conditions.

a) The basic observation is that the complexified octonions decompose as 1+1+3+3bar under SU(3) automorphisms leaving a preferred imaginary unit fixed (easy to remember if you have heard about leptons and quarks!).

[Notice that SU(3) has interpretation as color group and isometry group of CP_2 whereas U(2) would act as vector fields in the tangent space of X^4 as well as the holonomy group of CP_2 identifiable as electro-weak gauge group. Standard model gauge structure would have purely number theoretical origin.]

b) If you have a map HO–>HO you can form tensor product 3x3bar of the states of 3 and 3bar states defined by the map and identify it as a Lie algebra element of SU(3) and exponentiate it to an element g of HO-local SU(3). The resulting map g defines the foliation of M^4xCP_2 by hyper-quaternionic space-time surfaces as desired.

6. How Chern's last theorem could be relevant for TGD?

If the conjecture holds it would mean that the foliations giving families of solutions of field equations are characterized by two functions.

a) The function f: HO–>S^6 characterizing the selection of preferred imaginary unit in OH. Physically the function would characterize the choice of the ground state. This function has also an interpretation as SO(7) local group element with SO(6) gauge invariance. The interpretation would be in terms of zero modes.

It is here, where Chern's last theorem becomes relevant. The interpretation as zero modes would conform with the claim that S^6 does not allow complex structure. Indeed, Kahler structure is absolutely essential for the identification of these degrees of freedom as quantum fluctuating degrees of freedom in infinite-dimensional context. As a believer on TGD based world view I would dare to believe also the non-existence conjecture.

b) The hyper-octonion analytic function g: HO–>SU(3) or effectively g: HO–>CP_2 guaranteing the integrability conditions would be second function involved with the general solution ansatz. Here complex structure is present and quantum fluctuating degrees of freedom are in question.

7. Is number theoretical dynamics equivalent with absolute minimization of Kaehler action?

The basic conjecture is that the absolute minima of Kaehler action correspond to the hyper-quaternionic surfaces in the proposed sense. The enormous vacuum degeneracy of Kaehler action would relate to the local selection of octonionic imaginary unit characterized by the map f: HO–>S^6. The known facts about the solution spectrum of Kahler action conform with the proposed general picture.

This conjecture has several variants. It could be that only the asymptotic behavior of absolute minima corresponds to a hyper-octonion analytic function. It could also be that maxima of Kaehler
function K of configuration space of 3-surfaces of H, with K being determined by absolute minimum of Kahler action, correspond to this kind of 4-surfaces. Etc…

With Best Regards,

Matti Pitkanen

The Problem of Predictivity

January 11, 2005
Categories: Uncategorized

In recent years, as it has become clear that string theory can never be used to predict anything about the real world, string theorists have reacted to this state of affairs in various often bizarre ways. Tonight there's a new review article by Steve Giddings about string theory which doesn't even pretend that the theory will ever make a real prediction about anything. Giddings seems to think that the particle phenomenology archive hep-ph is the place to post this kind of thing, not the hep-th archive devoted to less experimentally based work. This is pretty funny, but the really hilarious thing is the way Giddings motivates string theory. In a section entitled "The problem of predictivity" he argues that our inability to make quantum gravity predictions at high energy is a problem of supreme importance, then goes on to use this to motivate the introduction of string theory, which in the end gives a theoretical framework unable to predict anything about anything at any energy.

The review does actually claim at various points that string theory "predicts" gauge theory, fermions, supersymmetry, Dp-branes, and the cosmological constant. It just neglects to mention that it doesn't predict any characteristics of any of these things (value of the cosmological constant, any observable characteristic of a Dp-brane, how supersymmetry is broken, what kind of fermions, what gauge groups). String theory actually has nothing at all to say about even the things Giddings claims it "predicts".

Giddings seems to be a hard core anthropist, he ends with the exciting recent insight from string theory that:

"It may in fact be that anthropic considerations fix the small relative size of the Higgs mass as compared to the Planck mass. If so this ultimately answers the question we started with, 'why is gravity so weak?' This is clearly a very interesting line of research, and debate continues on these and other important points."

Actually this is only the next to last paragraph. He finally ends with the news that exp{10^120} years from now our region of the Universe will spontaneously decompactify, which he thinks is pretty kewl.

With the current anthropic nonsense exemplified by this review article, string theory has finally reached rock-bottom. It has given up any claims to being a legitimate science and has taken on the characteristics of a cult. It is long past time for those leaders of the field with any remaining scientific integrity to take a public stand that what is going on is not all right.

Perhaps this is too much ranting. My excuse would be that I'm not in the best of moods because I've spent my entire break between semesters being sick (don't worry, I'm getting better). I just can't believe the way essentially the entire particle theory establishment, including many people I have the highest respect for, continue to allow this situation to go on without public comment.

Update: Lubos Motl has news of a new, more elaborate set of anthropic nonsense coming soon from Savas Dimopoulos, Shamit Kachru, and his senior colleage Nima Arkani-Hamed (their innovation is to divide the landscape up into "countries". I kid you not). Lubos evidently has seen this paper early, the rest of us will have to wait until tomorrow night. Even though he pretty clearly sees how unscientific this is, he has to try to find something nice to say about it since his career depends on these people. Sad to watch, actually. Postdocs and untenured people can't take on the fight against this garbage unless they want to commit career suicide. It's up to the tenured people. Where are they?

Further update: It seems the "countries" terminology is due to Lubos, the authors refer instead to breaking the landscape up into "friendly neighborhoods". Which sounds even sillier than "countries".

Yet further update: The Arkani-Hamed, Dimopoulos, Kachru paper is now available. It consists of about fifty pages of few equations and highly convoluted anthropic sorts of arguments, not about any particular theory but somehow about whole classes of theories. Kind of a meta-argument. They don't seem to get anything at all like an actual prediction of anything out of this, the closest they get is in their conclusion about what to expect at LHC energies:

"Instead of finding a large spectrum of new particles and interactions typically needed for naturalness, we predict sparse models with few new particles and couplings, with dimensionful parameters finely tuned but close to dangerous environmental edges."

Pretty poetic, but I think the experimentalists working on the LHC detectors are going to have trouble using that as guidance as to what to be looking for.

   Anthropicy is clearly a pretty desperate strategy, but what's a girl to do? QGr has been stubbornly resisting all sorts of attacks for 60+ years. What I object to is the string theory thought police, who seem to regard their theory as sort of a religion, and all other approaches as heresy. It's just possible that the QGr problem won't be solved without some new fundamental data.

   Peter said:
   "The problem with the quantized superstring is not that it can't describe interesting physical degrees of freedom, but that it can describe almost anything. It's too ill-defined for anyone to be able to show it is inconsistent, but it is increasingly clear that it is VACUOUS ."

   I find it very amusing in the last word. Thanks for the humor, but string theoreticians are over-qualified languists in inventing new words:-)

   ST doesn't just describe "almost" any thing. It describes much much more than everything in the world adds up. That's exactly the problem. When the complexity of a theory allows it to describe more than what this universe can hold, that's no longer a physics theory since physics strictly limit itself to the observables within this universe only.

   I keep seeing STers sing the praise how ST is rich of mathematics structures and how much beauty you can find within the theory, and they can't believe that a mathematical frame work so rich in content could have nothing to do with the real world at the end.

   What they don't realize is it is exact the problem when you have a theory too rich and provides too much structure than what is needed to encompass the whole observable universe!!! It makes the whole thing "vacuous" when you realize just what an insignificantly small portion of that theory actually describes the universe 🙂

   One could propose a theory living in 137 dimentions, it surely will provide even richer structures than the current 11-D string theory. It would also be more "vacuous".

   I think even a flat 4-D theory is alittle too bigger than what the universe can hold, as we already see. A theory of flat, infinitely extending 4 dimentional spacetime of precise coordinates provides more structures and information than what the actual universe holds. The result is we see a universe that is limited in size and has fuzzy coordinates. The richness of the universe is bounded by boundary, so it is described by the conditions of the 3-D boundary of the 4-D spacetime. That's the holographic view.

January 13, 2005

Peter – OK fair enough, but if you can't make a non-Abelian gauge theory from line sources I just can't see how YM is going to work…perhaps I'll post something to SPR about it.

-drl

4. **Peter**
January 13, 2005

Hi Danny,

Please don't repeat the argument. I took a look again at your comment I deleted, and it still seems to me that it is about a calculation that interests you but doesn't have anything to do with the topic of this posting (predictivity and anthropic reasoning in string theory).

I don't think you can convincingly argue that the current superstring theory framework can't support YM fields. The problem with the quantized superstring is not that it can't describe interesting physical degrees of freedom, but that it can describe almost anything. It's too ill-defined for anyone to be able to show it is inconsistent, but it is increasingly clear that it is vacuous.

5. **D R Lunsford**
January 13, 2005

Peter – the point of the comment you deleted was – I don't even see how string theory can support Yang-Mills, much less be a TOE. I thought this was on-topic.

I will repeat the argument if you wish.

-drl

(Sorry if I resort to bad humor sometimes. Nip nip nip.)

6. **superpoincare**
January 13, 2005

This landspace stuff is seriously leading nowhere. Weinberg's original paper was "OM" and had an interesting result.

I think this "landscape" business is just playing with words. Finally string theory has a lot of ground states and one doesnt know which one to pick. The best thing is that _none_ of these vacua come close to describing the real world.

7. **Quantoken**
January 13, 2005

Peter said:
"The only other senior person besides Gross I can think of who has spoken up about anthropism is Steinhardt. It really is remarkable to me that they haven't gotten others to back them up publicly."

That's not surprising. No one could say anthropism is wrong, since it is derived from pure logic. How could we possible living on a planet hostile to life, and the planet sits in a universe impossible to create stars and planets? So it is without question that anthropic principles are CORRECT.

The only thing that can be questioned against anthropic principles, is not whether it is correct or not, but whether it is science or not.

There are things that are absolutely correct, but is not science. Science does not necessarily have to be correct, since a theory we think is correct now may be replaced by a more accurate better theory in the future. Science have to be able to make predictions of the nature to be useful, science have to provide a mean for someone to potentially disproof itself through experiments or observations. Only when a theory makes prediction that can be verified or contradicted, and when it came out such predictions are verified instead of contradicted, will that theory be considered science.

What's being disputed, is whether anthropic principles, although correct, does it have that predictive power at all? Some think it has, some do not. I personally think it does have predictive power, but very limited and definitely does not explain things unrelated to the condition of our existence. For example it does not explain why there's homosexuality, which is strange from the biological point of view. I would say anthropic principle is probably some sort of semi-science.

Even the widely accepted standard of what is considered science may be subject to question itself, due to the Godel theorem. For example mathmatics, 1+2=3, that's absolutely true, it does not even provide a potential opportunity for any one to possibly contradict itself, using experiment or whatever, so, then, is it science or not if it can never be dis-proven?

8. **Aaron**
January 12, 2005

"They think that if they speak out, it will be the end of their careers in physics."

Hardly. I just don't think that they care. As I said, plenty of people are perfectly content to continue working on whatever they're working on and let the anthropic people do what they want.

9. **Peter**
January 12, 2005

The only other senior person besides Gross I can think of who has spoken up about anthropism is Steinhardt. It really is remarkable to me that they haven't gotten others to back them up publicly.

10. **JC**
January 12, 2005

I can't think of many anti-anthropic folks who have spoken loudly against the anthropic deterioration on the subject, other than perhaps David Gross. Other former colleagues who are "quietly" anti-anthropic, generally won't speak out loudly about it because they either don't have tenure and/or they're a postdoc with no "political" power. They think that if they speak out, it will be the end of their careers in physics.

11. **the guts of a blackhole**
January 12, 2005

String theory lacks its underlying geometric entanglement that would widen and flush its application through what Einstein terms as our "persistent reality." The problem is without this extensive symmetry the theory gets stuck in a theoretical cul-de-sac; what I'm suggesting would suggest, too, that string theory be more accuratly catagorized as _Spring Theory_.

12. **Peter**
January 12, 2005

Hi Quantoken,

This web-site is not supported by public funds. Columbia University is a private, non-profit university. The computer equipment involved and the salary of the person who supports it (me) are paid for by this private institution.

This private, non-profit institution supports educational and research activities. As part of this they pay my salary to maintain the computer system, teach classes assigned to me and engage in other research and educational activities of my choice. What I produce in the course of such research and educational activities outside the classroom belongs to me. This is the standard way universities treat this sort of intellectual property. One of my colleagues has gotten extremely wealthy through this arrangement. I haven't.

If I thought there was any doubt about the above I would move this web-site to a commercial service. This could easily be done, but I feel it naturally belongs on the university-supported web-site since it is part of the educational and research component of my job. I also believe that the university's standard protections of the intellectual products of their academic staff ensure that there is no question about my control and ownership of this material.

The comment section is intended to allow others to participate in the educational and research activity of which the web-site is part. To the extent that people further the educational and research goals of this site, I will do everything I can to encourage them. To the extent that they damage these goals I have to do what I can to stop them. Again, this belongs to me, and I'm solely responsible for it. It does not belong to you in any way, shape or form.

For the answer to the question you ask about Feynman's argument that a massless spin-two particle necessarily implies general relativity, see his book "Feynman Lectures on Gravitation"

13. **Quantoken**
January 12, 2005

Peter:

Hope you feel better now. I am sorry to see that you had to start deleting comments. But I respect that, plus it's not my comments that you deleted.

Not wanting to be picking, but your statement is only 25% correct: "It is something that I created, that belongs to me." It does not belong to you. The Columbia web site, plus all your research activities, are supported by public fund. The things you create while being supported by public fund does not belong to your private property.

I am in a good mode today since I just got a few patents filed today. I am the sole creator of the patents, but it does not belong to me, since I was paid salary to create the stuff. The same principle applies to you, Peter.

Also it is not completely true you created this place. People come and discuss various things in your comment section. Without that your blog would be dead water that no one wants to look at.

That said, it is still best that people would focus a little bit more on the topics. It's hard though because in any heated debate it is commonplace that you started in one thing, and it could leads to something else totally unexpected. I think it is perfectly healthy that different opinions get exchanged this way.

Now back to the Giddings paper. One thing I have been long puzzling is string theoreticians claimed they "predicted" gravity, and I never know exactly where that came from. Giddings's paper seem to provide some hint. Based on what I read, the reasoning goes like this:
a.String theory leads to a spin 2 mass less particle.
b.Feynman said long ago "ANY theory that describes a spin 2 massless particle must describe gravity".
c.So super string theory predicts gravity.

Now, does any one know any thing where b. came from? Why Feynman said any spin 2 mass less particle must be associated with gravity?

Quantoken

14. **Peter**
January 12, 2005

I am extremely pissed off right now. I just deleted the last two comments, which had nothing to do with the topic of this posting, and whose authors seem to feel that this is a good place for them to go on about whatever they feel like. It isn't. It is something that I created, that belongs to me, and that you are damaging. Don't do this again.

15. **Peter**
January 12, 2005

Giddings's claim (and that of the 10000 other similar string theory propaganda pieces) is not that it contains gravity and fermions. The claim is that whereas the standard perturbative quantization of the gravitational field is non-renormalizable, quantized superstring theory contains the gravitational degrees of freedom but is term by term finite in perturbation theory.

There are several problems with this:

1. It actually is not known to be true for more than two loops.

2. Even if it is, finiteness of the terms in the perturbation series isn't enough for a finite theory. The series diverges, and conjectural non-perturbative definitions of the theory have their own problems with infinities.

Introducing fermions into general relativity is not the problem. The problem is quantizing the gravitational field. Unless you have a good argument that the work of Chen addresses this problem, please do not discuss it further here.

16. **Dick Thompson**
January 12, 2005

Since Giddings' clain for strings boils down to; it contains both gravity and fermions, what if we create another theory that does this? Which brings me to a modest proposal.

X. Chen has just posted a double Kalusza-Klein theory on GR which supports spinors (but does not, I think, generate them) and which accounts for quantum phenomena by zitterbewegung caused by the compacted two extra time dimesions. All we need is a way to get dirac spinors defined K-K style in an extension of this theory. Then with both Em and Dirac in a unified space time we can let them interact and tune the theory to produce QED (maybe).

Now in 1933 Infeld and van der Waerden produced a theory of spinors as a sort of bundle over GR spacetime (Sitzb. Pruss. Akad. 1933, pp 308-401.) Could modern techniques unify their spinor manifold with GR via a K-K mechanism? Is it worth looking into?

17. **Tony Smith**
January 12, 2005

Aaron, in reply to Peter's post statement about String Theory
"… Postdocs and untenured people can't take on the fight against this garbage unless they want to commit career suicide. It's up to the tenured people. Where are they? …",
you say
"… If, all of a sudden, this starts to affect hiring patterns, then maybe that's a big deal, but I haven't seen anything like that. …".

Since the current String Theory movement started out about 20 years ago, it has grown so that for years the hiring/funding for theoretical particle physics has been about 90% String Theory and 10% Loop Quantum Gravity with other approaches being miniscule.

Since String Theory already has 90% of the pie, of course you "… haven't seen anything like … all of a sudden …[effects on]… hiring patterns …" during the recent past. You would have to look at the early part of the last 20 years to see when "anything like that" took place.

As of now, a point related to Peter's post is that String Theory may be choking out alternative approaches and
that such elimination of alternatives may be tolerable if the dominant approach (String Theory) actually does produce realistic models, but
if the dominant approach (String Theory) is sterile, then the field (theoretical particle physics) stagnates.

Perhaps String Theorist should admit that they have had their chance.
Two decades of the smartest people on earth working on an approach with no realistic results indicates to me that the approach is unsound, otherwise all those smart people would have already announced realistic results.
It is time to let 1000 flowers bloom and try lots of alternative approaches with equal hiring/funding and see which approach works best.

You also say
"… You want to work on that sort of stuff, you go work on it. If you don't, you don't. No need for bickering on the arXiv. …".

For some of us with unconventional viewpoints (even string theory related unconventional viewpoints such as CERN CDS EXT-2004-031), it is impossible for us to engage in "… bickering on the arXiv …"
because we are blacklisted therefrom (an example being that, since I am personally blacklisted, all my recent work including the paper I just cited is barred from the arXiv).

18. **Peter**
January 12, 2005

I'm in a bad mood and I've finally had it. Any more comments at all like the last two will be immediately deleted. Please take off-topic nonsense like this elsewhere. I'm not going to put up with it here anymore.

19. **plato**
January 12, 2005

Okay from the physics then.:)

At very high energies, the density of the gluons in this wall is seen to increase greatly. **Unlike the quark-gluon plasma produced in the collision of such walls, the color glass condensate describes the walls themselves, and is an intrinsic property of the particles that can only be observed under high-energy conditions** such as those at RHIC.

I was also given the pdf file for consideration and wanted to know if you fellows thought any revision to KK theory would have allowed a expanded view of this area I am pointing out?

Summing over all topologies?

I'll have to add pdf in later

drl writes:
The aether investigation was honest, and physically motivated. Propagation in itself required a medium before it was known that space and time were part of one geometry, and that propagation was a primitive fact that needed no more explanation – so it's not fair to compare the idiocies of string theory with the honest but ultimately wrong-headed search for the aether.

Wasn't the original motivation for string theory (even if indirectly), the problem of infinities, of f = qq'/d^2 when the distance gets so small, in other words, the inherent problem of point particles in a background of space and time?

If we could rewind the clock and go back before Schwartz and Green, and before Nambu, Nielsen and Susskind, and, knowing what's coming, prevent it, where would particle physics be now? Of course, I realize that no one can really say, but it points out something important: given that string theory is such a calamity, what's the more reasonable alternative?

How do we know that the "honest but ultimately wrong-headed search for the aether," a search for something that didn't exist, isn't being repeated again with an "honest but ultimately wrong-headed search" for the elementary particle? Remember the importance of epistemology: it's not what we don't know, but what we "know" that's not so, that can really hurt us.

The apparent "idiocy" of "stringpots" should serve to warn us of this, and instead of continuously ranting about it, maybe we ought to look back to what started it all and ask ourselves why we don't know what an electrical charge is much less a quark? If the standard model is so successful in some ways, but disconcertingly deficient in others, why is this? Could there be something that we think we "know," an erroneous assumption that we have accepted as a fact that is doing us in?

21. **Aaron**
January 12, 2005

I was referring to anthropic-types, not string theory in general.

22. **D R Lunsford**
January 12, 2005

Peter –

I suppose we can look forward to some coset argument that groups the countries into competing blocs and pacts.

"Witten, tear down this membrane!"

Trace, but verify.

-drl

23. **Thomas Larsson**
January 12, 2005

Lubos, I think you should admit one thing, at least to yourself. People like myself, Woit, Lunsford, Baez, Schroer or Rovelli have never written a positive word about anthropism. The only person on your hate-list that has been close to anthropism is Smolin with his fitness landscape (which I find disturbing), but he is also the only tenured person to publicly criticize Susskind.

We all know who the landscapers are: stringpots like Susskind, Douglas, Polchinski, Dimopoulos, Kachru, and Arkami-Hamed. And Witten and Weinberg are the ones that cannot find good arguments against the AP. Draw whatever conclusion you wish from this.

24. **Lubos Motl**
January 12, 2005

Peter, as you know, I don't plan any career and it has no implications for my statements.

"Country" is my terminology – they only use "friendly neighborhood". 😉

I don't think that the claims in their paper are really justified, on the other hand it is a nicely written paper with a lot of interesting technology.

25. **D R Lunsford**
January 12, 2005

"" _

The aether investigation was honest, and physically motivated. Propagation in itself required a medium before it was known that space and time were part of one geometry, and that propagation was a primitive fact that needed no more explanation – so it's not fair to compare the idiocies of string theory with the honest but ultimately wrong-headed search for the aether.

Nor is there any resemblance of the current phase to spectroscopy before quantum theory.

The string cult is like nothing since the pre-Baconian schoolmen.

-drl

26.
January 12, 2005

One does not have to say nice things about garbage from people on whom one's career rests; one can simply keep silent.

This branch of physics is perhaps going through its "models of the luminiferous aether" phase. Perhaps as a proportion of published papers in the 19th century there are as many on the aether as there are now on strings.

The change is going to come from some young researcher who has found a cocoon of safety in some small obscure university somewhere, who has a good idea; and who does not hesitate to comment on the nakedness of the emperor.

27. **D R Lunsford**
January 12, 2005

Oak – HA!

Actually, the notion of countries made me think of a marathon game of "RISK!". Watch it, Bon-Motl is attacking Kamchatka from Alaska!

-drl

28. **Chris Oakley**
January 12, 2005

    This whole phenomenon makes me think of the way that stars swell up to red giants before they use up their fuel. A branch of "physics" is dying spectacularly. Eventually the hundreds of string theorists will become just a handful and they will mostly be found in mathematics departments.

29. **D R Lunsford**
January 12, 2005

    Aaron –

    Explain why [this site] has won awards. I get excited questions from friends and acquaintences about string theory all the time, and have to explain over and over again that it is total horseshit and it practitioners charlatans.

    Just because you are up to the neck in sand from the other direction doesn't mean things aren't really bad. I honestly think the Western world is in deep shit.

    -drl

30. **Aaron**
January 12, 2005

    Fight against them? Who needs to fight against them? You want to work on that sort of stuff, you go work on it. If you don't, you don't. No need for bickering on the arXiv.

    If, all of a sudden, this starts to affect hiring patterns, then maybe that's a big deal, but I haven't seen anything like that.

31. **Tony Smith**
January 12, 2005

    Peter, about hep-ph/0501080 by Steven Giddings, you say:
    "… string theory … has given up any claims to being a
    legitimate science and has taken on the characteristics of a cult.
    … I just can't believe the way
    essentially the entire particle theory establishment,
    including many people I have the highest respect for,
    continue to allow this situation to go on without public comment. …".

    There have been notable physicists such as

    Richard Feynman,
    who said in Davies and Brown, Superstrings, Cambridge 1988, pp. 194-195):
    "… I do feel strongly that this is nonsense! …
    I think all this superstring stuff is crazy and is in the wrong direction.
    … I don't like it that they're not calculating anything. …
    why are the masses of the various particles such as quarks what they are?
    All these numbers … have no explanations in these string theories
    – absolutely none! … "

    and Sheldon Glashow,
    who said at http://www.pbs.org/wgbh/nova/elegant/view-glashow.html
    "… superstring theory … is, so far as I can see,
    totally divorced from experiment or observation.
    … string theorists … will say,
    "We predicted the existence of gravity."
    Well, I knew a lot about gravity before there were any string theorists,
    so I don't take that as a prediction. …
    … there ain't no experiment that could be done
    nor is there any observation that could be made
    that would say, "You guys are wrong."
    The theory is safe, permanently safe.
    I ask you, is that a theory of physics or a philosophy? …".

    They have declared that the String Emperor has No Clothes,
    but
    they seem to be dismissed by the current physics establishment
    as being dead or senile reactionaries, to be pitied for their
    inability to perceive the beauty of String Theory.

    I am reminded of Kipling's Gods of the Copybook Headings
    which says in part
    "… we worshiped the Gods of the Market Who promised …
    that Wishes were Horses …[and]… that a Pig had Wings. …
    But,
    though we had plenty of money,
    there was nothing our money could buy …
    … Then the Gods of the Market tumbled,
    and their smooth-tounged wizards withdrew,
    And the Gods of the Copybook Headings
    said: 'If you don't work you die.'
    … And the hearts of the meanest were humbled
    and began to belive it was true

That All is not Gold that Glitters, and Two and Two make Four …”.

So it seems to me that the smooth-tongued String Theory Wizards
have historical precedent and will eventually withdraw,
but I might not live to see that day.

Lest anyone think that I am opposed to any form of string theory,
I will refer to my paper at CERN CDS EXT-2004-031
which is also available from my web pages at
http://www.valdostamuseum.org/hamsmith/E6StringBraneStdModelAR.pdf
It is an outline of a construction based on the E6 Lie algebra
and an interpretation of strings as world-lines (as opposed to
little stringy subparticles), which construction gives
concrete structures consistent with the Standard Model.
Maybe my construction is valid and realistic,
and maybe it has faults that may or may not be remediable,
but
it is interesting to me that the String Theory establishment
seems to have very little interest in serious exploration of
such a model that, although somewhat complicated,
actually might be a way to connect String Theory with
the Standard Model.

32. **Matti Pitkanen**
January 11, 2005

The situation in theoretical physics is indeed sad to watch. String theorists have become a kind of religious sect refusing to receive any communications from the world outside.

When string models came around 1984, two years after my PhD and the realization that PhD would not help to get support for my work, one thing looked obvious to me. 2-D space-time would soon become a convenient toy model being replaced with a realistic theory based on 4-D surfaces representing both particles and space-time in which they appear as topological in-homogenities. If a time traveller from future would have tried to convince me that after two decades people would be filling hep-th with “predictions” of a non-renormalizable theory, I would have laughed him back to the future.

In these discussions people avoid saying aloud what the real problem is: average theoretical physicist (the finger points also to me!) is full of vulnerable ego and so concentrated in optimizing the career of this vulnerable ego that he will never take a risk of wasting time by listening a person without name and position. My consolation is that I still has some years to develop TGD while looking how colleagues are getting sick of string theory. I try my best to avoid feeling some malicious pleasure and thinking that colleagues are now getting just what they deserve. Fortunately, when farce continues forever it ceases to be fun for both actors and audience and comes to an end.

Matti Pitkanen

33. **D R Lunsford**
January 11, 2005

As usual, there are no equations, no derivations, no apparatus, lots of buzzwords, etc. IOW this paper is the gradient of a crackpotential.

Moreover this person writes on a 4th-grade level. Don’t future bullshitters understand the importance of rhetoric? Where are the great teachers of our day?

-drl

New Policy

January 13, 2005
Categories: Uncategorized

As of yesterday, I've started deleting comments from this weblog if they seem to me to be completely off-topic or make no sense. By the end of last year, the comment section here had begun to turn into something I couldn't stand to read and didn't want to be associated with. This was not a tolerable situation.

Please only post comments if you have something interesting to say related to the topic of the posting. If you want to share your thoughts with the world about the biological basis of homosexuality, quantum computing, etc., etc., please do it somewhere else than in the comment section of a posting about the issue of the predictivity of current formulations of string theory.

This has already wasted far more of my time than I would like. I don't want to moderate or in any way be involved in a public discussion of this, so the comment section for this particular posting is closed. If you absolutely feel you must discuss this issue with me, send me e-mail, although unless there is a very good reason, I'm unlikely to take the time to write back in response. People with on-topic comments are encouraged to continue to contribute them to earlier postings and to any future ones.

Quantum Diaries

January 13, 2005
Categories: Uncategorized

The world of particle physics web logging expanded by about an order of magnitude today, as a new web-site called Quantum Diaries came on-line. The idea seems to be to celebrate the 100th anniversary of Einstein's remarkable 1905 papers by getting 25 physicists from around the world to set up web logs so people can follow what they do during 2005.

Most of the participants are experimentalists, with just three theorists as far as I can tell. The theorists are John Ellis of CERN (see here for a story about him), Stephon Alexander of SLAC, and Jochen Weller of Fermilab.

Interestingly, all three of the theorists are spending at least part of their time working on cosmological or astrophysical topics, which gives you some idea of where the field is headed. Also, none of them are working on string theory at the moment, which also gives you some idea of where the field is headed.

As a completely unrelated aside, today I came upon the web-site of Brian Powell, a graduate student of Will Kinney's at Buffalo studying cosmology. He's more pro than anti string theory, but irreverently funny. His comment that "many people criticize string theory because it's sort of becoming fashionable to do so" warmed my heart. On the other hand, the fact that he links to something I wrote about Witten's talk at Santa Barbara with the terms "Witten gets socked in the groin" kind of upsets me.

   January 14, 2005

   Apprapos, I'd like to take this opportunity to plug my own blog at http://web.mit.edu/guarrera/www/blog.htm . It's the musings of a theoretical physics first year grad student (namely, me)…

3. **Fabio**
   January 14, 2005

   Ellis is one of the world's most published string theorists, and also one of the world's most cited (if you include self-citations).

4. **Lubo? Motl**
   January 14, 2005

   Dear Peter,

   it's very sad if I am taking your naive, innocent, childish ideals 🙂 from you, but most of the people are working in string theory in one way or another.

   I am not sure whether you will believe me that determining the ten-dimensional string coupling by John Ellis et al. in December (20th) 2004 is a recent work on string theory

   http://arxiv.org/abs/hep-th/0412240

   Also, Stephon Alexander has the biggest hobby right now – he was explaining it at Harvard – about determining the string scale in the heterotic models

   http://arxiv.org/abs/hep-th/0409014

   Jochen Weller is a hard astroparticle guy, sure.

   Best
   Lubos

5. **JC**
   January 13, 2005

   I always found "first person" accounts and/or diaries quite interesting in seeing what people were thinking at a particular point in time, without the benefit of hindsight. The real world of physics is a lot more messy and uncertain as one is doing research, unlike how it is presented in future textbooks and/or monographs. Everything in hindsight looks "obvious" and/or "simple" for many things.

6.
   January 13, 2005

   Thanks for the informative post. Notice that these sort of posts, which do not merely concentrate on (possibly justified) opposition to something, and are emotionally neutral, do not attract the flood of crackpots. If you really don't want them, you know what to do.

7. **Fabio**
   January 13, 2005

   Wow, this Quantum Diaries thing is great. I can't think of any better way to celebrate Einstein's legacy than to read a bunch of random physicists detail who they had dinner with the other night or the latest movie they saw.

8. **Sean**

January 13, 2005

Please don't stoop to smileys; I'll just try to fine-tune my tongue-in-cheek sensitivity.

Sure, a lot of particle physicists are increasingly working on astrophysics. Too many, actually, especially on the experimental side. Ten or fifteen years ago that would have been a great career move; but right now particle experiment is just beginning to get interesting again.

9. **Peter**
January 13, 2005

Hi Sean,

The part about string theory was meant to be kind of tongue in cheek (I really got to figure out how to put in those smileys the way Lubos does…). But surely you agree with the first part (about more and more particle physicists working on cosmological and astrophysical topics), that was meant seriously.

10. **Sean**
January 13, 2005

Oh come on, Peter. Do you really think that the choice of blogging physicists tells you something about where the field is headed, rather than the predispositions of the certain individuals that run the site? Shall we conclude that condensed matter physics is basically dead, since it doesn't appear here? All we can conclude is that the site was set up by HEP experimentalists.

Model Building

January 14, 2005
Categories: Uncategorized

For some interesting comments by Nima Arkani-Hamed about his model-building activities, followed by some of my own, take a look here.

Update: Jacques Distler has some comments on the Arkani-Hamed et. al. paper.

Comments

3. **Quantoken**
   January 15, 2005

   Superstar said:
   "For those of us outside the network, who nonetheless are the ultimate source of it's funding, what value does it provide? It's looking more an more like it's ultimate value is as entertainment. Or perhaps also as a way to impress the neighbors. Kind of like one great big living coffee table book for the nation."

   Entertainment is good. It is a much bigger sector of human expendition than what we collectively spend on the whole front of science research. Making one typical movie costs more than sending one PathFinder to Mars. My own daytime work relates to the routine creation of real multiverses in virtual spaces of many dimentions, for the joyful entertainment of the playful population.

   Expenditure on Superstring research is nothing compare with the rest of pork barrel. If it expands the imagination of a few SciFi novel writers or allows making of a few SciFi movies, that's more than the worth of the money already. The sad thing is so many of the smartest people jump into this seemingly hopeless quest, knowing full well they probably won't have better luck in the next 25 years than the previous one, and that it may ultimately be proven to a wrong road which leads to no where. If that's entertainment, isn't it a bit too much cruelty?

   I agree with the notion that "let 1000 flowers bloom". There should be an affirmative action in science research that when the main stream seem to be un-productive, alternative approaches and different tries should be encouraged, instead of being suppressed and censored.

   Remember, some of the greatest discoveries in science were made by a none-main-stream nobody, mere 26 years old, who could not even find a job teaching in a high school, and needed help to finally land a job as a third class clerk working in a small patent office. And whose ideas still look so wackered even today, that calling him "crackpot" would be a compliment to him.

   And this year is to be honored in his name.

   I still don't know how that guy managed to get his stuff published at the time. Wasn't there supposed to be a peer review process to maintain sanity in science publications:-)

4. **Superstar**
   January 15, 2005

   The sociological network effect is certainly a big factor in the current dominance of string theory.

   For those of us outside the network, who nonetheless are the ultimate source of it's funding, what value does it provide? It's looking more an more like it's ultimate value is as entertainment. Or perhaps also as a way to impress the neighbors. Kind of like one great big living coffee table book for the nation.

   Is it any wonder then that so many physicists are working on their own coffee table books these days, and the documentaries to go along with them?

5. January 15, 2005

   "So just as network benefits accrue to users of inferior software [windows], inferior videotape systems [vhs], community benefits accrue to the dominant, if unsuccessful, scientific fad [conference invitations, x-archive postings, fellowships, book contracts, interviews, pbs specials]."

   This seems a bit cynical. The analogy between windows and vhs users with string theorists is improper. The software and videotape users (together with sufficient numbers of similarly acting people) provide the funding that in turn enables the community benefits. Clearly this is not the case with string theory research or other research that is funded publicly or by others who are not members of the string community.

   If community benefits are the primary coin of the realm, then a better analogy would be a community of parasites [the opportunists in the string community] feeding off the hosts [the funding agencies]. Not all parasites end up killing the host; let's hope this one doesn't [e.g., drying up of physics research funding due to inadequate benefits returned to the rest of the world].

6. January 15, 2005

   Comment on Peter's comment on Nima's comment:

   Think of the string theory community as a social group with a "network effect" function of utility to it's members. See for example:

http://en.wikipedia.org/wiki/Network_effect

In other words, regardless of utility to outsiders [rest of world] the community itself generates it's own utility as a power or exponential of it's own size.

So just as network benefits accrue to users of inferior software [windows], inferior videotape systems [vhs], community benefits accrue to the dominant, if unsuccessful, scientific fad [conference invitations, x-archive postings, fellowships, book contracts, interviews, pbs specials].

This is to be expected. The good news is that because of the power law of network utility a competing technology or theory with clear benefits can grow in size rapidly and overtake the inferior competitor. However the benefits have to be substantial to the defecting members, and outweigh the lost utility from detaching from the previous network.

In the case of the competitors to string theory it seems that currently any apparent benefits do not offer enough utility for large numbers to defect.

8. **Tony Smith**
January 14, 2005

Commenting on the historical remarks of Nima Arkani-Hamed
"… a big realization leading to the SM was that gauge theories should be important to the description of nature. … But it did not uniquely predict 3-2-1 gauge theory! … during a period in 77 or so when the experimental situation got very confusing. Critics of gauge theory model-building … said "Its unconstrained! You can build so many models!". … When the dust settled, we had 3-2-1. …"
Peter Woit said:
"… in 1977 … SU(3)xSU(2)xU(1) with the SM particle content was … pretty well set in stone …".

Here is some chronology supporting Peter Woit's comment:

the electroweak force SU(2)xU(1) part of the SM was pretty much "set in stone"
in 1971 when 't Hooft proved its renormalizability;

the 1973 paper of Kobayashi and Maskawa, confirmed experimentally by the 1974 discovery of the charm quark and the 1976 discovery of the beauty quark, pretty much "set in stone" the color SU(3) 3-generation part of the SM; and

in 1974 the 3-2-1 SM was so well accepted that Glashow and Georgi constructed SU(5) GUT based on the fact that SU(5) contains SU(3)xSU(2)xU(1) as a subgroup.

Although some people in 1977 may have disagreed with the the 3-2-1 3-generation SM, their relevance to physics has been no more significant that the relevance of those who disagree with Einstein's relativity.

As to the situation today, it seems to me that string theory today has a financial / sociological dominance that is at least as strong as that of the 3-2-1 SM in 1977, but that string theory today has nowhere near the basis of detailed calculations and experimental results that the 3-2-1 SM had in 1977.

As Peter Woit said:
"… The real problem with particle theory these days is that the top-down approach has been nearly completely destroyed by the concentration on one idea of how to do this (string theory) and the refusal to acknowledge the colossal failure this has led to. …".

Another aspect of the problem is raised by Nima Arkani-Hamed's statement "… there are specific hardware triggers at the LHC that are about to be finalized … we're on touch with experimentalists and they will be modified …".
As Peter Woit said "… It's certainly a good thing that model-builders are pursuing as wide a range models as possible in preparation for the LHC, especially if they're talking to the people who are working on the LHC triggers. …".
However,
if the only model-builders who have influence with LHC trigger designers are conventional string theorists, then the LHC may fail to observe events that could be very useful in evaluating models not based on conventional string theory.

I repeat what I said in a comment to an earlier post:
It is time to let 1000 flowers bloom and try lots of alternative approaches with equal hiring/funding and see which approach works best.

For my part, since I have no influence on LHC trigger design, about all I can do is to be happy to defend my model in comparison with conventional string theory in any reasonable forum (for instance, I have submitted contributed talks about my model to the APS Tampa meeting 16-19 April 2005).

9. **Superstar**
January 14, 2005

In other words, Chris, you're saying string theory is meta-physics.

10. **Chris W.**
January 14, 2005

Arkani-Hamed's characterization of the work he and his colleagues are doing supports a picture* of string theory and landscape ideas as meta-theoretical frameworks — as theory generators. Given the constraints on the models he describes, this may well prove fruitful. However, any successes achieved by this path will be dubious empirical confirmations of string theory, since failures of these models couldn't be taken as empirical refutations of string theory. That is why I'm inclined to regard the specific models as the real physical theories, and string theory itself as a web of related ideas (largely formal schemes) from which testable physical theories might be derived.

Again, drawing an analogy with the case of general relativity, GR is the physical theory, whereas Riemannian geometry is only a meta-theoretical framework, notwithstanding the general notion that the structure of physical space (and later, spacetime) might be Riemannian and dynamic — an idea which was anticipated by Riemann and Clifford.

(* previously discussed in the comments on this post)

Not on the ArXiv

January 19, 2005
Categories: Uncategorized

Most new preprints in mathematics and physics these days are posted on the arXiv, but every so often I run into interesting new things worth reading that haven't appeared there for one reason or another. Here are some recent examples:

Some lecture notes on Lie algebras by Shlomo Sternberg. Lots of topics covered I haven't seen anywhere else, especially the material on the relation to Clifford algebras and the Kostant version of the Dirac operator.

Lecture notes by Constantin Teleman about his recent work on topological field theories and the Gromov-Witten theory of BG, the classifying space of a group. These are notes from talks given at Gregynog, Goettingen, and Miami. I confess that, like a lot of Teleman's work, I have trouble figuring out exactly what he is up to, but it looks quite interesting. I wish he and Dan Freed and Mike Hopkins would get around to finishing their paper on "K-theory, Loop Groups, and Dirac Families" that Teleman has been advertising as "coming soon" for quite a while…

David Vogan has an interesting draft of a review of A. A. Kirillov's book on the orbit method in representation theory. This is the most fully developed version of what is sometimes known as "geometric quantization". Vogan also has some notes from his lectures this past year on "Unitary representations and complex analysis" which include material on the Borel-Weil theorem and its generalizations.

Nikita Nekrasov has some Lectures on Nonperturbative Aspects of Supersymmetric Gauge Theories and a written version of his 2004 Hermann Weyl Prize lecture.

Eckhard Meinrenken has a a nice expository article on the de Rham model for equivariant cohomology.

Comments

   January 20, 2005

   If someone learns the theta functions, their expansions, the forces between D8-branes etc., then he or she is a person familiar with string theory, and if he or she writes a paper about it, then he or she is working on string theory.

   He or she may have a different approach to all these issues than others and may be more or less successful, but it is still string theory.

   I am not like the kind of people who would like to eliminate (and often they DO eliminate) every piece of data that is inconvenient to them. And moreover I think that John Ellis is an interesting person with inspiring ideas, and I have absolutely no reason to try to verbally eliminate him from some group.

2. **D R Lunsford**
   January 20, 2005

   Wow, those Sternberg notes are excellent, thanks for that. Sternberg reads like a novel!

   January 20, 2005

   Here is what Peter was referring to Lubos about the Penquins

   I thinks John's post today directs attention to a certain amount of responsibilty?

4. **Fabio**
   January 20, 2005

   For some good fun look up Ellis and Nanopoulos's work on noncritical louiville string theory applied to the physics of the brain (the kind in your head).

   Of course, I'd be surprised if they haven't already found a way to connect Brane physics to brain physics also, the potential for cute irreverent paper titles being too much to resist.

   Why Lubos wants to brag about this guy being a string theorist escapes me.

5. **Chris W.**
   January 20, 2005

   Yes indeed, they came up* with quite a Rube Goldberg contraption just to produce some effects attributable to spacetime foam. To say that they produced a *model* of spacetime foam is a stretch, to say the least. John Wheeler would be appalled.

   In my opinion this kind of thing shows string/D-brane theorizing in the worst possible light.

   (* Footnote 1 of this paper [gr-qc/0501060] cites the paper in which the model was initially presented.)

6. **Peter**
   January 19, 2005

   Well, the comment that Alexander and Ellis were not working on string theory was a bit of a joke, I wasn't under the impression that they weren't going to work on string theory any more.

   I took a look at the Ellis paper, it is pretty amazing. The guy is clearly smoking a lot more powerful weed than back when he was seeing penguins in his Feynman diagrams.

7. **Lubo? Motl**

January 19, 2005

John Ellis, whom you say is not currently working on string theory, has a new paper tonight about D8-branes and D0-branes:

Nice links. There are still quite a few mathematicians who don't routinely post their work on the ArXiv.

String Fellows

January 20, 2005
Categories: Uncategorized

Today's Guardian has an article by a writer who recently visited the Institute in Princeton to talk to Witten and others there about string theory. The author of the piece makes the obvious analogy between Witten and Einstein, and asks the string theorists about Einstein's 20-year misguided and failed attempt to unify gravity and electromagnetism during his years at the IAS. String theory and Einstein's failed program get further identified by the author's claim that if Einstein were alive today he would be working on string theory, and by a quote from Seiberg that "Being in the place where Einstein was is clearly an inspiring idea."

Seiberg also has something very true to say:

"Most string theorists are very arrogant," says Seiberg with a smile. "If there is something , we will call it string theory."

Witten's attitude towards string theory seems to remain unchanged, he's quoted as saying:

"Critics of string theory say that it might be too big a step. Most physicists in other fields are simply agnostic and properly so," says Witten. "It isn't an established theory. My personal opinion is that there are circumstantial reasons to suspect that it's on the right track. "

His recent work on twistor string theory is mentioned, including the fact that there was a workshop at Oxford last week on the subject. About this, the writer reports

"Witten is not convinced yet. 'I think twistor string theory is something that only partly works,' he says."

I wonder exactly what he meant by that. What's the part of twistor string theory that he thinks doesn't work?

Comments

1. **Matti Pitkanen**
   January 22, 2005

   Instead of twistors, I believe in hyper-octonionic spinors! "Hyper" means multiplying imaginary units with commuting sqrt(-1) so that sub-space of complexified octonions with Minkowski signature of number theoretic norm results.

   The generalization of the notion of calibration

   [see the homepage of Jose Figueroa-O'Farrill at
   http://www.maths.ed.ac.uk/~jmf/Research/susy_7.html%5D

   leads to the notion of Kaehler calibration. When combined with the number theoretic spontaneous compactification of hyper-quaternionic M^8 to M^4xCP_2, this leads to the conjecture that the basic theorems about connection between calibrations, minimal surfaces, and spinors generalize.

   Absolute minima of Kaehler action would correspond to the solutions of massless equation for octonionic 2-spinor satisfying Weyl condition representables as hyper-octonion real analytic maps and satisfying d'Alember equation as a consequence of generalized Cauchy-Riemann conditions.

   Incredible it sounds but classical TGD would reduce to free Dirac equation for hyper- octonionic spinors equivalent with hyper octonions!

   For an enthusiastic blurb see

   http://www.physics.helsinki.fi/~matpitka/newtgd.html#calib.

   A detailed representation can be found at

   http://www.physics.helsinki.fi/~matpitka/tgd.html#visionb

   With Best Regards,

   Matti Pitkanen

2. **Jian**
   January 21, 2005

   "…Most physicists in other fields are simply agnostic and properly so,"

   "An agnostic thinks it impossible to know the truth in matters such as God and the future life with which Christianity and other religions are concerned. Or, if not impossible, at least impossible at the present time."

   Bertrand Russell, "What is an Agnostic?"

3. **D R Lunsford**

   This made me laugh for a while….

good job 🙂

5. **Thomas Larsson**
January 21, 2005

as for the fate of N=1 SUSY in the LHC we just have to wait and see, don't we?

I have no doubt that people will look for SUSY at the LHC, and I am awaiting the results as eagerly as anybody. If it is found, then I will have learnt something. No big deal.

However, experimental particle physics did not start with the LHC. My post referred to several large and expensive experiments, and I think that it is wrong to simply ignore them. I have recently, and more than once, seen the situation summarized in the phrase "SUSY requires fine-tuning at the percent level". This is of course not conclusive, but it gives a hint what we may expect at the LHC.

Besides, LHC will not affect the outcome of a 2-loop calculation of the running coupling constants. If it has been done, I would like to see a reference. If not, it is about time that somebody does it.

Interest in SYM is not mainly due to hopes that it is a realistic theory, but that it is a more tractable version of SYM than those without SUSY.

Fine. But if some conclusion relies critically on SUSY (AdS/CFT perhaps), and SUSY is not part of nature, we haven't really learnt anything about physics, have we?

6. **raj**
January 21, 2005

"Most string theorists are very arrogant," says Seiberg with a smile. "If there is something [beyond string theory], we will call it string theory."

One wonders. Does arrogance among string "theorists" substitute for evidence among scientists? Quite frankly, I'd prefer evidence.

7. **Urs**
January 21, 2005

Interest in SYM is not mainly due to hopes that it is a realistic theory, but that it is a more tractable version of SYM than those without SUSY.

The goal is to understand field theory as such. YM is hard. So let's move in field theory space to a more symmetric version and try to understand that first. That's still hard enough. When done, we can try to move back to the asymmetrical point.

SYM in four dimensions is about the most symmetrical gauge theory that you can get. Therefore its importance. Therefore the interest in it.

See the introduction to the Clay millenium mass gap problem for a detailed discussion why field theorists want to understand SYM.

8.
January 21, 2005

The idea is to calculate QCD amplitudes by expressing them as combination of SUSY amplitudes (which can be now simplified using twistor methods), and one non-SUSY amplitude, that one can choose to be as simple as possible. In fact, one does not use SUSY directly in the calculations, just what is called "cut-constructibility" which works for some non-SUSY calculations as well. As nobody really knows the full ramifications of the idea before exploring them (and it does look good right now), it is not useful to make apriori judgements.

The twistor string itself was proposed only for N=4 anyhow; as for the fate of N=1 SUSY in the LHC we just have to wait and see, don't we?

M.

9. **Thomas Larsson**
January 21, 2005

I forgot: no deviation in muon g-2.

10. **Thomas Larsson**
January 21, 2005

Whether SYM amplitudes can be calculated with twistor methods may or may not be true. The big question is why physicists should care about SYM amplitudes in the first place, given the mounting evidence against supersymmetry (no sparticles, no proton decay, no light Higgs, no WIMPs, no permanent electric dipole moment, and perhaps the 2-loop result that coupling constants don't meet exactly at one point).

11. **serenus zeitblom**
January 20, 2005

"It sparked a whole slew of papers from his fellow theorists and interest is still growing."

103 cites after more than a year? By EW's standards, that is far from a "slew". Nor do I see any evidence that interest is growing in this rather dull, technical subspace of the string world.

12. **Lubos Motl**
January 20, 2005

Hi Moshe, I know that you can derive it (the connected expression) from the B-model, but you can also derive it from e.g. Berkovits' models. It's just too simple so that the details of the string theory are not too important. How's life? LM

13.
January 20, 2005

Lubos,

1. The "connected instanton" formula of Roiban et. al. is a new expression for helicity amplitudes which was not available before, and is "derived" (not very rigorously)

from the toplogical B-model. That expression is correct, though not as efficient as others.

2. The versions of topological strings currently on the market do not work on the loop level, but maybe there is some hope still, “whatever you do” covers a lot of ground…

Moshe

14. **Lubos Motl**
January 20, 2005

The picture of string theory – namely topological string theory – has not been too useful in any of the recent developments that shed light on the new formulae to calculate the Yang-Mills scattering amplitudes.

The picture of the topological B-model on CP3|4 is problematic also because it contains the extra conformal supergravity states, and it’s expected that whatever you do, you will get a disagreement at the loop level.

15.
January 20, 2005

Representation of SYM amplitudes in twistor space makes some of their simplicity manifest, and is very useful as a calculational tool. The idea of cooking up a topological string theory to reproduce these amplitudes works only at tree level, for loop level there are unwanted contributions (from conformal gravity) that one needs to decouple somehow.

16. **D R Lunsford**
January 20, 2005

What part of TST doens’t work?

Probably the usual issues of conformal ideas when sources are present (of whatever kind).

Dijkgraaf Coxeter Lectures

January 21, 2005
Categories: Uncategorized

Robbert Dijkgraaf is about the most lucid expositor around on the topic of what now goes under the name "topological strings". This week he's been giving the Coxeter Lectures at the Fields Institute in Toronto, and the slides and audio of his introductory talk are now available on-line. I hope there will be similar materials for his other, more detailed talks.

Last week the Fields Institute hosted a workshop on topological strings and the talks are on-line, although in many cases just the audio of the talk is available, which is pretty hard to follow.

NUMB3RS

January 23, 2005
Categories: Uncategorized

There's a new TV show called "NUMB3RS" starting tonight, whose main character is a mathematican named "Charlie", who solves crimes using mathematics. His motto is "Everything is Numbers".

A secondary character is "Larry", a Caltech physicist working on 11d supergravity. In one scene he shows up trying to get mathematical help from Charlie, whose graduate student sneers at him "Why don't you do your own mathematics, like Ed Witten or Feynman?".

Comments

1. **D R Lunsford**
   January 27, 2005

   Selrach –

   Well I think the point I'm trying to make is – very little needed to be deduced at that point! Klein had his program, his problem, and his methods, and all that was lacking was *physical insight* into the meaning of the non-Euclidean geometry (which turned out to be Minkowski space) that *he himself*, with his particular sort of intuitionist brilliance, had created, and had used in this problem.

   It's *physical insight* more than anything else that's needed to make progress in physics. Almost anyone can learn the math – even learn it "in the bones" so to speak – but physical insight is the rarest of all gifts it seems.

   -drl

2. **Selrach**
   January 26, 2005

   Hi Lunsford,

   I am not sure the Classical Top is a good example of the difference between a physicist and a mathematician . My own opinion is that out of all physicists only Galileo , Newton, Maxwell ,Einstein and Feymann could have made the deductions that you alluded to in 1896!

   I have been looking at the history of great discoveries in Physics, and it seems that the Great Man Theory does not stand up as well as it might. Essentially, many people have different models which turns out to be essentially the same, after mathematicial inconsistences are straighten out! (String Theory and Loop Gravity anyone?)

   For example, the reason why we remember Maxwell rather than Riemann as the discover of Electrodynamicism, is that Riemann mixed in Gravity! i.e Riemann realised that if there was a link between Electric and Magnetic phenomena, this would lead to symmetry constraints on the physics. Physicists need an Einstein to explain this in terms that they could understand PHYSICALLY.

   Selrach

3. **D R Lunsford**
   January 26, 2005

   Selrach,

   What does being classical have to do with it? It's about representations of the rotation group via the complex plane (stereographic projection). Klein noticed that his problem – to describe the motion of the top subject to external forces – was much simplified if he introduced a non-Euclidean geometry with the fundamental quadric (in the sense of projective/metric geometry)

   x^2 + y^2 + z^2 – t^2 = 0

   Again, Klein goes to some lengths to disabuse his readers of any "metaphysical implication" in introducing a non-Euclidean geometry. Now, this was in 1896! Klein has basically all the mathematical elements for relativity not only in hand, but at work!

   The irony of this is priceless – Klein had clarified the relation of affine, pseudoaffine, hyperbolic, and elliptic non-Euclidean geometry to each other – he'd written a classic book on the subject – he was past master of function theory and operations in the complex plane – yet he missed relativity – not only missed it, but turned it away when it knocked on his door – from the inside!!

   The point is – being a good physicist is a completely different metaphysico-realistic setup than is being a good mathematician.

   -drl

4. **Matti Pitkanen**
   January 26, 2005

   Poincare was great mathematician. Einstein was a great physicists. Someone said that Poincare was too much of a mathematician to discover special relativity which was in the air and although he discovered Poincare group. If a kind of cognitive complementarity is involved, the replacement Poincare-Einstein–>Witten-Witten would not make sense unless Witten enjoys a positive variant of multiple personality disorder;-).

   Matti Pitkanen

5. **Selrach**
   January 26, 2005

   Hi Lunsford,

   I do no understand what SR has to do with the mathematical theory of the Top! This theory is ENTIRELY Classical!

I agree that Einstein was a good mathematician. However he was not a great one, unlike Ed Witten.

6. **D R Lunsford**
   January 25, 2005

   How do these rumors get started?

   Einstein did NOT "often have a mathematician to help him with the hard stuff". In fact the great mathematicians of the day, including Klein and Poincare, fell all over themselves getting things wrong. See for example Klein's "Mathematical Theory of the Top". The locus for this work is the complex plane under SU(2) – really SL(2,C), because the quadratic form arises:

   x2 + y2 + z2 – t2 = 0

   Klein EXPLICITLY mentions that the non-Euclidean geometry he is using should not be taken literally. In fact, it should be taken VERY literally because it's Minkowski space. In other words, the greatest mathematician of the day was flat wrong about his OWN WORK!

   GEEZ, save me from Einstein bashing!!

   -drl

7. **Rafael**
   January 24, 2005

   I actually liked the show. Sure the mathematics is over the top but hey it's fiction! It seems as if they're trying to make it educational and I only say this because they have the main characters narrate their thought process like a PBS special.

   "Why don't you do your own mathematics, like Ed Witten or Feynman?"

   Perhaps this physicist guy is supposed to be more like Einstein since Einstein often had a mathematican who would help him with the hard stuff (like Riemannian geometry).

8. **plato**
   January 24, 2005

   Would it have been more credible to the mathematician that number theory be based on some principle as posted here?

   It would make sense to me, why string theory might be rejected, and a new method considered as a basis?

9. **Walt Pohl**
   January 24, 2005

   It's not quite as bad as the ads made look. It's still painful for math-savvy people to watch.

10. **R**
    January 24, 2005

    Not even close to PI, an excellent movie.
    I bet it doesnt go longer that 3.1415… episodes 🙂

11. **A.J.**
    January 24, 2005

    OK,

    Step up, folks, and place your bets! How long until the show gets cancelled?

12.
    January 24, 2005

    >But on the positive side, maybe one benefit is that >it will portray math as being 'cool' 🙂

    Perhaps…but I'm not convinced…

13. **Steven S**
    January 24, 2005

    Funny. Though the one advertisement I saw for the show made it look positively awful.

14. **Plato**
    January 24, 2005

    Made me think of the show called PI

15.
    January 24, 2005

    Hey! I know! Let's make a math show and call it numb2.71828rs? No, well, then how about numb2.718rs? NO, GEEZ! WELL IS NUMB3RS 0K WITH Y0U?!?

16. **DMS**
    January 24, 2005

    Amusing 🙂 But on the positive side, maybe one benefit is that it will portray math as being 'cool' 🙂

The Thin Line of Theory

January 26, 2005
Categories: Uncategorized

There's a quite interesting article on the controversy over string theory that appeared yesterday in the Boston University student newspaper. It gives some insight into the political battle now going on in many physics departments.

The Boston University physics department has always been in the shadow of its more prominent neighbors just across the river in Cambridge. A few years ago they attracted Glashow away from Harvard, and I've been told a big selling point for him was that he would no longer have to be part of a department dominated by string theorists. He's one of very few particle theorists who has consistently and publicly complained about what is going on in string theory. In the article, he forcefully makes the analogy between Einstein's failed unification efforts and string theory:

"It is tragic," Glashow said, "but now, we have the string theorists, thousands of them, that also dream of explaining all the features of nature. They just celebrated the 20th anniversary of superstring theory. So when one person spends 30 years, it's a waste, but when thousands waste 20 years in modern day, they celebrate with champagne. I find that curious."

Ken Lane, one of Glashow's colleagues at BU, says that "String theory is not physics" and that he doesn't know of any BU faculty who think that string theory belongs in the physics department. He does seem to think that it belongs in a math department, something I have some problems with. While certain parts of string theory are mathematically interesting and do belong in math departments, most of what string theorists do is not mathematics. For instance, the many string theorists making anthropic arguments about the "Landscape" are not doing mathematics and it's pretty insulting to mathematicians to say that they belong in math departments.

Lane believes string theory is on its way out, and that the LHC will finish it off:

"I think I can safely predict that string theory is going to wither and die when exciting results start coming out of the LHC."

Cumrun Vafa of Harvard seems to be spitting mad at the idea that BU won't hire string theorists, referring to them as "foolish" and "childish", which is not normally language academics use when talking to the press about their Nobel-prize winning colleagues at neighboring institutions. Vafa was a student of Witten's a year or two behind me at Princeton, but I haven't talked to him since my postdoc days. He's definitely a smart guy, but also definitely a fanatic.

Vafa graduated from Princeton in 1985, just as the string theory fad hit. He went to Harvard as a postdoc, where most of the senior people were pretty skeptical about string theory, although willing to hire smart young postdocs doing it. I heard he was very upset in 1986 when Glashow published his article with Ginsparg in Physics Today attacking string theory, and even threatened to leave. But over the next decade or so he managed to marginalize Glashow, get more string theorists hired, and consolidate power around them. Finally Glashow left, and by now the string theorists heavily dominate the theory group. Of the active theory faculty, Vafa, Strominger, Minwalla and Motl are full-time string theorists and Randall and Arkani-Hamed do more phenomenological work, work whose justification is often given in terms of string theory. This just leaves Georgi remaining, and at the moment he has his hands full dealing with the fact that the president of Harvard is a sexist buffoon.

For Vafa to accomplish this undoubtedly took some single-minded dedication to furthering the interests of string theory and thwarting its opponents, but now that string theory so overwhelmingly dominates the field, it's pretty disturbing to see him continuing to behave like a complete fanatic. I've been told that after Brian Greene's Nova TV show about string theory came out, Vafa was heard to say that he didn't care if it was any good; as far as he was concerned anything that promoted string theory was great. He's quoted in the article as saying

"Theoretical developments have indicated string theory is a very important part of physics," Vafa said. "It has already proven foolish. It's past the point."

I'm guessing there's a typo here, one assumes he doesn't mean that string theory is foolish, but that opposition to it is. He completely ignores the argument that string theory has not predicted anything and thus is not science, calling people who make this argument "childish". His arrogant attitude towards those who don't believe what he does is pretty breath-taking, matched only by that of his younger colleague Lubos. He finally dismisses the whole BU physics department with the logically incoherent:

"I think they are doing a disfavor to BU. I don't want to pass judgment, but not having a string theory group puts out of first rate in my opinion."

I think he does want to pass judgement and already has. If you're a theorist who might someday have to deal with him as someone evaluating your grant proposal, deciding whether to hire your student, etc., do you think you might think twice before making a "childish" or "foolish" public comment about what is going on in string theory these days?

Comments

1. January 28, 2005

   Levi,

   Did you see that the paper was dedicated to *Giordano Bruno*? And that he paraphrased a Pete Seeger/Peter Paul & Mary song?? And that there is not ONE equation in the entire paper?

   The amazing thing to me – this guy was invited to MIT and CERN for 3 years each. Who makes these decisions? I wonder if these people know how to actually do any calculations?

   -drl

2. January 28, 2005

   We must keep this from Ed, he'll be devastated. Poor fellow, he seemed so excited…

3. **Thomas Larsson**
   January 28, 2005

   Peter,

   I realize that it makes sense to spend for Witten to spend a year or two on the twistor string if he finds it promising. However, from what he writes (and that is my only source, I don't know anything about the subject first-hand) I most definitely get the impression that he doubts the project's viability. Now, I prefer to work on presumably correct projects rather than presumably incorrect ones, and I suspect that Witten thinks likewise. So that he works on the twistor string but doesn't believe in it seems to indicate that he doesn't have any attractive alternative.

4. **Levi**
   January 27, 2005

   Chris W.,

   Your link in the thread you reference is to the most bizarre paper I've seen yet on the ArXiv. It's hard to imagine that Cumrun Vafa endorses the views in the paper, but who knows? Besides the passage you cite, the author of the paper also thanks Vafa in a footnote on page 3. In fact the paper is worth reading for the footnotes alone. My personal favorite is footnote 4 on page 4, which correctly conveys the flavor of the whole paper:

   although they could send unwanted anti-prisoners, their arrival being known as gamma-ray bursts

5. **Peter**
   January 27, 2005

   I'm deleting the last couple posts claiming the Pound-Rebka experiment was a fraud because they are off-topic nonsense. If anyone wants to discuss this with quantoken, do it at
   http://quantoken.blogspot.com
   not here.

   By the way, R. V. Pound taught my advanced laboratory physics course, and was an extremely impressive scientist.

6. **Chris W.**
   January 27, 2005

   View this old post on this weblog, and use your browser to search for "Cumrun Vafa":

   > "Cumrun Vafa thinks that the fact that we do not see aliens around could be the first proof of the existence of brane worlds: all advanced aliens would have emigrated to better parallel universes (our Universe has zero measure)." [– Beatriz Gato-Rivera]

   If he seriously expressed this opinion it really says something about his judgment.

7. **DMS**
   January 27, 2005

   "Also, so much of the (suddenly overhyped) particle "phenomenology" these days, a subject which cannot really be done without actual experiments, is simply string theory done badly."

   This is a joke, right? In case you are serious, LHC will falsify most (perhaps all) these models. That is a good thing. If you want to do something unfalsifiable, there are other subjects like theology.

   The string theorists also show such appalling ignorance about particle physics: like Lubos' statement (in his blog entry) that phenomenology deals with issues like "adding new digits to the 3 x 3 neutrino mass matrix". Have they heard about oblique precision electroweak observables S,T,U (hint: nothing to do with dualities)? Do they even care? Details, details, to be worked out later; everything is massless relative to Planck scale… There is a certain comfort in doing such work.

8. January 27, 2005

   Lubos' willfull misreading of Peter's funding comment is a pretty common "technique", if you want to call it that, from usenet type flame wars. It baits your opponent to go on the defensive, "no, what I really meant was…". Not the level of discourse one would normally associate with Harvard faculty (even untenured ones).

9. **Peter**
   January 27, 2005

   Lubos,

   My comment about funding was just pointing out what more than one person has told me. They don't dare criticize string theory in public because when powerful figures like Cumrun make it clear that they think anyone who criticizes string theory is a "fool" or a "child", there's the implicit threat that they will oppose funding grant proposals by fools and children.

   The story about Cumrun's reaction to the Nova program was told to me by a string theorist who heard him say this.

   Thomas:
   I don't think it is irrational for Witten or others to keep working on twistor strings for a while even though they have run into problems. They do get very useful tree-level results, and it's reasonable to see what else they can get out of this idea. If they keep doing it for twenty years though…

   The real problem is that they don't have any other new ideas about string theory to work on.

   Quantoken:

   Please stop trying to turn the discussion here to your pet ideas about GR. I'll delete any further comments by you or anyone else about this.

10. **Thomas Larsson**
    January 27, 2005

    Ever thought about the concept of "work in progress"?

    Work in progress on a non-unitary theory like conformal supergravity? Not really. Sounds kind of LQGish.

11. January 27, 2005

Re: Fabio's comment

Just like the audience at Bush's inauguration who booed Kerry:

Cumrun Vafa = sore winner

12. **Quantoken**
January 27, 2005

It's indeed interesting Witten suddenly became interested in the Twistor Theory, though no one knows why. String theoretists are a group of sheep blindly following the leading shepherd. Predictably, many people will immediately follow Witten's footstep into this Twistor thing, though many of them never figured out why. Just look at how many references to Witten's paper have already been made!

I am not going to comment on Lubos's long article, except for that he seems amazingly CHILDISH to even hate to meantion the name Boston University. He must be feeling pretty good about himself being a Harvard assistant professor, not realizing that there is a tradition of manipulating science at Harvard. For example like this INFAMOUS "Harvard Tower Experiment" where they dodged the data to fit what they wanted:

http://hyperphysics.phy-astr.gsu.edu/hbase/relativ/gratim.html#c2

Any one with a little bit common sense in physics can see why the data can not be true and can only be dodged, although I do not doubt the theory of Einstein's GR itself. I might explain if some one wants to hear.

Quantoken

13.
January 27, 2005

Ever thought about the concept of "work in progress"?

About the actual topic of the post, many smaller dpt. decide not to pursue some areas so that they have better representation in others. Celebrating your (perhaps inevitable) deficiencies is an odd attitude to life.

Also, so much of the (suddenly overhyped) particle "phenomenology" these days, a subject which cannot really be done without actual experiments, is simply string theory done badly. Might as well have the real thing.

14. **Thomas Larsson**
January 27, 2005

I didn't see any explanation why Witten is pursuing the twistor string although he evidently thinks that it is wrong.

15. **Lubo? Motl**
January 27, 2005

I've posted an article about it on my blog.

16. **Thomas Larsson**
January 27, 2005

It's pretty remarkable that Witten is doing cutting-edge research on the twistor string, which he himself apparently thinks is wrong. Aren't there any right ideas to investigate at the cutting edge?

17. **Quantoken**
January 27, 2005

Lubos:

What "cutting edge" research you are talking about? The only edge superstring research is cutting is dominating the whole theoretical physics field and marginalizing alternative approaches. It surely doe not cut any edge in the physical world of reality.

I don't know why you would interpret Peter's original words as "threaten Cumrun of denying his proposals". Is that a deliberate distortion or your incompetence in reading logically?

Peter said:
"If you're a theorist who might someday have to deal with him as
someone evaluating your grant proposal, deciding whether to hire
your student, etc., do you think you might think twice before making
a "childish" or "foolish" public comment about what is going on in
string theory these days?"

The question is not whether super string research should be supported. I think in the spirit of scientific openmindedness, all approaches need to be allowed even some may seem reasonable or unreasonable based on personal opinion. I have no problem continue funding super string theory research, as long as there are people willing to waste their lifetime on that pursuit.

But I see a problem when one mainstream camp becomes so dorminate and marginalize people of different opinions, to the point that people like Glashaw had to find a refuge away from Harvard. It's harmful to science.

Quantoken

18. **Lubo? Motl**
January 27, 2005

Some of the things you write, Peter, are not right.

Cumrun had only judged the program from PBS after he saw it, and he was excited by it – simply because it was a great program. He described it as "something in between physics and video games". His sons apparently liked it, too.

Cumrun is also right, of course, that the question for today, 2005, is not "Whether we should study string theory at all?". This is a question from the Middle Ages that only the people who have lost contact with the current thinking – or those who never had this contact – ask. Theoretical high-energy physics in 2005 without string theory is like quantum mechanics without Hilbert spaces.

The question is, as often in the past, "What is the right next important step that will be done in string theory?"

Your proposals to threaten Cumrun with denying his proposals etc. are pretty childish – using Cumrun's diplomatic speech. I would probably use stronger words. Science is organized differently than you think and the people with enough influence are usually admired physicists.

Most of us like Shelly Glashow for his personality and we admire him for what he has done several decades ago. But that's a slightly different question than cutting-edge research.

19. **Thomas Larsson**
January 27, 2005

We may not know much about whatever theory will ultimately unify QM and GR, but we do know what it will be called: string theory! Nati Seiberg has admitted as much.

Unless, of course, somebody with the right idea has the foresight to protect his intellectual property 🙂

20. **Thomas Larsson**
January 27, 2005

The Glashow-Ginsparg Physics Today article can be found here.

21.
January 26, 2005

We may not know much about whatever theory will ultimately unify QM and GR, but we do know what it will be called: string theory! Nati Seiberg has admitted as much.

22. **D R Lunsford**
January 26, 2005

Fabio – this is an excellent point. I just finished a book, "102 Minutes", which is a narrative of the demise of the World Trade Center pieced together from survivor stories and cell phone calls of people who would end up as victims. Immediately after the tragedy, Giuliani, then mayor of NY, attempted to spin it into a tale of selfless heroism. In fact it appears that massive incompetence from one end of government to the other, on all levels, lead to the insane scenario of 200 or so firemen standing around in a nearly empty Tower 1, 20 minutes after the collapse of Tower 2, unable to communicate with people a few hundred feet away. The book is a tacit indictment of public policy and the culture of incompetence that has taken over so many aspects of American life.

I see the string theory debacle as a direct result of the involvement of incompetent government bureaucracies in science, who will throw money at anything that might one day produce a super-bomb or Buck Rogers death ray.

The more the incompetence of these bureaucracies is demonstrated by history and repeated failure, the more intransigent they become.

-drl

23. **Jan Eidissen**
January 26, 2005

"…any more than it makes sense to count the Harvard string theorists as part of the math department"

I believe string theory (or LQG) may turn out to be nothing more and nothing less than a highly sophisticated human invention enabling many theoretical physicists to keep busy while another physicist comes out with a sound theory of quantum gravity in which they can work. Meanwhile, labeling is pending.

"If, on the other hand, there is a rich phenomenology at LHC, string theory enetrprise will be in serious trouble"

String theory is a well-devised survival tool (for it's non-falsifiable), so it shall end up being a marginal subject at math departments only when a simpler theory is able to unify GR and QFT or a more plausible alternative comes to scene. I don't expect the LHC to make any big difference, even after conceding that only SM particle debris has been found within its full energy range.

24. **Quantoken**
January 26, 2005

Peter said:
"Ken Lane, one of Glashow's colleagues at BU, says that "String theory is not physics" and that he doesn't know of any BU faculty who think that string theory belongs in the physics department. He does seem to think that it belongs in a math department, something I have some problems with. While certain parts of string theory are mathematically interesting and do belong in math departments, most of what string theorists do is not mathematics."

Wow that really amazed me! Peter, according to you, super string theory are neither physics nor mathematics. Then into which category shall we classify super string theory? Maybe religion? Religious cult do seem to be a fitting category for super stringers 🙂

Too bad politics played such a big role in the science community. Nothing surprising to me, though. According to Darwin's theory, which is the ultimate truth in the universe, "survival of the fittest", the ones surviving in the science community must be the ones most capable of getting fundings. They may not be the ones doing real science, but probably the ones who know to play politics in their hands.

Ever since science has matured into a MASSIVE industry in where a great portion of the human population jump in to earn a living of bread and butter, politics has become an ever more important factor in the science community. Sad but true. "Science" is as dirty as politics nowadays.

Quantoken

25. **Peter**
January 26, 2005

I was talking to someone last night who told me that Coleman (who is 68) has not been well and has been on medical leave for the last couple years.

The kind of cosmology/astrophysics done by the people at the CFA you mention may have some connections to particle physics, but I don't think it makes sense to count these people as particle theorists (any more than it makes sense to count the Harvard string theorists as part of the math department). There are good reasons that they work at the CFA, not at Jefferson.

26. **Anonymous**
January 26, 2005

Among the phenomologists at Harvard you missed
Sidney Coleman , plus a few others at CFA who do
work on interface of particle physics/Cosmology
such as Avi Loeb, George Field, Matias Zaldarriaga
and maybe a few others. So I don;t think Harvard
is all string theory.

27. **DMS**
January 26, 2005

I too was taken aback by Vafa's arrogant tone. This is what happens if one is a true believer, I guess.

I noticed the amusing sentence: " But Harvard's Vafa said that string theorists share excitement about the LHC, and that experimental results it yields will not prove or disprove string theory."

There you have it: straight from the horse's mouth. So much for predictivity and uniqueness 🙂

Anyone know the ratio of string theorists being offered post-docs and faculty positions to non-string theorists (among high energy theorists) recently?

I think, if LHC shows SM Higgs+nothing else (or nothing), string theory will complete the dominance in high energy theory.

If, on the other hand, there is a rich phenomenology at LHC, string theory enetrprise will be in serious trouble. That should worry Vafa and explain his behaviour.

28. **Fabio**
January 26, 2005

You make an interesting observation about how Vafa's fanatasism has not been softened by near total domination of the field, and it begs an anology with the political right in the US, who seem to get more fanatical and vitriolic in their rhetoric the more power they accumulate. There must be something about having near absolute power but knowing that it's built upon such flimsy foundations which causes one to obsessively squash dissent.

29. **flack**
January 26, 2005

I wasn't aware Glashow had left Harvard.

I heard Shamit Kaku say a few years ago that Harvard basically capitulated to stringification because they realized that, whether it was good physics or not, that was the only way to remain "hot" as a theory department.

30.
January 26, 2005

Lane said. "One of the reasons Sheldon Glashow, a Nobel laureate, left Harvard was because they had become way too stringy. We sort of led the way. We did not emphasize string theory, and we attracted Shelly"

What an achievement that is! Ha! "We sort of led the way". Yeah, right…..

31. **D R Lunsford**
January 26, 2005

"So when one person spends 30 years, it's a waste, but when thousands waste 20 years in modern day, they celebrate with champagne. I find that curious." – S Glashow

Now THAT is quotable! 🙂 Nice article.

-drl

32. **Dick Thompson**
January 26, 2005

I suspect the influence, if not the hidden hand, of Sheldon Glashow in BU's decision to deemphasize string theory.

Oxford Twistor String Conference

January 27, 2005
Categories: Uncategorized

The transparencies from the conference on twistor string theory held two weeks ago at Oxford are now available on-line.

Quite a few of the talks deal with the technical details of computing amplitudes. For the motivation from phenomenological particle theory, see the talk by Zvi Bern. As for the motivation and present state of the whole idea of relating QCD to a string theory in twistor space, the only person who really seems to have much to say about this is Witten himself. His transparencies are in three parts: part 1a and part 1b from his first talk and then a second talk in which he explains what the problems with the whole idea are and some ideas he's been thinking about using to try and get around them.

Comments

1. **D R Lunsford**
   January 27, 2005

   Related to Atiyah's notes is the following very interesting paper:

   http://arxiv.org/PS_cache/hep-th/pdf/0105/0105179.pdf

   -drl

2. **D R Lunsford**
   January 27, 2005

   I've been meaning to look into this question…

   Since one apparently invokes twistors to get some knowledge of spacetime (M), is there a technical reason one must build on SO(4,2) vs. SO(3,3)? All the ideas of incidence will hold, with suitable replacement of real configurations by imaginary ones. Of course one will lose the real scalings in M but we don't experience these in any case.

   -drl

Branches of the Landscape

January 27, 2005
Categories: Uncategorized

If you've been following the story of the "Landscape" over the past year or so you'd remember that its proponents felt that if it could predict anything it should be able to predict whether or not there will be supersymmetry at low energies. They had great hopes for making this prediction before 2008 when the LHC presumably will tell us whether there is supersymmetry at LHC energies.

Well, tonight one of the biggest proponents of this point of view, Michael Dine, has a new paper out with two co-authors, entitled Branches of the Landscape. In it they conclude:

"From all this, it appears that it is difficult, in principle, to decide whether or not the landscape predicts supersymmetry."

So, many string theorists now seem to believe that:

1. String theory predicts a landscape of possible vacua.

2. Given the existence of such a landscape, one can't predict whether or not there will be low-energy supersymmetry (or anything else either).

One wonders it these string theorists ever studied elementary logic and can draw the obvious conclusion from 1. and 2.

Comments

1. **Peter**
   January 31, 2005

   Thanks for the information about Lane's letter to the editor!

2. **DMS**
   January 31, 2005

   Thought you might be interested in an update to
   "The Thin Line of Theory".

   http://www.dailyfreepress.com/news/2005/01/27/Opinion/String.Theory.Article.Slanted-843320.shtml

3. **JC**
   January 29, 2005

   These landscape papers seem to look more and more silly as time goes on. Has this anthropic trend affected the number of graduate students and/or postdocs entering into string theory over the last two years or so? If I was still a grad student or postdoc, I surely would be very skeptical of any science which attempts to use the anthropic principle.

4. January 28, 2005

   I wonder if it's totally out of the question to think of string theory as a branch of mathematics that is very relevant to physics, but is not, in and by itself, physics.

   An example that comes to mind is complex analysis: It is very relevant to physics, and one can give all theorems in the subject a physical interpretation: simple poles are electric charges, branch points are magnetic monopoles, etc. But it is a very simple, two dimensional physics, and although it coincides with certain simplified physical phenomena, it is far from being a complete, and closed description of physical reality.

   The theory of complex function will always be a fundamental and correct ingredient of any mathematical description of the physical world, but it is not the whole story, and one cannot use it to say anything about, let's say the big bang or the mass of the electron. For that, one needs many more ingredients, and input from experiments.

   My idea is that string theory is a much larger example of the above. It is wonderful, beautiful, very rich, and very coherent, but it is far from being the full story. My point of view is that this is the reason why it cannot make predictions about the physical world, such as the choice of vacuum, for example.

5. **Thomas Larsson**
   January 28, 2005

   String theorists get together and sign a pact to commit suicide if supersymmetry is not found at the LHC.

   Why wait? Isn't the anthropic principle intellectual harakiri?

   It is of course true that we live in a universe which is not too hostile to human life. If anything, this must be evidence for Intelligent Design.

6. January 28, 2005

   Peter:

   The only viable explanation of why university physics departments do string theory is the anthropic principle. We live in that branch of the landscape where string theory is correct and the anthropic principle is valid.

   That string theorists exist at universities is a well-confirmed 6-sigma fact, and string theory predicts string theorists must exist.

   Therefore string theory must be true.

   Elementary logic!

7. January 27, 2005

   I’ve got an idea for a new version of the anthropic principle:

   String theorists get together and sign a pact to commit suicide if supersymmetry is not found at the LHC.

   Then, in the event it is found, they can claim to have anthropically explained it (if the universe were not supersymmetric, they would all be dead afterall!) and award each other prizes.

8. **D R Lunsford**
   January 27, 2005

   This is obviously string complementarity.

   -drl

Two-Loop Superstring Amplitudes

January 29, 2005
Categories: Uncategorized

Eric D'Hoker and D.H. Phong this past week finally posted two crucial papers with results from their work on two-loop superstring amplitudes. The first one shows gauge slice independence of the two-loop N-point function, the second shows that, for N less than 3 and for low-order terms at N less than 4, there are no two-loop corrections to the low energy effective action.

D'Hoker and Phong have been studying superstring amplitudes for nearly twenty years, and are justly proud of their recent results, which are a tour de force of careful calculation. Over the years there have been many claims made about two-loop amplitudes, but until their work, no one had managed to really sort out the gauge dependence issues and write down gauge-independent amplitudes. For some comments about some of the issues involved at genus 2 and higher, see postings by Jacques Distler here, here, and here.

I don't think D'Hoker and Phong will be coming out with complete results for genus 3 anytime soon, so the state of the art is that there is now a finite and well-defined version of the two-loop superstring amplitudes, with the problem of higher loops still open. While claims abound about the finiteness of higher-loop amplitudes, before believing them one should first take a look at the tricky problems that D'Hoker and Phong had to overcome to get well-defined two-loop amplitudes.

Update: Jacques Distler has a new posting about multi-loop amplitudes and potential problems with the Berkovits version of the superstring (he explains in more detail the possible problems with the BRST and picture-changing operators I mentioned). For some mysterious reason Jacques neglects to refer to my posting or comments about this. I encourage those commenters who seemed convinced I didn't know what I was talking about to now take up their arguments with him.

   What would convince me of finiteness of these perturbative amplitudes would be hearing from the experts in these calculations that they understand theme well-enough to have a solid argument for finiteness. That's not what those I've talked to are telling me.

   I've given some detailed technical arguments about this and you're not addressing them or showing any signs of having looked into the details of what is going on in these two-loop calculations enough to even understand what I am talking about.

   If you talk to people who have done these recent two-loop calculations (d'Hoker-Phong, another group is Zheng-Wu-Zhu) or read their papers they'll explain to you the subtleties that happen at two loops and that they don't know what happens at three loops. As for covariant approaches like that of Berkovits, it is simply undeniable that he has yet to calculate a 2-loop amplitude.

   If you don't believe me, contact any of these experts, or sit down and read some of their papers. Until you've done that, you have no business going around making claims that finiteness of multiloop amplitudes is well-established fact. It isn't and such claims are extremely unfair to people who are working hard to actually understand what is going on, rather than making unsupported claims about the issue.

2. February 3, 2005

   Ok, you win, it is hard to imagine what will covince you of finiteness of perturbative string theory, you seem to be attached to the idea that it is insufficiently established. On the other hand you are quite convincing to your readers (there is a selection effect in place, of course).

   February 1, 2005

   D'Hoker and Phong are doing superstring theory the way it needs to be done: facing up squarely and honestly to specific and very hard technical problems, sticking with them over time, and getting rigorous results. I think this is the only way one can approach superstring theory because it remains a very wild beast to tame. This is in contrast to the waffling and speculative Landscape and string cosmology papers of recent times. Years ago I came across a review article in Physics Reports I think, written by D'Hoker and Phong on Differential Geometry and it was very readable and illuminating. These guys do know their stuff.

   Peter,

   Many, many thanks for your explanations and for pointing out a nice (very readable!) paper!

   The D=11 supergravity starts having divergences at 2-loops.

   The conclusion seems quite strong (for perturbative supergravity, at least):
   "…there is no local, unitary (ghost/tachyon-free) quantum field
   theory whose action reduces to QGR or classical GR that is also free of infinities; the latter are
   almost certainly there at every order, requiring an infinite number of input parameters to define
   these theories. The conclusion includes all possible SUGRA models, i.e., from D=4 through D=11, as well. Although the presence of new counterterms at all loop orders (or at an infinite set of them) cannot reasonably be rigorously demonstrable, the fact that the ones we did see appeared at lowest permitted order (so that no ?hidden? invariances prevented them), is quite convincing evidence."

   February 1, 2005

   Yes, the general assumption is that string perturbation theory gives an asymptotic series, and so people like to claim that the situation is no worse than in QFT, where the same thing happens. But, at least for non-abelian gauge theories, in that case there is a simple non-perturbative definition of the theory which appears to be well-defined and give finite answers.

   Again, there's no evidence of a problem that will occur at higher loops in superstring multi-loop amplitudes, there just isn't a solid argument showing that no problems can occur. I'd have to look up the precise facts about supergravity, I believe they depend on N, the number of supersymmetries. But it has been shown that the known symmetries of the theory are such that at high enough loops you get terms that have no reason to be zero and are presumably divergent. It is true that these problems are at high enough loops that no one has been able to actually compute the diagrams to be sure the infinities are really there.

A quick search turned up this reference
http://arxiv.org/abs/gr-qc/9911073

   February 1, 2005

   Peter,

   It is pretty sad to see (some) string theorists being unreliable even about technical aspects of the subject. Prior to this, I thought string theory had already been "proven finite" to all orders: thanks for pointing out D'Hoker-Phong's remarakable paper.

   A couple of questions:
   "…even if the multiloop amplitudes are finite, their sum isn't"

   Does that mean string perturbation theory series is an asymptotic series?

   "Maybe someone will find that, just like in supergravity, if you go to high enough order, you run into trouble. "

   Surprising result to me. Is it easy to understand why this happens? A reference perhaps?

7. **Peter**
   February 1, 2005

   I think there are still potential problems with singularities in superstring amplitudes at the boundaries in moduli space, not just the interior. But sure, the reason you give was a good reason for Schwarz et. al to look into superstring theory as a theory of quantum gravity 30 years ago.

   But for the last 20 years this idea has been beaten to death by thousands of theorists writing tens of thousands of papers on the subject. The bottom line of all this work is that, even if the multiloop amplitudes are finite, their sum isn't, so this idea doesn't give a well-defined, finite theory of quantum gravity. There's a lot of wishful thinking about hypothetical M-theory and non-perturbative versions of string theory, but wishful thinking is all it is right now. The main achievement of this whole program, the supposed calculation of the entropy of certain special black-hole like configurations using branes, is pretty underwhelming.

   You can't just keep repeating the initial motivation for a speculative idea, long after a huge amount of effort has gone into working on it, with extremely disappointing results. At some point you have to admit failure and move on, something that most string theorists seem incapable of.

8.
   February 1, 2005

   OK, just to summarize the situation in my mind: there is a powerful physical mechanism that cancels the divergences that cause real problems for any other attempts to quantize gravity. This is the old insight that caused many, who were not born string theorists, to be attracted to string theory as a quantum theory of gravity (if not as a theory of particle physics), and what is referred to by them as finiteness. The potential problems with the interior of moduli space have to be sorted through, but are as far as we can tell they are just a technicality. Regardless of the hype, the semantics, etc., if you were interested in quantum gravity, is it not a good enough reason to work on the field?

9.
   January 30, 2005

   OK, I think we do agree on the facts, though I seem to give much more weight to that UV finiteness and unitarity, again since it is not acheivable in any other context. As for your points:

   1. The particle like limit of the string corresponds to various boundaries of moduli space. I was under the impression that these limits are simple and one is able to make general statements about them, though I am far from being an expert. The tricky parts have to do with the interior of moduli space. If there were some problems there they would not be called UV or IR diveregences, they would be inherently stringy. No reason to suspect they are there, but in any event I am more impressed with cancelling the divergences we already knew about, not with the elimination of all logical possibilities for problems.

   2. Divergences are wonderful since they give rise to proper understanding of field theories via the renormalization group. This very understanding tells you GR cannot be treated as QFT, as it is not renormalizable. This is a concrete and straightforward problem, not an interpretational issue or an aesthetic displeasure (as in "background independence"), one simply cannot calculate finite and unambigous results.

10. **Peter**
    January 30, 2005

    Lubos,

    What's his argument that divergences in the interior of moduli space can't occur in his formalism? Do you mean the footnote where he says that in conformal gauge, there are no obvious potential sources of divergences since the amplitudes are independent (up to surface terms) of the locations of picture-changing operators?

    This isn't a very solid argument. How do I know there isn't a "non-obvious" potential source of divergences? And how do I know that the picture-changing operators are really well-defined and do exactly what they are supposed to? If Berkovits could explicitly work out what happens at two loops so one could be sure that at least in that case he really had well-defined amplitudes and there were no "non-obvious" problems, that would be a lot more convincing.

    That's about all I have to say about this, if you really are so interested in this topic, you should read D'Hoker and Phong's papers carefully. I think if you do this you'll see that this is an exceedingly tricky business and that it is far from obvious that Berkovits has a solid argument.

11. **Peter**
    January 30, 2005

    To whoever my non-abusive commenter is:

    I think we're agreed about the bosonic string and the fact that at one loop it doesn't have the same problems that come about at one loop in a field theory due to integration over arbitrarily high momentum going around the loop. Of course it has other problems.

But two points about this:

1. The superstring is much trickier. If you look at D'Hoker and Phong's two-loop calculation it involves very subtle cancelations of singularities in order to get a finite result. It's not a matter of combining together well-behaved bosonic amplitudes with signs to get something well-behaved. There are singularities that have to cancel precisely. They are able to show that this happens at two-loops, but aren't able to do this for more than two loops. Whether these singularities have an interpretation as "IR" or "UV" singularities I don't know. I was under the impression that you couldn't cleanly separate which was which.

2. In non-abelian gauge theories, the fact that loop integrations diverge as you take the momentum cutoff to infinity is not a bad thing, but a good thing. For one thing, it tells you about asymptotic freedom. For another, via dimensional transmutation, in pure gauge theory you end up with a theory with zero free parameters. If all your Feynman diagrams were finite and no renormalization was required you would have a theory with a free parameter (and in the pure gauge theory case would be conformally invariant). So the fact that your diagrams require renormalization leads to a proper understanding of the theory's short distance behavior, and as a final result a very non-trivial theory with a complicated spectrum and zero free parameters. What's bad about that?
OK, this doesn't work for the Einstein action, but it indicates the problem is not necessarily inherent in the divergent integrations in Feynman diagrams.

12. **Lubos Motl**
January 30, 2005

Just to explain more clearly why I wrote that Peter was ridiculous.

Peter Woit wrote:

Berkovits himself says his argument only gives finiteness if you assume "there are no unphysical divergences in the interior of moduli space". But this absence of "unphysical divergences" is a crucial part of what one needs to prove.

===========

This is very funny because the reason why Nathan wrote this is *exactly* because this problem (unphysical divergences inside the moduli space) can *not* arise in his formalism.

13.
January 30, 2005

I hope nothing I writen here qualifies as abusive, though I have to admit I find the sociological points less than fascinating.

I am not saying anything that you don't know. Take the bosonic string in flat non-compact space and calculate (for example) one loop scattering, you get results that are UV finite. I am explicitely talking about the bosonic string because:

1. It has severe IR problems, which is not what we are discussing.

2. It has no technical problems due to fermions.

3. One cannot claim miracles due to SUSY, which should be irrelevant for UV phenomena anyhow.

What I mean by UV finite is very well defined: you look at the contribution to the amplitudes from the limit where the string is particle-like, and that particle moves at very high momentum. This is the region which leads to all the celebrated UV problems of gravity. The contribtions to the string amplitudes from this corner are finite, and one can look for specific mechanical reasons for this. These are covered in all standard textbooks, and have to do with duality , or more physically the exponential softness of tree level string amplitudes, which suppresses the UV region when performing loop amplitudes.

These properties cannot hold in any local QFT with finitely many degrees of freedom (consequently they do not look very natural in string field theory, and are lost in any truncation thereof). Any other attempt to make these amplitudes finite, a subject with a very long history, involves some ad-hoc cutoff and the expected problems with unitarity. I am not aware of any other physical mechanism to cut-off the problematic region of integration without loss of unitarity.

This is maybe less than a complete finiteness, and I am not claiming that's the most impressive statement one can make, but this is already plenty impressive, at least for me.

14. **Peter**
January 30, 2005

I agree with your statement that it is reasonable to let the multi-loop problem go and think about other things. But when string theorists do this, they should stop using multi-loop finiteness as their big selling point for the theory (or thuggishly abusing anyone who mentions the problem to them)

This is not an argument about semantics, but about a very specific factual question. Are there well-defined, finite, multi-loop amplitudes for the superstring? Right now the answer is yes up to two loops. For three loops and higher the answer to this is yes or no, but we don't know which yet. Maybe Berkovits will develop his formalism to the point where he really can explicitly construct such amplitudes. Maybe someone will find that, just like in supergravity, if you go to high enough order, you run into trouble. Nobody has a specific proposal for what this trouble would be, so it is reasonable to guess that it doesn't occur, but who knows?

I'm not at all sure what you mean by "UV finite" or that there is any sensible meaning to such a phrase. What fact is true for what specific reasons special to the extended nature of the string? Remember, in the case of strings you can't disentangle UV and IR phenomena (think about T duality and the implications of modular invariance). Multi-loop superstring amplitudes are certainly different kinds of objects (for one thing, they're a couple orders of magnitude more complicated…)than Feynman diagrams. They don't have the same problems with integrating momenta running around loops that Feynman diagrams have. But that doesn't mean they don't have potential problems with singularities, some of which one could even interpret as coming from short distances.

15.
January 30, 2005

Ok, another way of saying things is that the difference in opinion is about semantics, not about the facts. Maybe a better formulation is to state that string theory is UV finite, a statement which refers to the type of infinities one finds in QFT, but does not cover absolutely everyhting one may think of. This fact is true for very specific and well-understood reasons to do with the extended nature of the string. This is a precise statement which is correct, I believe.

It is not proven that there are no other mysterious divergences that will be specific for strings and will somehow conspire to appear at 3-loops (usually potential problems appear as soon as you include quantum corrections), but there is no reason to suspect it. Given that, and that nobody has specific reasons to be interested in the result of the multiloop amplitudes, it is a reasonable attitude to just let it go and think about other things.

16. **Peter**

January 30, 2005

I understand well the difference between math and physics cultures about proof, since my Ph.D was in a physics department and I work in a math department. That's not what's at issue here.

The situation is not like in QCD, where there's lots of evidence from computer calculations for confinement. There's also the fact that whenever you can check QCD against experiment it works precisely, and you never observe free quarks.

For superstring amplitudes there's nothing like this. There's no experimental evidence concerning them and the only existing actual calculation of a well-defined multi-loop amplitude is the calculation at two-loops. No one has any kind of approximate or computer calculation of an amplitude beyond two loops. There's not much known about these things beyond formal expressions, expressions you still need to do a lot of work with to make sense of. If Berkovits did this in his formalism for two loops and things worked out as he expects, it would provide some evidence that things would work at higher loops, but he hasn't done this yet.

The only "physical" argument for finiteness of multiloop superstring amplitudes is the bogus one I've seen a couple hundred times now at the beginning of every general string theory talk. This is the one where you draw a world sheet and a Feynman graph and point out that while the interaction takes place at a point on the graph, there is no well-defined interaction point on the worldsheet. Then the speaker claims this shows string theory doesn't have singularity problems. This ignores all kinds of problems, many of them associated with the fact that there is a moduli space of metrics on the worldsheet. As you go to the boundaries of this moduli space there is all sorts of singular behavior to worry about. In addition there are lots of other possible sources of trouble. Berkovits uses BRST and picture-changing operator techniques involving composite operators. When you multiply operators together in QFT, there are plenty of new singularity problems to worry about. Whether all of these problems can be handled beyond two loops (or even at two-loops in the Berkovits formalism) is still an open problem.

I don't have any problem with string theorists hoping for the best, assuming that superstring multi-loop amplitudes are finite, and then going on to see if they can get a sensible TOE out of the theory. But what has happened is that this has failed, superstring theory has not lead to a sensible TOE. Instead of abandoning the theory, they keep promoting how wonderful it is because of its finite multi-loop amplitudes. It's only fair to point out to them that this is an assumption, not a result. Just because you would like something to be true, doesn't mean it is.

17.
January 30, 2005

A bit of a clash of cultures here, physicists usually do not care if something is proven beyond mathematical doubt, anyone you will ask these days will believe in confinement of quarks for example.
To convince a physicist something is false, after enough evidence is presented in favor of it, a counter-argument is needed. The mathematician's line "you did not prove it" cannot be convincing- almost nothing is proven rigorously in any non-trivial dynamical system (which is reason to suspect that if you are after rigorous proofs you will end up studying trivial dynamical systems such as TFT).

18. **Peter**
January 30, 2005

Hi Lubos,

It's kind of pathetic the way you just start spewing insults when you don't have an argument.

What is in the D'Hoker-Phong papers and in the Berkovits papers, together with what is not in the Berkovits papers (a two-loop calculation) speaks for itself.

If I had to bet, I'd bet that at three loops superstring amplitudes are finite. But I don't know for a fact that this is true, and neither does anyone else at this point.

19. **Lubo? Motl**
January 30, 2005

You're ridiculous, Peter. You have obviously searched the paper for something that could be argued to be a loophole, so that you can make your simple readers happier. Well, it's your decision that you don't care if the physicists think that you are about as stupid as your readers.

It has never happened that string theory would suddenly display some inconsistency, and your belief that something like that could suddenly occur at 3 loops or anywhere else is silliness.

20. **Peter**
January 30, 2005

Berkovits himself says his argument only gives finiteness if you assume "there are no unphysical divergences in the interior of moduli space". But this absence of "unphysical divergences" is a crucial part of what one needs to prove.

If you look at the history of the two-loop calculation before D'Hoker/Phong, there were many people claiming to have written these amplitudes down and to have proofs of finiteness. But their amplitudes were gauge dependent, and once D'Hoker/Phong finally sorted things out, it turns out the correct amplitudes have a different structure than what earlier people had assumed in their "proofs". Berkovits has yet to write down explicitly a two-loop amplitude in his formalism and see if it really has the properties he would like.

21. **Lubo? Motl**
January 29, 2005

D'Hoker and Phong are doing very difficult stuff. On the other hand, the finiteness is easier to prove in formalisms with manifest spacetime supersymmetry where the vanishing of the surface terms is easier to prove.

The only known working covariant formalism of this type is Berkovits' pure spinor formalism. Nathan's calculations are of course extremely impressive, but they were doable and finite for him, and he finished the proof of the finiteness of stringy perturbative expansion as far as we're able to say (although I don't follow all the details):

http://motls.blogspot.com/2005/01/pure-spinor-formalism.html

This kind of humiliates the rest of us, especially the skeptics who have been saying for years that it is impossible to prove the finiteness at all orders, or who – the more weird ones among them – were even suggesting that it does not have to be true.

Loop Quantum Gravity Debate

January 29, 2005
Categories: Uncategorized

A couple weeks ago, three string theorists, (Nicolai, Peeters and Zamaklar) posted on the arXiv a critical assessment of loop quantum gravity. Today I received from Lee Smolin something he wrote responding to them, and I'm posting it here with his permission. Lubos Motl also has put up Smolin's text on his weblog this morning, but I thought it would be a good idea to provide a version that doesn't include Lubos's interspersed rantings. Smolin has some very interesting things to say, and his comments are well-worth reading by anyone who wants to understand what is going on in this field.

Somewhat off-topic, I'd also like to mention a paper by Freidel and Starodubtsev from earlier this week called Quantum gravity in terms of topological observables. The idea of trying to use topological quantum field theory to understand quantum gravity is one that I've always found appealing, and this paper is an interesting attempt to make this idea work. I don't think I find it completely convincing, for one thing they seem to be breaking the topological invariance by hand. For another, TQFTs are very subtle QFTs, and the kind that might be relevant to gravity is still very far from well-understood.

Dear Friends,

Thanks very much for all the time and work you put into your review. While I disagree with a number of your assertions, both in point of detail and of attitude, what is certainly very much appreciated is your evident willingness to "get your hands dirty," learn the technicalities and attack key problems. It is very good that you do this, as indeed too few of us loop people have taken the time to try to learn the details and attack problems in string theory.

Some points you raise have been underappreciated. The issue of what happens to the chiral anomaly, and whether there is fermion doubling in LQG is one I have suggested to many graduate students and postdocs over the years, but so far no one takes it up. It would be good to know if LQG forces us to believe in a vector model of weak interactions.

At the same time, the major difficulties you raise were underestood to be there more than ten years ago. This is especially true with respect to issues concerning the hamiltonian constraint such as the algebra and ultralocality.

What is missing from your "review" is an appreciation of how the work done over the last ten years addresses these difficulties.
Indeed the fact that much work in the field has been on spin foam models is exactly because the problems you worry about do not arise in spin foam models. I will explain this below. Other work, such as Thiemann's master constraint approach, also is motivated by a possible resolution of these problems.

As you will appreciate, like any active community of 100+ people there is a range of opinions about the key unsolved problems. I have the sense that you are aware of only one out of several influencial points of view.

The view your concerns reflect is what one might call the "orthodox hamiltonian" point of view towards LQG. According to this, the aim of work in lqg is not so much to find the quantum theory of gravity as to work through the excercise of quantizing a particular classical theory, which is Einstein's. From this point of view, the program would fail if it turned out that there was not a consistent canonical quantization of the Einstein's equations.

While I will refer to my own views so as not to implicate anyone else, you should beware that this is not necessarily the dominant view in the field. It is a respectable view, and I have the greatest respect for my friends who hold it. But, were it to fail, many of us would still believe that loop quantum gravity is the most promising approach to quantum gravity.

This is not avoidence of hard problems, there are good physical reasons for this assertion, which I'd like to explain.

What I and others have taken as most important about Ashtekar's great advance is the discovery that GR can be writen as a diffeomorphism invariant gauge theory, where the configuration space is that of a connection on a manifold Sigma, mod gauge transformations and Diff(Sigma). This turns out to be true not only of Einstein's theory in 4d but of all the classical gravity theory we know, in all dimentions, including supergravity, up to d=11, and coupled to a variety of matter fields.

This is a kinematical observation and it leads to a hypothesis at the kinematical level, which is that the quantum theory of gravity, whatever it is, is to be written in terms of states which come from the quantization of this configuration space. This as you know, leads directly to the diffeo classes of spin net states. Furthermore, given the recent uniqueness theorems, that hilbert space is unique for spacetime dimension 3 or greater. Thus, o long as the object is to construct a theory based on diffeomorphism invariant states, it cannot be avoided.

The main physical hypothesis of LQG is not that the quantum Einstein equations describe nature. It is that the hilbert space of diffeo classes of spin nets, extended as needed for matter, p-form fields, supersymmetry etc, is the correct arena for quantum gravitational physics. Given that the theorems show that this hilbert space exists rigorously, this is a well defined hypothesis about physics. It may hold whether or not the Einstein equations quantized give the correct dynamics.

A lot already follows from this hypothesis. It gives us states, discreteness of some geometric diffeo invariant observers, a physical interpretation in terms of discrete quantum geometry etc.

But there is also a lot of freedom. We are free to pick the dimension, topology, and algebra whose reps and intertwiners label the spinnetworks. This then gives us a large class of diffeo invariant quantum gauge theories, of which the choices that come from GR in d=4 are only one example. These are possible kinematics for consistent background independent quantum field theories.

Now let us come to dynamics. I believe the most important observation for an understanding of quantum dyannics in this class of theories is that all gravitational theories we know, in all dimensions, super or not, are constrained topological field theories. (See my latest review, hep-th/0408048, for details and references for all assertions here.) This means they are related to BF theories by non-derivative constraints, quadratic in the B fields.

A lot follows from this very general observation. It allows a direct construction of spin foam models, by imposing the quadratic constraints in the measure of the path integral for BF theory. This was the path pioneered by Barrett and Crane. The construction of the Barrett Crane and other spin foam models does not depend on the existence of a well defined hamiltonian constraint. The properties that have been proven for it, such as certain convergence results, also do not depend on any dynamical results from the hamiltonian theory.

The relation to topological field theory is also sufficient to determine the basic form of fields and states on boundaries. In 4d these give the role of Chern-Simons theory in horizon and other boundary states. Thus, it gives the basic quantum geometry of horizons.

Once we have the basic form of spin foam models, which follow from the general relation to BF theories, we can consider the problem of dyanmics in the following light. Given the choices made above, the spin foam amplitudes are chosen from the invariants of the algebra which labels the spin networks. There is then a large class of theories, differing by the choice of the spin foam amplitudes. Each is a well defined spin foam model, which gives amplitudes to propgate the spin network states based on the chosen dimension and algebra.

The lack of uniqueness is unaviodable, because there is a general class of theories, just like there is a general class of lattice gauge theories. These theories exist, and the general program of LQG as some of us understand it, is to study them.

>From a modern, renormalization group point of view, the first phsyical question to be answered is which of these theories lead to evolution that is sensible, i.e. which spin foam ampltidues are convergent in some approrpiate sense. The second physical question is to classify the universality classes of the spin foam models and, having done this, learn which classes of theories have a good low energy behaivor that reproduces classical GR and QFT.

It is of course of interest to ask whether some of these theories follow from quantizing classical theories like GR and supergravity, by various methods. But no one should mind if the most successful spin foam model, in terms of both matheamtical elegance and physical results, was not the quantization of a classical theory, but only reproduced the classical theory in the low energy limit. How could one object from a physics point of view, were this true?

This is the point of view from which many of us view the problems with the hamiltonian constraint you describe.
The next thing to be emphasized is that there is no evidence that a successful spin foam model must have a corresponding quantum hamiltonain constraint. There are even arguments that it should not. These have not pursuaded everyone in the community, and this is proper, for the healthiest situation is to have differing views about open problems. But it has persuaded many of us, which is why many people in the field turned to the study of spin foam models after the difficulties you describe were understood, more than ten years ago.

For example, Fotini Markopoulou argued that, as the generators of infinitesimal spatial diffeos do not exist in the kinematnical hilbert space, while generators of finte spatial diffeos do exist, the same should be true for time evolution. This implies that there should only be amplitudes for finite evolutions, from which she proposed one could construct causal spin foam models.

This was partly motivated by the issue ultralocality. (Btw, you dont emphasize the paper that first raised this worry, which was my gr-qc/9609034). The worry arises because moves such as 2 to 2 moves necessary for propagation do not occur in the forms of the hamiltonian constraint constructed by Thiemann, Rovelli and myself, or Borissov. This is because they involve two nodes connected by a finite edge.

However, the missing moves are there in spin foam models. This concretely confirms Fotini's argument. In fact, as Reisenberger and Rovelli argued, invariance under boosts generated by spacetime diffeo requires that they be there. For one can turn a 1-3 move into a 2->2 (0r 1->4 into 2-> 3) move by slicing the spin foam differently into a sequance of spinnetworks evolving in time.

So we have two arguments that suggest 1) that the problem of ultralocaity comes from requiring infinitesimal timelike diffeos to exist in a theory where infinitesimal spacelike diffeos do not exist and 2) the problem is not present in a path integral approach where there are only amplitudes for finite timelike diffeos.

One can further argue that if there were a regularization of the hamiltonian constraint that produced the amplitudes necesary for propagation and agreed with the spin foam ampltidues, it would have to be derived from a point splitting in time as well as space. This suggests that there is a physical inadquancy of defining dynamics through the hamiltonian constraint, in a formalism where one can regulate only in space and not in time.

Let me also add that there is good reason to think that the other issues such as the algebra of constraints arise because of the issue of ultralocality. Thiemann's constraints have the right algebra for an ultralocal theory.

It was for these and other reasons that some of us decided ten years ago to put the problems of the hamiltonian constraint to one side and concentrate on spin foam models. That is, we take the canonical methods as having been good enough to give us a kinematical frameowrk for a large class of diffeo invariant gauge theories, but unnecessary and perhaps insufficient for studying dynamics.

At the very least, making a point splitting regularization in both space and time seems a much more difficult problem and hence is less attractive than spin foam methods where one can much more easily get to the physics. Given that the relation to BF theory gives us an independent way to define the dynamics, and path integral methods are more directly connected to many physical questions we want to investigate, there seemed no reason to hold back progress on the chance that the problems of the hamiltonian constraint can be cleanly resolved.

Nothing I've said here means that I am not highly supportive of Thomas's and others efforts to resolve the problems of the hamiltonian dynamics-I am. But it must be said that a "review" of LQG that focues on this issue misses the significance of much of the work done the last ten years.

Let me make an analogy. No one has proved perturbative finiteness of superstring theory past genus two. I could, and have even been tempted to, write a review of the problem, highlighting the heroic work of a few people like d'Hoker and Phong to resolve it. I think it would be useful if someone did that, as their work is underappreciated. But it would be very unfair of me to call this a review of, or introduction to, the state of string theory. Were I to do so, I would rightly be criticized as focusing on a very hard problem that most people in the field have for many years felt was not crucial for the development of the theory. This is not a perfect analogy to what you have done in your "review", but it is pretty close.

There are other mis-statments in your review. For example, there are certainly results at the semiclassical level. Otherwise there could not be a lively literature and debate about predictions stemming from LQG for real experiments. See my recent hep-th/0501091 for an introduction and references. Of course semiclassical states do not necessarily fit into a rigorous framework-after all, WKB states are typically not normalizable. But I would suggest that it may be too much to require that results in QFT that make experimental predictions be first discovered through rigorous methods. At the standards of particle physics levels of rigor, there are

semiclassical results, and these do lead to nontrivial predictions for near term experiments. It is possible that a more rigorouos treatment will in time lead to a rigorous understanding of how classical dynamics emerges-and that is a very important problem. But given that AUGER and GLAST may report within two years, may I suggest that it is reasonable to do what we can do now to draw predictions from the theory.
In closing let me emphasize again that your efforts are very well appreciated. I hope this is the beginning of a dialogue, and that you will be interested to explore other aspects of LQG not covered by or addressed in your review.

Sincerely yours,

Lee Smolin

   Urs, have a good time in California!
   Maybe we can resume this discussion next week when you get back.

2. **Urs**
   February 3, 2005

   Hi Ludwig,

   I will be flying to California this weekend visiting the deep M-theory thinker John Baez :-), right after end of semester. Last preparations will probably keep me from chatting on the web too much today and tomorrow. But when I find the time I will get back to you, maybe next week.

   One quick remark, though:

   Nice that we managed to agree on what is going on. In summary it seems to me that the following has happened:

   Somebody working on LQG/spin foams (namely Smolin and collaborators) has come up with some action S whose space of classical solutions (=extrema) contains (when suitably identified) those of 4-dimensional GR as well as those of some topological theory.

   This is a curious formal observation, though I am not yet sure if it is really deep or useful. But let's not argue about that. If something useful can be derived from this action (as suggested, but not yet demonstrated, by Freidel and Starodubtsev), fine.

   However, it should be made rather clear that this new action S is just some formal construct of which nobody has any reason to expect that it directly describes our world. Rather, it plays a role of a calculational trick so far. And this trick also so far has been demonstrated to work only classically. I think the authors of the papers that I have seen would agree with this statement.

   Even if any of these authors nourished hopes that this curious action S is actually phenomenologically important (in its full form, not just in its reduction to GR), one should make very clear that just writing down this action is not the same as doing LQG.

   But it now seems to me that, since Smolin is a prominent representative of LQG, and since he wrote about this action S, Vafa got the impression that this action is part of the program called LQG. Since this action has a 'sector' of solutions which are that of BF theory, it seems that Vafa concluded one can make the statement that 'the topological sector of LQG is BF theory'.

   Then, when he found BF theory in topological M-theory he commented that hence 'the topological sector of LQG' has appeared in topological M-theory.

   (If that is not what happened I'd be grateful for corrections. It sure *seems* that this is what is going on.)

   But really it is BF theory that has appeared in topological M-theory. BF-theory is not the 'topological sector of LQG', really, but merely the topological sector of the above discussed curious action – which was more or less *designed* to have BF theory solutions among its solutions.

   The statement that 'BF theory is the topological sector of that special action S, while GR is another 'sector" is true by construction of that strange action, really.

   The motivation for the construction of S is that it might help (which has not been shown yet, though) to approach GR with tools of topological field theory. But that should not be confused with the stament that 'LQG has a topological sector which is BF theory'.

   Unless, of course, one would go ahead and redefine the term 'LQG'. Maybe if something is investigated by Smolin people will tend to call it 'LQG'. In that case however it should be made very clear in every discussion what precisely is to be meant by the term 'LQG'.

   So in conclusion I think what happens is that

   Vafa found in topological M-theory a topological theory which, by construction is, classically, a certain sector of some action principle investigated by Smolin.

   If this is true it is nothing to be axcited about at all, I think.

   February 2, 2005

   Hi Urs,
   Hearty thanks for your reply!
   I am pleased that you approve my brief listing of some papers.
   For now I can only respond briefly to your question and comments.

   Urs said:

“Do you agree with this summary?
Again some comments:

1) What Vafa finds in topological M theory is BF theory, not any of its extensions that Smolin, Freidel and Starodubtsev discuss, right?

2) Having some action that involves BF theory is not yet the same as ‘doing LQG’, right?

3) I have more comments, but I gotta run. More later, if you like.”
Posted by: Urs at February 2, 2005 10:59 AM

To the extent that I can rely on my own inexpert judgment I agree fully with your comments:
1) absolutely! I do not hear Vafa connect top.M-theory to LQG (more like he creates a context or perspective in which both may be mentioned)
2) right! it is not the same as doing LQG
3) I am very glad you have more comments and hope you will share them with us.

One reservation is that I only heard the Vafa audio and did not see what he wrote at the board. I can only guess about some of what he said.

I also have several times read through your summary of the Smolin/Starodubtsev (2003) paper and find that I agree completely with your summary.

4. **Urs**
February 2, 2005

Hi Ludwig,

thanks for your efforts in replying and listing literature. It is appreciated.

I am short of time today so let me reply to your latest message first and postpone the previous discussion until later.

You wrote:

> After listening to Vafa’s whole talk, I would say that what he said, including towards the end where he again discussed LQG, has significant overlap with
> Smolin, Starodubtsev(2003)
> General relativity with a topological phase: an action principle

I have just had a look at this paper. Therein the following is discussed:

BF theory is a well known topological field theory. By adding a certain term to it that breaks both some gauge symmetry as well as the topological property one obtains an action that can be shown to be equivalent to the Einstein-Hilbert action.

Put the other way round: The Einstein-Hilbert action can be massaged into a form which is a topological term plus something else.

That ‘something else’ involves a fixed background structure (that gamma5 vector) which is needed to reduces the 5-d theory to 4-d.

In their paper Smolin and Starodubtsev proceed by adding yet another term to the action which makes this background structure dynamical. By the above discussion the result is a modification of the Einstein Hilbert action.

Because that first extra term is now dynamical, there are solutions where it reproduces the first step and hence the EH action, but there are also solutions where it takes other values and yields topological theories.

Hence, in conclusion, the authors find that there is an extension of the EH action which has some solutions that reproduce those of the EH action and some that don’t.

Do you agree with this summary?

Again some comments:

1) What Vafa finds in topological M theory is BF theory, not any of its extensions that Smolin, Freidel and Starodubtsev discuss, right?

2) Having some action that involves BF theory is not yet the same as ‘doing LQG’, right?

3) I have more comments, but I gotta run. More later, if you like.

February 1, 2005

The connection of TQFT (BF theory especially) with Loop-and-related Quantum Gravity seems to go back to 1995, see for instance the paper linked below
Smolin (1995)
Linking topological quantum field theory and nonperturbative quantum gravity

The first paper by Smolin dealing with QG in relation to BF theory explicitly, at least that I could find, is Smolin (1998), see link.

The history of the LQG/Spin Foam/BF connection has become interesting (for instance because of Cumrun Vafa’s discussion this month in Toronto, which was compensated by other remarks we saw tending to dismiss or downplay the relationship.
So I thought I would provide this sketchy bibliography to give some background perspective.

After listening to Vafa’s whole talk, I would say that what he said, including towards the end where he again discussed LQG, has significant overlap with
Smolin, Starodubtsev(2003)
General relativity with a topological phase: an action principle

It would be great to have a text copy of Vafa’s talk with some footnotes, because in the audio I couldnt catch what his sources were or if it was just general Vafa-knowledge

John Baez (1995)
4-Dimensional BF Theory as a Topological Quantum Field Theory
15 pages
http://arxiv.org/q-alg/9507006

"Starting from a Lie group G whose Lie algebra is equipped with an invariant nondegenerate symmetric bilinear form, we show that 4-dimensional BF theory with cosmological term gives rise to a TQFT satisfying a generalization of Atiyah's axioms to manifolds equipped with principal G-bundle. The case G = GL(4,R) is especially interesting because every 4-manifold is then naturally equipped with a principal G-bundle, namely its frame bundle. In this case, the partition function of a compact oriented 4-manifold is the exponential of its signature, and the resulting TQFT is isomorphic to that constructed by Crane and Yetter using a state sum model, or by Broda using a surgery presentation of 4-manifolds."

http://arxiv.org/gr-qc/9505028 (TQFT + QG)

Smolin (1998)
A holographic formulation of quantum general relativity
http://arxiv.org/hep-th/9808191 (explicitly BF + QG)

"…Thus, this approach is similar to that of MacDowell-Mansouri, in which general relativity is found as a consequence of breaking the SO(3, 2) symmetry of a topological quantum field theory down to SO(3, 1)[29]. However it differs from that approach in that the beginning point is a BF theory… "

John Baez (1999)
An Introduction to Spin Foam Models of Quantum Gravity and BF Theory
55 pages, 31 figures
http://arxiv.org/gr-qc/9905087

"In loop quantum gravity we now have a clear picture of the quantum geometry of space, thanks in part to the theory of spin networks. The concept of 'spin foam' is intended to serve as a similar picture for the quantum geometry of spacetime. In general, a spin network is a graph with edges labelled by representations and vertices labelled by intertwining operators. Similarly, a spin foam is a 2-dimensional complex with faces labelled by representations and edges labelled by intertwining operators. In a 'spin foam model' we describe states as linear combinations of spin networks and compute transition amplitudes as sums over spin foams. This paper aims to provide a self-contained introduction to spin foam models of quantum gravity and a simpler field theory called BF theory."

Smolin (2000)
Holographic Formulation of Quantum Supergravity
http://arxiv.org/hep-th/0009018

Smolin, Starodubtsev(2003)
General relativity with a topological phase: an action principle
http://arxiv.org/hep-th/0311163

"An action principle is described which unifies general relativity and topological field theory. An additional degree of freedom is introduced and depending on the value it takes the theory has solutions that reduce it to 1) general relativity in Palatini form, 2) general relativity in the Ashtekar form, 3) F wedge F theory for SO(5) and 4) BF theory for SO(5). This theory then makes it possible to describe explicitly the dynamics of phase transition between a topological phase and a gravitational phase where the theory has local degrees of freedom. We also find that a boundary between adymnamical and topological phase resembles an horizon."

Urs said:
4) What if spin foams could reproduce the kinematics of the canonical LQG approach. Would that imply that spin foams have no dynamics, either?
Posted by: Urs at January 31, 2005 01:11 PM

About Urs question #4, the answer is no, it would not imply that spinfoams have no dynamics. Indeed it has not been established that canonical LQG must have no dynamics. Nor has Smolin claimed this is necessarily the case. If anyone is interested in recent progress in LQG dynamics some relevant papers are
these five by Thomas Thiemann and Bianca Dittrich

http://arxiv.org/abs/gr-qc/0411138
Testing the Master Constraint Programme for Loop Quantum Gravity I. General Framework

Testing the Master Constraint Programme for Loop Quantum Gravity V. Interacting Field Theories
20 pages

"… Here we consider interacting quantum field theories, specifically we consider the non-Abelian Gauss constraints of Einstein-Yang-Mills theory and 2+1 gravity. Interestingly, while Yang-Mills theory in 4D is not yet rigorously defined as an ordinary (Wightman) quantum field theory on Minkowski space, in background independent quantum field theories such as Loop Quantum Gravity (LQG) this might become possible by working in a new, background independent representation."

Because of Urs' ungrounded assumption in his point #4, I must re-emphasize that not only has it not been established that a proper LQG dynamics is unattainable, but also Smolin does not say this. He says that at a certain point in history (in the 1990s) some researchers, including himself, redirected effort because they saw serious problems with constructing the Hamiltonian constraint in canonical LQG. So they began exploring other paths, like spin foams with their connection to BF theory and related areas, which have turned out to be interesting and are still being pursued.

Urs said:
5) If they can not reproduce the canonical LQG kinematics, what does this imply for the experimental predictions that it seems Lee Smolin wants to derive from these kinematics?
Posted by: Urs at January 31, 2005 01:11 PM

I believe the answer to Urs' question #5 is that it would not imply anything about Smolin's predictions. The latest word on what experimental predictions Lee Smolin has gone on record with is in this recent paper:
http://arxiv.org/hep-th/0501091
Falsifiable predictions from semiclassical quantum gravity
Lee Smolin
9 pages

"Predictions are derived for the upcoming AUGER and GLAST experiments from a semiclassical approximation to quantum gravity. It is argued that to first order in the Planck length the effect of quantum gravity is to make the low energy effective spacetime metric energy dependent. The diffeomorphism invariance of the semiclassical theory forbids the appearance of a preferred frame of reference, consequently the local symmetry of this energy-dependent effective metric is a non-linear realization of the Lorentz transformations, which renders the Planck energy observer independent. This gives a form of deformed or doubly special relativity (DSR), previously explored with Magueijo, called the rainbow metric. The argument is general, and applies in all dimensions with and without supersymmetry, and is, at least to leading order, universal for all matter couplings. The argument is, **illustrated in detail in a specific example in loop quantum gravity.**
A consequence of DSR realized with an energy dependent effective metric is a helicity independent energy dependence in the speed of light to first order in the Planck length. However, thresholds for Tev photons and GZK protons are unchanged from special relativistic predictions. These predictions of quantum gravity are falsifiable by the upcoming AUGER and GLAST experiments."

Urs gives the impression that he thinks Smolin's predictions concerning the up-coming experiments are derived from details of LQG kinematics. But this is not the case, although they can be *illustrated* as Smolin says by considering the example of LQG.

LQG is falsifiable, Smolin argues, and risks being refuted by GLAST. And the prediction is not based on particular LQG detail but is in a sense "generic". It applies to any of a broad class of approaches to Quantum Gravity which share the feature that they require an observer-independent energy scale but at the same time do not allow a preferred frame (they deform but do not break Lorentz invariance).

It will be interesting to see if GLAST falsifies LQG. This appears to me to be a valid prediction from the theory and a potentially solid experimental result. This has nothing to do with whether or not Spin Foams can or can not reproduce details of LQG kinematics (which was Urs question).

7. **Quantoken**
February 1, 2005

I think my message below is not off topic. But to not waste too much bandwidth on Peter's blog, please see the complete message at:
http://quantoken.blogspot.com/2005/02/blackhole-entropy-lqg-and-super-string.html

Both the super string camp and the LQG camp claimed their derivations of the Bekenstein-Hawking black hole entropy as their biggest success of their theories. In my judgement, claiming the derivation of Bekenstein Hawking entropy, such a trivial feat, as their biggest success, is completely "childish" and only shows the lack of "innate" ability on the part of each camp to comprehend what is the REAL physics behind the blackhole entropy!

I am going to show one very trivial derivation of the black hole entropy and how it is proportional to the event horizen surface area divided by Planck area. One that is different from Hawking's but much simpler.

But first, one has to realize two things:
1.Hawking entropy is not an empirical experimental evidence, but merely the result of a gedanken "experiment", e.g., mind exercise.
2. The entropy is a DIMENTIONLESS physical quantity.

See the complete message at
http://quantoken.blogspot.com/2005/02/blackhole-entropy-lqg-and-super-string.html

8. **Urs**
February 1, 2005

> it seems to me that it will not take long before LQG is "unified" into the stringy framework.

I don't think that the appearance of BF theory in 'topological M-theory' supports such an expectation.

Everybody interested in this question should pick up the recent paper

L. Freidel & A. Starodubtsev: Quantum gravity in terms of topological observables (2005) .

The crucial idea is expressed by formula (30).

It goes as follows:

Suppose we want to quantize some theory whose action can be written as a topological term plus a non-topological term.

Write down the generating functional for the action consisting of the topological terms alone.
Next consider the exponential of the non-topological part of the action as an observable. The expectation value of that observable can be computed by taking (infinitely many) functional derivates of the generating functional of the topological theory.

Since the topological theory is likely to be solvable exactly, this reduces the task of quantizing the full theory to that of computing that (highly nontrivial) expectation value of an exactly solvable theory.

Freidel and Starodubtsev demonstrate how this rewriting can be carried out for Einstein gravity in four dimensions with BF theory as the topological part.

The paper disucsses various path integral computations. It does not use any LQG techniques, though. At the end it says:

> This suggests that the techniques of loop quantum gravity and spin foam model are adapted to describe our perturbative expansion and lead to a finite result.

The authors want to study that in a followup:

> Our next paper is devoted to study in more details the perturbation theory in the context of spin foam.

So the relation of all this to LQG and spin foams is hypothetical at this point. Even if it can be made I don't see how the appearance of BF theory in topological strings has any bearing on it.

After all, at least in this paper, BF theory serves the purpose of a calculational trick in a way. The message is that some very compliocated expectation values in some theories are equal to partition functions of other theories. The hope is that computing some expectation value in some auxiliary topological theory reproduces the partition function of some other theory T. Right now I cannot see how the appearance of the auxiliary field theory in any context allows to make a connection to that theory T.

If the connection top-M-theory -> BF-theory -> LQG were meaningful, it would imply that topological M-theory is about gravity. But it is instead ordinary M-theory, which is.

But as I have said above, apart from all these considerations there is as yet no demonstration that spin foams and/or LQG are helpful in performing the calculation described by Freidel and Starodubtsev. To me, their discussion rather suggests that instead ordinary perturbative path integral quantization of gravity might maybe make sense if we were able to find a suitable reformulation of the EH Lagrangian.

February 1, 2005

From what I've learnt so far (from Vafa's talk, and comments by various people), and given past experience, it seems to me that it will not take long before LQG is "unified" into the stringy framework.

Whether it will be part of string theory proper, or only a "variation" on a stringy theme, is beside the point. I just don't think that the two theories will remain "two different approaches", the way that they are now, for too long.

Incidentally, it was Lee Smolin who predicted that this will be the case, many years ago, in an article in New Scientist.

10.
February 1, 2005

Interestingly enough Lee Smolin is giving a colloquim at
Lubos Motls 's university but in a different department:-)
later this semester.

Vafa: "…The dimension 4 makes full contact with another approach to try to quantize gravity, in the context of Loop Quantum Gravity, which has also the same flavor of replacing a metric degree of freedom with, in that case, not just a form but a gauge field…"

Lubos, Any comments on Vafa's statement?

PS Ludwig, Thank you very much for that. The audio is quite unclear on my machine.

12. **Ludwig**
January 31, 2005

O said:
I listened to Vafa's talk at the topo strings meeting in Toronoto, a few weeks ago. The audio is not very clear, but my recollection is that he mentions LQG as an example of "a form theory of gravity" in 3+1 dimension, and therefore related to topo string theory…

O piqued my curioslity so I listened to the audio just now. Vafa discusses LQG briefly around minute 6 and again in more detail at minutes 16-18 into the talk. On my speakers the audio was quite clear. I transcribed what he said starting around minute 5:35

Vafa: "…The dimension 4 makes full contact with another approach to try to quantize gravity, in the context of Loop Quantum Gravity, which has also the same flavor of replacing a metric degree of freedom
with, in that case, not just a form but a gauge field…"

It was at this point you can hear Vafa interrupted by someone asking if he had really said LQG and he confirms yes he said LQG.

At minute 15:57, or about 16, he returns to a discussion of LQG but does not mention that he is talking about LQG until minute 18, where he says "…this is one of the starting points of Loop Quantum Gravity…"
What he is doing in minutes 16-18 is outlining the Ashtekar "new variables" formulation of General Relativity. His discussion thereafter is enlightening and makes me wish the slides were also available as well as the audio.

So from reading Smolin's reply I get the impression that he is saying that

– there is little hope for the canonical quantization of the Einstein-Hilbert action

– one should instead study spin foams and see if one can come up with any amplitudes for these

– if so, one should check if the resulting spin foam theory has a limit in which it reproduces any known theory .

– The canonical approach is only good for studying kinematics, not dynamics.

– In conclusion, as Smolin writes:

> The main physical hypothesis of LQG is not that the quantum Einstein equations describe nature. It is that the hilbert space of diffeo classes of spin nets, […] is the correct arena for quantum gravitational physics.

So LQG = 'use diffeo classes of spin networks somehow' ??

Some comments:

1) The ordinary states of 2-dimensional conformal gravity coupled to matter are not diffeomorphism invariant and hence can hardly be expressed by diffeo classes of spin networks.

2) It is not known if spin foams reproduce any known theory and in particular not if any of them reproduces the kinematical results of the canonical LQG approach. So from the spin foam point of view what reason is there to keep the kinematical results of the canonical LQG approach?

3) What is a physical theory which has a kinematics but not a dynamics? Isn't kinematics pretty much just my choice of symbols that I am going to use for defining dynamics?

4) What if spin foams *could* reproduce the kinematics of the canonical LQG approach. Would that imply that spin foams have no dynamics, either?

5) If they can not reproduce the canonical LQG kinematics, what does this imply for the experimental predictions that it seems Lee Smolin wants to derive from these kinematics.

6) If one says that 'spin networks should play a role' shouldn't one go all the way and say that 'generalized Wilson lines should play a role'. (Which in particular generalizes the allowed groups from rotation groups to arbitrary Lie groups and their representations.)

7) If yes, then there is IKKT theory. 😉

16. **higgs boson**
January 31, 2005

"I think the reason Lubos (and other string theorists) is rabid on the topic of LQG is that it threatens the only remaining argument for string theory."

Perhaps they are afraid of what will happen if string theory is not valid. Think about it. They will have to drop string theory and spend a lot of time and energy to get up to speed on loop quantum gravity or they would have to think about creating some other theory. I would imagine that it would not be a pleasant prospect for your colleagues.

At least Brian Greene seems open to the idea that string theory could be wrong and if it does end up being wrong then perhaps he would be able to steer the other string theorists to better theories? If he has no sway with the physics community at large then you'll just have to wait until they all die off from old age.

I think Vafa is talking about BF theory. This is related to LQG, but it is not the same as LQG. I am not sure if it is helpful to call this the 'topological sector of LQG' as Vafa does.

See also the comment on that point made by Nicolai et al. in their recent paper.

18. **O**
January 31, 2005

I listened to Vafa's talk at the topo strings meeting in Toronoto, a few weeks ago. The audio is not very clear, but my recollection is that he mentions LQG as an example of "a form theory of gravity" in 3+1 dimension, and therefore related to topo string theory.

I think that someone in the audience was surprised by Vafa's statement and asked him to repeat it, and Vafa did, saying somthing along the lines of "in that case, there is not just a form, but the form is a gauge field".

Would anyone care to verify that my understanding is correct?

19. **Ludwig**
January 30, 2005

Blank said:Can we ignore the foam at the mouth and the shrill rantings and merely evaluate the merits and demerits of the arguments, please?

I agree it would be interesting to look at what Nicolai et al said in their article and how Smolin replied. I thought the tone was basically friendly and cool-headed and the points were substantive.

Nicolai et al pointed to difficulties with LQG dynamics, when attempted along lines of a canonical quantization of GR, and particularly with Thiemann's hamiltonian constraint (1997?).

Smolin replied that these difficulties were seen in the mid-1990s and that Nicolai and the others seem to have overlooked most of what has been happening in the past ten years in LQG.

Smolin could have cited many papers from the mid-to-late 90s backing up what he said: Loop people finding difficulties with the hamiltonian approach (which Nicolai was stressing) and beginning alternative lines of development. In fact Smolin only cited one paper, he 1996 gr-qc/9609034. I dont know if that was the most representative or the most obviously germane–he might have mentioned papers of about that time or a couple of years later by Lewandowski, Marolf, Gambini and others. I dont remember offhand but could get links if you wish them.

I thought Nicolai et al critique of Loop thoughtful and constructive but merely too narrow. It would be much appreciated, I think, if we could hear similar comment on what Loop people have been working on (for, I would say conservatively, the past 5 years, not as Smolin does, 10). These are approaches like Thiemann's master constraint programme, Gambini-Pullin discrete quantum gravity (which has an evolution operator, instead of a contraint), spin foams (with their connection to BF theory). To substantiate what I'm talking about I will try to fetch some links when I have time later.

The main thing that strikes me in the Nicolai-Smolin exchange is the absence of heat. Both Nicolai and Smolin work at institutes where research is balanced (both string and loop research is done at AEI-Potsdam and at Perimeter-Waterloo) and neither of them come across as threatened by the other's discipline. I was impressed by Nicolai's lively appreciation of the LQG research that he was familiar with and the overall friendly tone. Would like to see more like that and less of Lubos stink-bombs.

20. **Chris Oakley**
January 30, 2005

Only if you identify yourself … sorry to point out the obvious, but there is as yet no experimental evidence to suggest that we even *need* a quantum theory of gravity.

21.
January 30, 2005

Can we ignore the foam at the mouth and the shrill rantings and merely evaluate the merits and demerits of the arguments, please?

22. **Ludwig**
January 30, 2005

here's the Weinberg talk
http://online.itp.ucsb.edu/online/kitp25/weinberg/
and also Peter's October 8 blog commented on the talk and its
"only hope of extending SM to include gravity" or words to that effect utterance.
http://www.math.columbia.edu/~woit/blog/archives/000089.html
so the Only Hope notion goes beyond the rabidity and schadenfreude of a few and is at the foundation of string apologetics

23. **Ludwig**
January 30, 2005

Peter said:… string theorists) is rabid on the topic of LQG is that it threatens the only remaining argument for string theory. With the "Landscape", all hope is gone for ever saying anything at all about particle physics, so all that is left is to keep repeating loudly "only string theory can quantize gravity"…

I am hearing this as a kind of party line: string is "our one best hope", or sometimes "our only hope".

It has to be repeated a lot and defended zealously because appearances are rather to the contrary, I'd say, and it is the main premise justifying continued focus of research effort on string.

Steven Weinberg delivered the "one best hope" line in his KITP 25th anniversary talk last year. I'll get a link if anyone wants.
Still it's a thought that MTW fell on Lubos head when he was a baby.

24. **Peter**
January 30, 2005

I think the reason Lubos (and other string theorists) is rabid on the topic of LQG is that it threatens the only remaining argument for string theory. With the "Landscape", all hope is gone for ever saying anything at all about particle physics, so all that is left is to keep repeating loudly "only string theory can quantize gravity". If the idea gets around that LQG is a more promising idea about quantum gravity than string theory, there won't be any argument at all left for research on string theory as a TOE.

25. **serenus Z**
January 30, 2005

I must confess that I am totally fascinated by Lubos M's hysterical attitude to LQG. It obviously goes way beyond anything involving physics. Most people I know don't have much time for LQG, but I don't know anyone who gets even remotely as rabid as LM. In fact, it's pretty clear that LM has an intense fear of anything connected with general relativity; hence the various bizarre misunderstandings of the subject he has revealed over the years. What gives? Did a copy of Misner Thorne and Wheeler fall on his head when he was a baby? Or what?

26. **Wolfgang**
January 29, 2005

Caracciolo and Pelissetto investigated SO(5) on a 4D
lattice as a quantum gravity model back in the 80s.
The model goes back to a proposal by L. Smolin. I
wonder if the two lines of research are (or can be)
related ? It would be cute to dig out the old
results or redo the old simulations …

There was a great comment on Lubos' weblog:
Q: Why is the debate (between LQG and strings) so heated ?
A: The stakes are so low !

27. **Ludwig**
January 29, 2005

Peter, thanks for replying. I understand your point better now. I'm struggling to get a preliminary notion of BF theory and how they apply it. there seems to be a 4-manifold M and a principal SO(5) bundle P. I could be way wrong about this but I imagine it as a copy of SO(5) at every point of M, but each group is only a "torsor" or has lost track of its identity, so it is just something at each point of M that the real McCoy SO(5) can act on in a nice way. Sorry, have to go to lunch, back later.

28. **Peter**
January 29, 2005

Maybe I shouldn't have called it "breaking topological invariance", it was the breaking of SO(5) symmetry by hand that I was wondering about, which is more of a gauge symmetry (although since it is not an internal symmetry, but a symmetry involving local translations, I'm not sure whether "gauge symmetry" is the right way to refer to it either).

I haven't read this paper carefully yet, but often the subtlety with TQFTs formulated this way is that you have to somehow break topological symmetry to make sense of them, but then everything depends on how you do this. It seems to me that the whole game here is to start with a topologically invariant QFT, and somehow end up with a valid approximation to it that looks like perturbation theory about flat spacetime with the scalar curvature as low energy effective action. For such an argument to be convincing, I'd have to be sure that the final result one wants hasn't somehow been subtly smuggled into the derivation.

29. **Ludwig**
January 29, 2005

I agree with Wolfgang where he says
"I find it very interesting what Freidel and Starodubtsev have to say about perturbation theory."

It seems they have found a way to do background independent perturbative analysis, and they suggest that the non-renormalizablity and failure of perturbation in the past was due to going about it wrong: with a fixed background.

It does seem to be a very interesting paper and I hope we hear more comment.

I did not yet find any place where they broke topological invariance, either by hand or any other way.

It looks to me that they broke gauge symmetry by hand, from SO(5) down to SO(4)

but as to topological invariance per se they say in the abstract "We show that the partition function of quantum General Relativity can be expressed as an expectation value of a certain topologically invariant observable."

What am I missing?

30. **Wolfgang**
January 29, 2005

I find it very interesting what Freidel and Starodubtsev have to say about perturbation theory.

String Theory Article Slanted

January 31, 2005
Categories: Uncategorized

Ken Lane has written a letter to the editor of the Boston University student newspaper to complain about its article about string theory and the BU physics department discussed in a previous posting. Lane is annoyed about not having been given a chance to respond to Vafa's ad hominen attacks characterizing him and the BU physics department as "foolish" and "childish". He also complains that the author didn't seek other opinions about Vafa's claim that string theory is what the "youngest, most brilliant physicists" are all doing.

I don't remember whether they had shop classes at Harvard, but if they do now, maybe they should be talking to Vafa. According to the blurb for a recent talk by Jim Gates at Brookhaven, string/M-theory is "a 21st century lathe ? a machine capable of remarkable precision and versatility, but requiring a skilled and experienced operator for its success." Funny, back in the last millennium I remember when string theorists were claiming that string theory was a 21st century "supercomputer" or "spaceship" that had fallen into the 20th century.

   February 3, 2005

   It's amazing the sort of nonsense that Lubos Motl is able to transmute into a "story". Ed Witten posted a paper on the internet. Wow. That's impressive, especially if tens of billions of things are posted on the internet every day.

2. **Lubos Motl**
   February 3, 2005

   It's amazing what sort of nonsense Peter Woit is able to transmute into a "story". Kenneth Lane wrote a mail to a Boston University student newspapers. Wow. That's impressive, especially if tens of billion e-mails are sent every day.

   The student newspaper probably decided that Cumrun Vafa's opinion is more important than Kenneth Lane's opinion – and Vafa is the person who should have the final word, at least in some questions. I am not surprised. If Kenneth Lane – with all of my respect to his countless contributions to particle physics – finds it insulting, it's his personal problem.

   Lubos

3. **Matti Pitkanen**
   February 1, 2005

   "Boring" is my spontaneous reaction while reading the formulations of string models containing the bare essentials. Not a single basic principle is identified, just action and functional integral measure are identified, and Feynman rules derived. Principles are replaced with poorly defined ad hoc notions like spontaneous compactification and branes fabulated in hope of bringing in the real physics.

   Real progress starts from a real problem. State function preparation and state function reduction are very poorly defined concepts. Even better, there is also a paradox. The non-determinism of quantum jump is not consistent with the determinism of Schroedinger equation if the standard identification of geometric time with experienced time is accepted. It is hard to imagine a better gift for an ambitious theoretician. To solve these problems physicist must become part of physics, ceasing to be an outsider inducing state function reductions. One must not only define physically the notion of self, but also consider seriously the physical correlates of cognition, intentionality, sensory qualia, emotions. String theorists have not noticed that everything includes also consciousness.

   Matti Pitkanen

4. **D R Lunsford**
   February 1, 2005

   What is the REAL question in quantum gravity?

   "What is the meaning of 'wave function of a cosmology'?"

   To have a wave function you need an experimental setup. To have an experimental setup you must prepare a system for observation. How is one going to prepare the entire Universe for observation? How is one going to prepare the Solar System for observation? How is one going to prepare a child's top for observation? How is one going to prepare a buckyball for observation? It's a ludicrous idea.

   I don't care how grandiose, or subtle, or both, the math issues are in LQG vs. ST. There is no physics question that needs to be answered, or will be answered, by either program. That is why they are both mired in minutiae and why the world has split into ridiculous "camps".

   -drl

5. **O**
   February 1, 2005

   I don't think "mathematical physics", and all of mathematics that's inspired by physics, particularly strings, is boring at all at this moment.

   Of course, if you insist on restricting your attention to one and only one subject, then, yes, things can be quite slow.

   In this sense, phenomenological high energy physics has been very boring for decades.

6. **D R Lunsford**
   February 1, 2005

   This strings vs. loops debate is monumentally boring.

Amazing. Indy's gone, Daytona's gone, movies suck, no one can write worth a damn, music is nothing but electronic log-beating, and physics is *boring*. What happened? Did we pass through the tail of Comet Ennui?

Etcetera. It's very edifying.

10. **Not a Nobel Laureate**
February 1, 2005

After reading Motl's blog and making a few comments there . . . and being mistaken for a Nobel Laureate for my meager efforts . . . I've concluded that Motl is to String Theory as a Political Commissar was to Marxist-Leninist Thought in Czechoslovakia after the Prague Spring.

The sociology of HEP theory these days is far more interesting and entertaining than any current metaphysics being promoted by the waring sects of Stringys and Loopys.

11.
January 31, 2005

God Save Peter Voit

12.
January 31, 2005

If LM is the "youngest, most brilliant physicist", we are in very bad shape….. God save Nature! 🙂

13.
January 31, 2005

Since everyone knows that Lubos Motl is the "youngest, most brilliant physicist", and he is working on string theory, I don't see how Lane can argue with Vafa's statement.

Manin Article

February 2, 2005
Categories: Uncategorized

An expository article by the the algebraic geometer Yuri Manin always has something interesting in it, and his latest, entitled [The notion of dimension in geometry and algebra] is no exception.

In this article Manin discusses various ideas related to the notion of dimension, ranging over fractal geometry, non-commutative geometry and theoretical physics. He begins with a quote from Glenn Gould, which is quite amusing, but of obscure relation to the notion of dimension. Then he goes on to some history, from Euclid to Leibniz, finally veering off into a fascinating discussion of the relation of algebra and geometry, and ending with the sociological comment that visual mass media is leading to a dominance of right-brain mental faculties, and thus "projects us directly into dangerously archaic states of collective consciousness."

The body of the article includes comments on Hausdorff dimension, dimensional regularization of path integrals, the theory of operator algebras, non-commutative geometry, a weird digression on databases, and supergeometry. He also discusses "Spec Z" (the "space" naturally associated to Z, the ring of integers) making various comments about it and giving arguments for its dimension being 1, 3 and infinity. Next there are some comments on modular forms, and finally a section on fractional dimensions in homological algebra.

Its not clear how seriously one should take all of this, but Manin's article is definitely thought-provoking.

Comments

1. **Yuri**
   February 3, 2005

   Mirror Symmetry of Yuri Manin is reminiscent of Occam's razor principle."Entities should not be multiplied unnecessarily."

2. **fooltomery**
   February 3, 2005

   Peter, don't be so literal!

   You write that Manin "begins with a quote from Glenn Gould, which is quite amusing, but of obscure relation to the notion of dimension."

   Your own quick summary of Manin's choice of topics shows that there's a whole lot of dimension-discussing (and other-stuff-discussing) going on in the article.

   Manin decided to begin his wandering journey by making a little self-deprecating joke.

3. **Thomas Larsson**
   February 3, 2005

   I once observed that many interesting fractals living in 2D have Haussdorf dimension of the form D = (100 – n^2)/48, for n integer between 2 and 10. Apart from obvious D = 2 and D = 0, this series includes the percolation cluster (D = 91/48), the percolation hull (D = 7/4), linear polymers (D = 4/3), and red links, which cut the percolation cluster in two (D = 3/4). The formula comes from conformal field theory; D = 2 – 2h, where h is in the discrete series in the formal c -> 0 limit.

   This was very much in the air in 1986, and I later learned that Hubert Saleur made the same observation a couple of months before me, but at least my letter was submitted when his appeared in print. And this observation did earn me a four-year postdoc, so it was important to me.

4. **D R Lunsford**
   February 2, 2005

   Glenn Gould was notoriously hard on himself. Beethoven would slam the piano lid down when someone expected him to play. The idea of "disgust" is built into some of Beethoven's late work – he said about his early work "why does it make such a bad impression on me? From this day forward I mean to strike out in a new direction." Gould may have been similar. Actually, he must surely have understood that his fans didn't care how he played.

   His first and last recordings were of the Goldberg variations. He was a hypochondriac who died of a stroke.

Future and Present Particle Accelerators

February 2, 2005
Categories: Uncategorized

John Ellis's weblog has a new entry on Future Particle Accelerators which discusses prospects for a linear collider. The plan for an "International Linear Collider", or ILC is now in its design phase, with work proceeding on a detailed design for a .5-1 Tev collider. No one has yet figured out where this would be sited or how it would be financed. The agencies responsible for this funding seem to have agreed to put off a decision about going ahead with the project until 2010.

By that time there should be a couple years of data available from the LHC, and if the Higgs particle or superpartners are found, it would be clear whether the ILC design would have enough energy to study them usefully. Also around that time is should be clear whether CERN's more ambitious design for a linear collider, called "CLIC" and perhaps capable of reaching 3-4 Tev, is really a feasible one. If the decision is made to build the ILC design, the hope would be to have construction finished in 2015 (although this sounds overly optimistic to me), allowing several years of joint running of the LHC and ILC. If no Higgs or superpartners are found, or their mass is too high, the decision would be made to concentrate on CLIC, with construction done at the earliest in 2021.

Back in the present, the Tevatron at Fermilab is now seriously back in business after a long shut-down, recently reaching record values of luminosity. To follow what is going on there, you can keep up with the weblogs of Tommaso Dorigo and Sandra Leone of the CDF collaboration, as well as Gordon Watts and Ursula Bassler of D0.

   February 7, 2005

   "Lubos said: "I just got a mail from Bill Gates. He WILL pay the Gates Supercollider (up to 20 billion USD), assuming that it will be a proton-antiproton machine and assuming that the director will be Melissa Franklin…."

   Are you saying it seriously or are you telling a joke? If you are not joking, then it really amazed me how could a young and brightest Harvard assistant professor be SO intelligently challenged, that you would actually believe it was an email from the real Bill Gates?"

   Well, Lubos did deduce, by the superior application of pure reason, that my post was from first Sheldon Glashow, then later revised to Paul Ginsarg (I don't even know who he is) leading to the predictable result – he's not even wrong.

   I'm reminded of Bronowski's story of how Hegel had shown, using pure reason, that there can logically exist only 7 planets. Shortly afterwards the minor planet Ceres was discovered followed the 8th and 9th planets.

   String theory and loop QG strike me as similar exercises – attempts to deduce how the universe work solely by the application of "pure" reason.

   Expect similar results.

2. February 3, 2005

   Bill is a great man. Windows stinks. Why is saying the second a cheapshot against Bill?

3. February 3, 2005

   Despite my cheap joke and my love-hate relationship with Windows over the years, and not wanting to get off topic, I do actually have the greatest respect for B Gates, what he has achieved, and how he uses his wealth.

4. **Dick Thompson**
   February 3, 2005

   Re Gates: See the latest issue of the Economist about the Gates foundation's donations to poor countries' health – vaccinations, malaria eradication and much more. See also Bill's techno attitudes toward how to go about that, which are treated very respectfully by the mag. Maybe time to stop with the cheap shots at Bill?

5. February 3, 2005

   "Gates would insists that all accelerator computers use Microsoft operating systems…"
   I can just visualise that now.
   "Yes…I think we really can analyse this scattering data for evidence of supersymmetric particle production…but first of all we need to download another patch…"

6. February 3, 2005

   Gates would insist all the accelerator computers use Microsoft operating systems, so I'd scratch that idea off the list if you actually want to get useful data from the machine. On the other hand, if you goal is just to skim off a little of that $20B, then go for it.

7. **Lubos Motl**
   February 3, 2005

   So far I am joking, of course, but we've considered various things along these lines.

8. **Quantoken**
   February 3, 2005

    If letters are conserved I get
    MESON + SLIME BOLL + LOUT

11. **D R Lunsford**
    February 2, 2005

    Weyl was sure that his theory predicted 4D, because the Maxwell tensor squared was gauge invariant, in the original sense. In fact this actually doomed his theory from the outset. So Weyl was sort of doing “mathematical metaphysics”, which is fine.

12. **Fabio**
    February 2, 2005

    Personally, I’d like to collide Lubos Motl and Lee Smolin together at high velocity and see what comes out.

David Weise

February 4, 2005
Categories: Uncategorized

Slashdot today has something pointing to Larry Osterman's weblog where he tells the story of my ex-roommate David Weise's career, much of which has been spent at Microsoft. David is generally credited with almost single-handedly making Windows a viable product, when in 1988 he figured out how to get Windows to run on the 286 processor in "protected mode", something people thought couldn't be done. At the time Microsoft was planning on abandoning Windows and moving to IBM's OS/2, but David's work changed everything.

Osterman gets some things wrong. David, Chuck Whitmer and Nathan Myhrvold were fellow physics graduate students and my roommates at Princeton, not at MIT (for more about Nathan, see an earlier posting). David was in biophysics, Chuck was a student of Steve Adler's doing lattice gauge theory, and Nathan worked with Malcolm Perry on quantum gravity. It is true that David and Chuck were associated with the MIT blackjack team (this was the early eighties, just after casinos opened in Atlantic City, not the 70s as Osterman has it). There was a lot of practicing of card counting techniques and computer simulation of non-randomness in shuffles going on in our apartment during those days, although I never got really involved in it myself.

After getting their Ph.Ds, Nathan, Chuck and David (together with Nathan's brother Cameron) founded a software company called Dynamical Systems Research in Oakland, which they ended up selling (along with themselves) to Microsoft. They all ended up getting obscenely rich, with Chuck retiring quite a while ago, Nathan leaving more recently, and finally David is now leaving to work in molecular biology.

Comments

1. February 4, 2005

   The real issue is the "mode switch", which was nearly impossible on the 286. IBM had no 386 to shoot at when the idea for OS/2 was hatched, but they had ample time to change direction later, as "Windows 386" did. Once IBM got their plans right, they produced OS/2 2.0 and shortly after OS/2 2.11, which were fully preemptive OSes with a nearly perfect "DOS box", that is, a way of executing DOS programs in "virtual 386" mode. Windows NT was a solution to the very same problem, and a much inferior one until just recently. Windows 95 in contrast, and 98, 98SE, and ME, were still hybrids – cooperative tasking without full preemption. So Microsoft screwed the same pooch three times, and still won the game.

   The "DOS box" on early versions of Windows NT was, in contrast to that of OS/2, a total disaster. However, it didn't bite many people because by then, Microsoft had also captured the market for applications.

   You can still see the DOS box in action – fire up an old DOS program or 16bit Windows program under Windows XP, and look in the task list – you'll see "ntvdm", "NT Virtual DOS machine".

   -drl

2. **Larry Osterman**
   February 4, 2005

   Thanks D.R., I'll make the corrections… For some reason I'd assumed their PhDs came from MIT, don't ask why.

3. **D R Lunsford**
   February 4, 2005

   I thought the point was, that OS/2 ran on the 286 in protected mode, but the problem was getting into real mode again. Thus, OS/2 had a devil of a time running DOS programs. The 386 had a "virtual DOS mode" so it could go in and out of real mode at will. Windows was targeted at the 386 and the rest is history.

Distler on Multi-loop Amplitudes

February 4, 2005
Categories: Uncategorized

Jacques Distler has a new posting about multi-loop string amplitudes. It's mainly devoted to the Berkovits superstring formalism, and explains in some detail the possible problems with this formalism that one might worry about. I'd alluded to some of these in the comment section of my posting about this last week, responding to commenters claiming that Berkovits had a proof of finiteness of multi-loop amplitudes. At the time, all I got in response was abuse about how ignorant I was. Presumably the same people will be either showering Jacques with abuse, or apologizing to me. Funny, for some reason Distler doesn't mention what I'd written about this. He also seems to have somehow neglected to put "Not Even Wrong" in his list of links to physics weblogs.

Comments

1. **Lubos Motl**
   February 4, 2005

   Dear Peter,

   I think that your comments are relatively far from those of Jacques, although – I hope that Jacques won't be terribly offended – they're not infinitely far. 😉

Douglas at City College

February 4, 2005
Categories: Uncategorized

Michael Douglas gave a colloquium at City College this afternoon, with the title “Are there testable predictions of string theory?” I went up there to the talk, figuring that I knew more or less what he would say, but he really surprised me. Douglas has given many talks over the last year or so about his program for trying to get predictions out of string theory by doing statistical analyses of string vacuum states. He has concentrated on what looks like the most promising case, trying to see whether vacua with low-energy supersymmetry breaking are favored over ones where supersymmetry is broken at much higher scales (e.g. the GUT or Planck scales). If he could make a prediction that the LHC will see supersymmetry, that would count as the first real prediction of string theory, and in 2008 or so we would see if it was right. I was expecting Douglas today to explain this whole program, report on what he had achieved so far, and offer hope that he and his collaborators would have a yes or no answer about supersymmetry sometime soon.

Instead he very much downplayed hopes for this kind of prediction, answering a question about it by Nair at the end of the talk by explaining some of the difficulties. Presumably he now agrees with recent claims by Dine that it is too difficult, even in principle, to decide whether or not the landscape predicts supersymmetry. Given this, in the conclusion of his talk, I was expecting him to answer the “Are there testable predictions” question in the negative. Instead, he did something very strange. He announced that string theory does make predictions, lots of them, adopting the Lubos Motl definition of a “prediction” of string theory as being anything consistent with string theory. Examples he gave included Polchinski’s cosmic string networks, where one could tell from the behavior of the network whether the strings were fundamental or not, and short distance modifications to GR. Of course these are not in any sense real predictions; all sorts of different modifications of GR at short distances are compatible with string theory, as are either no visible fundamental cosmic strings, or visible ones with a huge variety of possible different properties.

The weirdest part of his talk was when he explained what he considered the best prediction of string theory. This involved the negative prediction that the fine structure constant can’t have varied with time in the early universe, since effective field theory arguments would imply a corresponding variation in the vacuum energy, something inconsistent with observation. So his best prediction from string theory isn’t really a prediction of string theory at all, but actually a prediction of effective field theory. Furthermore this “prediction” is the purely negative one that something that hardly anyone expects to be true actually isn’t true.

In the question section, some obnoxious guy who has a weblog asked him whether it was really true that the best prediction string theory could come up with was the no variation of the fine structure constant one that was really an effective field theory prediction, and didn’t that mean there was no hope of string theory ever really predicting anything. For some reason this made him rather defensive, and he began by saying it depended on the meaning of the word “prediction”. After having it explained to him what most physicists consider a prediction to be, he launched into a sequence of analogies designed to explain why you can’t get real predictions out of string theory. They all were of the same genre: imagine some situation where you can only observe phenomena that are related in a very complicated and hard to calculate way to the underlying fundamental theory, and somebody tells you what the fundamental theory is. Shouldn’t you work on it and believe in it?

This argument makes it clear where the whole subject is going to end up. The standard scientific method of deciding whether a theory is true or not by figuring out its implications and comparing them to observations is no longer operative. In the case of string theory there’s a new method. You just believe because authorities tell you to, and from now on the activity of professional theorists will consist solely in the construction of elaborate scenarios designed to explain why you can’t ever predict anything. Feynman’s line that: “string theorists don’t make predictions, they make excuses” has been changed from a criticism into a new motto about how to do science.

   February 10, 2005

   Concerning the Feynman quote, accidentally I stumbled upon the following (from http://infoproc.blogspot.com/2005/01/string-theory-quotes.html)

   “…I do feel strongly that this is nonsense! …I think all this superstring stuff is crazy and is in the wrong direction. … I don’t like it that they’re not calculating anything. …why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none! … ”
   –Richard Feynman: in Davies and Brown, Superstrings, Cambridge 1988, pp. 194-195.

2. **D R Lunsford**
   February 7, 2005

   Chris –

   I was trying to point out that Minkowski space also has features that are not realized in naive experience, but we seem very happy with it and find it “useful”.

   -drl

3. **Chris Oakley**
   February 7, 2005

   Danny – I’m not following you. Mass is not dilatation invariant & therefore a universe with massive particles is not dilatation invariant & therefore not conformally invariant. Why is it more complicated than that?

4. **Chris Oakley**
   February 7, 2005

   Following on from Peter’s point, the twistor theorists I knew at Oxford: Lane Hughston, Paul Tod and William Shaw (a graduate student at the time) were always completely honest about what the framework could and could not do (“Don’t ask about massive particles, don’t ask about interacting particles” is what I seem to remember William saying to me once). Although they were called the “Mathematical Physics” group they were well aware of the fact that what they were doing was much more mathematics than physics. One thing, though where physicists could learn from them is the elegance with which they deal with the SL(2,C) covering group of the Lorentz group (which of course is one of the steps on the road to Twistors).

5. **Matti Pitkanen**
   February 7, 2005

   I think that the key question is “At what level the conformal invariance is realized?”.

   Assume the representatibility of physically realizable space-times as 4-surfaces of space M^4xS, S some compact space. Assume that 3-D lightlike boundaries of spacetime surface act as “causal determinants”. Causal determinants could correspond also to light-like surfaces representing “shock waves”.

From these assumptions you end up with the realization that these light-like 3-surfaces allow generalized conformal invariance by their metric 2-dimensionality. Hence conformal invariance and 4-dimensionality of space-time are very tightly related. This conformal invariance has nothing to do with the rather trivial conformal invariance (as compared to 2-D conformal invariance) of M^4.

Best,
Matti Pitkanen

6. **D R Lunsford**
February 7, 2005

Chris,

It’s somewhat more subtle than that – as an affine space Minkowski space allows dilations, and we should experience these along with boosts and rotations. Since we don’t, we “can’t” be in Minkowski space. So the argument goes both ways.

I think conformalism will eventually play a crucial role, but the existing approaches based on SO(4,2) will not.

-drl

7. **Peter**
February 7, 2005

In a word, no.

The idea of using twistors to do fundamental physics has mainly been pursued by people working with Penrose’s group at Oxford. It never became very popular outside of people associated with this group. The new work on twistor string theory is a big change, causing a lot more people to learn about twistors.

There’s been a steady interest in twistor techniques among mathematicians for quite a while. Some of this goes back to the late seventies, when Atiyah and others got interested in the fact that you could use holomorphic techniques on twistor space to get solutions to the YM self-duality equations. There’s been a lot of work by Ward and others on using twistors to solve various kinds of equations.

Claude leBrun has gotten a lot out of twistor techniques in his work on 4-manifolds, and there are lots of other examples of the idea being useful in mathematics.

8. **JC**
February 7, 2005

Peter, Chris

Were twistors ever hyped up in the past in a similar manner to string theory, except maybe at a smaller scale?

I vaguely remember a popular press book by Peat which discussed string theory and twistors in the 1980’s. Other than that, I don’t recall twistors being really excessively hyped up.

9. **Peter**
February 7, 2005

Hi Thomas,
There weren’t that many string theorists in the audience. Of those who were there, some of them have told me in the past they’re not at all happy with the present state of string theory. I had to leave fairly quickly after the talk, didn’t get a chance to talk to too many people afterwards. I can say there definitely were some people in the audience sympathetic to my complaints.

By the way, Nair isn’t really a string theorist, although he has done some work on string theory. He has worked on a lot of different things over the years. This includes YM amplitudes in twistor space, where 15 years ago, he was one of the first (if not the first, I don’t really know the history) to calculate them this way. Before the colloquium we talked about what is going on in twistor string theory, which he’s working on (and about “Not Even Wrong”, of which he is a reader).

10. **Chris Oakley**
February 7, 2005

I can very easily think of so many very serious topics in science that are not getting far as fast as they should mainly because not enough people are working on them. One example that comes to mind is twistors.

No way. Twistors are dead in the water. They rely on conformal invariance. Particles have mass & therefore the world is not conformally invariant. Twistors are therefore a blind alley.

Feynman evidently used similar reasoning to rule out superstrings. Superstrings require ten dimensions. The world is not ten-dimensional. Ergo, superstrings are wrong.

11. **Thomas Larsson**
February 7, 2005

Peter,
I’m curious about how the string theorists in the audience (like Nair) reacted to Douglas’ talk and your question. Were they upset about your irreverence? Do they think that the Landscape makes predictions? Do they care at all whether string theory disagrees with observation?

12.
February 6, 2005

While quote about pathological science rings true to my ears regarding string theory. There was a time when it appeared perilously close to being revolutionarily right. It is still in fashion in high circles and so will correspondingly incur opprobrium when it does fall.

Of the six Langmuir attributes of pathological science, 5. is the most recognizable re: string theory, namely,

5. Criticisms are met by ad hoc excuses.

The other points would need rewording for string theory, e.g.,

3. It makes claims of great accuracy &
4. It puts forth fantastic theories contrary to experience

13.
February 6, 2005

Regarding Feynman's remark, I would like to make a remark on the sociology of science: The amount of effort that's invested over so many years, by so many remarkable people, to keep string theory afloat is incredible.

I can very easily think of so many very serious topics in science that are not getting far as fast as they should mainly because not enough people are working on them. One example that comes to mind is twistors.

If it were not for Witten's involvement, strings would probably have remained in 10D with E8xE8 to this day. (Happily, Witten has revived interest in twistors recently.)

14. **Peter**
February 6, 2005

Hi Dave,
I answered that it one of the previous comments. It comes from Lawrence Krauss.

If you look at what Feynman did say about string theory in print, one thing he complains about is that the most straight-forward prediction was for d=10 and SO(32) or E8xE8 symmetry groups. He refers to the activity of string theorists invoking Calabi-Yau compactifications, etc. to get around these naive predictions as making excuses for a theory that gives the wrong answer.

And to the previous commenter with the quote on "pathological science". Do you want to defend string theory as "pathological science?" Or do you have some other off-topic pathological science you want to promote, in which case I should delete the comment.

15. **Dave BAcon**
February 6, 2005

Peter, where did you get that Feynman quote? Or is it a paraphrase? I've seen quite a few things by Feynman about string theory (and who knows, his personal "war" with Gell-Mann may as much to do with his opinion as anything else) but I'd never seen it worded quite this harshly.

16.
February 6, 2005

"Nothing is to be gained by castigating those who followed false paths in good faith and with the honest determination to add to human knowledge. ?Pathological science? is an epithet applied to *potentially revolutionary* discoveries that did not pan out. The passionate disdain implied by the phrase is not justified by the actions of those who have been so criticized. Rather, it may be an instance of *odium scholasticum*: the criticism is so furious not because the thing is so far removed from the acceptable, but because it comes so infuriatingly close to being remarkably right. "

{ From the conclusion of
http://www.hyle.org/journal/issues/8-1/bauer.htm }

17. **Peter**
February 6, 2005

About the Feynman quote: kind of funny, given the other discussion here, but the source is Lawrence Krauss. Two or three years ago the Museum of Natural History here in New York organized a public debate about string theory. On the pro side were Brian Greene and Jim Gates, on the negative side Krauss and Glashow, with Lisa Randall also on the panel. It was during this debate that Krauss quoted Feynman. You'd have to ask Krauss for his source, possibly he heard Feynman say this.

18. **O**
February 6, 2005

Peter,

"String theorists do not make predictions. They make excuses".

Do you recall where you read that?

19.
February 6, 2005

Hey,

This string 'theory' thing is turning pretty much as the 'intelligent-design' (ID) type of argument. I hope these guys adding ID to its curriculum didnt hear about what physics is ending up being (nor about Lubos please! 🙂)
It will be very difficult to argue with them if, as probably lumo would love to do, people go around saying strings should be taught in highschools as the theory of everything….."The last one turn off the light please" 🙂

Dont get me wrong, I find both fascinating human construction (and a beatiful one in the case of strings indeed), nothing to do with nature so far though :). We should be careful where do we put each of them, it might sound silly but don't forget who is supporting science and what's the main purpose of it.

By the way, Michael Dine is a great guy, I asked him recently about the landscape, SUSY and string theory, I asked "let's assume we dont find SUSY at the LHC, does that mean string 'theory' would be possibly wrong?' He answered that so far the evidence is not conclusive and he wouldnt be able to conclude that either case. That kind of honesty I find remarkable. I asked Ed Witten some time ago how it was possible string theory, originally developed in a fixed background, could describe fluctuations of the geometry. His answer was: "I'm afraid we still dont fully understand that", as one would expect of a real genius. By the way, did anybody see the word 'landscape' written in his papers? 🙂

I love math as much as l love nature, and I agree there is a deep and meaningful conection between the two we still 'dont fully understand', perhaps, as I have been recently discussing with some friends of mine, Math is not invented but discovered, and there is always a 'deep reason' for any one of its many branches.

We ended up asking the following questions: Could one predict the existence of mathematics? Is logic an emergent phenomena?
Do have these questions any meaning, or even answer? Are they even wrong? 🙂

Oh well, I never said I was doing science :p

Some of us are necessary I admit (I hope 🙂) but taking control of the community hasnt been, and it isnt, healthy in particular for young people like us. I still believe philosophy is what motivate us in the first place, the 'big questions', we shouldnt forget though to look for a REAL answer, or at least something we can confront with Nature somehow. It is a tough call in any case, specially 'standing up and taking a look around'……

best regards.

20.
February 6, 2005

OK, sorry to get sidetracked by referring to Krauss and the "fate question" (only as an example, should have left it nameless). I did not realize he is a hot item here, not everyone pays such close attention to who said what to whom.
Needless to say he is a good physicist and a great populizer etc etc.

The point I was making (playing a bit of the devil advocate) is that the main paradigm of particle physics research- finding a simple model and comparing the properties of its ground state to reality is a theoretical prejudice. In the context of cosmology the question of the true minimum is unphysical, and simplicity is there only to help with the analysis. Maybe the true model of the world is complicated, and it's properties that are relevant to reality are not that of the ground state. Think about protein folding- if you were presented with the relevant potential (especially if you were told it came from string theory) you would give up immediately trying to find any structure. Maybe quantifying the kind of structure which exists there and using it is doable and interesting, even if it is motivated by string theory. It is a matter of judgement if you think it is plausible, but it is certainly not outrageous to give it a try.

Sociologically, what I find funny is that a large majority of string theorists would agree with you completely on landscape issues. You will have to take issue mainly with some cosmologists and particle phenomenologists (no names
this time).

21. **Peter**
February 5, 2005

If you really didn't know that Krauss recently was quoted in the New York Times describing string theory as a "colossal failure", and is one of a very small number of people in the field who has been willing to publicly criticize string theory in recent years, then apologies for my tone.

But frankly I find this hard to believe. If you want to attack someone for being obssesed with something whose physical effects can't be measured, it's kind of strange you chose the one string theory skeptic around instead of the huge number of string theorists one could make the same criticism of. Maybe you know Krauss personally so know about his obsessions. But looking at his papers from the last few years, including the one you mention, I see no evidence of this obsession.

22.
February 5, 2005

For the first paragraph, agreed, so far it looks like there is no structure, though the methods for determining such structure are underdeveloped (and possibly interesting), and it is hard to find structure without looking for one. The set of questions to do with such structures is independent of string theory, and in fact finds much more resistance among string theorists than among say cosmologists.

As for the second paragraph, look for example at astro-ph/9902189. Krauss and Turner actually proved there is no finite set of measurments that will determine the "fate question", which would make that question uninteresting, I think you would agree. I was not aware that Krauss challenges string theorists, but I'm sure you know more about that than myself.

The tone has turned unpleasant, some would say "abusive", so I guess I am no longer invited. Have fun talking to your regulars.

23. **Peter**
February 5, 2005

The problem with assuming physics is determined by a metastable state of some complicated potential function is that the idea is completely vacuous unless you have some idea what this potential function is and its metastable states have some non-random properties. Current ideas about string theory produce such a wide variety of extremely complicated possible potential functions that there is zero hope of ever getting any predictions out of the idea (something that should have been obvious to Douglas, Dine and others from the beginning). In the case of the vacuum energy, the complete randomness of this property of the potential function is actually considered a virtue. You may think this idea is an "intellectual challenge", but it's one that has nothing to do with doing physics. If it weren't for the iron grip of the string ideology, no one serious would be paying much attention to this idea that obviously goes nowhere.

And if it weren't for the nasty way string ideologues deal with anyone who challenges them, you wouldn't be making stupid attacks here on Lawrence Krauss.

24.
February 5, 2005

The problem is not specific to string theory- suppose you have a theory complicated enough to have many meta-stable states. For example a few scalar fields with scalar potential function that has a few valleys and peaks. In a cosmological context the classic problem of finding the true minimum of that function becomes irrelevant- no doubt you will find yourself there eventually, but we are not interested in that- we may well be in process of getting there now, stuck in a false vacuum for a while. What happens eventually (at asymptotically large times) is an unmeasurable and uninteresting question (though some cosmologists, such as Lawrence Krauss, are obsessed with it).

Thinking how to do physics in this context is a new intellectual challenge, there is no reason really a theory should be "simple" in a superficial sense (just a few degrees of freedom) and it is not clear there is nothing at all that can be said in more "complicated" theories. I think Douglas' work is a good starting point, though not very satisfying as of now.

25.
February 5, 2005

On Aaron's comment, I must say that I have never understood how "more probable" amounts to "a prediction". Even if Douglas' program would show that low energy susy is more probable, and that doesn't turn out to be true, that wouldn't rule out string theory.

I think the only (kind) thing to say about string theory right now is that it has had it's many ups and downs in the past, and that right now it's in one of its down phases.

26.
February 5, 2005

What about the running of alpha with energy though? I don’t want to get off topic and will be very brief. Quantoken, at around 100Gev, alpha becomes alpha ~ 1/128 and not 1/137. This has been measured. Please respond or comment at your own blog though and not here.

27. **Quantoken**
February 5, 2005

The talk of the so called “running” physical constants, like an alpha that varies against time, is NONSENSE.

Tell me what “TIME” you are talking about when your alpha is “time”-dependent, since Einstein’s special relativity tells us time is all different from one reference frame to the next one, and from one location to the next. You would have to set up a Newtonian absolute spacetime, against the relativity principle, to be able to talk about “time-dependency” of alpha.

The fine structure constant alpha, being a dimentionless parameter, is a TRUELY Lorentzian invariant quantity. You could measure spectrum lines of star lights in a fast moving spaceship. Although each spectrum line is red-shifted or blue-shifted, when you calculate alpha the end result is the same as measured on earth.

A “running” alpha would also be against the strong equivalence principle, which says that physics laws do not depend on position, time, or reference frame. If alpha and other physics constants are “running”, we could well measure them and use it as a basis to establish a Newtonian absolute spacetime reference frame, against the insight Einstein’s relativity, and hence turn clock back and retro-progress the science back a couple hundred years!

Why would people even start to talk about “running” costants?

Quantoken

28. **Aaron**
February 4, 2005

As everyone I know is sick of hearing, I don’t think Douglas’s program has much hope of being predictive. Counting of vacua has no experimental consequences — as long a vacuum is consistent with current experimental results, it matters little how generic it is amongst other consistent vacua. We still could be in it.

So, while it is an interesting question to understand what vacua are out there (if only because exclusion is predictive), it’s still taxonomy and not prediction.

29. **Peter**
February 4, 2005

Douglas explicitly said that his argument was an effective field theory argument, not really a string theory argument. Sure you can write down effective field theories where changing alpha doesn’t change the vacuum energy, but if this is an effective field theory for some unknown short distance dynamics that determines alpha and the vacuum energy, you would generically expect changing alpha to change the vacuum energy. This doesn’t have anything to do with string theory specifically.

30. **Lubos Motl**
February 4, 2005

Dear Peter,

you’re wrong about all the points that are not completely fuzzy.

Concerning varying alpha: you can find hundreds of people who argue that it is perfectly OK to have a time-dependent alpha that changes independently of the cosmological constant and other parameters. In effective field theory, there is nothing wrong if you make a parameter time-dependent. In string theory, it’s not possible to vary these parameters separately because string theory does not allow any non-dynamical parameters. These things are powerful and nontrivial predictions.

Best
Lubos

31. **Peter**
February 4, 2005

Actually, I don’t know who posted it, except that their IP is in Russia.

But maybe that could be a motto string theorists could put over their office doors.

32. **Selrach**
February 4, 2005

Wow, I think such a comment as below
deserves to be booed!

Worse, we all know who posted it!

33.
February 4, 2005

If you want a prediction, go see an astrologer or palm reader.

FY 2006 Budget Request

February 7, 2005
Categories: Uncategorized

The FY 2006 budget requests to Congress are out today. In the parts relevant to funding for mathematics and physics, the information about the NSF request is here, and information about the DOE request is here.

One should really be a lot more expert on the details of government science funding than I am to be sure what these numbers mean, but here's my interpretation:

NSF: Funding request for mathematics is precisely flat at about $200 million. The only real change from last year is that $3 million is being moved from "Enhancing the Mathematical Sciences Workforce" (which funded things like the VIGRE grant our department used to have) to fund things like summer schools, workshops, conferences, etc. One strange thing is that mathematics is listed as one of four NSF priority areas, but still gets a cut in real dollars. Some of the other "priority areas" have very large cuts. I guess this means the NSF is changing its priorities.

The NSF physics request is up 2.3% to about $230 million. $13.5 million of this is for operations of the LHC detectors (CMS and ATLAS), $14.7 million for CESR and $32 million for LIGO. The part of the budget that includes research grants in high energy physics increased by $6.4 million to $152.4 million and theoretical physics is listed as a priority. Maybe string theorists will get more money. "POU", or Physics of the Universe, is listed as the highest priority, with emphasis on the question of "What about that dark matter and dark energy?".

DOE: The high energy physics budget request contains a large cut, going from $735.4 million in FY 2005 to $713.9 million in FY 2006. Highest priorities are listed as the Tevatron and NuMI at Fermilab and the B-factory as SLAC, but overall experimental HEP funding is down. Theoretical physics funding gets a small increase, from $49.0 to $49.1 million, so at least the string theorists will be all right, even if the experiments aren't.

More details on all of this should be available at the HEPAP meeting next week.

Of course this is just the request to Congress. Something very different may emerge later this year from the Congressional committees.

Update: A document with just the HEP part of the DOE budget is here.

Weil's Letter From Prison

February 10, 2005
Categories: Uncategorized

The great French mathematician André Weil spent the months of February-May 1940 in a prison in Rouen, as a result of what he referred to as "a disagreement with the French authorities on the subject of my military obligations". Others might have called this "draft evasion", and the story has something to do with why one of the most famous French mathematicians spent his post-war career not in France, but in Chicago and Princeton.

Weil's sister was Simone Weil, who could variously be described as a moral, political and religious philosopher, an activist and mystic. She died in 1943 in England, from some combination of tuberculosis and starving herself out of sympathy with her compatriots in occupied France. During her brother's prison stay they exchanged letters which were later published. One of these letters is a remarkable mathematical document that André Weil wrote to his sister, although she would have had little chance of understanding what he was talking about. It is reproduced in his collected works, and an English translation has just appeared in the latest Notices of the AMS.

The focus of Weil's letter is the analogy between number fields and the field of algebraic functions of a complex variable. He describes his ideas about studying this analogy using a third, intermediate subject, that of function fields over a finite field, which he thinks of as a "bridge" or "Rosetta stone". For function fields over a finite field, the analogies with number fields are quite close and many facts one knows about one subject can be used to make conjectures about what is true for the other. Some examples include the Riemann-Roch theorem and the Riemann hypothesis. After getting out of prison and leaving for the U.S., in 1941 Weil was able to prove the Riemann hypothesis for the function field case; of course for the number field case it remains an open problem.

For much more detail about this analogy, there's an interesting textbook by Dino Lorenzini called An Invitation to Arithmetic Geometry.

   I think that the criticism of Bourbaki is over the top. If you are interested in philosophy, in particular of the analytical type, then actually Bourbaki group helped developed some very interesting mathematics which lead to these developments:

   Cleared up the notion of 'proof' for a mathematician (i.e there are an 'infinity' of levels at which mathematics can be done : – Category theory is just one)

   Created the machinery that allowed 2nd order logic to be formalised. This lead to P Cohen proof of the undecidablity of continuum hypothesis.

   Also to the proof that Mathematics is sound, of course you have to belive in ordinals greater than the continuum.

   Finally and not least, A A Markov 1958 proof of the impossiblity of solving the homeomorphy problem for manifolds, dimension 4 and above. A result I believe to be the equivalent of the impossiblity of solving 5 deg poly by radicals. This result in my opinion is the REAL reason why everyone is doing category theory. I must point out that category theory has many enemies in mathematics, who feel that it is only useful for expositionary work, not actual creative stuff (except for Grothendieck)

   Essential the Bourbaki spirit now lives in combinatorial group theory and model theory. At the moment these subjects are at the fringe, but I believe that out of these 2 subject will come the mathematics for the 21 century like topology was for the 20th!

   an amateur Mathematican

2. **Peter**
   February 14, 2005

   Hi Danny,

   Bourbaki's heyday was the fifties, part of the same over-emphasis on abstraction that lead to the "new math" disaster. By the 70s, Bourbaki's influence had started to wane. One reason was that mathematicians had begun to lose interest in overly formalist approaches, another was that Grothendieck showed that very different foundations were needed (i.e. category theory vs. set theory). The influence of physics on mathematics also had an effect.

   These days, Bourbaki has little influence in math. Some of their books are actually pretty good, but mostly they are used as technical references, nobody tries to learn anything from them. For a long time now the group has stopped writing more.

   Mathematicians still generally do a terrible job of writing readable expository material, but mostly they are no longer doing overly formalistic things. But what they do is inherently different than what physicists do, largely because there is a strong culture of not allowing people to be imprecise, and insisting on absolute clarity of in arguments. Physicists would do well to learn something from this.

3. **D R Lunsford**
   February 14, 2005

   Peter,

   One of my best friends was educated in the heyday of "new math", at Columbia and MIT. In high school of course he was at the top of his class, and in a class by himself technically. He related the following story. He learned calculus from Lang, was doing functional analysis as a high school student etc. etc. Then, he had to teach a course at MIT to engineers. He suddenly realized he couldn't do a simple surface integral da capo. He stated to me, that he began to consider the entire axiomatic program embodied in Bourbaki to be a total sham, and sought to restructure his knowledge on intuitionist lines (Brouwer, Weyl). Needless to say this was a complete success and now this peson is a world-authority on the math and modeling of turbulence. This was in spite of, not because of, the French program.

   I think it can safely be argued that Bourbaki and its intellectual worldview of lofty abstractions and airy-fairy axiomatics has been a disaster for science, has attempted to rip math and physics apart from each other at the sternum, and has created the mental climate in which a ruse like string theory can develop in the first place.

   -drl

4. **Peter**
   February 13, 2005

Hi Rafael,

It's not so much that prominent French Mathematicians were killed in WWI, but that many of the best math students were killed. Two-thirds of the students at the Ecole Normale Superieure died, this is the place that produced most mathematics teachers and researchers.

For more about this and about Bourbaki, see

http://planetmath.org/encyclopedia/NicolasBourbaki.html

5. **Rafael**
February 13, 2005

Hi Peter,

Which French mathematicians were killed in WW I? Also was Bourbaki created to "collect" all known French mathematics?

Thanks,

6. **D R Lunsford**

The parallel story of A. Raabe is worth mentioning. He was arrested in Krakow and died at Auschwitz before he could band together with other physicists for the purpose of making political statements or abstraction committees.

He did very interesting work on relativistic rotators as a kid.

7. **Peter**
February 11, 2005

No, he would have been too young (born in 1906). Weil started his career at a time when much of the generation just older than him had been wiped out by WWI. This had a lot to do with why he and others of his generation ended up banding together to form Bourbaki. Also probably had a lot to do with why he was evading the draft. He had seen one generation of French mathematicians killed in WWI and didn't want this to happen again, especially not to himself.

8. **Alejandro Rivero**
February 11, 2005

Now I think about, was Weil also in prison during WWI or was he too young?

9. **Peter**
February 10, 2005

Hi Daniel,

Oops, typo in html. Fixed now. Thanks for pointing this out!

Peter

Hi Peter,

I think that your link to the "English translation" is missing, at least as of now (10FEb05 @ 14:33:00h) it seems void. (Not that i can't find the link otherwise… but, just a heads up. 😉

Cheers,

The Road to Reality

February 13, 2005
Categories: Book Reviews

Roger Penrose's new book The Road to Reality is being released in the U.S. in a week or so. I'd been intending to write something about the book ever since I got a copy of the British edition a couple months ago, but this is quite a daunting task. The book is nearly 1100 pages long and actually comes close to living up to its subtitle: "A Complete Guide to the Laws of the Universe". It certainly is the most wide-ranging book on theoretical physics that I can think of, offering not just a summary of a lot of material, but an in-depth treatment of many of the more sophisticated ideas of the subject.

Penrose's point of view is that of a relativist, so his treatment of geometry, general relativity and classical field equations is the deepest and most detailed part of the book. But he also discusses quantum theory extensively as well as the various attempts to quantize gravity. Compared to the general relativity parts, his treatment of particle physics and quantum field theory is rather sketchy, but quite original.

One of the unique aspects of the book is its extensive use of drawings to illustrate mathematical, geometrical and physical concepts. In this respect it is unparalleled by any other mathematically sophisticated text I've ever seen. One of Penrose's main fascinations is the crucial role that complex numbers play, both in quantization and in the geometry of spinors. He has always been motivated by the idea that complex structures provide an important link between these two subjects, one that is still poorly understood. I very much agree with him about this. Related to this issue, some of the topics covered in the book that aren't in any non-technical reference that I know of are his discussions of hyperfunctions and the Fourier transform, the geometry of spinors and twistors, and the use of complex structures in quantization and quantum field theory.

Penrose also carefully lays out areas in which his point of view differs from the general consensus of most theoretical physicists. An example is his emphasis on the importance for cosmology of understanding why the universe had such low entropy at the Big Bang. For more about this, see a posting by Sean Carroll.

A second area where Penrose is less than orthodox is his belief that quantum gravity somehow modifies quantum theory and resolves its measurement paradoxes. He explains an experimental set-up that could in principle test whether gravity plays a role in quantum state reduction, but he doesn't have a concrete proposal for how standard quantum mechanics is to be modified.

Finally, there's a remarkable chapter on supersymmetry, extra dimensions, and string theory. Penrose is very skeptical of the whole idea of introducing more that 4 space-time dimensions. One reason is that the beautiful spinor and twistor geometry that fascinates him is special to 4 dimensions. Another reason he gives is the classical instability of higher-dimensional space-times. Under a small perturbation, such space-times should collapse and form singularities. The difficulties in stabilizing extra dimensions are at the heart of the problems of string theory, with the only known way of doing it leading to the "Landscape" picture and ruining any ability to get predictions out of the theory.

Penrose is critical of the supposed calculation of black hole entropy from string theory, noting: " As appears to be usual with such string-theoretic proclamations, this conclusion is very considerably overblown." He has quite a few other very critical comments about string theory and the way in which research in the field has been pursued. As you might guess, I'm very much in agreement with his point of view and glad to see it in print. I'd be very curious to know whether recent ideas about strings in twistor space and Yang-Mills theory have changed his views much on the whole topic of string theory.

Update: A commenter pointed out that Science magazine has a review of Penrose's book by Frank Wilczek (subscription required). Wilczek is right that there isn't very much about particle physics in the book and Penrose gets something wrong about neutral K-meson mixing. Wilczek also says Penrose makes incorrect statements about electroweak symmetry breaking, but in a quick look at the book I couldn't find what he was objecting to. He seems to object strongly to the speculative later parts of the book, but I don't quite understand why. Penrose is up-front about what is speculation (e.g. relations between twistor theory and QM) and what is solid science, and Wilczek's comment that "at present twistor ideas appear more as the desire for a physical theory than the embodiment of one", could equally be applied to string theory, leaving one wondering why he doesn't write strongly critical reviews of books on that subject.

If you want to read Lubos Motl's comments on a book he hasn't read, they're here.

Comments

1. **Peter**
   March 7, 2005

   Hi Matti,

   I've been deleting comments that seem to me off topic, repetitive, and purely designed to promote the interests of the writer. This has nothing to do with censorship of unpopular scientific ideas, I'd do the same if someone tries to promote their mainstream work on string theory or anything else here this way.

   If I allow you to continually post long comments promoting TGD, I also end up with long, multiple comments from Quantoken promoting GUITAR, and others promoting their favorite ideas, together with many hostile comments from other people who are annoyed that the comment section is being taken over by this kind of thing.

   If you want to write in detail about TGD, please do it on your own weblog, not on mine. If something I've posted seems to you really relevant to TGD, it would be best if you write a short comment here with a link to a longer discussion on your own weblog. I won't delete such short comments and links, as long as there is not an excessive number of them, and they do have some kind of relation to the topics I'm posting about.

   March 6, 2005

   I am one of the quite of many physicists who have been labelled crackpots after the establishment of M theory hegemony. In particular, it has not been possible to post anything to Archive-Org.

   Therefore the The Road to Reality was of special significance to me since it gives a clear signal for Paul Ginsparg and those responsible for this scandalous black-listing and also contains a reference to p-adic TGD. It is difficult to imagine that physicists like Roger Penrose would refer to the work of a crackpot.

   Roger Penrose's book The Road to Reality comes in two editions:

   UK edition (ISBN: 0224044478, Publisher: Jonathan Cape, July 29, 2004)

   and

   USA edition (ISBN: 0679454438, Publisher: Knopf, February 22, 2005).

The two editions are NOT identical.

For example:

The UK edition on page 1050 says in part:
"… Bibliography There is one major breakthrough in 20th century physics that I have yet to touch upon, but which is nevertheless among the most important of all! This is the introduction of arXiv.org, an online repository where physicists … can publish preprints (or 'e-prints') of their work before (or even instead of!) submitting it to journals. …as a consequence the pace of research activity has accelerated to unheard of heights. … … In fact, Paul Ginsparg, who developed arXiv.org, recently won a MacArthur 'genius' fellowship for his innovation. …"

but

The USA edition on its corresponding page (also page 1050) says in part: "… Bibliography … modern technology and innovation have vastly improved the capabilities for disseminating and retrieving information on a global scale. Specifically, there is the introduction of arXiv.org, an online repository where physicists … can publish preprints (or 'e-prints') of their work before (or even instead of!) submitting it to journals. …as a consequence the pace of research activity has accelerated to an unprecedented (or, as some might consider, an alarming) degree. …".

However, the USA edition omits the laudatory reference to Paul Ginsparg that is found in the UK edition.

For another example:
The USA edition adds some additional references, including (at page 1077): "… Pitkanen, M. (1994). p-Adic description of Higgs mechanism I: p-Adic square root and p-adic light cone. [hep-th/9410058] …".

I hope that this would serve as some kind of a signal also to Peter Woit, who has been continually censoring out my messages. This just to help the raise the level of discussion from what it is now.

Matti Pitkanen

3. **Tony Smith**
March 6, 2005

Roger Penrose's book The Road to Reality comes in two editions:
UK edition (ISBN: 0224044478, Publisher: Jonathan Cape, July 29, 2004)
and
USA edition (ISBN: 0679454438, Publisher: Knopf, February 22, 2005).

The two editions are NOT identical.

For example:
The UK edition on page 1050 says in part:
"… Bibliography
There is one major breakthrough in 20th century physics thatI have yet to touch upon, but which is nevertheless among the most important of all! This is the introduction of arXiv.org, an online repository where physicists … can publish preprints (or 'e-prints') of their work before (or even instead of!) submitting it to journals. …as a consequence the pace of research activity has accelerated to unheard of heights. … In fact, Paul Ginsparg, who developed arXiv.org, recently won a MacArthur 'genius' fellowship for his innovation. …"
but
the USA edition on its corresponding page (also page 1050) says in part:
"… Bibliography
… modern technology and innovation have vastly improved the capabilities for disseminating and retrieving information on a global scale. Specifically, there is the introduction of arXiv.org, an online repository where physicists … can publish preprints (or 'e-prints') of their work before (or even instead of!) submitting it to journals. …as a consequence the pace of research activity has accelerated to an unprecedented (or, as some might consider, an alarming) degree. …".
However,
the USA edition omits the laudatory reference to Paul Ginsparg that is found in the UK edition.

For another example:
The USA edition adds some additional references, including (at page 1077):
"… Pitkanen, M. (1994). p-Adic description of Higgs mechanism I: p-Adic square root and p-adic light cone. [hep-th/9410058] …".
Note that Matti Pitkanen was in 1994 allowed to post papers on the e-print archives now known as arXiv(obviously including the paper referenced immediately above), but that since that time Matti Pitkanen has been blacklisted by arXiv and is now barred from posting his work there. His web page account of being blacklisted is at http://www.physics.helsinki.fi/~matpitka/blacklist.html

It seems to me that it is likely that the omission of praise of arXiv's Paul Ginsparg and the inclusion of a reference to the work of now-blacklisted physicist Matti Pitkanen are deliberate editorial decisions.
Also,
since the same phrase "… physicists … can publish preprints (or 'e-prints') of their work before (or even instead of!) submitting it to journals. …" appears in both editions, it seems to me that Roger Penrose favors the option of posting on arXiv without the delay (and sometimes page-charge expense) of journal publication with its refereeing system.
Therefore,
a question presented by these facts seems to me to be:

What events between UK publication on July 29, 2004 and USA publication on February 22, 2005 might have influenced Roger Penrose to make the above-described changes in the USA edition ?

There are two possibly relevant events in that time frame of which I am aware:
1 – The appearance around November 2004 of the ArchiveFreedom web site at http://www.physics.helsinki.fi/~matpitka/blacklist.html which web site documents some cases of arXiv blacklisting etc;
2 – According to a CERN web page at http://documents.cern.ch/EDS/current/access/action.php?doctypes=NCP "… CERN's Scientific Information Policy Board decided, at its meeting on the 8th October 2004, to close the EXT-series. …". Note that the CERN EXT-series had been used as a public repository for their work by some people (including me) who had been blacklisted by arXiv .

Maybe either or both of those two events influenced Roger Penrose in making the above-described changes in the USA edition.
If anyone has any other ideas as to why those changes were made, I would welcome being informed about them.

Tony Smith http://valdostamuseum.org/hamsmith/

4. **D R Lunsford**
February 20, 2005

I got the book on Saturday, it should be in every physicist's library. It reminds me of Klein's various "Vorlesungen" – lectures, literally "readings". One thing Peter may not have mentioned is the clever prologue, which I assume takes place in Atlantis 🙂 This book appeals on many levels, including the very "tominess" of it!

5. **Paul Valletta**
February 17, 2005

Anyone who has purchased the Penrose book, will no doubt be daunted at 'not only' its size (the road to reality is a big one!), but must be prepared to journey across domains that alter the readers perspective about certain physical laws, I quote form the book:The spacetime singularities laying at cores of blackholes are among the known(or presumed)objects in the universe about which the most profound mysteries remain–and which our present-day theories are powerless to describe. As we have seen&&34.5,7,8,particularly, there are other deeply mysterious issues about which we have very little comprehension. It is quite likely that the 21st century will reveal even more wonderful insights than those that we have been blessed with in the 20th. But for this to happen,we shall need powerful new ideas,which will take us in directions significantly different from those currently being pursued. Perhaps what we mainly need is some subtle change in perspective-something that we have all missed…

Now correct me if I am wrong, or if I am not even right?..but Penrose clearly leaves the doors and windows open for 'a breath of fresh air', a humble way to entice the reader, whatever her/his previous thoughts were, you cannot help but wonder and reason?

I think it is a shame that Wilzeck seems to be riding the "BIG-NOBEL-WAVE", as his current joint undertaking in gravitational anomilies clearly shows?..would he have stepped into this arena previous to his 'nobel-prize'?..I think not, quantum-waves have more energy, and can travel further 😉

Lubos would never read such a book, but if the Epilogue is anything to go by, then he would definatly not understand the experience of…

6.
February 17, 2005

Thomas , see for example the panel debate on extra
dimensions at the Kavli conference on
http://www.phys.cwru.edu/events/cerca_video_archive.php
See the session on gravity and in particular the
panel debate on extra demisions (in that panel
wilczek argues against extra dimensions.)
See also http://mitworld.mit.edu/video/204/
and in particular his answer to scott hughes question about extra demisions.
However wilczek does believe in supersymmetry.
see also page 5 of astro-ph/0401347

7. **Ludwig**
February 17, 2005

Thomas asked:
"Where did Wilczek say that he doesn't believe in extra-dimensions? …"
Posted by: Thomas Larsson at February 17, 2005 03:47 AM

I dont know what Wilczek thinks or what he has said about extra dimensions. But here is something that could help round out the picture. Wilczek is evidently interested in quantum gravity and has just posted this paper with Sean Robinson
http://arxiv.org/abs/gr-qc/0502074
A Relationship Between Hawking Radiation and Gravitational Anomalies

—exerpt from Wilczek/Robinson introduction—
Hawking radiation from black holes is one of the most striking effects that is known, or at least widely agreed, to arise from the combination of quantum mechanics and general relativity…
…The literature contains several derivations of Hawking radiation, each with strengths and weaknesses. …

…Derivations based on string theory have a logically consistent foundation, but they only apply to special solutions in unrealistic world models, and they do not explain the simplicity and generality of the results inferred from the other methods[4, 5]…
—endquote—

to draw the obvious conclusion, Wilczek seems willing to entertain reservations about current attempts to join quantum mechanics and general relativity and to go out on his own looking for new ones, as in the case of this paper.
Hope this helps, even though not directly responding to the question.

8. **Thomas Larsson**
February 17, 2005

Where did Wilczek say that he doesn't believe in extra-dimensions? I know that he has worked a lot on supersymmetry and axions, which seems about as speculative as twistors, but maybe less so than strings.

9.
February 17, 2005

Incidently Wilczek and Penrose are in the same boat
as regards their opinions on extra-dimensions
(in other words both belive that they cannot be present.)

10. **D R Lunsford**
February 16, 2005

Peter,

Yes, that is the whole point, and is addressed by Weyl's ansatz. Hence, to make progress, one needs a way to introduce the gauge group in the context of conformal weight, which is just what I am trying to do.

-drl

11. **Chris W.**
February 16, 2005

Peter,
Sorry for that; perhaps the time of day (1:17 AM) had something to do with the manic state I was in when I posted. The articles in question aren't as far off-topic as one might think, but I won't push my luck by attempting to explain this assertion now. Thanks for indulging me and leaving the comment in place, if only as an example of misbehavior.

12. **Peter**
February 16, 2005

Hi Stephen,

I'll try and think if I can sensibly say more about this, but of course the underlying problem is that I don't have a good idea about how to control the dynamics of the metric degrees of freedom. In the Standard model the Yang-Mills + Dirac actions beautifully determine the dynmamics of the connections and spinor fields (leaving only scalar fields problematic). The Einstein-Hilbert action doesn't do the same for the metric degrees of freedom so one needs a new idea. LQG? TQFT? R^2 actions, twistors???

13. **stephen**
February 16, 2005

You should be trying to figure out how to use symmetries to gain control of the space-time degrees of freedom*, not throwing out the gauge symmetry, creating a higher dimensional mess whose dynamics you don't understand, then hoping to recover gauge symmetry as an effective low energy phenomenon.*

Posted by Peter at February 15, 2005 01:52 PM

Maybe at a later time you will speak to this in more detail? This clarifies to me the essence of your resistance to other theoretical approaches and helps to point towards more information to be look at. This is good.

Thank you

14. **Peter**
February 16, 2005

Chris and others,

Please do resist the temptation to post here about unrelated topics. Once one of you starts this, others join in and this starts to become like sci.physics again. I've deleted some comments and will delete any more that aren't about Penrose's book.

15. **Chris W.**
February 16, 2005

Sorry for the shift of topic, but I couldn't resist mentioning some interesting new and recent papers:

Supersymmetry and the Lorentz Fine Tuning Problem

This work was in response to the following, posted last March and last updated on 10/30/04:

Lorentz invariance and quantum gravity: an additional fine-tuning problem?

In January, none other than Seth Lloyd weighed in with an initial proposal (submitted to *Science*) for an approach to quantum gravity, starting with general notions of quantum computation theory, and with strong correspondences to causal set theory (Sorkin, Dowker, and others):

The Computational Universe: Quantum gravity from quantum computation

Finally, I'll draw these threads together more tightly by citing the following paper by Dowker, Henson, and Sorkin:

Quantum Gravity Phenomenology, Lorentz Invariance and Discreteness

I'll suppress my enthusiasm (and some thoughts begging to be expressed) and stop here.

16. **Peter**
February 15, 2005

Hi Lubos,

Thanks for plugging my "educational low-dimensional blog", I like that. From the picture I see I was completely wrong about Lane's lack of enthusiasm for string theory.

Actually I'll be up at Harvard next month for the conference there. If you want I could pose in front of the NYT article too, right next to the part where Lawrence Krauss makes his "colossal failure" comment…

17. **Lubos Motl**
February 15, 2005

Hi Peter!

I hope that your next article will also be celebrating 20 years of strings! See my blog – Kenneth Lane has already celebrated.

It's a matter of days before Shelly Glashow and others join! 🙂

Happy birthday 🙂
Lubos

18. **Peter**
February 15, 2005

Hi Z,

Anyone who wants to can look at what Penrose has to say about this stability issue, and then debate whether it makes sense or not. I'm just not interested enough in the question to spend time on this.

The problem with not fixing the moduli is that then your theory has massless scalar fields that couple to matter, producing long-range forces. We have very strong experimental bounds that these things don't exist. So such a theory is simply wrong.

I don't quite understand your last comment. If it's about the general landscape philosophy, which I see very good reasons to believe is inherently incapable of predicting anything, all someone has to do to prove me wrong is come up with a prediction. That hasn't happened yet.

19.
February 15, 2005

Peter Woit said:
"
Penrose's comments about higher dimensional theories were made in the context of a criticism of string theory, so I don't think it is unreasonable for me to discuss them in that context. If you have another context in which you want to discuss these issues, you'll have to make it explicit.
"

I think it was fairly obvious that the anonymous poster was talking about Penrose's claims on the classical stability of KK spacetimes encountered in the string theory literature. I think it is legitimite to dwell on what the precise objection here is. I don't think it is acceptable to show a tendency to sweep the issue under the rug if it turns out that this particular objection of Penrose's turns out not to be so well-founded, but put flashing banners if there is the slightest possibility that it might be a valid objection. This is not how scientists should work, though unfortunately similar tendencies prevail in both the string theory camp and the anti-string theory camp. (Penrose's objection *might* be well founded, I still don't understand what the precise objection here is.)

Peter also said:
"
If you don't like my commenting on string theory, just ignore it, or go somewhere else. I'm not going to stop. The situation with string theory is not, as you say, "almost the opposite of what you describe", it is precisely as I described it. The fact of the matter is that at the linearized level, you have a flat potential for moduli to deal with, and this leads to the disaster of predicting unobserved massless particles. Until recently, most proposals for getting a non-zero potential for the moduli lead to the disaster of moduli running off to infinity. Lately, the flux vacua proposals fix the moduli, but lead to the landscape disaster. Saying that "there is no known theoretical reason to fix the moduli" is absurd.
"

and concluded

"
The theoretical reason is that the theory is supposed to be a theory of the real world.
"

This sonuds to me like a strong claim about what a candidate "fundamental theory" (if such a thing exists) *must* be able to explain. (I am not saying that you believe in the existence of such a theory, but rather pointing out what you seem to be demanding from a candidate.)

Here is a fundamental objection of mine (which I think is a fairly obvious one) to the main theme in many of your posts againsts string theory (I am not a string theorist, by the way):

Little scientist bugs that live on a magnet might come up with a candidate microscopic theory of ferromagnetism. It might turn out that their theory cannot explain the mean magnetization that they so clearly observe. They might run around trying to invent schemes that would stabilize the "magnetisation modulus" thinking it is a fundamental thing that must be predicted by the "correct" microscopic theory. They might fail in doing so. Their friends might criticise them for working on a theory that has not shown the slightest possibility of coming up with the observed magnetisation. Despite all this, the bugs' theory might be correct.

Why not entertain a similar possibility for the issues about the "observed" gauge groups, etc.? Do you really think such a point of view would render a theory based on the latter totally unpredictive?
I don't think going after the quark masses etc. is the only way string theory can be tested.

z

20. **Peter**
February 15, 2005

To whoever you are who keeps posting hostile comments. First of all, unless you have a really good reason, I think you should put your name to your comments. At least pick a pseudonym, so I know when I'm having a back and forth exchange with the same person. At this point, the only way I can identify that the comments belong to you is that they generally contain some sort of criticism of me for publicly complaining about what is going on in string theory. When I want to be sure it is you I can go into the Movable Type software and check that the comment came from an IP in Ontario, but that is pretty tedious.

Penrose's comments about higher dimensional theories were made in the context of a criticism of string theory, so I don't think it is unreasonable for me to discuss them in that context. If you have another context in which you want to discuss these issues, you'll have to make it explicit.

If you don't like my commenting on string theory, just ignore it, or go somewhere else. I'm not going to stop. The situation with string theory is not, as you say, "almost the opposite of what you describe", it is precisely as I described it. The fact of the matter is that at the linearized level, you have a flat potential for moduli to deal with, and this leads to the disaster of predicting unobserved massless particles. Until recently, most proposals for getting a non-zero potential for the moduli lead to the disaster of moduli running off to infinity. Lately, the flux vacua proposals fix the moduli, but lead to the landscape disaster. Saying that "there is no known theoretical reason to fix the moduli" is absurd. The theoretical reason is that the theory is supposed to be a theory of the real world.

By the way, I notice you didn't take your argument that only an obtuse string theory hater would not believe that finiteness of superstring amplitudes has been demonstrated over to Jacques Distler's weblog, where he has written about this extensively. You really should; I think you and he would get along very well.

21. **Selrach**
February 15, 2005

Hi!

I have been following this discussion with interest.

I am shocked at what I have heared from the post after Peter's. Linearised stability theory was trashed in mathematical circles years ago as TOTALLY misleading. There have been Field Medals in mathematic given just for small advances in higher dimension stablity theory!

This is my interpretation of Penrose statement. Essentially, these states have large numbers of symmetries aka Solitons. The normally postion of the mathematical community regarding highly symmetric spaces is that they are essential CHAOTIC! This is because of problems of embedding conformal manifolds into real spaces.

Now, (my addition I apologise) recent research has confirmed this in admitted a low dimension setting. 3 dim constrained water waves have been show to have UNIVERSAL chaotic motions.

http://www-staff.lboro.ac.uk/~mamdg
/MarkGroves/Resources/spatialdynamics.pdf

Now, I should not have to tell you that if you had applied LINEAR analysis to this problem, you would have had never of found these CHAOTIC solutions!!!

Unfortunately, this analysis is effectly at the forfront of modern analysis and to write the sort of papers that is being asked is beyound anyone on the planet at this moment in time.

Is it really true that the Physic community believes in the stability of symmetric spaces due to Linear analysis?

I believe that it is time for a Hard Nosed mathematician to have a look at this problem and provide some help to the Physic community!

An amateur mathematician.

22.
February 15, 2005

General points of philosophy and arguments of authority are just a matter of taste. The facts are that the question of linearized stability of KK spacetime, to the extent that it is a mathematically precise question, was settled long ago by precise calcualtions. I suggest that if Penrose had something concrete to say about it, he would publish a paper on the subject, which would then be subjected to the usual scrutiny. In the absence of that there is really nothing to agree or disagree with. Just relying on his authority is unfair to many talented and devoted people who actually worked on the subject. Similar words can be said about Hawking and the fiasco of the information paradox resolution.

Now, the situation about string theory is almost the opposite of what you describe. There is no known theoretical reasons to fix the moduli, nothing is inconsistent or unstable in theories that have those moduli, not at the linearized level or any other level. This is a huge problem for string theory because we live in a world that does not have them. If Pensrose had some concrete way to kill these highly symmetric KK spacetimes, nobody will be happier than string theorists.

I really think you could understand everything I say if you actually read complete sentences instead of just look for points for
or against string theory.

23. **D R Lunsford**
February 15, 2005

Peter, that was extremely well said!

24. **Peter**
February 15, 2005

Penrose essentially claims that his and Hawking's singularity theorems also apply in this higher dimensional case. If you want the details, you have to take a look at the book, although Tony Smith just posted a relevant abstract.

I was just reporting what Penrose says, and I'm not interested enough in this issue to spend my time on the details of this. In any case I don't think Penrose has an air-tight argument against extra dimensions, because you can always claim that quantization solves the problem.

I'm certainly fond of true statements, In this case we have one of the world's leading experts on singularity theorems in classical GR making a claim about them in print. I strongly suspect that he knows what he is talking about here and is making true statements, that's why I reported on them. As for mathematically precise statements, they have their place, but in many contexts they're either not possible, not appropriate or not worth the investment of time and energy needed to get them.

In the case of string theory, there are much less subtle instability problems with extra dimensions than the ones you need Penrose's singularity theorems to see. You already have a huge problem at the linearized level. I'm referring to the well-known problems fixing the moduli parameters that describe the size and shape of the extra dimensions. Unless you first solve that problem, worrying about more subtle problems seems to me a waste of time. The only "solution" to this problem I know of leads to the "Landscape" and a completely useless theory.

As a general matter of philosophy though, I very much agree with Penrose's point of view about Kaluza-Klein. You've got enough trouble dealing with the metric degrees of freedom of space-time. You're just making things worse when you add in a dynamical metric for the fibers of your principal bundle or for some internal space.

Another way of saying it is that in the standard model you have an SU(3)xSU(2)xU(1) principal bundle, and the geometry of the fibers is tightly constrained by the gauge symmetry, which is why the theory works so beautifully. You should be trying to figure out how to use symmetries to gain control of the space-time degrees of freedom, not throwing out the gauge symmetry, creating a higher dimensional mess whose dynamics you don't understand, then hoping to recover gauge symmetry as an effective low energy phenomenon.

25.
February 15, 2005

Is there any scientific paper, peer-reviewed and published, which supports the claim that (some) spacetimes of the KK form are classically unstable to small perturbations?

This stability is a well-formulated question that can be answered precisely, there is no place to hide. Of course, it was answered precisely already for many such spacetimes, but some people don't like the answers. However, I thought the owner of this blog was fond of true and mathematically precise statements.

26. **Tony Smith**
February 15, 2005

Roger Penrose, in the UK edition of The Road to Reality, says at pages 905-907: "… 31.12 Classical instability of extra dimensions … a classical M x Y universe – subject to Ricci flatness – is highly unstable against small perturbations. If Y is compact of of a Planck size, then spacetime singularities … are to be expected to result within a tiny fraction of a second! … Let us first consider perturbations of M x Y that disturb only the Y geometry … That is to say, we examine a 'generic' ricci-flat (1 + [dimension(Y)]) spacetime Z ([Z is] the perturbed evolution of Y) … [and] E1 x Y …[is]… the (unchanging) 'time-evolution' … of Y … a singularity theorem … shows that we must expect Z to be singular. … As one of this theorem's consequences, any Ricci-flat spacetime that (like E1 x Y or Z) contains a compact spacelike hypersurface, and that is 'generic' in a certain specific sense … (and free of closed timelike curves …), must indeed be singular! The original E1 x Y escapes from being singular because the generic condition fails in this case. But the generically perturbed Z has to be singular. … If the perturbation away from Y is the same general scale as Y itself (i.e. Planck scale), then we must expect the singularities in Z to occur in a comparable timescale (about 10^(-43) s), but this timescale cold become somewhat longer if the perturbations are of a proportionally smaller size than Y itself. … the large Planck-sclae curvatures … that are likely to be present in Y will spill over into ordinary space, in gross conflict with observation, and will result in spacetime singularities in very short order. …".

Richard Feynman, in his book QED The Strange Theory of Light and Matter (corrected 7th printing, Princeton 1988), says in a footnote at page 129: "… perhaps the idea that two points can be infinitely close together is wrong – the assumption that we can use geometry down to the last notch is false. If we make the minimum possible distance between two points as small as 10^(-100) centimeters (the smallest distance involved in any experiment today is around 10^(-16) centimeters), the infinities disappear, all right – but other inconsistencies arise, such as the total probablility of an event adds up to slightly more or less than 100%, or we get negative energies in infinitesimal amounts. …".

Taken together, the Penrose and Feynman quotes seem to me to indicate that at the Planck scale spacetime (of any dimension) is probably discrete. It seems to me that a discrete spacetime is substantially consistent with a spacetime foam / LQG approach, and that it is consistent with physics models in which the M of M x Y is discrete (such as a Feynman Checkerboard) and the Y of M x Y is a compact manifold (such as my Clifford algebra model and perhaps Matti Pitkanen's p-adic model), but I am not sure that a discrete spacetime is consistent with conventional string theory (perhaps Lubos could comment on that).

February 15, 2005

The following might have been missed by the readers due to it having been posted a couple of days ago, but here it is (to humble ST people)

"…I do feel strongly that this is nonsense! …I think all this superstring stuff is crazy and is in the wrong direction. … I don't like it that they're not calculating anything. …why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none! … "

–Richard Feynman: in Davies and Brown, Superstrings, Cambridge 1988, pp. 194-195.

28.
February 14, 2005

The proceedings are published in a book format, knock yourself out, I only found words there.

BTW, nobody stands to profit more from some mysterious inconsistency of most (but not all) compactifications than string theorists, that used to be their holy grail.

29. **Steve M**
February 14, 2005

I am not convinced either of what Penrose is saying but what I briefly read about it (a few remarks in a preprint intro) sounded interesting and it stuck in my mind. Since I was'nt actually at the conference and since there seems to be no paper from him, one cannot really comment on it or really know what he has in mind. I agree that a solid argument from someone like Penrose for classical instability of higher-dimensional spacetime would be of considerable interest. If he was really serious though and had thought it
through then one might have expected it to appear by now in J.Class Quant Grav say.

30.
February 14, 2005

Steve M,

Even allowing for mights and mays, especially from such an accomplished scientist, it is hard to find an argument there. The usual singularity theorems, valid in 4dim asysmptotically flat space, are usually not taken to mean instability of flat space, or exclude it's existence. Even if there is some hypothetical singularity thm. in higher dimesnion, why would it imply the non-existence of higher dimensional gravitational theory?

A solid argument for a classical instability of higher dimensional space, especially coming from an authority like Penrose, would become immediately an extremely hot topic for research by at least 2 scientific communities, probably more. Alas, in this case it is hard to find some flesh behind the words. Maybe someone else here had better success.

Of course, Penrose himself is a hero for myself and many of my generation, but this is no reason to treat his assertions differently. I

33. **D R Lunsford**
February 14, 2005

Steve M,

For sheer fun, find and read Penrose's early paper on the appearence of a moving relativistic object.

I ordered the book as well.

Though it's not generally mentioned AFAIK, twistors go all the way back to Pluecker's "change of space element", i.e. homogeneous line geometry. I would be interested to know if he mentions that in this new book.

-drl

34. **Steve M**
February 14, 2005

I know Penrose has suggested (Talk given at Cambridge conference in honour of Steven Hawkings 60th birthday) that a variation of the singularity theorems might rule out the existence of compact extra dimensions ala KK. The idea is that wrapping of light rays around compact dimensions would create an effect analogous to trapped surfaces in gravitational collapse. I can't find a published article though giving the details unless the proceedings have been published. Penrose is always interesting and original though and his new book certainly seems to be worth getting.

35. **D R Lunsford**
February 14, 2005

I too would like to read an elaboration of this instability issue. Does he mean N space + 1 time or N space + M time, or both? Does he mean the same thing that originally did in Einstein's cosmology (thought of as say deSitter space)?

-drl

36. **icecube**
February 14, 2005

I got the book last july, it's *very* impressive from a mathematical point of view (I can't comment on the physics).

I find that the book explains the geometric concepts of fibre bundles and spinors perfectly well (certainly better than I would have thought they could be explained).

I'm not convinced that his exposition of fourier analysis would be easily graspible for the beginner, but I sure as hell enjoyed it!

One weird thing is that he *completely* skips over basic calculus – I guess that's ok though – it leaves more time for fun stuff.

Still though, it's remarkable, and it will, if it's commercially successful bring up a whole generation of young intellectuals with a grasp of some concepts (mainly geometrical) that were previously viewed as very advanced…because, let's face it, not many of the useful concepts of modern mainstream mathematics have been brought down to the popular level ("topology is rubber-sheet geometry" isn't a useful concept, it's an unmotivated generalization (well…locale theory is a pointless generalization…)).

Anyway, it'll be a good thing if it's successful

(mathematically anyway)

37.
February 14, 2005

Under a small perturbation, such space-times should collapse and form singularities.

care to elaborate? for the usual compactification on CY, or torus, etc., this statement is just false with the usual interpretation of all the words appearing there. All such solutions are stable (tachyon free) classical solutions of supergravity.

Not that this is necessarily what Pensrose means when he talks about collapse, though it is hard to tell precisely what he does mean.

In my mind Penrose has more problems with higher dimensions than string theory specifically, but again he is perfectly capable in providing a tight mathematical argument, if he had one.

40. **Daniel Doro Ferrante**
February 14, 2005

To complain about the 'objectivity' is just below the belt… and, in fact, it's a 'meta statement' in itself. I explain: Once "anonymous" is such an objective person, would you please do yourself (first and foremost) and ourselves the favor of checking out the reviews that the Lubos have on Amazon? Reviews of books like "PCT, Spin, Statistics and all that", "Local Quantum Physics", etc.

To me, at least, it sounds very awkward when a theoretical (hep-th or math-ph) physicist dismisses math as much STheorists do nowadays… and, before this last comment starts a flame war, let me just say that i only read about Donaldson Polynomials, Knot theory, gerbes and so forth on books either by the AMS (on QFT!) or by Kauffman or Baez. Personally, i never saw a single STheorist (mainly the 'pop' ones) talking about those topics; in fact, in more than one occasion i have been condemned for 'breaking up a discussion' with such 'mathematics' topics.

That's what you get for objectivity.

Besides, please, have and show (!) some respect for Penrose: He did more in a lifetime than most of us combined and/or put together will ever do! Or are you telling me that if Newton were alive you'd walk all over his ass because he 'was wrong'?!!! (Sorry, Peter, for the language; it's just too soon in the morning to read gigantic loads of crap… add that to a bit of Napolitan blood and you have a recipe for a (flame-)war! >;-)

Note that i'm not – nor do i intend to – defending Penrose or anyone else for that matter. I have the same opinion of folks like Witten (and others whose names decided to runaway just now, while i looked at the door). It's just hard to find, nowadays, people who are honest about what they know and about what they do not know. Then again, the market is kindda tight so, i guess this makes it all very understandable, does it not?! Afterall, we're all fighting to survive… and, as a good reductionist would deduct, in the end we are just trying to pass our genes forward… 🙁

41. **Thomas Larsson**
February 14, 2005

Meaning Penrose is untrustworthy. But surely Emperor's New Mind has already proven that. Interested in why the Lunsfords, Voits haven't lumped him in with the celebrity stringies they so detest. So much for objectivity I guess.

If you cared to look, e.g. in this thread, you would find that I have been quite critical of LQG in the past, for pretty much the same reason that I critized string theory: in order to quantize a constrained Hamiltonian system, like general relativity or the bosonic string, you must first understand its constraint algebra. As Urs Schreiber noticed in the link above, an infinite-dimensional constraint algebra is generically anomalous. In particular, GR has many constraint subalgebras isomorphic to infinite conformal symmetry in 2D, and most of these subalgebras should thus have conformal anomalies.

As for objectivity, I notice that people like Schreiber, Helling, Motl and Distler criticize LQGists essentially for missing conformal anomalies (this is a clear symptom if not the cause of the problem), but they have no interest in trying to understand why 4D diff anomalies do not arise in string theory. Note here that anomalies are physical effects seen in any reasonable quantization scheme – path integral quantization of the Polyakov action also singles out 26D, i.e. the conformal anomaly does not only arise in canonical quantizion.

Moreover, the string hype is without comparison, whereas LQG somehow reminds me of the description of earth in the Hitchhiker's Guide: "Mostly harmless".

42. **Robert**
February 14, 2005

" very interesting and challenging for beginners"

Perhaps the commonest response I've heard to this book, from working scientists (not neccessarily theoreticians) in the UK, is that of wishing it had been available to the reader when he/she was a beginning undergraduate. The exercises, friendly logos etc, sketches (by the author, not an illustrator) establish an intimate relationship with the reader not sought in the the Emperor's New Mind etc. It's hard not to see the whole thing as a textbook for the little Penrose – whose arrival is celebrated in rather extreme terms in the introduction – for use in later life.

43.
February 14, 2005

RE: but flawed at the highest level

Meaning Penrose is untrustworthy. But surely Emperor's New Mind has already proven that. Interested in why the Lunsfords, Voits haven't lumped him in with the celebrity stringies they so detest. So much for objectivity I guess.

44.
February 13, 2005

Real good review of Penrose's book by Frank Wilczek in current (Feb 11) Science. Not Free, unfortunately. Says book is very interesting and challenging for beginners, but flawed at the highest level.
Best,
Jim Graber

45. **D R Lunsford**
February 13, 2005

Lubos,

I have a gedanken experiment for you, which anyone with any familiarity with Penrose's work or indeed any real understanding of spinors will be able to immediately answer.

Just before a total eclipse of the Sun, the Moon is given a large velocity tangential to its orbit at mid-eclipse. Do the effects of relativity prevent the eclipse? Explain.

-drl

46.
February 13, 2005

Thank you Lubos for sharing your vacuous thoughts on a book you have not seen.

47. **Lubo? Motl**
February 13, 2005

Geez.

Penrose is a great and highly original guy, because of his contributions to GR, twistors, his triangle, his tiling, and so forth, but this kind of prayer is really bizarre. I have not seen the book.

Many of us have been fascinated with the complex numbers. But is this really a state-of-the-art fascination? I don't think so. The complex numbers are very important in advanced contexts – such as SUSY. Penrose's ideas about the relations between the interpretations of QM, quantum gravity, and collapses inside the brain would … well, let me not say anything because whatever I would say would be viewed as impolite.

Twistors are fun as a method to find solutions of various systems in 4D Minkowski spacetime, but the speculations that they could be related to quantum gravity or theory of everything just don't seem terribly promising right now (and they have not seemed promising for 30 years). Moreover, many recent gauge-theory calculations have been reduced back to the language of spinors, so that the idea of twistors plays less role than initially.

My guess is that the criticism of black hole string theory calculations is nothing more than misunderstanding. We've been told about his strange lecture in which he argued that string theory had some "problem" because of some singularities – he probably meant the singularities in the moduli space of Calabi-Yaus, or something like that. This is *exactly* the physical question that has been understood in detail by the string theorists. It seems that no one has explained him this stuff, which is sad.

But still, I admire him, don't get me wrong.

48. **Peter**
February 13, 2005

You're right that a lot of the book is quite technical, but it evidently did sell quite well in England. But even if most people could understand only half of it, they're getting 500 or more pages of interesting material to chew on, maybe they consider that a bargain at the price.

49. **Dave Bacon**
February 13, 2005

I also purchase a UK version of the book a few months back. It's definitely an interesting read (making up, perhaps, for "Shadows of the Mind" which I thought wasn't so great.) But the question I have is who exactly is going to read this book? I mean, for physicists who want a little easy and enlightening reading it's really a nice book, but I can't imagine the lay reader understanding more than half the book.

The Next Few Years in Particle Physics

February 17, 2005
Categories: Uncategorized

By far the most important event for particle physics during the next few years will be the beginning of operation of the LHC, now planned for 2007. Besides that, here are various sources of information about what else will be going on, especially in the U.S.:

A National Research Council committee called EPP 2010: Elementary Particle Physics in the 21st Century was formed last year, charged to:

"Identify, articulate, and prioritize the scientific questions and opportunities that define elementary-particle physics."

and

"Recommend a 15-year implementation plan with realistic, ordered priorities to realize these opportunities."

It has already had a couple meetings, and presentations to these meetings are available here. They plan to have more public meetings this year and produce a report by the end of the year.

If you want to follow the details of current and future funding for particle physics in the U.S., there's a lot of information in the presentations to this week's HEPAP meeting. The overall picture is for particle physics funding to decrease over the next few years, under the pressure of the huge U.S. budget deficits. Beyond a proposed 3.1% cut for particle physics next year, the DOE is planning for another 3.7% cut in its overall science budget over the following five years. In this environment it is very difficult to find funding for new projects. One proposed new one, called BTeV, which was to study B-physics at the Tevatron, is slated for cancellation. Another, RSVP, a search for rare decays at Brookhaven, is being reevaluated.

The DOE budget document points out that the future of Fermilab is a problematic issue. Tevatron operations are slated to wind down in FY 2009, when the LHC should start producing data. The new NuMI/MINOS neutrino beam and detectors will still be running then, but it is not clear for how long. Unless a major new machine (such as the ILC linear collider) is sited at Fermilab, it's not clear what the laboratory will be doing after 2010. Such a major new machine would be expensive, so it's not something that could be financed out of a DOE HEP budget that continues to decline. There's a comment about this in Jochen Weller's weblog.

There's a conference this week in Aspen on The Highest Energy Physics and some of the talks are already on-line.

Finally, Serkan Cabi at MIT has put together a nice collection of links to videos of physics seminars, he also has a weblog.

1. **Chris Oakley**
   February 18, 2005

   We don't need ten billion dollar experiments to tell us string theory is true!

   This requires further explanation. Are you saying

   (i) You can prove String theory for less than $10bn? or

   (ii) String theory is true regardless of what any experiment says?

   If (i), please tell us more. Apparatus, procedures, etc. If (ii), then I thought as much – String theory is a religion and not a science.

2. **Ludwig**
   February 17, 2005

   Anonymous poster Mr. Blank says (in jest? it is hard to tell)

   "We don't need ten billion dollar experiments to tell us string theory is true!"
   Posted by: at February 17, 2005 07:31 PM

   Astonishing. Is this a parody of what string-true-believers are supposed to be saying? Even as a joke it is in pretty poor taste.

3. February 17, 2005

   We don't need ten billion dollar experiments to tell us string theory is true!

4. February 17, 2005

   Don't be too worried about the futere of Fermilab. Steve Holmes (a higher-up there) gave a talk yesterday where he lays out some of the near future for the lab. The bottom line: BTeV is gone, but its kind of like getting that monkey off your back – so now they will be able to invest in Linear Collider and Proton Driver research. Research that had been held hostage to support the BTeV research program when LHCb was already well underway.

   http://tdserver1.fnal.gov/8gevlinacpapers/meeting_minutes/WeeklyMeeting/05_02_16_FY06_Implications_for_PD_Holmes.ppt

5. **Serkan Cabi**
   February 17, 2005

   Thank you very much for your kind advertisement Peter. I hope it reaches everybody who needs it. I know many places where listening a quality colloquium is a big event. We are very lucky here in US in this respect. But I am not sure how long it will continue. I should say that many interntional students here at MIT has severe concerns about staying US after their studies. I don't understand what Bush administration has in mind. I tend to think that they are just xenophobics and want us to leave the country.

Depression and Desperation

February 18, 2005
Categories: Uncategorized

In a Stanford University press release today, Susskind promotes the "Landscape", calling each different vacuum state a "pocket universe". Referring to people like David Gross who oppose the idea, Susskind says: "More and more as time goes on, the opponents of the idea admit that they are simply in a state of depression and desperation".

I'm wondering exactly which string theorists have admitted to him their depression and desperation.

It seems that Susskind's new book coming out in a couple months isn't about the Landscape, but rather black holes and holography. He's writing another one now, to be called "The Cosmic Landscape".

In other news, Witten will be giving a Distinguished Lecture Series in April at the Fields Institute in Toronto as part of their year-long program on the geometry of string theory. Witten seems to have decided that there's not much to say about string theory these days, since the topics of his talks are listed as "Relativistic Scattering Theory", "Gauge Symmetry Breaking", and "The Quantum Hall Effect".

   February 28, 2005

   Robert; Chris W,

   I agree that the funding of scientific-engineering activities is very limited to a rapid obtaining of tangible products.

   However, mi point is that all money devoted during 30 years to the string theory program has been, in general, a waste of money. 30 years x 1000 researches = a lot of money useful in other fields. My point is also that string theory was overly emphasized in mass media. I.e. all people will know the failure of the program and, yes I suspect that will be utilized by ?New Age anti-scientists?, ?political opportunists?, and TVC for the attack of our endeavour.

   The ?Depression and Desperation? that some of my colleagues have on theoretical chemistry is not used for attacking science, because the problem is known only by specialists on the field. Due to the success of string theory on popular media, I suspect that the ?Depression and Desperation? of string theorists will be exported to other fields of physics and science.

   Lunsford,

   With ?heroes? I mean that they have been advertising the heroic idea of that they are doing the most fundamental research, the most difficult stuff, they are even doing the mathematics for it, (so difficult that nobody more can understand it), they are solving all difficult questions on math and physics than mathematicians and physicists cannot, etc.
   Moreover, they have been sending the idea of that others physicists are very bad people and attacking them without compassion. Then people looked like authentic heroes.

   Of course, it is not true and people are completely misunderstood. Most part of string theorist are very, very arrogant people with a superficial knowledge of things. Moreover, they always were the first on heavy attack to every man that thinks or says the contrary.

   I think that all current non-string scientists (including ?renegades?) that heavily critiqued string program would joint now and write a letter explaining that the failure of string theory would be taken as a vital lesson on future funding of science, but also explaining that the rest of scientific communities would be ?favoured? in a future. I think that if a non-string theorist devoted many of its time to demystify string theory, now cannot be culpable (on funding, lost of public credit, etc aspects) of the failure of it.

   For example, I have read that perhaps Witten will research on a different field, perhaps biology. My question is, if Witten solicits funding from an agency for researching on Y biological point and Z respected biophysicist also solicits, will Witten get more ?credit? and thus money, even if most of their last decades research was nonsense? I think that Witten would be just a step below in the ?ranking? for obtaining funding when compared with Z author.

   That letter would be distributed between funding agencies, mass media, etc. I wait for interesting Woit questions on this topic.

2. **Chris W.**
   February 24, 2005

   Following up on Robert's post, the NIH and HHS are coming under significant pressure from the religious right, most notably the Traditional Values Coalition (TVC), to justify its granting decisions in most research related to HIV, AIDs, and sexuality and sexual behavior. The same critics sometimes pay special attention to research rationales that incorporate evolutionary arguments, including those that involve cross-species studies of behavior and physiology.

   For example, see the Washington Post (Oct 2003) and The Scientist (Nov 2003).

3. **D R Lunsford**
   February 24, 2005

   Penrose clearly states when he's speculating, and yes, "..Mind" is a turd of a book. "Road.." is not.

   -drl

4. **robert**
   February 24, 2005

   Funding in the areas ("engineering and "applied" research (medicine, electronic, etc.)"), assumed to benefit from cuts to that for "pure" research, is itself under very real pressure. Anything other than the next market driven quick-fix finds support very difficult to sustain. These less arcane fields of endeavour are also subject to attacks from New Age anti scientists, political opportunists etc; it's not just the hep-th guys who are feeling the pinch.

5. **Joe K**
   February 23, 2005

And Penrose (who you deeply admire) isn't a "carnival barking sensationalist"?

What is "Emperor's New Mind" if not ridiculous speculation?

6. **Matthew**
   February 23, 2005

   Laugh all you will, but it's a little known fact that Spears is an expert in semiconductor physics, as you can learn here. Likewise, Stephen Hawking is a bad ass gangsta rapper.

7. **D R Lunsford**
   February 23, 2005

   Juan R said:

   String theorists are "heroes" for people. I believe that is the direct result of string community propaganda.

   They mostly seem like assholes to me, or fawning Wittenite hero **worshippers**. Both attitudes are destructive of creativity. Perhaps you meant "heroes" with encheeked tongue.

   I predict a new era of further restrictions on funding of basci science on favor of enginnering and "applied" research (medicine, electronic, etc.). I also believe that people will look science carefully saying "perhaps this new book about the theory X is a fiasco as string theory was".

   I agree, and the fault lies with money-grubbing carnival-barking sensationalists like Greene, Davies, Zee, Kaku, etc. etc. etc. who sacrificed science on the altar of their own vaulting ambitions.

   Science was better when it didn't come in a Fisher-Price box.

   -drl

8. **Juan R.**
   February 23, 2005

   D R Lunsford said,

   "Good question, what will come next? One thing that won't happen – those who attacked string theory from the outset, and who have been proven abundantly correct, will get no credit."

   Sincerely, I hope that you are "wrong" in this aspect (I suspect that your comment was ironic here).

   String theorists are "heroes" for people. I believe that is the direct result of string community propaganda.

   I predict a new era of further restrictions on funding of basci science on favor of enginnering and "applied" research (medicine, electronic, etc.). I also believe that people will look science carefully saying "perhaps this new book about the theory X is a fiasco as string theory was".

   Will be the era for autolitarism, fanatic religion, and anti-thecnologists?

   How can we recover the image of science, so bothered by the string propaganda?

9. **Chris Oakley**
   February 23, 2005

   /:set\AI,

   I absolutely agree. Five years ago non-commuting catwalks would have been unthinkable. Now they are commonplace. Who do we thank for that? Britney Spears, of course!

10. **/:set\AI**
    February 22, 2005

    I think it is important to point out- that with all the Britney bashing many have forgotton that her work in blue shoes has led to important understanding concerning the uses of octonions in fashion

11. **Thomas Larsson**
    February 22, 2005

    Matthew,

    I didn't realize that SYM facilitates physical YM calculations. One is never too old to learn, and now the interest in super-twistors makes a lot more sense.

    However, when I said that the twistor amplitudes are "wrong at the loop level", I didn't meant that they disagree with YM, but that they disagree with SYM, due to various anomalies and connection to nonunitary conformal supergravity. At least, this is the impression I get from Witten and Berkovits, and especially from Motl. If Motl says that something is a problem in string theory, one can be sure that this problem is HUGE.

12. **Anonymous**
    February 21, 2005

    Note the "experimenter's wishlist" has at most 5 jets in the final state. Accompanied by W's and Z's. How are twistors going to help with this?

    In general, interesting physics channels have 2 or 3 hadronic jets in the final state, not counting b's — those would give you two or three more, but they aren't gluons.

    No one has ever shown me any convincing argument that N-gluon scattering amplitudes are at all relevant for LHC physics when N is not small.

13. **Matthew**

February 21, 2005

Well, my data point on the usefulness of the multi-leg YM amplitudes was the same talk that “anonymous” pointed to. I’m certainly willing to be corrected.

stop wasting your time and move to non-perturbative QCD

As a lattice person I’m forced to agree 🙂

The expressions may be concrete, but they are probably physically irrelevant (i.e. SUSic), and probably wrong on the loop level, no?

The tree level amplitudes are the same. So if you compute them in SYM or YM it makes no difference. At loop level, they’re “wrong”, but that’s misleading. Say you have an amplitude with a gauge boson loop in it. You can replace that with a combination of an N=4 SYM amplitude, an N=1 SYM amplitude and a regular YM amplitude, but with a scalar running in the loop rather than a gauge boson.

Now you can just write down the answer for N=4 SYM, it’s known. And it’s “easy” to compute the N=1 SYM amplitude (and the hope is that they’ll all be known soon), so all you’re left with is the scalar. And as we all know, computing loop diagrams with scalars in them is a lot easier than computing those with gauge bosons. You can pull the same game with fermion loops as well.

So the fact that you can write down all the N=4 SYM amplitudes really does make one loop regular YM calculations a lot easier. You can see the replacement rules in Lance Dixon’s lecture notes (hep-ph/9601359, equation 89).

14. **D R Lunsford**
February 21, 2005

Good question, what *will* come next? One thing that won’t happen – those who attacked string theory from the outset, and who have been proven abundantly correct, will get no credit.

This has really been an interesting episode in the history of science. We who were young in the 80s were in some sense not allowed a “championship season”, or even a career, but we got to see a timeless result proven with great force and clarity – you can be absolutely brilliant and have no Earthly f*cking idea what is really going on 🙂 Whatever physics is, mental horsepower is only one part of it. That in itself made it worth the ride. Good judgment still counts.

-drl

15. **Jean-Paul**
February 21, 2005

I don’t know the person who gave a talk at KITP listing what experimenters want to know about QCD etc. If you need a solid assertion, you should ask people like Kunszt, Keith Ellis, Mangano, Al Muller… who have no stakes in twistors. We won’t miss Higgs because of a miscalculated QCD background! More precision in hard scattering is completely washed out by our ignorance in soft fragmentation. To the anonymous QCD practitioner — stop wasting your time and move to non-perturbative QCD… unless you need a faculty position this Fall.

Jean-Paul

16. **Juan R.**
February 21, 2005

Hi,

I am completely sure that current string-M theory is wrong. My doubt is when this will be admited by own string-M theorists.

What will hapen then? A revolution on public perception of science? A new regime of ultraconservative funding of new ideas?

17. **anonymous**
February 21, 2005

Dear Jean-Paul,

I have to strongly disagree with your assertion that all relevant QCD amplitudes were known in the early 1990s.

There is a nice talk online which compares the (poor) theoretical status

http://online.kitp.ucsb.edu/online/collider_c04/campbell/oh/13.html

to “An Experimenter’s Wishlist”

http://online.kitp.ucsb.edu/online/collider_c04/campbell/oh/05.html

18. **Jean Paul**
February 21, 2005

I forgot the reference:
http://www.ims.uni-stuttgart.de/~jonas/piedpiper.html

19. **Jean-Paul**
February 21, 2005

SSC was the last challenge for perturbative QCD — by early 1990’s all QCD amplituted needed for the next 100 years of collider physics were known. The twistor business may be interesting in itself, but if you ask a honest QCD professional, he/she would tell you that it is completely useless for LHC jet simulations etc. The real challenge is to understand the fragmentation processes, i.e. soft physics related to quark confinement.

Now coming back to the interesting difference between blue shoes and twistors. By working on twistors, or in general, on the “hottest” (but in long-term completely irrelevant) topics a whole generation of high energy physicists were able to secure jobs at top ivy league institutions.
To conclude — you don’t get rich or famous by wearing Britney’s shoes but you do if you follow Ed the Piper.

Jean-Paul

20. **ksh95**
February 21, 2005

Matthew said

"…The difference is that Witten's work on twistors has lead to concrete expressions for Yang-Mills amplitudes, many of which could not be computed before…"

I'm not talking about YM amplitudes or the scientific usefulness of twistors. I'm talking about a herd mentality.

You say:

Everyone follows Witten because his utilization of twistors has guided us towards deeper understanding in the very important field of physics.

My wife says:

Everyone follows Brittney because her utilization of blue shoes has guided us towards deeper understanding in the very important field of accesorizing.

…I'm still not sure I see a difference in mentality.

21. **Thomas Larsson**
February 21, 2005

The expressions may be concrete, but they are probably physically irrelevant (i.e. SUSic), and probably wrong on the loop level, no?

22. **Matthew**
February 21, 2005

What's the difference between Britney Spears wears blue shoes so we all wear blue shoes, and
Ed Witten works on twistors so we all work on twistors.

The difference is that Witten's work on twistors has lead to concrete expressions for Yang-Mills amplitudes, many of which could not be computed before. There is a reasonable hope that this line of attack could lead to *closed*form* expressions for all one loop Yang-Mills amplitudes. That would be very useful, particularly in the LHC era, where huge QCD backgrounds will be the norm.

23. **D R Lunsford**
February 21, 2005

Umm, ST is based on one such dead end, KK theory. It was "dead before arrival".

-drl

24. **John Rennie**
February 21, 2005

http://relativity.livingreviews.org/Articles/lrr-2004-2/ gives a fascinating account of a previous dead end in field theory. Mind you he's writing about events 80 years ago so it's fairly easy to get a sense of perspective. Who knows how long it will take before a similar account can be written of the current era?

25. **Not a Nobel Laureate**
February 21, 2005

The last group that I can recall doing this type of "physics by press release" was Pons and Fleischmann announcing their discovery of "cold fusion".

But I'm being rather unfair to Pons and Fleischmann grouping them with Susskind.

Unlike Susskind's meta-physics, their result was testable.

Nor was the purpose of their press release to engage in emotional diatribes or ad hominem attacks.
It was to announce what they, mistakenly, believed to be a new physical phenomena.

As a physicist, I may not be driven to depression an despair by Susskind's sillines, but I certainly am embarrassed.

26. **Chris W.**
February 20, 2005

From Sean Carroll's summary of the AAAS meeting (just posted):

> [Lenny Susskind](http://www.itp.stanford.edu/~susskind/) went next, saying how happy he was to be at an AAAS meeting giving a talk on biology. That's because he went on to compare the number of possible vacua of string theory (the "landscape") to the number of possible biological organisms you could get by arranging base pairs in a DNA molecule — the former is perhaps 10500, while the latter is maybe 1025000000000. So biology wins, but the lesson we are supposed to learn is that a large variety of possibilities is what enables the development of intelligent life; in the context of string theory, it is the large number of stable vacua that makes it possible to find one with a sufficiently small vacuum energy so that life can evolve.

That line of argument strikes me as mostly fallacious, but maybe that's just because I'm depressed and desperate.

27. **ksh95**
February 20, 2005

Jean-Paul Said

"…The rise and fall of superstring theory is a fascinating social phenomenon that's certainly worth a book or two…"

Definitely fascinating, but in my opinion, not that surprising. An aptitude for complex mathematics is not an exemption from the hard wired instincts governing the rest of society.

What’s the difference between Britney Spears wears blue shoes so we all wear blue shoes, and
Ed Witten works on twistors so we all work on twistors.

This is absolutely no differnent that pet rocks, or the communist scare, or the Micheal Jackson moonwalk.

More on topic,

It’s also not surprising that Susskind would rather tear down the few hundred year old edifice of predictable testable science, than admit to himself that his lifes work and deepest beliefs are misguided.

We should just hope Susskind doesn’t succeed. History is rife with examples of highly intelligent people who, based soley on ego, pissed away a lot more.

28. **Jean-Paul**
February 19, 2005

ksh95 — you are making a good point. But one of the main reasons why too many young people went into
this type of pure research was hype and “false advertising” made under the presussure of your “public opinion”. The rise and fall of superstring theory is a fascinating social phenomenon that’s certainly worth a book or two — I assure that they would sell much better than “The Cosmic Landscape”.

Jean-Paul

29. **ksh95**
February 19, 2005

Jean-Paul Said

Even if it takes more than 20 years to figure out what (if any) is the physical content of superstring theory, serious scholars will keep working… while clowns will keep entertaining the public.

Hmmm, that’s easy to say for a physics purist who lives stricly in the physics world. It’s much harder to say for those of us living in the real world, where congressional budgets, public opinion, and academic politics reign supreme.

Personally, I haven’t a dog in the quantum gravity race, but I understand the value inherent in wowing the publics imagination, and framing research in terms of societal benefits.

It could be reasonable to question a clown’s contribution to pure research, but to question their global value…???

30. **Jean-Paul**
February 18, 2005

It is really puzzling how any serious physicist can listen to this nonsense. I think that the field was unintentionally brought down by “outsiders” who started proposing “n’importe-quoi”, as we say, ideas based on “everything goes”: large extra dimensions,
brane-worlds, which have nothing to do with strings but for general public appear far more comprehensible and sexy than superstring dualities etc. Split supersymmetry is another example of pure nonsense. Even if it takes more than 20 years to figure out what (if any) is the physical content of superstring theory, serious scholars will keep working… while clowns will keep entertaining the public.

Jean-Paul

31.
February 18, 2005

Perhaps in time physicists will look back and remember “the Landscape” as being but a pathological feature of string theory that eventually got sorted out, just like the infinities of quantum field theory were. But Susskind does remark:”Ed Witten worked very hard to show that there was only one or a small number of legitimate solutions to the theory and he failed–failed totally”. However, that does raise the obvious question: what chance does anyone else have of success then? It is noticable too that terms like “string”, “brane”, “M-theory” are not turning up in Witten’s preprints as of late.

32.
February 18, 2005

Well if I were still a string theorist, Susskind’s antics would certainly have driven me to depression and despair by now.

Atiyah’s Collected Works

February 25, 2005
Categories: Uncategorized

I recently acquired a copy of the new volume 6 of Atiyah’s collected works, which contains things he wrote from the late eighties until very recently (the latest article is his joint paper with Graeme Segal on twisted K-theory). Unfortunately the price of this book is very high (about $200). I’ve bought cars for less than what I paid for the book.

Even more expensive is the full six-volume set, which Oxford intends to sell for $1000. Luckily I bought the previous 5 volumes quite a few years ago at a somewhat more modest price. Atiyah is one of my great heroes among mathematicians. He’s up there among the top very few in any reasonable list of the greatest mathematicians of the second half of the twentieth century, and the extent of his influence in bringing together mathematics and physics is hard to overestimate. Witten’s great work on topological quantum field theory was done very much because of impetus from Atiyah. One of the articles in the new volume is the write-up of Atiyah’s amazing talk at the Weyl Symposium in 1987, where he first suggested that there should be a four-dimensional QFT whose observables were Donaldson invariants and whose Hilbert space was Floer homology.

Atiyah is also known as Sir Michael. Before I heard about this I had always thought that the British system of honorary knighthoods was pretty silly, but the fact that they chose him gave me some respect for the whole system.

It’s a shame the books are so expensive, since they are wonderful documents that deserve wide distribution. Atiyah has not only discovered wonderful new mathematics, but he writes about it in an elegant, inspiring and lucid way. The books contain many expository pieces he has written over the course of his career, and these are pretty much all well worth reading. I regard a large part of my mathematical education as having come from spending a lot of time with these volumes over the years.

Comments

1. **Peter**
   February 28, 2005

   Thanks for pointing out the problem with the link, should be fixed now.

2. **Anon**
   February 28, 2005

   I don’t know if it’s just me, but the link on twisted K theory doesn’t work.

   As for problem solvers? Um, Erdos is the only one that comes to mind for me at least.

3. **Juan R.**
   February 28, 2005

   Yes, they are expensive book,

   but that are $200 when compared with the $1200 of

   the Handbook of Molecular Physics and Quantum Chemistry by Whiley?

4. **DMS**
   February 28, 2005

   Noam Elkies (Harvard math) classified mathematicians in broadly two categories: “theory builders” and “problem solvers”. All three in the list are theory builders. Anyone know of major figures in the problem solver category (like Erdos)?

5. **Anon**
   February 27, 2005

   “About Beilinson and Drinfeld. They could learn a lot about exposition from Atiyah, Serre or even Grothendieck. Their writings make SGA look like a marvel of simple, lucid expository prose.”

   Hahaha. Did you poke around their recent text? (Chiral Algebras, I believe)

   But anyways, I agree; it isn’t pretty at all!

   🙂

6. **Peter**
   February 27, 2005

   I didn’t include Weil in my list of greatest mathematicians of the second half of the twentieth century since much of his most important work was done in the 30s and 40s.

   As for ranking Atiyah, Grothendieck and Serre; I guess I just don’t think their achievements are commensurable. All three have done amazing things, but of quite different kinds.

   About Beilinson and Drinfeld. They could learn a lot about exposition from Atiyah, Serre or even Grothendieck. Their writings make SGA look like a marvel of simple, lucid expository prose.

7. **Anon**
   February 26, 2005

   Interesting thoughts. I guess it’s hard (or perhaps a bad question to pose in the first place) about who is the “better” mathematician. Hm. Personally I’d lean towards Weil, Grothendieck or Serre.
   …

BUT since I'm at U of C, I have an obligatory vote for Beilinson and Drinfeld.

8. **JC**
February 25, 2005

Didn't Andrew Wiles (of the Fermat's last theorem fame) also get a British knighthood a few years ago?

9. **Peter**
February 25, 2005

If I had to list the greatest mathematicians of the second half of the twentieth century, I'd choose Atiyah, Grothendieck and Serre. Grothendieck and Serre are much more algebraists than Atiyah, who is much more a geometer than an algebraist. The parts of mathematics that have interacted strongly with physics in recent years have been much more geometrical than algebraic. So of these three, because my main interests lie at the intersection of math and physics, Atiyah is the one whose work I have found most directly relevant.

Grothendieck is an amazing figure, and he had a revolutionary impact on mathematics during the fifties and sixties. Unfortunately for mathematics, he stopped doing research during the seventies. If he had remained active, it would have been very interesting to see his reaction to the new ideas coming into mathematics from physics during the late seventies and eighties.

10. **anon**
February 25, 2005

And what are your thoughts on Grothendieck? Just curious. I've read of some of his work (Riemann Roch, etc), but I was curious of what you thought about it.

Best,
Anon

11. **Quantoken**
February 25, 2005

The books contain many expository pieces he has written over the course of his career, and these are pretty much all well worth reading. I regard a large part of my mathematical education as having come from spending a lot of time with these volumes over the years."

Peter, books will get even more expensive in the next hundred years, since they are becoming antique and outdated. Try to buy a mechanical typewriter today and it will probably cost you more than an old car, if you could ever find one.

We are now in an age where information is more readily distributed and accessed through electronic means, it makes less and less sense to rely on dead trees that can decay and rot, as means of dissipating information. Both for the sake of environment protection, and for the sake of not letting book shelfs clog up the limited living space of your home, it is better to avoid buying books at all if you can.

I have accumulated books that fill cabinets lining up a whole 20 feet of wall at my home. Most of them contain outdated and useless information and I do not know what to do with them since I rarely have time to read any of them. I have stopped buying books where similar information is already accesible on the web.

As for the expensiveness of books. Part of it goes to the cost of killing trees and make paper and printing on them. A little part goes to the loyalty of the authors. And the biggest chunk goes to the greedy commercial publishers, especially publishers of scientific materials.

I think if it were not for publishers, today's scientific information would have been much more readily available on electronic medias and for very low cost or even free. wouldn't most paper authors agree that they would be happier if more people can access their work more easily? So publishers are really an obstacle to science developments.

Quantoken

12. **Steve M**
February 25, 2005

I am glad Atiyah has chosen Edinburgh University, my old undergraduate stomping ground. (Higgs is there too). I don't know where publishers get their prices for these kinds of books. There are many such books out there I would like but simply can't afford. If they would put out good paperback versions at reasonable prices I am sure they would actually make more money and shift more copies. Students (and even some professors) don't have that kind of money to spare. Incidently, Sir Roger Penrose has a knighthood too.

UFOs

February 25, 2005
Categories: Uncategorized

Last night ABC News ran a two-hour primetime special on The UFO Phenomenon — Seeing is Believing. As part of this special program, they interviewed "one of the world's leading theoretical physicists", who, according to Bob Park, "looked a lot like Michio Kaku." This physicist told ABC that UFOs should be taken seriously since "You simply cannot dismiss the possibility that some of these UFO sightings are actually sightings from some object created by ? a civilization perhaps millions of years ahead of us in technology." He also explained how aliens could get here using wormholes.

Kaku appeared yesterday on the radio show "Coast to Coast" to discuss UFOs and the ABC special. He appeared on the same show (in different hours) as Al Bielek, who evidently had a job in California, but regularly traveled by secret underground subway to Montauk, Long Island to work on the "Montauk Project". During the 1980s he traveled to Mars on several occasions, as well as to "a research station in 100,000 BC, other planets to get canisters filled with Light and Dark Energy, and to the year 6037."

Comments

1. **Quantoken**
   February 28, 2005

   Wake up Aaron, you don't even know what you are talking about. Because you are speaking from the opening of a wormhole: -)

2. **Aaron**
   February 28, 2005

   Quantoken —

   There are many problems with creating and utilizing wormholes. Unfortunately, all the ones you've put forth are wrong.

3. **J.F. Moore**
   February 27, 2005

   Kaku has been on coast-to-coast many times. He also has his own weekly hour-long syndicated radio program on Pacifica. Coast-to-coast is clearly and almost exclusively a bunch of fringe crap, not just a "popular forum", and they eschew the skeptical angle. It's below the critical thinking level where Larry King resides, if that is even possible. For a scientist to go on the show repeatedly and throw red meat to that select audience is pretty sad, but at least he makes his position regarding how he approaches science clear. What's truly unfortunate is that he somehow now occupies the public space that Feynman and Sagan once did.

   As for the ABC show, well, personally I've become numb to how uncritical and pandering the mass media have become. I guess they expect that very few people would tune in to hear Bob Park say that an instrumented balloon crashed at Roswell, nothing more; so they don't run it with that. At some point such choices become predestined.

4. **Quantoken**
   February 27, 2005

   Peter said:

   "In this case, the whole wormhole business is pure speculation. No one has any idea how to, even in principle, construct a wormhole that will connect to some other point on the universe. If you want to speculate that such a thing is possible, fine, but that's not really science right now, it's science fiction."

   One has got to understand science fiction is a much bigger enterprise than science itself. It's an industry worth several hundred billion dollars per year. For humans, the need of entertainment far exceeds the need of curiousity.

   The idea of wormholes is popular because it's entertaining, not because there is any scientific base in it. There is absolutely none.

   Theoretically spacetime wormhole can exist. But the only thing that can bend spacetime is the GR effect of mass/energy. To form any wormhole at all would take at least the amount of mass enough to form blackholes, or the equivalent amount of energy. Doesn't matter whether it is energy or mass, as far as GR is concerned.

   To form a wormhole of just a thousand light years long, like say, would take the amount of mass enough to form a blackhole a thousand light years in radius. Just being able to utilize all the energy of a star would be far from enough. You collect all mass of a giant galaxy and it is still not enough to form such a wormhole.

   You would need to collect the mass of a few million galaxies just to construct one wormhole allowing you to reach just a few thousand light years away. But to be able to collect masses of neighboring galaxies you need to be able to travel to those neighboring galaxies first, and that requires you need to have wormholes connection to those galaxies first. It's a chicken first or egg first dilemma.

   OK, now assume the alien civilization had already invented time travel machine. They could go to futuristic world to borrow a wormhole first. They would then be able to empty out a million galaxies nearby and construct a wormhole practical for inter-galactic traveling.

   What then? There would be a pretty big void in the space near our galaxy, suppose such a civilization is our next door neighbor and their wormhole is close enough to access the earth. They had used up all masses of a few million galaxies to construct their wormhole. We would then be able to see such a huge void if we aim our telescope into the sky. But no such huge void has been found?

   Or has such void been found? I heard rumors that astronomers do find big voids hundreds of millions of light years across with no galaxies. Maybe that's the evidence that aliens have used up all those galaxies to construct wormholes 🙂

   But after all, even if the alien civilization know something we don't know, and has the technology to carry out inter-galaxy travels. We can imagine it still costs an astronomical amount of resources to carry out, even if it does not take wiping out whole galaxies.

   They must also have some sort of political system, some sort of congressional budget committee, special interest groups and all that. Although their scientists would want very much make contact with the pity little creatures on earth called human, the prohibitive cost of resources would surely kill any such proposal just like how SSC was killed 🙂

So no, I do not think wormholes exist and I do not think any UFO is associated with alien visitors. But who knows, maybe the quantum teleportation is more practical than wormholes?

Quantoken

5. **Stephen**
February 27, 2005

Hi Wolfgang,

the Josephson paper claims that:
"Our mathematical skills are assumed to derive
from a special ?mental vacuum state? [..]"

I think what is being established here is how math models might have issued from the deeper recesses of math minds, to explain things.

The impact of visualization is relevant to how math minds work?

Peter Woit:*Grothendieck is an amazing figure, and he had a revolutionary impact on mathematics during the fifties and sixties. Unfortunately for mathematics, he stopped doing research during the seventies. If he had remained active, it would have been very interesting to see his reaction to the new ideas coming into mathematics from physics during the late seventies and eighties.*

George Lakoff :*Our answer is that the ordinary embodied mind, with its image schemas, conceptual metaphors, and mental spaces, has the capacity to create the most sophisticated of mathematics via using everyday conceptual mechanisms.*

http://www.edge.org/3rd_culture/lakoff/lakoff_p4.html

This process is very interesting to me. A keen eye, to a world that few of us could imagine?

regards,

6. **Peter**
February 26, 2005

Hi Tony,

I also haven't seen the TV show or heard the radio show, so I can't speak to the details of what Kaku did or didn't say in these programs.

Sure, I think it's not a bad thing, but a good thing, for physicists to appear in a popular forum. But when they do, they should be acting responsibly, and explaining to people real science. Both here and in his recent books, Kaku seems to me to be completely blurring the distinction between science and science fiction. In his recent book, he doesn't bother to clearly explain what is real science that we have good evidence for, and what is pure speculation.

In this case, the whole wormhole business is pure speculation. No one has any idea how to, even in principle, construct a wormhole that will connect to some other point on the universe. If you want to speculate that such a thing is possible, fine, but that's not really science right now, it's science fiction.

Shows like Coast to Coast are heavily caught up in the "paranormal" and the belief that there is all sorts of stuff going on that is completely incompatible with our understanding of science. People find this very appealing for deep psychological reasons. For a serious scientist to go on such a program and encourage this seems to me extremely irresponsible.

7. **Tony Smith**
February 26, 2005

Peter, thanks very much for clarifying your post about Kaku. As you say, "… "Coast to Coast" is a show often devoted to UFOs and similar topics. It is not unusual for them to be running interviews with the likes of Bielek. Kaku … decided to appear on Coast to Coast …".

Do you think that it is a bad thing for a physicist to appear on a popular forum ?

If it is a bad thing, then how will the general population who listens to such shows learn anything sensible about real science ?

If it is a good thing, is it fair to criticize a physicist for appearing on such a show ?

Please note that these questions are more general than the question of the validity of Kaku's statements, which I have not heard because I did not hear either the ABC show or the Coast to Coast show.

However, http://abcnews.go.com/Technology/Primetime/story?id=528724&page=1 and the page 2 that follows it contain the following material quoting Kaku on the ABC UFO Show:

"… Feb. 24, 2005 ??There have been countless accounts of alien visitations around the world, but one of the things that prompts skepticism is how they would get here in the first place. If aliens are from another world, they must have some extraordinary means of travel ? nothing like what is available anywhere on Earth. It is hard to underestimate the difficulty of going from star to star. …
However, Michio Kaku, one of the leading theoretical physicists in the world, says many scientists are too quick to dismiss the idea of other civilizations visiting Earth. Einstein may have said nothing can go faster than the speed of light, but he also left a loophole, said Kaku, a professor at the City University of New York. In Einstein's theory, space and time is a fabric. Kaku explained: "In school we learned that a straight line is the shortest distance between two points. But actually that's not true. You see, if you fold the sheet of paper and punch a hole through it, you begin to realize that a wormhole is the shortest distance between two points."
A civilization that could harness the power of stars might be able to use that shortcut through space and time, and perhaps bridge the vast distances of space to reach Earth, he said.
"The fundamental mistake people make when thinking about extraterrestrial intelligence is to assume that they're just like us except a few hundred years more advanced. I say open your mind, open your consciousness to the possibility that they are a million years ahead," he said. Kaku believes that only this type of civilization ? millions of years more advanced that us and capable of using wormholes as shortcuts ? could reach Earth and might be one explanation for UFOs.
"When you look at this handful of [UFO] cases that cannot be easily dismissed, this is worthy of scientific investigation," he said. "Maybe there's nothing there. However, on that off chance that there is something there, that could literally change the course of human history. So I say let this investigation begin." …".

Personally, I don't see any quoted Kaku statement that is inconsistent with generally accepted physics (bearing in mind that a lot of physicists such as Kip Thorne have written a lot about the physics of wormhole construction, etc).

It also seems to me that Kaku's statement "… "Maybe there's nothing there. However, on that off chance that there is something there, … let this investigation begin." …" is consistent with the scientific spirit of observation, experimentation, and inquiry, and is NOT a gullible Oh-Wow-look-at-the-aliens type of statement.

Again, my primary question is: If physicists are to be pilloried for merely appearing on a popular forum about subjects that interest the public, how is the public to become better educated about physics ?

The primary question having been put, I want to make clear that I have some substantial disagreements with Kaku about physics, such as his statement on his web page at http://www.mkaku.org/articles/proposal_uft.shtml where he says "… The fundamental problem facing physicists is that General Relativity and the quantum theory, when combined into a single theory, is not ?renormalizable, ? i.e. the theory blows up and becomes meaningless. … So far, only superstring theory can … give us a finite theory which combines these two formalisms. …".

My disagreement is with Kaku's statement that only superstring theory can so combine GR and the SM.

I also note that he is careful to NOT say that superstring theory HAS done such a thing, only that maybe it can, sort of like maybe the advanced civilizations can build such wormholes.

It would have been nice if the ABC UFO show had also had somebody like Thorne to point out how very difficult such a wormhole construction project might be, but it seems to me that ABC is being as one-sided in its view of UFOs as some conventional superstringers are in their views of approaches to theoretical physics.

Tony Smith http://www.valdostamuseum.org/hamsmith/

8. **Peter**
February 26, 2005

Hi Tony,
The schedule of the show that I saw didn't make clear they appeared in different hours, so it was incorrect to say that they appeared "together", and I'll change that.

But I don't think my comments were fundamentally unfair. Kaku was the one who decided to appear on ABC and lend his reputation to the pro-UFO side of their show. "Coast to Coast" is a show often devoted to UFOs and similar topics. It is not unusual for them to be running interviews with the likes of Bielek. Kaku was the one who decided to appear on Coast to Coast to discuss UFOs in a positive light, and I think it is likely that he would have known what the nature of that day's show was, and who else was appearing with him on the same day.

9. **Tony Smith**
February 26, 2005

Peter, you said:
"… Kaku appeared yesterday on the radio show "Coast to Coast" to discuss UFOs and the ABC special. He appeared together with Al Bielek, who evidently had a job in California, but regularly traveled by secret underground subway to Montauk, Long Island to work on the "Montauk Project". … he [Bielek] traveled to Mars on several occasions …".

I think that is a dishonest criticism-by-association of Kaku.

The Cosat-to-Coast website at http://www.coasttocoastam.com/shows/2005/02/24.html says:
"… Thursday's first hour guest, theoretical physicist Michio Kaku commented on the ABC special Peter Jennings Reporting: UFOs which had aired earlier in the evening.
…
…
In the middle two hours of the show Al Bielek revisited his claim that he participated in the Philadelphia Experiment aboard the USS Eldridge in 1943 as a man named Edward Cameron. … Bielek stated that while at Montauk he traveled via a wormhole to Mars …".

It appears clear to me that Kaku appeared in the first hour to discuss the ABC UFO special, while Bielek appeared on the middle two hours to discuss the Philadelphia Experiment and Montauk/Mars stuff. Obviously (to me), the first hour and the middle two hours were quite independent radio shows.

I think that it is highly intellectually dishonest to smear Kaku with guilt-by-association-with-Bielek, and I am disappointed in your failure to maintain the otherwise very high level of integrity that I have seen in your blog.

Just for the record, my own personal opinion of Kaku is somewhat mixed.

On the one hand, I agree with drl's comment to an earlier post (More Science Fiction, January 02, 2005) in your blog where drl said "… I like Kaku's field theory book …",
and
I also agree with Dolomite's comment to the same earlier post where Dolomite said "…The table of contents …[of]… one of Kaku's graduate level textbooks on String theory … looked quite impressive, but the body of the book turned out to be a smorgasborg of equations … with the symbols changed around in a failed attempt at making the different chapters look consistent, in the process removing much of the logical connective tissue and adding in typos. …".

Tony Smith http://www.valdostamuseum.org/hamsmith/

February 26, 2005

Stephen,

the Josephson paper claims that:
"Our mathematical skills are assumed to derive
from a special ?mental vacuum state? [..]"

While this 'mental vacuum' state seems to be
important for superstring theory, I would
assume it also describes some of the contributers
to this discussion here pretty well …

11. **Quantoken**
February 26, 2005

People take UFO seriously not necessarily because there is good evidence UFOs are associated with aliens, but because such ideas are entertaining. People tend to believe things that are amusing and entertaining, and tend to reject things that's boring even though they are true. That's psychology. The same thing could explain why string theoretists so believe in their theory religiously, even though there hasn't bee any evidence their theory has anything to do with nature.

Just for entertaining, but also seriously, for the UFOs that do sudden motion changes. It does not necessarily mean their inertial masses have been reduced to virtually none-exist. More likely they acquire momentum change without excerting opposite momentum change to the immediate vicinity. That's why there is no shock waves.

One possible scenary is they are capable of ejecting strong directional streams of gravitons. The GR predicted existence of gravitons. If these particles exist then theoretically they can be controled using certain technology of another civilization, and be emitted towards certain direction in a controled way.

But then gravitons can be used to break the equivalence principle. How come? A particle invented by the GR theory comes back and destroy the very principle that GR is based on? I do not know how to reconcile that inconsistency? If UFOs exist they do provide evidence of existence of graviton and gravitational wave, right?

Do gravitons themselves gravitate and observe the equivalence principle? i.e., do they have equal inertia mass and gravitational mass? Or do they have inertia mass only?

Quantoken

12. **Matti Pitkanen**
February 26, 2005

Leaving aside ontological considerations and what to think about people taking UFOs seriously, one could take UFOs as a source of thought experiment.

Suppose for a moment that UFOs represent a real technology. According to the reports, UFOs seem to have a very small inertial mass (butterfly like motions involving sudden accelerations and changes of direction of motion without producing any shock waves). A technology able to reduce dramatically inertial mass of a material object would thus exist. What could this tell about fundamental physics?

A possible answer would be a modification of Equivalence Principle. Gravitational mass would be absolute value of inertial mass, which can have both signs.

One of the most obvious implications is an explanation for why gravitational energy is not conserved in cosmological scales whereas there is no evidence for the non-conservation of inertial energy. The simplest cosmology would be that creatable from inertial vacuum by energetic vacuum polarizations creating regions of positive and negative density of inertial mass. The 4-D universe could replace itself by a new one quantum jump by quantum jump and the difficult philosophical problems formulated as questions like "What was the initial state of the Universe and what were the initial values/densities of conserved quantities at the moment of big bang?" would disappear. The observations motivating the anthropic principle would find a natural explanation: the universe has gradually quantum engineered itself so that the values of these constants are what they are.

Technological implications would be also interesting. Forming an tightly bound state of systems with positive and negative inertial mass a large feather light system could be created. Could UFOs be real and utilize this kind of technology?

Accepting negative energies, one cannot avoid the questions whether negative energy signals propagate backwards in (geometric) time and whether phase conjugate light discovered at seventies could be identified as signals of this kind. Positive answer would have quite interesting technological implications. Negative energy signals time reflected as positive energy signals from time mirrors (lasers with population reversal for instance) would allow communications with geometric past. Our memory might be based on this mechanism: to recall memories would be to scan the brain of geometric past by using reflected in time direction (rather than in spatial direction as in seeing in the ordinary sense). Communications with the civilizations of the geometric future and past might become possible by a similar mechanism.

February 26, 2005

Peter Woit,

I do not understand this presentation from what I have read of your work here?

Is there a clear distinction from your position of what you would like to exemplfy of intelligent people, like Michio Kaku and others to that of string theory?

Allen Hynek was a disbeliever, and headed project bluebook, but eventually changed his tune. H eis shunned, by those of his peers. Is this what happens when those of science step outside of the box?

Brian D. Josephson

Ed Witten, TV writer

February 26, 2005
Categories: Uncategorized

There's a story in this Sunday's New York Times television section describing how Ed Witten pitched a story idea to the people who make the new TV show Numb3rs. According to one of the show's executive producers, Cheryl Heuton, "Ed sent our script back along with an episode idea, which we used, telling us we should do something about a rogue mathematician who tried to crack Internet security by solving the Riemann hypothesis." Witten had received the Numb3rs script to look at from his brother, the writer Matt Witten.

For more about the Caltech mathematicians who are the main consultants for the TV show, see this USA Today article.

Comments

1. March 1, 2005

   I guess Ed should keep his day job.

2. **Alejandro Rivero**
   February 28, 2005

   "a rogue mathematician who tried to crack Internet security by solving the Riemann hypothesis".

   Plot already used, in the movie "Sneakers". The mathematician gets killed fast along the plot. According some web pages, the mathematical advisor contacted was Len Adleman, "the A in RSA".

3. **Chris Oakley**
   February 28, 2005

   I thought that Matt Damon was an actor. Or is this what "method acting" is about – totally getting into the part. So if you play Hitler you have to be a crazy megalomaniac who wants to annex the Sudetenland (not likely to be good for the Czech tourist industry) & if you play Lord Byron you have to have a "fling" (well, possibly) with your half-sister – ?

4. February 28, 2005

   Solving an undergrad level matrix problem might not seem like much to you, but this is Matt Damon we're talking about. A math coach can only do so much.

5. **Quantum_Ranger**
   February 27, 2005

   The programme that I recall Ed Witten walking through the countryside, was Stephen Hawkings "Universe"?..it also shows Smolin walking across stones of a stream/river?

   I met Ed Witten when he was here in Swansea University(the re-located stringtheory summer school for postgrads 95-96?)..where I first seen the words Brane and T-Duality. The conference was very intense, most of the Post-Grads were 'rebelling' against the new generalized theory of 'M-THEORY' and such.

   Ed Witten had a lot of problems with the post-grad students, and a number of them left the lectures totally bemused. One outcome was the emergence of VSL, which was put forward by a number of 'persons', in the snooker room, over the snooker table.

   I played my part in asking certain questions,(I was Porter at the Uni!), and some of the postgrads were really interested in some of what I asked regarding of why the speed of light had to be different if one rewinds Einsteins Field Equations, one response I recall:The speed of light and its constancy, is one of the most sacred postulates of science, you dont mess with any constants, if you want to get anywhere in the future,(context was wrt Academia).

   Rogue mathematician I am not:http://groups.msn.com/RelativityandtheMind/shoebox.msnw?Page=1

   😉

6. February 27, 2005

   The program with Witten walking through the wilderness and walking on a dry lake bed was probably a NOVA show on PBS about string theory.

7. **Redouan**
   February 27, 2005

   Steve,

   >Speaking of Witten and tv does anyone know what program/series >featured Ed Witten wandering through the countryside…

   Well, it's not exactly that program, but there was another one broadcasted on Dutch television showing some parts with Witten in Amsterdam during the 1997 summer String Theory seminar. For the most part, however, it's Michio Kaku in Manhattan doing the talking. [the program is 24 min. long.]
   You can watch it on
   http://www.vpro.nl/wetenschap/index.shtml?3626936+2848322+3855404+5409638

   Funny part: Einstein arriving in 1930 in NY surrounded by a horde of reporters.

   Reporter: What do you think of Prohibition professor?
   Einstein: Ich drinke nicht, also… ist mir dann ganz gleich.

8. **Chris Oakley**
February 27, 2005

Re: *Good Will Hunting*, it looks like someone at Harvard has posted the blackboard problem. I don't think that he is saying that one would need to be a genius to solve it, though.

9. **Alejandro Rivero**
February 27, 2005

The initial version of Bretch' Galileo was discussed by the author with the physicist of Copenhagen.

10. **Santo D'Agostino**
February 27, 2005

Chris (and anonymous),

Some of Good Will Hunting was shot in Toronto. University of Toronto high-energy physicist Pat O'Donnell was having lunch one day at a Chinese restaurant in Toronto's Chinatown. Pat's got a full white beard and a thick accent. The casting person from the movie was having lunch at a nearby table and offered him a small role in the movie. When the movie people found out his profession, they also made him a consultant, and Pat was responsible for putting the mathematics on the blackboards.

I seem to recall Pat saying he consulted with number theorists, but in any case one shouldn't rush to blame him if the math didn't come out realistic without finding out more about the situation. Hollywood has its own agenda, and being accurate is not necessarily part of that agenda in most cases. They may have given Pat certain instructions about what the math should be like, but I don't have any information about that.

Santo D'Agostino

11. **Stephen**
February 27, 2005

Steve

Speaking of Witten and tv does anyone know what program/series featured Ed Witten wandering through the countryside and sitting by rivers scribbling on a notepad, and walking across the boulders on some dried-up lake bed?

This is firmly emblazoned within my mind as well. Can't recall the name of this program either though.

Because of what it signified, and what I concluded, is that intense mental dealings with math could stifle the mind from finding anything further, but it was from these silent walks and divergences from the hectic, that allowed the breakthroughs to manifest.

I think this was the point that Witten was showing then. It also open up the idea that complex mathematics might from perspective, as if in some meditative stance, takes us closer to finding the language most relevent in innovation, when such math structures are contemplated.

Invention is no less in the same sequence of events as math might be in creativeness, that if you leave it, it will come later.

Looking for these areas of further intelligence developement in mathematics, raise the issue of cognitive functions spoken in previous post.

Why metaphorically, bubbly structures rising to the surface, from unconsious processes, might be more revealing then first anticipated?

For example it was Ramanujan's enviromental god processes that spoke to him about the math , but of his mind was dealing with complex variables in a way that metaphorically was the sign post of probabilities?

Yet out of the hectic, a system emerged. You just had to be aware of what the mind was capable of producing and how it would do that.

Ramanujan was no different then you and I and the envirnoment that we deal, with could manifest creative possibilties, as math would in comparison. Why Susskind's light switch turned on, with those loops called strings?

Perspective views of other systems could awaken more comlex structures, as seems to be the way of math structures continung to build on itself , when these minds become involved and contemplate.

regards

12.
February 27, 2005

I noticed that too Chris. You would at least think they could get a consultant mathematician and get it looking right. I guess they figure it is good enough to fool the layperson majority in the audience. At least this Numbers series has consulants, which I think is important. You see this all the time though in old sci fi films. In one old film I saw once there is a "scientist" talking away and on a black board behind him is chalked F=Gm1m2/r^{2} and nothing else! Why?! I guess it was meant to show that he was a "scientist". I did see the movie "Supernova" on dvd recently. Not a great sci-fi movie but not bad. In once scene the ship's computer does a stunning mathematical analysis of an alien weapon, that was dug up on an ice moon in orbit around a giant start about to explode. The weapon contains "9-dimensional matter"–I guess it must be superstring. Freezing the scene on the dvd remote the equations look pretty good. At least they put some thought into it. I also need to get a life:). Incidently the guy exposed to the superstring weapon becomes a deranged superhuman psychotic who proceeds to murder all the crew. So string theorists might enjoy the movie:)

13. **Chris Oakley**
February 27, 2005

Re: the *USA Today* article, Ramakrishnan is right on target about *Good Will Hunting*, the tale of a janitor at an Ivy League university who writes solutions to cutting edge mathematical research problems on white boards in between mopping floors. IIRC (I only saw the film once, on a noisy aeroplane) the "solutions", insofar as they were comprehensible at all, were just first-year-undergrad matrix calculations which, scarily enough, had *actual numbers* in them – something a true mathematician would shun at all cost.

14. **Steve**
February 27, 2005

I guess they are a very talented family. How many Witten brothers are there anyway? There is a Monty Python sketch–"the Golden Age of Ballooning" where they discuss "Barry Zeppelin" the "least talented of the Zeppelin brothers" so I am wondering if there is a "Barry Witten" somewhere:)who has been completely overshadowed by his brothers. It does happen. Speaking of Witten and tv does anyone know what program/series featured Ed Witten wandering through the countryside and sitting by rivers scribbling on a notepad, and walking across the boulders on some dried-up lake bed? I remember seeing this in the 90s on some science series…I really liked that scene though. It was the most memorable. In fact the only part I actually remember.

15. **Lubo? Motl**
February 26, 2005

    Maybe Juan has proved the Riemann hypothesis, and Ed has shown how to use it to compromise the internet security…

Wick Rotation

February 28, 2005
Categories: Uncategorized

There's a quite interesting discussion going on about Wick rotation over at Lubos Motl's weblog.

In flat space-time, the situation is well-understood: if your Hamiltonian has good positivity properties you can analytically continue to imaginary values of time, and when you do this you end up with "Euclidean" path integrals, which actually make sense, unlike QFT path integrals expressed on Minkowski space, which don't. You can see the problem even in free field theory: the propagator is given by an integral that goes through two poles, so is ill-defined. The correct way to define it to get causal propagation for a theory with positive energies is to go above one pole, below the other, which is equivalent to "Wick rotating" the integration contour 90 degrees to lie on the imaginary time axis.

In a curved space time, things are much trickier. And in a path integral approach to quantum gravity it is very tricky. Do you integrate over all metrics with Lorentz signature (ignoring the fact that the path integral doesn't really make sense for a single one), or do you integrate over Euclidean signature metrics (Euclidean Quantum Gravity)? There are arguments against either choice, not to mention the non-renormalizability problems that both may have. For some of the arguments, see the debate in Lubos's comment section, which gives some idea of how confused the state of this question is. Another good reference is the article by Gary Gibbons in the Hawking 60th birthday celebration volume. It doesn't seem to be on-line, but his talk at the workshop is.

I've always thought this whole confusion is an important clue that there is something about the relation of QFT and geometry that we don't understand. Things are even more confusing than just worrying about Minkowski vs. Euclidean metrics. To define spinors, we need not just a metric, but a spin connection. In Minkowski space this is a connection on a Spin(3,1)=SL(2,C) bundle, in Euclidean space on a Spin(4)=SU(2)xSU(2) bundle, and these are quite different things, with associated spinor fields with quite different properties. So the whole "Wick Rotation" question is very confusing even in flat space-time when one is dealing with spinors.

Over the years I've tried to sell the outrageous idea that one should define QFT in Euclidean space time, with one of the two SU(2)s in Spin(4) being Spin(3), the spatial rotations, the other being the SU(2) of the electroweak gauge group. I've never been able to get anyone to take this seriously, partly because I've never come up with a well-defined way of writing down path integrals which implement this idea.

Comments

1. **Quantum_Ranger**
   March 3, 2005

   Is there any chance of 'Peter', actually giving a glimpse of :Nucl Phys. B paper?..a direct link would be useful.

2. March 3, 2005

   Fixing the causal structure of spacetime will not work. A simple thought experiment will show this. A universe with no black holes initially which forms a black hole as a clump of matter collapses has a very different causal structure from a universe where no black hole ever forms. But this is the crucial point; whether or not some matter collapses to form a black hole depends upon the dynamics of matter and gravity. Clearly, this means making the causal structure independent of the dynamics will lead to a contradiction.

3. **Anonymous**
   March 3, 2005

   Dear Lubos,

   I must say that I find your posts, always, very entertaining. But, please, remember that you are no longer in your home satellite. In the US, the terms of discourse are somewhat different. Your commissar-like behaviour of trying to shout down critics with insults and denunciations will not work. You merely appear ridiculous. You may keep your stalinist committments (if you must), but you need to change your methods (hint: learn from Distler). I think there is a book called "Getting power in the US while keeping your stalinist committments intact"; will let you know the Amazon link.

   Peter: I don't think Distler is "better" because of english. He just understands the subtle power-politics here much better than Lubos, who is still trying out his stalinist vilifications techniques.

4. March 3, 2005

   Incidentally, \int dx e^{ikx}=2 \pi \delta(k).

   Therefore, we have a clear example of a case where Wick rotation doesn't hold. 🙂

5. March 3, 2005

   formally, we can still perform calculations with unbounded path integrals. Let me give you an example of what I mean.

   \int_{-\infty}^{\infty} dx e^{kx} looks divergent and not well-defined, but let's pretend its value is f(k), which is of course infinite. Then, f'(k)=\int dx x e^{kx}. Ignore for a moment the fact that this integral diverges badly and pretend that integration by parts works. Then, f'(k)=-\int dx 1/k e^{kx}=-f(k)/k. Solving this differential equation, we obtain f(k)=f(1)/k. But recall f(k) is infinite. So, we normalize everything by dividing infinity by infinity to get a finite value.

   \int dx e^{kx}/\int dx e^{x}=1/k

   I know this is vulgar speech which wouldn't be appropriate in the polite company of mathematicians, but we're all physicists, right? You won't get offended. Peter may be a "mathematician", but when it comes to physics, he has the mindset of a physicist.

6. March 2, 2005

   Is it possible to add higher order terms to the Einstein-Hilbert action so that the Euclidean action is bounded from below?

7. **D R Lunsford**
March 2, 2005

Lubos,

The thing that makes invariant integrals is sqrt(det(g)), not -det g whatever that is. So the issue is, do I take sqrt(det(-g)) as do the relativists, or, as demanded by tensor analysis, sqrt(det(g)) ipse, which, if g has 1, 3, 5.. – signs, imaginary (and branched)?

-drl

8.
March 2, 2005

Lubos, how can we have both signature changing metrics AND a global gauge fixing where -|g| = 1 everywhere?

9.
March 2, 2005

Rest assured, Lubos will never have to distort his text to look less smart.

10. **Frank**
March 2, 2005

On the Topic of Lorentzian vs Euclidean, I'm reminded on stuff by Renate Loll in 2 Dimensions a while back:
a couple of slides: http://cgpg.gravity.psu.edu/online/Html/Seminars/Spring1999/Loll/Slides/s01.html

Insisting on causal paths in the path integral the theory can be defined in the continuum limit and differs from what you get in Euclidean theory.
Something analogue to the Wick rotation is still going on in that an imaginary cosmological constant is required to ensure the existence of the continuum limit.

More recently numerical investigations suggest that a smooth 4D (Hausdorff Dimension) macroscopic geometry emerges from these causal path integrals.

http://arxiv.org/abs/hep-th/0404156

11. **Lubos Motl**
March 2, 2005

Dear "", diffeomorphisms don't change the value of the action which is exactly the reason why the modes induced by diffeomorphisms are pure gauge. Locally, one can always choose a gauge where (-det g)=+1.

Sometimes I wonder, "", that "" is really Jacques Distler who just distorts his text a bit to look less smart, by a few orders of magnitude, so that there is an "independent" debater who supports his viewpoints. 😉

12. **Peter**
March 2, 2005

I think it would be best if people discuss Lubos's mistakes on his blog, mine on this one….

13.
March 2, 2005

Dear Lubos, what you say sounds as an error that would prevent a first-year grad student of general relativity from passing her exam.

Of course that your confusion about diffeomorphisms and the conformal factor shows a complete lack of understanding of general relativity.

That's not so hard to see. Diffeomorphisms would not change the value of the action.

One can't be confused about elementary general relativity theory if she wants to seriously work in quantum gravity. 😉

By your own admission, Distler's objections are perfectly valid. So now, you're completely unable to describe what the mistake in Distler's reasoning was supposed to be, are you?

14. **D R Lunsford**
March 2, 2005

Well that joke went over like a plaster of paris bagel…

-drl

15. **Lubos Motl**
March 2, 2005

Peter, you can always learn new things here. For example, Dr. Lunsford now teaches you that the determinant of the metric tensor (i.e. the product of -1 times 1 times 1 times 1) equals "i". Enjoy your learning! 🙂

16. **D R Lunsford**
March 2, 2005

Um, -det g = -i 🙂

Funny, this is also the y5 issue.

-drl

17.
March 2, 2005

In response to Lubos:

The gravitational action is arbitrarily large if the conformal factor varies fast enough.
You thought this behavior can be "gauged away" because one can "always set (-det g) = 1.

Is this explanation good enough for you?
If not I suggest you read the available literature.

18. **Lubos Motl**
March 2, 2005

Dear "", it was not subtle, except that you're completely unable to describe what the mistake was supposed to be, are you? 😉

19.
March 2, 2005

In response to Lubos Motl:

I did not write (-det g) = 1 and your mistake was not subtle at all.

20. **D R Lunsford**
March 2, 2005

Peter,

Yes, something "funny" is going on and it amounts to using the wrong "i" in the context of spinors, which need spacetime algebraic invariants. In a representation of the Dirac algebra in which y5 is diagonal (Weyl rep) the spacetime "I" (-iy5) reduces (almost) to the usual "i". This issue comes up again and again and leads me to believe the "via regia" to geometry in the context of field theory is y5.

Here are references to the papers I mentioned before:

D. Finkelstein, J.M. Jauch, S. Schiminovich and D. Speiser, Foundations of quaternion quantum mechanics, Journal of Mathematical Physics 3, 207 (1962)

D. Finkelstein, J.M. Jauch, S. Schiminovich and D. Speiser, Some physical consequences of general Q-covariance, Helvetica Physica Acta 35, 328-329 (1962)

D. Finkelstein, J.M. Jauch, S. Schiminovich and D. Speiser, Principle of general Q-covariance, Journal of Mathematical Physics 4, 788-796 (1963)

D. Finkelstein, J.M. Jauch, S. Schiminovich and D. Speiser, Quaternionic representations of compact groups, Journal of Mathematical Physics 4, 136-140 (1963)

You'll find, essentially, WSG electroweak theory, long before gauge theory was cool.

-drl

21. **Lubos Motl**
March 2, 2005

Who are the others you learn from, Peter?

The anonymous guy below who believes that one can't set (-det g)=1 by gauge transformations (diffeomorphisms)?

Of course that you can always find a simple coordinate redefinition such that (-det g) is whatever function or constant you want.

I retracted a statement that all problems related to (-det g) are pure gauge problems (it's a very subtle question), and an anonymous reader immediately celebrates that I retracted something, even though she or he misunderstands what exactly was retracted.

22. **Peter**
March 2, 2005

Actually one ot the best aspects for me of this weblog is that I often learn new things from people who write in with comments. Sometimes even from Lubos….

23.
March 2, 2005

It is not such a big deal as long as you can admit them quickly WITHOUT insulting everybody.

24.
March 2, 2005

If Lubos celebrates the fact that Peter stumbled a bit in this case, then I would like to point out that he made a much worse blunder 2 days ago on his
Wick rotation thread.
He was of the opinion that the conformal factor in higher-dimensional gravity can be set to 1 by gauge transformation.
People make mistakes. It is not such a big deal as long as you can admit them quickly with insulting everybody.

25. **Peter**
March 2, 2005

Unlike some people I'm not claiming to have a wonderful theory here. All I'm pointing out is that there seems to me to be something funny going on when you try and think about Wick-rotating spinors. The standard point of view is that this is a purely technical problem, but I suspect it might be a clue to something much more interesting and mentioned some reasons for thinking this. There are others in my 1988 paper. But this is a vague idea about where to look for a new theory, not a new theory, and I haven't claimed otherwise.

26. March 2, 2005

    Theatre critics should never act. It's an important rule. Probably best to just keep knocking everyone else's work Peter. Much easier.

27. March 2, 2005

    The kinematics doesn't seem to work. It may work for fermions; the left handed ones are also the ones charged under electroweak SU(2), while the right handed ones are uncharged. The photon, however, transforms under both SU(2)s of the Lorentz group, while it is uncharged under the electroweak symmetry. This might already invalidate your proposed identification.

28. **Peter**
    March 1, 2005

    Hmm, it's too late at night for me to straighten this out but I think you're right I was saying something incorrect. But all I was trying to say was SO(4)/SO(3)=S^3, which as a manifold can be identified with SU(2), although you're right it doesn't get its group law from the SO(4) one.

    I got into this mixup by trying to oversimplify things by just counting degrees of freedom. A more accurate way of saying what is in my 1988 paper is that I look at the twistor space of orthogonal complex structures over a 4d Riemannian manifold, and try and identify the electroweak U(2) as the subgroup of SO(4) at each point in twistor space that commutes with the complex structure.

    I haven't thought about this much in a while and don't have time to try and write out more details, especially not here where it is hard to write math. If people want more details now, they should take a look at the paper.

29. March 1, 2005

    But the set of elements of the form (q_1,q_1^{-1}) doesn't form a group! SU(2) isn't Abelian. And we know the electroweak SU(2) forms a gauge group. And if you wish to identify the electroweak SU(2) with torsion, since you're not identifying it with gravitation, that can't work. The electroweak coupling has the form \bar{\psi} A_\mu \gamma^\mu \psi, not \bar{\psi} \Gamma_{\mu\nu} \sigma^{\mu\nu} \psi. It's a vector (well, V-A) coupling, not a tensor coupling.

30. **Peter**
    March 1, 2005

    Here's one way of thinking about what I meant:

    Pick an identification of R^4=H (H is the quaternions). Then elements of SO(4) are given by pairs (q_1,q_2) of unit quaternions, and they act on an element q of H=R^4 by

    q goes to q_1qq_2^{-1}

    Note that SU(2)=group of unit quaternions, SO(4)=SU(2)xSU(2) modulo a Z_2, since (q_1,q_2) and (-q_1,-q_2) give the same action. Spin(4)=SU(2)xSU(2), but if you only act on vectors you just see SO(4).

    With the standard choice of identification q=x_0+x_1i+x_2j+x_3k, the diagonal subgroup of elements of the form (q_1,q_1) leaves x_0 invariant, acts as SO(3) on the other 3 variables. By "anti-diagonal" SU(2) I was thinking of elements of the form (q_1,q_1^{-1}).

31. March 1, 2005

    My apologies, that's only true for Spin(n) for even n. "Inversions" act trivially upon Spin(n).

32. March 1, 2005

    Sorry, I accidentally hit the Post button.

    SU(2) × SU(2) has infinitely many diagonal subgroups, one for each automorphism of SU(2). Basically, if f is an automorphism of SU(2), the subgroup of elements (g,f(g)) forms a diagonal subgroup. The outer automorphism group of SU(2) is the two element group Z2, i.e. correspoding to a "reflection". This, I'm pretty sure is what Peter meant by the anti-diagonal subgroup.

33. March 1, 2005

    SU(2) × SU(2) has infinitely many diagonal subgroups, one for each automorphism of SU(2). Basically, if f is an automorphism of SU(2), the subgroup of elements (g,f(g)) forms a diagonal subgroup. The outer automorphism group of SU(2) is the two element group Z2

34. **Lubos Motl**
    March 1, 2005

    Dear Peter,

    your comment about the trademark Lubos Motl (R) is very illuminating and entertaining. Nevertheless you may want to focus on the essence which is the SU(2) x SU(2) group in this particular case. Once you see that there are only two truly inequivalent ways how to embed SU(2) into SO(4) and only one of them has another SU(2) left, you may decide whether you want to follow my advise or the advise of the other straw man.

    Good luck
    Lubos

35. **Alejandro Rivero**
    March 1, 2005

    A glimpse of the role of the electroweak group:

a_\mu=
{m_\mu \over m_Z}+ {m_e \over m_W}+
\frac12 {m_\mu^2-m_e m_\tau \over m_W^2}=.001165825

The conventional perturbative calculation (without hadronic corrections) of muonic (g-2)/2 gives .0011658487, about a 0.003% respect to the value given by the above empirical formula.

36. **Peter**
March 1, 2005

Hi Lubos,

I can't imagine why someone here was referring to the "trademark Lubos Motl mixture of straw man arguments, willful misreading, and insults"….

37. **Lubos Motl**
March 1, 2005

Dear Peter, what you say sounds as an error that would prevent a first-year undergrad student of linear algebra from passing her exam.

Of course that your things would violate the Coleman-Mandula theorem. But more easily, there is nothing such as "anti-diagonal" SU(2). You can divide the SU(2) x SU(2) generators to the diagonal ones, and the rest. The diagonal ones form a closed algebra, but the anti-diagonal don't.

That's not so hard to see. These are generated by J14, J24, J34, and the commutators of those are again in the diagonal algebra generated by J23, J31, J12.

One can't be confused about elementary SU(2) group theory if she wants to seriously unify interactions. 😉

38. **Peter**
March 1, 2005

Coleman-Mandula says you can't find a larger symmetry group that includes both Poincare and internal symmetries, mixing them in a non-trivial way. I'm not trying to do that.

39. **Thomas Larsson**
March 1, 2005

Peter,

If you try to unify spatial rotations with electroweak SU(2) without SUSY, don't you run into trouble with the Coleman-Mandula theorem?

Nobody seems to have mentioned AJL's simulations, which distinguish between Lorentzian and Euclidean spacetimes in a different way. Thay insist on strict causality everywhere, which means that topology change is ruled out. They work with Wick-rotated Lorentzian spacetime, which is thus different from Euclidean spacetime with topology change allowed.

I like their results for several reasons. The obvious one is that they get a smooth 4D manifold rather than a crumpled mess, in agreement with observation. Another feature is that if you couple the Ising model to Lorentzian gravity, as in hep-th/9904012, the critical exponents remain at their Onsager values, unlike Ising coupled to Euclidean gravity. This is good, because the one thing we do know that quantum gravity is that it is unimportant compared to electromagnetism; the Ising model is a condensed-matter model, and as such it is a rough model of electromagnetism. Moreover, claims that AJL violate unitarity are, AFAIU, false.

40. **Peter**
March 1, 2005

When you decompose Spin(4) as SU(2)xSU(2), you're making a choice of how to do it. Standard thing is to identify R^4 with 2×2 complex matrices, identifying the time-direction as the unit matrix. Then the diagonal action leaves this invariant, but rotates the space directions. From this point of view I'm hoping to identify the anti-diagonal SU(2) with the weak SU(2). The details of this are in my old Nucl Phys. B paper.

41. **Lubos Motl**
March 1, 2005

Dear Fyodor,

your criticism is of course completely valid. On the other hand, mixing up one of the SU(2)s with the diagonal SU(2) looks like an innocent idea compared to Peter's main proposal that the other part of the Euclideanized Lorentz symmetry is actually the SU(2) electroweak symmetry. 😉

With such Woitian proposals, anything goes.

Incidentally, in loop quantum gravity there is also a confusion about the self-dual vs. spatial SU(2) within SO(4). Originally the SU(2) gauge group of loop quantum gravity was derived as the self-dual SU(2), i.e. one of the factors, but eventually it's only kinematics that works, and therefore you're equally justified to say that the SU(2) used in the spin network constructions is actually just the spatial rotational group.

All the best
Lubos

42. **Fyodor Uckoff**
March 1, 2005

The subgroup of Spin(4) corresponding to rotations is the *diagonal* SU(2), is it not? So I'm not real sure what you mean by

one of the two SU(2)s in Spin(4) being Spin(3), the spatial rotations

43. **Peter**
March 1, 2005

For a biography of Gian-Carlo Wick:

http://books.nap.edu/books/0309066441/html/333.html

Sorry Lubos, it just can't be helped that you're more entertaining than Wick Rotation.

44. **Lubos Motl**
March 1, 2005

That's pretty interesting. Peter's article would suggest that the people would discuss the Wick rotation, but on this blog it's not such an interesting topic. So the participants discuss the first interesting topic related to the Wick rotation that happens to be Lubos Motl. 😉

Does someone know who Wick was or is?

45. **Peter**
March 1, 2005

Hi Robert,

The way in which Witten's N=2 twisted supersymmetry trick works to turn a QFT that is relatively close to the Standard Model into a TQFT, by mixing the internal and space-time SU(2) has always fascinated me. I suspect it's related to the idea I mentioned, but don't understand how. My general feeling about supersymmetry is that we don't understand its geometrical significance very well. If we did, we'd see that it was some "twisted" version of it, like Witten's TQFT, that was what is really interesting. Unfortunately I don't see how to use this specific TQFT to get what I'm looking for, maybe someone else will. Or maybe it requires some slightly different, but still unknown, construction.

46. **Arun**
March 1, 2005

If Lubos is the topic, then, in my opinion, he is best when he expounds on physics that he understands well; he is lucid and is a pleasure to read.

-Arun

47. **Matti Pitkanen**
March 1, 2005

A comment about possible connection of electroweak gauge group with Minkowski space that Peter is pondering. I hide the real background and just represent some observations, which I find intriguing.

a) If you construct stringy vertex operators in Minkowski space by the standard construction you have 2 transversal polarization degrees of freedom having interpretation in terms of a Kac-Moody algebra associated with some 2-D Cartan algebra. It extends by the standard vertex operator construction to SU(3) Kac Moody algebra. As if color group were somehow inherent to 4-D Minkowski space.

In fact, G_2 having same Cartan algebra is the maximal extension, but I have not managed to find whether the construction extends to the generators of G_2 representing its short roots (Olive et al argues that this is the case but do not give the construction in their 1984 article).

b) On the other hand, when you divide SU(3) by U(2) you get CP(2) having U(2) as holonomy group and couplings are just those of electroweak gauge group (once you couple spinors to Kahler potential to get a proper spinor structure, this was done already by Hawking and Pope). Isometry group is of course SU(3) and CP_2 spinor connection codes for standard model symmetries.

These observations lead you to ask what do you get if you construct SU(3)/U(2) coset theory. U(2) Kac-Moody would act precisely like electroweak gauge group in this theory. Is this theory analog of an electroweak gauge theory with symmetry broken down to U(2) and constructed using solely strings in M^4? Or could one somehow generalize the theory to get also color multiplets? In any case, spin (transverse polarizations) and "color", "ew" qnumbers, and spin are very intimately related in this picture.

Matti Pitkanen

48. **DMS**
March 1, 2005

Peter,
I am sure I am completely wrong here, but is the idea (of the two SU(2)s in Spin(4)) proposed similar to "twisting" used by Witten to derive the new invariants for 4-manifolds based on his Seiberg-Witten on N=2 SUSY?

PS1: Yes, the contribution to your earliest posts by two senior physicists are amusing reading 🙂

PS2: Although a recipient of a few LM insults myself, I actually feel he is being misunderstood and needs help. But in the hyper-aggressive/macho string community, such talk is likely verboten. I do hope some senior guys (whose opinion he respects) have the decency and humanity to help him out of whatever is bothering him (the example of the mathematicians' help to Nash comes to mind).

Often, when LM talks about QFT or strings (and not busy insulting people) he can be quite lucid (if too verbose, at times). And he does take time to answer some basic questions on physics from people, something you don't see from similarly capable physicists (ok string theorists :)).

49. **Robert**
March 1, 2005

This interpretation of the the left handed part of the euclidean Lorentz group sounds a bit like a topological twist: There (in the D=4 version) you start with a N=2 theory that has a SU(2) R-symmetry and swap the roles of SU(2)_left with SU(2)_R. By this trick, one of the supercharges becomes a scalar and can be used as a BRST operator. The upshot being that the BPS-states become elements of the BRST-cohomology and thus physical states. Is there a relation (given your background in TFT)?

50. **Matti Pitkanen**
February 28, 2005

Lubos Motle gave a nice summary about Wick rotation. An approach inspired by the conviction that the difficulties of path integral approach reflect deeper problems of principle is discussed in the mini article which I titled "How to put end to the suffering caused by path integrals?" at http://matpitka.blogspot.com/ .

51. **Peter**
February 28, 2005

I saw that too, and suppose he is tired of Lubos's rants and the nonsense they generate. Funny that he should have more trouble with Lubos than me. I guess it's because I don't engage in political commentary here, so Lubos and I have only one topic to disagree about.

52.
February 28, 2005

just read on preposterous universe that sean banned lubos from his weblog. is he serious?

53. **Peter**
February 28, 2005

The main thing that is weird about this idea is that you don't have the full Lorentz symmetry. You have in some sense picked a time direction, which determines an SU(2)=Spin(3) subgroup of Spin(4), which will be the spatial rotations, which are not spontaneously broken. The weak SU(2) acts non-trivially on this choice of time direction, which behaves somewhat like a Higgs field, perhaps spontaneously breaking the weak SU(2). (But still, I haven't written down dynamics that does this).

54.
February 28, 2005

One obvious problem would seem to be that the electroweak gauge symmetry is spontaneously broken, while Lorentz symmetry is not. How would you get around this?

55. **Peter**
February 28, 2005

Gravitons aren't quanta of the spin connection. With the standard Lagrangian, the field equation for the spin connection determines it in terms of the vierbeins. It's the vierbein fields, or equivalently the metric, whose quanta are the gravitons.

I wrote a paper about this "Euclideanized boosts=weak SU(2)" idea many years ago

Nucl. Phys. B303, pg. 329, 1988

but I certainly know a lot more now than I did then, and should write an updated version someday.
For one thing that paper wasn't even written in the context of QFT, just of a single-particle model.

56.
February 28, 2005

If one of the Wick rotated SU(2)'s happens to be the electroweak SU(2), this would explain why only left handed fermions interact with the weak interaction, but but wouldn't it also mean the W and Z bosons are gravitons?

57. **D R Lunsford**
February 28, 2005

I've never seen any evidence that LM has a clue about anything at all.

-drl

58. **D R Lunsford**
February 28, 2005

Peter – well said again, I agree in detail that the real problem in physics is the relation of QFT to actual geometry.

Have a look Finkelstein/Jauch, "Quaternion Quantum Mechnics", which may be related to what you are "selling".

-drl

59. **Peter**
February 28, 2005

Distler is no slouch himself when it comes to "straw man arguments, willful misreading, and insults", although he is capable of more subtle insults than Lubos since English is his native language. Check out his contributions to some of the early postings of this weblog.

Pretty funny to see him and Lubos in action. Do you think it's statistically significant that the two most prominent string theorists with weblogs are both incredibly arrogant and incapable of admitting that anyone who disagrees with them might have a point?

60. **Fabio**
February 28, 2005

That LM discussion is pretty interesting, especially the part where Jacques Distler tries to make a point, runs up against the trademark Lubos Motl mixture of straw man arguments, willful misreading, and insults, then ultimately decides it's not worth the bother.

61. **Alejandro Rivero**
February 28, 2005

Wow! Welcome to marginality, Peter!

2004 TopCites

March 3, 2005
Categories: Uncategorized

The SPIRES database is used each year to produce a list of the most frequently cited papers in particle physics. This year's list has appeared, although the usual annual discussion of the list from Michael Peskin still hasn't yet. The trends I commented on last year in the 2003 list are even more pronounced this year.

The top ten most highly-cited papers in particle physics are now dominated by experimental results in astrophysics and cosmology with five papers in this category. Particle theory is represented by three large extra dimension papers from 1998 and 1999, and a single string theory paper, Maldacena's 1997 article on AdS/CFT. The Maldacena paper is now the fourth most highly cited particle physics paper of all time, surpassed only by citations of the Review of Particle Properties, Weinberg's 1967 paper, and the 1973 Kobayashi-Maskawa paper.

Even more so than last year, this data shows that particle theory and string theory flat-lined around 1999, with a historically unprecedented lack of much in the way of new ideas ever since. Among the top 50 papers, the only particle theory ones written since 1999 are a paper about pentaquarks by Jaffe and Wilczek from 2003 at number 20, the KKLT flux vacua paper at number 29 and a 2002 paper on pp waves at number 32.

How many more years of this will it take before leaders of the particle theory community are willing to publicly admit that there's a problem and start a diiscussion about what can be done about it?

For some other interesting statistical data gathered from this database, check out the SPIRES playground.

One relatively recent idea that probably hasn't fully shown up yet in the yearly citation counts is Witten's late 2003 idea about relating gauge theory and the topological string in twistor space. While the idea of working in twistor space has lead to a lot new results about gauge theory amplitudes, Witten's original hope of relating gauge theory and string theory seems to be in trouble.

Comments

1. **Thomas Larsson**
   March 8, 2005

   Everyone would like to know what can be done about it. Of course, the right thing what to do about it is to discover new revolutionary ideas.
   Do you know how to do it?

   What about diff anomalies in 4D? At it should be new, since Weinberg (chapter 22) claims (correctly, within his axioms) that no such things exist.

   But diffeomorphisms generate a gauge symmetry, and you have repeatedly stated that the right approach to gauge anomalies is ignorance. Just tell me one thing, though. How can you know that there is something special about the bosonic string in 26D if you don't know about conformal (gauge) anomalies? Or, why is it ok to be ignorant about the quantum reps of the constraint algebra of GR, but not about the reps of the Virasoro algebra? After all, both GR and the bosonic string are constrained Hamiltonian systens.

2. **Lubos Motl**
   March 7, 2005

   I agree with Peter's statistics.

   As far as I know, everyone knows – and admits – that the high-energy theoretical physics is in a quiet period.

   Everyone would like to know what can be done about it. Of course, the right thing what to do about it is to discover new revolutionary ideas.

   Do you know how to do it? Let me just warn you in advance that the Dirac operator is not a revolutionary idea anymore. 😉

3. **Geoffrey Haselhurst**
   March 7, 2005

   Hello,
   I saw reference to a webpage of mine on Cosmology.
   I think in your discussion of a career in Physics and the censorship inherent in the system, that the Internet is now changing all the rules for the evolution of cultural knowledge.
   Plus there is a very simple sensible language for describing reality. I can't imagine this being ignored for that long. So I think physics will blossom in next 20 years, along with philosophy.
   Thoughts?
   Geoff Haselhurst

4. **Peter**
   March 4, 2005

   I'm deleting the last few comments responding to Pedro about grad school and where particle physics is going since this discussion is getting both off-topic and there are some people who just can't stop themselves from being hostile and obnoxious, others who find it hard to ignore them.

   His question is a difficult and legitimate one. If people have some useful, non-hostile, advice about what the current situation means for people thinking about grad school in theoretical physics, go ahead and comment. But stop it with the obnoxious off-topic abuse.

5. **quantoken**
   March 4, 2005

   Petro:

   You are going to have a miserable life with little achieved, if you want to get into the field of theoretical physics research. As the state it is it is unlikely going any where until something is changed. You can not afford to waste your life on a pursuit that every indications show it's not going any where within your limited lifespan.

Please read this:

http://infoproc.blogspot.com/2004/12/dont-become-scientist.html

And read this:

http://wuphys.wustl.edu/~katz/scientist.html

And this, too, to open your mind a bit:

http://www.suppressedscience.net

And this, to see what exile scientists are like:

http://www.spaceandmotion.com/Cosmology-Big-Bang-Theory.htm

It is completely possible to make a **much easier and more comfortable living** on something more connected to reality, while at the same time pursuit some interests in fundamental physics research, with total freedom of mind, like I do. Einstein was a very young (26) amateur "crackpotist" who barely graduated from college, and would be unable to publish anything on today's ARXIV, when he made some of the greatest discovery in human history, within a period of just one year. Relatively, his professional career in his second half of lifetime achieved virtually nothing. See my blog:
http://quantoken.blogspot.com

Quantoken

6. **Alan**
March 4, 2005

I know that Peter W. is a stickler for keeping these discussion threads to the topic at hand (in this case, citation counts and whether they're a valid measure of the intellectual vitality of ideas), although in this case he appears to have let the thread veer off in some other directions.

For Pedro, who inquired about directions to take in graduate training, I would highly recommend the "Academic and Career Guidance" board at http://physicsforums.com . A direct link to the academic board is:

http://physicsforums.com/forumdisplay.php?f=139

In particular, there was an interesting recent thread comparing different graduate schools:

http://physicsforums.com/showthread.php?t=65634

7. **Wolfgang**
March 4, 2005

Pedro,

as Peter has pointed out on his blog several times before,
there are many interesting questions open in physics apart from quantum gravity or string theory.
If I were young, I would focus on those areas.

8. **pedro**
March 4, 2005

That is quite true – and by no means am I looking for a conciliation between competing approaches just for the sake of it. Rather, given the absence of significant empirical evidence towards either string theory or its 'main' competing theories and the fact these theories are, at the moment, incredibly open-ended; while at the same time, given the attractive 'transempirical' results/content of such theories, what are presently, if any, mathematically consistent and 'physically sound' alternatives to them (which could, perhaps, incorporate appealing elements of both fronts)? Or better, assuming there *is* a problem with current particle theory, *what* would be its tentative solutions? (either way, I grant you these are probably incredibly naive questions)

9. **Wolfgang**
March 4, 2005

Obviously I meant "view points" not "few points"

10. **Wolfgang**
March 4, 2005

Pedro,

I am afraid physics is not so much about "conciliate" different few points and rather about
finding and weeding out wrong assumptions and hypothesis.
The main tool to eliminate wrong ideas (experimental evidence) unfortuantely does not work so well due to the high energy scale at which quantum gravity becomes important. But this could change overnight if somebody discovers evidence in favor of one idea or the other.
I am afraid that there are no "safe bets" one way or another and I am afraid there is no good advice for you in this situation other than to work on ideas which may also apply to areas where empirical evidence is available …

11. **Pedro**
March 4, 2005

Hi,
I guess this is going to bring the tone of the current discussion down a bit; but since the ongoing argument seems to touch on something that has been bothering me for a while, thought of posting my concerns here.
I'm a physics undergraduate student, hopefully soon to embark on graduate studies, and, given the apparent polarisation of the 'unified theory' theoretical physics research into string theory and quantum gravity, I have to say I'm quite torn between which direction to follow.

Now, from my current quite limited perspective, it seems that both 'areas' are generally problematic: while a lot of the quantum gravity approaches (I'm thinking, slightly more specifically, of the 'causal' approaches) seem to provide a nice 'intuitive' picture/potential unification of QG and GR, say, they are still quite far (but I could be immensely wrong here!) from properly tackling the behaviour of particles and their interactions (I have the impression a lot of research is done on the structure of 'empty' space-time only); string theory, on the other hand, while growing out of theoretical particle physics research and despite all its mathematical 'triumphs', not only paints a very odd picture of the universe, but is also a long way from connecting to current 'experimental' particle physics – is that the case? If so, is there any current research projects attempting to perhaps conciliate this polarisation?
Lastly, assuming your conclusion from the 2004 TopCites is correct, and there really is a big problem with current particle theory/string theory, what are the viable alternatives, or one candidate for an alternative be? (and this is a genuine question – I don't mean to sound agressive).

12. **Peter**
March 4, 2005

Hi Wolfgang,

I agree with you that work on topological strings is the most interesting thing going on these days in string theory. Problem is, this is a case where people who say that string theory is "math, not physics" are right. There's a lot of interesting mathematical work going on in this area, and if SPIRES also included pure math papers, maybe Vafa's papers would get bumped up into the top 50.

I do disagree with you about 1990 though. At that time Witten's Chern-Simons theory and TQFT stuff had just come out, things which I think are far more interesting both for math and for physics than the topological string ideas of recent years. Of course topological strings have their origin in precisely this work of Witten's.

13.
March 4, 2005

Regarding citations of the Weinberg's '67 paper, physicists did not know then if spontaneously broken YM theories were consistent or renormalizable; it was a 'conjecture/belief'. Soon after 't Hooft (and Veltman)'s brilliant work on renormalizability of YM theories was understood (circa '71/'72), the citations on the Weinberg paper naturally picked up.

14.
March 4, 2005

"The NSF and DOE should stop giving grants to people who intend to pursue a dead idea that doesn't work."

Funding system works by innovating over ideas we known. The risk about calling for a "stop" is that there is no guarantee of getting funds for new ideas; just an increase of funds for the other old competing ideas.

An interesting system could be that each university had the right to claim a percentage tax on each group "justified research" funds in order to fund "unjustified research" of every tenured professors, without restriction. That should be a return to academic freedom and perhaps a way to get new ideas into the game.

15. **wl**
March 4, 2005

>
If either you or Matthew have a better objective measure for the number of new ideas coming out of particle theory that many people think are interesting enough to work on during a given period, let's hear it. I think the one I have given is pretty meaningful, and agrees with the perceptions of most working theorists.
>

Well I do not agree. For example, the things that happen in topological strings right now are in my opinion totally fascinating and meaningful. And more so than eg 5 years ago – there has been lots of substantial progress in this field, in contrast to what you seem to convey.

That these papers do not collect as many citations as others, like those on flux compactifications, is quite irrelevant. For example, it reflects how many people are working in the field, how many are able to follow the subject and make contributions, how difficult it is to write papers in this given field.

These are all sociological factors and there are others, eg it is also matter of taste what people find interesting/promising/rewarding. So one cannot draw general conclusions such as yours, namely that string theory would be declining, from such crude data. On the contrary, I find it an especially interesting time, definitely much more interesting than eg around 1990. I remember having heard similar statements at the time, and indeed physics was pretty boring then in comparison to today.

16. **DMS**
March 4, 2005

"Well, Michael, …"

Oops, that was Mathew, not Michael. Sorry.

Well, I do not have a problem with phenomenological attempts, like the Little Higgs models, that can be tested/falsified. It is amazing how many models can be discarded from precision measurements, which is a good thing.

This is very different from "superstring phenomenology", the TOE approach. Supposedly, a "unique" string theory leads to so many possibilities that it is not at all predictive. In what way is it more predictive than an arbitrary QFT, when it comes to being testable experimentally? The "bottom-up" approach is more meaningful when it comes to phenomenology, IMO.

But I think there is no compelling reason to believe any of these models are correct (unlike say GIM which predicted existence of charm and even a rough estimate of its mass based on Gaillard-Lee (?)'s famous calculation).

17. **Peter**
March 4, 2005

Hi Wolfgang and Matthew,

I often say things on this weblog that I know relatively few people in the field agree with me about, but I'm finding it strange that you object to this posting, because I don't think the point I am making is controversial at all among working particle theorists. Without exception, everyone in the field I've discussed this with privately in recent years, string theorist or non-string theorist, feels that the last few years has been a period of unusually few interesting new ideas. It's true that I mostly talk to more mathematically-minded theorists, perhaps more phenomenologically-minded ones don't so much feel this way.

For Matthew:

I guess you've only been working in this area for a few years, so I don't think you have first-hand experience about what the particle theory research environment was like 10,15,20,25 years ago and how different things were then. I encourage you to ask your more senior colleagues how they see the activity of the last five years as compared with earlier periods in their careers, especially consulting any string theorists you may know.

I also looked at the 94-96 topcite data, found 3 theory papers in the top 10, (4 in the top 11), and 12 in the top 50 (I think you missed Hull and Townsend, one Isgur-Wise, and a parton model paper). I think that it is undeniable that

1. 0 is less than 3 (number of papers in top 10)

2. 3 is less than 12 (number of papers in top 50)

and that these differences are statistically significant.

I'm not going to waste my time anymore today trying to get you to distinguish the difference between the way you're using the word "prediction" and the way most scientists in the world understand it.

Wolfgang,

The list I linked to orders papers by how often they were cited during 2004. For a paper to be in the top 50, it would have to have been cited by 155 or more papers written during 2004. None of Vafa's papers satisfy that criterion.

If either you or Matthew have a better objective measure for the number of new ideas coming out of particle theory that many people think are interesting enough to work on during a given period, let's hear it. I think the one I have given is pretty meaningful, and agrees with the perceptions of most working theorists.

18. **DMS**
March 4, 2005

Well, Michael, Peter has answered the "predictive" aspect of the brane models better than I could have. I suppose it depends what the meaning of the word "prediction" is; I am old-fashioned in that regard.

Aaron, Thanks for your comments and pointing out the Strassler-Klebanov paper.

On the Little Higgs models, (according to hep-ph/0502066), the initial hope that such models (at the least the popular ones) have less fine-tuning than the MSSM (already needing fine-tuning at 2% level) from precision electroweak constraints, may not be valid.

19. **Matthew**
March 4, 2005

Hi Peter,

I don't doubt you can find papers about brane models containing the word "prediction", but I do doubt you can find an actual prediction in any of them.

The paper I cited has acutal predictions in it.

None of these models is capable of making a real prediction that could falsify the brane world idea. For one thing, the energy scale of these things is completely undetermined (other than that it better be big enough so that you wouldn't already have seen something).

Well, I think technically this is true. But from a model building perspective, it's not. You construct a model to solve certain problems. If the energy scale is too low, then it's already rule out. If it's too high, then you no longer solve the problem you set out to solve.

What a legitimate "superstring phenomenology" should do is tell us what the size and properties of the brane will be.

Well, that would be nice, but since the string theorists haven't delivered said predictions yet us "mere mortals" build models.

The papers you quote are more along the same lines. They say something like: if we choose a Little Higgs Model with properties A, B, C, it has a particle X whose mass we know nothing about other than that it better not be too large (and we don't really know exactly what too large means).

Not quite. They say if I build a model with these parameter/this structure then it predicts X. Now of course you can change the parameters, but that's true of *any* model. Some models allow more flexibility on this point than others.

As you note, it is very hard to figure out how to distinguish such a model from anything else.

So we should not build models at all? Look, part of the problem of distinguishing models is because the LHC is a messy hadron collider. Since we can't change that, we make do as best we can.

Does any Little Higgs model actually predict the mass of anything?

Sure, pick the parameters, and the model is predictive. Not unlike the standard model. The second little higgs paper I linked has a plot of the new spectrum, for a certian choice.

I wasn't saying that there are fewer particle theory papers these days than ten years ago, I was saying there are many fewer that people think are worth citing. This indicates there are virtually no new (good) ideas coming out of the field.

And this is where I disagree. You're linking citations with "new ideas" is wrong. Nobody cited Weinberg's 67 paper for several (5?) years. Yet it was a good idea.

Look at the SPIRES topcites list of ten years ago, and you'll see lots of recent theoretical papers,

Okay, I did. The 94-96 top 50 list has 9 theory papers published from 1990 on. Two (Amaldi, Langacker) have do do with LEP, two (Isgur, Georgi) with heavy quark effective theory and one (Lepage and Mackenzie) with lattice field theory. Of the other four, two are Seiberg and Witten, one is Witten by himself, and one is Polchinski. Safe to say, this is not a hive of new ideas of what's just beyond the standard model.

20. **wl**
March 4, 2005

What's the logic of that spires list ? I know many famous papers
which have hundreds of citations, in particular have more citations than certain
papers which do appear in the list and which even are more recent. Eg do in Spires
http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=find+a+vafa&FORMAT=wwwcitesummary&SEQUENCE=
however not a single paper of Cumrun's appears in the list you cite.

I don't see how any conclusion, esp on an alledged "flatness" of how string theory evolves, can be drawn from this.

21. **Quantoken**
March 4, 2005

Peter,

Thanks for providing the URL to the paper you wrote several years ago. It is because of honest people like you, rare nowadays but still exist in the science research community, who are brave enough to speak out the truth, that the public can still maintain SOME confidence in science.

No need to pay attention to Michael, who as DRL put it best, is just "pissing in the wind". Some of his comments are worse than vulgarity. Shame for him that his "It just doesn't suit you well" comment kind of tried to intimidate you to shut up and mind your own business and stop criticize string theory, or else. It's not the kind of language an educated person will utter.

You comment of cutting funding is right on the spot! One has got to understand scientific researches are funded by tax moneys from the general public, and therefore it should serve the interests of the wellbeing of the public only. How much longer should the public continue to allow their tax money to be wasted on such totally fruitless pursuit?

Cut the damn funding now! String theoretists certainly are totally free to continue their fruitless pursuits, but on their own money, not the public's money. Or, like Lee Smolin did, go talk to some rich guy and convince him that your theory makes sense to him, so he can fund you.

Frankly I think the LHC project now is just a waste of money. Since no one is willing to make any definite prediction beforehand. And you are all waiting for the machine to start running, and then you can outfit your theory with whatever comes out of it. So at the end of day your theory will still be un-falsifiable but still useless and unable to make predictions. What is the use of experiments if it can not help falsify some of the theories and confirm some others?

Quantoken

22. **Aaron**
March 3, 2005

To Peter — If they don't find SUSY at the LHC, a lot of people will give up on weak scale SUSY definitely. Not because of fine tuning, but because if it's not there to stabilize the weak scale or to unify the couplings or provide a dark matter candidate, there's not much reason for it to be down there at all. High scale SUSY is what it is, but it's not particularly of experimental import.

To JC — The MSSM is actually a very pretty exercise. The reason people got excited about it wasn't because it was some slavish following of stringy fashion. It stabilized the weak scale, it provided a natural mechanism for electroweak susy breaking and it seemed to unify the couplings. There were good reasons to call it the best candidate for an extension to the standard model (other than neutrino masses). The problems really come when you break the supersymmetry. It's the effective lagrangian for the broken susy that has the 109 or whatever parameters that people always refer to when denigrating susy. But those aren't free parameters; they just depend on an undetermined model for breaking the supersymmetry. That's where things start to get ugly.

Split supersymmetry is pretty straightforward, at the cost of some major fine tuning (which Nima and co would like to attribute to some anthropic hand waviness). You just break susy at some high scale. Thus, most of the SUSY partners are very massive, resolving all the difficulties with FCNCs, proton decay and the like. Then, you have the gluinos be at the weak scale. Since they're chiral, this is technically natural (but not plain old natural). They give you some nice dark matter candidates and unify the couplings. Assuming I got all the details right, at least.

To Tom — you can have nonconformal stuff in AdS/CFT (oxymoronic, I know.) The most famous example of this is the Klebanov-Strassler solution, hep-th/0007191.

23. **TripleIntegral**
March 3, 2005

In re: the post's comments on leadership from the top particle theorist community, it seems to me that in his public statments Witten has at least recently been fairly honest about hopes for string [whatever] theory and its accomplishments and prospects. Others less so. For example, Susskind seems to be his own type of legacy-enhancing pathology. The small fry need someone's skirts to hide behind and crumbs to lick off the floor. Thus has it always been.

24. **JC**
March 3, 2005

Split SUSY and some of the SUSY models beyond MSSM, sure seem like the equivalent of "Rube Goldberg" machines in the particle phenomenology world.

25. **Tom Larsson**
March 3, 2005

AdS/CFT is interesting because it holds out some hope of producing strng theory duals to 4d QFTs you care about, like QCD.

My point was that dS/non-C QFT would be a lot more interesting duality, since it might have something to do with the real world. AFAIK, QCD is not conformal, although classical chromodynamics is.

PS. When I said that Nair was a string theorist, I might have confused him with Narain.

PPS. This is my first night with broadband. My oldest daugther has just reached the Internet chat age, and the telephone bills started to become scary.

26. **Peter**
March 3, 2005

What's the gluino mass bound? Is it within the reach of the LHC?

If the LHC really could rule out split supersymmetry, as well as regular supersymmetry since the fine-tuning required is implausible, will people really give up on supersymmetry for good?

27. **Aaron**
March 3, 2005

Split supersymmetry was born out of anthropic nonsense, but by itself, it's just a fine-tuned model that has some straightforward signatures. Split supersymmetry has most of the fermionic partners to avoid issues with FCNCs, proton decay and the like. It has the gluinos (IIRC) light, however, so as to give coupling constant unification. You either see that or you don't. If you don't, split supersymmetry's wrong. Simple as that.

28. **Peter**
March 3, 2005

Isn't split supersymmetry even less predictive than standard ideas about supersymmetry? Supersymmetry was supposed to eliminate the need to fine-tune the Higgs mass, which meant that superpartners couldn't be too massive.

In split supersymmetry, you decide to throw out the main motivation for supersymmetry and trust in God or the anthropic principle to explain why the Higgs is so light. The only thing you're left with is the (not quite accurate…) coupling constant unification. Perhaps if you want to keep this you get some constraint on how heavy your fermionic superpartners can be, but this is a long way from a definite prediction of anything.

29. **Aaron**
March 3, 2005

Split supersymmetry, at least, is a predictive fine-tuned model. If they turn on LHC and don't see what it predicts, it's dead. Coupling unification is a assumption of the model, and thus you need some lightish fermions to achieve it.

30. **Peter**
March 3, 2005

Hi Matthew,

First of all, just saw your response to DMS. I don't doubt you can find papers about brane models containing the word "prediction", but I do doubt you can find an actual prediction in any of them. None of these models is capable of making a real prediction that could falsify the brane world idea. For one thing, the energy scale of these things is completely undetermined (other than that it better be big enough so that you wouldn't already have seen something). Saying that "if there's a brane with this size and these properties I predict the LHC will see X" completely begs the question. What a legitimate "superstring phenomenology" should do is tell us what the size and properties of the brane will be.

And by the way, I (and I suspect many other people here) do read hep-ph.

The papers you quote are more along the same lines. They say something like: if we choose a Little Higgs Model with properties A, B, C, it has a particle X whose mass we know nothing about other than that it better not be too large (and we don't really know exactly what too large means). The problem with this is that you can get an extremely wide range of different things by changing A,B,C and choosing all the undetermined parameters and masses. As you note, it is very hard to figure out how to distinguish such a model from anything else. I said none of these classes of models give a "definite picture" of what will happen at the LHC and I stick by that. By a definite picture, I mean something like actually predicting the mass of a particle. Does any Little Higgs model actually predict the mass of anything?

I wasn't saying that there are fewer particle theory papers these days than ten years ago, I was saying there are many fewer that people think are worth citing. This indicates there are virtually no new (good) ideas coming out of the field. I don't think it is at all helpful to try and deny this in face of strong evidence. Look at the SPIRES topcites list of ten years ago, and you'll see lots of recent theoretical papers, few of which have anything to do with LEP data. The difference then was that people were still regularly coming up with new ideas about string theory that other people thought were promising enough to work on and to cite. This has stopped happening.

31. **rob**
March 3, 2005

There is one factor that has been overlooked. Spires has recently added the astro-ph to it's collection of papers. It is not surprising that all those astronomy papers cause cosmology papers to have a higher number of citations than they had in the past.

32. **Matthew**
March 3, 2005

DMS

Do you (or anybody else here) actually read hep-ph?

I know enough about the superstring "phenomenology" (like the wonderful brane "models") to know that they are not useful for particle pheonomenology and definitely not predictive.

The very first paper returned on a hep-ph abstract search for "collider brane" is hep-ph/0502031,

"In the context of an universal extra-dimensional scenario, we consider production of the first Kaluza-Klein electron positron pair in an e^+e^- collider as a case-study for the future International Linear Collider. The Kaluza-Klein electron decays into a nearly degenerate Kaluza-Klein photon and a standard electron, the former carrying away missing energy. The Kaluza-Klein electron and photon states are heavy with their masses around the inverse radius of compactification, and their splitting is controlled by radiative corrections originating from bulk and brane-localised interactions. We look for the signal event $e^+e^- +$ large missing energy for $\sqrt s = 1$ TeV and observe that with a few hundred fb^{-1} luminosity the signal will be hard to miss since standard model backgrounds remain well within control. We also comment on how this signal can be distinguished from similar events from supersymmetry."

My simple search pulled down 78 hits, with some more work I'd bet you can find over hundred papers on the predictions of various brane models.

33. **Matthew**
March 3, 2005

Hi Peter,

If you look at the SPIRES topcites data from ten years ago, you can see that things were very different than now

Yes, things were very different, LEP was new and taking data. There was experimental data to work with. I'm not arguing that the number of theory papers isn't down, just that this represents a problem. I'm much more inclined to think that this will be par for the course in the era where there is one experiment at the cutting edge at any one time.

It's not a problem though, when the LHC turns on, balence will be restored 🙂

Also, one has to couple in the massive amount of cosmology growth in the past ten years. That's a whole new set of papers that impact HEP citiations in a new way.

The new ideas you mention, like split supersymmetry, aren't getting a lot of citations because they aren't very promising.

There no more or less promising than any other new idea. That's the point.

They don't really explain any known experimental result

Sure they do. Most of them explain why the Higgs mass is not at the planck scale. Others attempt to explain the ferimon mass hierarchy. Now you might not think that the explanations given are good or sensible, but that's a different arguement.

or give definite predictions about what future accelerators will see

Sure they do. Some of the people here are engaged in making these predictions. Indeed, it's an active field of research trying to figure out what one should look for in order to distinguish different models, many predict very similar signals at the LHC.

If one of these ideas actually gave a definite picture of what will happen at the LHC, it would attract a huge amount of attention and number of citations.

Again, this is simply untrue. Any model builder worth his or her salt will give a picture of what will happen at the LHC (the level of detail depends on the model builder). For example hep-ph/0402037,

"We discuss possible searches for the new particles predicted by Little Higgs Models at the LHC. By using a simulation of the ATLAS detector, we demonstrate how the predicted quark, gauge bosons and additional Higgs bosons can be found and estimate the mass range over which their properties can be constrained."

or, to highlight some colleagues, hep-ph/0411264,

"We begin the study of the LHC phenomenology of the littlest Higgs model with T-parity. We find that the model offers an interesting collider signature that has a generic missing energy signal which could "fake" SUSY at the LHC."

Work like this appears for all sorts of models, the collider phenomenology of the MSSM, for example, is worked out in massive amounts of detail.

I think phenomenologists are in a very tough spot and will be for at least the next few years, through no fault of their own. I don't think there is much that can be done about this until there's new experimental data.

My own observations are different. Phenomenology has been getting more active over the last few years. The difference between when I started as a grad student, and now, is clear. There are more new ideas, and more people exploring them.

34. **Peter**
March 3, 2005

Hi Thomas,

AdS/CFT is interesting because it holds out some hope of producing strng theory duals to 4d QFTs you care about, like QCD. So, if you're a bit optimistic, it may help you solve QCD. But it has really nothing at all of any use to say about the idea of an 10/11 d string/M theory TOE.

35. **Thomas Larsson**
March 3, 2005

Anyway, your case it not convincing. String theory has evolved in phases, often referred to as "string revolutions". I'm not sure if Maldacena's ADS/CFT qualifies as a revolution, but I perceived it as one.

I find the enormous interest in AdS/CFT somewhat curious, since I thought that both AdS (negative cosmological constant) and CFT (absense of massive particles) were ruled out experimentally. And in order to establish the connection between these experimentally falsified ideas, you probably need SUSY, which itself has *a lot* of problems with observation (or lack thereof). But perhaps I'm just old-fashioned to believe that physics has anything to do with nature…

36. **DMS**
March 3, 2005

Michael,

Although I do not understand D'Hoker-Phong's brilliant achievements, I know enough about the superstring "phenomenology" (like the wonderful brane "models") to know that they are not useful for particle pheonomenology and definitely not predictive.

It may be sufficient for you what the "experts" say/think, it is not sufficient for me.

37. **Peter**
March 3, 2005

Hi Michael,

I've exchanged e-mail with Witten about this, so know exactly what his circumstantial evidence is, and think it is extremely weak. I have an incredible amount of respect for Witten, both for his talents and for his accomplishments. By far the best argument for string theory is that he believes it, but I happen to think he's wrong about this. What's superstitious is to just accept what someone says without evaluating the evidence for yourself.

What you quote Maldacena as saying was actually said by Seiberg. I don't think joking about how arrogant you are is really "self-criticism". Far too many string theorists are incredibly arrogant, and while some of them would admit this I don't notice any of them thinking there is anything wrong with it.

38. **Peter**
March 3, 2005

Hi Matthew,

First of all, I think there's a straightforward objective issue here: when was the last year in which, if you put together a list of the 50 most heavily cited particle theory papers, only a couple would date from the last five years? I'm pretty sure you would have to go back to around 1945, when WWII interrupted research for about 5 years. I don't know much about what things were like in the earlier part of the century, but I suspect you might have to go back to the 19th century to find another year in which this happened. If you look at the SPIRES topcites data from ten years ago, you can see that things were very different than now, and if anyone knows of a source of similar data from earlier periods I'd be interested to hear about it. Particle theory is in a new situation, quite unlike any other one of the modern period, and people should be thinking about what this means.

The new ideas you mention, like split supersymmetry, aren't getting a lot of citations because they aren't very promising. They don't really explain any known experimental result, or give definite predictions about what future accelerators will see. If one of these ideas actually gave a definite picture of what will happen at the LHC, it would attract a huge amount of attention and number of citations.

As I mentioned in a previous comment, I think phenomenologists are in a very tough spot and will be for at least the next few years, through no fault of their own. I don't think there is much that can be done about this until there's new experimental data. Whatever overhyping of ideas that is going on amongst phenomenologists is relatively harmless.

String theory is a very different story….

39. **Michael**
March 3, 2005

Hi Peter,

what you say sounds reasonable under the assumption that string theory is not worth pursuing. This assumption is what's in question, and I submit to you that it may not be for you to decide. The big figures in string theory have a lot better grip on this than you do. If you listen to them, they are very reasonable and smart people who do not rush to any conclusion — like you do.

Witten for example states that it's his personal opinion that there is circumstatial evidence that string theory is on the right track. How could you possibly argue with this without being superstitious? Let me tell you: you can't.

Maldacena says that string theorists are arrogant enough that whatever comes up in their research, they will call it string theory.

So you can see that these people show a measured amount of self-critcism. At the same time they are the ones who do prove that string theory *is* worth pursuing, even if we can't be sure at this point what it's relation to nature is.

You have absolutely nothing to add to this. Can you be honest enough to admit it?

Your claims of intimidation and such are unsubstantiated and wrong. You have no evidence and you just make up such things because you know that in the absence of such claims your authority in this matter drops to it's true value, namely zero.

Do you find it attractive to sit in one boat with crackpots like quantoken (see quantoken.blogspot.com, if you have the stomach for it)? You have learned a number of serious things in math and you can make your little contribution to this field. Why waste it and bark with the crackpots instead?

Best, Michael

PS: DMS, you know enough string theory to arrive at a conclusion that is completely inconsistent with that of the experts in the field? Who are you kidding?

40. **D R Lunsford**
March 3, 2005

Michael – I've read your betters, and what you say is just a lot of pissing in the wind. I'm sure it suits the postmodern intellectual Narcissus in you, but you aren't fooling anyone.

-drl

41. **DMS**
March 3, 2005

Michael,

I know enough physics to know string theory is highly over-hyped. All papers on "string phenomenology" are total, pure, unadulterated garbage. The people practising it know little about precision electroweak physics. It has made *zero* predictions: no, consistency with anything is not a wonderful thing.

Of course, some of the mathematical work is very valuable, but that is a very small portion.

It also does not help when people practising string theory start bullying and throwing insults at people who point out the obvious.

So far, the paying public has a pretty high regard and respect for physics and physicists. But it will not take much (a couple of "landscape" books?) before they catch on to the gimmicks, and unfairly lump theoretical physics with some other fields, like climate science.

42. **D R Lunsford**
March 3, 2005

It was clear since “An Evaluation” that what you are doing is rather heroic, and it is just great to have someone with the balls to tell the truth on the planet.

-drl

43. **Peter**
March 3, 2005

Hi Michael,

I’d be much happier not to be spending my time doing this, but the problem is that no one else is. A lot of people are out there hyping the glories of string theory, but virtually no one who understands the theory has been willing to publicly criticize what is going on. Several people who agree with me have told me they won’t do this because they fear retribution: string theorists are on the panels deciding whether they get a grant and whether their students get jobs. There’s a really ugly atmosphere of intimidation going on here, including nasty personal attacks from people like you, Motl, Distler, and others on anyone who dares to criticize the string theory hype.

The people who should be doing something about what is going on, tenured people at major research institutions, for one reason or another aren’t doing it. When they start, I’ll shut up.

44. **Peter**
March 3, 2005

Hi Kyle,

I’ve addressed this in various places, including the first public thing I wrote on the subject four years ago:

http://www.arxiv.org/abs/physics/0102051

Here’s a summary of what I think needs to be done:

1. Publicly admit the problem. As long as leaders of the field go around giving talks and writing books about how well things are going, no one is going to be willing to change anything.

2. Publicly admit that the idea of string theory as a TOE is a failure and needs to be buried. More phenomenologically motivated approaches to particle theory are in trouble because of the lack of new data, and unless the Tevatron or someone else comes up with something unexpected, this situation will last until 2008, when maybe the LHC will change things. But more mathematically driven “top-down” research still has a chance of getting somewhere. Some radical new ideas are needed, but as long as it is extremely difficult to get a job doing mathematically oriented stuff unless you are doing string theory, hardly anyone is going to be working on this.

3. The NSF and DOE should stop giving grants to people who intend to pursue a dead idea that doesn’t work. Once the community admits the problem, the NSF and DOE could play a role in promoting funding of proposals to try something new and different, discouraging funding of proposals to do the same old thing. As long as it is very hard to get a grant or a job working on mathematically sophisticated approaches to particle theory unless you are doing string theory, nothing is going to change.

What has been going on for far too long is that bright young people who come into the field end up spending years of their lives mastering the intricacies of string theory. They end up not knowing enough to do anything ambitious that isn’t string theory, and the reward system is such that even if they wanted to try they would soon be without a job. People have to think about how to change this reward structure. It’s not going to change until the underlying problem is acknowledged.

45. **Matthew**
March 3, 2005

My comment got a little long, so I posted a short response on my blog. In short, Peter, you’re wrong 🙂 Number of citations does not correlate with number of new ideas. Particle theory is acutally pretty active these days.

46. **Michael**
March 3, 2005

Hi Peter,

Sorry if I offended you too much. I didn’t mean to be what you called me.

Anyway, your case it not convincing. String theory has evolved in phases, often referred to as “string revolutions”. I’m not sure if Maldacena’s ADS/CFT qualifies as a revolution, but I perceived it as one. Understanding gauge theory using gravity and vice versa is extremely exciting if you keep in mind that gauge theories are proven to describe nature and gravity is what we need to understand better.

Are you worried about no more such major steps forward in the last 6 years? I doubt it. For one, your critisism has been around for several years, so you didn’t wait until nothing terrific had happened in 6 years. Also the time period between the string revolutions in the past was typically longer than that. The next may be just around the corner, and what are you going to say when it comes?

Peter, you are more outspoken about string theory than people like Ed Witten and Juan Maldacena. It just doesn’t suit you well. It is not humble and it is not honest on your part. You could earn a lot more respect by doing a good job at Columbia in the position you hold, talking about the things you do understand. Do you crave attention and publicity so much, even if it’s negative one?

Best,
Michael

47. **Peter**
March 3, 2005

Hi Michael,

I just presented some definitive evidence that string theory is intellectually dead. Instead of addressing this evidence all you can do is attack me personally. This is just pathetic.

Guess what? I’m not going to “knock it off”, no matter how many assholes like you I have to deal with.

48. **Alejandro Rivero**
March 3, 2005

I like to see Randall-Sundrum work (and Nima’s, and Antoniadis 1990 &c.) there in the top. It was clearly a provocative idea already back five years ago, and thinking pentadimensional is a funny thing, even if it is to go back to our beloved 3+1 dimensions Or 3+1+0 for a Connesian as I am.

It is funny that while the WMAP (what about the old presunt fractal behaviours, now?) replaces neutrinos in the top ten, the more quiet oscillation research has brough back a couple works of the past, Cabibbo 1963 and Maki, Nakagawa, Sakata 1962.

49. **Michael**
March 3, 2005

I know why string theory is in trouble! It’s because string theorists haven’t paid enough attention to the Woitian off-diagonal SU(2) embedding. Ignoring this crucial concept dooms any project in theoretical physics.

Knock it off, Peter, will you?! Your criticism is lame and repetitive.

I understand you must have dreamt of becoming a brilliant theorist until you found out that you are not capable of that. I know it hurts, but bitching about other people’s work for the rest of your life won’t help it.

Best wishes,
Michael

50. **Kyle**
March 3, 2005

(sorry, I was refering to the scentence that ends “admit that there’s a problem and start a diiscussion about what can be done about it?” in my comment below)

51. **Kyle**
March 3, 2005

If you’ve posted your opinion on what the solution is before Peter, could you link it? If you haven’t, or your opinion has changed, any chance you could lay out a reasonably concrete plan concerning it?

Thanks for your time,

Kyle

RSVP

March 4, 2005
Categories: Uncategorized

I recently mentioned that funding for the RSVP experiment is being reevaluated. More details about this are available in a recent issue of Science magazine.

The Rare Symmetry Violating Processes (RSVP) project is a proposed experiment at Brookhaven that would have two components. One, "MECO" would search for neutrinoless conversion of a muon to an electron, observation of which would indicate new physics beyond the standard model. The other component, "KOPIO", would try and measure the decay rate for neutral kaons to a pion, neutrino and anti-neutrino, a CP violating decay whose rate is predicted by the standard model.

Last fall the NSF had allocated money to start building the experiment, which was projected to cost $158 million. The idea was to use the AGS accelerator at Brookhaven, which in recent years has mainly been used as an injector for the heavy-ion collider RHIC. It seems though that revamping the AGS for use by RSVP may cost a lot more than people had originally thought, pushing the cost of RSVP up to as much as $300 million. The potential cost of RSVP is being reviewed, and HEPAP has been asked to evaluate the results that RSVP may be able to achieve at different levels of funding. According to Michael Turner, head of mathematical and physical sciences at the NSF, "We will reevaluate scientific value, its cost, and then make a decision."

   March 6, 2005

   Chris,
   Finding something precise experimentally beyond the Standard Model will wonderfully focus theorists' minds, IMO, and will liberate some of them from the thralls of string theory. We would have a precise term in the effective Lagrangian that has to be accounted for by theory.
   -Arun

2. **Chris Oakley**
   March 5, 2005

   Sorry to comment "on topic", but it is a general principle that if you want a precise answer you have to ask a precise question.

   Precise question, example 1: is there such a thing as luminiferous ether?

   Precise question, example 2: is there a narrow resonance in e+e- scattering at 3.1 GeV?

   And so on. Vague searching around for unexpected things does not fit this particular bill and is probably a reason to be pessimistic about the RSVP project. After all, the universe of possible unexpected things to look for is huge and it does seem slightly pointless to pick on two particular things forbidden by the standard model when no-one actually has a theory that could be brought into play if SM-violating events *are* found.

   What is more, with theory in its current state, I see no prospect of theorists being able to deliver any predictive, realistic alternatives to the SM.

3. **Peter**
   March 5, 2005

   Hi Lubos,

   Just wondering, are all the connections to my weblog from strings.*.*.edu and famoustheorist.physics.harvard.edu coming from stupid readers or very stupid readers?

   I also recommend that people in search of high-level intellectual discussion about Feynman check out Lubos's website. Just please keep that discussion over there amongst the much smarter readership.

4. **Lubo? Motl**
   March 5, 2005

   Feynman did not like string theory, so I suppose that both types of readers of this anti-string-theoretical blog – the stupid readers as well as the very stupid readers – will enjoy an article about Feynman here.

5. **Lubos Motl**
   March 4, 2005

   I personally don't know what we would do if we knew that mu can decay to e+gamma with some rate etc. We would know there is physics beyond the SM (which we know anyway), but what exactly it is would remain highly ambiguous.

   KOPIO would probably just confirm the Standard Model.

   But there are other people who may find this project very important, so let's not overestimate the importance of particular personal comments.

Higgs Search at the Tevatron

March 5, 2005
Categories: Uncategorized

Tommaso Dorigo of the CDF collaboration at the Tevatron has just posted (with commentary), the slides for his talk at Moriond later this month about the status of the search for the Higgs at the Tevatron. The bottom line is that with the data they have already analyzed they are still quite a ways from being able to see the Higgs, but, if its mass is just above the lower limit set by LEP2, they should be able to see it by two years from now. With quite optimistic assumptions about the performance of the Tevatron, by the end of 2009 they should be able to see the Higgs if its mass is less than 180 Gev. He ends by saying that at "95% confidence level" he thinks the Tevatron will be able to end up seeing a Higgs up to 135 Gev mass, and if its mass is just above the LEP2 limit at 115 Gev, they should have 3 sigma evidence for its existence.

By 2009, the LHC should be producing data and putting the Tevatron out of the Higgs discovery business. For a bewilderingly complicated schedule of the LHC construction and installation, go here. From what I can tell, they are still on track for first colliding beams in spring of 2007.

Update: See Tommaso's comment to this posting for a clarification. By "seeing the Higgs" I didn't mean to imply that they would be able to prove the Higgs was there, just that they would be starting to see some evidence of its existence.

Comments

1. **D R Lunsford**
   March 7, 2005

   "".

   Yes, that's the paper and the analysis is IMO very solid. One need not take the latter papers as seriously, however it should be mentioned that Penrose also points out how highly implausible it is that electrowesk symmetry breakdown should be the same everywhere in the Universe, as current comso. models assume.

   Note that his analysis is not at all controversial – he's simply pointing out the consequence of having the Higgs enter into the Lagrangian in just the way needed to supply masses to the gauge bosons, much as in the problem of a ball rolling on a surface as solved with Lagrange multipliers, where the multiplier term represents the "just right" normal force on the ball needed to keep it on the surface. There is also an obvious analogy in the BCS theory of superconductivity.

   -drl

2. **Alejandro Rivero**
   March 7, 2005

   Hello again… more magic from physicsforums, this morning. Just do this

   mu/mz+ mu^2/(114.5)^2.

   where mu= 0.105658369
   mz= 91.1876 +- 0.0021

   try some values around mz and compare with
   .001159652187

3. **Peter**
   March 7, 2005

   Hi Tommaso,

   Thanks for the clarification. My use of the term "seeing the Higgs" was intentionally ambiguous, meaning something like "seeing some evidence of the Higgs", not meaning "proving" the Higgs was there.

   Am I confused or is the situation the following: in 2007, if there is a 115 Gev Higgs, you hope to have a signal 2 sigma different than the null result, no? Do you then write a a paper with the title "Possible evidence for a 115 Gev Higgs" or are you more disciplined than that?

   I very much enjoy your weblog!

4. **Tommaso Dorigo**
   March 7, 2005

   Thanks for citing my blog here. However, we claim that in two years the Tevatron can probably _update_ the LEP2 _limits_, which is different from seeing it if it is there!
   It is typically easier, in fact, to exclude at 95% CL something, than to prove it at 5 sigma (95% is like two standard deviations).
   Same goes for the 180 GeV reach by 2009: we will probably be able to exclude it at 95% CL if we do not see any evidence, but finding it is a totally different matter…

5. **Alejandro Rivero**
   March 7, 2005

   I am not surprised, Lubos. Physics in the internet was mostly dead except by four or five pages, including Woit and your's.

   If you want to analyse web relationships, TouchGraph provides a visualizer for the proximity engine of google at http://www.touchgraph.com/TGGoogleBrowser.html

   You can click in any webpage to get more proxies to it, or right-click to go to the page.

   (Needs java. There is also a GoogleScholar version, you could had noticed it in physcomments at the lower left side).

6. **Lubo? Motl**
   March 7, 2005

   Wow, Not Even Wrong is the largest website that refers to The Reference Frame! See the counter on my blog.

7. March 6, 2005

   After the top discovery at 1/sqrt(2) of the Higgs vacuum, a lot of people will surely enjoy to have the W particle at 1/sqrt(2) of the Higgs.

8. March 6, 2005

   http://arxiv.org/pdf/physics/0006049
   http://arxiv.org/pdf/astro-ph/0003065

   Electric charge loses meaning above the SM symmetry breaking scale, there is no photon, no speed of light, no time, and hence no gravity. "It is hypothesized here that the Universe came into existence when the electro-weak symmetry was broken spontaneously".

   I think this qualifies for Not Even Wrong.

9. March 6, 2005

   drl, i suppose you're referring to
   http://arxiv.org/pdf/hep-ph/9912243 ?

   "…the full structure of the SM stands intact without constraining the quantum numbers isospin and/or hypercharge of the Higgs to any specific value."

   "The hypercharge of all the other particles are specified as being proportional to the Higgs hypercharge which itself remains unconstrained".

   "Higgs is a manifestation of the vacuum structure of the SM. Higgs shall never get pinned down as an isolated physical particle, but makes its presence felt through charge quantization and giving the SM its complete structure and consistency. **Hence it is predicted that Higgs shall not be discovered as a particle.**

   "No basic principle demands that the mass of the matter particle be given by Yukawa interaction, but since as we have no idea of where these masses come from, one just demands that they arise from such a coupling. If this be so then the Higgs isospin is necessarily T= 1/2. This just tells you that the 'vacuum' has this particular structure. But as Y_phi {hypercharge} is not constrained in any way, the Higgs cannot be a particle but just 'vacuum' which behaves in this fundamental and basic manner.

   "In summary, we have shown that the basic and fundamental structure of the standard model stands intact without specifying and constraining the quantum numbers of the Higgs. As such Higgs is very different from any known physical particle. Hence Higgs cannot be a 'particle' but represents the omnipresent vacuum with provides the 'root' to support the Standard Model'

   –
   I think when people talk of finding the Higgs, they mean the Yukawa-coupled Higgs, i.e., a definite isospin. Certainly all the theoretical constraints on Higgs mass come from such models. Since the hypercharge of all the particles are proportional to the Higgs hypercharge, one could equally well set the hypercharge of one of the particles as basic – i.e., if indefinite hypercharge makes the Higgs not a particle, then the same holds for all other particles.

10. **D R Lunsford**
    March 6, 2005

    The Higgs will never be seen, see the work of Afsar Abbas.

    -drl

11. **Quantoken**
    March 6, 2005

    The problem is obviously the standard model fails to predict and tell us how a Higgs boson should look like or how much its mass is, or we would not be guessing here. If the standard model is unable to confine the value of Higgs mass, then that means its mass really doesn't affect anything in the model. Then what will happen if you exptrapolate that mass to realy big or real small scale?

    There are certainly two possibilities that Higgs may or may not exist. Within the case it does exist, we can also list a number of possibilities.

    One, its energy is totally within reacheable range of today's running accelerators, but the cross-section is just too small to be detectable.

    Two, it's energy is many order's higher than reacheable level, and even approach Planck mass scale. Then it's beyond the technology in the near future to detect it.

    In the case Higgs does not exist, there are also several possibilities:

    One, physicists will just continue to search at higher and higher energy for Higgs particle, until they reach the Planck mass, at which point a wormhole occurs and physicists enter into another universe through the wormhole and continue searching for Higgs, because they simply can not believe that the standard model is wrong.

    Two, at certain energy level they detected something. Because of their eagerness to find Higgs, they call it Higgs boson. But it's actually not the Higgs boson they look for.

    Three, the third possibility does not exist, go back to possibility one above and search at higher energy.

    I think the odd that LHC exactly provides the right scale of energy, not too high and not too low, for detecting Higgs, and that the cross-section is big enough for detection. Is going to be very low.

    I do not know why some one worries about LHC creating blackholes? You need at least one Planck mass to create the smallest possible blackhole. LHC is many orders below that.

    Quantoken

12. March 6, 2005

    Ah, we already know that the Standard Model is correct, so discovery of the Higgs is "trivial". Seeing our first fundamental scalar is trivial. Why even waste money on this?

The corollary is that the most interesting result will be if the Higgs fails to show up at all.

13. March 5, 2005

    Isn't there a non-zero probability that the creation of a Higgs boson will create a black hole that will swallow up the Earth?

    If so, then the discovery of the Higgs truly will be only a few-day celebration as Lubos desires.

14. March 5, 2005

    not really. There are Higgsless models around

15. **Lubo? Motl**
    March 5, 2005

    My personal preferred guess (30%) is that the Higgs is at the 115 GeV level, and it's one of the light Higgs scenarios that are natural in SUSY.

    But the discovery of Higgs will be a few-day celebration only. It's a trivial thing. We know that something like the Higgs must be there to make the WW WW scattering unitary, and the fundamental scalar is simply preferred by precision measurements.

    The real question to answer is SUSY below TeV, and other potential new physics.

Hans Bethe 1906-2005

March 7, 2005
Categories: Obituaries

[Hans Bethe] died at home in Ithaca, New York on Sunday. There's an extensive [obituary] in the New York Times.

I believe Bethe was the last remaining figure still alive from the generation of physicists who came of age with the new quantum mechanics during the mid-to-late 1920s. Some popular lectures on the topic of "Quantum Physics Made Relatively Simple" that he gave for his neighbors in 1999 are available [on-line].

Update: There's more about Bethe and Cornell at Matthew Nobes's [weblog].

Comments

1. **Alejandro Rivero**
   March 9, 2005

   Hans A. Bethe, matured in 1928 in Zurich,
   was a disciple of Arnold Somerfeld
   who was a disciple of Von Linderman
   who was a disciple of C. Felix Klein
   who was a disciple of Julius Pl?cker
   who was a disciple of Christian Gerling
   who was a disciple of Carl Gau?
   who was a disciple of Johann Pfaff
   who was a disciple of Abraham Kaestner
   who was a disciple of Christian Hausen
   who was a disciple of Johann Wichmannshausen
   who was a disciple of Otto Mencke

   From Renardy: " Otto Mencke, founded the first academic journal in Germany, titled Acta Eruditorum, jointly with Leibniz (the journal existed 1682-1782). Otto Mencke should not be confused with his grandson Friedrich Otto Mencke."

   Bethe is survived by, among others, Roman Jackiw and John Irwin. If you know of more disciples, please feel free to add them to my wiki page.

2. **D R Lunsford**
   March 8, 2005

   RE his work:

   A nucleosynthesis "Dreimaennerarbeit" – "Alpher, Bethe, and Gamow" 🙂

   http://www.npr.org/templates/story/story.php?storyId=4505414

3. **Eleggua**
   March 8, 2005

   Hi Lunsford,

   Well he was recognised!

   Unlike Feymann he won the Nobel by HIMSELF!

4. **D R Lunsford**
   March 8, 2005

   That reminds me of a comment by the chessmaster Ludwig Mieses – he was being feted on his 80th birthday and said "Life expectancy is around 75 years. Now that I'm out of danger, I may as well go on living forever!"

   Bethe was 98 or 99! That's a good life. I think he should get more credit for his role in the development of QED than he seems to, in the various tomen. His calculation of the Lamb shift was really the turning point in the development of field theory.

   -drl

5. **raj**
   March 8, 2005

   A sad passing, but a reminder that people don't last forever.

   I wonder. Was the title "Quantum Physics Made *Relatively* Simple" meant to be something of a pun on the tension between quantum mechanics and relativity?

6. **Steve**
   March 7, 2005

   A sad loss but he lived to a very good age indeed.
   I read that when they were to detonate the first H bomb some people were worried it would set of a chain rection in the atmosphere and blow up the world. Bethe did the calculation that proved it would'nt. Such were his abilities that they trusted him with the fate of the world!

7. **Matthew**
   March 7, 2005

I believe Bethe was the last remaining figure still alive from the generation of physicists who came of age with the new quantum mechanics during the mid-to-late 1920s.

John Wheeler is still alive, though he was slightly behind Bethe's generation, I'd still put him in that class.

Brane Damage at Fermilab

March 8, 2005
Categories: Uncategorized

Last week Shamit Kachru gave a colloquium at Fermilab with the title String Theory and Cosmology. The scariest part was the beginning when he noted that what he would be talking about was work due to 500-1000 theorists and he put up a couple slides listing many of them.

He spent the first part of his talk laying out the "Landscape" story, somehow neglecting to mention that it was ugly, completely unpredictive, and told us nothing at all about the properties of the world today. He then moved on to discuss branes and cosmology, not making clear that branes explain absolutely nothing about the early universe or cosmology, although they do give you a new slogan he has come up with:

"Big bang as brane damage"

There were a couple questions at the end, with no one standing up and asking if this was a bad joke or something. I'm curious if anyone from Fermilab can explain to me what a typical experimentalist's reaction is to this kind of talk:

1. Are they impressed by this stuff and don't realize they've been fed a load of pointless nonsense for an hour?

2. Are they smart enough to realize they've just sat through an hour of pointless nonsense, but are too polite to say anything about this at the end of the talk?

3. Are they so smart they know in advance this will be an hour of pointless nonsense, so don't even attend, and are off somewhere else getting real work done?

Comments

1. **Juan R.**
March 14, 2005

Ok there is a problem with "less than sign".

I rewrite as Y > X.

2. **Juan R.**
March 14, 2005

Chris,

I forgoot the name and the second postulate that read X

3. **steve**
March 11, 2005

Edward Witten, Five-branes and M-Theory on an orbifold, preprint
available as hep-th/9512219. (1996)

the M stands for "magic", "mystery",or "membrane", according to taste.From a mathematical viewpoint a better term might be "murky", since apparently everything known about M-theory is indirect and
circumstantial, except for the classical limit, in which it seems to act as a theory of 2-branes and 5-branes, where an "n-brane" is an
n-dimensional analog of a membrane or surface.

4. **Chris Oakley**
March 11, 2005

Well, anonymous humorist, unfortunately it looks as though Weisskopf (Kon. Dan. Vid. Sel., Mat.-fys. Medd. XIV #6 (1936)) has beaten you to it. Inventing a new form of mathematics that allows physicists to "calculate" without having to worry about the consistency and logicality demanded by spoilsport mathematicians.

5.
March 11, 2005

According to the usual bizarre model of research on string theory, I propose the following theory of everything without the difficulties of compactification and saving both string theory and the scientific method.
The I-theory is very sImple, since is based in four postulates; moreover, it is ?background Independent? and explains the mysterious value of the cosmologIcal constant without the appeal to anthropIc principles!
Postulates of I-theory, being X and Y physical observables:
1) X > Y
2) X

6. **Kyle**
March 11, 2005

Those poor "working class" steelworkers. I mean, metallurgical engineers only make 60-80k a year. I bet most theoretical physicists would spit on such a dismal, blue collar salary.

More importantly, being involved with massive factories that use machines to produce steel makes people stupid and policitally uninvolved. That's why the government is frightened of string physicists and keeps them under tabs. University academians are far more dangerous than workplace engineers who have a couple of years less schooling.

Right?

7. **J.F. Moore**
March 11, 2005

Sorry, that was me below. Public machine, didn't change name.

8. **loser**
   March 11, 2005

   quantoken: well, my point was that hamburger makers _are_ pretty much replaceable. But in general I agree with your comments. Not too many people in society were crying when SSC was cancelled.

   I think it is important to be a little careful in arming the enemies of science funding with caustic and public criticism of sub-fields. Scientists generally lose when they compete for funding at the policy level with other scientists. Keeping the arguments "within the family" is wise. This blog is a good example of doing that.

9. **Arun**
   March 11, 2005

   I am sure we can show high correlation between economic growth of a country and the presence/absence of string theorists. This, in a Larry Summers way, proves the value of string theorists.

10. **Alejandro**
    March 11, 2005

    Perhaps it is shown in the Spanish Civil War and in the previous experience with the Escuela Moderna (anarchistic, at Barcelona) and the Instituto Libre de Ense?anaza (sort of socialistic, at Madrid), that the real danger is when both steel workers and science works start to develop links.

    Os to put it in a riddle, it is perhaps no coincidental the source from where [the money of] the Nobel prize come.

11. **quantoken**
    March 10, 2005

    J.F.Moore: Yes I appologize for my comments on steel workers. I did not mean to put down steel workers, McDonald workers, or any people of work classes. They are an inseparable part of the whole society and contribute values that's irreplaceable. On the other hand, I agree with you that I do not see any value (other than public entertainments) that string theoretists are contributing to the society, until the day they can some what make some association between their theories and the reality world, it's not even clear whether such a day will ever come.

    Quantoken

12. **J.F. Moore**
    March 10, 2005

    Quantoken, your glib comment regarding steelworkers isn't really warranted. They make much more than someone working at McDonalds, and rightly so, since they produce something of substantially more value, with more risk, and more skill involved. It is not beneficial to society or that person to have them underemployed. On the other hand, it's not really clear what society has lost if it is no longer supporting a string theorist.

13. **quantoken**
    March 10, 2005

    Surely jobless academics are much more dangerous than jobless steel workers. A steel worker who loses his job can just turn around and find a job at a street corner McDonald's before he was able to go home and report the unfortunate news to his wife.

    But what if a string theorist loses his job? A string theorist who have to go through decades of training, maybe some brain washing as well, before he could grasp all the math tools and be able to talk fluently in the vacuous stringy language. I do not know what these people can do if one day it is announced that string theory is a dead end and no more "research" in string theory is going to be founded by public money. Not only is it a total disater to these people personally, but it is also a disaster to the public's confidence of the general science research community.

    I do not think any one wants that to happen. A more likely scenary is the old people will continue to be supported until they die out and fade away. Meanwhile young generations should be discouraged from going into the field, with full and honest disclosures that this field has been fruitless in the past decades and could remain so for the foreseeable future.

    Currently CERN feeds half of all the world's scientists conducting research in particle physics and fundamental physics theory. Everybody is talking about the prospective of what to expect once the LHC starts to operate in 2007.

    But no body is talking about the prospect that the whole **LHC could be killed or left bleeding to death**, before it even begin to operate. Or that upon completion, this thing is unable to operate in the way it is designed. That's completely plausible. So why no one talks about THAT discouraging possibility?

    http://www.theglobeandmail.com/servlet/story/RTGAM.20050307.wphysics0307/BNStory/specialScienceandHealth/

    To me, the listed budget figure of merely **$1.8 billion US dollars** for the whole LHC budget, sounds **very suspiciously LOW** to me, for an undertake of this scale and this technological challenge. Digging a hole 27 km long underground would have costed far more than that. I know they already have the old tunnel to use, but constructing a new vacuum chamber 27 km long would have cost more than $1.8 billion already. Compare that with space shuttle launch. That's merely a feat of accelating a 90 ton sealed pressurize chamber containing some computers and electronics to 7.9km/second, which is certainly much easier than maintaining a high vacuum in a 27 km chamber and accelerate protons to 14 trillion eV.

    So I do not know where that **$1.8 billion** figure came from, or has scientists been totally honest about how much it could actually cost. If it ends up costing $18 billion, or even $180 billion, instead of $1.8 billion. It could well be killed by the budget committee half way through construction. Remember the SSC?

14. **Wolfgang**
    March 10, 2005

    The "patrons" might be smarter than you think.
    I assume that one reason to lock academics in their ivory towers is to ensure that they do not cause trouble in the real world.
    In the case of Russian physicists after 1989 this was explicitly stated as one reason.
    And jobless academics are much more dangerous to politicians than jobless stellworkers etc.

    Just my 2c

15. **Alejandro, again**
March 10, 2005

"by patrons who have no idea what the issues are"

I'd not be so sure of this neither. Back to the Aristotelian nonsense, a lot of people was being paid by patrons who know very exactly that the issue was "not having issue". To keep status quo, a class of educated priests, a determinate shape of society, etc… Small barons paying other researchers for practical reasons (ballistic and fortress theory, in the case of Galileo) caused havoc in the status quo. Which, on the other hand, was the real issue of these barons too.

16. **Alejandro Rivero**
March 10, 2005

Doug, I would not say it is unprecedented, I am sure we can find someone. For sure, all the Aristotelian blah blah before Galileo, Pascal and Kepler. A bit later, Cartesiasism, ie, the vortical theory of the universe, could qualify for a predecessor of strings, in the "not even wrong" sense.It could be interesting also to check what theories were being "investigated" in Cambridge when it happened that Cavendish left his appointment as teacher to keep researching privately (he come back to Cambridge later). Also, and relating to Bethe thread, I wonder where had particle physics gone in the mid XXth century were not by the Lamb shift anomaly and its almost instantaneous calculation by Hans et al.

17. **Doug**
March 10, 2005

Lubos: There is a point that is never raised in all this discussion: that the current crises in theoretical physics is not only ludicrous, but unprecedented in all the history of science, and that such erudite discussion of esoteric knowlege is being paid for, to the tune of billions, by patrons who have no idea what the issues are, let alone why they arouse such passionate discourse amongst the learned benefactors of their largess. It's a good thing too, because if they did, they might rise up and cut off all these high-priests who cloak themselves in the robes of the false priesthood we call academia.

18. **Alejandro**
March 10, 2005

The funny thing, Chris, is when the folder "reasons why the universe must be 3+1" relabels to "reasons thy the universe must compactify to 3+1". With a postscript added by hand, "or to stay in a 4-brane".

19. **Chris Oakley**
March 10, 2005

Here is an interesting thing for historians of science to contemplate. What is the value of the variable *date* below? I am guessing, about 1984.

"We've got this great theory, but it only works in *N* dimensions, where *N* is significantly greater than four."

Answer (pre-*date*):

Very interesting. File it in the circular file and try again.

Answer (post-*date*);

The universe must therefore be *N*-dimensional. Cool! Let us dedicate the rest of our lives to examining the consequences.

20. **Fyodor Uckoff**
March 10, 2005

Chris W said: What you're suggesting is what quite a few string theorists have been trying to do for years.

They have been *talking* like this for years, but surprisingly few of them have actually done much concrete work along these lines. For example Adams et al have shown that very strange things can happen to AdS orbifolds if you break enough supersymmetry. I guess that large chunks of the landscape can be shown to be internally inconsistent in such ways. As Lubos said, we don't really understand supersymmetry breaking very well; I would not be surprised to find that when we do, a lot of candidates for cosmological models will be ruled out and the landscape will collapse. If you can point us to some [failed?] efforts along these lines it would be useful.

21. **Steve**
March 9, 2005

Will some very smart person please write a killer paper that finally buries the landscape dogma, thus saving both string theory and the scientific method. To date, string theory has been formulated mostly perturbatively in classical backgrounds–the strings can be quantised but the background remains rigidly classical. Until string theory is (somehow) formulated in a way that goes beyond this it can't connect to the real universe nor can it say anything really concrete and certain about cosmology. The CC mystery is kind of like the mystery that surrounded superconductivity:when it was discovered around 1911 or 1912, superconductivity was a total mystery and all perturbative attempts to explain it failed. It was a quite a long while later that the correct (nonperturbative) explanation was finally found. I would say the situation with the CC today is something similar.

It seems that the only known way to stabilise the moduli leads to this landscape scenario. So there are three choices:
(a) You find an effective way to kill the landscape of string theory and reinterpret string theory (perhaps even starting the 3rd string revolution)and the theory can evolve again. From a string cosmology perspective it is also more natural to think of 3 dimensions decompactifying and 6 remaining compact (ala Brandenberger-Vafa) than compactifying down 6 large dimensions on CY space.
(b)You finally accept that higher-dimensional spacetimes, ala KK, simply can't actually work in physics, are not stable to perturbations and so you are forced to accept the universe is actually 4-dimensional after all.
(c)You simply refuse to give on up the idea of extra dimensions no matter what, fix the moduli or do whatever it takes to hold onto the idea (no matter how contrived) and accept that it leads to a landscape of quadzillions upon quadzillions of superfluous and redundant vacuua. Although it predicts nothing, this is then more acceptable and believable to you than a single 4-dimensional universe (for which there is some evidence!)

As much as I would be disappointed if there are no extra dimensions (it is a profound and beautiful idea) that might just be the way the universe really is. The KK idea has been around a long time now and has not really worked out. Nevertheless, from both a mathematical and physical perspective, there is something very special about 4-manifolds. Maybe you find 4-manifolds boring, but Kepler had to give up his cosmic system based on the Pythagorean solids and accept that planets actually just move on boring ellipses. Giving up your most deeply cherished beliefs and visions for the hard truth, no matter what it may turn out to be, is the heart of science after all.

22. **Quantoken**
March 9, 2005

Sorry Chris W. I did not credit you for the quote. If you had put an extra line breaker after the colon, it would have made it easiler to recognize it as what you say to Fyodor, not what Fyodor said. The style of Peter's blog is just different from some other blogs I visit.

Quantoken

23. **Chris W.**
March 9, 2005

That quote was in my *reply* to Fyodor, not in his own comment.

24. **quantoken**
March 9, 2005

Fyodor said: The oft-repeated refrain that **"the theory is smarter than we are"** is being invoked in this context.

I read the above sentence in the logically equivalent form that string theoretists admit "we are more stupid than the theory we invent, (which is a useless theory)" 🙂 Which is the unfortunate fact.

Peter said: "The **scariest part** was the beginning when he noted that what he would be talking about was work due to 500-1000 theorists and he put up a couple slides listing many of them."

What is scary is NOT that his talk is backed up by very solid scientific works of 500-1000 people. But rather the fact that such a **vacuous** thing is **all that they can show us**, after decades of work by 500-1000 of the most sophisticated theoretists. It's 10^120 more vacuous than the cosmological constant itself:-).

Quantoken

25. **Chris W.**
March 9, 2005

Fyodor: What you're suggesting is what quite a few string theorists have been trying to do for years. So far they haven't had much success. Susskind (at al) recommends that they stop worrying and learn to love the Landscape, while brushing aside concerns about testability as manifestations of an obsolete viewpoint on the philosophy of physics (and science) that has been transcended by the theory. The oft-repeated refrain that "the theory is smarter than we are" is being invoked in this context.

26. **Fyodor**
March 9, 2005

Well, with reservations I agree with both Peter and Lubos. I thought that Peter was just complaining about the evident bizarrerie of what Shamit K was talking about. For Lubos: it seems to me that what you should be doing is to look at cosmological models coming out of or inspired by string theory, and try to show that nearly all of them are somehow unstable or internally inconsistent. There are lots of examples of backgrounds in string theory that look ok until you consider some non-perturbative effect, and then they die or [AdamsPolchinskiSilverstein] get turned into something completely different. Maybe one can cut that 10^500 down to 10^1? Or 10^0 ?

27. **Lubo? Motl**
March 9, 2005

Shamit is a nice and extremely smart and technically powerful guy – which of course makes it slightly more difficult for me to say that I essentially agree with Peter.

The level of anthropicity of this thinking has been increasing in the past few years. A couple of years ago, Shamit would tell me things like "you don't need to believe the anthropic principle; this is a question we should understsand anyway". This kind of disclaimer has been disappearing.

It seems that now it is expected that one believes the anthropic thinking as the ultimate answer we can have about nature. It is the motivation for this kind of research as well as the broad framework in which the research is done. I just can't imagine how could I ever be convinced that a theory of this kind is a correct one because it lacks quantitative predictability.

Some people really seem to be excited by the very fact that they can embed a relatively convincing framework into string theory whose conclusion is that we can't predict anything – or perhaps, we can even choose which things can't be predicted and which things can be predicted, even though we can't actually make these predictions.

This opinion is contrary to everything I believe about constructing theories and determining their value. String theory is valuable only because it can naturally predict the right spectrum of particles and interactions (including gravity), at least qualitatively, from a starting point that has many less assumptions. The anthropic framework may be describe by the opposite words.

It has always been trivial to construct a theory that can't predict. The Bible, via the power of God and His Son, has also an "explanation" for everything – God wants it this way. The landscape of all possible field theories is another example.

The main difference between the anthropic explanation and the God explanation is that the Christians are often right-wing and prefer the church and family, while the anthropic people are mostly left-wing and better in calculating quantum field theory. But as far as the explanation goes, it seems on equal footing.

A theory can only become a convincing scientific theory if it explains more data than what is inserted, and this is a dogma for me, if you wish. Otherwise it's just a story, fairy-tale, mnemotechnical bookkeeping device at best. In effective QFT, we must insert a rather small value of the C.C. But if we create whole untestable God stories with 500 fields and complicated potentials etc. just in order to get one number, I just can't imagine that this approach can ever be promoted to science.

Equivalently, the probability that (assuming that there is a complicated mechanism that only generates the C.C.) we would guess the right mechanism behind the C.C. – just by looking at the single number and the plethora of tools that string theory gives us – is something like 10^{-200} and I see no point in trying to find the "right" mechanism.

It seems more appropriate to say that we don't understand one number, we won't know the right explanation of the C.C. (we only have real problems with the C.C. after SUSY breaking, and therefore the ignorance is because we don't understand SUSY breaking) until the complete theory of everything – which includes string theory in the cosmological context – is understood – and we should focus on places where we have a lot of data to unify into one theoretical description. (Well, we don't have too much data right now even beyond the C.C. but that's a different topic.)

Also, in some sense, the landscape business is "politically correct". For example, treating all conceivable vacua as equal is the ultimate example of egalitarianism and political correctness (and I would also add stupidity).

28. **Peter**
March 9, 2005

I don't object to Kachru's work because it's hard to believe or weird, I object because it's not science. It not only doesn't predict anything about anything, it inherently is a framework that can never predict anything about anything. To see leading figures in particle theory giving pretentious talks like this that are not science in any sense of the term is outrageous, disgraceful, and someone should call them on it.

No, Kachru doesn't "predict" the CC, he sets up a framework in which you can't predict the CC, and thinks that is a great achievement. I have no idea whether the CC will be computable in an ultimate theory. Right now we don't have a convincing unified quantum theory of particle physics and gravity. When we do, maybe the CC will be computable within it. But the problems with string theory go way beyond the CC. If Kachru's framework allowed one to calculate something, but not the CC, one could take it seriously. But it doesn't allow you to calculate anything. Not one single thing, nada, zip.

29. **Fyodor Uckoff**
March 9, 2005

Basically what you are saying, Peter, is that you find the work of Kachru et al hard to believe. And I agree — I think we should try our best to explain things within one Universe. And I'm pretty sure that Shamit would agree that such efforts should [also] be pursued. But what I find puzzling is this: you find this stuff hard to believe. But the observed fact that the cosmological constant is non-zero and small is utterly, completely mind-boggling from *any* conventional point of view. So when somebody comes along with a correct theory of all this stuff, it is *guaranteed* that it is going to be something extremely weird. I'm sure you don't expect someone to do a conventional quantum field theory calculation, however clever, and have the value of the CC fall out at the end. So the mere fact that Kachru's colliding branes in higher dimensions *looks* utterly incredible means nothing. The *correct* theory will probably look weirder still, no? So what's your problem with weird theories?

30. **Peter**
March 9, 2005

I didn't attend the Kachru talk in person, just looked at his slides online and watched some of it on the online video. When I have personally attended talks like this I have generally at the end stood up and asked a question along the lines of "From what you have said, isn't it true that this is a theory that can never predict anything" (most notably when Susskind gave a colloquium here, and when Douglas gave one at City College a while back). No I don't enjoy publicly confronting people like this, but I think it's outrageous that they give this kind of talk, then no one says anything.

I did attend Smolin's talk, don't remember why I didn't write anything about it. He basically went over his recent paper in which he argues that any quantum gravity theory based on connection variables implies "doubly special relativity" effects, effects that he was claiming have implications for the AUGER and GLAST experiments.

31. **Thomas Larsson**
March 9, 2005

In a way, all this reminds me of the contrast between Lorentz's and Einstein's explanations of the null result of the Michelson-Morley experiment.

We live in a region of the Landscape where the aether wind is very small, because a large aether wind is not compatible with human life.

32. **Chris W.**
March 9, 2005

In a way, all this reminds me of the contrast between Lorentz's and Einstein's explanations of the null result of the Michelson-Morley experiment. The fact to be explained had a stark simplicity about it, whose full significance Einstein grasped and Lorentz couldn't quite perceive, in spite of his gifts as a theoretician and mastery of the subject.

Of course, it has become clear that for Einstein the Michelson-Morley result was expected and almost trivial; he was led to the underlying principles by thinking about Maxwell's electrodynamics and certain observations which by themselves had not heretofore appeared to be problematic.

In contrast, string theory's birth was oddly accidental. The hope has been maintained for 25 years that its underlying physical principles would eventually become clear. Instead, it has begun to seem like a mockery of the very idea of physical explanation — a massive virtuoso exercise in mathematical modeling, supported by the "accursed fertility" of differential geometry (to use Kant's phrase*). As Kachru says without apparent irony:

> "In studying any of these issues in depth, [the] most striking feature is the *diverse array* of possibilities the theory encompasses."

Again, why is this diversity supposed to be a virtue, when there is so little empirical basis for believing that most of these possibilities are actually realized, and so little real insight offered to account for their absence?

—
* from the following remark, as quoted by Karl Popper:

> "Concerning metaphysics in general, and the views I have expressed on their value, I admit that my formulations may here or there have been insufficiently conditional and cautious. Yet I do not wish to hide the fact
> that I can only look with repugnance and even with something like hate upon the puffed-up pretentiousness of all these volumes filled with wisdom, such as are fashionable nowadays. For I am fully satisfied that the wrong way has been chosen; that the accepted methods must endlessly increase these follies and blunders; and that even the complete annihilation of all these
> fanciful achievements could not possibly be as harmful as this fictitious science with its accursed fertility."

33.
March 9, 2005

I heard Lee Smolin, the LQG guy, spoke at the string group at Columbia recently. Did you attend? If so why no comment?

34. **Jean-Paul**
March 9, 2005

Well, Shamit is an exceptional case, in a way similar to Douglas. Unlike most landcape loonies, they are respected string theorists so they deserve some attention.
Now they want to establish themselves as "phenomenologists", talk to experimentalists, give public lectures etc. Unfortunately, this leads to ridicule. The line "big bang as brane damage" joins "solution of unification by nullification",
"out of this world solution of the hierarchy problem", "little Higgs" and other absurd one-liners that dominate the infamous "physics beyond the standard model".
I remember one Witten's colloquium on unification: he started from experimental data and after 10 minutes he was deep into linear bundles. Fortunately, he didn't try jokes, so he avoided ridicule — it was just another weird talk…
Jean-Paul

35. **anonymous**

March 9, 2005

Peter, I take it from “and told us nothing at all about the properties of the world today” that you were there for the talk. If so, then why didn’t you make this comment? Is it easier to be brave online?

36. **Peter**
March 8, 2005

The same thought had occurred to me….

37.
March 8, 2005

I’m guessing that if one compared “stephen”‘s IP to “plato”‘s one might notice a pattern.

38. **stephen**
March 8, 2005

Not sure why you’re quoting this press release (which doesn’t have anything to do with Kachru’s talk).

I was aware of the cyclical universe idea and brane collisions, and watched the cosmic string develope from supersymmetrical valuations.

Please be patient.

One would have to know how to get there and “if,” from early comsological idea of a early universe, and we assume it is cyclical, something had to exist before the strings?

I used the whole example of Dvali’s analogy as a comparison to all the dimensions (yes I am listenng to you), in context of the fermions on the brane(what is held to it?) the water(represents the dimensions), and the idea of bosonic production off the brane, concealed as gravitational wave production.

If the torus existed from the genus figure collapse, how would rejuvenation take place? Anti-gravity production indicated by the jets? Swiss cheese universe?

Do you not feel such geometries/topologies can be comparative to cosmological associations Peter?

39.
March 8, 2005

“Big bang as brane damage”??
I think I will go off and read some of Bethe’s old papers instead…

40. **An experimentalist (Monad)**
March 8, 2005

Years ago, I went to one general ST talk by Brian Green. My (very) crude grasp of it was that even when they get it right and the masses of all the quarks and leptons roll out of an ab initio calculation, they will have exchanged the 20 or so free parameters of the SM for the free parameters of the topology of thier multi-dimensional space.

When (if) they get that far, I’ll take another look. But for now, yes, I stay in my lab.

41. **Peter**
March 8, 2005

Not sure why you’re quoting this press release (which doesn’t have anything to do with Kachru’s talk).

Dvali’s extra dimension nonsense doesn’t predict anything about anything (he has no idea how many extra dimensions there are, their sizes or properties). This isn’t science in any reasonable sense of the term.

42. **stephen**
March 8, 2005

I am sorry, I just realize the mistake I might of made.

I compared the metal plate Dvali hits, to a brane?

43. **stephen**
March 8, 2005

If gravity is modified at large distances, it’s modified everywhere. That would make it possible to verify modified gravity by measuring the orbit of the moon to within one millimeter

http://www.eurekalert.org/pub_releases/2005-02/uoc-sma021405.php

So would Arkani-Hamed, Sava Dimopoulos, and Gia Dvali doing extra dimensions… and the attempts to explain these dimensions, be a fruitless and not worth finding experimental opportunities?

44.
March 8, 2005

They probably showed up to hear professor Kaku talk about alien visitations and were sorely disappointed.

Clifford Modules

March 11, 2005
Categories: Uncategorized

John Baez had a weblog long before the term was even invented, and for many years now has been consistently putting out interesting current material about math and physics under the title This Week's Finds in Mathematical Physics. The latest edition has a beautiful explanation of the structure of modules of the Clifford algebra.

Traditionally one thinks about geometry in n-dimensions in terms of n-dimensional vectors and tensors built by taking tensor products of vectors. These are all representations of the general linear group GL(n), or if one has a metric, the othogonal group SO(n) of transformations that preserve the metric. However, it turns out that there are representations more fundamental than vectors, the spinor representations. These require a metric for their definition, and are projective representations of SO(n), or true representations of the double-cover Spin(n). When one tries to construct spinors, one quickly runs into a fundamental algebraic structure associated with a real n-dimensional vector space: the Clifford algebra C(n). Spinors occur as "modules" of the Clifford algebra, i.e. vector spaces that the Clifford algebra acts on. The structure of these possible Clifford modules is rather intricate, with a certain eight-fold periodicity. Baez gives a beautiful explanation of part of this story.

Physicists generally complexify everything in sight (i.e. assume all numbers are complex), which makes things much simpler. Then the story is periodic with period 2 instead of 8, and Clifford algebras are just one or two copies of a complex matrix algebra of k by k matrices, where k is some power of 2. Clifford modules (including the spinors) in this case are just complex vector spaces of dimension k, and tensors built out of these. One good place to read about all this, together with its relation to the index theorem, is in the book "Spin Geometry" by Lawson and Michelson, but there are by now lots of others.

If one believes in a deep relation between physics and geometry, these Clifford modules should somehow come into play in the structure of the most fundamental physical theories. To some extent this is already in evidence in the way spinors and the Dirac operator occur in the standard model. There are also tantalizing relations between the idea of supersymmetry and the Clifford algebra story. Many, many people have been motivated by this kind of idea over the years to try and use Clifford algebras to come up with a fundamental particle theory, one that would explain the structure of the standard model. While some of these attempts have very interesting features, none of them yet seems to me to have gotten to the heart of the matter and used this kind of geometry to give a really convincing explanation of how it is related to the standard model. Some crucial idea still seems to be missing.

Comments

1. **Chris W.**
   March 20, 2005

   New preprint on an application of supersymmetry in a condensed matter model:

   Supersymmetric Model of Spin-1/2 Fermions on a Chain

   Introduction (excerpt):

   > For many condensed matter systems, the key to understanding the physical properties lies in the analysis of a quantum many body problem with strong correlations. For the analysis of such systems, approaches that go beyond the standard perturbative techniques are always needed. It has recently been proposed [1, 2] that, for a special class of lattice models for correlated fermions, supersymmetry can provide a tool for non-perturbative analysis. In these models, questions about the existence and degeneracies of strongly correlated ground states at zero energy are easily answered with the help of supersymmetry and elementary combinatorics. Explicit properties of these same ground states are being studied with techniques that are, in various ways, associated with supersymmetry [1, 3, 4].

   Conclusion (excerpt):

   > We have introduced a model of interacting spin-1/2 fermions on a chain with a manifest SU(2) extended N = 4 supersymmetry. Our representation of N = 4 supersymmetry is highly non-linear, as it is entirely built from degrees of freedom that are fermionic. We have looked for a supersymmetric model where SU(2) spin symmetry is faithfully represented, and this has led us to a somewhat unusual restricted Hilbert space, with anti-ferromagnetic correlations built in from the start. The algebraic structure we have uncovered is very rich, but we are lacking a systematic mathematical framework. Such a framework will be most valuable, as it will allow us to further work out our present model and to decide on possibilities for alternative realizations of N = 4 supersymmetry.

   [For some background, see (eg) hep-th/0210161.]

Linking Geometry and Dynamics

Introduction

In a comment on his weblog posting "Clifford Modules" (3/11/2005), Peter Woit said the following (in a reply to Tony Smith):

> …… But I still think there is a crucial idea missing here and wonder if you really strongly disagree with this. To be a little more specific, what seems to me to be missing is some deeper link between the geometry and the dynamics. In the path integral formalism, why are we integrating over a space of connections the exponential of the norm squared of the curvature of the connection? Why the determinant of the Dirac operator? I tend to think we need some insight into these mysteries in addition to more kinematical ideas about Clifford algebras.

In a brief email correspondence I had with Ray Streater 9 months ago he made the following remark in reference to Irving Segal:

> I notice that Baez was a student of Irving Segal, for whom I was research assistant in 1965, and from whom I learnt a lot of things. But my sympathies are with Chandrasekhar whose face fell when Segal introduced space-time as a poset: we want physics.

From Streater's brief memoir of the encounter (linked above):

> Atiyah then invited Chandrasekhar, as the century's most eminent astrophysicist, to open the questions. Chandra complained that gravity was nowhere mentioned, and that there were *no dynamical laws in the theory*. [emphasis added]

In the following I will introduce a simple (and fairly familiar) notion of dynamics that can be connected immediately with geometry in a way that may be initially surprising, but is quite natural. Furthermore, this notion will prove to be unexpectedly fruitful, in a way that is also initially surprising, but is again natural, indeed, almost obvious after some contemplation. More specifically, I will be drawing tight linkages between elementary geometrical (and topological) notions, a primitive notion of local gauge freedom which bears a provocative resemblance to supersymmetry, and causal sets, which are, of course, posets (partially ordered sets) as mentioned by Streater.

A Boolean Network as an Abstract Simplicial Complex

Consider a simple collection of binary elements or Boolean variables. Initially we assume no structure on this set other than the assumption that each of its members possess a binary state, which may change. Of course the collection (or ensemble) has a collective state, which may also change.

Assume that the changes of (and within) the collection can be recorded. We can accumulate a history:

S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S
S _ S S S _ S _ S S S _ _ _ S _ S _ S _ S _ _
S _ S _ S _ S S S _ S _ S _ S _ _ _ S _ S _ S
_ _ S _ S _ S _ S _ S _ S _ S _ S S S _ S _ _
S _ S _ S S S _ S _ S S S _ S _ S S S _ S _ S
S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S

Bear in mind that in representing the set this way we have assigned an implicit labeling of its members, which may be considered an integer {1, …, N} assigned from left to right. The changes in state are tracked with respect to this labeling, and we are forced—for the moment—to assume that the labeling can be meaningfully carried forward in "time", as the state of the collection changes.

We may now ask ourselves, what are the dynamics? We can record a history, but can we predict successive states? Can we describe stable correlations among members of the collection?

We must guess at the dynamics, and then test our guesses. The simplest thing we can do that seems likely to yield non-trivial results is to associate transition functions of two variables (two input states) with each element in our collection. These functions must of course be Boolean, and the number of possibilities are very limited. In fact, there are 16 *functionally complete* options from which to choose, all interrelated by a familiar web of dualities:

NAND(x, y) = ~NOR(~x, ~y)
NAND(~x, y) = ~NOR(x, ~y)
NAND(x, ~y) = ~NOR(~x, y)
NAND(~x, ~y) = ~NOR(x, y)

NOR(x, y) = ~NAND(~x, ~y)
NOR(~x, y) = ~NAND(x, ~y)
NOR(x, ~y) = ~NAND(~x, y)
NOR(~x, ~y) = ~NAND(x, y)

Here "~x" or NOT(x) can of course be taken as a shorthand for NAND(x, x) = NOR(x,x).

We specify a complete transition on our set of N binary variables by selecting functions from this set of 16, assigning them to ordered triples ({c; a, b}) taken from the set of N variables; one variable receives the "output"—the "next" state—and the other two provide the inputs. The elements of the triple are not necessarily distinct.

Let us focus attention on the inputs of the transition functions. In the “typical” case they associate each member of our set of Boolean variables with another member. This makes clear that in this context the variables may be thought of as vertices, and the transition functions as edges or links. Collectively they define a simplicial complex, which is carried forward in “time” as the set of variables evolves according to the transition rules.

We have arrived at the roots—at least in part—of geometry.

A Boolean Network as a Gauge Field

There is another way to view the foregoing. Let us reconsider the brief history of our small sample collection of variables:

```
S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S
S _ S S S _ S _ S S S _ _ _ S _ S _ S _ S _ _
S _ S _ S _ S S S _ S _ S _ S _ _ _ S _ S _ S
_ _ S _ S _ S _ S _ S _ S _ S _ S S S _ S _ _
S _ S _ S S S _ S _ S S S _ S _ S S S _ S _ S
S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S
```

It was mentioned before that the representation of the collection as a one-dimensional array implied nothing more that a simple labeling by a set of integers. It may now be noted that the representation employs a labeling of the states of the variables which is equally arbitrary. We can globally invert the assignment of our state labels (S, _) without making any essential change to the information content of our history:

```
_ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _
_ S _ _ _ S _ S _ _ _ S S S _ S _ S _ S _ S S
_ S _ S _ S _ _ _ S _ S _ S _ S S S _ S _ S _
S S _ S _ S _ S _ S _ S _ S _ S _ _ _ S _ S S
_ S _ S _ _ _ S _ S _ _ _ S _ S _ _ _ S _ S _
_ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _ S _
```

It is crucial that the state relabeling be *global*. We have no sensible way to propagate a selective relabeling of some variables throughout the history without corrupting our knowledge of the correlated changes in the collection, because we have no notion of dynamics, other than the raw fact of change reflected in our data.

Everything changes when we introduce dynamics, that is, our set of transition functions. An arbitrary local state relabeling can now be absorbed into the transition rules using the dualities that interrelate them. In this austere context we have hit upon two central ideas of gauge symmetry. (1) The variables’ states are like phases; we can detect changes and variations across the collection, but we can’t assign an invariant meaning to the states themselves. This dictates a global symmetry. (2) *The introduction of dynamics allows us to turn this into a local symmetry.*

A Boolean Network as a…Supersymmetric Gauge Field?

As we think about this more deeply we start to see some subtleties. There is another relabeling freedom in the collection of variables—the labeling of the variables themselves. We can permute the labeling, and as long as we do this consistently throughout our recorded history—prior to any assumption of dynamics—we change nothing essential in the record. On the other hand, if we have segments of a history that precede and follow relabelings of variables we must remember the permutations that were performed in order to compare the segments.

Now, let us consider again what happens when we perform a local relabeling of states and absorb the relabeling into the set of transition functions. The functions fall into at most 16 distinct classes or types; of course we may not have used all the types in equal proportions. The absorption of the state relabeling will transform the type of the affected functions, and the distribution of transition functions assigned to the variables among the possible classes will change, in general. Of course, in a very large Boolean network of this type with suitable statistical properties, the distribution may not change much at all. Indeed, we may merely witness what appears to be merely a shuffling—a permutation—of the *positions* of the affected instances of the 16 classes with respect to the labeling of the variables. It is quite conceivable that this shuffling could be *undone* by following the state relabeling with a relabeling of the variables, which implies a relabeling of the transition functions assigned to them.

It is clear that understanding the structure of these transformations is becoming rather delicate, and the structure—the geometry—of the simplicial complex is deeply involved. However, we can at least offer the observation that the internal gauge transformation—the state relabeling—appears to be intertwined with the “external” or positional transformation, ie, the selective relabeling of the Boolean variables. Indeed, they seem to be in some sense inseparable. This strikes me as deeply reminiscent of supersymmetry.

A Boolean Network as a Generator of a Causal Set

What precisely is being preserved in the gauge transformations we have been discussing? I hope it quite clear by now that the relabeling transformations preserve the identity of *events* or state transitions in our collection, and the causal connections among those events. In other words, the collection’s history has an invariant temporal “skeleton” which fits the description of a causal set. For those who are unfamiliar with causal set theory the significance of this can be better appreciated after reading a review such as this September 2003 article by Rafael Sorkin:

Causal Sets: Discrete Gravity (Notes for the Valdivia Summer School)

Also, in January, a highly speculative but extremely interesting and detailed preprint by Seth Lloyd appeared that sets forth an attempt to ground general relativity, and by implication, quantum gravity, in quantum computation. The idea, roughly speaking, is to generate the causal and metric structure of spacetime out of the dynamics of an ensemble of qubits. Lloyd acknowledges that his approach, as an attack on the problem of quantum gravity, is closest in spirit to causal set theory among the various competing alternatives.

What of Spinors and Clifford Algebras?

I will cut this short and simply assert that the relevance and role of spinors is near at hand. The reasoning behind this is still sketchy (like most of the above) but is deeply inspired by the following two articles, to be read in the given order:

Relativity in binary systems as root of quantum mechanics and space-time
(hep-th/0408116)

Spin foams, causal links and geometry-induced interactions
(hep-th/0403137)

Pregeometry and Entropy

In closing, I should acknowledge that the potential role of Jaynes’ Maximum Entropy principle has played a central role in my thinking about these questions for over 15 years. I recently attempted to sum this up in an email to Lee Smolin (8/5/2004) which can be taken as something of a manifesto:

Dear Dr. Smolin,

See http://www.arxiv.org/abs/nlin.AO/0408007. I thought this paper would be of particular interest to you, in light of your recent preprint (hep-th/0407213) and your past collaboration with Stuart Kauffman and long-standing interest in the structures of discrete networks and their relevance to spin networks and quantum gravity.

This new paper is to my mind relevant to the effort to put putative explanations of "anthropic" features of the universe on a sound scientific basis. The general point of view I have in mind is this:

One would like to in some sense show that:

- the fundamental theme of entropy maximization under constraints underlies the laws of physics and the structure of spacetime, and ultimately, cosmological structure and evolution,
- at the same time underlies the evolution of biological systems and, ultimately, sentient life,
- and *binds the two realms together* in a way that genuinely explains the familiar observations that have previously motivated the more problematic formulations of the anthropic principle.

The key element is this: Rather than suppose that there is a kind of super-universal selection of law-like alternatives (including values of fundamental constants), imagine that a sort of optimization through maximally unbiased selection constitutes, in essence, the foundation of physical law. Of course one might reasonably ask if this is so different than more conventional formulations. That is, fundamental symmetries provide the constraints, and some sort of selection sorts out the alternatives allowed by these constraints. The crucial question becomes, does this selection happen in time, along the lines suggested by biological evolution, or does it effectively happen outside of time, via a kind of timeless optimization principle? The latter is suggested by the intimate relationship of variational action principles and symmetries of an action functional. Can such extremization under variation be understood or recast as a entropy maximization under constraints?

Given the profound connection of MaxEnt principles to statistical mechanics and thermodynamics, and the equally profound "thermodynamic" character of general relativity, as witnessed for example in Ted Jacobson's gr-qc/9504004, one wonders if this might not be the preferred avenue to explore.

However, in his article Jacobson expresses a traditional point of view. If a putatively fundamental physical law has the character of a thermodynamic equation of state, then it can't be that fundamental. There must be a complicated microstructure (and micro-dynamics) underlying it whose governing law is obscured by statistical regularities. I am suggesting, in essence, that the statistical regularities are most of the story. The underlying microstructure is primordial, not derived (ie, not a "solution"), and possesses some primitive combinatorial symmetries and nothing more. Everything else comes out of a kind of statistical optimization (entropy maximization?) of the microstructure subject to its symmetries.

I would suggest furthermore that the symmetries follow largely from background independence of the microstructure. Because its possible configurations cannot be distinguished by differences in their "pinning" to a background, they must fall into equivalence classes — probably very large equivalence classes. This is fertile ground on which to build a potent kind of statistical mechanics.

What remains, then, is to say something more definite about the nature of the microstructure.

8.
March 13, 2005

I don't get it. Why is a theory bad if it does not explain the gauge coupling strengths, the Yukawa couplings and the exact matter content? In principle, the standard model is enough to determine the unitary evolution. Why must we explain the parameters of the standard model? Why can't they just be what they are?

9. **Alejandro**
March 13, 2005

A serious puzzle when trying to relate Clifford algebras to the real world is the existence of three generations of particles, all having equal charges. I mean, you can suspect that the fact of having fermions around could have a geometrical motivation, and you can even be happy about having four fermions which you could perhaps use to build a well oriented slice of space time or whatever geometrical construct. But 12 formions? What in the hell does Nature expects we should do with them?

Peter wrote:

If one believes in a deep relation between physics and geometry, these Clifford modules should somehow come into play in the structure of the most fundamental physical theories. To some extent this is already in evidence in the way spinors and the Dirac operator occur in the standard model. There are also tantalizing relations between the idea of supersymmetry and the Clifford algebra story. Many, many people have been motivated by this kind of idea over the years to try and use Clifford algebras to come up with a fundamental particle theory, one that would explain the structure of the standard model. While some of these attempts have very interesting features, none of them yet seems to me to have gotten to the heart of the matter and used this kind of geometry to give a really convincing explanation of how it is related to the standard model. Some crucial idea still seems to be missing.

Peter, everyone: With all due respect, trying to use the Clifford algebras to "come up with a fundamental particle theory" that "would explain the structure of the standard model," actually could be the reason that "some crucial idea still seems to be missing." However, please understand: in making this statement it's not my intention to attack the greatest intellectual achievement of the 20th Century by suggesting this.

Nevertheless, I believe that it's important to recognize that string theory exists as a direct result of trying to avoid the difficulties of a "fundamental particle theory," and maybe we need to consider that the need to resort to the concept of fields was motivated in the same way: the idea that the existence of a fundamental particle, or set of fundamental particles, can explain nature, seems to be misguided.

However, replacing the point particle with the concept of a field, and the idea of force with the concept of interaction, does not change the basic assumption underlying a theory of fundamental particles, anymore than replacing it with the concept of a vibrating string does, even though we can point to the "spectacular" success of QED/QCD, and string theorists can point to the "astounding" beauty of their M theory. As we all know, the most important aspects of any theory for investigators is its failures, not its successes.

The most obvious failure of the standard model is its lack of an explanation of mass and the associated interaction (force) of gravity, yet we steadfastly fail to see this as a failure of a "fundamental particle theory." Frankly, though, what this seems to be shouting at us is that we really need to look for an alternative to a fundamental particle theory. If there is indeed "a deep relation between physics and geometry," and "these Clifford modules [actually do] come into play in the structure of the most fundamental physical theories," shouldn't we stop trying to force that structure into a particle theory and look for an alternative?

"What is time" is a question so profound that it is beyond mathematics to try to find an answer. The concept of time and time arrow inheritantly associates with the concept of causality. If there is no causal relationship between things, then time does not exist. But is the causal relationship just our perceptions of the world, or is it part of the reality?

It doesn't have to be that hard, though. Time has the same effect on motion that space does, and space, while it's also a problematic concept in some ways, it's not as mysterious. However, it's the concept of space and time in the definition of motion that is important.

Clifford algebra recognizes this in its noncommutativity: a^b = -b^a, a directed area. Clockwise rotation is different than counter-clockwise rotation. It doesn't mean that time can run backwards, but it does mean that there is an inverse, a mirror image to all directions, and if it exists in all directions then it follows that it exists in the relationship of space and time, or motion, as well. In fact, we can see it: A decrease in time has the same effect on motion as an increase in space. They are reciprocally related. That's the important thing to understand.

This reciprocity in turn implies a deeper symmetry: whereas time continuously progresses, so should space; and whereas space has three dimensions, so should time. Now that we can actually observe the progression of space in the receding galaxies, we are even more justified in assuming three dimensions of time to complete the symmetry, which, of course, means three independent dimensions of motion should exist as well.

In Cl3, we see a similar symmetry: 1 scalar, 3 vectors | 3 bivectors, 1 pseudoscalar. What does this mean? I'll offer one, simple, but profound idea: The scalar magnitude of motion can easily progress continuously outward from the origin of vectors (outward translational paths diverge, think of expanding volume), but, on the other hand, it cannot continuously progress inward translationally in the same manner lest, passing zero, it again becomes outward motion (inward translational motion converges, think of shrinking volume). Therefore, for continuous inward scalar motion to exist, it must exist as a rotation, not a translation.

To find that these two fundamental modes of scalar motion are represented perfectly in Clifford algebra, is sobering.

Peter, I am somewhat concerned that this message may be drifting off-topic with respect to this thread subject of Clifford algebras, so it is OK with me if you delete it, but I am initially posting it mostly to respond to a couple of comments by others.

Quantoken, you say, about my approach: "… That is not how a theory gets accepted as science. … acceptance of a science is really acceptance by the general public …".
My objective is NOT for my model to be "… accepted … by the general public …". It is for my model to be available in the archived records of physics so that anyone who is interested in it can study it, criticize it, and perhaps improve it or make use of it or some part of it.
You also say: "… if at the end of day, only ten people out of the whole population of this planet manage to figure out what your theory is all about, and agree with you. So you have acceptance of 10 people. Does that make your theory an accepted scientific theory? No. …".
Actually, I would be happy if 10 people figured it out and accepted it. As I said above, my objective is NOT to make my model THE accepted theory.
In fact, I think that the current abysmal situation with superstring theory shows that it is BAD for ANY single model (mine included) to become so "accepted" that alternatives cannot be made available in the archived records of physics for evaluation by anyone with interest. The "archive" part is important, because sometimes it is decades before some useful stuff is appreciated as being useful.

Steve M, you say that you "… think your work is more suited to something like Journal of Mathematical Physics, Communications in Mathematical Physics or Advances in Theo. Math Phys. J. Math. Phys. … Phys. Rev. D is rigid and pretty conservative …".
My comments here may have been misleading to you in that I have emphasized mathematical structures. However,
I consider the phenomenological part of my model (not mentioned by me hereinbefore because of less connection with the topic of Clifford algebras) to be equally important. An example is the relevance of my model to the interpretation of Fermilab's T-quark event data, and the idea (based on a paper by Froggatt at http://xxx.lanl.gov/abs/hep-ph/0307138) that the data show not one single peak for the T-quark at around 170 GeV, but also two other peaks (one higher, one lower) that can be reasonably interpreted by seeing the Fermilab T-quark data as showing three peaks coming from a T-quark – Higgs – Vacuum system. Such material seems to me to be off-topic for the mostly purely mathematical journals that you recommend. It is my opinion that the most appropriate journal (in my home country of the USA) that covers both the math/theory and phenomenology aspects of my model is Phys. Rev.D, which is why I chose it as the journal for my prize offer.

Tony Smith said:

"Unless someone is already familiar with ALL of those things, they CANNOT understand my model without spending a lot of time and effort on learning background material that may not be of interest to them for any other reason."

Tony, I am troubled by that and your $100,000 reward. That is not how a theory gets accepted as science. Put it this way, if at the end of day, only ten people out of the whole population of this planet manage to figure out what your theory is all about, and agree with you. So you have acceptance of 10 people. Does that make your theory an accepted scientific theory? No. You could argue that your theory is correct, it is only because 99.9999% people are unwilling to spend the time to try to understand your theory. But that is useless.

Let's look at another example. Super string theory. Seemingly this is an **"accepted"** theory at current time, despite of the fact that it's unable to make any predictions. Super string theory is taught on almost every colleague campuses and many students accept it because their teachers seem to accept it. As for the general public, they are unable to understand the math involved, but they too have learned a few basic ideas like elementary particles are made of little ringy strings, etc. And they have watched scifi movies about wormholes and cosmic strings and such, and think those stuff are neat and cool. So they too, accept super string theory as a legitimate scientific theory.

So, at currently time, super string theory is a theory **accepted** by the general public and the general scientific community, and opponents are only minority, due to the propagation. That's a sad fact.

But it could change, eventually people will say: This thing can't make any predictions and seem to be useless, why should we accept it and continue to support it? By the time, there may still be a couple thousands "experts" in this field that continue to believe in the stuff, including all of the well known names like Witten, Lubos, Vafa etc. But they will be a minority groups and marginize and be reject as a colt group, once the GENERAL PUBLIC, I repeat, the GENERAL PUBLIC, not the elite peoples in ivory towers, become uninterested in the ideas. You can argue: "But I am the expert in the field" but it really doesn't help you if your whole field is rejected by the general "none-experts".

So acceptance of a science is really acceptance by the **general public**, not just acceptance by a elite group. Another example is General Relativity. There is a saying that initially there were only 12 people in the world who can understand GR. If it stay that way, GR will never become an accepted scientific theory. The truth is even most people are unable to understand the tensor mathematics. They are perfectly capable of underdstanding, and accepting the equivalence principle, so they have no problem accepting the GR as a correct theory derived from equivalence principle.

So my point is, whatever theory you have, to have any hope of being accepted. You must be able to describe the **basic idea or basic principle** in very simple language, to the general public. So even the general public can accept the basic principles of your theory. Then those interested can further study the detailed mathematics.

Science is not an enterprise in the ivory tower. Science is an enterprise in which not only researchers exchange ideas among themselves. But they also need to actively promote their ideas to the widest audiences in the general public.

That's why it's so important for dissident scientists like Peter et all, to turn towards the general public audience, and explain to them why there is a problem and why string theory does not work. The big problem is different opinions are **SUPPRESSED** in the public medias, so the public never realize that the main stream scientific theories have problems in them!

It seems to me that the idea that beautiful mathematics will lead to new physical principles is as likely to succeed as string theory. I think it is the other way round, mostly, physical insight bends beautiful mathematics into its service. However, there seems to be no other way to proceed, so I can only hope that someone is successful.

16. **Steve M**
March 12, 2005

Hi Tony,
$100,000 eh?:). I am a (theoretical) physicist and have also worked as a freelance editor/copyeditor in the past for some pretty technical stuff in physics and biology. If I could make a few points. First I think your work is more suited to something like Journal of Mathematical Physics, Communications in Mathematical Physics or Advances in Theo. Math Phys. J. Math. Phys. is particularly open to new mathematical approaches and interpretations to physical problems and for development of mathematical ideas relevant to the formulation of physical theories. They publish some really mathematically dense and technical stuff. Second, I think you should be flexible about the title. As a journal Phys. Rev. D is rigid and pretty conservative. They reject a lot of technically sound papers (probably the most interesting ones).

Generally, it is very difficult to get a "new paradigm" published and accepted by the community (dreadful word I know:) especially as a single author, and much easier to publish something interesting or minor within an ongoing and accepted research direction. At any rate, a totally professional Latex presentation is always essential nowadays. Two or three readable shorter papers is also better than a huge submission, which is offputting to reviewers. A thorough review of the existing literature relevant to the problems you are attempting to solve is always essential, explaining what you think are the shortcomings of the standard approaches and why your approach might make progress where others have failed. It is also better to be have a modest but interesting presentation style/title rather than making huge claims. Making massive claims in titles and abstracts and having a pompous and self-important style of presentation (I am not saying this applies to you)usually results in a crackpot label and instant rejection, even if the paper has a lot of substance and very good ideas. Anyway, these are just some thoughts based on my experiences both editing papers and publishing my own.
regards

17. **Tony Smith**
March 12, 2005

Hi Garrett. You say that I should use LaTex in a self-contained introductory paper. Actually, back in the days before I was blacklisted, I did put up such a paper on what is now known as arXiv. It is at http://xxx.lanl.gov/abs/hep-ph/9501252 It does not incorporate some changes and corrections that I have made in the last 10 years, but the basic ideas are similar. It is over 100 pages long, and the part about the Mayer-Trautman-Kobayashi-Nomizu material does not appear until about page 60 or so.
Even though it was extensive and in LaTex, nobody paid any (contructive) attention to it, so I really don't think that any lack of the LaTex look is why people don't understand it. I think that the real difficulty is that you cannot formulate the model without using such things as:
1 – Clifford algebras;
2 – Quaternions and Octonions;
3 – the Mayer-Trautman-Kobayashi-Nomizu material;
4 – theory of bounded complex domains and their Shilov boundaries, as described by L. K. Hua in his book Harmonic Analysis of Functions of Several Complex Variables in the Classical Domains by Hua (Am. Math. Soc., 1979;
5 – generalization of MacDowell-Mansouri mechanism for gravity;
6 – I. E. Segal's conformal gravity material; and
7 – how to generalize the Hyperfinite II1 von Neumann factor to the case of real Clifford algebras from the case of complex Clifford algebras on which the usual Hyperfinite II1 von Neumann factor is based.
8 – For the lattice version of my model, familiarity with generalization of the Feynman Checkerboard is needed (see my paper at CERN-CDS-EXT-2004-030).?

Unless someone is already familiar with ALL of those things, they CANNOT understand my model without spending a lot of time and effort on learning background material that may not be of interest to them for any other reason.

Since I am a lone individual with no institution that could provide grants or jobs related to studying my work, it is understandable that nobody would spend such time and effort.

It is with that in mind that I have put up a $100,000 prize for the first person to meet its conditions, which include writing up my model, getting it posted on archives in

arXiv, and getting it published in Phys. Rev. D. A statement of the prize details is at http://www.valdostamuseum.org/hamsmith/VoDouPhysicsPrizeV.html
Maybe nobody will try to do the work for the prize, but on the other hand maybe somebody will, and at least the first person who succeeds will get some money for the time and effort expended.

Tony Smith http://www.valdostamuseum.org/hamsmith/

March 12, 2005

Doug:

"What is time" is a question so profound that it is beyond mathematics to try to find an answer. The concept of time and time arrow inheritantly associates with the concept of causality. If there is no causal relationship between things, then time does not exist. But is the causal relationship just our perceptions of the world, or is it part of the reality?

Mathematics, on another hand, is totally incapable to understand what is causality. Because causality relationships do NOT exist in any branch of mathematics. In math you can say 2+3=5, or you can say 5-3=2. But among 2,3,5, who is the cause, and who is the result caused by the cause? The answer is none, "2+3=5" is NOT the reason why "5-3=2", nor is it a result of "5-3=2". They are equivalent to each other but does not depend on each other as cause and result, so there is no causal relationship.

All of our difficulties in understand spacetime is because math does NOT have a causality relationship, but causal relationship must be introduced to understand time properly.

March 12, 2005

Hi Peter,
First off, thanks for keeping such a cool journal — and for being a voice of reason speaking out on the current physics emperor's state of undress. Your posts and the poignant reactions to them have been very amusing to read. You've also now hit upon a subject close to my heart — it always bothered me that spinor fields seemed to be "cooked up" rather than really derived from geometry, so I got drawn into looking around for a better way. I've also been inspired by the attempts to derive the structure of the standard model using Clifford algebra — so far my favorite has been by Greg Trayling:

http://arxiv.org/abs/hep-th/9912231

The only cool thing I've found myself is a way of deriving spinors as BRST ghosts associated with the Clifford adjoint invariance of a frame in GR:

http://arxiv.org/abs/gr-qc/0212041

That's the closest I've been able to get to a true geometric derivation of what spinor fields are. Using that and Kaluza-Klein to connect with Trayling's work has been giving me fits because it's so close but not quite there. The universe doesn't just laugh at string theorists.

I see that Tony Smith is hanging around your journal as well (Hi Tony). I have looked around at his stuff, and found it to be very interesting and potentially good but I only wish he would spend the painful extra time necessary on exposition for people without his same eclectic background. If he put together an introductory paper to his stuff, maybe even using LaTeX… he'd probably get a much better reception, and I for one would have a better chance at really getting some of what he's saying. He especially needs to keep in mind people are lazy and need straightforward presentations of background material all in one place, rather than just references.

Anyway, good to finally come out from lurking and post something here.

Best,
Garrett

20. **Doug**
March 11, 2005

If fundamental physics deals with the matters of space and time, and fundamental mathematics deals with the matters of geometry, then the connection between the two should not be surprising, because ultimately geometry is the study of space. When advances in mathematics enabled men to add time concepts to these geometrical aspects, mathematics became indispensable to the investigators of physics.

However, it's the fundamentals of space and time that are the core of physics, not the mathematical expressions of space-like and time-like constructs, or various unions of these. The fact that spinors are a mathematical construct hearkens back to others, more primitive, but similar, such as Pythagoras' theorem. Clearly, Pythagoras' theorem tells us something about space and spinors tell us something about time, but whatever it is can be misleading if we begin to think of these properties as real. Space can have no meaning without time because you can't draw a line without the time to do it. Time can have no meaning without space, because, no matter how much time you have, you can't rotate it.

All that this suggests is that "the deep relationship between Clifford algebras and spinors, geometry, index theory and physics," exists because of the deep relationship between space and time. That relationship is reciprocal and symmetrical in the equation of motion, just like the 8 hour "Clifford clock," is reciprocal and symmetrical. What Lubos apparently doesn't understand is that the difference between the elementary and sophisticated is not profundity, but elaboration. The profound secrets we seek to uncover are hidden in the simple, but correct relationship of space and time. Sophisticated elaboration of an incorrect understanding of this elemental relationship only serves to further obscure the error.

21. **Tony Smith**
March 11, 2005

Peter, you say that you "… wonder if you [Tony] really strongly disagree [with the thought that] … there is a crucial idea missing here … what seems to me [Peter] to be missing is some deeper link between the geometry and the dynamics …".

I can see how what I think is an intuitively natural link between the geometry and the dynamics might appear to others as an ad hoc construction.

Roughly (again ignoring a lot of technicalities) the way that I link geometry and dynamics is:

1 – describe dynamics by a Lagrangian;

2 – define the Lagrangian in terms of Clifford algebra structure:

a – the 8-dim spacetime over which integration takes place is represented by the 8-dim vectors

b – the gauge term in the Lagrangian is based on the 28-dim bivectors

c – the Dirac term is based on the 8-dim fermions and antifermions.

3 – See what happens to the Lagrangian when the freezing/choice of a quaternionic subspace of the initial 8-dim spacetime changes it to a Lagrangian over a 4-dim spacetime. This is highly nontrivial but it does take you from a very simple-looking Lagrangian with 8-dim spacetime to a much more complicated one with 4-dim spacetime, but it turns out that the complicated 4-dim Lagrangian is actually quite realistic.
This is done by using some geometric techniques done about 20 years ago by Meinhard Mayer http://www.ps.uci.edu/physics/mayer.html who worked with A. Trautman. They used some key ideas from Kobayashi and Nomizu's book Foundations of Differential Geometry, vol. 1 (John Wiley 1963), particularly Proposition 11.4 of chapter II, and their work in some detail can be found in Hadronic Journal 4 (1981) 108-152, and also articles in New Developments in Mathematical Physics, 20th Universitatswochen fur Kernphysik in Schladming in February 1981 (ed. by Mitter and Pittner), Springer-Verlag 1981, which articles are:
A Brief Introduction to the Geometry of Gauge Fields (written with Trautman);
The Geometry of Symmetry Breaking in Gauge Theories; and
Geometric Aspects of Quantized Gauge Theories.

It may be from some points of view regrettable that my link between geometric structures and Lagrangian dynamics is heavily dependent on really understanding that material, but that is the way it is.
If the Mayer-Troutman-Kobayashi-Nomizu material seems so natural to you that it is (to use a phrase that is sort of a joke among mathematicians) intuitively obvious, then my link might seem natural.
Otherwise, my link would probably be thought of as a missing link.

The details are in my papers and web site, but I am not the world's best expositor (I wish I has 1/10 the talent of John Baez in that regard).

Anyhow, long story short, if anyone does not clearly understand the Mayer-Troutman-Kobayashi-Nomizu material then they will definitely not see my model as a natural construction.

On the other hand, when (years ago) I began to work through the 8-to-4 dimensional reduction part of my model using the Mayer-Troutman-Kobayashi-Nomizu material and to see how after grinding out the results that they actually look realistic, it made me think that there must be something fundamentally right/useful about the work.

I could go into more material related to dynamics of Lagrangians and path integral quantization, but this comment is already long and I thought that the most basic point was how the parts of the Clifford algebra give a realistic 4-dim Lagrangian, which is fundamentally an application of the Mayer-Troutman-Kobayashi-Nomizu material.

Peter said:

"But it definitely is one of my deepest beliefs that the most fundamental structures in mathematics are intimately connected with the most fundamental structures in physics. There seems to me to be a lot of evidence for this."

I can almost totally agree with you, except for one small reservation (which is actually not small). That is, what is considered **"most fundamental structures in mathematics"** is really "in the eyes of the beholder". i.e., it's totally opinious unless that judgement (what is more fundamental) is guided by empirical physics experimental evidences.

Mathematics is much bigger than physics. There are infinitely many possible self-consistent theories in mathematics. It's hard to make a judgement what is fundamental and what is not. And not all mathematics can have something to do with physics. Number theories, or the study of prime numbers or such, seems totally unrelated to physics. At least all I know, any prime numbers bigger than trivial ones like 2,3,5, never occurs in any physics formulas. The string theory, for it's "11" dimentions, may break this rule. But then maybe not if ultimately it's shown that string theory has nothing to do with physics:-)

Tom Smith, what you claim seems to be interesting if it is true:

"In short, you get all the particles of the Standard Model and none of the unobserved wino, gluino, squark, zino, etc particles of naive 1-1 supersymmetry, and you get reasonable values for all the otherwise ad hoc parameters of the Standard Model. "

But I glanzed at your web in the past and could not associate its content, which is hard to read and understand, with your claim. Maybe I will try to spend a little bit time figuring out exactly what your ideas are.

March 11, 2005

Hi Tony,
Sure, you're one of the people I had in mind when I wrote the posting. I've always been intrigued by the kind of thing you're doing (and think it's absurd that the arxiv happily accepts absurd string theory related papers but not yours). But I still think there is a crucial idea missing here and wonder if you really strongly disagree with this. To be a little more specific, what seems to me to be missing is some deeper link between the geometry and the dynamics. In the path integral formalism, why are we integrating over a space of connections the exponential of the norm squared of the curvature of the connection? Why the determinant of the Dirac operator? I tend to think we need some insight into these mysteries in addition to more kinematical ideas about Clifford algebras.

24. **Tony Smith**
March 11, 2005

Peter, you say:
"… none of … [the] attempts … to try and use Clifford algebras to come up with a fundamental particle theory … yet seems to me [Peter] … to give a really convincing explanation of how it is related to the standard model. …".

I cannot disagree with that statement because "seems to me [Peter]" is a statement of subjective opinion and you [Peter] are certainly entitled to your opinion.

Also, Lubos asked:
"… Which "ideas" exactly do you think would "explain the structure of the Standard Model"? …".

About the only strictly relevant thing that I can say is that I am one of the "… Many, many people [who] have been motivated by this kind of idea …", and that my efforts use structures related to Cl(8) which, as John Baez points out in his week 211 (among other writings) is, due to real 8-periodicity, a natural building block of any arbitrarily large real Clifford algebra. Roughly (ignoring many technical details) my physical interpretation is:

The 8-dim vector part of Cl(8) represents an 8-dim spacetime;

The 28-dim bivector part of Cl(8) represents 28 gauge bosons;

The 8-dim +half-spinor part of Cl(8) represents 8 first-generation fermion particles (e-; r,g,b up quarks; r,g,b down quarks; nu_e);

The 8-dim -half-spinor part of Cl(8) represents 8 first-generation fermion anti-particles (e+; r,g,b up anti-quarks; r,g,b down anti-quarks; anti-nu_e).

If you break the 8-dim spacetime into a 4-dim physical spacetime plus a 4-dim internal symmetry space,
by freezing out at low (current experimental energy levels) a particular quaternionic subspace, then:

The 28 gauge bosons split into 16 for U(2,2) which contains the conformal group SU(2,2) = Spin(2,4) which along the lines of work of I. E. Segal and MacDowell and Mansouri give you an Einstein-Hilbert lagrangian etc plus 12 for the SU(3)xSU(2)xU(1) Standard Model; and the fermion particles and antiparticles get a 3-generation structure.

If you look at the geometric structures in a way motivated by (but not identical to) the work of Armand Wyler, then you can unambigously calculate particle mass and force strength ratios, getting results that are at tree level quite realistic if you consider the quark masses to be constituent quark masses.

In short, you get all the particles of the Standard Model and none of the unobserved wino, gluino, squark, zino, etc particles of naive 1-1 supersymmetry, and you get reasonable values for all the otherwise ad hoc parameters of the Standard Model.

It is OK with me if you [Peter], Lubos, and anyone else find my structure unconvincing, because that is just an expression of your personal opinions and tastes, but it would be interesting to imagine what the PR blitz would be if a prominent string theorist were to come up with similar results.

Details of my work exist, but they are too long for this message. However, they can be found on my web site and on a few papers such as CERN EXT-2003-087 which I was able to post before CERN terminated the EXT series (in October 2004, possibly at the behest of arXiv, which has blacklisted some people including me and may have been unhappy that CERN EXT provided a way for some of us blacklisted people to post our work where it might be preserved for posterity (note that web sites, ISPs, etc come and go, and CERN's web site is likely to last much longer than any web site I might have)).

Tony Smith http://www.valdostamuseum.org/hamsmith/

25. **Peter**
March 11, 2005

Hi z,

I'm a bit leery of the term "beauty" in this context, what with "all in the eye of the beholder" and everything. Somewhere on the internet there's an argument between me and Lubos about the beauty of string theory.

But it definitely is one of my deepest beliefs that the most fundamental structures in mathematics are intimately connected with the most fundamental structures in physics. There seems to me to be a lot of evidence for this. In my posting I was explaining a bit about how fundamental Clifford algebras and spinors are in geometry (and I didn't even get into their importance in K-theory). One of the other most fundamental ideas in modern geometry is that of a connection and its curvature. The fact that all these structures show up in the standard model seems to me not a coincidence.

But neither mathematics nor physics is a finished subject. As another commenter mentioned, it's still a matter of debate among mathematicians whether we really understand the right way to think about the geometry of spin. We know spinors are fundamental because they are the representations we can build all others out of. But there are several different ways of constructing spinors, some that don't use Clifford algebras at all (see e.g. Graeme Segal's Borel-Weil sort of construction as a space of holomorphic sections). Clifford algebras are part of the story, but maybe not the most fundamental one. I don't think we know yet. Similarly, in physics we know that spinor fields, the Dirac equation, connections and the Yang-Mills functional are fundamental parts of the story, because we have strong experimental evidence for this. But there quite possibly is some more fundamental way of looking at these things, one which would give us the right idea about how to get beyond the standard model. I'm guessing that such a new idea exists, but is missing now, and that whatever it is, it will be related to some new perspective on the geometry of spin.

There's more detailed speculation of this kind in my paper of "Quantum Field Theory and Representation Theory". Maybe I'm wrong, and in any case, it's certainly historically been true that theorists have needed help from experiments to figure out what the right fundamental mathematical structures are. But in these times of no help from experiment, I don't think we have much choice but to try and see if mathematical insights can help us see which way to go with the physical theory.

26. **quantoken**
March 11, 2005

Z:

It's a profound philosphical question that has been debated for thousands of years. That is whether fundamental physics structures, like the standard model, can be derived from fundamental mathematics structures, like say if there can be a mathematics based theory naturally leads to the particular value of all 17 free parameters of the standard model, or you can not?

Every one can have an opinion on that. But I think it's far from being settled. So it is totally legitimate for Peter to ask that profound question as being insightful, and it is childish for Lubos to question Peter's intelligence in raising the legitimate question.

Personally, I do believe that the standard model as we know it, must be reducible in some way. Not all 17 free parameters can be foundamental. There must be a connection between them and there must be a mathematical model describing that connection, and therefore it would allow us to reduce the standard model into something simpler with less number of free parameters.

But I do not believe physics can be reduced to pure mathematics. When the ultimate theory of everything is discovered, you would have reduced all physics parameters to just a few, or maybe just one, the famous alpha. But you can not reduce it further to zero free parameter. The very last un-explained physics constant, be it alpha, would have absolute no mathematical explanation whatsoever why it is the value it is. It is just happenedness, just the way it is in this universe, with no more question allowed to be asked why or how.

Peter said:

“Many, many people have been motivated by this kind of idea over the years to try and use Clifford algebras to come up with a fundamental particle theory, one that would explain the structure of the standard model.”

I can sympatize with these attempts–wouldn’t it be neat if some simple/nice algebraic structure were behind our “fundamental” theories? However, this kind of an approach tends to remind me that of trying to use platonic solids in planetary astoronomy. That, too, would have been neat if it worked.

I find Peter’s last sentence

“Some crucial idea still seems to be missing.”

rather strange. There seems to be a presumption here, that this idea of explaining the structure of the standard model by using Clifford algebras in some cool way is, in fact, correct.

There is no strong evidence for this. Beauty of a mathematical structure does not guarantee its relation to a field of physics of one’s choice.

I have to say I am rather amused by seeing this kind of a statement about such an issue, made by Peter.

z

March 11, 2005

E:

Indeed this is an open question far from being settled. And peter is rightful in pointing that Lubos had said nothing intelligent but just personal attacks. But forgive him for feeling depressed a bit that people are unable to post comments on his weblog this past few days.

And why do you think Lubos is a “prominent” figure, just because he made himself famous by being active on the internet? He is just a junior assistant professor. In my judgements, Lubos is a smart guy and he may have learned a bit of math tools useful for string theory research but he is absolutely lacking in basic physics instinctions that I think any one with some good basic training in general physics should have.

One good example is he could not think of a possible method of measuring solar radiation intensity above the atmosphere, without a tool or mean to actually go above the atmosphere to measure it.

Quantoken

29. **E**
March 11, 2005

Dear Lubos,

You may be misunderstanding something… or perhaps you are simply part of a muscular new wave within the academy.

Peter is simply aligning himself on one side of a decades-old debate between some of the most distinguished living mathematicians. On one side are mathematicians, like Singer, who believe that after the rediscovery of the Dirac operator, spinors have been nearly perfectly understood. On the other side are mathematicians, like Sullivan, who have amassed evidence that we are merely nibbling around the edges of a giant poorly understood structure.

I suppose what suprises me is that someone as prominent as yourself could be simply unaware of the debate. Perhaps physicists have recently resolved this issues amongst themselves. Mathematicians are probably nowhere close to this point. Look at how long it took both groups to replace self-dual equations with SW. Think of how mysterious the spinor condition was in the role of the rigidity of the signature operator on loop space.

I myself am not sure which group is correct, but the idea of personally deriding people like Lawson, Sullivan, Woit, Bourguignon, Taubes, Hitchin, who have spoken publically about this belief in the incompleteness of spinor theory is quite bold (given the above).

Of course, I have heard Is Singer explain his convictions on this point which I suppose vaguely echo your beliefs. But even given his role in the history of the Dirac operator, he was always humbly aware that he might be wrong. Perhaps your impatience indicates that you will soon delight us with profound contributions in this area that will settle this debate conclusively. Should that happen, we will all be glad for the light shed on this fascinating topic.

I will read your blog with interest and wish you every success.

30. **Peter**
March 11, 2005

If anyone has anything intelligent to say about the topic of my posting, please do so, but I’ve already had to delete comments from people who think an intelligent response to anything I write is to personally attack me. If string theorists feel my comments about string theory are attacks on them and feel the need to personally attack me when I write about string theory, that’s fine. But I’m not going to put up with juvenile attacks based on my explanations of what a Clifford module is.

31. **Lubos Motl**
March 11, 2005

I just can’t resist. Your last paragraph, Peter, is such an incredible stupidity that I must emphasize it a bit more clearly.

Spinors and Clifford algebras are of course closely related and this relation is well understood. By “understood”, I don’t mean that everyone understands everything about it. I mean that mathematicians and physicists have understood it for decades (especially the physical consequences of it), in most aspects long time before the Standard Model was constructed. Spinors and their properties are just an elementary mathematical piece of a Standard Model, one of many technicalities. Spinors in 3 or 3+1 dimensions were understood a few months after quantum mechanics was first proposed.

Which “ideas” exactly do you think would “explain the structure of the Standard Model”? Spinor is just a spinor. It’s an almost complete triviality that the physicists today must understand as undergrads. Your “ideals” about physics are equivalent to those of a high school student who learns about spinors earlier than when she’s ready to comprehend them fully.

Of course that there are “tantalizing relations between supersymmetry and Clifford algebra” – it’s because the generators of supersymmetry transform as spinors. It’s not really tantalizing; it’s elementary.

You’re making an invisible mysterious elephant out of an ordinary gray rat.

32. **Lubos Motl**
March 11, 2005

Hi Peter,

is this article directed to the laymen, or the physicists? In the latter case, I suppose that it is a part of your plan to convince all physicists to study the Dirac operator. 😉

The things you write is elementary math from the early 20th century.

Best
Lubos, 2005

33. **Jody**
March 11, 2005

Hi, Peter,

There is a very nice discussion by Atiyah of the deep relationship between Clifford algebras and spinors, geometry, index theory and physics in the short article he wrote “The Dirac equation and geometry” for the book:

Paul Dirac: The Man and His Work
Edited by Peter Goddard
Cambridge 1998

BTW: I really enjoy reading your blog! Keep up the rant.

Cheers,
Jody

Skeptical SF Chronicle Article

March 14, 2005
Categories: Uncategorized

Today's San Francisco Chronicle contains an article about string theory entitled "Theory of Everything" Tying Researchers Up In Knots. It's by science writer Keay Davidson, and is about the most skeptical article on string theory I've seen in the mainstream press. The lead sentence is:

"The most celebrated theory in modern physics faces increasing attacks from skeptics who fear it has lured a generation of researchers down an intellectual dead end."

Davidson contrasts Michio Kaku's very pro-string theory point of view in his new book Parallel Worlds, with the much more skeptical views of Lawrence Krauss, who evidently has a book entitled "Hiding in the Mirror: The Mysterious Allure of Extra Dimensions" coming out in September. He also got comments about the current state of string theory from quite a few different people, including yours truly. The article contains a link to this weblog.

Some of the string theory critics quoted are just inherently opposed to any new mathematical approach to fundamental physics, something I have no sympathy with. One of these is Stanford's Robert Laughlin, who makes the point that string theorists are trying to camouflage the theory's increasingly obvious flaws by comparing the theory to "a 50-year-old woman wearing way too much lipstick." Because of Laughlin's extreme anti-mathematical theory views on the one side and those of his colleagues like Lenny Susskind on the other, "The physics department at Stanford effectively fissioned over this issue" says Laughlin. He goes on to say "I think string theory is textbook 'post-modernism' (and) fueled by irresponsible expenditures of money." For the record, I'm no more of a fan of Laughlin's views about particle theory than I am of Susskind's.

Some of the quotes from defenders of string theory are a bit strange, with none of them addressing the fundamental problem the theory is facing these days as it becomes obvious that it can't predict anything. John Schwarz is quoted as saying "string theory is the only approach that has the potential for explaining dark energy" which is kind of peculiar since it is well-known that superstring theory naturally leads one to expect a value for this energy density that is off by 120 orders of magnitude. The only way around this seems to be the "landscape" argument, in which you essentially give up any hope of ever predicting anything. The other defenders of string theory quoted in the article mainly try and claim that twenty years of work on the theory is still nowhere near enough, that it is way too early to be able to evaluate it yet. They don't give any indication of how much longer we should wait for such an evaluation, but if twenty years isn't long enough, it sounds like they hope this won't occur while they're still alive.

Update: For a very different take on this, see Lubos Motl's posting.

Comments

1. **Aaron**
   March 20, 2005

   To ksh95: You don't actually seem to have read anything I've said beyond the first sentence.

   Try, for example "On the other hand, I firmly believe that we have to practice science as if the anthropic principle were false, but that's another story."

2. **D R Lunsford**
   March 19, 2005

   ksh95, very funny, but..

   The real problem is, I don't think it's possible to argue with these folks. They just don't care. The watchword is, "Be the Wibble."

   -drl

3. **ksh95**
   March 19, 2005

   I forgot to mention, as presently formulated the anthropic principal isn't even a useful calculation tool. If, for instance, an anthropic principal based string theory could reduce the 20some parameters of the standard model to 5 parameters, then I would be at least willing to acknowledge the anthropic principal as a valuable calculation tool.

4. **ksh95**
   March 19, 2005

   Aaron said
   "…And, I agree with you that the anthropic principle is nonpredictive. My only point is that it really could be the right answer…"

   Your point of view really makes no sense to me.

   The anthropic principle can never be the right answer any more than it can be the wrong answer.

   As far as I'm concerned the anthropic is equilivant to:
   The reason Peter really started this blog, and the reason I replied to your post is because there is an acausal point in spacetime that effects all other points. That point is inside
   Wibble the three-toed chicken's head at time infinity + 7. Wibble determines the past by thinking in the future….Actually, this argument is slightly better than the anthropic principal since it may be possible to rule out
   acausal influences on present events.

   If, as you say, the anthropic principal is really the true state of the universe, then the answer produced by science **must** be that the true nature of the universe in unknowable. At this point physics reaches its end. Some go on to believe in the anthropic principal, others believe in Creation, while I believe in Wibble the three-toed chicken.

   Susskind may cloud his ideas in prose about a cloud covered earth and such things, but what he really advocates is reformulating science such that it looks something like "…If we assume A (which can never be proven or disproven) then the rest of the universe follows…"

   I say why make it hard on ourselves by letting A=multiverse. If we would have let A=Wibble the three-toed chicken we could all have avoided a lot of years of schooling.

5. **Juan R.**

March 19, 2005

Since Peter deleted my previous post, I reproduce it again but extended and without the **supposed** ?*speculations on own work*?.

During some time I wrote several comments regarding the impressive failure of stringy research. It is unnecessary a costly experiment for showing this.

The basic idea of stringy research is as follows: to take the hypothesis *A* and make one article, next neglect the hypothesis and make another article contradicting the first one. Even with this infinite malleability, string theory has shown to be a failure. Perhaps failure is a harsh strong word for sensible people, but I would remark that physics is just one of hard sciences, and ?hard? signifies hard.

Dear ??, do you know that some people is working in more than 11D whereas others are claiming for a 4D string approach?

The history of dimensionality (I do not include Kaluza-Klein) is
4D -> 26D -> 10D -> 11D -> 12D? 13D? 4D?…

History shows us that if you write two columns and at one (left) write the past claims of stringys and the other (right) our current knowledge, you find a surprising feature.

the entire left column was completely wrong!

Of course, string theorists will say you that the topic is open. *This is not an excuse!* Decades ago, stringys claimed in public that the theory was the Last Formulation. What arrogance! Some of use already knew that the elementary stringy approach could not be applied to simple piece of hot water. Now, they are using the TFD approach for a generalization of the ?old? brane theory based in the outdated Hilbert-Fock space mathematics and the standard vacuum. However, even using TFD, brane theory is still not sophisticated enough.

Therefore is not necessary experiment for understanding that string theorists are in the wrong way. I am not saying that are clever guys or no, just saying that are in the wrong way as Eisntein when ignored the rest of science and focuses on its own (wrong) idea about the world. Therefore, the recent words of Susskind are not surprising for some of us that studied string theory and pointed to its obvious flaws.
?*Many physicists hoped that string theory would be the mathematical ?silver bullet? that would uniquely explain our world. But the more we learn about cosmology and the more we learn about string theory, the less likely this seems*.?

Lisa Randall (from Harvard) says:

?*Originally, string thoeirsts hoped string theory would dictate these parameters. But this is looking increasingly unlikely*.?

On a this year comment, Witten states:

?*One of the few things we do know is that, with string theory, theoretical physicists have stumbled upon a theory that looks like it might be the unified field theory*.?

Humm… He now abandons his earlier grandiloquent evaluation of the theory and carefully uses the combination **look like it might**. Interesting!

6. **Thomas Larsson**
   March 17, 2005

   More comments on this article can be found here.

7. **Catt acolyte**
   March 17, 2005

   Witten is denounced by his mentor Penrose, 'Road to Reality' (UK ed., 2004). On page 896, Penrose analyses those who use string ?theory? as an obfuscation of gravity?s cause:

   ?In the words of Edward Witten [E. Witten, ?Reflections on the Fate of Spacetime?, Phys. Today, April 1996]:

   ? "String theory has the remarkable property of predicting gravity,"

   ?and Witten has further commented:

   ? "the fact that gravity is a consequence of string theory is one of the greatest theoretical insights ever."

   ?It should be emphasised, however, that in addition to the dimensionality issue, the string theory approach is (so far, in almost all respects) restricted to being merely a perturbation theory ??

   More at http://members.lycos.co.uk/nigelbryancook/Penrose.htm

8.
   March 16, 2005

   Lubos,

   Thank you for explaining your position. You are right: the article was weak and should have been stronger.

   I think you are however, exactly missing the point from my perspective. I hope you find this post informative; no one wants you to become yet another string theorist who never matured into a particle theorist.

   Richard Feynman (a non-expert in string theory who might have been interviewed if he were alive) left us the following admonition:

   "Details that could throw doubt on your interpretation must be given, if you know them. You must do the best you can–if you know anything at all wrong, or possibly wrong–to explain it. If you make a theory, for example, and advertise it, or put it out, then you must also put down all the facts that disagree with it, as well as those that agree with it. There is also a more subtle problem. When you have put a lot of ideas together to make an elaborate theory, you want to make sure, when explaining what it fits, that those things it fits are not just the things that gave you the idea for the theory; but that the finished theory makes something else come out right, in addition."

   Can you hear the music, or is your mind already thinking about retorts?

   Those of us non-string theorists have been waiting for the informed self-critique of string theory to come FROM the string community. Some of us have been waiting for 20 years.

Because String theory is nearly opaque to an outsider, we are actually dependent on string theorists to be their own worst critics.

By all means Lubos, save us from the Woits, the Andersons, the Friedans, the Feynmans, the Glashows. Now is your moment. Tell us EVERYTHING you know to be seriously wrong with the theory, its practitioners and its history. When theories, mature, they become a bit more humble. Unfortunately, it appears from your posts that you do not yet enjoy that luxury.

Of course, maybe you just don't know the history.

Do you know that people who used to work on 11D supergravity before strings were derided by early string theorists who thought it irrelevant? That for years 10 and 26 were proclaimed as the ONLY relevant dimensions? Are you aware that there were once a provably small finite number of string theories and that this fact was used relentlessly to sell string theories to a sceptical and largely disbelieving world? Are you aware that for years there were emphatic dismissive answers to the question of 'why are strings the only extended objects with branes irrelevant'?

One could go on I suppose. Let me simply observe however that as string theory improves, it has been proving itself to be wrong in its earlier zeal and dogmatism for years. It just never stops to face its former incarnations.

Lubos, you are young and will be forgiven because of what I assume is your brilliance and contributions. But, like others before you, you will also run out of time if you don?t make contact with the world beyond string theory. We have been cheering for the String community for what is beginning to feel like an eternity. We hope like the Red Sox you will eventually get it together and win one for all of us.

Oh and one last thing. The theory community as a whole has built up a lot of good will over the years by achieving a great deal scientifically while teaching its non-experts critics rather than deriding them. Just make sure you put back scientifically far more than you withdraw.

That is quickly becoming a tall order.

9. **Aaron**
March 16, 2005

"My objection to Aaron is that he seems willing to take seriously theoretical ideas that don't make any predictions."

These days, I'm mostly interested in the mathematics part of strings. And, I agree with you that the anthropic principle is nonpredictive. My only point is that it really could be the right answer.

Depressing, I know, but not impossible.

10. **Peter**
March 16, 2005

I saw the Kolb et. al paper last night, was thinking of writing something about it here, but have been too busy. Also, I'm not enough of a cosmologist to know how to evaluate what they are doing. I hope we'll hear from Sean Carroll about this. (Sean, you reading this?).

If they're right, and the CC really is zero, that would be quite something. It would certainly put a big dent in the "Landscape" nonsense.

11. **Anonymous**
March 16, 2005

Peter, check out http://www.arxiv.org/abs/hep-th/0503117 : Rocky Kolb and some others obviate the need for dark energy by explaining how standard inflationary cosmology gives you accelerated expansion. If there's no cosmological constant, will string theorists give up on any of their nonsense?

12. **Lubos Motl**
March 16, 2005

Thanks, Peter, I've added a link, too. Today I have also huge traffic – because of the no-confidence vote – so it's about a fair deal… 😉

13. **Quantoken**
March 16, 2005

Peter said:

"There's nothing inherently wrong with the idea of fundamental constants varying with time and place."

I disagree. There is something inheritantly wrong by assuming fundamental constants may vary. It's inheritantly inconsistent with the principles of relativity, which says there is no special reference frame and no special place and time. All physics laws should look the same regardless where you make your observation and from what reference frame you make your observation.

Should findamental constants, like alpha, varies. Then we have to assume that all atoms and elementary particles around us would have to have the magic power of knowing where in space and time they sit, and collectively but independently decide on a specific alpha value, which is appropriate for their position and time, on which alpha value they thus exhibit their behaviors for us to see in the lab. Where would they acquire that **"magic power"** of knowing what is the "right" constant value? And how they would acquire that information? It's simply incomprehensible that is the case.

Certainly it is possible that experiments could indeed reveal a changing alpha, then we would have to re-think our reasoning and exam where it got wrong. But so far any experiment attempting to reveal a changing alpha has been very sketching, very doubtful, none-repeatable, and unconfirmed.

Remember the big noise of "changing light speed" by the Weber group 5 years ago? I was skeptical to start with. Where is that noise today? Why there is no followups or independent verifications? None!

In today's fiercely competitive academy environment there is full of dishonesty every where and one has got to be very skeptical in carefully evaluating any experimental results.

The so called CSL-1 cosmological string thing, is going to be the same Weber story 5 years from now. By this time there should be plenty of telescopes around the world take photo shots on this object. There is no independent confirmation so far! Isn't it laughable that string theorists jumped up to their joy at the first moment seeing this insignificant peck of dust in the image as "amazing confirmation (of their theory)" which is actually just a straw.

March 16, 2005

Hi Lubos,

Sure, I'll put a link to your posting. I had thought you would be too busy with the Summers affair to write about this….

15. **Lubo? Motl**
March 16, 2005

Great that I convinced you, Peter. For the sake of hearing both sides, I propose that we exchange links to our reviews of the article.

All the best
Lubos

16. **Peter**
March 16, 2005

Hi Lubos and anonymous,

No, I'm not anonymous. I also think Lubos's comment is perfectly relevant. I encourage anybody who is interested in the whole question of what is going on in string theory these days to read both what I write and what Lubos writes, then make up their mind themselves who has the better argument.

17. **Lubo? Motl**
March 16, 2005

Dear "anonymous",

it is not hard to determine that the author is not actually "anonymous" but it is Peter Woit.

All the best
Lubos

18. **Anonymous**
March 16, 2005

Dear Peter,

Could you please delete the last post — its completely irrelevant to the topic.

19. **Lubo? Motl**
March 16, 2005

For all readers who come from San Francisco Chronicle, a trivial comment: Peter Woit is ignorant not only about string theory, but also about modern theoretical physics and particle physics in general.

If you prefer a treatment of the string theory and theoretical physics topics that is more sensible by a few orders of magnitude, read

Lubos Motl's reference frane

L.M., Harvard

20. **Peter**
March 16, 2005

There's nothing inherently wrong with the idea of fundamental constants varying with time and place. But if you want to turn this idea into physics, you have to come up with a specific theory that implements this, one that makes some sort of predictions you can then go out and check. My objection to Aaron is that he seems willing to take seriously theoretical ideas that don't make any predictions. I'm not, especially when the whole motivation for doing this is to prop up a failed research program.

21. **Tlogmer**
March 16, 2005

Peter: Correct me if I'm wrong — I'm not a physicist — but the idea of multiple universes, while counterintuitive, seems grounded in reality, not merely "concievable". Relativity divides any unimaginably large, temporally bounded area into smaller universes (not with objectively defined borders, of course, but you get the idea); all you need in an unbelievably large area with fundamental constants shifting slowly over distance and voila, a huge number of slightly different universes.

(I'm not sure the terminology in that paragraph was right; hopefully the point came through.)

22. **Thomas Larsson**
March 16, 2005

Judging from a post in the beginning of this thread, Prof. Nauenberg, who was on the faculty (perhaps visiting) when I was a graduate student, has come out as a string (or at least Landscape) skeptic.

23. **Chris W.**
March 16, 2005

I posted a long comment on Peter's previous post ("Clifford Modules") whose final section elaborates on the ideas sketched in my comment below (somewhat off-topic) on science and the Anthropic Principle. The preceding sections are more directly concerned with the topic of that post (but perhaps not enough).

24. **D R Lunsford**
March 16, 2005

JC – I should also mention that the prime mover behind the Weyl theory, strict locality (what Weyl called "pure infinitesimal geometry"), is the very same prime mover behind the various conservation laws that appear in particle physics, and lives on nearly identical mathematical territory.

-drl

25. **D R Lunsford**
March 16, 2005

JC – Weyl's theory was almost exactly carried over into particle physics, only the gauge parameter was not the spacetime scale as such, rather, the phase of the wave function. I'd say this qualifies as "continuing essential relevance since 1918". In contrast, KK theory was already an historical footnote by 1935, and should have remained so in light of Pauli's analysis of its structure. It was clear to many of us that the string program was utterly doomed from the beginning, precisely because it relied essentially on retrieving a total failure from the dustbin of history. This has proven to be exactly right.

-drl

-drl

26. **JC**
March 15, 2005

When was the last time there was an ambitious theory or experiment which tied up 20+ years of many physicists' working lives, but still ended up in failure?

The only cases I can think of offhand were all those guys which worked on various unified field theories in the 1920's and for some decades afterwards, which largely produced nothing. Other than perhaps Kaluza-Klein theory, one hardly hears about any of their old theories today.

27. **Peter**
March 15, 2005

Quantoken + Tony,

Please discuss this somewhere else. I'll delete any further comments about this that are submitted.

28. **Quantoken**
March 15, 2005

Tony Smith:

Your calculation is pure numerology and has nothing to do with super string theory. It's not even an impressive numerology at all, to get a rough match of 75:20:4.5. I have looked at various forms of numerologies and I am getting good at recognize them when I see one. Unfortunately some times it is hard to make a distinction between real hard science and true numerology.

Quantoken

29. **Tony Smith**
March 15, 2005

Peter, you say:
"… there isn't … any string theory argument for the CC other than the landscape because one (Ooguri, Vafa, Verlinde certainly don't have one …) …".

If you allow "string theory" to include theories in which the strings are physically interpreted as world-lines (long strings as real particle world-lines, short strings as virtual particle world-lines), then you can get a path to a unique "string theory":

1 – 26-dimensions comes from usual string theory considerations;

2 – require Jordan algebra structure, which gives you the 26-dim traceless part of the exceptional Jordan algebra J3(O);

3 – require complex domain structures and Jordan symmetry, which give you the E6 Lie algebra with grading
8-dim g(-2) + 16-dim g(1-) + (28+2)-dim g(0) + 16-dim g(1-) + 8-dim g(-2)

4 – that graded structure, plus orbifolding, gives my physics model as described in my paper at CERN-CDS-EXT-2004-031 (note that it is in LaTeX, so those who are picky about style should be happy).
Once you are in contact with my model, you can then, using Segal's conformal ideas, calculate the ratio Dark Energy : Dark Matter : Ordinary Matter getting a result that is close to the WMAP observations.
If you interpret Dark Energy as CC, then the above is an example of a uniquely defined (without landscape) string theory model that quantitatively describes the CC. As to the WMAP calculations in detail, they are given in pdf form in a paper at http://www.valdostamuseum.org/hamsmith/WMAPpaper.pdf Such a paper was rejected by arXiv in 2004 because I am blacklisted, and by the time I got around to thinking about putting that paper on CERN EXT, it had been terminated, so neither arXiv nor CERN EXT has archived my work on the WMAP ratios.

It is interesting that no string theorist has ever communicated to me either:
A – a specification of a fatal error in the above (negative comments have not pointed to technical flaws, but only said that my work is complicated, that it involves orbifolding, or that it does not use the usual naive 1-1 supersymmetry of superstring theory, all of which are true);
or
B – said "thank you" for finding a specific string theory model that agrees qualitatively and quantitatively with gravity plus the Standard Model.

That indicates to me that not only are string theorists unable to do anything useful (re constructing physics models) with their stuff, but also that they don't like it when that is done by an outsider.

Tony Smith http://www.valdostamuseum.org/hamsmith/

Aaron said:
"Do you agree or disagree with the statement that it's **conceivable** that there are lots of universes with differing fundamental constants in all of them?"

Peter answered: "Sure, it's **conceivable** that there are lots of different universes with different values fundamental constants. It's also **conceivable** that Ed Witten is an alien, that we live in a Matrix controlled by evil supernatural beings, and that the Reverend Moon is the son of God. But there's no evidence for any of these things (OK, maybe for the first one….)."

Please note the keyword I highlighted, "**conceiveable**", which is a string word since human brains are amazing thinking devices capable of **conceive** ANYTHING describable or even none-describable by human languages.

Put it simple, anything that is EVER uttered from any piece of mouth by any one, is certainly completely **"conceiveable"**, for if the idea has not been conceiveable by one of the brains, if would never haven been spoken out by one of the mouths.

But that is not physics at all. Physics strictly does NOT deal with conceivable concepts. That's the domain of psychology, not physics. Physics strictly deal with **Observable** evidences only, not conceiveable ones. Any one not understanding this needs to see a psychologist, not a physicist 🙂

There is not any evidence for multiverse and logic forbid the very existence of such evidences. THIS universe is all we can observe and physics deal strictly with what we can observe in THIS universe only, not what we can conceive out of this world.

Quantoken

31. **Peter**
March 15, 2005

Hi Aaron,

Sure, it's conceivable that there are lots of different universes with different values fundamental constants. It's also conceivable that Ed Witten is an alien, that we live in a Matrix controlled by evil supernatural beings, and that the Reverend Moon is the son of God. But there's no evidence for any of these things (OK, maybe for the first one….).

What really bothers me is not serious physicist's willingness to consider the "multiverse" idea, but their willingness to adopt it without a shred of evidence, or even a reasonable hope for ever having evidence. The only reason for doing this is to evade the fact that the string theory framework is a complete failure as a TOE. Being willing to trash the entire scientific enterprise to protect your failed ideology is just pathetic.

32.
March 15, 2005

"It's not impossible". Boy, we've really set the bar high haven't we. The same argument could be made in favor of reincarnation, or mental telepathy, or alien visitation (paging Dr. Kaku…)

33.
March 15, 2005

"I have a question to the phenomenologist who loves experimental data….actual high energy (I mean non-astro) data? If yes, what are the most interesting recent data and how did superstring theory help you or inspire your work on these data? "

Its not that there's new significant data (non-astro), it's that explaining the existing data, within the context of so called 'natural' solutions to the hierarchy problem is already very hard. These include SUSY, and all sorts of composite, technicolor like models of electroweak physics (here i just name 4d approaches).
Each of these approaches has predictions for what the LHC should see, which hopefully we can disentangle.
The problem is that all these approaches to stabilize the higgs mass introduce lots of junk that then has consequences on all sorts of precision measurements and predicts particle processes we have not seen. one winds up using all sorts of tricks to avoid this problem, some of them where inspired by string theory and
extra dimensional approaches (themselves inspired by string theory), though they are completely four dimensional. Most tricks involve cleverly controlling how symmetry breaking
is communicated to the SM.

The fact that none of these solutions/tricks are particularly simple or elegant, is part of the reason people are now looking
to anthropic explanations of the Higgs mass. I my self have not really bought into this, but here's how it goes:

for example, if you vary only the Higgs mass in the SM and nothing else, you can convince yourself that varying it even within a factor of ten or so of its current (estimated) value you quickly loose all of chemistry. you wind up with a universe containing nothin more complicated than hydrogen. obviously any life needs chemistry and stable elements besides hydrogen – therefore, the higgs
mass is roughly what it is. Since you dont need to worry about stabilizing the Higgs mass, you now motivate electroweak physics by requiring for instance that there be a stable particle at the weak scale which can be dark matter. Within SUSY such an anthropic scenario has very distinct predictions for physics at the electroweak scale. it might be very hard to see at LHC because there are very few predicted particles and none of them interact strongly, so you need to get clever. there could be some possible indirect signals though. so this is an example of how anthropics motivates concrete testable predictions. of course it depends highly on what you think can vary (in this case the higgs mass) and what cannot, so it is certainly arbitrary.

Also as I mentioned, QCD data (some of it really old) about
various strong particles perhaps can be explained using
AdS/CFT type of models – there has even been some
success in this – even quantatative: predicting particle masses
and decay rates. This is for those of you who doubt holography will ever make conact with experiment – maybe it already has and we just dont know it yet.

However I agree that thinking of string thy as TOE in the traditional sense is probably silly and that a lot of misleading marketing is being done by the popularizers of this field.
on the other hand, it is true that explaining to the public the various theoretical ideas to come out of string theory and motivating the existence of the field using those is really a difficult task, since of course we dont know which of these ideas will ultimately be useful in explaining data somewhere down
the line.

34. **Aaron**
March 15, 2005

"I'm not willing to admit any hypothesis about how the universe works unless I'm provided with evidence for the hypothesis. And by evidence I mean scientific evidence: the hypothesis explains something about nature that can be checked. So, if the "landscape" can't predict anything, it's in the same category as religious belief. Not my thing."

I didn't ask you to say that the anthropic principle *was* the correct answer, just that it's not impossible. Do you agree or disagree with the statement that it's conceivable that there are lots of universes with differing fundamental constants in all of them?

35.
March 15, 2005

I have a question to the phenomenologist who loves experimental data and has a high esteem of the accomplishments of superstring theory. Have you ever worked with actual high energy (I mean non-astro) data? If yes, what are the most interesting recent data and how did superstring theory help you or inspire your work on these data? Did it help you with understanding neutrino masses?

I agree with the comment that superstring theory was a reasonable thing to do while waiting for new experimental data. When the actual data starts coming, those string theorists who cared about "phenomenology" whatever it means these days, even if it's such a nonsense as the anthropic landscape, will have a headstart.
Being smart also helps: if worse come to worst, Witten will be remembered for his 1976 paper on deep inelastic scattering.

36. **Juan R.**
March 15, 2005

In the past, it was thought that string theory was correct.

At present many people opines that it is not even wrong.

Some of us already know that is wrong. In fact, string theory pointed (and still point) in the wrong way in each research topic that i have studied: irreversibility, time arrow, quantum gravitation, molecular dynamics, catalysis, decoherence, relativistic invariance, nanothermodynamics, TFD, etc.

When I read a recent "high-level" paper by Witten, Vafa, Schwartz, Greene, etc. I find stuff abandoned even decades ago in the sophisticated fields that I and others work!

When will "string" theorists understand that their research is NOT the last theory nor the most advanced formulation of Nature?

37. **Peter**
March 15, 2005

To make my statement precise and unambiguous: there is not now any viable superstring theory explanation of the CC other than the anthropic one. I'm talking about what is actually known to be true, not what is wishful thinking. String theorists seem to have lost the ability to distinguish these two things.

You're quite right that many string theorists hope that "one day" superstring theory will find another way to explain the CC. I didn't deny this, but I was talking about what is known to be true, not about some what some people would like to be true even though they have no evidence for it. They also hope that "one day" superstring theory will explain the parameters and structure of the standard model. But this is pure wishful thinking, with a huge amount of evidence now built up that it can't be true.

38. **Fyodor**
March 15, 2005

"You haven't provided any string theory argument for the CC other than the landscape because there isn't one (Ooguri, Vafa, Verlinde certainly don't have one, I've read that paper)."

So have I. They don't claim to have one. Nobody does, do they? I was just giving that as an example of a line of research that might, *one day*, lead to a theory of the CC that has nothing to do with the landscape. My point, which you are evading, is that many string theorists believe that there are other approaches than the Landscape. Your statement in the article was misleading.

"Susskind and many others are right about the fact that there isn't one."

How do you know? The truth is that you are engaging in wishful thinking: you *hope* that there is no alternative to the landscape because it makes string theory look bad. I repeat: a great many string theorists have no truck with the landscape. You know this, via your dear old friend Lubos. Why did you pretend to be unaware of it?

39. **Arun**
March 15, 2005

We know that some observations have anthropic explanations. The distance from the earth to the sun is the most common example. That's not a fairy tale; it's just how things are.

And this same anthropic theory explains Mercury, Venus, Mars, the asteroid belt, etc., how????????

The only thing the anthropic principle explains in this situation is why we live on earth and not on Mercury, Venus, Mars, etc.

40. **Thomas Larsson**
March 15, 2005

Wouldn't it be ironic if the correct ToE turned out to be essentially general relativity coupled to the standard model. After all, such a scenario would be in excellent agreement with experiments (though I realize that young theorists today disdain the E-word), and it would explain why so little beyond-the-SM physics is observed.

There are of course some theoretical problems with such a scenario, namely that QM and GR are incompatible and that the SM is somewhat ugly, especially in the Higgs sector. But it seems to me that these problems should be cured by some minor fix, rather than positing a plethora of unobserved phenomena and 10^500 unobservable universes totally different from ours. Finding the right fix is perhaps not so easy, but history teaches us that such a strategy has worked once before. In the 1930s people thought that QM was incompatible with special relativity, and especially electrodynamics. The small fix in that case was renormalization, which saved the situation without introducing any new physics.

41. **Peter**
March 15, 2005

Aaron,

I'm not willing to admit any hypothesis about how the universe works unless I'm provided with evidence for the hypothesis. And by evidence I mean scientific evidence: the hypothesis explains something about nature that can be checked. So, if the "landscape" can't predict anything, it's in the same category as religious belief. Not my thing.

Fyodor,

You haven’t provided any string theory argument for the CC other than the landscape because there isn’t one (Ooguri, Vafa, Verlinde certainly don’t have one, I’ve read that paper). Susskind and many others are right about the fact that there isn’t one. He’s also right that the whole field has been engaging in a huge amount of wishful thinking for years, although his wishful thinking is even more ridiculous.

Bottom line: you have an ugly, complicated, unfinished theoretical framework, and strong evidence that it either predicts nothing or something off by 120 orders of magnitude. You can bury your head in the sand and talk hopefully about how Ooguri, Vafa and Verlinde or some other recent paper will save the day, even though there is zero evidence for this. Why do you want to do this, other than to defend what looks like pure religious belief in an idea that doesn’t work?

42. **Fabien Besnard**
March 15, 2005

A child’s question to his mother : “why did you have a child ?”

Anthropic answer : “because if I had not you would not ask the question.”

This is easily generalized : “why…(put a question here) ?” answer : “because if things were not this way you would not ask this question.”

More seriously, I think some “anthropic” arguments about, say, the coupling constants needed for carbon production make sense but are only an indirect and not very accurate way of extracting these coupling constants from the experimental data.

43. **Fyodor**
March 15, 2005

“If you have a string theory argument for the value of the CC other than the anthropic landscape one, tell us what it is instead of just writing “Who says” in response to my post. I’m the one saying it. If you think I’m wrong, tell us why so we can learn something.”

No, you aren’t the one saying it, Lenny Susskind is. You are talking as though LS were the accepted spokesman for string theorists on this matter, when you surely know that most string theorists do not approve of his dogmatic announcements on the Landscape. Quite a lot of us think that it is too early to say where the cosmological constant comes from, because we don’t understant supersymmetry breaking and because we don’t have a good understanding of dynamical spacetimes in string theory yet. To take but one example, I have been speaking to someone who is working on the recent ideas of Ooguri, Vafa, and Verlinde; he thinks we may be able to get some sort of understanding of cosmology out of that, but he admits that it is too early to say anything definite yet. And that is the attitude of most people in this field : they are far from believing that the Landscape is the only way to go. The theory is still too primitive for that. I can imagine someone saying to Lagrange and Hamilton: this is just fancy mathematics, what does it predict beyond the Standard Newtonian Model? What could they have said, except: “Restrain your impatience!”?

44. **Quantoken**
March 15, 2005

Aaron said: “But that last bit’s where you’re wrong. We know that some observations have anthropic explanations. The distance from the earth to the sun is the most common example. That’s not a fairy tale; it’s just how things are.”

The anthropic principle is extremely vacuous. You think it explains why the earth-sun distance is the way it is, **ONLY BECAUSE** you have inappropriately narrowed possible forms of life to the one similar to what earth bound life forms look like. You think life is only possible as a carbon based devices that evolves with the help of a chemical called water. That’s too narrow a definition of life.

I think a more broader definition of life would be anything that can carry, process and duplicate any form of information. Further I would define intelligent life as any thing that can carry, process and duplicate a sufficnet amount of information. But that definition, as long as the universe is big enough to contain a large amount of quantum information, it would breed certain forms of life, using certain chemical or other forms of matter.

Life really does not have to be carbon-based devices only. Why can’t silicon based devices by life as well?

Quantoken

March 15, 2005

Mr “” said:

“For example, the idea … that a QM system with gravity in some number of dimentions is equivalent to a non-gravity system in a lower dimension might by itself merit 20 years of string thy.”

What? That a kindergarten problem is what you spent 20 years on? Let me show you how trivial it is. To describe trajectory of a particle in N dimentions requires exactly N-1 equations, not one more and not one less. That’s kindergarten math, alright?

Now you put in one constraint, be it gravity or whatever. The constraint can be described by one equation. Plug it in and you have reduced the equation set fro N-1 to N-2. So you have successfully reduced dimentions from N to N-1. Simple, right? The rests are just technical details. But the math is rather simple!

Took me 20 seconds to describe it. If string theorists have spent 20 years to figure the same thing out. Too bad that’s a waste of their lifetime.

Quantoken

46. **Aaron**
March 15, 2005

“If the string theory framework is not predictive, you’re right that doesn’t logically imply that it is wrong. But it does imply that it is something worse than wrong. It is not science, is completely useless, and is nothing more than a fairy tale.”

But that last bit’s where you’re wrong. We know that some observations have anthropic explanations. The distance from the earth to the sun is the most common example. That’s not a fairy tale; it’s just how things are. And, so it might be for the parameters of the standard model, if not through string theory, then through whatever is the correct theory of whatever.

If that’s true, there’s nothing you or I can do about it. No amount of dogmatism about the nonpredictiveness of the anthropic principle will change it. It’ll just be how the universe is.

And I agree with that dogmatism. The anthropic principle isn’t predictive. No amount of counting vacua will ever tell you anything about this universe. But I’m willing to admit that the anthropic principle may, nonetheless, be the right answer. Are you?

47.
March 14, 2005

Holography is a nice idea. My phenomenological ami — have you ever heard about Cauchy's theorem?
Unfortunately, physical systems are not necessarily analytic (unless you go far "beyond the standard model"), so holography will remain as a nice but a physically irrelevant idea. Take my word.
Jean-Paul

48. **Peter**
March 14, 2005

Certainly string theory has lead to a lot of interesting things, including a huge amount of interesting work on 2d CFTs, new insights into 4d QFT via AdS/CFT, quite a lot of beautiful algebraic geometry, and many other things. But what I object to is the entrenched ideology that a 10/11 dimensional string/M-theory can give you a TOE. This is the claim that is being used to sell the theory, and it motivates a large fraction of what string theorists do. But the evidence now is overwhelming that this idea doesn't work.

If you want to understand string theory better and really see what can be gotten out of it, the TOE claims are a huge impediment. People have got to admit failure and move on, or they will be stuck for the next hundred years lost in the "landscape". However you evaluate whether string theory is interesting, it is no longer interesting as a TOE. That idea has failed. But until people acknowledge that, the field won't move on to something more interesting, and remain stuck in the hopeless dead-end it has gotten itself into.

49.
March 14, 2005

I think you people are missing the whole point as to why string theory is interesting. It is interesting because it has been a great
toy model for many astounding theoretical ideas, whether or not it at the moment is directly linked to data.

I speak as a particle pheonomenologist who loves experimental data and certainly prefers writing papers about predicitve and testable theories. When confronted with difficult problems, theorists often try to solve much simpler, non-realistic examples which contain some features of the real problem but lack the complexity of the real world. This helps overcome the biggest challenge in theory – even knowing what is the right question to ask.

String theory has certainly proven to be a great laboratory for quantum gravity and QM in general, whether it is the right formulation for a full quantum theory of GR or not.

For example, the idea of holography (which you might have discussed) that a QM system with gravity in some number of dimentions is equivalent to a non-gravity system in a lower dimension might by itself merit 20 years of string thy. This idea (though first postulated indirectly without strings) was first fleshed out in certain concrete string theory examples where one can actually understand to some extent how it works. This idea has deep implications – changing our concept of dimension of a QM system, enriching our idea of how a QM system becomes classical, and changing our perspective on the data that QM gravity system requires.

Also, it has offered a method of building models which have qualitative agreement with features of QCD (a theory which has proven difficult to solve fully by any method thus far developed). My point is that string theory has changed our vocabulary for what are the right questions to ask in ways that we could not imagine before. And even if at some point this particular theory will be thrown out, i'm sure the toy examples it generates will further our understanding of fundamental issues.

As a side note, let me also mention that it has indirectly
influenced the creation of many mechanisms (completely garden variety four dimensional field theory ones) that are very useful in totaly predicitve, experimentally falsifiable theories of electroweak physics (which we might see at the LHC).

Of course this doesnt mean that all string thy research is useful – it is true that there are many people who dive into some techinical very specific aspects of the theory, rather than viewing it more as a lab for ideas, they take it very literally as a model for our world. i think though, that the really good string theorists are always seeking a general lesson, rather than some
specific solution in their work.

50. **Peter**
March 14, 2005

Phil Anderson been involved in the hiring of several generations of both particle theorists and condensed matter theorists at Princeton, and knows exactly what he is talking about.

Keep in mind that Anderson is about 80 years old, a Nobel Prize winner, and a good case can be made that he's the one who discovered the Higgs mechanism. He was applying QFT to condensed matter problems during the 50s and 60s when most particle theorists had abandoned QFT. Over the years I'm sure he has developed some resentment at how particle theory has gotten much more attention that condensed matter theory, especially at Princeton. He's famous for his opposition to the SSC and for his anti-reductionist "more is different" philosophical views. Over the last twenty years he has seen the Princeton particle theory group get completely taken over by string theory, a takeover facilitated by a huge amount of hype. He's knows what it is like to really understand something new about physics and knows that string theorists haven't been able to do this, despite all the hype. He has been upset and complaining about this situation for years.

Whatever you think about him, he's someone who definitely is honest and definitely is honestly telling you what he thinks. He's old enough and famous enough that he doesn't need to worry about who he might offend by speaking his mind.

51.
March 14, 2005

It's a very interesting article. Look at this quote from Philip Anderson: "we from outside the (string) field are disturbed by our colleagues' insistence that every new semi-adolescent who has done something in string theory is the greatest genius since Einstein and therefore must occupy yet another tenure track…". Has the Nobel Prize winning Dr Anderson ever participated in hirings of condensed matter theorists? They are usualy presented with even more hype because in addition to being genius they bring "million-dollar" grants. Do you believe that Dr Anderson criticism is honest? Welcome to the WWF physics of the XXIst century.
Jean-Paul

52. **Chris W.**
March 14, 2005

Quantoken said, *Science is not a part of nature, but the part of human culture which tries to interpret what we know about nature, in ways we human can understand and* *reason with*.

In a very real and non-trivial sense, science *is* a part of nature. It does not seem that arbitary changes to the known laws of nature (including apparently universal constants) are, in general, compatible with the existence of life. For many of the same reasons, it is not at all clear that science could get anywhere unless the physical universe had certain crucial properties.

Why might this be the case? If the evolution of life and science itself are fundamentally processes of trial and error, then one must ask: Under what circumstances can trial and error be effective? For example, suppose it was much harder than it is to construct and maintain isolated systems. How could one design and interpret experiments? What if effects like those assumed by astrologers were pervasive? One might have theories, but testing them would be much more difficult.

One of my objections to the more familiar formulations of the anthropic principle is that they short-circuit this question, although they implicitly or explicitly acknowledge its relevance. Aaron said, "On the other hand, I firmly believe that we have to practice science as if the anthropic principle were false." I would say that we must either do that, or reformulate the anthropic principle in a way that is truly fruitful, and doesn't subvert the whole enterprise.

I think this may well be possible. The key idea is to consider the logic of trial and error, and how it can lead to conclusions about the features and behavior of physical systems. In some sense I think the logic of trial and error, combined with certain very simple dynamical notions, may ultimately largely dictate these features and behavior, and the laws of physics themselves. I have been influenced in this direction by the writings of Karl Popper and Edwin Jaynes* and some younger (and still living) Bayesians, such as Carlton Caves. I'm not sure what they would make of the ideas I'm advancing here. (Incidentally, the relations between Popper's philosophy and that of the Bayesians is a topic for a long article or a book.)

Peter said:
"I'm just completely amazed by the fact that **intelligent, trained scientists** are unwilling to admit an absolutely undeniable fact staring them in the face. If it really is true that string theory can't predict anything, it's not physics, and anyone claiming to be a physicist has to admit that, as physics, it's a worthless idea and has to be abandoned."

Peter, don't you see as I already pointed out. Doing so for string theoretist amounts to career suicide. **No amount of scientific training is enough to prepare one to commit suicide**. An intelligent scientist would want to continue to survive in the establishment camp. Science honesty is only secondary thought after survival is taken care of first.

For people old enough to have established tenureship and un-shakable credibility in the science community, but still young enough to have enough lifetime left to explore completely new exotic ideas. They may listen to you, Peter. Anything above or below that age threshold, I do not think they will ever listen.

54. **Peter**
March 14, 2005

Aaron,

Yes, nature is what it is, not what we want it to be, and this is a lesson string theorists are having a hard time facing up to.

If the string theory framework is not predictive, you're right that doesn't logically imply that it is wrong. But it does imply that it is something worse than wrong. It is not science, is completely useless, and is nothing more than a fairy tale. People who don't believe in the scientific method are free to promote it as having something to do with reality, but they have no business doing so from within university physics departments.

A few years ago, if you had told me that once it became clear string theory was a non-predictive framework, string theorists would refuse to abandon it and instead would start going on about how "we may have to rethink what it means for a theory to explain experimental data", and basically give up on the whole idea of science, I would have refused to believe you.

I'm just completely amazed by the fact that intelligent, trained scientists are unwilling to admit an absolutely undeniable fact staring them in the face. If it really is true that string theory can't predict anything, it's not physics, and anyone claiming to be a physicist has to admit that, as physics, it's a worthless idea and has to be abandoned.

Aaron said:
"I think it's sometimes worth pointing out that just because the landscape isn't predictive, that **doesn't make it wrong**. It's not imaginable that that's how the world really is. It'd be disappointing, but nature is what it is, not what you want it to be."

You forget the title of this BLOG is "**Not Even Wrong**.", which is worse than being wrong 🙂

Nature is what nature is. Science is not a part of nature, but the part of human culture which tries to interpret what we know about nature, in ways we human can understand and reason with. Therefore, the whole idea of science is based on the philosophical belief that the nature is rationable, knowable and predictable. If you give up on the notion of nature's predictability, you give up your right of being called part of science.

Michael Nauenberg: What you said is wishful thinking. For string theorists to do what you said would be professional suicidal, to admit that the whole idea is a dead end and they have wasted tax payer dollars for decades on a futile pursuit, which is also a waste of their own intelligent lifetime. It simply would not happen.

Change is only possible, IMO, when the old generation die out and the idea of super string gradually fade out. Unless there is a up-down revolve of changes starting with re-appropriation of research fundings.

I think it's sometimes worth pointing out that just because the landscape isn't predictive, that doesn't make it wrong. It's not imaginable that that's how the world really is.

Aaron, how would you establish that the landscape is correct?

57. **Aaron**

March 14, 2005

I think it's sometimes worth pointing out that just because the landscape isn't predictive, that doesn't make it wrong. It's not imaginable that that's how the world really is. It'd be disappointing, but nature is what it is, not what you want it to be.

On the other hand, I firmly believe that we have to practice science as if the anthropic principle were false, but that's another story.

58. **michael nauenberg**
March 14, 2005

It seems to me that at this point it would be
best if string theorist would stop going public
with unscientific hyperbole. Whatever
merits the theory may have, announcing that the string "landscape' of 10^500 (or is it 10^501) multi-universes explains
the observed constants of nature
in "our" universe (anthropic principle) is nonsense characteristic of theologians of the middle ages.

59.
March 14, 2005

> So don't fool yourself that a
> tenure track position taken away from a string
> group will be used to hire a mathematical
> physicist working on (fascinating) Clifford
> modules — such a position will go to a nano-
> theorist..

.. which in fact is very good, isn't it? One can be a mediocre nanoscientist and still be useful. Obviously this is not so in string theory.

60. **Wolfgang**
March 14, 2005

> Parallel universes, time travel,
> miniature black holes

Your examples are all pretty old stuff and were "invented" before the superstring mania.
This shows that superstring theory did not even contribute to science fiction, like all other great theories before.

61.
March 14, 2005

These days it seems that obsessive hype-mongering is a prerequisite for any field to maintain a degree of public attention. With nanobots, age-reversing immortality drugs, hyperintelligent AI all just around the corner, according to the press releases, how is the physicist to compete? Parallel universes, time travel, miniature black holes- at least it gets your picture in the paper.

62.
March 14, 2005

The present problem of high energy phsyics started 30 years ago when the great success of theorists attracted many brillant students to theory, but at the same time closed main problems and ultimately slowered experimental progress. In this situation string theory was a good attempt of doing something. Passing to some other mathematics would not solve the problem.

Hopefully LHC will make real progress and indicate where good physics is. And a few more hyped theorethical books will indicate where it is not.

63.
March 14, 2005

Peter – Being at the math department of Columbia, you maybe not be aware of the situation outside Princeton, Harvard etc. Everywhere else any non-applied theory is under constant attack of the prophets of new physics who work on applications of such advanced theory as Hooke's Law to molecular motors etc and bring tons of money from NIH, DOD etc.
The criticism of some Very Famous theorists comes from jalousy how such an underfunded field like string theory could create so much hype and publicity. Unfortunately their response is to follow the bad example and to create their own hype — promise that physicists can find a cure for heart attacks, explain the origin of life etc.
So don't fool yourself that a
tenure track position taken away from a string group will be used to hire a mathematical physicist working on (fascinating) Clifford modules — such a position will go to a nano-theorist. Make your own call…

64. **Peter**
March 14, 2005

I'm actually not of the opinion that the amount of money spent on string theory is a problem. It's negligible compared to all sorts of other things, many of which are no more worthwhile.

The motive behind the string theory hype is not only to protect NSF and DOE grants, it is also to ensure the dominance of string theory in those physics departments where it has become entrenched (Princeton, Harvard, etc., etc….). The important question to me is about how to make it possible for good young people to try to do something new. In his comments in the article Phil Anderson also focuses on this saying he is

"disturbed by our colleagues' insistence that every new semi-adolescent who has done something in string theory is the greatest genius since Einstein and therefore must occupy yet another tenure track."

What can be done to change things so that young people don't feel their only hope of a permanent job in mathematically-based particle theory is to do string theory? I happen to think that puncturing the string theory hype is a necessary first step, but far from sufficient.

65.
March 14, 2005

String theory at Average Respectable University is a negligible fraction of the total funding as compared to bio, nano and neuro. While it is fair to criticize its scientific merits and outrageous self-promotion of some individuals, your over-funding criticisms should be directed towards other fields: these days hype and lies are everywhere (which of course doesn't justify saying that strings solve the dark matter problem or that you can see them in the sky or that LHC will be a black-home factory…)

66. **quantoken**
March 14, 2005

Dear Fyodor Uckoff,

Even if super string theory becomes the ONLY theory funded by public money, so you have no competitor funding wise, and even Lee Smolin et al., John Baez et al. all publicly acknowledge that their approches are wrong. Does that make super string theory a winner?

No, absolutely not. You are still a complete loser since you still can not predict anything. And you would be a very **sore** loser since you can't even acknowledge your failure, while Lee Smolin is at least ready and willing to acknowledge failure if they can not succeed.

Theory developments are not ball games in which there is always one and only one winner. Theories are not used for competition of funding, but for explaining the nature. So **there doesn't need to be a competition**. If none of the existing theories can make a verifiable prediction, then all of them are losers. If two theories can both explain the same thing, then both are winners and there may be a third winner unifying them behind.

So a good theory really doesn't need to compete against any one else. If it is correct it will be correct on its own merit. If it is wrong it is wrong on its own fault.

The fact that string theorists are SO jealous against other theories, really tells you that they simply can not establish their own validity on their own merit, but will have to base it on "competition" against other theories, and declare their victory based on their dominance on fundings. What a sore loser!

Quantoken

67. **Dave Bacon**
March 14, 2005

Fyodor said "And even if it were true that string theory has been "hyped", what harm would that have done?"

You can't be serious, can you? If a field of physics is hyped and turns out to be totally and completely wrong (or worse, totally unpredictive), then this has done serious damage to the progress of science. It slows down science by (1) maintaining a monopoly on what is considered acceptable for theorists to work on (and not just theorists in high energy physics), (2) stripping money away from other fields of physics and science which are more deserving of funding, and (3) reducing funding for all of science by reducing the public's trust in science. If the "great" leaders of string theory turn out to be following nothing more than a dead end, then it does serious damage to all of science.

Further, while there may be no alternatives to string theory at present, this does not mean that we should continue to fund it. It may be that the idea(s) necessary to reconcile quantum theory with gravity simply have not been put forward, and spending my money on a dead end (if that's what it is) doesn't seem to me like a very productive thing to do.

68. **Peter**
March 14, 2005

If you have a string theory argument for the value of the CC other than the anthropic landscape one, tell us what it is instead of just writing "Who says" in response to my post. I'm the one saying it. If you think I'm wrong, tell us why so we can learn something.

I have never said "there are lots of theories out there which would have explained everything by now if only they had not been starved of funding by the string theorists". There aren't any good ideas out there about how to go beyond the standard model, but having most of the community working on an idea that has failed and refusing to face up to the fact that it has failed doesn't help the situation. The reward structure of the field is still that if you are a smart young theorist and decide to work on a speculative idea that is not string theory, you probably are ruining your hopes for a career, whereas if you work on a speculative string theory idea (even if it is clear that it doesn't work), you can do quite well for yourself.

I don't expect Witten to announce tomorrow "String theory has failed as a TOE, people should go out and try and find other new ideas". But he really should do this, and it would have a very positive effect on the field if he did.

69. **Fyodor Uckoff**
March 14, 2005

Peter Said: The only way around this seems to be the "landscape" argument,

Who says?

And even if it were true that string theory has been "hyped", what harm would that have done? It's not like the theory has any competition. The notion that there are lots of theories out there which would have explained everything by now if only they had not been starved of funding by the string theorists is pure conspiracy theory at its most ridiculous. The people being starved of funds and attention are the kooks who tend to post in blogs like this one until Peter kicks them out. Where's the real competition? Does anyone really expect Ed Witten to announce: "String theory has failed. Go work on something else. What else? Go look at Tony Smith's or Quantoken's web pages….."

70. **Quantoken**
March 14, 2005

Peter said:
"…since it is well-known that superstring theory naturally leads one to expect a value for this energy density that is off by 120 orders of magnitude."

Sorry I must set the record straight here, although I am definitely not a defendent of super string theory. That 120 orders of magnitude is NOT the fault of string theory alone, but the fault of whole existing physics theories which could not unify QM with GR. You have the 120 orders of magnitude ever since vacuum energy was proposed and calculated, which is much earlier than the occurance of super string theory. You can not blamn super string theory for a problem that occurs before it, although super string theory does not lead to any thing better.

Put it simple, regardless of what theory you are in, any time you put the three constant hbar, C, G together, you naturally get the Planck Scale. Any time you deal with Planck Scale, the characteristic energy density, which is approximately one Planck mass per Planck volume, is automatically 120 orders of magnitude too larger, compare with the cosmological constant.

So any theory, not just super string theory, that talks about Planck Scale at all, inevitably runs into 120 orders of magnitude. That is, **unless** the math of the theory itself leads to a dimensionless number which happen to be very small but none zero, approx. 10^-120, which exactly cancel out the other 10^120 figure from Planck Scale. That is what the “landscape” business is all about. But that’s a complete failure as we know.

There are theories which discard the Planck scale and so get rid of the 10^120 as well as difficulty in explaining the cosmological constant. But obvioulsy Peter is not interested in hearing alternative theories and I am not going to elaborate here.

Quantoken

No Cosmological Constant?

March 16, 2005
Categories: Uncategorized

A paper appeared on the arXiv last night entitled Primordial Inflation Explains Why the Universe is Accelerating Today by Rocky Kolb of Fermilab, together with Sabino Matarrese, Alessio Notari and Antonio Riotto. There's also a Fermilab press release about it today.

I'm no expert on the subject, and would love to hear the opinion of someone who is. As near as I can figure out the idea is that what is really responsible for the effects that have been ascribed to a cosmological constant is a "cosmological perturbation" of the gravitational field. This is supposed to be a perturbation that expanded during the inflationary period so that its wavelength is now larger than the Hubble radius. According to the authors, this predicts a different magnitude vs. red-shift relation than the standard cosmological constant does, so their idea should in principle be testable.

If they're right, this certainly will cause a huge problem for the whole "Landscape" business, which has advertised as its greatest success the "prediction" of a non-zero cosmological constant of the right order of magnitude.

Comments

1. **steve m**
   March 19, 2005

   Well sometimes important ideas emerge in an incomplete or confused form but this paper of Kolb et al. is going along the directions of the sort of thing you really want–a clean conservative scientific resolution of the cosmic acceleration/dark energy problem. They are approaching the problem in a sober way and hopefully they can develop and refine more details. Seems to have generated much interest already. If it works out then the whole landscape business will look increasingly silly.

2. **Matthew**
   March 18, 2005

   Well, we had some discussion about this paper today in our lunchtime seminar. The consensus seems to be that they might be on to something, but there are a few things in the paper that don't quite make sense. For one, around equation (7) they make the claim that their formula for \Psi(x,t) is valid to all orders in perturbation theory. Yet the longer paper that they refererence only gives a result to second order.

   Of course, this is largely a function of the length of the paper (which is clearly intended for PRL), a lot of details get glossed over.

   Still, the cosmo people here were interested, but skeptical. One group member also had an email from a big time cosmologist who said this was an ineresting idea…

   It'd be nice if there was a longer paper, it's hard to get much from a PRL. For those who want to look into it more, it seemed fairly clear that you should track back at least one layer to their previous work.

3. **D R Lunsford**
   March 17, 2005

   This is the only blog that has much interest because it's about something other than the owner.

   It will be nice to see what Sean has to say about this further.

8.
   March 17, 2005

Quantoken, this whole blog is built around an idea Peter does not believe.

9. **Quantoken**
March 17, 2005

Click on my name below to see why the experimental evidence for an “accelerating” universe is questionable and extremely weak, plus some useful links to the original ARXIV papers.

Peter does not allow discussion of ideas he does not believe, but said simply providing a link and discuss it some where else is fine. So go and see for yourself: http://quantoken.blogspot.com

Quantoken

10. **Lubo? Motl**
March 17, 2005

I would be happy, of course, if the true LAMBDA was zero after all, the expansion explained different, and we would return to the original C.C. problem “why it’s exactly zero”. But one must distinguish wishful thinking from reality. Longer-than-horizon fluctuations are always problematic.

If the effects like that are true, then these trans-Hubble oscillations may effectively be able to change many kinds of “constants” within the Universe. They’re frozen, they don’t change, yet the expectation values of the scalars may have an effect.

11. **ALejandro**
March 17, 2005

Cabi blogs on this issue too:

12. **Alejandro Rivero**
March 17, 2005

Also Stephon Alexander pre-announces, in his blog
http://qd.typepad.com/17/, some advance in the question of the cosmological constant:

“Now I’m out of the cave with an answer.
Whats the answer?
I’ll tell ya tomorrow.”

13. **Matti Pitkanen**
March 17, 2005

For a different view about accelerated expansion and problem of cosmological constant see No cosmological constant after all?

Matti Pitkanen

14. **Serkan Cabi**
March 16, 2005

Even though I posted my blog on this issue I wanted to join the discussion here by pasting my opinion:

“I should say that I did not like the proposed solution. We always thought that solution of the acceleration of the universe puzzle will also solve two other great mysteries. Namely; why we do not see a cosmological constant in the Einstein-Hilbert action although the known symmetry principles allow it, and why the QFT vacuum condensates (ground state) do not gravitate; or why they cancel out. If the acceleration is due to super-Hubble fluctuations, I think we will be in a worse trouble. At least they are offering observable differences from a pure cosmological constant and nature will say the last word.”

15. **Haelfix**
March 16, 2005

These sorts of issue are very sensitive to gauge freedom issues in GR, and he is explicitly fixing a gauge in his model. That raised alarm flags in my head.

Regardless this is jsut as ugly as the landscape in principle, it again sticks us at a very unusual spot in phase space.

16. **Peter**
March 16, 2005

Hi Sean,

Thanks for sharing the quick opinion, I hope we’ll hear more when you’ve had a chance to look at this more carefully.

As to string theory. Sure, there are plenty of string theorists who aren’t happy with the landscape, and the disappearance of the CC wouldn’t change things for them. But they still would face the perennial two huge problems of

1. how to break Q (supersymmetry generator), but not Q^2 (Hamiltonian operator).

2. finding some argument why there aren’t at least 10^500 solutions to the theory, ruining its ability to predict anything.

By now a large number of prominent string theorists have publicly announced that they believe string theory has to have an exponentially large number of consistent ground states. They have argued this is a point in the theory’s favor since it allows the anthropic explanation of the value of the CC. If this disappears, and the existence of so many ground states becomes purely a bad thing for the theory, it will be interesting to see if they change their mind about them.

17. **A non-cosmologist.**
March 16, 2005

Sean wrote:

there's no way that the situation outside our Hubble patch can influence our observed dynamics.

But just because these modes have wavelength larger than Hubble radius, that doesn't mean they're entirely outside our Hubble patch — they still have some energy density inside our Hubble patch.

How the time-dependence arises is a bit of a mystery to me, but it is just scaling like a(t). They seem to claim to have derived this from Einstein's equations. (They don't seem to say phi is time-dependent, just that it has a time-dependent effect on the metric, parametrized by Psi.)

As a non-cosmologist, I was hoping you would have all the answers. Can you get Kolb to explain it all?

18. **Matthew**
March 16, 2005

Hi Peter,

This paper has caused some discussion around here already. You've got the gist of it, the crucial point seems to be that these super-hubble perturbations have some time dependance (constant perturbations could be scaled away). You can see this in equation (6), if the super-hubble part of the potential was constant, you'd get the standard result.

It's going to be the subject of our Friday lunch discussion, so I might be able to tell you what the experts around here think.

19. **Sean**
March 16, 2005

Oops, I left a link to my home page instead of my blog. For a minute there I was thinking like a scientist instead of a blogger!

20. **Sean**
March 16, 2005

My first impression, upon an admittedly brief reading, is that this mechanism won't work — there's no way that the situation outside our Hubble patch can influence our observed dynamics. But I have to think about it more to understand exactly what they are claiming.

Of course, if any cosmological observation shows that the dark energy is not a cosmological constant, people will abandon the landscape idea. String theorists, like everyone else, will go back to trying to understand a way to get a vanishing vacuum energy without unbroken supersymmetry. You try to build models that are consistent with the data, that's the way it works.

"The landscape" is not the same as "string theory"; it is an idea within string theory that may or may not be right. String theorists themselves argue back and forth about whether the landscape is the right way to think about things; the fact that there is so little experimental guidance makes it a difficult task, but not necessarily an impossible one.

21.
March 16, 2005

Common-sense suggests that super-Hubble fluctuations generically mimic an anisotropic expansion. While supernova data are consistent with an isotropic acceleration. Is this a problem? The text below eq. (12) seems a (plausible but not sound) attempt of addressing it.

Anniversary

March 17, 2005
Categories: Uncategorized

It's now been exactly one year since I first set up this weblog. At the time I thought the number of those sharing my interests would be very small and hardly anyone would be looking at whatever I put up here. Things have turned out very differently, with an ever increasing number of connections. I started gathering statistics in May of last year. Here's the average number of connections to the main page per day (there's a similar number of connections to other pages, from Google searches and links from elsewhere).

May 2004 146
June 2004 240
July 2004 281
August 2004 336
September 2004 315
October 2004 514
November 2004 514
December 2004 572
January 2004 735
February 2005 955
March 2005 (first half) 1109

I've enjoyed and learned a lot from many of the comments posted here (at last count there have been 2728, concerning 168 different postings), but a recurring problem has been that many people would like to turn the comment section into a discussion forum for their own personal speculative ideas about physics. This threatens to completely overwhelm discussion of the topics I'm actually posting about. This morning I had to delete several several such comments from different people. Please do not post comments here of this kind. Get your own weblog and do it there. If every so often you want to post a link here to something you've written of this kind elsewhere, that's fine.

It's been quite a year, especially as the story of string theory just gets weirder and weirder. I have no idea what will happen during the next year, but I'm looking forward to finding out.

5. **ali**
   March 18, 2005

   Congratulations Peter! (from a former Rabi sch.)

   As someone who spent a couple of years at princeton (1998-2000) and witnessed first-hand the mad rush to study string theory (half of my entering graduate class wanted to do a string thesis), I very much appreciate your willingness to confront this openly and intelligently. For a while it seemed like it was really just Glashow (and the ghost of Feynman)…

   By the way, I went to Lawrence Krauss's talk (to a lay audience) this week at the CUNY graduate center. He summarized pretty well the evidence for the standard model of cosmology, leaving the audience to contemplate the mystery of the dark matter and energy. At the end, he asked if there were any questions. A few people asked, but he seemed frustrated with the caliber of the questions. He said he'd take one more question, if someone had something GOOD. I shot my hand up and said (truly unsarcastically), "What about string theory? Isn't it supposed to explain everything?"

Krauss smiled and then said that string theory is a failed theory in his opinion. He got into cosmology in the 80's to understand the fate of the universe and the smallness of the cosmological constant. He said that string theory has completely failed in addressing either of these. He then plugged his book coming out in September.

In retrospect, the way that last question played out made me look like "jeff gannon" to Krauss's "George Bush". But I couldn't help myself! 🙂

   March 18, 2005

   Congratulations on your first blog-bday, Peter! 🙂 It's a real "ritual of passage"… something along the lines: "If i made it so far, i can keep on making it!" 😉

   As for the "comments about the comments" (gotta love meta-statements… and G?del!), sometimes i think people forget that this is **your** space, not theirs… and, this pretty much gives you the right to do whatever you please. I guess some concepts are complicated…

   Anyway, if you ever need a boost on your stats, just let me know… i can easily make your blog beat the 1.000.000 hits/month! (Yeah, you're reading it right: one million. 😉

   Take care! []'s!

   March 18, 2005

   Peter said: "many people would like to turn the comment section into a discussion forum for their own personal **speculative ideas about physics**."

   Oh Peter, that's a good one. **Speculative**. Don't you realize that ALL research into a new candidate theory unifying QM and GR are ALL **speculative ideas**? If something makes a solid prediction and then be verified by experiment beyond doubt. Then it's no longer just a speculation, but an accepted theory. Nothing like that happened yet to any of the theories being investigated.

   So every one is **speculative**, yours included. You just like your own speculation better than others'.

   And sometimes you erase purely **none-speculative**, but factual comments. Like last time when I talk about stars radiate energy and it acounts exactly for the right amount of CMB energy. It's a fact, not speculation. Even proponents of BB, like Edward Wright, accepts that there is a "coincidence" between the two. But to you, since you can not agree with that fact, you call it "speculative".

   Quantoken

8. **Nonspeculating man**
   March 18, 2005

   "many people would like to turn the comment section into a discussion forum for their own personal speculative ideas about physics."

   Good iniciative, bad methodology!!

9. **Kyle**
   March 18, 2005

   Thanks for your time and effort Peter!

10.
    March 18, 2005

    Peter, Congratulations. Your blog is very informative.

11. **rich_w**
    March 18, 2005

    Thanks, Peter, for blogging and keeping the site going – it's been informative, enjoyable and, on occasion, controversial. Thanks again, from this humble mathematician wannabe…

12. **Peter**
    March 17, 2005

    One trend I've noticed is that even a year ago many string theorists automatically assumed that anyone who criticized the theory was an idiot and/or did not know what they were talking about. I see less and less of that these days…..

13. **Not a Nobel Laureate**
    March 17, 2005

    How about graphing that data as a "landscape".

    😉

14.
    March 17, 2005

    Wow, hard to believe it's been a whole year. Out of curiosity I went back and looked at your first several posts and comments. I must say, as a former particle theorists, I feel embarrased on behalf of some of my former colleagues for some of knee-jerk abuse you've been subjected to. And that's even before the arrival of Lubos!

15. **Peter**
    March 17, 2005

Sorry, I don’t want to spend time massaging this data. Connections are from all over the world. Quite a few academic machines with a name that includes the string “strings”…..

And Lubos, if I really wanted to compete with you on traffic numbers, I could start expressing opinions about Columbia’s Mideast-related political controversy (don’t anyone even think of submitting comments on that here….)

16. **Lubos Motl**
    March 17, 2005

    Congrats, Peter your numbers are pretty encouraging for others. 😉

17.
    March 17, 2005

    Or how about some geographical visitor info? It would be nice to see from where the various visitors are.

18. **Steve**
    March 17, 2005

    How about posting a graph of that data with a fit curve?

Coleman Conference

March 20, 2005
Categories: Favorite Old Posts, Uncategorized

I spent the last two days up in Cambridge, mainly attending the conference in honor of Sidney Coleman. Sadly, Coleman is in poor health, suffering from Parkinson's disease, and was unfortunately unable to attend the talks in his honor. They were videotaped so that he could watch them later.

For me as for many particle theorists, taking Coleman's quantum field theory course at Harvard was one of the great intellectual experiences of my life. Another such experience was reading and learning from his great Erice lectures, both the late seventies ones as they came out, as well as going back to his earlier ones that started in 1966. These were collected in 1985 in the book "Aspects of Symmetry", allowing me and many others to replace a stack of dog-eared Xeroxes with a more durable volume. The fact that Coleman stopped giving these lectures after 1979 was to me one of the first indications that particle theory was entering a much less promising phase of its history. Coleman never really warmed to the topics of supersymmetry and string theory.

For much of his career Coleman played the role of guru for the particle theory community, generously sharing his unmatched insights into quantum field theory. He would sleep through the morning (famously announcing that he couldn't teach a 9am class because he couldn't stay up that late), get into his office late in the afternoon, then spend hours dealing with a long line of people waiting to talk to him to try and get some help with whatever problem they were working on. Steven Weinberg spoke for many people at the conference when he said that Coleman was the single person he had learned the most physics from.

The conference was extremely well-attended, with the large lecture hall in the physics building at Harvard overflowing on Saturday. I don't think I've ever seen so many Nobel prize winning particle theorists in one place. They included Gell-Mann, Glashow, Weinberg, 't Hooft, Gross, Wilczek, Wilson, as well as Fields medalist Edward Witten. One of the few living Nobel particle theorists who couldn't make it was David Politzer, who very much directly owes his prize to Coleman.

I won't describe the talks in detail, this has been done pretty accurately already by Lubos Motl (who I got to meet in person for the first time). Physics weblogging was very well represented at the conference: besides Lubos, Jacques Distler was liveblogging from one corner of Science Center B on Friday, and Serkan Cabi was also there. Sean Carroll also has some comments about Coleman.

Among the more historical talks, perhaps the most interesting was that of Gerard 't Hooft (Lubos seems to have missed 't Hooft's comment that he shouldn't be referred to as "Gerardus", a formal version of his name that appears on his Nobel citation and his passport, but is otherwise not much used). 't Hooft gave his version of the asymptotic freedom story. He said that he had computed the Yang-Mills beta function a couple years before Gross-Wilczek-Politzer, but didn't realize that this result wasn't known to the experts. He pointed out that everyone else had experience only in computing the scaling behavior of non-asymptotically free theories, whereas the first theory he did the computation for was an asymptotically free one, so he thought this was unremarkable. He did say that Gross-Wilczek-Politzer deserved the Nobel since (besides being the ones to publish the beta-function result) they had understood how to use this to explain Bjorken scaling, something that he hadn't known about. He said his advisor Martin Veltman had told him that the Yang-Mills scaling behavior wasn't relevant to experiment since experimentalists only cared about what happens on mass-shell. Luckily Veltman was one of the few Nobel theorists not in attendance, since he would likely have blown a gasket if he had been there to hear some of the things 't Hooft had to say about him. 't Hooft went on to say that he had learned one important thing from this episode: always immediately publish any new result you have.

There was significant mention of string theory in only two talks, those of Gross and Witten. Gross gave essentially the same talk he gave last October at the 25th anniversary of the KITP. He joked that he had managed to time the award of the Nobel with the KITP celebration by every year for the last thirty years writing to the Nobel Committee and asking them to wait a while before awarding him the prize, something they had been happy to do. At the point of his talk when he said that the question "What is String Theory" was one of the big questions for the future, he stopped to defensively note that since we don't know what string theory is, it is an idea that can't be killed, no matter how much certain members of the audience wanted to do this. He went on to claim that since AdS/CFT kind of connects string theory with QCD, string theory is in some sense part of the standard model, so it's importance is secure. This argument seemed to me pretty disingenuous, since presumably he's well aware that the problem most critics have with string theory is not with the idea of using it as a dual representation of QCD, but with the idea of getting a TOE out of it, a project which some have called a "colossal failure". He didn't have anything to say either about this failure or about the whole Landscape mania.

The last talk was Witten's, entitled "Emergent Phenomena in Condensed Matter and Particle Physics". He started by saying that he was afraid the title of his talk might be more exciting than the talk itself. By "emergent phenomena" he meant roughly non-perturbative phenomena in QFT, where the long distance degrees of freedom one observes are not directly related to the local degrees of freedom. He gave QED as an example of a non-emergent theory, QCD an emergent one, with the nature of the electroweak theory still up in the air until we know more about the origin of electroweak symmetry breaking.

He went on to say that gravity messes up this distinction between local and emergent phenomena, since one doesn't have diffeomorphism invariant local observables. He then quoted his 1980 work with Weinberg (and with help from Coleman) to the effect that you can't get a massless spin two bound state in a theory with a local stress-energy tensor, saying that this showed that you can't start with a local theory in Minkowksi space and generate Einstein gravity as an emergent phenomenon. For him the lesson is that if you want gravity as an emergent phenomenon, you need to find a way to first get space-time as an emergent phenomenon, and he believes that whatever the primoridial M-theory underlying string theory is, it should do this. While such a theory doesn't now exist, he went on to give the AdS/CFT correspondence as the kind of thing he had in mind. There the Weinberg-Witten argument is evaded since a QFT in 4 dimensions is related to a gravity theory in a different number of dimensions (5).

Comments

1. March 23, 2005

   Maybe I am missing something, but how can QCD be dual to a gravitational theory in AdS_5 when it doesn't have a massless spin-2 particle?

   Isn't that the same problem which killed string theory as a dual theory to QCD? The absence of a massless spin-2 particle?

   Or perhaps the graviton IS a QCD bound state? That would be shocking!

   But I guess if you don't have a Planck brane…

2. March 23, 2005

   I want to talk about Sidney Coleman. I met him almost 25 years ago. I was a 1st year grad student. He struck me as an "old" man. Now I know that he couldn't have been older than 45.

   Unlike the rest of the Harvard "superstars", he was not arrogant, he was not patronizing, and he was not abnoxious. He was approachable, and he very patiently listened to questions, then very kindly answered them. Sometimes his answer was an honest "I vaguely know these things. I'm not an expert".

In those days, there was a joke circulating around the physics dept at Harvard (I think it's attributed to Claude Bernard who was a grad student of Weinberg's at the time):

"How do you do physics at Harvard? You go to Witten to give you a problem to work on. You go to Coleman to tell you how to solve it. Then you go to Weinberg to write you a reference letter."

I'm saddened by his illness, and by the fact that he can longer teach physics and discuss physics.

3. **Arun**
   March 22, 2005

   "That's only possible for massive particles and the theorem doesn't apply."

   I thought the purpose of the theorem was to rule out massless bound states; not to assume that all bound states are massive. Anyway, I'm probably missing the point.

4. **Johan**
   March 22, 2005

   Regarding the "gravity as a gauge theory" issue, Deser's bootstrap approach does give you the Einstein-Hilbert action but I believe it only works for spacetimes that are topologically R^4. Penrose has shown that there is no map from Schwarzschild spacetime to Minkowski spacetime that takes lightcones into lightcones, which jives well with the Witten-Weinberg argument.

5.
   March 22, 2005

   P.S. you're describing a topological quantum field theory.

6.
   March 22, 2005

   That's only possible for massive particles and the theorem doesn't apply.

7. **Arun**
   March 21, 2005

   Probably a dumb question, but what happens to the Witten-Weinberg theorem if the particular QFT admits of no single-particle states except on length scales very much smaller than the natural scale of the theory?

8. **Peter**
   March 21, 2005

   No, Lee Smolin wasn't there. But a message from him was read at some point I recall.

9. **Anonymous**
   March 21, 2005

   Peter, was Lee Smolin there for this conference since he
   was Coleman's graduate student?

10.
    March 21, 2005

    Chris W.

    I seen this issue has people all tied up in knots?:)

    This idea is called emergence. It's a familiar phenomenon in the theory of condensed matter, which is Laughlin's background. Solids and liquids sometimes play host to strange entities that bear little resemblance to the atoms making up the substance. For example, in some materials there are things called spin waves. Every atom acts a bit like a small magnet, with a north and a south pole aligned along its spin axis, and spin waves are oscillations in the alignment of these spins. "Somewhat like what would occur if one took a supple picket fence and rapidly twisted one end back and forth," says Laughlin. Because this is the quantum world, waves can be considered as particles, and vice versa, so spin waves behave like a kind of emergent particle.

    http://www.fortunecity.com/emachines/e11/86/beneath.html

11. **Chris W.**
    March 21, 2005

    Maybe the views expressed a few years ago by Laughlin and Pines, and by Laughlin in his new book, have something to do with Witten's choice of the word "emergent". Chris Quigg's forceful response is contained in this article.

12. **Peter**
    March 21, 2005

    Quantoken,

    I talked to Lubos for more like 20 seconds, not 20 minutes. I often have perfectly civil e-mail exchanges with him, your guess is as good as mine why he adopts the obnoxious hyper-aggressive persona in his public internet writings.

    Tony,

    I kind of agree with you that Witten's choice of the buzzword "emergent" wasn't such a great idea. This is a subject that really would benefit from precision of language to combat the wide-spread fuzzy and wishful thinking going on. But his talk did give some insight into hows he thinks about this, which I found interesting.

13. **Tony Smith**
    March 21, 2005

Peter, a theorem is a theorem is a theorem is a theorem, and I have no problem with the Weinberg-Witten theorem (or any other theorem) IF it is clearly and correctly stated, thus making clear its domain of applicability (and inapplicability).

I DO have a problem with Witten's use of the popular buzz-word "emergent" in such a restrictive sense that it excludes such well-known formulations of gravity as Deser's (mentioned by jkg) and MacDowell-Mansouri,
and
then, having dismissed Deser, MacDowell-Mansouri, etc, by artful language, claiming that "… a theory [of]… gravity as an emergent phenomenon … doesn't now exist …"
and
then claiming that HIS pet AdS/CFT model is "… the kind of thing he had in mind …" to describe emergent gravity because in AdS/CFT "… the Weinberg-Witten argument is evaded …".

Tony Smith http://www.valdostamuseum.org/hamsmith/

14. **Quantoken**
March 21, 2005

Peter:
To me a bigger mistery than graviton and gravity is what you had to talk to Lubos when you meet. Does he seem like the same mean and aggressive Lubos we see on the blogs? What is your impression of him? You talked for 20 minutes. Is it aboout string theory, none-string theory? Or you could only talk about Boston's weather and global warming, and nothing in physics? Just curious.

Quantoken

15.
March 21, 2005

About Deser result, is it true? can we recover full Einstein gravity? There has been a recent paper which discusses that,

gr-qc/0409089
Title: From Gravitons to Gravity: Myths and Reality
Authors: T.Padmanabhan

any comment?

16. **Thomas Larsson**
March 21, 2005

Where does an emergent spacetime leave perturbative string theory? What is the meaning of maps from the worldsheet into spacetime, if the latter only exists as a long-distance approximation?

17. **Peter**
March 21, 2005

By the vague statement of Witten's I quoted, he was referring to something very precise: his 1980 work with Weinberg. There they show a problem with the idea of getting the graviton to appear as a non-perturbative effect, as a bound state of some more elementary constituents.

In MacDowell-Mansouri, I think the vierbeins are components of the gauge field, the graviton comes from them, not as a non-perturbative bound state. Anyway, you can argue with Witten's vague statement, but Weinberg-Witten is more or less a theorem.

18. **jkg**
March 21, 2005

I am also puzzled by Witten's comment that "you can't start with a local theory in Minkowski space and generate Einstein gravity as an emergent phenomenon. …". Perhaps this is because I do not understand what "emergent" means in this context. I always believed that it was clear since Deser paper of 1970 that if you want to couple spin 2 field to energy momentum, then you must end up with Einstein theory, with possible higher order corrections (that's why it is not surprising at all that in beta function calculation for heterotic string for example you get einstein action in the leading order.) Perhaps what he has in mind is that graviton is not fundamental and emerges only in low energy approximation (I remember that there were some works on this in 80s). But then again, whatever the fundamental theory is, Einstein gravity must emerge, just as a result of its universality.

Could anyone clarify this.

19. **Tony Smith**
March 21, 2005

Peter, you describe "… Witten's … saying that … you can't start with a local theory in Minkowksi space and generate Einstein gravity as an emergent phenomenon. …".

How is that reconciliable with the obvious existence of the MacDowell-Mansouri mechanism that produces the Einstein-Hilbert action from a Spin(2,3) = Sp(2) gauge theory in 4 dimensions ?

References to the MacDowell-Mansouri mechanism include Frank Wilczek's hep-th/9801184 in which he says that the MacDowell-Mansouri "… approach to casting gravity as a gauge theory was initiated by MacDowell and Mansouri … S. MacDowell and F. Mansouri, Phys. Rev. Lett. 38 739 (1977) … , and independently Chamseddine and West … A. Chamseddine and P. West Nucl. Phys. B 129, 39 (1977); also quite relevant is A. Chamseddine, Ann. Phys. 113, 219 (1978). …".
Other references include M. Botta Cantcheff who says in gr-qc/0010080 "… MacDowell and Mansouri proposed a gauge theory of gravity based on the group SO(3,2) …", and a number of other papers and books, including Mohapatra in section 14.6 of his book Unification and Supersymmetry, 2nd edition, Springer-Verlag 1992 and Freund in chapter 21 of his book Introduction to Supersymmetry, Cambridge 1986 and Ne'eman and Regge (Riv. Nuovo Cim. v. 1, n. 5 (1978) 1, at pages 25-28) and Nieto, Obregon, and Socorro in gr-qc/9402029.
It is true that construction of the MacDowell-Mansouri mechanism was motivated by using it in supergravity models, many of which involved dimensions higher than 4, but as some of the references (for example, Freund's book) explicitly show, the mechanism can
be applied and does work in the context of a 4-dim spacetime.

Am I stupidly missing something basic, or was this an error by Witten? If it were an error, then why was it not caught by Witten or a coworker before he made such a widely attended talk?

Tony Smith http://www.valdostamuseum.org/hamsmith/

20.
March 20, 2005

Found on the web: “PBS recently aired a series on ?string theory? which, to me at least, seemed to lay some groundwork for mathematical proofs of the existence of God ? not that God needs such a proof to exist. “

21. **Alejandro**
March 20, 2005

So extra dimensions are but a trick to formulate no local theories. Fine.

Recent Conferences

March 24, 2005
Categories: Uncategorized

Last week the 2005 International Linear Collider Workshop was held at SLAC, and the talks are available on-line. At the conference it was announced that Barry Barish of Caltech would lead the Global Design Effort for the International Linear Collider. The hope is to finish a design for the ILC in 2007, have a site chosen in 2008 and construction done by 2015, allowing the ILC to run at the same time as the LHC for several years, with each machine providing data that could help decide how best to use the other one.

This schedule seems overly optimistic to me. Because of the huge US deficits, getting the kinds of increases in the DOE budget needed to build the ILC in the US looks quite difficult, and, even if this were possible, funding constraints would probably stretch out the construction schedule. In Europe, CERN is devoting all its resources for a while to the LHC, and is backing an alternate, more speculative linear collider technology called CLIC. The most likely course of events seems to be that people will be waiting to see what the LHC finds and how the CLIC technology works out before fully committing to a new linear collider. If so, a decision about what to build and where to build it would probably not take place until almost 2010, with another decade probably required to actually construct the machine.

At the SLAC conference, the main theoretical talk was one by Savas Dimopoulos on New Models about his work with Arkani-Hamed on split supersymmetry and models where both the cosmological constant and the weak scale are anthropically determined aspects of the "Landscape". There increasingly seems to be a disconnect between the experimentalists planning experiments at the LHC and ILC, whose plans often revolve around the search for low-energy supersymmetry, and the string theory inspired theorists, who are spending their time wandering around the landscape. From the landscape point of view, it seems that low-energy supersymmetry is extremely unlikely.

For more from theorists wandering around the landscape, see the talks at this week's Workshop on N=1 Compactications at the Fields Institute in Toronto. The talks from this workshop are starting to become available on-line. Next week there will be even more of this at the Fields Institute, as it hosts a Workshop on String Phenomenology.

Comments

1. **Lubos Motl**
   March 25, 2005

   Peter, you should know that Savas and Nima are still leaders in SUSY phenomenology, and if they try something along different lines, it's because they have broad interests.

   Similar things apply to Shamit.

2. **quantoken**
   March 25, 2005

   DRL:
   I aready posted something about this paper a few days ago. I pointed out that:
   1.There is no credible experimental evidence for Casimir force or for vacuum energy. The calculated vacuum energy, which is 10^120 times too big so it does not exist.
   2.The Casimir force is supposed to be inverse proportional to the FOURTH power of the gap. Such a sensitive dependency on distance can not be measured by balance of force of balancing a torque, as the Lamoreaux method. His experiment, (which he himself) admittedly conducted using **$300** lab scratch materials, can not be trusted.

   Quantoken

3. **D R Lunsford**
   March 25, 2005

   Flash

   On SPR, T Larsson points to an interesting paper by Jaffe, which argues that the Casimir effect has no direct bearing on the issue of zero-point fluctuations:

   http://www.arxiv.org/abs/hep-th/0503158

   Some sanity! Hope! Of course, some of us are not surprised.

   -drl

4. **Aaron**
   March 24, 2005

   "From the landscape point of view, it seems that low-energy supersymmetry is extremely unlikely."

   Enh. The landscape can tell you pretty much whatever you want it to.

5. **Arun**
   March 24, 2005

   Maybe China could be persuaded to finance the ILC, instead of increasing its defence budget by 12.6% over last year? The increase amounts to about 3.4 billion dollars.

New This Week's Finds

March 27, 2005
Categories: Uncategorized

John Baez has just put out a new issue of his This Week's Finds in Mathematical Physics, dealing partly in more detail with the material about Clifford modules mentioned here a couple weeks ago. I've added as the first comment here something he had some trouble submitting as a comment to the older posting on this topic.

John briefly mentions a relation of all this to Bott periodicity in topology, using a very abstract homotopy construction involving spectra. A more concrete version of this can be found in Milnor's book on Morse theory. For the relation of Clifford algebras and K-theory, the standard refererence is the 1964 paper "Clifford Modules" by Atiyah, Bott and Shapiro published in the journal "Topology". The crucial fact they describe is how the Thom isomorphism in K-theory (which is essentially the same fact as Bott periodicity) is related to the structure of Clifford modules. Greg Landweber has recently worked out an interesting equivariant version of this story.

Greg also has a nice new paper with Megumi Harada about the K-theory of a symplectic quotient, that looks like it should imminently appear on the arXiv.

John also mentions some recent work of Dror Bar-Natan, Thang Le and Dylan Thurston on the Duflo isomorphism. This is a beautiful story, and also has a relation to Clifford algebras that John doesn't mention. For this, see Eckhard Meinrenken's talk at the 2002 ICM in Beijing.

Comments

   Thanks, should be fixed now.

2.
   March 27, 2005

   Your link to the Landweber-Harada paper is broken.

3. **John Baez**
   March 27, 2005

   Dear Peter –

   I'm glad you liked week211 of This Week's Finds. I just put up week212, which digs deeper into the relation Clifford algebras and supersymmetry. A bunch of it comes from Deligne's talks at the Institute for Advanced Studies – the ones that became part of that book *Quantum Fields and Strings: a Course for Mathematicians*.

   I think there are still hopes for understanding the details of the Standard Model with the help of a deeper understanding of Clifford algebras, division algebras and related algebraic structures. Garrett Lisi mentioned Greg Trayling's work. I've never taken the time to properly understand that, in part because of some nonstandard terminology that it uses, but I'm encouraged by the fact that Garrett thinks it's good. I've spent a lot more time on Geoffrey Dixon's work. The SU(5) and SO(10) grand unified theories, and Jogesh Pati's work on left-right symmetric theories, also have something very beautiful about them. I suspect that they're all grasping various parts of some truth that we're not yet able to fathom, perhaps because we don't have the right language.

   If none of these theories are currently fashionable, well, that's in part because none of them quite hit the nail on the head – but also because the most influential particle theorists seem to have given up hope on the idea of staring at the Standard Model until something clicks and a beautiful theory takes form which explains all its baroque peculiarities. Most of the physicists who are really good at math seem willing to let the internal logic of string theory guide them where it will: either to a triumphant victory in physics, or to a journey through beautiful mathematics increasingly distant from the physical world. It's a pity that pondering the Standard Model is being left to mere "phenomenologists".

   Best,
   jb

Landscape Architecture

March 30, 2005
Categories: Uncategorized

The Perimeter Institute in Canada is known as a center for research in Loop Quantum Gravity. This week they have come up with an extremely clever way to make string theorists look bad. They've scheduled a week of talks on String Phenomenology, ending this Friday on April Fool's day. Most of the talks are related in one way or another to the "Landscape", with talks by Kachru on "Landscape Architecture" and DeWolfe on "More Landscape Architecture". If you're in the mood for a giggle, tune into these talks tomorrow: it will be all landscape, all the time, from Michael Douglas in the morning to a panel discussion in the evening moderated by Herman Verlinde on the topic "Landscape: What Is It Good For?". It's quite possible the panel discussion will be very short.

   It is always a disappointment when one discovers that people are not acting from the best of motives. For example, when I discovered that Schr?dinger used to run a pay porn site using the University of Zurich's web space, I was devastated (I *think* that he was, anyway).

3. **Fyodor Uckoff**
   April 1, 2005

   "— Why is this all a good thing?"

   Why, that's a terrible thing to ask. I bet somebody will get the Nobel for this work some day, if indeed they haven't already.

   Meanwhile, I hear that Peter Woit is actually writing a popular book about Dirac Index Theory! Seems that his website was just to gain publicity for his new book, "Black holes, White holes, Worm holes, Bore Holes, The Bermuda Triangle, and Embeddings of SU(2) in SO(4)". And you thought it was only Stanford and Harvard profs who did that kind of thing. Michio Kaku, when asked to comment, would say only: "I think I'll wait for the movie."

4. **Arun**
   April 1, 2005

   "Remarkably, it is only in the modern context of the landscape that we can appreciate such a finely tuned theory. It would have been rejected out of hand by traditional effective field theorists only a decade ago. In the modern context, it is a strong competitor to other theories of physics at the weak scale."

   "…unlike traditional unwieldy model-building, in which additional fields are added and their phenomenological consequences studied, here we remove fields and their associated phenomenological problems."

   — Why is this all a good thing?

5. **Peter**
   April 1, 2005

   I get the joke about supersplit supersymmetry. But I still don't see why split supersymmetry isn't a joke. And please, somebody tell me that what has been going on at the Perimeter Institute this week is an elaborate hoax. It would be too depressing if this were not true…

6. March 31, 2005

   Wow. It's not often you see a theory paper with such a high author:page length ratio.

7. **Aaron**
   March 31, 2005

   Peter — there's a fascinating new paper on the ArXiV which shows how the landscape can lead to some radically new ideas in phenomenology.

   I find it hard to believe that people would have considered such a model before anthropic ideas became prevalent.

8. **Urs**
   March 31, 2005

   > People have been working on the idea that the
   > Dirac operator answers all our questions for 25 years now

   Beyond the intended parody it is maybe interesting to note that Dirac operators and index theorems and all that play a prominent role in superstring theory. The index of the heterotic worldsheet supercharge, which is a Dirac operator on loop space, is related to the elliptic genus, for instance.

   I think anyone interested in Dirac operators in general can hardly find a more fruitful area than superstring related topics.

9. **Quantoken**
   March 31, 2005

   I looked at the URL Peter provided, and find the LHC Stretch Exercise to be interesting. Any string theoretist up to the challenge of coming up with a theory to explain the presumed “data” from LHC, before Friday the April Fools Day?

I did a little bit calculation and find that the original author must had the figure of exactly 2000 GeV in his mind when he proposed that “data set”.

I guess the point they try to make is: If you can’t say anything about a clean set of hypersised data from your theory, then how could you say anything when the REAL data comes out, which is full of ambiguity and therefore much less useful? Isn’t it a complete waste of money if LHC doesn’t help you to tell which theory is right and which is wrong?

Quantoken

10. **Juan R.**
March 31, 2005

I agree with the “obscure instructor” on that “Dirac operator theory” is outdated. I’m sorry Peter, but your ideas are pure “speculation” (really is bad math)!

But, and this is an important point, string theory has derived lot of stuff outside of the standard model but **nothing inside it**!

String theory is so outdated as Dirac operator and *young and brilliant people would work in some more general and revolutionary theory*!

11. **Fyodor Uckoff**
March 31, 2005

Meanwhile, the 4/1/2005 issue of the SF Chronicle has an interview with a certain P Woit, a leading authority on Dirac Index Theory, the dominant theory in theoretical physics for the last quarter century. The theory has however attracted some criticism. Edward Witten, an obscure instructor at Princeton, says: “People have been working on the idea that the
Dirac operator answers all our questions for 25 years now, and the theory predicts absolutely nothing beyond the Standard Model. It’s long past time that people like Woit should admit that Index Theory is a failure; he should be persuading young people to try something new and radical. I’ve always thought that string theory deserves a lot more attention, attention it would have received if the Index Mafia had not dominated the physics departments of the great universities for so long.” Asked to comment, Woit said: “Talk to the Hand.”

12. **John Bell**
March 31, 2005

Spooky Processes

Scattering processes are always interesting and with regards to the Perimenter institute, Smolin retains a well balanced view of what needs to be done there.

We would need proof to this ascertion of Fool’s day. We know some people like to make use of it in regards to appling labels. Alan Sokal crying wolf?

This does not in anyway make the idea less tangible in what String Theorist think of. In regards to the information that comes out of the blackhole. They think they can get much closer theoretically.;)

New Institute at Stanford

April 1, 2005
Categories: Uncategorized

Stanford University will officially announce later today the founding of a new research institute, with major funding from the John Templeton Foundation. Many of the faculty and research staff of the new institute will come from the present Institute for Theoretical Physics which will be shutting its doors.

Co-directors of the new institute will be Stanford faculty member Leonard Susskind, and Gerald Cleaver, who is currently head of the Early Universe Cosmology and Strings Group at Baylor University. Susskind, who is one of the co-discoverers of string theory, has in recent years been the most prominent promoter of the theory of the "multiverse", which he describes in a recent interview. Later this month he will be giving the Einstein lecture at Brown University on the topic of String Theory and Intelligent Design. He is widely considered to be the leading candidate for next year's Templeton Prize. Cleaver, a prominent string theorist who was a student of John Schwarz (the co-discoverer of superstring theory) at Caltech, has published more than 40 important research articles on string theory. Like Susskind, his recent interests have been in the area of string cosmology.

Next year the institute will open its doors with a year-long program on the topic of the multiverse, led by theoretical cosmologist George F. R. Ellis visiting from the University of Cape Town. Ellis, the 2004 Templeton Prize winner, explains that the traditional view of an opposition between faith and science has been made obsolete by the latest research in string theory and cosmology. Says Ellis, "In the end, belief in a multiverse will always be just that — a matter of belief, based in faith that logical arguments proposed give the correct answer in a situation where direct observational proof is unattainable and the supposed underlying physics is untestable."

The new institute will be named the Stanford Templeton Research Institute for Nature, God and Science (STRINGS) and will collaborate with other related Bay Area organizations, including Stanford's own KIPAC (Kavli Institute for Particle Astrophysics and Cosmology) and Berkeley's CTNS (Center for Theology and the Natural Sciences). Steve Kahn, the director of KIPAC, welcomed the formation of the new institute saying "We're very pleased to have such a major institution on campus led by two such prominent physicists working on cosmology. In this era of declining NSF and DOE budgets, we need to branch out from traditional approaches to science. We expect to collaborate with the new institute to help us seek funding from sources such as the President's FBCI initiative." Besides the physicists, several faculty from other Stanford departments will be affiliated with the Templeton institute, including computer scientist Donald Knuth, author of the recent book Things a Computer Scientist Rarely Talks About.

According to Dr. John M. Templeton, Jr., president of the Templeton foundation, "the idea for the institute grew out of our involvement with a series of lectures at Stanford in the area of biology. At those lectures the biologists pointed out to us that it was the physicists on campus who were doing work most closely related to our foundation's interests, something we had already noticed through our Cosmology and Fine-tuning Research Program. As the latest cutting-edge research in physics has caused physicists to rethink what it means for a theory to explain experimental data, the wedge driven by Galileo between science and religion has begun to close. We're very proud to be able to support and encourage this trend."

Encouragement also comes from some other members of the Stanford physics department. Nobel-prize winning theoretical physicist Robert McLaughlin was quoted as saying "theoretical particle physics is just getting old and losing its youthful good looks. Even Ed Witten has given up on it. This latest plan for the cosmology/multiverse/string theory crowd to join up with Templeton reminds me of a woman deciding to become a nun when she gets too old to attract men. But if it gets them out of the physics department, I'm in favor of it. Don't let the door hit you on the way out, guys."

   April 7, 2005

   Hi J, thanks you by detail on Ellis and Hawking. I searched the old article by Ellis that I discussed below.

   Los l?mites de la Cosmolog?a

   George f. R. Ellis

   El enfoque epistemol?gico de la cosmolog?a lleva a recordar algunas perogrulladas y a plantear verdaderas dificultades. El hecho de que no exista m?s que un ?nico universo observable impide cualquier comparaci?n de este objeto con otro, una condici?n que sin embargo es necesaria en cualquier procedimiento cient?fico.

   That is, cosmology is not one of positive sciences.

   For fans of ?landscapes? and all stuff, simply to say that Ellis considered the vague discourses about ?multiple universes? like outside of physics.

2. **cvj**
   April 4, 2005

   April 3, 2005

   "A few years ago I followed a good course of super-strings, together with good students. But at the end I found no way of applying the interesting things I learnt to physics, and it was too early for discussing this problem. So I sent an e-mail to students (modifying its header such that it seemed sent by the teacher) telling that, instead of a formal examination, they had to give seminars choosing from a list of topics. Each topic was a nonsense, obtained by combining in a pseudo-random order the usual words of stings papers.

It was an instructive joke.

Many of these students now are at major US universities."

So we are witnessing the final convergence between
String Theory and Post-Modernist Deconstructionist
Literature Theory.

My only question. Why did it take so long?

5. **Not a Nobel Laureate**
April 3, 2005

Excellent April Fool's parody.

April 3, 2005

Thanks for Quantoken for the comment concerning proton decay.

If quark and lepton numbers are conserved separately, the GUT mechanisms of proton decay are excluded. This is achieved in TGD framework since quarks and leptons correspond to different
conserved chiralities of M^4xCP_2 spinors induced
to space-time surface. The couplings of quarks and leptons to CP_2 Kahler gauge potential are n=1 and n=3 multiples which gives standard model quantum numbers correctly. Color is now not a spinlike quantum number but basically angular momentum like: this means a profound difference compared to QCD.

One can of course consider the possibility that quarks have lower mass states. TGD indeed suggest the existence of fractal hierarchy of QCD like theories for colored excitations of also leptons and there are some experimental findings giving some support for this conjecture. This picture is consistent with W and Z^0 decay rates if these QCD like theories are not asymptotically free and exist only in some finite energy and momentum transfer range. This framework allows to consider the transformation of ordinary baryons to baryons of scaled down hadron physics by a kind of tunneling mechanism.

Best,
Matti

7. **Quantoken**
April 3, 2005

Regarding proton decay. I must emphasis that it is not just the standard model that predicted that proton decays. The point is we all know proton is not the most fundamental building block. It clearly has internal or intrinsic structures. Because of that **ANY reasonable theory would have to lead to a prediction of proton decay**.

The current lack of evidence for proton decay can be interpretted in one of several ways:
0.Protons indeed does not decay ever.
1.Protons decay in ways predicted by the standard model, but its life time is too long to be detectable.
2.Protons decay in ways we do not know, and our current detection technology would not have registered any signal.

I think the 3 is the most possible scenary. There are plenty of things that the standard model can not explain. The most notable ones would be super high energy particles detected in nautral occuring cosmic rays. The energy is many times higher than the energy/mass of most elememtary particles, like proton and neutron.

What kind of cosmic process would leads to that kind of energy? There has been no plausible answer so far. You can throw in a black hole or things like that, but at most you can get something with an energy level of the same order of magnitude as

8. **Matti Pitkanen**

9. **Randall Rhodes**
April 2, 2005

I realize I just made an acronym mistake. I meant to say String Theory rather than SUSY (supersymmetry.)

10. **Randall Rhodes**
April 2, 2005

I've been reading the Greene book "Fabric Of The Cosmos." I like the way it was written. Of course, when you get to the SUSY part, the end of that chapter becomes murky in terms of resolving questions (In the same sense that the Standard Model explanations cannot continue to provide many more answers.)

I trust Greene's reasoning and articulate descriptions of SUSY, I understand the concepts better than I did before. But I can't help but feel that I'm reading about a framework that is literally being reverse-engineered to fit models that have already demonstrated tangible results. It will be interesting to see which will be discovered first: The Calabi-Yau shape predicting all particle charges, forces and masses or direct proof of the Higgs particle in the LHC.

P.S. The search for the right Calabi-Yau shape seems contrived in the way that re-normalization seemed contrived. Feynman invented re-normalization but was openly hostile towards it. Are any SUSY theorists at least showing mild skepticism about this issue?

11.

13. **Peter**
April 1, 2005

Hi Tony,
The period when I was at Harvard (75-79) was after GUTs had already been formulated, but proton decay experiments were just getting underway. Glashow and Georgi especially were working on various GUT models.

There are plenty of people (for instance, besides Glashow, Georgi and Wilczek) who never thought much of string theory. But after the initial failure to see proton decay, most people felt that ruled out the simplest SU(5) GUT, which got them more interested in supersymmetric GUTs. I don't know anything about the background problems you mention, but I find it hard to believe Glashow would give up his ticket to another Nobel prize easily. As for why Glashow is the only one to complain publicly, you'd have to ask the others. But part of it is that Glashow has a stronger personality, is less likely to keep his views to himself than many others.

Milnor wasn't at Stony Brook when I was there, at the time he was a professor at the Institute in Princeton. I've never talked to him about string theory, but most mathematicians are pretty impressed by string theory, partly because Witten has pushed it so hard and he has a well-deserved Fields medal, partly because some very interesting math has come out of string theory.

14. **Tony Smith**
April 1, 2005

Peter, you say in your personal background blog entry at http://www.math.columbia.edu/~woit/blog/archives/000006.html
"… 1979: B.A. and M.A. in physics, Harvard University. …
1984: Ph. D. in theoretical physics, Princeton University, …
1984-87 Postdoc at the Stony Brook ITP Got interested in spinor geometry,TQFT and representation theory, started talking to a lot of the mathematicians at Stony Brook In 1987 it became clear to me that someone who didn't believe in string theory but wanted to apply mathematics to QFT didn't have much of a future in physics depts in the US. …".

So, you were at Harvard during or just after the birth of the Standard Model, and around the birth of GUT models, and you got to see all that up close and personal. It seems to me that would have been a fascinating experience, and here are some questions:

Did anyone other than Glashow keep the faith of the Standard Model, and if so where are they now and why don't they say something about the present state of superstring theory ?

It seems to me that models such as (non-susy) GUT that are based on the Standard Model have been (by most of the physics community) abandoned and that a lot of hype has gone to supersymmetry (with no experimental support) and to beyond-the-standard-model stuff (also with no experimental support). Is a reason for such abandonment the stated position of most neutrino laboratories that proton decay has not been observed within the predicted lifetimes of GUT models?
If so, then what if all those laboratories have been using incorrect background models in their data analysis ? Did ANY of the GUT founders (including but not limited to Glashow) do a detailed study of the background models used to refute GUT ? If not, why not ?
One reason that I ask about such background is that one study done independently of the big neutrino observatories was Experimental evidence for G.U.T. Proton Decay http://xxx.lanl.gov/abshep-ex/0008074 by Adarkar, Krishnaswamy, Menon, Sreekantan, Hayashi, Ito, Kawakami, Miyake, and Uchihori.
Roughly, they conclude that a different (and at least equally reasonable) choice of background, if applied to the raw data from many neutrino observatories, would produce results not inconsistent with GUT.
Even though this seems to me to be an important result reviving a class of models that are by construction quite consistent with the Standard Model, as far as I know NOBODY, not even the inventors of GUT, ever attempted to bring the discussion of background into a foreground of discussion in the world of physics of the viability of GUT models.
Why ?

One last question – was Milnor at Stony Brook math while you were there? If so, did he express opinions about superstrings, and if so, what did he say? (I have thought of him as a very reasonable (as well as brilliant) person whose opinion I would respect.)

Tony Smith http://www.valdostamuseum.org/hamsmith/

22. **Peter Woit**
    April 1, 2005

    A couple comments on the long posting about my ascension to the status of assistant professor from someone at MIT who doesn't have the guts to publicly put their name to what they write using the machine sci-22.mit.edu.

    Soon after I started writing this weblog I found that partisans of string theory almost uniformly preferred to personally attack me and my academic qualifications rather than to deal with any of the issues I was raising here. I wrote a posting explaining my academic background, it's at

    http://www.math.columbia.edu/~woit/blog/archives/000006.html

    Note that I held the title of assistant professor at Columbia for four years (1989-1993), a status I'm not interested in going back to. I'd turn it down if the department tried to reappoint me to it. Since I wrote that posting, my formal status at the university has changed slightly. The non-standard "Director of Instruction" title I held for many years was regularized a year ago when Columbia instituted a new system for permanent non-tenured positions. I'm now officially a full-time, non-tenured member of the faculty of arts and sciences with the title of Instructor. It's a permanent non-tenured position, with a schedule of reviews of my performance.

    Over the years I've often heard from particle theorists who tell me they agree with me about string theory but don't dare say so publicly due to the personal attacks they fear they would be subject to. This ugly atmosphere of intimidation is a disgrace and string theorists should be ashamed of being associated with it.

23. April 1, 2005

    This is the same "Ellis" as in Hawking and Ellis of "Large Scale Structure of Space-time"

25. **Dennis Overbyte**
    April 1, 2005

    April 1, 2005, New York — Today Columbia University Mathematics Department chairman Prof. John Morgan announced the appointment of Dr. Peter Woit to the position of assistant professor.
    Prof. Morgan would make no further comment on the appointment, but several members of the mathematics department were willing to speak off the record. According to these sources, Prof. Morgan received a Monday morning call from Donald Trump, offering to make a substantial donation to the mathematics department. Apparently Mr. Trump was recently in San Francisco for the taping of an upcoming episode of "The Apprentice", "How to buy and sell the Golden Gate Bridge; a new approach to an old idea", when he happened upon a copy of the San Francisco Chronicle. He was immediately drawn to an article that was critical of the recent craze
    in string theory. Mr. Trump felt that string theory was being overplayed, saying "Come on! Brian Greene's name is in the Times, more than mine. How ridiculous is that?!" He read the article and was especially impressed by the comments of Dr. Woit who was listed as a member of the mathematics department at Columbia.
    Mr. Trump was impressed that Columbia's mathematics department had hired someone like Dr. Woit and wanted to show his appreciation. However, during their telephone call, Prof. Morgan
    informed Mr. Trump that Dr. Woit was not actually a member of the faculty, even though Dr. Woit might have given that impression to Keay Davidson, the author of the Chronicle article.

At this point, Mr. Trump, according to several sources, hurled more than a few expletives at Prof. Morgan, yelling "How can he not be on the faculty, he is your most famous guy?!!". When Prof. Morgan tried to explain that Dr. Woit had not published a paper since 1989 and that it would be impossible to get the rest of the faculty to agree to a promotion, Mr. Trump countered, "Who the f@*k cares about publishing in peer reviewed journals. That is so 20th century. Blogging is where the intellectual activity is at. Peter has shown how to cut through all the crap that passes for real science nowadays! If you want the donation you better f%!king hire him!"
At this point, Prof. Morgan promised to hold an immediate faculty meeting to decide on the appointment. After a fractious Tuesday afternoon meeting, the faculty voted to promote Dr. Woit. In order to save face, Prof. Morgan got Dr. Woit to promise that a paper on representation theory would be forthcoming within five or ten years. The title of the paper is purported to be "Quantum Field Theory and Representation Theory: An Etching"
After the announcement, Prof. Erick Weinberg, chairman of Columbia's physics department said, "I think it is great that the math department hired Peter. If nothing else it will piss off Brian."
Asked for comment, Gerald Cleaver, a recent victim of one of Dr. Woit's April Fools Blogs said, "I am actually happy for Peter. As Peter knows, I am a practicing Christian, but I am happy with who I am and I feel that I have done good, solid work in string theory and have the publication record to prove it. Anyway,
I am more of a `turn the other cheek' guy than an `eye for an eye' guy. But my wife thinks he is an asshole."

26. **Kyle**
April 1, 2005

I fully expected to click on the " Things a Computer Scientist Rarely Talks About" link and find a blank page.

27. **Fyodor**
April 1, 2005

I see that Cleaver's site refers to his
"PREPINTS".

I think that post-pints would have been more apt. Post quite a lot of pints in fact. Does whiskey still come in fifths, by the way?

PS: Peter, it is always a mistake to parody people like Laughlin, when he is so good at it himself, albeit unintentionally. Also it is bad strategy to draw attention to a string critic who is much more of a fool than any string theorist.

28. **Juan R.**
April 1, 2005

Is this "Ellis" not the same Ellis that openly critiqued the standard view of cosmology some decade ago?

If I am not wrong, Ellis thought that cosmology was not one of positive sciences. He tought that cosmology was more a semi phylosophical field, where scientific method was not applicable.

Interesting.

P.D: The "success" of string theory is independent of the number of centers devoted to it.

29. **Mark Trodden**
April 1, 2005

Wickedly funny post Peter. When I was out at LCWS04 at Stanford a couple of weeks ago I was dismayed to find out that there was a Templeton conference going on at the same time and that a number of prominent people were attending it rather than LCWS04.

30. **a**
April 1, 2005

From a theological point of view the landscape multiverse is an extension of Darwin natural selection. Therefore I do not believe that it can get much financial support. Your 1 April post seems unrealistic.

Witten in Canada

April 4, 2005
Categories: Uncategorized

Edward Witten is in Canada this week, giving a series of lectures at the Fields Institute, the mathematics institute at the University of Toronto. He's also giving a public lecture at the Perimeter Institute in Waterloo.

The first of his lectures in Toronto, on the topic of Relativistic Scattering Theory is now available on-line. It's a nice, simple explanation of scattering theory, using the "geometric quantization" point of view about quantum field theory. For a quantum theory of a real scalar field, one chooses a complex structure on the space of solutions of the free field equation, making this a priori symplectic infinite dimensional manifold actually a Kahler manifold. Witten's next two lectures in Toronto will be on "Gauge Symmetry Breaking" and "The Quantum Hall Effect".

I'm curious what he'll be promoting in the public event at Perimeter on Wednesday. Will it be string theory? Will anyone ask him about the appalling nonsense his fellow string theorists were spouting there all last week?.

Comments

1. **Quantoken**
   April 6, 2005

   Peter said: "The problem with the multiverse is not that it invokes things you can't **directly observe**, the problem is that it predicts nothing about anything."

   I would accept any **indirect observation** as a legitimate observation of nature, as long as the observation can be consistent and has the potential of rule-out/rule-in certain theoretical models. The problem is even INDIRECT observation of multiverse is impossible. It simply does not interact with our universe in any way that is observable, or at least not in a way that allows us to speculate any property of the multiverse.

   Anything that does not deal with objective observation of this particular universe we know, is not science.

   On a side note, I think it is pretty stupid for us to send THREE presidents to the funeral of a leader of a private religion, in a tiny country embbeded in a country full of street mafias and burglars, at a time when 100 other national heads also gather, in an era that we constantly face terriorist threats. It's recklessly dangerous and do no good other but provide a golden opportunity to those who want to do harm.

   Frankly I do NOT think they have any significant police force to provide any meaningful protection in any way, shape or form, in such a complete chaos when a couple million people around the world all want to rush in to see the Pope, including the one who attempted on his life in 1981!!! I can only hope that nothing bad happens.

   Quantoken

2. **Peter Woit**
   April 6, 2005

   Hi Mark,

   I took a look at the Spergel talk and the discussion afterwards. What really amazed me were the people trying to defend the whole multiverse nonsense by claiming it was just like the situation in the sixties with the quark model, which posited entities one couldn't see. This is really absurd. The quark model made all sorts of predictions which could be tested by experiment, most notably the prediction of the existence and properties of the Omega-minus. The problem with the multiverse is not that it invokes things you can't directly observe, the problem is that it predicts nothing about anything.

3. **robert**
   April 6, 2005

   Carl,
   1+2+3..=-1/12, surely. Still, what's a factor of two amongst theorists.

4. **Mark**
   April 6, 2005

   On an unrelated note see the discussions on anthropic
   principle, multiverse and string theory after David Spergel's
   talk at STSCI on dark energy

   Dear ____,

   The point is, the existence of this Kaehler manifold is apparently equivalent to the need for antimatter. See this thread from SPR:

   http://www.lns.cornell.edu/spr/2003-04/msg0050057.html

   -drl

6. **Carl Brannen**
   April 5, 2005

   Dear Dr. Wotit,

   Around 5 years ago, I picked up a two-volume textbook on string theory that was supposed to be the most widely used text for graduate classes and figured that I would update myself on QFT. I was horrified to discover that the iffy premise of analytic continuation (as mentioned in the Witten lecture) had been replaced by dimensional regularization. Before I had gone more than a few dozen pages the author was had summed 1+2+3+… to get -1/6, which reminds one of divergent series analysis from the early 20th century, but was not what I expected a theory of everything to provide. So I decided to begin studying QFT again, to see if I could bring the standard model into a generalization of the Dirac wave equation.

The analytic continuation of the electron from past to future reminds me of the fact that the handedness of anti-particles are the opposite of the handedness of the spinors that represent them. In order to generalize the Dirac equation into a Clifford algebra equation, I had to use the handedness of the spinors rather than handedness as it is usually defined. Instead of conserving angular momentum, in this language, the usual interaction vertices conserve the difference between the handedness of the particle spinors and the handedness of the antiparticle spinors.

Anyway, it was interesting to see Witten's lecture.

Carl

7. **Alejandro**
   April 5, 2005

   BTW quantoken, I like the aspect of your new journal.

8. April 5, 2005

   An entire lecture by Witten (I was hoping for something more profound) leading up to… crossing symmetry? How anticlimatic!

9. **Quantoken**
   April 5, 2005

   No need for dark energy

   Have a look at my latest blog entry, where I talked about the possibility of "dark energy" being just the regular baryon matter, distributed throughout the voids of the universe, in the form of micro meteorites that's hard to detect but yet constitute 70% of the mass of the universe.

   Click here.

   BTW it is also a better blog server than username.blogspot.com. I encourage people, like Lubos et al. to use livejournal instead of username.blogspot.com.

   Quantoken

10. **DQOTD**
    April 5, 2005

    Dumb Question of the Day:

    If T, C or P is not a symmetry, then does the holomorphic S defined on Sym(r+s) H_C acquire additional interesting structure?

11. **Alejandro**
    April 5, 2005

    So, after all, Witten surrenders string theory and promotes barebones QFT.

12. **D R Lunsford**
    April 5, 2005

    Very interesting. Compare Feynman's Dirac Memorial Lecture (reproduced in the little Dover book "Elementary Particles and the Laws of Physics").

High Energy Physics: Exit America?

April 6, 2005
Categories: Uncategorized

Science magazine has an article this week entitled High Energy Physics: Exit America?. It describes the US HEP budget situation, and gives details of the probable cancellation of the BTeV experiment. Evidently neither Michael Witherell, the Fermilab director, nor any of the physicists working on BTeV, had any idea this was going to happen until the day the FY 2006 budget was released.

The Science article is a lot more pessimistic about the future of high energy physics in the U.S. than any of the public reports you will read produced by the US high energy physics community, but it is also a lot more realistic. The underlying reality is that after the Tevatron stops operations in 2010 (because it can't compete with the LHC), for the first time in the history of modern physics there will be no machine operatiing at the high energy frontier in the US. Fermilab is planning an active neutrino physics program, but this will be much more limited in scope than what the lab is doing today and has been doing since its founding.

The only plan on the table for the US to get back into the high energy accelerator business is the International Linear Collider (ILC), but the question of how such a machine would be financed, and whether it would even be constructed in the US at all, remains up in the air. In a very real sense, the future of experimental high energy physics in the US after 2010 is a very large question mark.

   April 9, 2005

   I think that high-energy physicists fail to recognize the point,
   I don?t agree with Quantoken about ?energy economics?. The reason of decreasing of interest by society is that High-energy physics is mainly a useless discipline.
   Therefore, it is rather natural to stop its funding.
   Dear Peter, I sincerely think that you are chosen the wrong discipline.

3. **Chris Oakley**
   April 9, 2005

   Re: The Pauli anecdote, the version I heard was this.

   Pauli dies and goes to heaven. Before St. Peter gets a chance to look through his records, Pauli demands to see God. St. Peter eventually gets tired of arguing and leads him to God.

   "WHY IS THERE A MUON!?" demands Pauli.

   "Well, my son, let me explain …"

   God then writes down the equations and just as he starts to wade through the deeper mathematics Pauli says,

   "THAT'S IT! THAT'S WHERE YOU'VE GONE WRONG!"

4. **Heinrich**
   April 9, 2005

   Another reason why the anthropic principle is wrong is the one given in some internet book I read recently (I think it was Schiller's): Also apes can claim that the laws of the universe are made in just that way that apes could evolve. It would therefore be equally correct to call it "simian principle".

   From the quality of the argument it might even be the better name.

   Heinrich

DMS –

It's peculiar because we were born as an *intellectual* experiment. Madison, Jefferson, Hamilton, even Washington, most of these folks were intellectual titans. The great divide for us came with Jacksonian populism. Like a gas expanding into a vacuum, the type of person needed to settle everything we bought or stole or inherited through Indian genocide was the "man of action", not the man of sober reflection. And right there, the intellectual experiment ended. A free republic can't exist with dolts at the levers. I submit that we've been in mental and moral decline since the first generation died out.

Now, we're just as natively smart as everyone else, but the populist/collectivist stain prevents us from individually enjoying knowledge for its own sake, for the most part. Knowledge and culture is for "sisses". Math is for "nerds". Science is for psychos.

Maybe someone with charisma will manage to get across to the hammer-headed people here that we're getting our ass handed to us by China. Mabye. It's possible.

Nah.

-drl

(PS: Did you notice how Q made my point for me? He instantly began a good old Republican harangue on power, and how I was "whining" to dare criticize my knotheaded neighbors.)

12. **DMS**
April 7, 2005

I have to agree 100% with what DRL wrote.

As a foreigner, who studied in the US, I was struck (and surprised) by the sharp intellectual divide in the US. In fact, a significant fraction of the US population is vehemently anti-intellectual (larger, I think than anywhere in Europe or emerging economies in Asia like India and China).

Of course, in every country popstars and sports people are always very popular. But at least in Asia, people with mathematical and scientific talent (like, say a Nevanlinna prize winner;)), are practically revered. History and tradition of learning plays an important role.

A couple of years back, BBC World did a worldwide poll on who the world thought was the greatest Briton. Thanks to the large population of India, the clear winner was Issac Newton. Interestingly, Charles Darwin also got the most votes from 'backward' India. (I suspect that if Germans were to hold a similar poll in India, Gauss would be on top.)

I think it is a safe bet to say that neither of the two Britons would be the top Briton in such a poll in the US.

13. **Quantoken**
April 6, 2005

DRL:

Quit whining. Frankly I think the American taxpayers have been pretty generous in funding science research. The problem is the return is disproportional to the investment. What we get for funding super string theory research for a quarter century? Nothing. You need to work out something useful to be worthy the public's money.

What is the name of the department you get most of your funding from. It's not DOE as you would call it, but "Department of **ENERGY**". The key word is **energy**. We are facing an energy crisis! Oil reserves are being depleted! The top funding priority for the department of energy should be to find a solution to the energy crisis. Particle physicists should be spending their time figuring out better ways of utilizing nuclear energy. That's where they can make some contribution!

But on second thought, forget about it. The research of controlable thermal nuclear fusion has been going on for four decades with little success. Even if it can be success it is probably too late to save us from the oil crisis.

Even if controled nuclear fusion can be put into industry production, I heard that one liter of sea water contains enough deuterium to produce the energy equivalent of 1.5 liter gasoline. The problem is extracting the deuterium would probably cost a couple thousand liters of gasoline in terms of dollar cost, and a few hundred liters of gasoline in terms of energy cost. So it's just not feasible.

I just realized that scientists have been singing the praise of one liter seawater equivalent to 1.5 liter gasoline, and talks about going to the moon to mine Helium 3 and bring back. But **no one ever meantioned the possible prohibitive cost**, which is orders of magnitude higher than the potential benefits. Why are scientists so dishonest?

The department of energy should shift the bulk of their fundings to researches of biodegration that may generate the replenisheable replacements of gasoline. Which is the only feasible solution to the energy crisis certain to come pretty soon.

Quantoken

14. **D R Lunsford**
April 6, 2005

Why is anyone surprised? Party conversation:

"What do you do for fun?"

"I work on my physics problems."

"OH! I'm just terrible at math!"

Americans loudly and proudly proclaim how bad they are at math. They pay lip service to science, but really they are afraid of everything, and particularly math. When we need to "whup the Russkies" we poured money into weapons research by the trillions, and this gave the surface appearence of interest in science. But in fact Americans have always seemed to actively hate science, "mad scientists", and the spirit of inquiry. Knowledge is the wrong palliative for their overarching fear.

American science is not about knowledge – it's about power. We care about science only insofar as it makes us seem powerful. We want to feel powerful because in fact we are trembling little children, afraid of each other, afraid of ourselves, our fellow inhabitant on this world, afraid of everything.

-drl

15. **Peter Shor**
April 6, 2005

The budget for fundamental science in other areas in the U.S. isn't good either. Despite the fact that theoreticians cost next to nothing, compared with experimentalists, the projected funding levels for theoretical computer science at NSF in the next few years look dismal. And I believe that NASA is being forced to cancel a number of its planned expeditions.

16. **Steven S**
April 6, 2005

Hi, Peter

Lower energies are not doing so well either. Recently the proposed Rare Isotope Accelerator was cut from the next federal budget with only $4 million remaining for research and development. It has officially been delayed but looking at future federal budget projections to me it looks effectively dead.

17. **a**
April 6, 2005

Since 20 years US colliders have not been competitive with SppS, LEP and hopefully LHC.
TeVatron is a poor substitute for SSC, and ILC will not reach an energy much above LEP. A likely scenario is that US will build TESLA (which is the original German name of ILC) in order to avoid the collapse of its hep experimental community.

18. **Peter Woit**
April 6, 2005

Hmmm, actually if theorists could confidently tell us what such a machine would see, that would be a really good reason not to waste the taxpayer's money on building it. But we don't know a fundamental fact about how the world works (how electroweak symmetry is broken) and such a machine might tell us. I don't think it is hard to argue that finding that out is worth the very small fraction of the US budget that would be required.

19. **Quantoken**
April 6, 2005

I think it is a good thing for the US government to stop throwing **money**, which is a linear term, towards **orders of magnitude**, which is an exponential term. It makes no sense especially when the current theoretical models clearly can NOT tell us what we will expect to find at certain specific reachable energy levels. When scientists can tell us without ambiguity, but with an adequate confidence, that we shall find particle X at energy level Y if we do experiment Z, then maybe we can give it a try. Before that happens I do not see why we need to do a multi billion dollar gamble regarding what we could or could not find, especially when the national debts are piling up.

Scientists are also members of the society and they need to respect the tax payer's money a little bit more, especially since they are supported by that money, frankly, I think. There are better usages of the money.

Quantoken

Not a Joke

April 7, 2005
Categories: Favorite Old Posts, Uncategorized

A week or so ago I wrote up as an April Fool's joke a posting claiming that the Stanford theoretical physics group was joining a new Templeton foundation devoted to religion and science. At the time I had no idea of the degree to which Templeton-funded pseudo-science has infected mainstream cosmology. This joke turned out to be much closer to reality than I had imagined. In my quick research before writing it, I had missed the fact that the Templeton Foundation two years ago organized a symposium at Stanford on the topic of Universe or Multiverse?. The participants, presumably funded by Templeton, included a large fraction of the senior Stanford ITP faculty (Dimopoulos, Kallosh, Linde, Susskind). Someone also wrote to me to tell me that Gerald Cleaver had spent a sizable amount of time at Stanford at Susskind's invitation, something I was completely unaware of when I picked him to co-direct the Templeton institute with Susskind. Finally, Mark Trodden reported in the comment section that "When I was out at LCWS04 at Stanford a couple of weeks ago I was dismayed to find out that there was a Templeton conference going on at the same time and that a number of prominent people were attending it rather than LCWS04."

One of the other attendees at the Templeton conference was Alexander Vilenkin, and yesterday Lubos Motl had a report on Vilenkin's talk at Harvard on "Probabilities in the Landscape". Lubos explains in some detail what a load of pseudo-scientific nonsense this all is, and I'm in complete agreement with him, down to his last paragraph about how "Finally, I am sure that various people who have a similar opinion about the anthropic thinking will use this admitted frustration as a weapon against string theory." Certainly. By the way, Vilenkin's research is funded by a Templeton grant.

It seems that Cambridge University Press will be publishing a volume this year also entitled "Universe or Multiverse?" based on the Stanford symposium. It's being edited by Bernard Carr, a professor of Mathematics and Astronomy at Queen Mary College in London. He's the recipient of a Templeton grant for a project entitled "Fundamental Physics, Cosmology and the Problem of our Existence". When he's not working on cosmology and religion, he is President of the Society for Psychical Research, which investigates poltergeists, parapsychology, survival after death, etc. You couldn't make this stuff up. "Universe or Multiverse?" will include as least one sensible article, Lee Smolin's Scientific Alternatives to the Anthropic Principle, which explains clearly why the Anthropic Principle is not science.

Another participant in the Stanford symposium was Robin Collins, and he's contributing an article on "A Theistic Perspective on the Multiverse Hypothesis" to the Cambridge volume. He's supported by the Center for Science and Culture of the Discovery Institute, a right-wing organization dedicated to promoting "Intelligent Design" research. The Discovery Institute has just started up a new weblog devoted to Intelligent Design called Intelligent Design The Future which has drawn scorn from (among others) Sean Carroll and Jacques Distler. Jacques claims to have fallen off his chair laughing at this posting with its claim that "mainstream physics is now quite comfortable with design in cosmology" and question "Why should inferring design from the evidence of cosmology be scientifically respectable, but inferring design from the evidence of biology be scientifically disreputable?", but again I'm with Lubos that this is not funny. Actually it's scary.

It's becoming increasingly clear that the theory of evolution is under concerted and well-funded attack in the United States by a wide array of religious fanatics and pseudo-scientists, who are doing everything they can to stop the teaching of evolution in US schools and promote the pseudo-science of Intelligent Design. This is a fight that scientists need to join, but the extent to which pseudo-science has already infected mainstream physics and cosmology is becoming dangerous and is going to make it very difficult to effectively answer the Intelligent Designers. Susskind is giving a talk at Brown soon entitled The Cosmic Landscape: String Theory and the Illusion of Intelligent Design. Unless he's gotten even crazier than I would have imagined, I guess he'll be claiming that the string theory landscape/anthropic principle stuff he has been pushing only appears to support Intelligent Design. Behind it all is not an intelligent designer, but a wonderful physical theory called string theory. But the reason Intelligent Design is pseudo-science is that it is a non-predictive framework. It doesn't predict anything, so you can't test it and show that it is wrong. This is exactly the situation that string theory is in these days, and, for the life of me, I have no idea what response physicists can now honestly make to someone who says: "Look, you have a non-predictive framework involving a very complicated and incomplete mathematical structure that you believe for emotional and sociological reasons. I've got a different non-predictive framework tracing everything back to an Intelligent Designer, and I think mine makes more sense than yours."

Comments

   Modest scientists life:

   Take a problem (normally a problem important from application side); apply the scientific model developing the necessary number of new concepts and mathematical tools and obtain solution. If resolution is bad, begin again or abandon the problem. If it is good, then obtain ?fame? but continue working.

   Self-important scientists life:

   Choose a problem (a problem important for obtaining notoriety); apply the scientific model and obtain an adequate resolution. If this is not possible, choose one of several possibilities:

   – falsify the data forcing the fit with your ?marvellous? theory (e.g. Pons cold fusion).
   – ignore the failure and begin a new theory **named equal for notoriety purposes (e.g. string theory)**
   – take a good idea by other less recognized man (including coworkers and students) and publicly like if were your (e.g. Rutherford).
   – ignore the scientific method and use other methods like religious faith, trivial like antrophic, metaphysical, own ones (developed specifically for the occasion), etc.

   If you are critiqued by ?stupid? scientists, attack fierily them (this is familiar for us here 🙂

   Remember that you are right and other are stupid because you are… **The Best**.

   ****

   Comparison:

   – The first scientific searches true, the other searches notoriety.

   – The honest scientist talk using a firm discourse (of course can evolution), the other modifies his discourse (yesterday I said black, today I say white, tomorrow I say black again) when he needs.

   – The first helps to colleagues, the other puts obstacles to the progress of others.

   – The first is mainly interested in the solving of important society problems (e.g. energy crisis, cancer cure, etc.). The second ignores agony of people and just claim for more funding for studying a ?stupid thing? that only helps to him or herself (by obtaining notoriety).

– The first scientist admit that there is interesting disciplines and other scientists. The second think that just his/her field is important. The rest of science is trivial or only ?engineering?.

Of course, Weinberg, Witten, Hawking, Greene, Schwartz, etc. belong to the group of self-important physicists.

Note: Of course, initially both Weinberg and Witten did some significant progress in science, but now they are more focused on self-importance than in real progress.

Peter, I remember that you wait that Witten recognizes that all string endeavour is a waste of time. This will succeed on one of two possibilities: there is a new theory where he can be selfimportant once more (highly improbable because Witten is old enough for beginning again from zero even if you develop that theory), there are significant experimental data showing his theory is wrong (also highly improbable because current string theory is not falsifiable).

   Why not e-mail Nima and ask? I'm not so up on the phenomenological details.

3. **Jo?o Carlos**
   April 10, 2005

   I don't think medling religious point-of-view with scientific research can lead to any good. The best example I know is Lysenkoism in (now defunct) USSR. You know: atheism **is** a religious point-of-view…

4. **Peter**
   April 10, 2005

   Hi Aaron,

   It's the landscape I've been claiming is inherently unfalsifiable pseudo-science, not split supersymmetry. Sure, I'm willing to believe that split supersymmetry is in principle falsifiable, if you could go to arbitrarily high energies. But the question I can't get an answer to is whether it is falsiable at the LHC, although people seem to claim it makes predictions for the LHC. Sure, if the gluinos are high enough mass you're doing supersplit supersymmetry, which we know is a joke. But, to ask the same question I've been asking in a different form: if split supersymmetry predicts a gluino below a certain mass, what is that mass? You're telling me that if you push the mass too high, coupling constant unification won't work, but you've got a lot of free parameters to play with. At what mass does coupling constant unification conclusively fail? And, assuming the LHC runs for a few years at design luminosity, up to what mass will it see these gluinos? Will its reach be high enough to falsify the idea of split supersymmetry? I'm still not getting an answer to this….

5. **Aaron**
   April 10, 2005

   Peter, you're wrong about split supersymmetry. You may be unhappy with the philosophy — you'd certainly not be the only one — but, in and of itself, it is simply a fine tuned model. It *is* falsifiable. And fairly easily falsifiable, IIRC. I can't quote luminosities for you, but the gluinos cannot be too heavy as they're there to ensure coupling unification. I don't know the mass bounds offhand, but they're there. You either see them or you don't.

6. **Peter**
   April 10, 2005

   Hi JC,

   I think the landscape pseudo-science is a result of string theorists being unwilling to wave the white flag. By any sensible version of the scientific method, once you realize that the speculative hypothesis you've been investigating is, if consistent, unable to predict anything, you're supposed to abandon it and try something else. I find it just shocking that serious physicists are unwilling to acknowledge this, and would prefer to totally trash the subject and turn it into a pseudo-science.

7. **JC**
   April 10, 2005

   Peter,

   Why do you think otherwise legitimate physicists, end up indulging in pseudo-scientific activities like the anthropic principle? Do you think it's the equivalent of them waving a white flag?

   If I didn't know any better, one reason I would think that some physicists would use to justify indulging in pseudo-science, would be that all their personal "pet theories" were a washout and that they're engaging in desperate measures to salvage their life's work. Admitting defeat is a hard thing to do for many folks' egos.

8. **Peter**
   April 10, 2005

   Hi David,

   Well, you now seem to agree that Weinberg doesn't describe his bound as giving a "prediction". He's careful to avoid this misuse of terminology, even if many others with an agenda of passing off pseudo-science as science aren't so careful these days.

   Your example of falsifying split SUSY by finding something it doesn't predict is kind of silly. By the same reasoning I could argue that of course split supersymmetry is falsifiable because it is incompatible with angels with trumpets blaring being produced in a 14 TeV proton-proton collision, so if the LHC sees an angel with a trumpet blaring coming out of the interaction region, then split supersymmetry will be falsified. Clearly this is an abuse of what people generally mean by falsifiability: the theory is supposed to make a definite prediction that something will happpen if you do a certain experiment. The prediction should be definite enough that the theory must be wrong if you do the experiment and don't see the predicted behavior.

   Your example of long-lived gluinos is better. So now, what does split supersymmetry predict for the mass and lifetime of these gluinos? How much integrated luminosity will the experimenters at the LHC have to acquire and analyze so that they can rule out split supersymmetry?

   We still completely disagree about the significance of Weinberg's bound. Again: as far as the CC goes, the statement: "there's a multiverse out there with a random distribution of CCs" is experimentally indistinguishable from the statement "I don't have a clue what determines the CC". You're doing pseudo-science not science when you start going on about this statement giving scientific predictions. You're doing dishonest pseudo-science when you start crowing about "Weinberg's successful prediction" when it's:

1. Not really a prediction.
2. Off by at least an order of magnitude anyway.

There's nothing inherently wrong with people investigating the multiverse hypothesis, if they have an idea about how to get a legitimate scientific prediction out of it. All I've seen so far coming out of such investigations is pseudo-science, without even a plausible idea about how they'll ever get a real prediction. I've specifically asked people doing this kind of work to tell me what they expect to be able to really predict. For a while the answer was the scale of supersymmetry breaking, but recently they have given up on that, and they don't have any other answer.

You may not find very worthy my spending my time complaining that the landscape is pseudo-science. I happen to think it's a lot more worthwhile than trashing the field of theoretical physics by turning it into a pseudo-science, or allowing one's colleagues to successfully do so without raising any objection.

9. **Quantoken**
April 10, 2005

David said: "As for split susy, it's **very simple to falsify**: find squarks or sleptons at LHC. It also provides a distinctive smoking gun in the long lived gluinos."

It's neither simple nor easy. What if nothing is found? It is always much more difficult to prove something does **NOT** exist, **experimentally**, than to prove that something **DOES** exist.

Actually I would say it is **impossible** to prove something does NOT exist. For example there has NOT been a conclusive experiment proving that **ghost** does NOT exist, although no experiment showing it exists either. You can replace the keyword **ghost** with **sghost**, **ghostino**, **sghostino**, or **god**, **sgod**, **sgodino**. Same thhing can be said.

You could well claim that squarks exist at an energy unreachable by LHC, or claim that the cross section of interaction is too small that the LHC has not run for the many million years needed to detect a single event yet. Or the ultimate fudge factor would be the squarks do not interact with the rest of the world in any of the 4 know forces, since it only interacts using sforces. Certainly no one knows what a squark that only interact with sforces would look like.

All the new English words invented by super string theoretists are making me dizzle already.

Quantoken

10. **David**
April 10, 2005

Oops – sorry. Forgot to sign my name to the last post.

11.
April 10, 2005

I think everyone would accept the criticism that Weinberg's work on the cc isn't as predictive as his work in other areas. I'm happy that we're in agreement about this. A clear statement of his view can be found in the 97 paper where he says the calculation "suggests" a value of the cosmological constant at the bound, goes on to explain how this exceeds observational limits by an order of magnitude (this was before the supernovae observations) and then descends into bayesian analysis in an attempt to rectify the situation.

As for split susy, it's very simple to falsify: find squarks or sleptons at LHC. It also provides a distinctive smoking gun in the long lived gluinos.

But these details cloud the main point. We have a big problem with the cc. And Weinberg's calculation remains the only one to give a value in the right ballpark. Either you reject this fact and continue to look for a new mechanism. Or you treat it seriously and study the (potentially unpalatable) consequences. Both approaches are valid, presenting interesting scientific questions that can hopefully be answered with work. And both approaches are more worthy than launching polemics from the sidelines, denouncing anyone who dares consider the latter.

April 10, 2005

"If you guess a theory and then seek money to test it, you are promoting belief"

Yep, you believe in Money.

(Which is a problem by itself. A reason for bankers to contract physicists instead of economists for market calculations, is that the physicist is more able to see money as a number, not as Money)

13.
April 9, 2005

If you guess a theory and then seek money to test it, you are promoting belief, hence you need religious faith. Mathematicians from Pythagoras onward have had faith in numbers, and can easily mislead people into weirdly believing that litmus paper is not a test for real acid:

?I don?t demand that a theory correspond to reality because I don?t know what it is. Reality is not a quality you can test with litmus paper. All I?m concerned with is that the theory should predict the results of measurements.? ? Dr Stephen Hawking in S. Hawking and R. Penrose, The Nature of Space and Time, Princeton University Press, Princeton, 1996, p. 121.

At the same time, this good guy publishes books with graphs admitting that his gamma ray emission rate from black holes is swamped by the background radiation noise and so cannot be confirmed by measurements.

14. **Peter Woit**
April 9, 2005

Hi David,

"Weinberg's prediction (and it is a prediction – you should read his papers)"

You must be a string theorist. They seem to think it is a clever put-down to tell people to read the basic papers of a subject. I've read Weinberg's papers and nowhere have I noticed him claiming a "prediction" of the CC. Maybe I'm wrong, but instead of stupidly telling me to read a paper I've already read, please provide a direct quote from

Weinberg in which he explicitly claims to "predict" the cosmological constant. He knows how to use the word, he uses it in these papers to refer to real predictions: supersymmetric GUT predictions of the weak mixing angle, and predictions of light-element abundances. In his first paper on this, he refers to his result, as I did, as a bound on the CC. In later papers he investigates possible probability distributions of the CC, but I've never seen him claim that the assumption of a flat probability distribution for the CC (whether motivated by the landscape or just the fact that we have no idea) allows him to "predict" the cosmological constant.

"Any complaint that their motivation is distasteful is frankly irrelevant."

I wasn't saying that their motivation was distasteful, I said they can't get a prediction out of the landscape. You should read their paper about this (hep-th/0501082), where they note that their assumptions can lead to the Standard Model, the MSSM, split-supersymmetry, or much else besides (their paper was written before the discovery of super-split supersymmetry, hep-th/0503249, which you could also get from their assumptions). They do claim to have "predictions", but they are seriously abusing the English language when they say this. If you think they have a prediction for the LHC, explain to me exactly what measurements the LHC experimentalists can do to show split supersymmetry is wrong. What integrated luminosity will the machine have to produce to test the Arkani-Hamed/Dimopoulos prediction and show that split supersymmetry is wrong?

15. **David**
April 9, 2005

That's the spirit Peter! Ask questions to see how this anthropic reasoning holds up. What happens if we allow the weak scale to change? What about the magnitude of density fluctuations? Are there some quantities which change and others which are fixed in this framework? Are there rules to this game, or are they arbitrary? Carry on like this and you'll soon be writing papers on the subject. It seems to me that these are interesting questions that may or may not have good answers. But I don't think it's reasonable to attack people for thinking about them.

The phenomenological interest in anthropics is due almost entirely to the cc and our complete failure to understand this in any other way. Weinberg's prediction (and it is a prediction – you should read his papers) is out by a factor of 30. And while everyone would like a beautiful mechanism that fixes the cc, this is the closest we've got and it deserves further attention. So what if the cc is fine tuned? Does this mean the Higgs mass could also be fine tuned? Is our understanding of naturalness wrong? What would be the consequences of this? I think asking these questions is much more worthwhile than simply being rude and shrill and insisting that it's all obviously wrong.

Finally: Arkani-Hamed and Dimopolous' split susy model does what every good model should: it offers a prediction for LHC. If it's not seen then their model is wrong. Very simple. Any complaint that their motivation is distasteful is frankly irrelevant.

16. **Peter Woit**
April 9, 2005

No, funding for particle theory is actually not doing that badly compared to many other things, with increases for FY 2006 in the proposed DOE and NSF budgets (although the DOE increase is negligible and doesn't make up for inflation). In particle physics recently, it's the experimentalists whose funding is seeing sizable decreases. Theory is relatively cheap, cutting that by a few percent doesn't save much, unlike the experimental funding.

17. **JC**
April 9, 2005

Peter,

Are there any ominous signs of the NSF and/or DOE planning to drastically reduce or outright cancelling funding for particle theory or theoretical physics in general?

18. **Peter Woit**
April 9, 2005

Hi David,

If people were actually getting legitimate scientific predictions out of the landscape that would be fine, but they're not. The Weinberg "prediction" is not a theoretical prediction. He's just noting that the observation of galaxies implies a bound on the CC. The so-called "prediction" that the CC is some randomly distributed number below the bound is:

1. Wrong. It seems that it is 10-100 times smaller than the bound, which is statistically unlikely. If you allow other parameters to vary, the bound is much much larger and the "prediction" is completely wrong.

2. Not a real prediction of a physical theory. It's exactly the same prediction I would make by saying "I have absolutely no clue whatsoever about what the physics of the CC is, so all I know is that, because I see galaxies out there, it's some random number below Weinberg's bound". There is no real link here between a physical theory and an experimental observation of the kind one normally means when one uses the word "prediction". The "landscape" is just an absurdly complex model that has exactly the same implications as not knowing a thing about what is going on.

As for Arkani-Hamed/Dimopoulos, I don't believe they have a legitimate prediction either. They make a large number of assumptions, of dubious relation to any underlying theory, then end up with some very vague "scenarios" of what might be seen at the LHC based on those assumptions. A real prediction would be to tell us something that the LHC should see based on the landscape, such that if the LHC didn't see this, the landscape was wrong. They don't have anything like this, neither does anyone else doing this kind of "string phenomenology", and I think anyone who thinks seriously about the implications of these 10^500 or more vacua should quickly realize that no one will ever be able to extract a legitimate scientific prediction from this framework.

While any individual can certainly justify taking Templeton money, I think anyone who cares about science should be worried to see funding decisions being made by people whose agenda is not to promote good science but to promote religion.

19. **Wolfgang**
April 9, 2005

Peter,

you wrote
> And I think it's a terrible idea for
> physicists to get into bed with them [Templeton]

In the past, physicists 'got into bed' with all
kind of supporters with irratinal motives,
e.g. cold-warriors (the DOE is a relic of this time).

In the end the motive is not important, only

the results and they should be scrutinized and
critized according to the scientific method.
It is the responsibilty of the scientific
community to keep the quality standards high.
(And you and your blog are very important contribution
to this effort by the way.)

20. **David**
April 9, 2005

Peter, it looks like there are two seperate issues here:

1) Emminent scientists with proven track records are attempting to think deeply about speculative ideas which appear completely crazy to others. Some, like Weinberg, even had the temerity to make an experimental prediction based on anthropic reasoning. Others, like Arkani-Hamed and Dimopolous, are continuing this ridiculous trend, making assumptions and following the reasoning through to extract experimental predictions from fine-tuning scenarios.

This abandonment of science from some of its leading stars is appalling. People simply shouldn't consider these ideas as it's obvious that they're wrong and won't lead anywhere.

2) Other leading scientists, like Dyson and Vilenkin, are receiving money from templeton, an organisation which clearly has an agenda that many of us disagree with. While there's no suggestion that templeton is dictating the research of these people, it's disgusting that they would accept the money, especially in the current climate where the DOE are showering departments with funds.

I agree that we should try to get serious scientists to sit up and discuss how we can stop this happening in the future. We must act now. Before it's too late.

21. **Quantoken**
April 9, 2005

Peter said: "I don't think anyone should be forcing anyone to work on anything in particular. But when leading figures in a scientific field decide to abandon science … serious scientists should sit up, take note, and start debating why this has happened and what can be done about it"

No one should be forced to accept or reject any ideas. It is essential to protect freedom of mind for science to be healthy. Freedom of mind means any different opinion, no matter how far fetched you think it is, shall be tolerated. Burning Bruno alive definitely is not protecting science.

Ever since I learned Darwin's evolution theory, I was deeply impressed by its simplicity and profoundness. It's not even science, it's pure logic. Survival of the fittest. Isn't it absolutely true logically, that the more fitting you are, the more surviveable you are? It's not even logic, it's linguistics, since what it means some spices are "fitting", is simply defined as that they are more likely to survive the environment.

So, while other scientific theories may need to be tested by experiments. There is not even a need to test the Darwin's theory by experiment or observation, because it is already correct by definition and logic. It's one of the few truely universal truth, as much true as "1+1=2".

You can applying darwinism to almost anything, including to the researchers' community. Scientists are paid scientists merely because they are the result of natural selection rules imposed by the **system**, only those fit the system survives. So if anything is wrong with the science community, we should look for problem in the system, instead of pick on individual person.

I think there are roughly two stages of development of the scientific inquiries. In the early stage, in which I envy, are the era from Newton to Einstein, where scientists' inquiry of science are free from interference by the daily chore of providing for a living and family. These scientists are either from prestigious family background, thus have sufficient resources to support their daily life and they can concentrate their mind on science research, like Newton. Or, in the case if Einstein, he had an alternative day time job and his scientific inquiry is independent from what he did to make a living.

That is the era when science research was much more healthier, because no financial factors play any role to impact scientific thinking in any way.

But that has changed completely, nowadays science is no longer just a curious inquiry of individuals regarding the nature. It has been turned into a huge industry where millions of people jump into it for the purpose of making a living of bread and butter.

Once that happens, science is no longer pure, no longer healthy. That's because at any given moment of time in history, bread and butter is always much more important than freedom of thinking. You can't think if you are hungry, and you can't survive if you do not eat. Simple, right? Put it simple, once your scientific research activity is connected to earning your bread, you are no longer a free thinker, since your research activity will have to earn your bread and allow you to survive in the system.

That is why so many people would blindly follow the main stream ideas. Each individual may believe that he/she had the freedom of thought and he/she independently chooses to trust the main stream, and there was never any pressure to force them to do so. What they don't understand is they are the result of natural selection. The system constantly eliminates people of dissident opinions so only the main stream will dorminate in the field.

What we need to change is minimize the natural selection power of the system. We need to look at the source of the funding. Appropriation of research funds are now dorminated by some powerful figures who has a very strong bias towards some particular ideas, and aginst some others. The more so, the more Darwinism will be in play in the field and more thorough the science will be purified that only the main stream voice remains. And that's dangerous.

The fundings must be appropriate by some one who does NOT have such bias. And it must be diversified in such a way that different ideas have equal opportunity of getting funded and supported. And let the scientific reasoning become the only eliminating factor in deciding what ideas is right and what is wrong, **let NOT the financial factors play a role**. This is the only way to allow science to return to a healthy state.

To this end, I would support and endorse Templeton, as well as other private sources, to donate money to support science research. The matter is, if there is just one Templeton, it's biased. But if there are different Templeton biased towards different directions, it is more likely cancel out and the whole system will have a better chance of being none-biased, due to such diversification.

22. **Peter Woit**
April 9, 2005

I don't think anyone should be forcing anyone to work on anything in particular. But when leading figures in a scientific field decide to abandon science (and are encouraged to do so by funding from a right-wing-financed organization devoted to promoting the interests of religion over those of science), serious scientists should sit up, take note, and start debating why this has happened and what can be done about it.

23. **David**
April 9, 2005

Freeman Dyson is another that has shamefully taken large sums of money from the templeton foundation. And, it appears that Vilenkin has combined his important work on cosmology with more speculative anthropic-like pursuits for years.

There's clearly a disease in the community. I think we have to face up to the fact that many of our leading scientists, despite making enormous contributions in their past, are now unable to decide for themselves which research path to follow. Something should be done about this. Do you think there's some way we can force these people to work on what we want? It's such a waste.

24. **robert**
April 9, 2005

More pedantry, I'm afraid. G.H. Hardy was a socialist, albeit of the etiolated Bloomsbury variety. He sported a picture of Lenin on the walls of his rooms in Trinity College and was, for two years, President of the Association of Scientific Workers.

25. **Carl Brannen**
April 8, 2005

I see that the spirit of G.H. Hardy chimed in here a few days ago, and that now we are talking about religion and physics. As far as I know, Hardy was neither Jewish nor socialist, but he did get a letter from Ramanujan (also neither Jewish nor socialist) with the formula 1+2+3+… = -1/12. Frankly, I'd rather prefer to take money from the Templetons.

Carl

26.
April 8, 2005

?Science is best defined as, in the first place, objective knowledge, plus, in the second place, the activity to enlarge, and make use of, this permanent and universal knowledge. Scientific objectivity stubbornly and irrefutably exists and refers to the permanent and universal knowledge of facts and phenomena of nature which are independent of any individual's whim: political affiliations, ideological persuasions, moral beliefs, and so on….

?The most striking instance of the mix-up between science and ideology, and that which generated the greatest harm is the following: Many elements of so-called 'modern physics' (relativity, quantum) were rejected by the Nazis because many (but by no means all) of their creators happened to be Jews or socialists or both. In this way, the military defeat of Hitler sealed the fate of twentieth century theoretical physics. As Hitler was (morally) wrong, those who criticise modern physics must be (scientifically) wrong, too.? ? Theo Theocharis, 'Science and Society', Wireless World, July 1981, p. 52.

27.
April 8, 2005

That the ID crowd would somehow glom onto the anthropic variants of string cosmology has been a fear of mine for quite some. It's a slippery slope when prominent physicists try to curry favor with the public by "sexing up" their work with references to God and stuff, however oblique. On the bright side, it will be entertaining to see Lubos Motl be sued someday for teaching non-creationist cosmology, under some "academic freedom" law devised by his political buddy David Horowitz.

28. **Quantoken**
April 8, 2005

Mark T.:

It is not news that **scientists ARE driven by the funds** that support them. It's the theory of evolution and darwinism applied to the scientists themselves. survival of the fittest.

The only reason that Templeton supported cosmologists is a small number, is that the Templeton money is a small porportion, comparing with the bigger cake. If say the Templeton money becomes the 99.9% of the whole cake, guess in which camp will you will find most of your cosmological colleagues in, Mark? And would you be able to continue to support your family and do research etc, with no funding? Would you???

And don't assume that as long as you accept Templeton money, without necessarily supporting their view of the world, you are OK. You do not automatically get funded by Templeton as long as you are willing to come forward timidly. There is a **natural selection process** here. They certainly are more inclined to support some one who are more likely endorse their agenda. And who can say that those in the power of controling public money, does not have an agenda, or some sort of bias, of their own, to endorse some particular point of views and suppress some others?

It doesn't matter if you think you can keep yourself clean by remaining scientifically honest, while receiving money from a source that has its agendas. The point is you are constantly being subject to the natural selection rules of the system and only those fit the system will manage to survive.

If you look at a gold fish in a fish tank. You wonder whether it likes or hates its fluffy tail, which makes it so hard for it to move around. But it doesn't matter, it rely on the food put in by the owner to survive. And it's up to the likeness of the owner to decide who shall survive and breed offsprings, and who shall perish. So a gold fish has a fluffy tail only because the one feeding it prefer to see a fluffy tailed gold fish.

That darwinism point of view explains why some of the crackpots, like super string theory, global warming, big bang, etc, could become fashionable and mainstream. Because these point of views obviously appeal to some of the people in power that has their own point of view and agendas.

Quantoken

29. **Arun**
April 8, 2005

In these times, restating the obvious perhaps may be forgiven.

Whatever our faith in science to probe all of Nature, science, in practice, has boundaries, that are set by the limits of our experimental abilities.

In the past, I think the boundaries of science were recognized. Today, we are under the illusion that there are no more boundaries.

Knowledge can be arrived at by any means – by super-Witten mathematics, or Kekule's dream of a benzene ring – but it enters the realm of science only when it becomes experimental. Otherwise, it is, at best, scientific speculation. Such speculation should never be mistaken for the real thing.

The whole enterprise of science was founded on not seeking explanations beyond our ability to experiment or observe, to abandon the unknowable as being outside the realm of science, and to hope that one day our capabilities would grow to be able to address these. Right now, Theories of Everything are outside our experimental reach, and are, at best, scientific speculation.

31. **DMS**
April 8, 2005

Actually, the Templeton Foundation (and variants) as possible significant sources of funding in the future for physics is reminiscent of the situation in economics, where ideological think-tank funding and *visibility* for economics (like supply-side economics) far exceeds the unbiased sources of funding for economics in academia. Or the situation in medicine, where studies often promote the health benefits of their sponsor's products.

It will take only a few physicists, not hard to find in times of spending cuts, to cause great damage. Seems like there already are a few (who should know better) doing this.

Depressing times indeed.

32. **Mark Trodden**
April 8, 2005

I couldn't agree more with Peter's comments about the Templeton Foundation. There is no excuse for scientists taking their money and those who do so threaten the reputation of the subject and elevate Templeton's ideas by association.

I do think it is worth pointing out that the number of cosmologists involved in Templeton funded research is quite small. I wouldn't describe it as an extensive infection. By far the vast majority of my colleagues have never used Templeton money, never attended a Templeton conference, and find the whole thing silly. Nevertheless, Templeton activities are high profile (by design) because the Foundation has managed to get some well-known people to come to their conferences. I agree with you that these people are hurting science, particularly in the current climate.

I also worry that the disastrous federal funding situation in the US right now may tempt more people to consider taking Templeton money. They won't believe in the goals of the Foundation, but it won't matter – they'll be supporting it by association.

33. **Peter**
April 8, 2005

Fixed the bad URL.

36. **Matti Pitkanen**
April 8, 2005

I would be very cautious in labelling people as pseudo-scientists just because they are willing to consider the possibility that intentional action in some sense is a part of (even grand) design of the Universe. The undeniable fact is that Universe seems to be tailored for life.

To me the use of fine tuning to deduce "predictions" from a theory otherwise unable to predict anything, is bad science. But why not pose the fine tuning as an additional challenge for the theories of everything? And why not be even more ambitious and ask whether the gap between religious and scientific world views might be filled after all. Perhaps future physics could say something non-trivial about consciousness and about what is behind religious experience?

Biological evolution is accepted as a fact and the mere scale invariance of physical laws suggests evolution in all scales. The challenge would be to understand this evolution as part of properly generalized laws of quantum physics.

It is practical to start something from which is not understood. Quantum jump has remained more or less a complete black box thanks to the silly attitude of theoreticians towards clear thinking without formulas, which they label as "philosophy". It is perhaps not too weird a guess that the anatomy of quantum jump could provide a royal road to a deeper understanding.

For instance, could one imagine that the quantum state representing universe is gradually replaced by a new one in a continual re-creation (you can call it self-organization if re-creation makes you emotional)? This requires a new view about time distinguishing between experienced time having quantum jump as chronon and the geometric time of physicist. Of course, also the notion of time is one of the black boxes, or should I say taboos, of recent day methologically oriented theoretical physics.

Given infinite number of quantum jumps already occurred, a universe containing/possessing advanced intelligence could develop. Universe would be at the same time a theoretician able to even test his/her theories by patiently by jumping around the quantum landscape of states of the Universe, whereas the theoretician predicting and living in a single deterministic universe is strictly speaking not able to test his theory. The more general view about time would also resolve the problem about initial values at the moment of big bang. The problem disappears since the initial values change quantum jump by quantum jump.

Just a proposal, do not kill the messanger or, listen at least the message before doing it;-),

Matti Pitkanen

Peter:

It's shocking to me. But never to me. A while ago I posted this comment on Lubos's blog, since I could not believe a famous guy like Leonard Susskind could be so **intelligently challenged**.

Since Sean is reading here, I am still curious to know whether he thinks a 3-torus universe should be Lorentz invariant or not. And why? 🙂

Quantoken

39. **JC**
April 7, 2005

Why do some physicists accept any of these Templeton grants in the first place? Is NSF and/or DOE funding so bad today that theorists are searching for other sources of funding?

40. **Peter Woit**
April 7, 2005

Hi Sean,

I suppose I should have made clear that the Templeton foundation has somewhat different goals than the evangelical anti-evolution right. While looking around the net, I did run into the following for instance

http://www.answersingenesis.org/docs2002/0806templeton.asp

But still, I don't think the Templeton foundation's goal is to promote good science, it is to promote Templeton's own view of religion and science. And I think it's a terrible idea for physicists to get into bed with them.

On the question of the role of the religious right in American politics, Templeton himself has made clear which side he's on:

http://www.newsmax.com/archives/articles/2004/6/26/111715.shtml

41. **Sean**
April 7, 2005

It might seem like splitting hairs, but it's probably worthwhile to distinguish between "people who believe in God and look for evidence in the universe we observe" and "people who deny the basics of evolution and cosmology." For the most part, the Templeton folks are in the former category and the Discovery Institute is in the latter, although of course there is some blending between them. I strongly believe that they are both *wrong*, but I wouldn't classify the Templeton folks as anti-science in the way the Discovery folks are.

(I can't believe I am actually defending the Templeton Foundation, however mildly.)

42. **Peter Woit**
April 7, 2005

Thanks for mentioning this. I did notice this, but forgot to include it in the posting. I'll add it now.

Peter

43. **Simplex**
April 7, 2005

Peter, last year when Smolin posted "Scientific Alternatives to the Anthropic Principle" which made Susskind so mad (and you blogged the ensuing fracas) the original arxiv posting said that Smolin's essay was intended for the book "Universe or Multiverse" to be published by Cambridge. It probably still says that. I dont know any more particulars.

This Evening's Finds in Theoretical Physics

April 10, 2005
Categories: Uncategorized

It's late tonight and I have to prepare a class for tomorrow, so I don't have time now to figure out what is going on here. But if you want to see something really strange, take a look at Susskind's latest, together with the revised version of an earlier paper.

Another new paper this evening is Witten's latest. This looks quite interesting, but definitely will take some serious effort to understand.

Comments

1. **Kyle**
   April 13, 2005

   DR Lunsford,

   At first I thought your link was too over the top to be funny. By the time I reached the meat of the page I found it quite amusing (quotes like "The details of the calculations have been (/are being/will be) presented elsewhere; here we give cartoons." I thought were rather ingenious).

   However, after thinking about it, I've decided it is much too serious to be funny.

   Just somenobodies opinion,

   Kyle

2. **Fyodor**
   April 13, 2005

   I'd just like to clarify that there is nothing wrong with making a mistake, and I too thought the way Susskind retracted was rather funny. But this attitude, that you can do research without reading the literature, that it's ok to write really stupid papers as long as you are prepared to retract the following week, gets my goat. Susskind should remember that despite all his recent vagaries he is still a very influential figure in this field. Subjects like wormholes [in which I've never published, by the way, and I have no intention of doing so] have a somewhat dubious status, and Susskind is propagating the notion that this field is not quite respectable: either you respect his "deep physical intuition" and assume that in some way he will turn out to be right, or you think he is an idiot and that only idiots work on wormholes. Either way, the subject loses. People should never underestimate the importance of these vague feelings about which things are respectable and which aren't.

   Finally, I note that everyone seems to think that Susskind's misadventures are funny, and that nobody should think the less of him because he has written a stupid paper. But nobody laughed when Chapline went off the rails. What's sauce for the goose ought to be sauce for the turkey.

3. **D R Lunsford**
   April 12, 2005

   Abstract: *In an earlier paper, the author made an elementary blunder, rectified here.*

   0 Overview

   The paper is question is wrong. Ignore it.

   1 References

   (none)

6.
   April 12, 2005

   It must have been humiliating for Susskind. Is that why he refered to himself as "the author of that paper"?

7. **Chris Oakley**
   April 12, 2005

   we can hope that the faint possibility that they are about to make utter fools of themselves will make them hesitate.

   The worrying thing is that they *don't* seem to make fools of themselves when they publish. Except, of course, to the majority of the followers of this web log.

8.
April 12, 2005

Good one Fyodor!

Susskind has obviously crossed into a higher plane of existence in which quaint academic formalities such as citations are obsolete. The obvious next step is for him to stop publishing altogether and transmit his thoughts directly via an EEG connected to a blog.

9. **Fyodor Uckoff**
April 12, 2005

First Chapline, then Susskind….
Surely, *surely* these gentlemen know that there are huge literatures on the subjects into which they have stumbled. And yet, in their vast ignorance and pride, they think that they can dispense with a little background reading, and revolutionize these fields with the help of a little freshman physics.

I would like to suggest a cure. The arxiv should automatically reject any submission with fewer than 20 references, not counting popular books or articles in the National Inquirer. True, this would not force the likes of Chapline and Susskind to undertake the onerous task of finding out what mere mortals have said, but at least it would acquaint them with the sheer volume of previous work. And then we can hope that the faint possibility that they are about to make utter fools of themselves will make them hesitate.

10. **Aaron**
April 11, 2005

Lenny knew about the flux through the cycle, although he didn't use those words to describe it in the original paper. As he says in the followup paper, the result depends on what initial state you prepare the flux through the wormhole in.

11. **Robert**
April 11, 2005

Everybody I talked to reagarding Susskind's paper (V1) agreed that obviously he missed the flux through the non-trivial cycle. So, why bother. This 'discovery' didn't make it into the popular press ("Stanford scientist disproved wormholes") so there was no need to send letters to the editior (as I did for newspapers reporting on Chapline's discoveries).

12. **Aaron**
April 11, 2005

Check out Kapustin's paper in conjunction with Witten's, I think.

13. **garrett**
April 10, 2005

Heh, nothing like an April fools joke on himself to boost his credibility. Bet he's sorry he left the topic of the anthropic principle to try and tackle something interesting.

New Quantum Field Theory Textbook

April 12, 2005
Categories: Book Reviews

I recently ran across a very good new quantum field theory textbook in the bookstore. It's called [Quantum Field Theory: A Modern Perspective] and is by my ex-Columbia colleague [V. Parameswaran Nair], who is now at City College nearby.

The first half of the book covers the sort of standard material about perturbative quantum field theory that appears in pretty much all quantum field theory books, including Peskin and Schroeder's [An Introduction to Quantum Field Theory] which seems to be the most popular one these days. But the second half of Nair's new book very much does live up to his "Modern Perspective" subtitle, containing a wealth of important material that anyone learning quantum field theory should know about, but that has not made it into the standard textbooks until now. This includes a very geometrical approach to gauge fields, anomalies and the index theorem, material on the WZW model and 2d fermion determinants, as well as an introduction to important non-perturbative ideas such as dual superconductivity and the 1/N expansion. Finally, Nair also includes a wonderful final chapter on the ideas behind geometric quantization and their application to the quantization of the Chern-Simons-Witten model.

I highly recommend the book for anyone who wants to seriously learn quantum field theory. Even if you've studied the subject already using a book like Peskin and Schroeder, the additional material in Nair's book makes it well worth reading.

Comments

1. **JC**
   April 17, 2005

   Carl Brannen,

   In terms of drinking the "poison" of string theory, I haven't really found many really good presentations of string theory in book or lecture note form. Though if I had to choose one, I would probably pick Kiritsis's "intro to superstring theory" lecture notes

   http://arxiv.org/abs/hep-th/9709062

   though it seems to be a bit dated these days.

   None of the books like Green/Schwarz/Witten, Polchinski, or Zwiebach seem to be satisfactory for the most part. I mainly learned string theory from reading various lecture notes and original papers, when Green/Schwarz/Witten was not being very clear.

2. **Alejandro**
   April 15, 2005

   Indeed. I never know if to refer the book as CdWD or BMB. Typical problem about married/maiden names. In any case, the underlying point is that for geometry and tensors one must have a index-based book and a index-free one.

   Off topic, some old news about Fomenko:

   http://jcolavito.tripod.com/lostcivilizations/id13.html

3. **D R Lunsford**
   April 14, 2005

   Ugh THAT book…

   -drl

4. **Peter Woit**
   April 14, 2005

   I assume Alejandro means

   Analysis, Manifolds and Physics by Yvonne Choquet-Bruhat, Cecile Dewitt-Morette and Margaret Dillard-Bleick

5. April 14, 2005

   "The book from the three girls"?

6. **JC**
   April 14, 2005

   Over the years I got the sense many field theory books seemed to fit into one of two categories:

   (I) books which are pedagogical and relatively "easy" to read and learn from

   (II) books which are hard to read and difficult to learn from

   Peskin/Schroder, Feynman's QED, Griffith's particle physics, Ryder, Bjorken & Drell, etc … seem to fit into the first category (I).

   Itzykson/Zuber, Zinn-Justin, Weinberg, Faddeev/Slavnov, Berestetskii/Lifshitz/Pitaevskii's QED, etc … seem to fit into the second category (II).

   The second category (II) books seem to be akin to Dirac's quantum mechanics book, which is very nice once one knows the subject but is terrible for a first book to learn from.

7. **Alejandro**

April 14, 2005

Dubrovin-Novikov-Fomenko I like too. I use jointly with the book from the three girls.

8. **h**
April 14, 2005

Is this new book readable for a mathematician? In any case, what book do you recommend for a mathematician (student) who wants to learn QFT?
I don't need the usual mathematical precision, but I do need clear indication of the underlying structures (imho the lack of this is what makes it very hard for math people to read physics literature) and also some sort of "big picture".
I know Weinberg, that's an example of what I cannot read. I also know the double IAS volume "Quantum Fields and Strings: A Course For Mathematicians", that is like chinese… (the target audience of that is very narrow I think)

9.
April 14, 2005

I on the other hand enjoyed Itzykson & Zuber's textbook. It was very clear, easy to read, complete and intuitive. Generally, I like old style textbooks, alot more physics unlike "modern" crap. Combine Itzykson/Zuber with Slavnov/Faddeev's book on gauge field theory + Dubrovin-Novikov-Fomenko for fantastic diff. geom. and you are good to go.

10. **Juan R.**
April 14, 2005

What are the main conflictive points of usual QFT (beyond renormalization of course)?

I used some textbooks like QED by Feynmann and the first two volumes by Weinberg, but I dislike with both.

Feynman is a calculation recipe based in many asumptions and "intuition".

Weinberg's manual is a unsatisfactory attempt to present us an axiomatic view of the field.

11. **Kristjan Kannike**
April 14, 2005

I find Robin Ticciati's "Quantum Field Theory for Mathematicians" a very good book. The title is somewhat misleading. It covers basically the same material as Peskin & Schroeder, but does not shy away from the fine points. In fact, for it being a bit more formal, I found it more clear than Peskin & Schroeder.

12. **Fabien Besnard**
April 14, 2005

I agree Itzykson/Zuber is hard, but it's interesting as a reference because they go into all sorts of details. (Incidentally I attended J.B. Zuber's lectures, and they were way clearer that their book)

What do you think of Ticciati's QFT for mathematicians ? I haven't been through all of it yet but I like its mathematical clarity.

13. **Alejandro**
April 14, 2005

What about Huang? His book on the Standard Model is very readable, and now I have ordered (not received yet) his QFT book, which seems to be a complement.

14. **JC**
April 13, 2005

Years ago I first learned quantum field theory from both T.D. Lee's "particle physics & intro to field theory" book, and Feynman's quantum electrodynamics book. They were not exactly the best books at the time.

Ryder's quantum field theory book seems to be one of those books which looks "deceptively simple". On the surface you think you understand what's going on, but you really don't.

15. **Alan**
April 13, 2005

Coleman's notes are very nice. Look here:
http://my.harvard.edu/icb/icb.do?course=fas-phys253a&pageid=tk.page.phys253a.dir.96baa9f5f565ad359215beb46d7685a9

16. **Carl Brannen**
April 13, 2005

I&Zuber: This really was horrid. Long and hard to understand.

B&Drell: Unfortunately, I lost my copy, which I
miss. But it is dated.

Weinberg: The concentration, at least at first, is on what can be deduced from Lorentz symmetry. I don't like this text. I should admit that I also doubt that Lorentz symmetry is exact, and that the assumption that it is has held physics back. For example:
http://arxiv.org/abs/astro-ph/0311576

Peskin&Schroeder: This is my favorite. It is widely used as a text and for good reasons. My only complaint is the part where they quantize the Dirac equation as bosons.

Zee: I have this, but I don't read it much. My belief is that one should have as many QFT books as possible because different ways of expressing the same theory help one in understanding. If I recall, it starts with a description of field theory from bed springs.

Ramond: I hated it when it was new, and now it's dated.

Brown: This book has some interesting expositions but I can't stand the typography. Dr. Brown is professor emeritus at a local school (UW), and his text is used there.

Ryder: This one I don't have. I guess I will order it and see if I learn anything.

We should put together a list of guage theory books, and for those of us who have tasted the poison, string theory texts.

17. **Alejandro Rivero**
April 13, 2005

DMS, I join in your gasp to "Itzykson and Zuber", the book that devastated one whole generation of physicists (mine). Perhaps the motivation to go (to escape) towards strings? I have also some doubts about Weinberg, because he, after all, is a disbeliever, seeing every QFT as an "effective theory", but no more.

I wished the Bjorken Drell were scanned somewhere, or at least cheaply reprinted. And wonder about these Coleman's QFT lectures.

Besides Schwinger, also some frenchies were into the source theory. A young Kastler, I believe. But they are better at Critical Phenomena. Zinn-Justin and Le Bellac. For Schwinger action plainly, the Dyson 1951 lectures. In the net:
http://hrst.mit.edu/hrs/renormalization/public/documents.htm

18. **D R Lunsford**
April 13, 2005

DMS – I highly recommend the Maggiore book, if for no other reason than the worked problems.

-drl

19. **DMS**
April 13, 2005

I am always interested in learning about QFT, and will pick up a copy of Nair's book. I have not seen Maggiore's book. Gone are the days when the only references were Bjorken and Drell and Itzykson and Zuber (Ugh!).

Three of my favourites on QFT are:

* Weinberg's QFT (of course). It is needlessly too complicated in parts (especially early on in Volume 1), but has excellent, modern discussion of various topics. Plus, it has the classic references, and is very to up-to-date (Weinberg having conferred with the experts on the topics). Even though his third volume on SUSY is not as complete, I found his discussion very well explained (despite his notation).

* Zee's QFT: It has very nice discussion of several topics.

* Siegel's Fields (on arxiv): Although highly idiosyncratic, it is an excellent book that teaches one a lot of things not found in many books. Plus, you cannot beat the price!

But I have also heard that Coleman's QFT lectures at Harvard (not to be confused with his classic Aspects of Symmetry) are exceptionally clear. I am not aware if it available online.

20. **pfedor**
April 13, 2005

Hello. Until now I only lurked your blog (which I find very interesting), but today's topic is of particular interest for me, since it's my ambition to really learn QFT at some point in life (sadly, I didn't manage to do it during my studies). So forgive me a few questions.

How does this book compare with Weinberg's "The quantum theory of fields"? Does it contain material that cannot be found in Weinberg's book? Is it easier? Harder? Which one would you recommend to someone who used to study heavily Peskin & Schroeder but only managed to understand about 2/3 of the material (I remember that most difficult were the parts about anomalies and operator expansion)? Does prof. Parameswaran's book include any discussion of bound states?

With best regards,

Aleksander

21.
April 12, 2005

Real men learn QFT from the collected works of Julian Schwinger.

22. **D R Lunsford**
April 12, 2005

On another level, a new book by Michele Maggiore replaces Sakurai as a beginner's book, and includes solved problems! I would recommend this book to any first-timer.

Maggiore, "A Modern Introduction to QFT" (Oxford)

-drl

23. **Alejandro**
April 12, 2005

There is a nascent new generation of books. Zee, Huang, now Nair. Curious.

24.
April 12, 2005

Off topic, but regular readers of this blog will want to see this exchange, where string theorist Eva Silverstein schools Lubos Motl for his overreliance on straw man arguments.

Dine on the Landscape

April 13, 2005
Categories: Uncategorized

Michael Dine from Santa Cruz was here at Columbia this afternoon to give a talk on "Branches of the Landscape". His talk more or less corresponded to his recent paper with the same title. He's following the philosophy pioneered by Michael Douglas of trying to look at the statistics of KKLT vacuum states, fixing the observed values of the cosmological constant and electro-weak breaking scales. The hope is that the distribution of supersymmetry breaking scales one gets would allow one to in some sense predict what this scale will be.

Dine finds three disconnected "branches" of the landscape, sets of vacua with different properties. The bottom line is that on two of them you have various problems getting something that looks like the real world, but you can do some kinds of counting. But on one of the branches you get lots of states with badly broken supersymmetry and the vast majority of states are in a region where there seems to be no hope to analyze what is going on. You can't even say whether the number of these states is finite or infinite. So, he isn't able to get the sort of prediction he and others were hoping for, but intends to keep working in this area nonetheless, with various ideas of what to try calculating. To me, he didn't seem to have even a glimmer of a hope of ever getting even the vaguest sort of prediction out of any of this.

He did say that the landscape is now the only idea on the table for getting physics out of string theory. Brian Greene was in the audience and somewhat objected to this. Brian's point of view appears to be the more traditional one that people should just try and cook up vacua with as many features as possible close to the Standard Model, and that once they've got such a thing it will have other implications for physics that can be checked. It seems to me that that kind of work has been going on for more than twenty years with no sign of success, but Brian still believes this will ultimately work out. Dine's ideas for the future are converging somewhat with Brian's older point of view. He seems to be giving up somewhat on the idea of counting all vacua in the Landscape, instead thinking about counting vacua satisfying some chosen conditions, e.g. being on one of his three branches. So he may be getting back to the older idea, looking at complicated constructions with some set of conditions imposed on them to make them look like the Standard Model, then hoping to extract something new, perhaps in terms of probability distributions rather than the more specific predictions people used to hope for.

Of course I find this whole thing pretty bizarre, since it's horrifically ugly, and appears to me to have not the slightest hope of success. It's discouraging that I don't see any way of having a rational discussion with the people doing this. They are motivated by a hope that somehow, some way, they will find amidst this complicated mess the Standard Model, in some context that allows them to predict something else. As far as I can tell this is the purest of wishful thinking. They aren't claiming to find anything encouraging, but they are pressing on, and convincing an increasing number of people to join them. One hopes that sooner or later they'll get tired of this and move on to something more promising.

Comments

1. **Eli Rabett**
   April 19, 2005

   The problem with Lubros Motl on climate is he knows neither the data nor the theory but tries to pull himself up by naive postulates based on a set of partial truths that he has been spoon fed by political allies. When he ventures out of his cozy blog to the real world he gets his ears pinned back and responds with vitriol.

   For a reasonable demonstration of his naivete take a look at http://tinyurl.com/77uqq.

   Since this is a high energy physics blog I won't press the point but in general I advise against asking oceanographers about string theory and visa versa. In both cases, it is not what you don't know that kills you, but what you think you know and is dead wrong.

2. **Peter Woit**
   April 19, 2005

   Hi JC,
   No, "overhead" (also known as ICR = Indirect Cost Recovery) is payments built into most grants for "Indirect Costs". The idea is that while the grant is specifically paying for costs to the university directly associated with the grant, there are also other costs the university is paying that indirectly support the grant (i.e. the lights in the building, the library, etc.). So universities typically add a charge for ICR as some specific fraction of the grant amount. The fraction is generally quite large.

   So, if you go out and get a grant that is supposed to pay for $100,000 worth of stuff, you actually have to ask the granting agency for more, say $150,000, to pay $50,000 directly to the university for ICR. Universities love this: this is money they can do anything they want with, and coming in in sizable amounts.

3. **JC**
   April 19, 2005

   Peter,

   What's the exact nature of these "overhead" payments? Are they like some form of matching funds?

4. **Peter**
   April 19, 2005

   Hi JC,

   Most theorists who are funded by grants are funded as part of a group. If the group were to lose funding, they'd typically lose funds to hire one or more post-docs, funds to support graduate students, a big chunk of personal cash ("summer salary"), and their university would lose large "overhead" payments.

   This is clearly extremely undesirable. If the NSF or DOE authorities funding work on the landscape ever realize that they are funding pseudo-science and shut off grants to people doing it, "landscape architecture" will quickly become a rather unpopular subject. This probably won't happen though as long as string theory peer reviewers keep telling the NSF and DOE what geniuses these people are.

5. **JC**
   April 18, 2005

   Peter,

   What normally happens to tenured theory professors who end up losing most or all of their grant funding? The cases I'm familiar with were of tenured experimentalists who lost their grant funding, and subsequently had things happen like their lab space being eventually taken away. Some "deadwood" theorists I can recall, seemed to be mostly guys who just sat around all day drinking coffee or reading a newspaper. (I don't know offhand if any of these "deadwood" theorists lost their grant funding).

If a bunch of tenured folks working on the string landscape (and/or string folks in general) end up losing their funding, do you think they will lose much of their influence in the physics world? (ie. Will the reference letters written by these guys be worth more than the paper they're written on?)

6. **Peter**
April 18, 2005

JC,

I'm curious how this will play out too. I would think a lot of physics departments would have trouble with this, but probably not those whose theory groups are dominated by string theorists. One thing I didn't mention about Dine's talk. He spent a lot of time going on about what a genius Michael Douglas is, along with some of his collaborators. People doing totally loony-tunes landscape stuff will probably end up having recommendation letters from people like Dine saying they are geniuses, and this may get them a job.

Fred,

One problem with your analogy of string theory to QFT or the measurement problem in QM is that those are both subjects for which there is a vast amount of experimental data. Figuring out exactly what is going on with rigorous QFT is hard, but you know you are doing physics since non-rigorous QFT describes the world so well. There's not a smidgen of experimental evidence for string theory, so why should you believe that
its problems can be solved, but for mysterious reasons this is incredibly difficult?

7. **Fred**
April 18, 2005

I don't agree, many theorists are very much against the anthropic principle. In fact those who subscribe to it I would say are in the minority. Of course a few bigshots do believe in it, and they have decent reasons, but its not the last word on the subject.

The Landscape is a generic feature of string theory, but it does not a priori exclude a selection mechanism. People are actively looking for such a thing, even though the problem is *hard*.

But then again many problems in physics are hard and have resisted years of study. Like trying to make mathematical sense out of quantum field theory, or the measurement problem etc etc. It doesnt mean that there isn't a good answer for all of them, its just we haven't found it yet.

8. **Quantoken**
April 18, 2005

Peter:

Well said! Good points made!

I might also add that most people discussing about Lubos's publicationsnever meant any personal attack at all. We LOVE lubos. He made this blog of Peter's so much fun to read because of his participation. It would have been very boring and no fun at all if only one voice can be heard on Peter's blog. Lubos had been outspoken on a lot of things and I like that, although I think that might hurt himself sometimes.

Talk about the peer review process. You do not publish a paper for your personal archival purpose, do you? You publish something to make it available for others to discuss it, comment on it, and criticize it, and pick it apart. Sometimes this leads to evaluation of the person who write papers. It's quite normal. And this peer review process can also be extended to the fact that one writes many papers, or one does not write at all for a while. What's wrong with that?

Quantoken

9. **JC**
April 18, 2005

Peter,

Do you think any untenured folks working on the string landscape stuff will get tenure in the near future (at a research university physics department, that is)?

On the surface it would seem a bit odd for a physics department to be awarding tenure to somebody who's working on an pseudo-scientific anthropic problem. Though awarding tenure for somebody working on anthropic stuff wouldn't be too surprising in another department like philosophy or one that does postmodernism stuff.

10. **Peter Woit**
April 18, 2005

Hi Jean Paul,

Sorry, but I'm not going to remove the comments, partly because I try to err on the side of letting people say what they want, partly because I think the discussion does have some relevance to the subject of Dine's talk.

As I've made clear, I think the whole landscape business is pseudo-science and the fact that it has become the latest fad in particle theory is a complete disgrace and disaster for the field. This disaster is happening because virtually no one in the field is willing to speak up against what is going on. Gross famously complained nearly two years ago at Strings 2003, invoking Churchill's words from the Battle of Britain, but he has been publicly quiet about this recently. Lee Smolin has written a paper about why this is not science, but he's a very polite sort. Lubos is the only string theorist I can think of who is forcefully making the case against this nonsense. I think it's brave of him, although perhaps foolhardy since he doesn't have a permanent job.

The whole issue of what a young, untenured theorist should be working on now is a very important one. If the latest fad is complete pseudo-science, can one survive professionally by arguing strongly against it, especially if you yourself don't have any really good ideas to work on?

As for his career prospects, I wouldn't worry too much. Historically, Harvard junior faculty generally don't end up getting tenure there, but do end up getting a good permanent job elsewhere.

One argument for removing the comments would be that some of them are inappropriate personal criticisms, which in many cases might be a good reason for removal. However, in this case since Lubos has never been shy about vociferously personally criticizing those who disagree with him (if they're not string theorists….), I'm not going to worry too much about his feelings getting hurt by this.

11. April 18, 2005

    Peter — please remove this whole chain of comments on Lubos' academic qualifications from amateur/aspiring scientists like Barry, N et al. It is inappropriate and completely
    off-track from Dine's talk. Poor Michael Dine — I wish his talk had stimulated more interesting comments, but it's very hard to believe in a genuine change of mind of a physicist who used to be one of the outspoken believers in the traditional dogma
    of predictability. I am still one of them, and instead of the landscape, I work on more formal things these days and spend more time in the garden, thinking about the next step.
    Jean-Paul

12. **Barry O'Genesis**
    April 18, 2005

    Well, "Michael" [what's your real name by the way?] you have managed to completely misunderstand my point. Suggest you re-read the part beginning with "I fear that he may be a victim …." I'm pro-Lubos, not anti. Just to spell it out, there are plenty of young string theorists out there putting out papers very regularly, and they are going to be the ones getting tenure. It's true that young profs are sometimes cut some slack at first. But not in string theory. And certainly not at Harvard. I hope by the way that nobody thinks that this discussion is off-topic. On the contrary, the real way to judge the state of a subject is to see what its prominent practitioners are, or in this case aren't, publishing. In that connection I think that all this stuff about the landscape gets more attention than it merits. Look at Vafa's papers over the last year to get an idea of what other people are doing.

13. **Thomas Larsson**
    April 18, 2005

    From here: "My efforts to get a strings course at MIT for next fall seem to be failing. At Harvard, too, it seems that there will also not be a strings course next year. How can this be?"

14. April 17, 2005

    N – your dislike for Lubos' style does NOT justify your cheap shots. Just stay away from his blog. I guess that you are not an academic, and even if you are, judging from your manners, certainly somewhere in the boondocks.
    Whatever your profession is, you are just a little mean and frustrated person, to avoid some French expletives that you deserve.

    Jean-Paul

15. April 17, 2005

    Let me ask you something Mike, are you Lubos' squire?
    You seem to know what Lubos' reaction was, can you please tell us why did he decide to shut down anonymous coments?
    This is funny, I wasn't pretending anything and Lubos' paranoia, which you describe and seem to be aware of, is frightening.
    Maybe he is really busy insulting people, or perhaps he doesnt have anything in mind, the true of the matter is that you are as contemptuous as he is and that's just sad. I dont even know who you are either (Michael Jordan? Michael Schumacher? Michael Jackson? oh god please dont!), and dont really care to be honest. If Lubos were in peace with himself he wouldn't have reacted as he did… 'say no more'

    best,
    N

    ps Sorry Peter, this stops here.

16. **M**
    April 17, 2005

    'I agree we should stop discussing about Lubos, but the landscape is so boring and hopeless …'

    This begs a question: Lubos doesn't embrace the landscape idea, but much of the action seems to be taking place there. Is his recent publication rate a symptom of a more widespread lack of other ideas outside of exploration of the implications of a landscape?

    M

17. **Chris Oakley**
    April 17, 2005

    I thought the tenure system is supposed to encourage academic freedom, but it seems to have exactly the opposite effect precisely because it is given too late and not easily.

    The tenure system is designed to protect useless, burned-out old men from being sidelined by those younger, brighter, and more dynamic than themselves.

18. April 17, 2005

    Perhaps Lubos hasn't published anything because he is too busy insulting on the internet?

19. April 17, 2005

    I thought the tenure system is supposed to encourage academic freedom, but it seems to have exactly the opposite effect precisely because it is given too late and not easily.

20. **Michael**
    April 17, 2005

    Dear N,

It is just too plausible that you are being dishonest. If you were so close to Lubos that you can casually ask him about his work, he'd probably know who you are even if you go by the name of "N". By only pretending this, you cause Lubos the discomfort of wondering who in his immediate environment is so disloyal towards him — transparently the strategy of a foe.

Also, if you had more experience with academia you'd know that your assessment of the situation is simply false. I have known many young professors and 95% of them did not publish in about a year after getting their first job. Tenure is going to be decided based on what is published eventually, even if it took more than a year.

Finally, if you were not a foe of Lubos', why would you drag this discussion into the public? There is absolutely no benefit in doing this, unless you hate the man — which you partially admit.

I don't know who you are, but I dislike your dishonest cowardly attitude. The same is true for that other "Barry" person who's posting here.

Michael

21. April 17, 2005

'This discussion is pathetic.'

Dear Mike,
There was no discussion to begin with, I just pointed out what Lubos reaction was to a simple question : "What are you working in, I havent seen a paper of yours in a year, is this your miraculous year?". The last part was a joke I hoped he would understand considering the amount of 'jokes' he produces per post.
Nobody reacts like that (shuting down anonymous comments) unless something is going on, and as Quantoken pointed out, I wonder what that is. I dont really care if Lubos gets tenure (although it would be very sad for him if not, which is the most likely scenario btw) I dont like his attitude in general but he deserves my respect as anybody else.
With respect to timing, the only time where a phyicisist stops production is 1) the year he/she graduates and gets his/her first postdoc, 2) The year of two applying for jobs and 3) the day he/she dies…and I am not sure about the later 🙂

I agree we should stop discussing about Lubos, but the landscape is so boring and hopeless that I cant find anything there to talk about 😉

best wishes,
N

22. **Michael**
April 17, 2005

Dear "Barry O'Genesis",

if I had jealousy dripping from my nose, I'd hide behind a silly nickname, too.

Best wishes,
Michael

23. **Barry O'Genesis**
April 17, 2005

Don't you worry, he's going to do just fine.

No, he isn't, not at this rate.
I fear that he may be a victim of the widespread superstition that one should only publish if one has done something really important. In reality one should let other people decide whether one's ideas are any good.

24. **Michael**
April 16, 2005

This discussion is pathetic. It is evidence of the fact that few people here have any experience in academia. When someone gets their first faculty job, they tend to publish everything they got right before that, in order to get the job. Then, starting with no work in progress, there are plenty of new responsibilities: teaching, advising, faculty meetings etc. pp. This slows down any project one might take on. In fact, it seems most young professors need at least a year to "get back on track" with research.

You guys are just jealous big weenies, admit it! Don't you worry, he's going to do just fine.

Michael

Is this blog about theories that are not even wrong, or is it about Lubos Motl?

26. **Quantoken**
April 16, 2005

Some one said: "By the way, I asked Lubos why he didnt publish anything in a year and what kind of projects he had in mind. He always talks about others ideas, I gave him the chance to talk about his. After that, anonymous comments are no longer allowed in his blog."

I am also curious what happen to Lubos. It is nothing unusual that one has not published anything in one year. The guy who proved the Fermat big theorem did not publish in 9 years. And Peter doesn't publish in years also. Frankly I think scientists should spend more time doing REAL researches, and spend less time publishing papers, if you can write just one paper that really means something useful, in your lifetime, that's pretty good. 99.9% of publications on arxiv are rubbishes that only waste time of those people who read them.

But it is odd for some one like Lubos, who needs count of published papers to help him get tenureship. And it's especially odd that merely asking him about this would make him turn off anonymous comments on his blog, some thing he never did before. What's going on?

Maybe he really is NOT that much of a diehard string theorist as he wants us to believe. I feel his religious belief is probably shaking, evident from the fact that he became increasingly skeptical to point of views of other string theory people. I guess he is beginning to realize something is wrong.

He is a smart guy and certainly has an independent mind, evident from the fact that he is able to question and challenge the global warming theory, an establishment crackpot theory that's endorsed by 99% of experts in that field. If he can see something wrong in global warming, he surely is able to see something wrong with his own establishment camp.

He reminds me of Anakin Skywalker, a young and fearless jedi who has fatal weaknesses, and who was turned towards the dark side but ultimately his sould is salvageable.

As a much more appropriate analogy than Hamilton-Jacobi theory, let us compare string theory with aether theory. 110 years ago, aether theory had accomplished great things, such as the unification of electromagnetism with acustics and the confirmed prediction of electromagnetic waves. Moreover, all good mathematics, at least PDEs, is really aether mathematics. It is true that aether theory has problems to explain the Michelson-Morley experiment, but the vanishing aether wind is just one number. In view of the other great successes of aether theory, should we really worry about just this one number, when aether theory does so much else? Why not just leave this one number for future generations who will know more?

One reason to worry about the vanishing aether wind is that it is incompatible with the basic postulates of aether theory: the logic goes
no aether wind => no aether => no aether theory.
The positive cosmological constant has a similar effect. We have all heard Lubos lecture about the S-matrix being the only observable in string theory. Well, if the cosmological constant is positive, the universe looks like de Sitter space, and there cannot be any S-matrix in de Sitter space. So here the logic goes
positive CC => no S-matrix => no string theory.
The same argument applies of course if you replace S-matrix by boundary CFT. No wonder that people do higher acrobatics to avoid this simple conclusion.

To see the problems, look e.g. at Jacques Distler's Supercritical post:

Two types of backgrounds have been proposed:
1. A flat background, with a linearly varying dilaton (varying along a timelike direction).
2. An AdS background.

To me, it sounds like he is really saying:

Two types of values for the cosmological constant have been proposed:
1. Zero.
2. Negative.

Anyone who has not been asleep for that past six years would realize that (2.13 +- 0.1) 10^-3 eV is neither zero nor negative by some 20 sigma.

Or look at Lubos' post Behind the horizon. The idea here is that because the cosmological constant is found to be positive in our universe, we posit by royal fiat that it is negative in an unobservable multiverse in which our universe is merely a bubble, and that everything worth knowning in fact lives on the boundary of this multiverse. Note that physics does not take place neither in our universe nor at the boundary of our universe, but rather at the boundary of the unobserved and unobservable multiverse. For some reason this appears to involve anthropic reasoning as well.

This work is apparently due to Steve Shenker, whom I admire for FQS. However, nowadays it is F rather than S who is doing the right thing by declaring defeat.

28.

'[Lubos] (has) made lots of really awesome blog posts. I'm sure the tenure committe will take that into consideration.'

Good, we started with peer review in journals, then we moved to the arxiv and lots of garbage per day, now do we also need to think on appearing in Lubos' blog the get tenure?
I am not against blogs, I do read the posts, but come on where are we gonna end! in friendster with a link to Ed?

By the way, I asked Lubos why he didnt publish anything in a year and what kind of projects he had in mind. He always talks about others ideas, I gave him the chance to talk about his. After that, anonymous comments are no longer allowed in his blog.

Genius…they dont understand us right Lubos? 🙂

best,
N

29. **Quantoken**
April 15, 2005

I agree there is absolutely NOT an analogy between the Hamilton dynamics and string theory. The Hamiltonian description of dynamics and the Newtonian description are completely identical in physics and completely equivalent in mathematics. They describe the same physics, but merely use different mathematical language. Hamilton dynamics is certainly useful even if it predicts nothing more than what Newtonian dynamics already predict, because the particular mathematics form may help our understanding. It's like "5-3=2" and "2+3=5". It's different ways of decribing the same thing, but to a kid he may find it easier to understand addition than subtraction.

And it is **ridiculous** to suggest that without Hamilton form of dynamics, there would be no quantum mechanics. It's a pure random happenedness of human evolution that we come across particular specific mathematical forms to describe nature. Mathematically there can be an infinite number of different but all equivalent ways of describe the same thing in nature. The Schrodinger Picture was invented because we have Hamiltonian dynamics. But we also have the Heisenberg Picture. And even we have not invented Schrodinger or Heisenberg picture, we would have invented some other pictures, use some other mathematics tools, to describe exactly the same thing in nature. As long as quantum effects are discovered experimentally, theory will be developed using whatever mathematics tool is available to describe them.

But super string theory is totally different. It does NOT describe the same world that existing theories are describing. Our world is 3+1 dimention and SS describes a 10 dimentional world. Any competent mathematician will have no problem deriving Newtonian dynamics from Hamiltonian one, or vise versa, but SS theory so far fails to figure out a way to "compactify 6 extra-dimentions" and derive our 4-D world.

There is also no experimental observation that leads to a postulation that leads to SS theory, the way equivalence principle leads to GR. Certainly there is also no theoretical calculation of SS that relates to anything to experimental observation.

So, so far, SS has nothing to do with physics, but is merely a pretty good **mind buggling mind exercise**, that we see has the good potential of **driving a few good mathematicians crazy or go nuts**. Same thing as the 3-torus world exam problem Sean Carroll gave to his students. He gave me zero point because I pointed out to him that it's merely good mind exercise but does not have anything to do with physics or GR, since 3-torus world does not describe our own universe.

Quantoken

30. **D R Lunsford**
April 15, 2005

String theory is being set up as a fundamental theory of nature, that matter "really is" made from umpteen-dimensional hair scrunchies. It should be obvious that there is no analogy. There *is* a direct analogy with Ptolemaic epicycles, or the elastic ether, or even say the Bohr-Sommerfeld atom (this gives too much credit to ST). It's easy to make outlandish models and push them to infinity. It's hard to have insights that lead to real physical progress.

-drl

31. **Fyodor**
April 15, 2005

Hamilton's reformulation of dynamics was not set up as a fundamental theory of nature.

Exactly — and yet it eventually led to great new discoveries. If the mentality at that time were similar to today's, somebody would immediately have suggested, "hey, let's complexify the Hamilton-Jacobi function and see where that goes!" And then I can easily imagine Maxwell coming up with the Schrodinger equation. And I can also imagine somebody in 1870 saying, "What a load of rubbish! You'd need an accelerator at least three feet long to check that!" But if they had pushed ahead, who knows, we might have had the Oprah show beamed into every home in 1914, and ghetto blasters in 1921. The possibilities are endless.

And it fact it does have observational consequences – geometric optics would have been impossible to discover from F=ma.

I hope you don't mean to say that Hamilton's work is only interesting from that point of view.

Look, jokes aside, all I am saying is that it took close to a century to get from Hamilton to Schrodinger. I don't see why string theory has to publish or perish so fast, particularly when there are no serious alternatives. If string theorists just come up with a new angle on general relativity from a quantum point of view, well, Hamilton did no more for Newton. And anyone who proposes to put a stop to string research had better have a damn good alternative on offer. Finally, the best way to prove that the landscape is crap is to work on it.

32. **D R Lunsford**
April 14, 2005

Well F, this is a non-point – sophistry. Hamilton's reformulation of dynamics was not set up as a fundamental theory of nature. And it fact it does have observational consequences – geometric optics would have been impossible to discover from F=ma. So what you've inadvertently done is to illustrate how real physics works with both reality and mathematical models.

-drl

33. **Arun**
April 14, 2005

Fyodor neglects the fact that String Theory does not have in its predictions any of the physics that we already know.

36. **Alejandro**
April 14, 2005

"Let's see if I've got this right: they're looking for SM properties amongst the vacua, like a three-leafed clover, and completely ignoring the wonderful work of Connes, Marcolli, Kreimer et al on the SM?"

It is because this work does not allow enough lateral publications. Even the experts on the field take a long time between paper and paper, and most of them include a review of the previous work.

I lived both the presentations of S T dualities by Witten (at Paris IAMP) and Renormalisation Trees by Connes (at Vietri), and the reception was clearly different. The excitation in Witten was not about the theoretical exposition, but about how many papers could be generated along his lines.

By the way, the Connes-Marcolli-Kreimer (and Moscovici, and Brouder) line is about renormalization theory in a general way, not only standard model. The line about the standard model is the one starting from Connes-Lott (and Coquereaux et al.) and taking seriously Weyl fermions as carriers of geometrical meaning. Both lines could be married in a unforeseen future.

37. **Quantoken**
April 14, 2005

Who said: "Did you notice that Lubos has not published a paper in 1 year!"

No paper? No problem! You can easily generate one paper with just a few mouse clicks, and it even gets accepted to a conference. No kidding:

http://www.pdos.lcs.mit.edu/scigen/

It's too serious to be funny. But most of "scientific" publications nowdays are not much better than computer generated random gibberish.

April 14, 2005

When is a Vacuum a State?..according to Brian Greene:When it can be described by a Non-Vacuum 'Dual' Solution.

What string theorists seem to be creating, is Two-Half holes out of one hole. You can Take a single brick from a completed or un-completed wall, thing is if one removes the brick prior to completion , you can classify the wall as being incomplete. Likewise if one removes the brick after completion one can never classify it as being complete!

If one imagines that the FIRST-FOUNDATION brick replaces a Vacuum/hole, the very last brick laid must not be constructed out of material/vacuum identical to the very first brick, it must be comparable to the W-HOLE wall.

So one arrives at:When is a brick a brick, and a hole a hole!

39.
April 13, 2005

"Did you notice that Lubos has not published a paper in 1 year!"

But he's made lots of really awesome blog posts. I'm sure the tenure committe will take that into consideration.

40.
April 13, 2005

Somewhere—I think in *Disturbing the Universe*—Freeman Dyson described Einstein as the savior of physics in the early years of the 20th century. Hyperbolic as this characterization may have been, I find myself thinking that we truly need another such person now—a synthetic intellect who can arrive at a radically simple, unifying perspective on all this, and has the technical chops and rhetorical gifts to make people pay attention and think hard about it. Sounds silly, I know.

For the time being sheer technical chops has outrun genuine* insight. We have lots of interesting ideas that lend themselves to mathematical development, but don't seem to get at the heart of the matter. Instead we hope that by exploring the mathematical landscape we'll stumble on something that somehow just works.

—-
(* I mean something distinct from, albeit akin to, mathematical insight—something like a new and fruitful metaphysical vision. I don't think physical insight, as most people now understand it, is up to the task.)

[*"…one should always know what the result of a calculation should look like before attempting it…"*]

41.
April 13, 2005

Hey Peter, I am sure you have probably realized by now but I'd like to point it out anyway. Did you notice that Lubos has not published a paper in 1 year! One day like today but of 2004….
Either this is his miraculous year or really the string comunity does not have anything promesing to do 🙂
I know this is unrelated to the landscape, or perhaps not….
Anyway, I like Ed's attitude, he got his fields medal, let's keep doing math 🙂

best regards,
N

-drl

43. **JC**
April 13, 2005

Any guesses as the what the anthropic string folks will be doing if the entire landscape thing ends up as a total failure, and they actually give up?

44. **Quantoken**
April 13, 2005

Peter said:

“It’s discouraging that I don’t see any way of having a rational discussion with the people doing this. They are motivated by a hope that somehow, some way, they will find amidst this complicated mess the Standard Model, in some context that allows them to predict something else.”

Why, peter? This is their jobs, remember? What can they do if they do not do research on super string theory? Where do they get **funding** if they work on SOMETHING ELSE?

And don’t worry about they getting tired or bored of trying, as long as there continue to be funding for such research. You eat three meals a day and always seem to be eating the same food, do you ever get tired eating? No, you could never be tired of food. So scientists also will never be tired of trying certain ideas, as long as that particular idea continue to bring them funding and something to eat.

Quantoken

45.
April 13, 2005

Let’s see if I’ve got this right: they’re looking for SM properties amongst the vacua, like a three-leafed clover, and completely ignoring the wonderful work of Connes, Marcolli, Kreimer et al on the SM?

46.
April 13, 2005

Simple, the Intelligent Designer chose this particular vacuum, because he liked it.

47.
April 13, 2005

But even if they do find a vacuum which gives rise to the Standard Model — and given the astronomical number of vacua, it may even be likely — don’t they still have to explain why that particular vacuum was chosen?

Conferences Not To Go To

April 18, 2005
Categories: Uncategorized

This week in Santa Fe there's the International Conference on Science and Consciousness, where Michio Kaku will be giving a keynote address. He'll explain how "Many physicists today believe in the multiverse, i.e. Genesis is constantly taking place in a timeless ocean of Nirvana, creating Big Bangs even as you read this sentence" and will tell about experiments to confirm the multiverse theory. He's also running a workshop at the conference on "Visualizing Higher Dimensions" in which you can learn about how to capture different planes of existence (connected by wormholes) in simple pictures. His fellow speakers include Gary Schwartz, Ph.D. who will explain how new experiments involving deceased parapsychologists and Princess Diana provide evidence for life after death, Steven Greer, M.D. who "has taken teams around the world to make contact with Extraterrestrial Lifeforms", and a host of others. Kaku is also interviewed in this week's New Scientist, where he explains that the Standard Model is "supremely ugly" and string theory is "gorgeous".

This fall the Metanexus Institute, which is somehow part of the Templeton Foundation will be organizing a symposium honoring Charles Townes called Amazing Light: Visions for Discovery at which the Templeton Foundation will be announcing a "multi-million dollar, multi-year effort to catalyze research and dialogue at the boundaries of physics and cosmology" called Foundational Questions in Physics and Cosmology. Not clear exactly what this will be funding, but if you check the Templeton website you'll find that "we do not support what might be called standard or mainstream science research", so at least it won't be any of that. In case you're having trouble keeping them straight, this is real, this is a joke.

If you're wondering how Templeton has convinced 18 Nobel Prize winners to attend, Sean Carroll has a very interesting posting explaining how he decided to pass up the \$8000 + expenses he could have made by speaking at this conference. Also if you're wondering why Templeton gave Townes a \$1.4 million prize this year, you can read his remarks upon accepting it, where he explains that "Increasingly, science is showing how special our universe and we are, which has raised questions about whether it was indeed planned or influenced."

In other news, Susskind seems to have ruined his chances at the \$1.4 million today. In his talk at Brown, according to Daniel Doro Ferrante he "repudiated any connections with Intelligent Design".

Comments

1. **Juan R.**
   April 29, 2005

   Two comments,

   I would say canonical gravitodynamics for no confusion with canonical quantum gravity that is other thing.

   The concept of curvature is ambiguous in application of GR. Please remember that newtonian gravity is a consistent theory of gravity working on flat space.

   Remember also standard conformal transformations on cosmology. Perhaps the concept of curvature of GR is just a calculation procedure valid in some situations, somewhat like one can obtain a flat Mk -type metric for the universe from conformal transformations. This last discussion is still speculative. I continue to research.

2. **Juan R.**
   April 29, 2005

   Thanks drl

   Of course, perhaps I am wrong, but it is highly improbable. Only a "cosmic fluctuation" could do that I obtain the correct values for those relativistic values more the correct Newtonian limit from canonical gravity.

   You would be highly skeptical of my work, i understand that, but please be also of standard well-accepted theories.

   For example, recently it has been demonstrated (Phys Rev E) that usual LW potentials of electrodynamics does not verify Maxwell equations and therefore all computation based in LW are Maxwell violating ones!

   Curiosly canonical electrodynamics predicts that failure. Another coincidence?

   A crucial question for you.

   Who said that there is no tensors on canonical gravity?

   However, "complete" tensor calculus is not necesary for both light deflection and perihelion.

   In fact, the derived standard GR formulas for computing light deflection and perihelion anomaly are non tensorial, are scalars ones based in scalar magnitudes like M, R, e, G, and p.

3. **D R Lunsford**
   April 28, 2005

   The value of the light deflection and the sign and value of the perihelion precession force one to make a tensor theory, and curvature is inevitable. There is no way out of this.

   -drl

4. **Juan R.**
   April 28, 2005

   If this is of interest here, I have finisihed my research on GR.

   Effectively, I can derive well-know experimental phenomena from a new theory of gravitation on flat space.

   Next, some of experimental data explained from canonical gravity:

– Mercury anomalous perihelion.
– Light deflection.
– Radar time delay
– Redshifts

Moreover, the theory corrects the conceptual and thecnical problems of Einstein GR and can be quantized!!

More details will be shown on the non-technical paper (on strings) quoted below. Technical details will be shown in papers.

Thanks

5. **Juan R.**
   April 25, 2005

   Tom

   Thanks by your reply but I thik that are misunderstanding the point.

   My criticism is not conceptual, string theory formulas do not work. That will be shown in papers.

   I am not talking about toy models (e.g. cosmological 4D branes, idealized models for blackc holes, etc.) I am saiyng that complete string theory framework is wrong.

   I am not talking about fine-tunning of a almost good theory I am talking about a bad TOE. string theory is a waste of time. They will not work. It is not a problem for adjust one or two parameters or add a new correction to usual equations. All the framework is outdated!

   Moreover, when string theorists talked about Calaby-Yau they really thought that was the geometry of universe. When Scwartz talks about unitary he is not talking about a toy model. He is talking about string theory.

   "1) no-one has written down a Lagrangian for M-theory"

   Of course, it does not exist. Even I doubt that exists a hamiltonian for M-theory!

   "2) compactification has to be done by hand
   But they believe that the flaws/holes can be fixed."

   If compactification is done by hand then the derivation of GR from string theory is just the modification of string theory for adequately it for obtaining the correct reply (known before string theory): GR. This is not a **derivation** for a theoretical scientist I am.

   "This just shows that only referring to popular scientific books is not good enough."

   The ideas below my paper is not referring to popular literature are refering to string literature.

   "Yes, I still say that no string theorist says that they have the right theory."

   I'm sorry to say this but your statement is not honest and contrasts with own Greene statement opening my "paper": "String theory continues to show ever increasing signs of being the correct approach to understanding nature at its most fundamental level."

   I show that string theory is not fundamental.

   Yes it's like a photographer. One taking pictures of a dog and attemp to convince you that it is a car!! 🙂

   It is not true that basic concepts like extended objects and extra dimensions remain in all string literature. It is not fine-tuning of almost good theory, it is a disaster.

   In fact, some people claim that correct theory may based in poitlike particles (graviton, string are derived like aproximated concepts). Others claim that there is no extradimensions, and we are mising 4D versions of string theory!!

   "Again, misinterpretation. GR will still be a very very good model of gravity and very helpful in studying large scale behaviour of the universe. Even if there are some new experiments contradicting GR, they would be very small correction to GR. And actually everyone believes that GR will break down at small scales."

   No!! you are completely wrong!

   I am not talking about Planck scale modification of GR or similar. I am talking about the complete failure of GR like a theory of gravitation even in solar or cosmological scales. I am not talking about fine tuning of GR (that is an action with GR more corrections terms). I am talking about the failure of the concept of GR. E.g. the idea of that gravitation is not delayed, the idea of there is not gravitational fields, the idea of that curvature is not gravitation, the idea of Lorentz forces do not exist, etc.

   Almost all of this has been proved and now I am working in experimental tests. This is fascinating!!

9. **Quantoken**
April 22, 2005

Some said: "Gavin Esler talks to Michio Kaku, one of the world's leading experts in theoretical physics, about the prospect that **the world will end in a 'Big Freeze'** and the possibility of organizing an **'exit strategy'** from planet earth."

Wow, I never thought about that:-) So what are their proposed salvation plan for the earth?

Maybe they should attach the ends of **some strings** to **galaxies** to prevent them from **flying away**. No, not the 25 pounds cheap fishing strings bought from Wal-Mart. That breaks too easily.

What we need to tire galaxies together is the **SUPER STRING**, something that is safe, **permanently safe**, so it could never fail and never break. How could it ever break if there are **10^500** of them? 🙂

Super String Saves the World. WOW! They probably should put that in their research funding proposals 🙂

Quantoken

10. **Tom**
April 22, 2005

Dear Juan,

>>> "it just shows a complete misunderstanding of what is really going on." It is easy talk, please (if you desire) demonstrate your words quoting real papers.

I dont need to quote papers. I only need to put forward arguments.

As I said you often make factually correct statements, but your interpretation of them in relation to every thing else is not correct. You constantly make subtle to moderate misinterpretations, which then lead to a complete misunderstanding of the area. AGAIN, you need to do physics formula by formula for a few years, just looking at the conceptual arguments is not enough. Remember the pope! 🙂

For example, in your non-technical paper, you say that there are too many models etc. Yes, but they are just toy models, and not realistic models. As I said "string theory" is more of a research program, where often theorists are creating simpler versions of the realistic model they really like to solve and play around with it. You often misinterpret them as the real models.

> I do not find "String theory is full of flaws" on my copies of CERN seminars, talks, papers, magazine reports (e.g. above quoted by Peter) or books (e.g. The elegant Universe)

Every "string theorist" would agree e.g. that
1) no-one has written down a Lagrangian for M-theory
2) compactification has to be done by hand
But they believe that the flaws/holes can be fixed.

And, for that matter, I had lunch with Brian Greene (Elegant Universe) in Erice five years ago and I proofread the German version of his book for him. He readily admitted that there are several open issues but that they could be fixed… And so did Michael Green and Mike Duff.

This just shows that only referring to popular scientific books is not good enough.

> If you state that no string theorist would claim to have the right theory is that you have not read string literature.

Yes, I still say that no string theorist says that they have the right theory. But they claim that they can make the string idea into a workable theory for unification.

>>> But even your words sound like "don't worry if 90% of string garbage is wrong because you can call string theory to everything you do." Also canonical science? Everything will be called string theory?

No, it's like a photographer. You take hundreds of pictures and take the one that fits. Same here, theorists are playing around to find the right models. But a subset (the string theorists) is led by concepts like extended objects and extra dimensions.

>>>Of course, there is NO unification even if GR in its actual status were correct. Recent experiments (by real people working in real 4D word and publishing in real journals not in ArXiv) suggest that gravitation velocity is bounded by 10^8 c invalidating "archaic" Einstein's thinking.

Again, misinterpretation. GR will still be a very very good model of gravity and very helpful in studying large scale behaviour of the universe. Even if there are some new experiments contradicting GR, they would be very small correction to GR. And actually everyone believes that GR will break down at small scales.

Tom

Michio Kaku today on BBC World:

19:30 HARDtalk Extra (r)
Michio Kaku
Gavin Esler talks to Michio Kaku, one of the world's leading experts in theoretical physics, about the prospect that the world will end in a 'Big Freeze' and the possibility of organizing an 'exit strategy' from planet earth.

12. **Juan R.**
April 22, 2005

To all "blogers"

Do you see some strong failure on my ideas? Of course, I am sure of that will do errors, but it is difficult for a scientist see his/her own errors. Help?

To ""

"Hmm in page 12 a strange kink to chemistry is done. Alchemy somewhere around?"

Please define Alchemy.

My appeal to chemistry on page 12 means that if S. Weinberg has no idea of the implication of his own field of QWD for chemistry, how can he have idea of other fields of science that he newer studied? The problem with Weinberg is double:

– 1) He needs demonstrate that exists the TOE and we are close to it. Therefore he needs say that all of chemistry is already known.

– 2) He talk in popular media. I have no problem if Weinberg says barbage on Phys. Rew or in his own specialized manual on QFT because readers are scientist and can verify he says. THE PROBLEM is that Weimberg says garbage on popular media. So many policy makers retire funding to chemistry because Weinberg says thah all is already known? So many young students are leaving the field for more glamorous fields like string theory thanks to him?

Of course Weimberg idea of all of chemistry is studied with electrostatic interactions more QM is a complete garbage. Theoretical chemists say that in their papers and reviews but no in popular media.

Dear "TOM"

I am perplexed by your "high-quality" reply.

"I doubt anyone will endorse your "paper"."

First, it is not a paper, it is a nontechnical work. In fact I submited it to pop-phys category 🙂 Don't worry if it is not endorsed. He is just a popular magazine work.

Tecnical work cannot be contained on a single paper and will be published elsewhere. Around 20-30 papers * 25 pages per one = —-. I leave you this difficult computation. Note: can use renormalization tricks.

"it just shows a complete misunderstanding of what is really going on."

It is easy talk, please (if you desire) demonstrate your words quoting real papers.

You say: "String theory is not yet a scientific theory as such (and as a consequence full of flaws) but a research program led by ideas like extended objects like strings instead of particles, or extra dimensions, etc."

I do not find "String theory is full of flaws" on my copies of CERN seminars, talks, papers, magazine reports (e.g. above quoted by Peter) or books (e.g. The elegant Universe)

But even your words sound like "don't worry if 90% of string garbage is wrong because you can call string theory to everything you do." Also canonical science? Everything will be called string theory?

The idea of extradimensions is wrong because it arises directly from consistency (taquions, etc.) of basic string equation. Since basic string equation is wrong, (even is wrong the idea of a classical manifold R4, Calabi-Yau, G2, etc.) the extradimensions are not here!!

The idea of extended object is good but "like string" is also wrong. In fact, it is wrong the idea of branes including a theory of **pointlike** particles on 11D like Banks suggests.

I think (sincerely) either you have a distorted idea of real status of string theory or you are doing joke.

If you state that no string theorist would claim to have the right theory is that you have not read string literature.

As said, the idea of that "string theory" is the way forward to unifying QFT and gravity may be a joke. A joke during more than 30 years!!

Of course, there is NO unification even if GR in its actual status were correct. Recent experiments (by real people working in real 4D word and publishing in real journals not in ArXiv) suggest that gravitation velocity is bounded by 10^8 c invalidating "archaic" Einstein's thinking.

I continue working durely in this fascinating topic. Yesterday, I discovered that one well-known equation used by experimentalists for extragalactic dynamics (they do NOT use standard GR because don't work) can be derived like a special case of the canonical gravitation. Whow!!

I don't think that I have quantized gravitation satisfactory, but the distance between real equations I derive, which are used in real experiments, and the garbage, conjetures, bad mathematics, etc. used by "string theorists" and without link with nothing (even there is no real link with GR) looks your appeal to Pope and sex.

I agree with your three last points.

Kaku waxes poetic because he is following his passion and he lives for the glimpses of beauty that his researches allow him to behold.

You mean he’s gay, too… ?

14. **Alejandro**
April 22, 2005

The paragraph below defies my understanding of English. It seems than on one side it is critiquing people who effortlessly uses others’ work, but on other side it is welcoming the possibility of effortlessly using other’s work, from Aliens or even from G-d Himself. Is it?

Funny that the same people that put down the efforts of others without themselves producing any significant work, are also the people so afraid of any challenges to their little materialist bubble that all they can do is sneer and scoff when mention is made of things like aliens, homeopathy, prayer, consciousness, etc.

15. **D R Lunsford**
April 22, 2005

How’s the dihydrogen oxide escribio:

Kaku waxes poetic because he is following his passion and he lives for the glimpses of beauty that his researches allow him to behold.

It’s not “poetic”, it’s self-indulgent crap designed to pump up his own inflated ego – he’s in denial because he doesn’t get it. Dirac is poetic.

On this blog, instead, the talk is all about putting others down, denigrating ideas that are daring and challenging, being petty. Little minds that dont seem to be finding much beauty or inspiration splurting sour grape juice at those who are.

We’re venting, because we’re pissed off to see the thing we love debased by these charlatans.

You dont like string theory? You think it sucks? Well, lets see your theory that does better.

http://cdsweb.cern.ch/search.py?recid=688763&ln=en

You think Steven Greer is a loony? Maybe he is, but have you seen the Disclosure Project material, testimony by dozens of retired military and intelligence officers, FAA officials, and military and civilian aviation experts and pilots, all willing to take an oath before congressional hearings as to their knowledge of the extraterrestrial presence and our government’s cover-up of their involvement in it? Have you heard of or read the COMETA report put out in France in 1999 by a panel of high ranking military and scientists concerning UFOs and the implications of a possible extraterrestrial presence?

Speaks for itself.

Funny that the same people that put down the efforts of others without themselves producing any significant work, are also the people so afraid of any challenges to their little materialist bubble that all they can do is sneer and scoff when mention is made of things like aliens, homeopathy, prayer, consciousness, etc.

Palliatives for the frightened mole.

Yes, there is more in heaven and earth than is dreamt of in any of our philosophies. I suppose the great divide is between those who recognize this and are actually excited by it, and those who react to this idea with fear.

The alien-mongers and water-talkers are the ones who are afraid.

I for one find the possible confluence of this new “Landscape” thingy, many worlds quantum interpretations, and the age old recognition of the existence of other dimensions and other consciousnesses found in many indigenous religions and philosophies, very exciting.

What’s the moment of inertia of thin disc about its symmetry axis? I thought so.

I’d like to read more here about what others find exciting, not just what they think sucks and are afraid of because it threatens their world-view.

I’d like to see my science get back its self-respect, and for the sensationalist carnival barkers to STFU.

-drl

16. **Como el Agua**
April 22, 2005

Reading the essay by Michio Kaku that is linked to from this latest blog entry, I was struck by the contrast between his writing and the kind of writing found here.

Kaku waxes poetic because he is following his passion and he lives for the glimpses of beauty that his researches allow him to behold.

On this blog, instead, the talk is all about putting others down, denigrating ideas that are daring and challenging, being petty. Little minds that dont seem to be finding much beauty or inspiration splurting sour grape juice at those who are.

You dont like string theory? You think it sucks? Well, lets see your theory that does better.

You think Steven Greer is a loony? Maybe he is, but have you seen the Disclosure Project material, testimony by dozens of retired military and intelligence officers, FAA officials, and military and civilian aviation experts and pilots, all willing to take an oath before congressional hearings as to their knowledge of the extraterrestrial presence and our government’s cover-up of their involvement in it? Have you heard of or read the COMETA report put out in France in 1999 by a panel of high ranking military and scientists concerning UFOs and the implications of a possible extraterrestrial presence?

17. **L.E.J. Brouwer**
    April 21, 2005

    I must say I was pleasantly surprised with the delightful topics being presented at this conference until I stumbled across the photographs displaying the dreadful physical condition of the contributers.

    I have now surmised that they are all meat eating algebraists of the worst degree, unworthy, of further consideration.

    Tow,

    L.E.J.

18. **Torbjorn Larsson**
    April 21, 2005

    Tom:
    Your clarification is clear. However, I think responsiveness is redundant in your list.

    “You think that my examples are useless, because you think that consciousness is only awareness and self-identity, which indeed can be at least in theory programmed.”

    No. As you, I don’t have a ready definition. The definition I used was how I understood yours. I think your examples are useless since you ask what functions, including consciousness, will be observed by replacing with a functionally identical part.

    About consciousness in non-humans: Imagine a biological, mechanical or whatever species visiting. It would be rude and conflict creating to suggest to them that we had a monopoly on consciousness.

    If they act and describe themselves as conscious, we must accept that. Regardless of details like that they don’t see colors, dream, hurt or such minor differences. It is a different consciousness, but it is consciousness.

    If any couple of computers that we make start to act like this, they will be conscious by definition.

19. **Chris Oakley**
    April 21, 2005

    Dear Anonymous,

    As it happens, for me, writing software for investment banks comes a poor second as a career choice to doing quantum field theory research, but I had no choice other than to leave. No-one in authority seemed to like being reminded of the fact that their subject had roots about as substantial as Birnham Wood. I got tired of arguing, and they got tired of listening to me. Nothing much has changed in the subject in twenty years except that the fad that I thought would lead nowhere (String theory) actually *has* led nowhere. It seems that it is alright to be wrong, provided that you are part of a large team that is wrong. I could ignore it, but I choose not to as, like Peter, I actually care about the subject and find it offensive that custodians of such a valuable and important part of human knowledge should discard the principles of scientific investigation so lightly.

20. **D R Lunsford**
    April 21, 2005

    Chris O – ROFL!

    “The Message from Water” – So does the hydrogen speak 66% of the time, or the oxygen 89%? And is heavy water more boring?

    That reminded me of a New Yorker cartoon. Two toga-clad academics are standing at the blackboard, on which is written “AIR EARTH FIRE WATER”. One of them gesticulates at the four words and states excitedly – “What do you MEAN it’s a good start? That’s all there is!”

    -drl

21. April 21, 2005

    Chris Oakley-

    I notice from your site that you basically work helping rich people get richer and further skew the distribution of wealth on the planet. Kudos on your fine humanitarian work.

    The majority of the people on the page you take such pains to point to disparagingly are involved in exploring the frontiers of knowledge and helping people heal and grow.

    Funny that one such as you should so stridently make fun of ones such as them. Perhaps deep down you realize how shallow your work is, and thus seeing those folks pushes a few of your buttons?

22. **Chris Oakley**
    April 21, 2005

    OK – just so that you know, here’s how you put a link to a web page in the comments section here:
    Enter the wonderful world of pseudo-scientific bullshit

    Which appears as

    Enter the wonderful world of pseudo-scientific bullshit

    which you can of course click on to take you there.

23. April 21, 2005

http://www.canonical.chemicalforums.com/stringcriticism.pdf

Hmm in page 12 a strange kink to chemistry is done. Alchemy somewhere around?

24. **Tom**
April 21, 2005

To Pope Juan,

I doubt anyone will endorse your "paper".

Your statements might sometimes in itself be factually correct, but it just shows a complete misunderstanding of what is really going on. You are clearly intelligent, but you remind me of the pope talking about sex. You wont get it until you go through the motions i.e. spending several years doing physics formula by formula.

String theory is not yet a scientific theory as such (and as a consequence full of flaws) but a research program led by ideas like extended objects like strings instead of particles, or extra dimensions, etc. I am not a "string theorist" myself, but I would claim that no "string theorist" would claim to have the right theory, but they all claim that that's the way forward to unifying QFT and gravity.

The only thing I am a bit uncomfortable with is.
1) Too many permanent posts are being filled by "string theorists".
2) Too many PhDs in string theory, provoking a drain brain, leaving them unemployed (too few postdocs), and sometimes depriving bright people from a satisfactory career in other areas.
3) Too much publicity, which then leads to complete misunderstanding by the public on the subject.

Tom

25. **Juan R.**
April 21, 2005

For a point of view contrary to Kaku and why string theory is already **outdated**
see

http://www.canonical.chemicalforums.com/stringcriticism.pdf

This nontechnical article has been submited to ArXiv. I am waiting for endorsement.

26.
April 21, 2005

Unemployed Parapsychologist,

Blackmore's book "Consciousness: Introduction" is a textbook discussing the pro&cons of different views on many different aspects of consciousness, and not a description of her own views.

But I do like the ideas of memes.

Tom

27.
April 21, 2005

"… more adventurous minds."

http://bizspirit.com/science/sspeakers.html

Inspirational note for David Duval. There is falling really hard and then there is…KAKU

28. **Unemployed Parapsychologist**
April 21, 2005

Tom,

I think I can save everyone the bother of buying Ms. Blackmore's book…she states her position quite eloquently in her latest book on memes:

"The next chapter takes up the ancient questions as to what constitutes the self and consciousness. After a brief review of some of the current theories on the matter, Blackmore proposes her own idea: that consciousness or self is a memeplex: an agglomeration of countless memes which survive best as a group. If you call this a soul, you are being religious and that is bad. But call it selfplex, and you are talking science. The selfplex is formed by the coming together of so many memes which "form a self-organizing, self-protecting structure that welcomes and protects other memes that are compatible with the group, and repels memes that are not (p. 231)." We are not just a bunch of neurons, she reminds us, we are "a pack of memes too (p.235)." "

And check out the chapter entitled "An orgasm saved my life". Very scientific indeed.

http://www.metanexus.net/metanexus_online/show_article.asp?3056

Susan Blackmore ? Stopped lecturing and abandoned parapsychology altogether, because she could no longer endure the near fanatic and rude behavior of both believers and non-believers.

http://en.wikipedia.org/wiki/Parapsychology

…headin down to the memeplex to buy a case of beer and a pack of memes

29.
April 20, 2005

“Aperion” showed his ass by blithering:

“I don’t think I’ve ever seen a bigger collection of freaks, hucksters, lamiacs, charlatans and deviants than the hit-parade of losers on tap at the Consciousness Conference. Where are are the vitamin and juicer pitchmen and the no-money-down people when you need them? At least they drive expensive cars and are much better looking.”

Another example of a post by someone who no doubt has contributed little or nothing to humanity heaping invective upon more adventurous minds.

Please do us all a favor and immediately stop taking vitamins and vegetable juices, so your self loathing will be inflicted upon us for a lesser amount of time.

thanks.

30. **Apeiron**
April 20, 2005

I don’t think I’ve ever seen a bigger collection of freaks, hucksters, lamiacs, charlatans and deviants than the hit-parade of losers on tap at the Consciousness Conference. Where are are the vitamin and juicer pitchmen and the no-money-down people when you need them? At least they drive expensive cars and are much better looking.

Is that an intemperate or insensitive comment?

Tough shit.

31. **Chris Oakley**
April 20, 2005

Most HEP theorists today will happily “bend over and spread their legs” for whoever pays their bills.

I really doubt that that is true. No-one paying the bills would have agreed to dozens of their hirelings going off on a crazy tangent for decades.

32. **Not a Nobel Laureate**
April 20, 2005

Most HEP theorists today will happiliy “bend over and spread their legs” for whoever pays their bills.

So whoring at the Templeton Foundation comes as no surprise.

33. **island**
April 20, 2005

People put too much stock in what consciousness is about, since it essentially just enables a level of comparitive uniqueness when it comes to our contribution to the entropy of the universe.

Local increases in complexity and order necessarily equate to increases in the potential for disorder in an expanding universe, and this effect gets compounded as negative pressure increases to bring about emergent properties that enable the system to pay back the ever incresing entropic debt.

Our unmatched ability to process information and isolate the release of enough energy to directly affect the symmetry of our universe defines good physical reason why the expanding universe would “need” us into existence via the isolation of its forces, especially if the negative pressure component is increasing.

I agree with disgusted, string theroy utter bullshit, but I also think that everybody is so stuck on the either/or mentality of chaos vs. god that they can’t see the REAL importance of the most predominant freaking physical need in our universe.

The whole fanatical world is not even wrong…

34.
April 20, 2005

To Torbjorn,

I dont claim to actually have a definition for consciousness, as I dont know what it exactly is or whether it even is (like aether or elan vital).

I only want to clarify that by consciousness I dont mean responsiveness (i.e. being not unconscious), awareness (i.e. being conscious of something) or self-identity (i.e. knowing to be an entity). But rather what is left, what some call first-person experience, qualia, sentience. Someone can still have a conscious experience without being either responsive (lost all control of body), aware (of outside events), or self-conscious (some states of meditation)?

You think that my examples are useless, because you think that consciousness is only awareness and self-identity, which indeed can be at least in theory programmed.

Of course, computer might behave like us but are they mimicking us functionally or really experience like us i.e. “is there anyone home?”

All my examples are trivial if you believe that a standard computer can be conscious by just running the right software. But here I would quote you by saying “examples are useless since you can’t make them work.” Unless you implement the computer like a brain maybe?? 😉

Tom

35. **Thomas Larsson**
April 20, 2005

I still think that it is instructive to compare string theory to aether theory, because the parallels are so obvious. All the cool and smart people worked on these theories for decades, arguably with one successful physical prediction (electromagnetic waves/gravity), and they definitely led to some mathematical progress. However, both theories were eventually slain because one necessary thing was not observed (aether wind/low-energy supersymmetry), and one impossible thing was indeed observed (photoelectric effect/positive cosmological constant).

Does this mean that string theory is wrong? Perhaps it is aether theory that is not even wrong; in a sense, it was resurrected in the form of cosmic microwave background radiation.

36. **big bang**

April 20, 2005

completely disgusting.

37.
April 19, 2005

Is a theory that cant be proved right automatically (even) wrong?
I mean, if there is not a single experiment which can totally disproof the theory but nevertheless the theory predicts possible outcomes which might be realized in nature, is that science?
I have myself an answer for that question, but I wonder, we might have reached a point where perhaps many possible outcomes are allowed and we just happen to live in one of them.
That's not totally rubbish, and even though I dont like the uses of the anthropic principle and the landscape I wonder myself whether or not a GUT (something that I dislike too) could even make sense or not and what can we infer about the universe in either case. I do believe that philosophy is important for science, and asking deep questions have led us into new roads of understanding. I used to have discussions with historians, if what they do could be called 'Science'. If doing forensic studies and retrodiction is equivalent to predicting things. Certainly we can sort of disproof theories by an incorrect account of known results, but can we affirm their theory is 'correct' if leads consistently to what has been seen?
I myself spare my time between deep questions and hardcore science. I do believe that a real scientist should 'tink a little' about foundational issues once in while….after tenure preferably 🙂

best regards,
N

38. **Torbjorn Larsson**
April 19, 2005

Tom, to clarify: _all_ your examples are useless.

They amount to ask: "If one changes a part to a functional equivalent, will one see a functional difference?"

Computer consciousness can however be given an operational definition, as stated.

39. **Torbjorn Larsson**
April 19, 2005

Tom: Consciousness is (still) badly defined in general, and by you in particular. Your 'mental world' seems like awareness and selfidentity.

These things are observed in higher animals and humans. How do I know another person is conscious? I know I am, I observe them to behave like that and they describe themselves to be. One day computers will likely do the same to each other; they are then equivalently conscious as we are.

The other examples are useless since you can't make them work. They amount to asking "If I replace the Sun with an identical sun without you noticing it, will you notice it?"

40. **Tom Weidig**
April 19, 2005

To Travis,

I think consciousness is not as conceptually straightforward as you might think. Awareness and Self-identify seems acceptable to be created by the neuronal firing, but first-person experience (our mental world) seems very different.

Here are a few questions:

if you could duplicate the brain functionally on a computer, would the computer be conscious (in the sense of having an "inner life" or first-person experience)?

what if I train all Chinese to simulate the brain functionally like the computer, would there be a consciousness different to the billions of Chinese spread across China?

Suppose I step-by-step replace your brain with chips simulating each a neuron, will you loose your consciousness?

If I clone you physically identical, are there two yourselfs??

Buy the textbook, it's worth reading. As I said before, I dont know what to think, but it's certainly more intriguing than you think it is.

Tom

41. **Disgusted**
April 19, 2005

I guess the string nuts must already be chomping at the bit:

"it is clear that consciousness is equivalent to the abstract patterns formed by firing neurons and their dendrite connections in the brain"

to join the ranks of consciousness (whatever that is) "scientists" when their own funding dries up.

Should be good for another 20 years of worthless speculation and philosophy while avoiding real-world accountability.

42. **Peter Woit**
April 19, 2005

Hi Travis,

My comment about Susskind in this posting wasn't a criticism at all. It sounds like he was doing the right thing and disavowing any support for "Intelligent Design". When I said that by doing this he "ruined his chances at the $1.4 million", that was meant as a compliment. I think his behavior in pushing the landscape pseudo-science has been outrageous, but I never thought he was an Intelligent Designer and never accused him of this (OK, on April Fool's day, as a joke, I kind of implied it…..)

You and lots of others keep talking about predictions of Arkani-Hamed and Dimopoulos derived from the landscape and how they'll be testable before long. I've read their papers and see nothing there that looks like anything I would call a "prediction". I'll ask you the same question that I keep asking everyone who says this. Give me a prediction that they derive from the landscape (and a real prediction, one that if it is wrong, the landscape scenario is wrong), and tell me whether it is testable at LHC energies. If it isn't what energy is required? If it is, how much integrated luminosity will be required to falsify their prediction and show that the landscape is wrong?

43. **Travis Garrett**
April 19, 2005

Speaking a staunch atheist, I think the comment on Lenny was a cheap shot. There is an enormous difference between the landscape (it is certainly possible that chaotic inflation produces many different stable string vacua – and hopefully testable before too long along the lines of Savas & Nima…), and all of the obviously false religious/supernatural non-explanations. Of course Lenny doesn't have any connection with ID just because he finds the landscape intriguing – so do I – and it is disingenuous to imply otherwise.

Hi Tom – I also think that it is clear that consciousness is equivalent to the abstract patterns formed by firing neurons and their dendrite connections in the brain. And it works in the classical limit – each neuron adds up all the excitatory and inhibitory impulses and if the sum crosses a threshold then it fires too and so forth (and the Penrose stuff is crazy – the Chinese room and Godel arguments against classical AI are obviously wrong, and the decoherence time is tiny). Of course, more precise detail would be great (so that, say, you could study the topology of the connected graph that gives rise to the sensation of red and so on). In the end, consciousness will be nothing more than a (very interesting) subset of neuro & computer science.

44. **Jo?o Carlos**
April 19, 2005

I remember reading a science fiction story many years ago about a society which had highly advanced technology, but had lost the capacity to understand that technology scientifically and instead had shrouded the technology in religious mysticism. Could have been by Asimov, I'm not sure. Anyways, perhaps that's where we are headed.
Isaac Asimov's **Foundation**.

45. **Jo?o Carlos**
April 19, 2005

Well… I'm religious, I'm mystic, I'm a credulous person, and **I happen to know G?ddel's Theorem**. Trying to meddle religous beliefs with science is **stupid!** Faiht and science are opposites! Anyone who disagrees may email me. I've got a lot of *gold bricks* to sell…

46. **JC**
April 19, 2005

Anybody know where some of these pseudo/anti-science attitudes in America came from (whether government decreed or a general societal mentality)?

Only widespread case of a government and/or societal censure of a science in recent times that I can think of offhand, would perhaps be during Nazi times in Germany where various government decrees attempted to ban all "jewish physics" like relativity, quantum mechanics, etc ….

47.
April 19, 2005

I remember reading a science fiction story many years ago about a society which had highly advanced technology, but had lost the capacity to understand that technology scientifically and instead had shrouded the technology in religious mysticism. Could have been by Asimov, I'm not sure. Anyways, perhaps that's where we are headed.

48. **Steve m**
April 19, 2005

This will make you cringe Peter

http://www.web-books.com/GoodPost/Articles/Prologue.htm

Especially the line, "Physicists have discovered the laws that prevents us from seeing the Kingdom of God". The stuff on "String Theory and the Resurrection of the Dead" was especially BS.
While I am not antistring I am disturbed people abuse it in this rediculous way and a lot of scientists who should know better (eg Kaku and others) are as much to blame. I imagine this is the sort of stuff the so called "Templeton Foundation" will actually promote as real scholarship. Real scientists should not be whoring themselves out to these sorts of agenda-driven foundations. Maybe someone could submit a Sokal-type joke paper to one of these conferences? I get the very worrying sense these days that physics and science and the scientific method are getting trashed and undermined from all sorts of angles; that we are moving into some sort of "anti-enlightenment". All this metaphysical religious-motivated nonsense going on at these conferences simply does not "lie along the line of what we are able to understand if we devote ourselves to it" (to quote Jacob Bronowski, the great secular humanist). I worry greatly that science might ultimately not survive in the far (or perhaps not so far)future. I think it was Jacques D recently who made the analogy of a few threads coming off a sweater but eventually the whole thing can unravel. I really hope that in a hundred years from now we are not back in the dark ages burning witches once again.

49. **Steve Esser**
April 19, 2005

Folks like you Peter and Sean Carroll are convincing me that despite good intentions, Templeton and similar efforts do more harm than good and serious scientists should stay away. The line-up for the Science and Consciousness conference you linked to was particularly nutty (whereas the Consciousness conferences at Arizona mentioned earlier are mostly high quality with just a few sprinkles of nuttiness).
On the other hand I also fear that scientific explorations of consciousness probably suffer from this inability to keep the topic crackpot free and this is unfortunate.

50. **D R Lunsford**
April 19, 2005

I'm the one hurling epithets at Kaku, because he's a goofy charlatan. Don't blame the nice guy Peter. I'm not a nice guy and don't aspire to be one. My edge has been sharpened on the idiocy of my generation.

-drl

51. **Peter Woit**
April 19, 2005

Well, at least in this posting I'm not hurling epithets, making any ad hominem attacks, or using the words "crazy" or "bullshit". All I did was accurately quote Kaku's own words and link to information about the conference he is speaking at. If you drew the conclusion that the conference was devoted to crazy bullshit, I'm not going to argue with you.

You're right, this stuff does push buttons with me. I care very deeply about this subject and have been working in it for 25 years. I know exactly where these ideas came from and why they're getting so much attention, and I'm not happy with it. Kaku and others are devoting their lives to trashing something very important to me. They've gone a long way towards turning the field of particle theory from a serious and important science into a depressing pseudo-science, and in recent years this has gone from bad to worse. If you don't like this point of view and think Kaku's behavior is fine and I shouldn't be even implicitly criticizing it, you're really not going to enjoy this weblog.

52. **Todd Sieling**
April 19, 2005

I'm not a proponent nor an opponent of M-theory, Kaku etc., but I'm wondering why there is such a tendency to hurl epithets and ad hominems just because you disagree with someone. This stuff is obviously pushing some buttons with you, but is it so off the chart that it reduces you to labels like 'crazy' and 'bullshit' rather than triggering your curiousity about why ideas you hate are getting so much attention? I'm sure the latter would produce a much more interesting discussion than what I'm reading here.

**************** CONSCIOUSNESS SHOULD BE TAKEN SERIOUSLY, BUT MOST WHO STUDY IT NOT!!*********

Hi,

I have been reading your blog for a while, and finally I think I have something to say! My background is PhD theoretical particle physics, but I now work in finance.

Over the last two year, I have been looking at consciousness. I read some books and attending the Consciousness 2004 conference in Tucson last year.

Here are my impressions.

1. Consciousness is a very intriguing subject, and certainly a conceptual minefield for the weaker minds.

2. It should not be dismissed as irrelevant or unscientific. After 2 years, I still dont know what I should think of "consciousness". By consciousness, I mean "first person experience", not just "awareness". You sit at your computer, and ask yourself "Am I conscious now? What do I perceive". Can you build a computer that will ever have this experience? If not, what is special about consciousssness? If yes, explain me how the brain manages to create this experience, the unity of ourselves. Is it really just a big illusion?

3. Consciousness is really part of the neuroscience agenda. In the last decade due to new brain imaging technology, scientist can now look into the brain. And it is very fascinating. How can the brain work? How does it generate first person experiences?

4. Ultimately, it has to have an impact on physics/science itself, because effectively a bunch of neurons consisting of atoms study the universe and create theories (like standard model or string theory). The we-physicists you-nature separation is an extremly well working approximation, but does not really exist.

5. It is very unclear whether QM has any impact on the functioning of the brain, let alone is responsible for consciouness. But it is valid to ask whether there are QM effects in the brain. For example, the proteion folding can only be described QMically. but is it important?

6. The field of consciousness attracts a mix of people: serious scientists, "ufologists", and scientists "who have gone overboard". The last two give the field a bad name, as serious scientists themselves commit a logical fallacy by dismissing the whole field based on the theories propagated by a few people from the last two categories. The conference I went to was really strange. On the one hand you had very clever people from neuroscience, and on the other hand I had to listen to people telling me that Einstein was wrong and it's all a conspiracy.

7. A comment on Kaku and Penrose/Hameroff. I think Kaku is just doing PR for himself. I have read his quantum field theory book, a bit sloppy, and noticed that he semi-copied several parts from other books, like Rajaraman's book on solitons. He is a 20/80 person. Only do 80% of the quality but in only 20% of the time. I dont know what to think of Penrose, as he has such a high reputation. But I have met Hameroff, and the guy speaks of QM and the brain and a final theory. And he doesnt really understand QM at all.

Anyone seriously interested in the study of consciousness should read "CONSCIOUSNESS: An introduction". A textbook by Susan Blackmore. Very well written and very scientific, too. If you think I am wrong, then at least have a look at amazon.

Tom

Nec spec nec metu,

I do not agree. Scientific materialism is good. Mystical bullshit is bad.

Let me take a concrete example.

Your e-mail address would suggest that you are Tibetan. This is relevant because I spent most of yesterday trying to figure out the Tibetan calendar. It seems that the days are based on 12 degree segments of the lunar month and begin on the new moon, like the Hindu tithis, but despite searching the only book in English on the subject and Googling furiously, no-one seems to want to tell me (a) the criterion for matching lunar days to solar days and (b) the rule for inserting leap months. In the case of (a) somebody somewhere says that the lunar station has to occur between 5 AM on the solar day and the same time the following day, but he did not say which time zone is used, if any, and in the case of (b) the zodiac sign at the new moon determines the name of the lunar month, but it is not clear whether the tropical zodiac is used, like the Chinese or the sidereal one like the Hindus.

It would seem therefore that instead of one being in a situation where anyone with the ability to calculate or reference lunar/solar tables being able in principle to work out the calendar, as happens in the rest of the world, you have to rely on the Tibetan Medical and Astrological Institute, or whoever, to generate the dates for the calendar. Why is this good?

55. **D R Lunsford**
April 19, 2005

In the linked interview, Kaku proves that he is crazy (probably from spending too much staring out the window at Manhattan traffic..) He makes the fantastic statement that the Schroedinger equation “looks horrible” because it is not relativistically invariant! No one who understands a fig about the development of science and the theory of differential equations could make such a statement.

The problem these loons have is with their aesthetic judgment, mistaking their own screwy ideas of “beauty” for truth. Instead of staring out the window, Kaku should amble down to MOMA, or take a course in pottery. (What he says about music in the interview is also ridiculous. The implicit self-comparison with Beethvoen and Mozart made me cringe.)

56. **D R Lunsford**
April 19, 2005

I’m seriously considering throwing out my Kaku book. I saw a show last night on Discovery concerning Einstein (horrible) and as usual, the omnipresent Kaku was there spouting nonsense about both the man and the subject. He’s become a sort of Carl Sagan-san for physics. (I think Kaku is a clone. I swear he was also playing left field for the Mariners.)

The fact is that there is a rough consensus emerging among those engaged in research about how the future will evolve. Because the laws behind the quantum theory, computers, and molecular biology are now well established, it is possible for scientists to generally predict the paths of scientific progress in the future. This is the central reason why the predictions made here, I feel, are more accurate than those of the past.

What is emerging is the following.

The Three Pillars of Science

Matter. Life. The Mind. [what horseshit]

These three elements form the pillars of modern science. Historians will most likely record that the crowning achievement of twentieth-century science was unraveling the basic components underlying these three pillars, culminating in the splitting of the nucleus of the atom, the decoding of the nucleus of the cell, and the development of the electronic computer. With our basic understanding of matter and life largely complete, we are witnessing the close of one of the great chapters in the history of science. (This does not mean that all the laws of these three pillars are completely known, only the most fundamental. For example, although the laws of electronic computers are well known, only some of the basic laws of artificial intelligence and the brain are known.)

This to me is filled not only with mysticism, but also a sickly egoism and pessimism. I could not make such statements with a straight face. Has the large influx of Easterners into hard science since the war also brought along the underlying mysticism, even fatalism?

-drl

57. **Nec spe nec metu**
April 19, 2005

There is more in heaven and earth than is dreamt of in your philosophy.

“Official” science shows its arrogance when it either dismisses or “suddenly discovers” that which has been known to many throughout history. “Many dimensions” is old news to the vast majority of the world’s cultures and philosophies. The kind of scientific materialism that your attitude represents is just a blip in the history of human (and non-human) consciousness. Fortunately, you and those who think like you will also enjoy your multi-dimensionality when you overcome your fear and grow up a little.

It is not felicitous for those who have not made a mark at all to snipe at the brave explorations of greater minds who do not shrink from possibilities that may require major paradigm shifts.

The greater minds are too busy exploring to gossip, the lesser minds are too busy gossiping to explore.

58.
April 19, 2005

You ruined it Peter.

Lenny had it all planned out. He was gonna pocket the 1.4 mil, and then publicly repudiate ID as soon as the check cleared. Your little April Fool’s hoax forced his hand early.

59. **Matti Pitkanen**
April 19, 2005

To my opinion one should not lump together the desperate state of M-theory and the fact that leading physicists are finally beginning to realize that physics must sooner or later become also a theory of consciousness.

Personally I have spent 10 years working with quantum consciousness theory and the purely physical insights gained in this manner have been decisive for the mathematical formulation of quantum TGD proper. This vision about consciousness based on general principles of physics leaves only one conclusion: the standard view about consciousness as epiphenomenon fully deserves the attribute not-even-wrong. What else it could be when even the word “consiousness” has been and still steems to be a taboo for most physicists?

I have done this as unemployed and have not received a single coin of any kind of research money. Therefore I do like the light-hearted labelling of individuals who see farther than average colleagues as some kind of businessmen cheating money from religious organizations.

To avoid misunderstandings, I still emphasize that the open minded attempt to understand consciousness and intentionality using physics is something totally different from the desperate attempts to save M-theory by using anthropic principles. The recent miserable situation in M-theory is a logical consequence of the reductionistic and materialistic world view taken to its Planck length extreme, and the only way out is to jump out of the system and widen the scope of physics itself. My personal dream is to see the day when brightest theoretical physicists fully devote themselves to the problem of consciousness.

Matti Pitkanen

Taking a Break

April 22, 2005
Categories: Uncategorized

This week I'm quite busy so I'm taking a break from landscape-bashing. Instead I'll just quote someone else; it's up to you to guess who.

"Suddenly it's not too important whether a theory teaches us something new about the real world – either predicts new unknown phenomena or previously unknown links between the known phenomena and objects. It's more important that such an unpredictive scenario might be true and we should all work hard to show that the scenario is plausible because we should like this scenario, for some reasons that are not clear to me."

"The anthropic strategy is to pick as complicated Calabi-Yau manifolds as possible, to guarantee that there will be a lot of mess, confusion, and possibilities, and that no predictions will ever be obtained as long as all the physicists and their computers fit the observed Universe… This means that you don't want to start with Calabi-Yaus whose Betti numbers are of order 3. You want to start, if one follows the 2004 paper, with something like F_{18}, a toric Fano three-fold. That's a 3-complex-dimensional manifold that is analogous to the two-complex-dimensional del Pezzo surfaces, in a sense. But you don't want just this simple F_{18}. You take a quadric Z in a projective space constructed from this F_{18} and its canonical bundle. OK, finally the Euler character of the four-fold X is 13,248. Great number and one can probably estimate the probability that such a construction has something to do with the real world."

"Do we really believe that by studying the orientifold of the weighted projective space CP^{4}_{}, we will find something that will assure us (and others – and maybe even Shelly Glashow) that string theory is on the right track? … If we deliberately try to paint the string-theoretical image of the real world as the most ambiguous and uncalculable one, I kind of feel that it's not quite honest."

"Some people used to blame string theorists that they were only looking for the keys (to the correct full theory) under the lamppost. It's unfortunately not the case anymore: most of the search for the keys is now being done somewhere in the middle of the ocean (on the surface). Maybe, someone will eventually show that the keys can't stay on the surface of the ocean, and we will return to the search for the keys in less insane contexts."

Comments

   April 28, 2005

   Of course, I can be wrong. It is obvious that all man is wronmg some time, but I follow the philosophy of sending copies of my papers to people that is directly critiqued on my work.

   I sent a copy of Is this dynamics? to Weinberg and also to other people, specialist in different topics that I studied, and nobody find failures on the mathematical derivations. On specialist on molecular dynamics did a three page reply manuscript but I think that I show that his criticism was not satisfactory.

   Weinberg found no failure.

   My philosophy of scientific research is different and i am not proud of making mistakes.

   Your philosophy is very strange for me but i respect it!!

   April 27, 2005

   Juan R.,

   If I make the same mistakes as Weinberg, I'm proud of it.

3. **Simplex**
   April 27, 2005

   According to the poster of 26April@1:44PM it was pointed out in 1957 by Wigner and Salecker that in QM there are no perfect clocks.

   Ideal classical time evolution is unphysical (just a convenient approximation) and at a more fundamental level is replaced by correlations between observationscorrelations between readings on real quantum clocks (which have finite lives and do not necessarily agree) and other observables.

   The poster cited 3 recent papers from Phys. Rev. Letters. I am wondering if anyone has looked at them? I found the arxiv numbers of the preprints and posted them also on 26
   April in case anyone might wish to have a look.

   I looked at the papers and I believe one of the main points is that if one describes time evolution by real-world clocks then time evolution can not, for theoretical reasons, be unitary. There is an interesting theoretical bound on how precise, and at the same time long-lived, a real clock can be.

   Here is an exerpt of the earlier post:
   "Unitarity is not needed to conserve probabilities. The existence of an 'ideal classical' time in which physics is unitary is simple 'wrong' within any QG framework. As emphasized originally by Salecker and Wigner (Rev.Mod.Phys. 29 (1957) 255) and more recently by Ng(Mod.Phys.Lett. A9 (1994) 335) and Camelia (Mod.Phys.Lett. A9 (1994) 3415-3422), there exist limits in nature to how 'classical' even the best possible clock can be. When one introduces realistic clocks, quantum mechanics ceases to be unitary and indeed, a fundamental mechanism of decoherence of quantum states arises…"

   April 27, 2005

   Thomas Larsson wrote:

   "You cannot give up unitarity without making a drastic modification of quantum mechanics. I didn't realize that this was controversial."

   It is not controversial that giving up unitarity will require modification of quantum mechanics. It is controversial that giving up unitarity means probabilities will not longer add up to 1. Recall –

"Unitarity encodes the idea that all probabilities must add up to unity. Although the technical requirement of unitarity might perhaps be relaxed in some way, I don't understand how this underlying idea could be wrong. At some point Dirac had some strange ideas about probabilities taking values between -2 and +2 (according to Dyson), but that evidently didn't work out either. "

In the Copenhagen interpretation of QM, measurements do not preserve unitarity. If all time evolution is indeed unitary, i.e., measurement itself is described in QM, then QM is able to provide excellent approximations to non-unitary time evolution. Maybe, just like free quarks are unobservable, unitarity is not directly observable when gravity plays a role.

5. **Juan R.**
April 27, 2005

Canonical science shows that unitarity is an approximated concept.

Unitarity –> conservation of probability and conservation of norm for closed systems.

But the inverse is not true. One can maintain non-unatirity with conservation of probability and well defined quantum states.

non unitary evolution is responsible for collapse of wave function and also for the increase of entropy (second law).

Usual mathematical proofs on the adequacy of unitary are simply wrong. E.g. Chapter three of Weinberg QFT is full of mathematical mistakes. I demonstrated time ago (manuscript sent to Weinberg) that there at least three mathematical mistakes in Weinberg derivation of master equation.

6. **Thomas Larsson**
April 27, 2005

I had pure states in my mind; I haven't thought about mixed states for a long time and really don't want to say anything about them. However, unitarity simply means that the norm and hence the total probability is preserved, so you cannot give up unitarity without making a drastic modification of quantum mechanics. I didn't realize that this was controversial. That it is difficult to define an invariant inner product without a background Minkowski metric is another matter.

One way to ensure unitary time evolution is to have a unitary rep of some symmetry group containing time evolutions as a subgroup, e.g. the Poincare or diffeomorphism groups. However, the only unitary, proper rep of the diffeomorphism group is the trivial one, so there seems to be no time evolution at all in quantum gravity; this is one version of the problem of time. One can avoid this paradox, at least in 1D, by allowing for projective reps, since the Virasoro algebra has many non-trivial unitary reps with positive central charge. The only alternative is apparently to formulate quantum gravity holographically using some sort of AdS/CFT, but that idea has serious problems since AdS is ruled out experimentally.

7. **D R Lunsford**
April 26, 2005

Thomas – I think I would say unitarity amounts to the possibility of setting up an isolated system and assigning it a wave function.

-drl

8. **D R Lunsford**
April 26, 2005

Arun said:

I thought unitarity encodes such a rule against probability amplitudes. Any process where a quantum mechanical pure state evolves to a mixed state would violate unitarity.

Well that's the whole point – a system that is fully described remains so. "Describe" means to give an exhaustive accounting of possibilities of measurements. Unitarity means new possibilities don't just appear or disappear from the blue. Insofar as quantum theory has a variational principle, something *has* to have this property.

String theorists are still looking under the lamp post, in that I have not found many willing to concede that the universe might not be unitary. Loop quantum gravity theorists are much more open to non-unitarity.

Unitarity encodes the idea that all probabilities must add up to unity. Although the technical requirement of unitarity might perhaps be relaxed in some way, I don't understand how this underlying idea could be wrong. At some point Dirac had some strange ideas about probabilities taking values between -2 and +2 (according to Dyson), but that evidently didn't work out either.

Anyway, the LQG people evidently have a unitary rep of their C* algebra, called the Ashtekar-Isham-Lewandowski representation, so I don't think that they really give up unitarity. Unfortunately, this rep is not of type usually encountered in quantum theory, and apparently it leads to all kinds of trouble, like the energy not being bounded from below in the harmonic oscillator.

Being?very skeptical about all kinds of new ideas, I would like quantum gravity to keep all the key concepts in quantum theory and general relativity, i.e. unitarity, locality, causality and general covariance. There is of course a no-go theorem forbidding the combination of locality and diff invariance ("there are no local observables in quantum gravity"), but this is evaded by allowing for projective reps of the diffeomorphism group (this was a major motivation for finding these). With a positive cosmological constant, I don't really see what the alternative to locality could be, since there is no S-matrix and no good boundary on which a boundary theory could live.

For a while during the development of computer science, a ridiculously large fraction of the incoming students wanted to do the highly hyped field of Artificial Intelligence, while the number leaving with a thesis in AI was much smaller. They arrived, realized that AI was to a great extent a scientific failure, and changed fields at some point during their graduate career.

I spent a couple of years in my youth working for a startup company whose product was an implementation of the AI language Prolog. Like the rest of the AI industry, this company went bankrupt after the demise of the Japanese Fifth Generation project. We had a rather cool motto, though: Artificial intelligence is better than none.

13.
April 25, 2005

"For those physicists forecasting doom and gloom, missteps of artificial intelligence don't seem to have hurt the larger discipline of computer science much. "

Well, then, what do the Japanese have to say about that (re: The Fifth Generation Project)…if the parallel is to hold such that an deliberately overly ambitious grandious program leads to unforseen benefits along the way.

Did the Japs benefit or not?

14. **Aaron**
April 25, 2005

> I think this is because there's a narrative (I can't judge how true it is) that string theorists tell. This is that they start with the hypothesis that physics is unitary, is consistent with general relativity and quantum field theory, and they are led inexorably to a ten- or eleven-dimensional world with string theory.

I hope nobody's telling that narrative, because it certainly isn't true. String theory is simply the best guess out there for something that unifies gravity and QM. It certainly does not come close to following from just naively attempting to unify QM and GR; it's origin is much more convoluted.

I should also mention that the counternarrative by some LQG-types that string theorists are closeminded about other directions simply isn't true. I came into grad school well-versed in these myths and was disabused of them. This is not to say that everyone knows everything about the flaws in the other approachs, but the idea that LQG (as the only other major example, really) is rejected simply out of prejudice is just plain wrong.

15. **JC**
April 25, 2005

Perhaps Lubos' terminology of the "haystack" (instead of the "landscape") is more telling sign.

16. **Peter Shor**
April 25, 2005

String theorists are still looking under the lamp post, in that I have not found many willing to concede that the universe might not be unitary. Loop quantum gravity theorists are much more open to non-unitarity.

I think this is because there's a narrative (I can't judge how true it is) that string theorists tell. This is that they start with the hypothesis that physics is unitary, is consistent with general relativity and quantum field theory, and they are led inexorably to a ten- or eleven-dimensional world with string theory. But if it is true, then at some point, if they start coming to more and more unbelievable conclusions, they might want to start questioning their hypotheses.

17. **Peter Shor**
April 25, 2005

For graduate students, the relevant number is not the number of students going to grad school determined to do string theory, but the number of students leaving grad school having done string theory. For a while during the development of computer science, a ridiculously large fraction of the incoming students wanted to do the highly hyped field of Artificial Intelligence, while the number leaving with a thesis in AI was much smaller. They arrived, realized that AI was to a great extent a scientific failure, and changed fields at some point during their graduate career. In the defense of AI, let me say that since then it has reinvented itself, and now has much more modest goals which it is (to a large extent) truly succeeding in accomplishing.

I leave the parallels with string theory to the readers. For those physicists forecasting doom and gloom, let me note that the missteps of artificial intelligence don't seem to have hurt the larger discipline of computer science much.

18.
April 25, 2005

String theorists and Creationists give the anthropic principle a bad rap, which gets compounded by its only being a truism that's necessarily as incomplete as Dirac's Large Numbers hypothesis was flawed.

Tack on the entropic interpretation and you've got good reason for it if the universe is 'closest to Einstein's hand"

Based on the typical actions of humanity tho… it's the only thing keeping us alive!… 😉

19. **D R Lunsford**
April 25, 2005

Arun – that was a well-turned phrase 🙂

20. **CW**
April 25, 2005

It's worth remembering that even a physicist as great as [Wolfgang Pauli](#) was moved to despair at certain points in the development of quantum mechanics. During one such episode he declared that he wished he had become a magician instead of a physicist.

21. **Daniel Doro Ferrante**
April 25, 2005

JC: I don't have any particular stats on the number of grad students entering ST… however, something that i have been noticing over the years is that more and more folks are coming into grad school with their minds set into ST; as if there was nothing else in physics other than ST. That is, apparently these folks have "bought" the "marketing" without knowing the "merchandise" well enough.

22. **JC**
April 25, 2005

Anybody have any statistics on the number of graduate students entering string theory these days?

It would be interesting to compare it to the situation in the mid-late 1990's and/or mid-late 1980's.

23. **Thomas Larsson**
April 25, 2005

Two more Lubos quotes:

If string theory is gonna require an infinite sequence of refinements and increases of the complexity (and decreases of expected predictivity) of its vacua to match reality, then I would definitely love to know this fact as soon as possible, because in such a case I would consider string theory to be a wrong theory of physics – much like other incorrect theories in the history of science that were first corrected 100 times before they were abandoned (recall Lorentz's explanations of Morley-Michelson experiments) – and people should move on.
*Of course I don't believe that this is correct, but allowing something like that for a theory *does* mean to construct a scientifically unjustifiable theory.*

*More frustratingly, using the words of Steve Shenker, AdS/CFT now says that nearly every QFT may be assigned a "gravitational dual" – i.e. every quantum theory is, in some loose sense at least, a theory of quantum gravity (in a higher-dimensional space). We definitely don't want to be *this* broad because then the term "quantum gravity" would become pretty vacuous.*

Dan Friedan was quiet for decade before he declared that string theory was a complete scientific failure. Lubos hasn't published for a year. Let's see what happens in nine years.

24.
April 25, 2005

science will not be on a firm footing until it rocognizes the primacy of consciousness. All we experience is the awareness that cognizes shapes and colors, and the stories we tell ourselves about those shapes and colors. The stories are always changing, the shapes and colors are always changing. Only the awareness abides.

25. **Arun**
April 24, 2005

Science survived Sir Isaac Newton. It will survive the anthropic principle and superstring theory.

26. **island**
April 24, 2005

Somebody asked:
Is Lubos starting to doubt? Is he experiencing a conversion moment?

Nah, but he hates the anthropic principle enough to put his foot right into his own mouth. He thinks he's got a new and better idea:

http://motls.blogspot.com/2005/02/entropic-principle.html

… that he got from here:

http://www.arxiv.org/abs/hep-th/0502211

So now he's decided to jump on a bandwagon of denial instead, because the anthropic coincidences don't just go away because of this, and an "entropic" anthropic principle requires that the forces of the universe be constrained to produce intelligent life as a special and integral contributor to the thermodynamic process.

The probability that the cosmological evolution will end up as a Universe with a particular shape of the hidden dimensions (and particular values of the fluxes) is determined by the (exponentiated) entropy of a corresponding black hole whose geometry flows via the attractor mechanism to the given shape of the Universe near the horizon. Note that this contrasts sharply with the "anthropic principle" – which itself is not a principle, rather a lack of principles. In the anthropic principle, the corresponding probabilistic weight is determined by the ability of the Universe to support intelligent life.

Not quite, since Black holes and humans share a comparitively uniqueness when it comes to the entropy of the universe, since both can isolate the release of enough energy to make real particles from the negative energy of the vacuum, which serves to reverse the normally destructive consequences of the second law of themodynamics on a grand scale, while directly affecting the symmetry of the universe.

What they've actually managed to accomplish is to identify yet another of the vast and growing number of cosmic coincidences that define the many ecosystematic balances that are common to the anthropic principle, but in this context it's become a "biocentric" principle, where intelligent life is now more probably required on most every banded sprial galaxy that has a black hole at its center.

Way to go, Lubos, et. al… you've turned it into an epidemic… 😉

Lubos Motl. These are remarkable thoughts indeed.

LHC Startup Scenarios

April 25, 2005
Categories: Uncategorized

Everyone in the particle physics community is avidly awaiting the startup of the LHC accelerator at CERN, scheduled for 2007. A new preprint by Gianotti and Mangano entitled [LHC physics: the first one–two year(s)] gives some idea of what to expect.

The design luminosity for the LHC is about $10^{34}cm^{-2}s^{-1}$, which is about 100 times the current luminosity of the Tevatron. Current plans are to first cool down the machine in spring 2007, followed by commissioning single beams over the next few months, with first colliding beams in the second half of 2007. During 2007, most effort will be devoted to commissioning the machine, followed by a shutdown for a few months. A seven-month long physics run at luminosities of up to 2 x $10^{33}cm^{-2}s^{-1}$ will take place during 2008. This is 20 times the current Tevatron luminosity and the Tevatron seems to be averaging a total of about 15 pb^{-1} per week, so one could expect a total luminosity of up to about 10 fb^{-1} to be collected during 2008. This is probably much too optimistic. Experience with the Tevatron when it was turned on at the beginning of its latest run was that for quite a while it was running at only a tenth of the hoped for luminosity. So perhaps 1 fb^{-1} during 2008 is a more realistic expectation.

According to Gianotti and Mangano, 1 fb^{-1} will be enough to see squarks and gluinos at masses of up to about 1.5 Tev. Seeing the Higgs is more demanding, especially if its mass is low. If its mass if above 180 Gev, it should require 5-10 fb^{-1}, if it is just above the LEP limit (114 Gev) it is likely to require more like 20 fb^{-1}.

Personally I think it's quite unlikely the LHC will be seeing supersymmetric particles, so, of the things it is looking for, it will require good luck to get the data required to see the Higgs during 2008. Even if this does happen, I'd guess that analyzing the data would take us into 2009. If the LHC has trouble getting anywhere near design luminosity, things could take longer. Of course everyone hopes that something completely unexpected will be found. If this is dramatic enough, maybe there will be some exciting news in 2008.

   -drl

5. **Peter**
   April 26, 2005

   Hi JC,
   As another commenter mentioned, I've written about this before in various places. Basically the minimal supersymmetric extension of the standard model (MSSM) is much more complicated and ugly than the standard model, introduces nearly 100 new free parameters, generically has problems with flavor-changing neutral currents and proton decay. The only real argument for it is the coupling constant unification calculation, and that's not that convincing. The popular "hierarchy stabilization" argument never seemed very convincing to me (and has technical problems besides, see the so-called "mu problem". Many of the landscape artists have already happily abandoned the idea of using supersymmetry to stabilize the hierarchy. Now of course anthropic reasoning explains all such things.

6. **Alejandro**
   April 26, 2005

   "If its mass if above 180 Gev, it should require 5-10 fb-1, if it is just above the LEP limit (114 Gev) it is likely to require more like 20 fb-1."

   This already means exciting times if the Higgs sector is not minimal. Say there is a particle at exactly 246 GeV… people would hail it as "the Higgs" and then when going down successive particles of the sector should appear. Funny.

7. **Alan R.**
   April 26, 2005

   Until Peter answers JC's question, readers might want to look at an earlier posting of Peter's entitled, "Attack on the Main Argument for Supersymmetry."

   http://www.math.columbia.edu/~woit/blog/archives/000025.html

   The fact that I can pick out this old citation off the top of my head tells me I'm probably spending too much time at this site, but I enjoy it!

8. **JC**
April 25, 2005

Peter,

What are your main objections to supersymmetric extensions to the standard model?

Ignoring GUTs, my main objection is that SUSY seems to be a symmetry that is just imposed by decree, with very little to no convincing experimental basis. The picture of the coupling constants converging to a "possible" single point with SUSY, isn't entirely convincing. All the arguments I've heard of over the years used to justify SUSY seem to be various aesthetic and/or theoretical "beauty" types of arguments, such as the coupling constants "converging" to a single point.

IF the universe was truly following some theoretical "beauty" type of principle, then why didn't the experiments confirm the simple SU(5) GUT model? (This is one counterexample to the many silly theoretical "beauty" types of arguments).

50 Years of Yang-Mills Theory

April 27, 2005
Categories: Book Reviews

There's a new book out, entitled 50 Years of Yang-Mills Theory, edited by Gerard 't Hooft. It contains some excellent review articles about topics related to Yang-Mills theory, together with short introductions by 't Hooft. Many but not all of the articles have already appeared at the arXiv as preprints.

The book begins with an article by DeWitt, unfortunately unfinished at the time of his death, about the space of gauge fields. 't Hooft's introduction and DeWitt's historical comments makes clear that "Fadeev-Popov" ghosts really should also have DeWitt's name attached to them. The full Faddeev-Popov paper is included in the book, a good idea since I don't think it was ever published. It appeared in Russian as a Kiev preprint in 1967, was translated into English and appeared as a preprint in 1972. While looking for information about this paper on the web, I noticed that Fermilab has put up scanned versions of their preprints, which is useful for the ones from the seventies and eighties that predate the arXiv.

There's an excellent review of the "Higgs mechanism" by Englert, where again Englert's name deserves equal time with that of Higgs. This paper has appeared as a preprint. Steven Weinberg contributes an interesting review article about the making of the standard model and his role in it. There are three articles related to renormalization of Yang-Mills: a detailed one by the master himself ('t Hooft), a mystifying one about Koszul complexes by Raymond Stora, and one about Slavnov-Taylor identities by Carlo Becchi.

Steve Adler has a long article about the history of what is now known as the "Adler-Bell-Jackiw" anomaly, and Jackiw has one about various topics related to Yang-Mills theory that he has contributed to, including anomalies, Chern-Simon terms, and gravitation. There's also an article by Frank Wilczek, mainly about asymptotic freedom, and one by Alexander Bais about magnetic monopoles in Yang-Mills theory.

On the non-perturbative side of things, there is Alexander Polyakov writing about string theory and confinement (he thinks string theory needs to have its head examined, see an earlier posting here). Pierre van Baal contributes a very interesting article on "Non-perturbative Aspects of Gauge Fixing", Michael Creutz a mainly historical article about lattice gauge theory. Peter Hasenfratz writes about chiral symmetry on the lattice. Both he and Creutz note that, while progress has been made, handling chiral gauge theories on the lattice remains somewhat problematic, so there is still no really satisfactory non-perturbative version of the electroweak part of the standard model.

Alvaro de Rujula has an entertaining discussion of events surrounding the "November Revolution" in 1974. Finally, there's a review article about supergravity by Peter van Nieuwenhuizen, and one by Witten reviewing the twistor space formulation of perturbative Yang-Mills amplitudes. Witten's article doesn't seem to have appeared on the arXiv (although there is a new review article by Cachazo and Svrcek which covers this material and much more).

4. **JC**
   April 27, 2005

   drl,

   What's a good counterexample, where spin 2 is NOT gravity?

5. **D R Lunsford**
   April 27, 2005

   Weinberg has the best line for years – "radial and azimuthal physicists" – ROFL!

   I was somewhat confused by the SG review. Apparently everyone just assumes spin 2 "is" gravity.

   -drl

6. April 27, 2005

   Off-topic, but I thought I should mention it: The BBC's "The Changing World" (broadcast here by PRI) is doing an hour tonight on the effects of visa restrictions on foreign researchers in the U.S.

   In the same vein see Sean Carroll's recent post.

Road Trip From Hell

April 28, 2005
Categories: Uncategorized

According to a new article in New Scientist entitled The Theory of Everything: Are we nearly there yet? (unfortunately not available for free on-line), "The hunt for the theory of everything is turning into a road trip from hell – and don't even ask who's reading the map." The article quotes Susskind and Weinberg as believing in the existence of a multiverse, even if this means that "all we can hope for from a final theory is a huge range of possibilities".

Witten is referred to as a "string grandee", and quoted as saying about string theory "More work has always given more possibilities – far more than anyone wanted… I hope that current discussion of the string landscape isn't on the right track, but I have no convincing counter-arguments." He's welcome to my counter-arguments if he wants them: there's not the slightest evidence for the landscape scenario pseudo-science, it's incredibly ugly, not based on any kind of well-defined theory, explains nothing, and holds out no reasonable hope of ever explaining anything.

The article goes on to discuss the wishful thinking surrounding "M-theory", quoting Witten as believing that M-theory may have a unique solution that fits our universe and explains the constants of the standard model. "Hope springs eternal" he says. Somebody seems to have given the writer the idea about M-theory that "theorists can prove that it exists as a mathematical construction, but they can't actually write down its equations and there is no clear route towards doing so", which is only true under a peculiar interpretation of the words "prove", "exists", and "it". Lisa Randall is quoted as follows about M-theory: "We probably need fundamentally new principles… it's not hopeless, but it's going to require some deep new insight that we don't really have." She promotes her own work with Mukohyama on an alternate explanation of the cosmological constant.

The only person quoted in the article as thinking that there may be any problem at all with the way particle theory has been pursued for the last twenty years is Lee Smolin, who takes the absolute lack of any experimental evidence for string theory as a sign that the field may be off on the wrong track. He notes that "If you look back over the last 200 years, every decade or two there's a dramatic advance, people always understand something new that couples theory and experiment… I suspect there is some right question that we're not asking."

   May 8, 2005

   Stephen,

   I don't understand your question very well. I don't know if you are claiming for some fractal behavior.

   In canonical gravitodynamics, gravitation depends of the scale with a parameter that is different for macro, astro, or cosmo scales.

   I still don't understand well that parameter but it appears compatible with certain cosmological requirements like expansion.

   Unification will be no achieved by usual high-energy methods. Sure!!

   My approach is not based in geometry or topology, just in AAAD.

2. **Stephen**
   May 3, 2005

   Peter and Thomas,
   Could it be that the critical mistake that is being made in the Unification theories is the assumption that gravity is not analogous to van der waals forces and is only representable at *all scales* as geometry/topology?
   I am aware that Sakharov's initial idea was fraught with problems, but is that sufficient to dismiss the entire class? I have reasons to think that current research in this direction is naive, cf: http://www.calphysics.org/articles/zpf_apj.pdf, but again my question remains.

3. **Simplex**
   May 2, 2005

   Stephen wrote: *How many more epicycles are going to be added to this theory before it collapses into some kind of Scholastic argument?*
   Might it be possible that a lot of money and brain power is being wasted on this theory that doesn't seem to be able to make any measureable predictions?

   Good questions! My personal guess is yes, a lot of time and research talent is being misdirected. To a large extent because leaders in the field have not been sufficiently frank and forthcoming. And then the hype—which distorts public and political support for science.

4. **Stephen**
   May 2, 2005

   T. Larsson wrote: "…we could have seen e.g. a light Higgs, proton decay, muon g-2 deviation, permanent electric dipole moment, WIMPs, and probably many other things…";
   Would it not be more correct to write "should" instead of "could". How many more epicycles are going to be added to this theory before it collapses into some kind of Scholastic argument?
   Might it be possible that a lot of money and brain power is being wasted on this theory that doesn't seem to be able to make any measureable predictions?

5. **Thomas Larsson**
   April 30, 2005

   There are many potential signals of supersymmetry, some of which should already have been triggered. Apart from direct discovery of sparticles, we could have seen e.g. a light Higgs, proton decay, muon g-2 deviation, permanent electric dipole moment, WIMPs, and probably many other things that I don't know about. An arxiv search for the keywords "tuning supersymmetry" gave 35 hits during the past year, the most recent one being hep-ph/0504246. Let me quote from the introduction

   "Another problem comes from the fact that LEP II did not discover any superparticles or the Higgs boson. In most supersymmetric theories, this leads to severe fine-tuning of order a few percent to reproduce the correct scale for electroweak symmetry breaking. This problem is called the supersymmetric fine-tuning problem".

I am no expert on SUSY phenomenology and never claimed to be. But if the experts say that there is a fine-tuning problem, I see no reason to doubt that.

It was, I believe, the need for SUSY fine-tuning that motivated the introduction of split supersymmetry. For almost 20 years, Witten used to say that string theory makes one prediction, supersymmetry (and one postdiction, gravity), but I haven't heard him make this claim for a couple of years. One cannot help noting that string theory apparently stopped predicting SUSY once this claim became accessible to experimental tests.

6.
April 29, 2005

SUSY requires fine tuning? Are you refering to the mu problem or the flavor changing neutral current problem?

7. **Peter Woit**
April 29, 2005

Sure, there was a lot of work on unification before 1984, including work on GUTs going back to Georgi-Glashow in 1974. But this all involved pretty well-defined QFTs, so people could fairly quickly see if realistic models that predicted anything were possible. GUT models made predictions about proton decay that were falsifiable, and the models were falsified in relatively short order. Witten showed fairly quickly that supergravity Kaluza-Klein couldn't produce a chiral spectrum (although now it has been revived as "M-theory" using singular compactification spaces).While Witten did a lot to promote supersymmetry, it was only one of many different research programs people were pursuing.

What changed in 1984 is that an overwhelmingly large number of people started working on string theory, abandoning and killing off many other research programs. String theory was and is so ill-defined that more than 20 years later no one can agree on what it is or extract any kind of prediction about it. This new phenomenon of the field being completely taken over by something this incoherent is what I had in mind in my remarks about how things changed in 1984.

8.
April 29, 2005

Peter,
Unification was big business before 1984. The name was supergravity Kaluza-Klein. It became really big business when Witten got into it around 1978. That's also when he introduced supersymmetry/supergravity in the USA. It was mainly a European thing till then.

9. **Thomas Larsson**
April 29, 2005

This pessimism about string theory over the last year or two, seems to be quite different and more ominous than what happened during the temporary lull string theory experienced around 1990 (before D-branes, duality, AdS/CFT, etc …).

Another reason why the present situation is much worse than 1990 is that we know more now. In particular, we know that the cosmological constant is positive (so AdS is ruled out) and that supersymmetry requires fine-tuning at the percent level (which in some sense means that the odds that SUSY is realized in nature is down to the percent level). Since SUSY and a non-positive CC are the main soft-predictions of string theory, it seems rather problematic that both are ruled out by experiments. Not surprisingly, it is precisely these two results that have triggered the recent anthropic excuses.

Hence I disagree somewhat with the premise of this blog. I don't think that string theory is not even wrong, but rather that it in fact *is* wrong.

10.
April 29, 2005

hey she's a fox

11.
April 28, 2005

Hi
Peter and other interested folks,
you might want to look at this talk
"Can cosmology test Stringly physicis" by Hiranya Peiris and one of her collaborators
is Brian Greene
See http://www.stsci.edu/institute/center/information/streaming/archive/HubbleFellows2005/HubbleFellows2005Overview

12.
April 28, 2005

Peter – nevertheless I thought it was interesting to get enough involved to see what was wrong. It was great fun to read all those papers.

-drl

13. **island**
April 28, 2005

I assume Peter doesn't mean that to mean that you can't challenge my statement.

… and don't feel bad, Michael, Dirac apparently didn' feel that he had need to consider that you have to condense Einstein's static vacuum energy over a finite region of space in order to achieve positive matter density and pressure, or his hole theory might work a lot better… 😉

14. **Peter Woit**
April 28, 2005

I've just deleted a bunch of comments from people insulting each other. Please stop doing this here and save me the time of having to delete these comments.

15. **island**
April 28, 2005

Lisa Randall… "promotes her own work with Mukohyama on an alternate explanation of the cosmological constant."

lol

16. **island**
April 28, 2005

Einstein didn' know that particle creation in his finite closed spherical near-flat positively curved static model, affects expansion.

"We probably need fundamentally new principles… it's not hopeless, but it's going to require some deep new insight that we don't really have."
-Lisa Randall

"I suspect there is some right question that we're not asking."
-Lee Smolin

"It never hurts to look in the basment"
-Danny Ross Lunsford

"I think it'll be something that we've all missed."
-John Baez

17. **Peter Woit**
April 28, 2005

In the late eighties it was clear there were potentially a large number of possible string vacua, but they all had the problem of unfixed moduli parameters. So, one could hope that whatever mechanism was found to fix these would eliminate all but a small number of possibilities. More recent work such as KKLT seems to show that you can fix the moduli, but the mechanism for doing this just makes things much worse.

In the late eighties, string theory was very popular, but still pretty new. People didn't have a huge amount invested in it, and if the 10^500 stabilized vacua had shown up then, quite possibly most would have been willing to abandon string theory altogther. Now you've got a whole field filled with people who have devoted either their whole careers or at least 20 years to working on string theory. What's remarkable is how they show no willingness to admit failure in the face of utterly overwhelming evidence.

18. **JC**
April 28, 2005

This pessimism about string theory over the last year or two, seems to be quite different and more ominous than what happened during the temporary lull string theory experienced around 1990 (before D-branes, duality, AdS/CFT, etc …). Despite the estimates of 10^100 possible Standard Model-like string vacuum states, nobody in the early 1990's was really seriously talking about using the anthropic principle. This time around it seems to be the "serious" use of the anthropic principle in string theory, which has been producing more ominous signs of decline in the field.

19. **Peter Woit**
April 28, 2005

Hi JC,
I don't think it's quite fair to label Einstein's efforts to extend GR to a unified theory as "semi-crackpot". They turned out not to work, but were not an unreasonable thing to work on, and he didn't go around claiming any great success. Until 1984 there were always plenty of people running around doing various incoherent work for which they made grandiose claims about unifying everything, explaining the big bang, etc. But serious people pretty much just ignored them since they weren't getting anywhere and there were plenty of more promising things to think about. The lack of any unexpected new experimental data, together with the lack of any good new theoretical ideas, is what has changed since 1984. Now the kind of pseudoscience that everyone used to scorn and ignore is being promoted by many of the most prominent people in the field.

20. **JC**
April 28, 2005

Peter,

How common were persuits of "theories of everything" in physics, during the time period after Einstein died and before string theory? It seems like most of Einstein's life at Princeton was largely in pursuing various semi-crackpot "unified field theory" ideas which ended up as failures.

Frist Filibuster

April 28, 2005
Categories: Uncategorized

For the last couple days students at Princeton have been protesting the Republican's plan to invoke the "nuclear option" and stop Democrats from filibustering a small number of Bush's judicial nominees. This protest has taken the form of organizing a "filibuster" in front of the Frist Campus Center at Princeton, which was underwritten by Senator Bill Frist (Princeton '74). Today Edward Witten and his wife, physicist Chiara Nappi, have joined the protest. I can't tell what Chiara is reading from, but Ed is using a bullhorn to regale the crowd with passages from Introduction to Elementary Particles by David Griffiths.

Many thanks to my correspondent who wrote to me today to tell me about this.

Update: It seems that Josh Marshall of the Talking Points Memo weblog had something to do with this. Ed and Chiara got awarded a Privatize This! Talking Points Memo t-shirt, and there are still two more available.

1. **JC**
April 30, 2005

   On the other side of the coin in an unrelated way, I've heard of many stories about graduate admissions committees in less "scientific" areas, from folks who have served on them. In some departments like economics, business, finance, law, etc … many folks have mentioned they actually prefer applicants with a math/science/engineering background, than a liberal arts or social science background. This is the case even if the applicants with the math/science/engineering background have very little to no background knowledge of economics, business, finance, law, etc …. My best guess is that they must think that folks with a math/science/engineering background have an easier time picking up a new field of study relatively quickly. (I don't believe admissions committes are doing this because of a lack of "qualified" applicants).

   I haven't heard as much about the coverse case, with somebody with a liberal arts or social science background applying for graduate school in math/science/engineering. The closest cases I've heard of over the years were folks who either minored in math, and/or took some more higher level math courses beyond freshman calculus, linear algebra, and statistics. A few other cases I've heard of were folks who worked in a university or government lab on some research projects, and were able to get some reference letters and/or even their name on some papers published in a half-decent peer-reviewed journal.

   Other than that, it seems to be more of a longshot in going from liberal arts/social science to math/science/engineering, than the other way around.

2. **Peter Woit**
April 30, 2005

   I don't personally know anything about how Witten was admitted to Princeton, but I'd guess he took some courses at Brandeis in math and physics, did well in them and did very well on his GREs. His father was a physicist, so he probably picked up a lot of math and physics growing up. From looking at a lot of graduate school admission folders, I can say that the kind of thing one looks for is

   1. some excellent letters of recommendation

   2. excellent performance in at least a few higher level courses

   3. excellent standardized test scores.

   Its quite possible Witten managed to put together these for his application, even though he majored in a non-scientific subject.

3. **anon**
April 30, 2005

   Yah, I'm sorta curious how that's possible too. (the previous poster's question)

4. **quantumhobby**
April 30, 2005

   How could Ed Witten have been accepted into the applied math program at Princeton without having majored in math or physics as an undergrad? I thought you needed to have recommendations and a demonstrated potential for research to get into a top-notch grad program in the sciences. I majored in business as an undergrad and I always assumed it would be impossible to get into a good graduate science program, coming from that background. I know Witten is a brilliant guy, but it seems like that must have been difficult, even for him.

5. **Alejandro Rivero**
April 30, 2005

   should we link this thread to the previous comments of Lubos blog about the left-windy side of physics?

6. **Peter Woit**
April 30, 2005

   I believe that Witten graduated from Brandeis in 1971 with a major in history and a minor in linguistics. He published an article in the Nation in 1968 when he was 17, but I don't think he ever worked for them. He did work on the 1972 McGovern campaign, then entered graduate school at Princeton in 1973 (he started in the applied math program, soon switched over to the physics department).

7. **R Gambi**
April 30, 2005

   Wilczek's contribution was pretty cool. He read a few excerpts from Einstein and Minskowski's original papers on relativity.

8. **anon**
April 30, 2005

I don’t know if this is true, but I heard Witten orginally graduated from Brandeis with a degree in Journalism (or a related field?), and only after a brief stint with the Nation, did he choose to become a physicist. In a way, it’s not terribly surprising, but still cool. (Is this story true, or just urban legend?)

He should do more of this stuff. Very cool guy.

9. **Alan R.**
April 29, 2005

Frank Wilczek has apparently joined in, too. His name appears on the list of speakers.

Lubos Motl has taken to signing some of his postings with "leashed", and Capitalist Imperialist Pig has speculated that "My dark suspicion is that he might have gotten caught in a PC violation in the Summers Affair, forcing him to do a T reversal to save his Lorentz invariant m ass". Lubos wrote in to tell him "Unfortunately your intuition is perfectly correct, but I am not sure whether your imagination is big enough to imagine the scale."

I have no idea who is responsible for the leashing of Lubos or what the reason for it is, but I figured this meant his blog would stop featuring the right-wing ideological political commentary he's fond of. But today he has a posting about the Frist Center "filibustering" in which he says "I currently do not enjoy the freedom to tell you what I think about these things." Actually he manages to make it pretty clear what he thinks about these things.

This leashing of Lubos is too bad, especially since I was finding myself more and more in agreement with his postings (not the ones about politics, but we seem to agree about the Landscape), and generally think the First amendment gives everyone the right to make a fool of themselves with crazed political rants if they feel like it. Lubos's blog has also played another important role for me. Whenever people won't believe me that string theorists can be smart and well-informed, but still crazed ideologues, all I've had to do is point them his way.

   Hi JC,

   Presumably physics theory groups worry about how whoever they hire will affect their grant, but this depends on the department's situation, and I only have direct experience with math departments.

   In my experience in hiring decisions the question of grants hasn't come up. The general assumption is that the criteria being used to hire people is similar to the criteria used by grant agencies, so the kind of person we're trying to hire is the kind of person who should do well in trying to get grants. In math departments like Columbia, few of the grad students are funded by grants, most are funded as teaching assistants by the university. So grants aren't that important: they aren't needed to fund labs and they aren't really needed to fund graduate students. The university and the department do make money off grants, but the amounts are not large or crucial to the department.

2. **JC**
   May 9, 2005

   Peter,

   When it comes to a physics department hiring new faculty for assistant professor jobs, what is the exact criterion for hiring new theorists?

   From stories I've heard over the years about experimentalists, I got the impression they're mainly interested in folks who they think will have a good shot at maintaining consistent grant funding year after year. On the surface I can understand perhaps why this is the case for an experimentalist, considering they're more or less out of business if their funding grants are not renewed. Kind of hard to pay for new lab equipment, facilities (ie. telescope time, accelerators, etc …), postdocs, etc … if one has no money. I remember several experimental particle guys mentioning they spend time writing a number of grant proposals every year or so.

   I haven't heard as much about what faculty search committees look for when they're hiring a new theorist, other than the obvious criteria of looking for somebody they think will have a good shot at maintaining consistent grant funding and not losing it so easily.

   Is this also true for math departments when they're hiring new faculty?

3. **Peter Woit**
   May 9, 2005

   Hi JC,

   Actually I think some mixture of 3. and 4. is a perfectly rational reason why people take these jobs. You get to work with the most prominent people in the business, and if things go well you have a bit of an inside track at a permanent position at Harvard or Princeton. Even if you're not going to get tenure there, you're in an excellent position for getting a permanent job elsewhere.

4. **JC**
   May 9, 2005

   Peter,

   Why do some people take junior faculty jobs at places like Harvard, Princeton, etc … in the first place, when they know very well that their chances at tenure are slim to none?

   Offhand, the few reasons I can think of are ones like:

   (1) It was the only job they were offered.

   (2) They are "overconfident" of their own abilities and/or they have a huge ego.

   (3) They see it as a means to an end, where Harvard/Princeton is just a step up along the way to a permanent tenured job somewhere else.

   (4) They produced a paper or two which got hundreds, if not thousands, of citations in a very short period of time, and that they're willing to "roll the dice" at the tenure game at Harvard, Princeton, etc …

   The only case which appears to have a half decent chance at getting tenure at Harvard, Princeton, etc … would perhaps be (4).

5. **JC**

May 8, 2005

Peter, Quantoken

The folks I know of who went the community college route all mentioned that their teaching loads were so heavy that they had very little to no time to do their own original research. For a few of these folks their mentality towards research became “why bother?”, when publishing original research papers wasn’t going to help them much anymore in their careers.

I’ve noticed some tenured professors who became “burned out”, eventually took on the same “why bother?” mentality towards research. One day they eventually reach the point where they don’t even bother publishing research papers anymore, and gradually become “deadwood”.

On the surface I can perhaps understand why some folks gradually fall into the “why bother?” mindset after they get tenure. During a postdoc, there’s the goal of getting an assistant professor job. During an assistant professorship, there’s the goal of getting tenure. Folks who are after these goals usually keep their eye on the “8-ball”. Once somebody gets tenure, what becomes the “8-ball” besides higher professor ranks? Teaching the same sorts of courses year after year, seems to become less and less interesting each successive time, especially freshman undergraduate courses. Some folks may start to question whether their research is going to mean anything in the long term, considering a large number of published journal papers become largely forgotten with the passage of time. How many folks today still regularly read papers from 100 year old physics journals, besides science historians? If string theory ever falls out of favor, I would imagine many string papers over the last 20 years will become largely forgotten with the passage of time. These days how many people still regularly read papers on the bootstrap analytic S-Matrix theory stuff? I would imagine that for every one “superstar” like an Einstein, Dirac, Schrodinger, Hilbert, etc … there must be easily thousands of researchers who were largely forgotten with the passage of time.

6. **Peter**
May 8, 2005

Hi JC,
At places like Harvard and Princeton, most junior faculty don’t get tenure, and the department gets most of its tenured people by hiring stars away from other places. I remember talking to someone I knew who had taken a junior job at Harvard, at the point when it was clear he couldn’t stay there and had started looking for jobs elsewhere. He told me he wasn’t sure whether it had been a good idea going to Harvard, because when he was just out of grad school, people may have thought he might be the next Witten, but after several years out, it was clear he wasn’t. So he thought he might have done better to go somewhere else where he would have been likely to get tenure. But things worked out for him, and he’s now a prominent member of the community tenured at a well-known place.

So, no matter how he behaves, I don’t think Lubos is a shoo-in to get tenure at Harvard, but he’s likely to be able to get a good permanent position elsewhere no matter what. Similarly for Sean Carroll: I was surprised to hear he didn’t get tenure at Chicago, but I’m sure he’ll have other offers elsewhere.

The people who are in trouble are the ones who don’t get tenure at less well-known places where one would normally expect tenure to be likely. They then have a much tougher time finding a permanent position, and may not be able to get one at a place where it is possible to do much research. Teaching a full load at a community college is hard work, and if you’re doing that it’s not easy to find the time and energy to do much original research. You also typically aren’t in a good environment in terms of colleagues, seminars, students etc. for research.

7. **Quantoken**
May 8, 2005

JC said:
“a few folks of the latter case I’m aware of did decide to go into teaching community college for a few years, but they **didn’t really publish any research papers** afterwards.”

Why so? Is that 1.They **do not want to** write papers any more, or 2. they **are unable to** write papers any more, or 3. their papers **unable to be accepted** for publication? (because their institution affiliation doesn’t seem impressive?)

A hundred years ago, a little 26 year old patent office clerk who also tutored high school kids half time for a living could publish papers on one of the best academy journals. Today, instituion affiliation is every thing.

I do NOT think Lubos will be denied tenure at Harvard. As smart as he is, I do not think he will **sit and wait** like Sean did till the day to be told that his tenure is denied, instead he will **beat the clock and deny Harvard a tenureship and find another job first, before he could be turned into a sitting duck.**

You have a much better chance if YOU take it to turn down a position at a prestigious institution to get a better job some where else, instead of you be turned down. Sean could have done that! There are plenty of good excuses to leave U of Chicago: It’s too cold a place to live, or U of Chicago is not good enough to keep me and I want to be in Harvard, I am not paid good enough, etc. etc. But as he sitted to wait for the UofC deny, his choices are now limited and he will have a hard time trying to explain why he would be fired, something his new boss must be curious to find out.

Fire the boss before the boss could fire you, Lubos :-)!

Quantoken

8. **JC**
May 7, 2005

Peter,

When somebody is denied tenure at one university, what is the likelihood of them finding another academic job (with chances at tenure) at another university?

Over the years I’ve noticed some folks who didn’t get tenure at places like Harvard, Princeton, etc … seemed to have been able to find another academic job at another university. For folks who didn’t get tenure at a less prestigious university (ie. state universities, 4-year liberal arts colleges, etc …), few seemed to have found another “half decent” academic job. Without mentioning any names, a few folks of the latter case I’m aware of did decide to go into teaching community college for a few years, but they didn’t really publish any research papers afterwards.

9. **Anonymous**
May 7, 2005

One thing is for sure. Should Lubos ever gets denied tenure, there won’t be any huge outpouring of sympathy for him, unlike Sean Caroll.

10.
May 7, 2005

Weather forecasts are done by simulations. Lattice QCD calculations are done by Monte Carlo simulations. etc.

11. **JC**
May 6, 2005

I wonder what would happen if academic tenure ceases to exist in America by congress passing a new law, where only existing tenured professor jobs remain while no new tenured jobs are produced in the future. On the surface one can perhaps see this being done by the republican congress, as a way of striking back at the "liberal left" in academia.

12. **Chris Oakley**
May 6, 2005

"Shut up, or I'll set Lubos on you." – That would have stopped Hoppe's persecutors in their tracks.

13. **Not a Nobel Laureate**
May 6, 2005

Academic freedom in the US is mostly an illusion.

"My Battle with the Thought Police – Hoppe"

http://www.mises.org/story/1792

The irony is that the academic left demands that same type of cultural conformaty as the religious right when it comes to their own set of beliefs.

A plague on both their houses.

As for global warming, it's become an quasi-religious meme that cannot be questioned to far too many people rather than a hypothesis. The fact that it's based on simulations should be the first warning flag.

D R Lunsford May 2, 2005 05:53 PM said:
We should stick to physics here. LM isn't exactly a fascinating topic.

and again D R Lunsford May 4, 2005 09:46 AM
Interesting penta-quark news

http://www.sciencedaily.com/releases/2005/05/050502203532.htm

but the topic here is LM. the lead post is "Lubos leashed".
I think there is something to be learned from watching Lubos, as a sensitive compass needle.

Now (immediately after the leash episode) he points to Albert Einstein Institute at MPI-Potsdam where the director of string research is Hermann Nicolai.

http://motls.blogspot.com/2005/05/e10-billiards-and-m-theory.html

LM has some chips because of his visibility. IMO he won't come out a victim, nor be easily repressed: too agile.

Suppose one were to ask what is the top center for string research which is immune to the Landscape disease. If Harvard should be infected, to such an extent that one cannot criticize what LM calls the "haystack", where would a bright person want to go?

"Sean Carroll was…just told that his tenureship was denied at UofC

Wow, that's horrible news. I wish him the best of luck in his upcoming search.

17. **Quantoken**
May 4, 2005

Sean Carroll was leashed, too. He just told that his tenureship was denied at UofC. That shocked many people. And I wish him the best in finding another job.

Peter would you not want to comment on that a bit? Here is a guy who wrote books and published a lot of papers, and he is still not good enough to earn his tenureship 12 years after his Ph.D. What's the odd for some one like Lubos on the expectation of tenureship? I guess this really gets a lot of none-tenured people worried.

Does it have to do with politics? Sean is an openly Atheist. Could that has something to do with it? No body knows how tough it is if you are one refusing to believe in God in this country.

Quantoken

18.
May 3, 2005

Why are you mistaking a superstring department for a physics department? Lubos realized his mistake and attended a real physics talk for the first time in his life.

19. May 3, 2005

    Lubos, if you are out there reading this, can you tell us what exactly is going on? I'd hardly expect this sort of thing in a PHYSICS DEPARTMENT

20. May 3, 2005

    Peter said:
    … Whatever it was, it doesn't seem to have slowed him down much since he is still posting political commentary not especially distinguishable from before. He does seem to have stopped criticizing the Landscape, maybe that's what all this is about.

    If so it is bad news. there are surprisingly few voices openly defending traditional scientific standards against attack from within

    Blank 10:26AM said:
    Isn't it strange that Lubos is being so secretive and tantalizing as to how he was "leashed" and by whom? And isn't it strange that he still posts his usual political views despite being "leashed"?

    I take that as an indication that the pressure came from someone in his own department.

    And why did he remove his "leashed" signature and other cryptic sentences like "I don't enjoy the freedom to tell you what I think"?…

    the quote about "don't enjoy the freedom" was at the end of some rather muted comment on a recent paper by Vafa et al called "Baby Universes in String Theory"

    the next poster sounds convinced by a smoke screen—a false explanation rumored by "Well-informed sources" in the department

    In response to Peter's
    "He does seem to have stopped criticizing the Landscape, maybe that's what all this is about."
    Blank 10:33AM said:

    *Well-informed sources 🙂 🙂 tell me that it was his climate stuff that finally went too far. Earlier versions of his latest post on that theme "raised ethical questions about the funding of climate research" — and what I've written is an extremely sanitized version….that was changed, with LM complaining that he was not allowed to say those things …. and now he's not allowed even to say that! I really doubt that his landscape stuff would result in any problems. People in this line are used to trashing each other's papers, no big deal. Though Eva Silverstein did blow a fuse, that's very exceptional. But raising questions about where money is going — well, that's *really* playing with fire.*

    I see, the real reason was his mentioning money (in the case of some climate research). It is normal to trash each other's papers. Eva did blow a fuse but that's very exceptional. Ha ha. Yes, it was really about funding in climate research.

    At least one subsequent poster seems to have bought the screen. The conversation turned to issues like ivy league liberals, Sean Carroll's views of women in science, and the superior analytical acumen of physicists.

    I think Lubos was getting out an important message about the Landscape school of pseudo-physics, that his language in his "Kennedy Landscape" piece was too effective, and that departmental authority, conceivably in the shape of Cumrun Vafa or someone equally august, stepped in. I think that we can expect anti-global-warming blogs as usual from Lubos, but nothing further that equals his "Kennedy Landscape" piece. I do not think the turn of events is humdrum (some have suggested it is boring to discuss these Motl matters) but, on the contrary, appalling.

21. **Arun**
    May 3, 2005

    There is nothing particularly "humanistic" or "scientific" in pointing out a logical fallacy. It also seems orthogonal to "aptitude for interpersonal relationships, social graces, understanding".

    Perhaps ksh95 should follow his/her own advice and not confuse "superior analytical acumen, for superior acumen in other more humanistic topics" (incidentally, physicists' superior analytical acumen is a bit of myth as well).

22. **ksh95**
    May 3, 2005

    "…I shouldn't speak for Sean Carroll, but what he has said is that the differences between men and women are not explanatory for the specific observed phenomena of the gender ratios in science…"

    Either way. My point isn't about Lubos or Sean. My point is, as physicists we should not mistake our superior analytical acumen, for superior acumen in other more humanistic topics.

23. **Arun**
    May 2, 2005

    I shouldn't speak for Sean Carroll, but what he has said is that the differences between men and women are not explanatory for the specific observed phenomena of the gender ratios in science.

24. **D R Lunsford**
    May 2, 2005

    We should stick to physics here. LM isn't exactly a fascinating topic.

    -drl

25. May 2, 2005

    ksh95 is very correct. It's sad, but true.

26. **ksh95**
May 2, 2005

Didn't your mom ever tell you…

" As brilliant as you are, you have no common sense"

Translation: An aptitude for Field theory is a very different thing than an aptitude for interpersonal relationships, social graces, understanding society…etc.

My mom clearly understands that free speech does not mean you have the right to challenge orthodox political or scientific views. Go to San Fransisco, scream I believe marriage is between a man and a women, and then try to open a corner store. Go to West Virginia, scream there is no god, and then try to find some fishing buddies.

Lubos was leashed…big surprise there!!!

As an assistant professor, in a physics department, in a flamingly liberal school, one can not expect to **PUBLICLY** attack liberal philosophy while simultaneously **PUBLICLY** declaring that the ayatollahs new theories are nonsense, and avoid consequences.

Brilliant, young, theoritician, completly lost when it comes to understanding people.

And just so you don't think I'm anti Lubos.

How did Sean Carroll convince himself that 4 billion years of evolution have resulted in a perfect equivilance between men and women (except for a few obvious differences).

A brilliant, theoritician, completly lost when it comes to understanding people.

It seems to me. At best social or interpersonal intelligence is completly uncorrelated to analytical intelligence. At worst social or interpersonal intelligence is negatively correlated to analytical intelligence.

27.
May 2, 2005

I have nothing against LM and wish him well.
I also strongly feel he should be allowed to express his views freely on physics and politics regardless of whether I agree with them or not.
Jumping between this blog and LMs there has been a lot interesting stuff debated and argued this past year. Nevertheless, I am getting really tired with all the conversation and attention that focuses upon him. Last week it was a debate about his publications for example. And I even am talking about him right now! But I think this is part of what is going on: the "leashing" has probably something to do with the fact that he has a very high profile among the online physics community and has now somehow become (inadvertantly) the voice and representation of Harvard's physics department. (If other Harvard physicists had blogs I guess this would balance things out though.) They probably want him to tone it down quite a bit.

Having been at an Ivy League school myself for a while I do know that you are there and are hired for the greater glory and image of the school more than you are to serve yourself and your own needs and views. LM is also probably realising that the US is not the land of the free and free speech it claims to be (at least not any more). I know young faculty can have a very hard time and are under a lot of pressure so I do wish him well and hope he gets through things ok if he is having a bad time. In the end though you have to be true to yourself and what you believe in and be in an environment where you are comfortable doing that and free to do that.

28. **island**
May 2, 2005

This is getting fanatically rediculous and ideological bias should be outlawed from science altogether.

Imagine how left-wing extremists would react to finding out that humans have a real practical function in nature that results from the growing "higher-level" physical "need" of our expanding universe.

http://www.taipeitimes.com/News/edit/archives/2004/09/30/2003204990

Imagine how right-wing fundie creationists would react to finding out that their "higher-power" is actually the second law of thermodynamics.

Science and humanity is doomed if it comes down to right-winged fanaticism vs. leftist liberalism

29.
May 2, 2005

Is the previous anonymous none other than Lubos himself? It certainly seems like it. If he really is Lubos, the whole "leashing" thing sounds extremely suspicious to me. If there is anything fishy going on with the funding of climate research, it's most likely to be coming from the side of global warming skepticism, but Lubos is on their side…

It certainly seems out of place for global warming researchers to "leash" a blogger with little credibility.

30.
May 2, 2005

I don't think it's no big deal to trash each others ideas. It may be the cultural norm in physics, but it can still be very hurtful, which is even the more so if the trasher is wrong.

And I don't think Silverstein blew a fuse. It seems more like she was defending herself from unfair attacks.

31.
May 2, 2005

"He does seem to have stopped criticizing the Landscape, maybe that's what all this is about."

Well-informed sources 🙂 🙂 tell me that it was his climate stuff that finally went too far. Earlier versions of his latest post on that theme "raised ethical questions about the funding of climate research" — and what I've written is an extremely sanitized version….that was changed, with LM complaining that he was not allowed to say those things …. and now he's not allowed even to say that! I really doubt that his landscape stuff would result in any problems. People in this line are used to trashing each other's papers, no big deal. Though Eva Silverstein did blow a fuse, that's very exceptional. But raising questions about where money is going — well, that's *really* playing with fire.

32.
May 2, 2005

Isn't it strange that Lubos is being so secretive and tantalizing as to how he was "leashed" and by whom? And isn't it strange that he still posts his usual political views despite being "leashed"?

And why did he remove his "leashed" signature and other cryptic sentences like "I don't enjoy the freedom to tell you what I think"? Isn't this a free country?

33. **Apeiron**
May 2, 2005

Which is scarier – that someone told him to cool it on his political beliefs or academic thoughts?

I think it's possible that someone advised him that his instantaneous trashing of papers and talks as soon as they came out within the small world of string theory physics is not how the game should be played.

I think he should behave as he sees fit, with an understanding that there are consequences to free speech as well – especially in closed communities like academia.

34. **Peter Woit**
May 2, 2005

I certainly support Lubos's right to say whatever he wants, but before protesting too loudly his "leashing" I'd like to know exactly what happened. Did someone tell him he should stop expressing right-wing political viewpoints? Or did they just tell him he was often making a fool of himself? Whatever it was, it doesn't seem to have slowed him down much since he is still posting political commentary not especially distinguishable from before. He does seem to have stopped criticizing the Landscape, maybe that's what all this is about.

35. **Arun**
May 2, 2005

I agree with Anonymous at May 2, 2005 06:53 AM that if Lubos is being leashed, his would be a case to defend strongly.

36. **Anonymous**
May 2, 2005

Well, I can't understand why Motl feels "leashed" (putting aside his psychological motivations for putting this show). And I think if people really believed in freedom of speech etc., if indeed he is serious in his being "leashed", his would be the case to defend vigorously. And that's precisely because his views are so obnoxious (he's basically the equivalent of a party hack here; old habits die hard).

So, if he indeed is feeling constrained in any way, I think this would be the situation to strongly defend his rights (however repugnant his stances). Especially relevant for Peter to do that – would be nice for Peter (he mentioned it briefly in this post though) to have a post staunchly supporting Motl's right to say whatever he has to say, plainly and unequivocally.

37. **JC**
May 2, 2005

Offtopic, but about today's (May 2, 2005) appearance of one new hep-th preprint. This sure seems odd for the otherwise normally "busy" hep-th board. Has there been any other days in the past which only had one, or even zero, new hep-th preprints?

(I don't believe this is a sign of reckoning).

38. **Simplex**
May 1, 2005

[i] But who would feel so threatened by a lone ravings of a scientist with no political clout?[/i]

If Lubos has been subjected to pressure or warnings about the content of his blog, I would guess it is not because of his reactionary politics but rather because of this:

http://www.math.columbia.edu/~woit/blog/archives/000184.html

that is, "leashing" if it has really occurred, was more likely prompted by his outspoken and effective criticism of string theory Landscape research.

His "Kennedy Landscape" posting of 22 April, which Peter quoted and gave a link to, would have been the last straw.

Everything else Lubos does on his blog is a "petty misdemeanor" by comparison and the authorities would be petty themselves, were they to discipline him for it.

39.
May 1, 2005

lubos does not seem to be the type of person who can be silenced easily. The "leashing" probably involves his tenure or something. If that's the case, I must say that's an awful abuse of the tenure system. But who would feel so threatened by a lone ravings of a scientist with no political clout?

40. **Alejandro Rivero**
May 1, 2005

I got it! "Politically Correct" (I was trying "Communist Party" in a first guess)

41. **Alejandro Rivero**
May 1, 2005

I missed something. I thought that PC was standing for "Parity times Charge".

42. **Apeiron**

May 1, 2005

Hmmm…..I guess loony political beliefs are those you disagree with?

Is it loony to megaphone nonsense in the campus courtyard? (cf Witten and Co.). I guess not if it conforms to the PC orthodoxy.

Pretty weak-minded stuff from smart people, but it's predictable from those who never made it off campus.

43. **JC**
May 1, 2005

Over the years I've heard of a few cases of untenured folks either saying all kinds of loony things, and/or burning all their bridges behind. In these particular cases, the untenured person in question knew they were never going to get tenure at their university nor at any other research university for that matter. With this realization their mindset is basically in a "lame duck" phase where nothing "academic" matters to them anymore, and they're already sending out their resume looking for another job outside of academia. During this "lame duck" stage these folks took on an attitude of goofing off and being an annoyance, before they get the eventual boot.

44. **Arun**
May 1, 2005

In what way has Lubos Motl's right to speak been curtailed? Has there been any formal sanctions? Or has been informal, some faculty member or official hinting at something?

My doubt being that if we interpret graphs of world ocean temperature, or the scientific value of string theory differently, then do we know that we would interpret whatever lead to being "leashed" in the same way? Without more facts, there is no objective way of judging the matter.

-Arun

45.
May 1, 2005

Fred,

When was Feynman "chastized on many occasions"?

I'm sorry if Lubos got into trouble. I thought Harvard was "The Crazy Academic's Last Stand", so to speak.

46. **Chris Oakley**
May 1, 2005

It is possible that Motl has been restrained because of this politics, but far more likely – in my opinion, at least – is that Harvard took a dim view of his generally behaving like a mad dog. If so, I will miss him. A least he put his head above the parapet, for example, in posting here – something that few other string theorists have been prepared to do, and certainly not to the degree that he did.

47. **Fred**
May 1, 2005

Fortunately scientists are somewhat immune to the politics of tenure/academic thought police with regards to someones particular idealogy.

This is not always the case, women had a great deal of difficulty in the past, as have notable conservatives (Edward Teller and Feynman both were chastised on many occassions). The same holds for liberals (the Colorado proffessor with the loony views on the WtC for instance).

However when you make enough of a buzz about yourself (say in lectures or on a blog) invariably you will end up with a backlash. Being a string theorist or most any high profile scientist kinda gives an intellectual edge to any conversation that might be seen as threatening to the average public or academic figure. I mean it wasn't long ago that scientists were sorta seen as high priests/priestesses of Ishtar when the nuclear age was dawning on us.

Still, its shocking that there is this 'leashing' taking place. I've seen it happen to other people too to a lesser degree (morally speaking).

48. **Tony Smith**
May 1, 2005

Peter, you say "… There certainly were plenty of people who had trouble in academia because of their political beliefs during the fifties. When I said I wasn't aware of any cases I meant during the last 25 years or so …".

Could that mean that a pendulum has swung over a 50-year period so that we are now entering a new era of politicized academia, in which the role of the McCarthy bad guys of the 1950s is now being played by the PC bad guys of today in the 2000s ?

(I admit that "bad guys" is a subjective term, but it is how I view them.)

May 1, 2005

Hi Tony,

There certainly were plenty of people who had trouble in academia because of their political beliefs during the fifties. When I said I wasn't aware of any cases I meant during the last 25 years or so that I've been around universities.

50. **Tony Smith**
May 1, 2005

Peter, you say that you have "… never heard of any case in math or physics where this … political beliefs … was in any way an issue in a tenure decision. …".

What about David Bohm's expulsion from Princeton?

According to the Bohm biography Infinite Potential, by F. David Peat (Addison-Wesley 1997) at pages 101, 104, and 133:
"… when his [Bohm's] … Princeton University … teaching … contract came up for renewal, in June [1951], it was terminated. … Renewal of his contract should have been a foregone conclusion … Clearly the university's decison was made on political and not on academic grounds … Einstein was … interested in having Bohm work as his assistant at the Institute for Advanced Study … Oppenheimer, however, overruled Einstein on the grounds that Bohm's appointment would embarrass him [Oppenheimer] as director of the institute. … Max Dresden … read Bohm's papers. He had assumed that there was an error in its agruments, but errors proved difficult to detect. … Dresden visited Oppenheimer … Oppenheimer replied … "We consider it juvenile deviationism …" … no one had actually read the paper … "We don't waste our time." … Oppenheimer proposed that Dresden present Bohm's work in a seminar to the Princeton Institute, which Dresden did. … Reactions … were based less on scientific grounds than on accusations that Bohm was a fellow traveler, a Trotskyite, and a traitor. … the overall reaction was that the scientific community should "pay no attention to Bohm's work." … Oppenheimer went so far as to suggest that "if we cannot disprove Bohm, then we must agree to ignore him." …".

May 1, 2005

Anonymous (Posted at May 1, 2005 12:39 AM),

Sounds like stuff in Erich Fromm's "Escape From Freedom" book.

52.
May 1, 2005

It is a liberal illusion that people (as a whole) liberated from oppression understand freedom. The experience in most of the world is that freed peoples turn around and behave like their former oppressors; just as the abused individual is likely to become an abuser, like the harassed daughter-in-law becomes a terror of a mother-in-law; the victims of racism are racist; the persecuted dissenter becomes intolerant of dissent.

It is also both a liberal and a Christian misconception that suffering confers virtue.

53.
May 1, 2005

Conservatives love to feel sorry for themselves.

If he is denied tenure, I'm sure Lubos would find it much more comforting to nurse the illusion that he was persecuted for his political beliefs, than to face the fact that he has wasted his life on silly pretend physics.

54. **Daniel**
April 30, 2005

(I don't know Lubos Motl personally, or in any capacity except for his blog)I do know however, that he comes from a country that has in the past been "leashed" by communism, economic stagnation and stifling bureaucracy. A country where free speech and the individual were suppressed by corrupt people who thought that *they*, and *they* alone, knew what any given person *should* be doing at any given time. With this background Lubos, I would imagine, understands what makes *your* country, Dr. Peter Woit (assuming you are an american), a great country. His "right wing idealism" that you refer to, is an exaltation, a rejoicing cry, an exhausted relief in the simple fact that there *does* exist a place in the world where one man can rise above the rest, where reason isn't inhibited by political correctness and adherence to the majority belief. Given the stark contrasts that he has seen perhaps he and others like him who have emerged from behind the Iron Curtain know better than any of us what America really stands for and what we as members and visitors of this society should exalt in. (Forgive me for this slightly sarcastic final comment,…but Lubos stands in the extreme minority with his political views (in academic circles) and is unafraid to challenge the norm, and you stand in the face of the majority string theorists and are also unafraid to challenge the "standard" view. You are quite similar in many ways!!)

55. **Peter Woit**
April 30, 2005

Annoying your colleagues with loony political beliefs certainly doesn't tend to make them better disposed to your tenure case, but I've never heard of any case in math or physics where this was in any way an issue in a tenure decision.

56. **JC**
April 30, 2005

Peter,

How common is it for somebody to be denied tenure because of their political beliefs?

One extreme case of this sort I've heard of, though not having to do with tenure directly, was of some professor who was posting up Nazi white supremecist propaganda on his www homepage. The department eventually moved his office to some dark corner in the basement or the boiler room.

Various Mathematical Links

May 5, 2005
Categories: Uncategorized

I've recently run across various interesting mathematically oriented sites, each with some connection to physics:

Alain Connes now has a web-site. He's now a professor at Vanderbilt University as well as at the College de France. I can see him in Robert Altman's movie "Nashville". His site contains quite a few interesting things, including most of his research articles and some interesting survey articles about his work on non-commutative geometry. For instance, take a look at his "A View of Mathematics", which starts off with a wonderful description of doing mathematical research and some interesting history of geometry, before surveying his recent work relating non-commutative geometry and physics.

David Ben-Zvi at Austin is organizing a new lecture series to be made available over the web called GRASP (for Geometry, Representations and Some Physics), which sounds promising although it is just getting started.

The MIT math department sponsors something called the Talbot workshops. Last year the topic was elliptic cohomology, this year geometric Langlands. Notes from the lectures are available courtesy of Megumi Harada who also maintains a useful website of geometry conferences, many of which have some sort of physics component.

2. **stephen**
   May 11, 2005

   I learnt a lot of things in this blog of yours Peter. A you can see many links come from your posts.

   I have included a correction to previous post quotation. I might have given the wrong link. I had to give credit to Alain Connes for the statement, and it did not show this. I stand corrected here now.

3. **Juan R.**
   May 9, 2005

   I think that Connes idea of a "map" between geometrical items and operator ones is interesting, but I doubt that we can obtain some really fundamental.

   I am not sure of that noncommutative geometry solves some of the more difficult open questions in differential geometry. See, e.g. my criticism to infinitesimals on page 5 of Official launching

   Moreover, It is unlikely that noncommutative geometry alone can be the key for our understanding of quantum gravitation.

4. **D R Lunsford**
   May 8, 2005

   I followed Connes up through ds=1/D then he sort of lost me. But that's a great read. Anything with Desargue's Theorem in it is worth reading.

   May 8, 2005

   Part of the ability of good mathematicians is to provide new language where our previous discriptions were lacking

   Part of the ability of good scientists is to provide new models of nature where our previous discriptions were lacking

   A mixture of bad math more bad physics is of litte interest for us.

   Humm. Bad math more bad physics. where do i read some similar?… perhaps in some 10D universe in my last travel?

   0 + 0 = 2?0 = nothing vibrating.

   An additional dimension does not change the result.

6. **stephen**
   May 7, 2005

   Most mathematicians adopt a pragmatic attitude and see themselves as the explorers of this mathematical world" whose existence they don't have any wish to question, and whose structure they uncover by a mixture of intuition, **not so foreign from poetical desire", and of a great deal of rationality requiring intense periods of concentration.**

   Each generation builds a mental picture" of their own understanding of this world and constructs more and more penetrating mental tools to explore previously hidden aspects of that reality.

   Like Lenny Susskind?

   Isn't this part of the ability of good mathematicians is to provide new language where our previous discriptions were lacking? New forms/models of math?

7. **Florian**
   May 7, 2005

   He.
   I'm reading your blog for some time now and enjoy it very much. Personally, I'm more on the "mathematical side" but with some interest in how ideas from physics motivate new mathematical questions and insights (like the paper of Witten on Morse-Theory or the one by Kontsevich on Deformation Quantization) and I appreciate the mathematical posts very much.

   Best regards,
   Florian.

8. **Levi**
   May 6, 2005

   Just wanted to say that I always appreciate the math links. Thanks.

   Thanks. "Integral conformal invariants" sound interesting 🙂

   -drl

10. **Peter Woit**
    May 6, 2005

    Hi Danny,

    Kind of too big a topic, since "geometry" in one form or another covers maybe at least a third of all mathematics research. For some idea of the range of things people work on, there's a conference here at Columbia this week in honor of a great geometer, my colleague Masatake Kuranishi, who is 80 and retired this past year. See

    http://www.math.columbia.edu/%7Ewoit/kuranishi_schedule.html

    One hot topic is the curvature flow technique pioneered by Richard Hamilton, and used by Perelman to give at least an outline of a proof of the Poincare conjecture. Besides trying to nail down the details of this, people are applying this kind of technique to questions in complex geometry.

11. **D R Lunsford**
    May 6, 2005

    Could you give an overview of what is going on in geometry these days?

The Stormy Onset of Group Theory in the New Quantum Mechanics

May 9, 2005
Categories: Uncategorized

When I first started studying quantum mechanics I read quite a bit about the remarkable history of the subject, especially about the brief period from 1925-27 when the subject grew dramatically out of the incoherent ideas of the old quantum theory to the full quantum mechanical formalism that is still taught today. This was the work of a small group of physicists: especially Heisenberg, Born and Jordan in Göttingen, Schrödinger in Zurich, Dirac in Cambridge, and Pauli in Hamburg. Recently I've been reading again about some of this history, but paying attention especially to the interactions of mathematics and physics during these years. An excellent very recent article that covers some of this is by Luisa Bonolis, entitled "From the Rise of the Group Concept to the Stormy Onset of Group Theory in the New Quantum Mechanics". (It seems that this link is inaccessible unless you're at a university site that has a subscription. The article should also be available at most physics research libraries as vol 27, numbers 4-5 of the 2004 issue of Rivista del Nuovo Cimento.)

I've written a bit about this history before, especially about the mathematician Hermann Weyl's role, but quite a few other mathematicians were closely involved, including Hilbert, von Neumann, Emmy Noether, and van der Waerden. Much of the interaction between mathematicians and physicists took place at Göttingen, where Hilbert was the leading mathematical figure, and Weyl was sometimes a visitor, with both of them lecturing on quantum mechanics. This period was very much a high point of the interaction of mathematics and physics, interactions of a sort that were not seen again until the 1980s. Heisenberg and his collaborators learned about matrices from Hilbert and the other mathematicians at Göttingen, and Weyl was responsible for educating physicists about group representation theory and turning it into an important tool in quantum mechanics.

The Bonolis article has some amusing quotes from physicists who were having trouble absorbing what the mathematicians were telling them. Heisenberg wrote to Jordan "Now the learned Göttingen mathematicians talk so much about Hermitian matrices, but I do not even know what a matrix is," and to Pauli "Göttingen is divided into two camps, those who, like Hilbert (or also Weyl, in a letter to Jordan), talk about the great success which has been scored by the introduction of matrix calculus into physics; the others, like Franck, who say that one will never be able to understand matrices." Pauli was scornful about this new, unphysical, mathematical formalism of matrices, drawing a testy response from Heisenberg: "When you reproach us that we are such big donkeys that we have never produced anything new physically, it well may be true. But then, you are also an equally big jackass because you have not accomplished it either."

Immediately after having to get used to matrices, physicists were confronted by Weyl with high-powered group representation theory, which they found even harder to understand than matrices. Famously, Pauli referred to the group theory that mathematicians were talking about as the "Gruppenpest", but the late twenties saw a very fruitful exchange of ideas between mathematicians and physicists around this topic. Weyl's proof of the Peter-Weyl theorem and von Neumann's work on representation theory grew out of quantum mechanics, and the Brauer-Weyl theory of spinor representations was inspired by Dirac's work on the Dirac equation.

It's also interesting to note how in the years just preceding this period, much interaction between math and physics had grown out of general relativity. Noether's work on what is now known as the Noether theorem came about because she was asked questions by Einstein and Hilbert who were trying to sort out conservation laws in GR. Weyl took up representation theory as a result of his work on the symmetries of the curvature tensor.

An amusing story I hadn't heard before that is in the Bonolis article was one told by Edward Condon about Hilbert. He claims that when Born and Heisenberg went to Hilbert to get help with matrices, he told them that "the only times that he had ever had anything to do with matrices was when they came up as a sort of by-product of the eigenvalues of the boundary-value problem of a differential equation. So if you look for the differential equation which has these matrices you can probably do more with that. They had thought it was a goofy idea and that Hilbert did not know what he was talking about. So he was having a lot of fun pointing out to them that they could have discovered Schrödinger's wave mechanics six months earlier if they had paid a little more attention to him."

   May 16, 2005

   No, I was up in Boston at another conference, which I'll write about soon.

   Matti and Juan,

   Please stop using this weblog as a discussion forum for your own ideas that have nothing to do with the topics here. I'll delete any further comments of this kind.

4. **Anonymous**
   May 16, 2005

   Sorry, Peter to change the topic.

A question I have is, did you attend the
workshop on string cosmology at Columbia organized
on Friday 13th which Lubos Motl discusses in his blog. Maybe you can report on it if you did
thanks

5. **Juan R.**
May 16, 2005

Thanks Matti,

It has been a pleasure read your post. Still i may apologize because i do have studied TGD, but when I have some time free i will do.

I also work with a two-time formalism, therefore some times i talk about a 4+1D formalism. Humm, interesting! What is the status of the "geometric time appearing in field equations of physics" in your formalism?

I think that with apparently breaking of the second law in self asemmbly you mean integral decreasing of disorder or perhaps or on a diferential rate sense (negative production of entropy).

I found time ago that spacetime cannot be represented by usual differentiable manifolds (bye bye Calabi-Yaus), but still I cannot claim for fractal-like behavior, since i do know if a fractal description would be exact or only an approximation valid in certain regimes. I simply are not sure.

Really interesting, in my approach the failure of scattering theory is associated to density of matter. In particle physics with small effective densities, S-matrix work perfectly. for condensed matter situations, all the formalism breaks down and one works with phenomenological issues ad hoc.

The failure of usual relativistic description of bound states is more complex in my approach

Yes i also found that reductionsim fail, in fact it is a proven fact (usually ignored by physicists and by all string theorists) that string theory does not verify the equation for complexity level.

In my approach nature has a hierarchical structure and no one level is in deep more important that other. Upper levels are not totally reduced to simple lower levels, in fact there is information that is not contained in lower levels, e.g. particle. That is the failure of particle physics to explain upper structures for example biomolecules.

A priori my theory contain MOND approach like a limiting case for the explaining of anomalous acceleration and the missing matter problem.

6. **Matti PItkanen**
May 16, 2005

To Juan R.:

Thank you for interesting comments.

The most obvious apparent violations of second law relate to self assembly and behavior of phase conjugate light.

In my own theoretical framework they are apparent violations so that here we agree. I feel it necessary to distinguish between two times: the geometric time appearing in field equations of physics and the experienced time whose basic unit is quantum jump and which corresponds in average sense to some increment of geometric time which is however proportional to hbar so that there is a hierarcy for the geometric average durations of quantum jump (moment of consciousness) just like there is hierarchy of material systems: elementary particles, hadrons, nuclei, atoms…

The differences between these times are obvious: consider only reversibility (irreversibility) of geometric (experienced) time. With respect to the experienced time second law holds still true but since TGD predicts that both positive and negative arrows of geometric time (positive and negative sign of conserved inertial energy, two possible manners to select the fermionic Fock state in second quantization), processes such as self assembly for which controlling process proceeds backwards in the geometric time, apparently break the second law.

Concerning the "more quantal" issue. Increase of hbar means essentially fractal scaling: quantum coherence lengths and times are scaled up. For scattering cross sections in perturbative regime the effect is perhaps somewhat surprisingly just the opposite since higher order corrections come in powers of alpha= g^2/4*pi*hbar, which is reduced. For bound state energies which cannot be understood perturbatively the situation is different: in the case of hydrogen effects is simple scaling by 1/hbar^2 proportionality of binding energy. An interseting hypothesis is that hbar increases when the perturbative series for S-matrix fails.

Macrostructure indeed affects microstructure and reductionism fails: this is one of the main implications of TGD. This is already implied by what I call topological quantization: space-time surface has a many-sheeted structure with sheets having outer boundary (magnetic flux tubes, "topological light rays", etc..) identifiable as quantum coherence regions and forming a length and time scale hierarchy. Quantum classical correspondence together with the fact that these regions can have arbitrarily large but finite size suggests a generalization of quantum theory and dynamical and quantized hbar provides it.

Concerning strange unobserved matter: I am believer in TGD based variants of string like objects identifiable as magnetic flux tubes. Simplest of them are cosmic strings, 4-D surfaces X^2xY^2, where X^2 is string orbit in M^4 and Y^2 holomorphically imbedded 2-manifold of CP_2. A cosmic string traversing through the nucleus of galaxy in a direction transverse to the galactic plane (naturally assignable to the galactic jet) creates a Newtonian 1/rho potential, which explains the constant velocity spectrum of stars: no dark matter elsewhere would be the minimum option. I do not know how closely this relates to your explanation. Actually TGD allows to identify galactic black hole as a highly convoluted cosmic string. Galaxies would be pearls in a cosmic necklace.

I think that the limits of classical physics are encountered when one tries to understand intentional action and the coherent behavior of the matter in living organisms.

Matti Pitkanen

7. **Juan R.**
May 16, 2005

For Matti.

Some time ago I revised some of supposed violations of the second law in quantum regimes. The famous San Diego conference. Finally i discovered that all revised claims of violation of the second law were based in obvious misunderstanding of thermodynanmics and/or errors.

I also "showed" that formation of structures is compatible with a new generalized version of the second law for mesoscopic regimes.

Therefore, since that i known several of usual methods in laser physics, i doubt that any group can find real violation of the second law in laser phenomena.

8. **Juan R.**
May 16, 2005

Thanks,

I am not completely sure now of that the increase of hbar in Delta x*Delta p=about hbar–>hbar_s would make the system more quantal, just more uncertainty in coupled observables. I don't think that can be exclusively represented like more quantum character in all situations. Remember classical statistical mechanics, asumed to be classical but with Delta x*Delta p different from zero.

Therein my emphasis in that **perhaps** you are working with some like alpa?h, with alpha a system parameter, instead of with variable h.

Could variation of your h explain cosmological redsift like the effect of travel of light for different phases of universe? Or am i wrong?

I don't know the details of TGD and therefore I cannot do any serious comment still. However, I think that there is no real dark matter in the universe (this is another argument against ST and supposed dark matter explained from "cosmostrings").

My explaining of galaxies and cluster "dark matter" like a discrepancy in standard gravity appears to be supported by experimental data. In fact, i can derive the well-known (1/r) behavior without invoking to strange unobserved matter.

What is your opinion?

"The possibility of several values of hbar would allow interaction between widely different time and length scales."

It appears a fractal like behavior. Does macrostructure affects to microstructure in your TGD? If yes, this may be a violation of typical reductionism of particle physics.

Living matter is really interesting, still i found no sufficient time for doing research in that. Now i am working in gravitation and cosmology.

My point is that living matter is characterized by "long-range correlations", but i don't call that a "gigantic quantum structure", since formulas for understanding living phenomena are really classical ones, e.g. chemical kinetics.

Of course, perhaps i am wrong, but i don't know any macro-quantum effect violating classical laws usually applied, with success, in biology.

Cannot the movement of your hand be modelled with chemical kinetics (muscle) + transport theory (electrons, ions, etc.) + EM + classical mechanics (skeleton)?

9.
May 16, 2005

In reply to Ben:

I'm a mathematician (though unlike some – most? – people here, I like to think that math and physics are essentially the same; like two different sides of the same thing). What you describe/ask (abstract commutation relations vs. concrete PDSs) happens very often in mathematics. For example, consider finite groups; every finite group is a subgroup of some symmetric group (that is, all permutations of a set), and indeed that was the way people thinked of groups in the 19th century. Only in the 20th century started people think about abstract groups and their representation. Similarly, in the 19th century, continuous groups mostly meant groups of transformations of vector spaces; manifolds meant submanifolds of euclidean spaces (and again, every smooth manifold can be imbedded in a large euclidean space), etc. So why consider abstract objects instead "concrete" ones?
First, it is not always true that all abstract objects can be realized as "concrete" ones (like subobjects of some model object); and, even more significantly, the abstract viewpoint turned out to be very fruitful. For example, you can make a difference between intrinsic and extrinsic properties of an object: which are properties of the abstract object itself and which are consequences of the particular realization of it.

10. **Matti PItkanen**
May 16, 2005

To Juan R.:

The increase of hbar in Delta x*Delta p=about hbar–>hbar_s would make the system more quantal.

One can imagine that a system consisting of ordinary elementary particles can make a transition to a large hbar phase without an appreciable change in four momenta of particles but with an increase in quantal size hbar/m defined by the Compton length. Macroscopic quantum phase is a natural outcome due to the quantum overlap of particles.

For instance, suppose that hbar_s/hbar= about 2^11 (a preferred value for hbar_s for certain reasons). Ordinary IR photon with energy of 1.24 eV corresponds to wavelength of one micrometer whereas "dark photon" would correspond to a microwave wavelength of 5 millimeters.

There are good arguments (in TGD Universe) for believing that dark matter particles form analogs of Bose Einstein condensates and emit coherently BE condensates of dark photons behaving very much like laser beams and decaying to ordinary photons with wavelength shorter by a factor 2^(-11) in our example (decoherence).

The possibility of several values of hbar would allow interaction between widely different time and length scales. This kind of interactions characterize living matter. Consider only how my intentional action to raise my hand eventually boils down to *coherently* occurring interactions in molecular and atomic length and time scales.

Matti Pitkanen

11. **Juan R.**
May 16, 2005

Matti,

You claim for modifications of the Planck.

What is the interpretation of deltaE = hw in your theory for large systems?

Are you perhaps really claiming for the substitution

h –> alpha?h

in formulas, with alpha a parameter instead of asuming that h is not a real constant?

12. **Matti Pitkanen**
May 16, 2005

To Chris:

My purpose is not to propose any ad hoc modifications of quantum theory. The value of hbar remains free in quantum theory: this is a fact. Second fact is that TGD leads to a well-educated guess for the spectrum of allowed values of hbar based on mathematics associated with so called hyper-finite type II_1 factor of von Neumann algebras (see the chapter at my homepage). This appears naturally as the Clifford algebra of infinite-dimensional spaces (now the space of 3-surfaces in certain 8-D imbedding space) and are partially characterized by the requirement that infinite-dimensional unit matrix has unit trace (might be relevant for the finiteness of the theory). A considerable generalization of the structure of quantum theory is involved.

As far as energy conservation is involved, I am extreme conservative. TGD was born from the requirement that inertial energy is strictly defined and conserved: in general relativity this is of course not the case and has led to numerous difficulties discussed also in this blog. Non-trivial representations of Diff^4 required by the identification of momenta as Diff^4 generators have central extension and lead to Diff anomaly. The problem finds an elegant resolution if Poincare symmetries correspond to those of imbedding space rather than space-time surface.

To blame that free energy people have never heard of energy conservation and second law is of course cheap rhetoric. The anomalous effects involved with free energy effects and cold fusion (to name only few of them) represent the borderline of our knowledge, and it could be very rewarding for theoretical physicists to come down from the academic heights, and start to think more what refinements of the basic concepts are required by these anomalies if they are indeed real. There are also strange effects apparently breaking second law associated with phase conjugate laser beams. Self assembly in living systems is also very interesting in this respect. Of course, the conceptual problems of general relativity alone should provide enough food for original thought.

Matti Pitkanen

13.
May 16, 2005

To Ben:

Remembering the basics: QM algebra mumbo jumbo describes discrete values of observables not just a time-continuous evolution of probability waves (in the Born interpretation). The discrete values of an observable are nothing but the eigenvalues of a Hamiltonian acting as a hermitian operator on a Hilbert space which is spanned by orthogonal vectors representing solutions of the Schroedinger equation (the eigenvectors of the Hamiltonian). If hermitian operators of different observables cannot be simultanously diagonalized, measurements on the observable can not be measured accurately the same time. The Schroedinger-equation connects the Hamiltonian with continous time evolution and Hilbertspace/Matrix formalism connects the same Hamiltonian with observable spectra. Each element of the mathematical formalism has a clear physical interpretation.

To Matti:

If You want to vary physics on demand of some unobserved speculative effect, why not dispute energy conservation or entropy law (which makes people depressive)? The “free-energy” crowd that creates and sells perpetuum-mobiles would be grateful.

14. **Chris Oakley**
May 16, 2005

Hi Ben,

I think that the reason for wanting to base QM/QFT on commutation relations is simply that you have got to start somewhere. But I agree that it is a mistake. After all, it does not work for quantum fields other than spin zero, and even if one accepts mathematically meaningless constructs such as the differencing of divergent integrals, “quantization” of GR always fails. One might also add that the premise of quantization if nonsensical: we start with a classical theory and then “quantize” it – are we really saying that the classical theory is the fundamental thing here rather than just some kind of limit?

15. **Matti Pitkanen**
May 16, 2005

Thanks for Ben, the engineer, for very thoughtful comments. The canonical commutation relations for observables are often taken as a more or less sacred thing although there are of course generalizations. Symplectic geometry phase space gives a good justification for the general form of commutation relations apart from the value of hbar in the case of quantum mechanics. Bose (Fermi) statistics is behind the commutation (anticommutation) relations in quantum field theory, and in two-dimensional case braiding statistics leads to more general commutation relations.

What puzzles me is why the value of Planck constant is taken as sacred (and that also I took it as sacred for so long) so that it disappears from quantum physics formulas totally by the choice hbar=1,c=1. Dynamical, possibly quantized, Planck constant able to have large values, would be well-come to anyone attempting to understand living matter as a macroscopic quantum system since Compton lengths, etc. would be scaled up. A phase in which protons have atomic Compton lengths would be very different from ordinary condensed matter and might allow to understand some claimed anomalies such as cold fusion.

Variations of hbar do not lead to any dramatic effects in scattering of free particles if the classical cross sections representing hbar=0 limit are non-vanishing so that only higher order perturbative effects are affected (in fact reduced, since gauge coupling strengths are proportional to 1/hbar). Situation is different for processes like photon-photon scattering for which classical cross section vanishes. Also the spectrum of binding energies for say hydrogen atom scaling like 1/hbar^2 would be strongly affected.

One could play with the thought that the value of hbar must be such that classical bound states make sense also quantally. In the case of gravitational bound states of masses larger than Planck mass this would have rather interesting consequences. Planck constant would become gigantic and the black hole formation as a gravitational counterpart of infrared catastrophe for hydrogen atom would be prevented by the formation of quantum gravitational bound states. This line of thinking would mean a bottom-up approach to quantum gravity starting from gravitational wave mechanics (of dark matter perhaps) instead of not so successful top-down approach provided by M-theory.

For these and many other reasons I see the possible effects related to the dynamical hbar as worth of studying. More ponderings about this at my blog site.

Chris W said: “In quantum field theory and general relativity we seem to have left this simple starting point (and its closely related predecessors) way behind, and modern mathematics has been absolutely essential in doing so. Have we lost something as well? ”

Hi, I’m Ben the (not terribly mathematical) engineer, and thanks to those who answered my post about Feynman vs. Schwinger. They’re both great of course!

Expanding on this discussion about abstract math in modern physics, please indulge me in a sweeping and naive question about quantum physics. Also, please forgive the length of this post, but this is the first (or rather second) time I have dared participate on a physics list and I wish to unload something that has been bothering me for a long time. The basic question is:

Why are the commutation relations so sacred?

This may seem like a strange question, but what I mean is, Why is a certain formal manipulation of symbols taken as sacred dogma by ALL physicists? Yes, I know it works in QED and QCD to upteen decimal places and all that, but why do the superstring and other quantum gravity people simply transplant it without any questions? Every other crazy idea can be entertained, but this is sacred. Why? At least, that’s the impression I get. Perhaps it is this blind faith in the commutation relations which is the reason that gravity and the other forces have not yet been unified. Perhaps they simply don’t work for gravity. Perhaps they don’t even work for the other forces in the regimes explored by unification theory.

If I could elaborate a bit, my question might make a bit more sense. As an EE (electrical engineer), I have no problem with wave equations. In fact, I love them. So naturally, I take a Schrodinger view of things, which I know is the simplest quantum approach. Hence, to me, the commutation relations simply express a straightforward relationship between partial differential operators. I know that the modern view is that the latter are only a *representation* and that the truth, following Dirac and others, is to be found in the abstract approach of a mere algebraic relationship between operators, which have themselves become quite abstract. (How ironic that Dirac started out as an engineer!)

Well, this clashes with a strong philosophical prejudice of mine, namely, that I want to be able to *visualize* everything. After all, whatever is happening down there is happening in space and time, so it must involve regions of space distorting and evolving in some way, and this means that it can be imagined in principle. Never mind what the regions are filled with, if anything at all. The point is that there must be regions in which whatever is happening is happening. (By ‘regions’ I am thinking primarily of boundaries in spacetime, though I realize that according to GR the spacetime itself may be distorting and evolving.)

So the bottom line is that I want to be able to visualize what is happening, even if there are profound ontological issues with *what* is being visualized. The idea of a probability wave may seem esoteric in some sense, but even engineers can feel happy with the complex exponentials or Bessel functions or Hermite polynomials or whatever that one gets when one solves the Schrodinger equation. At least we can *draw* them.

(Note that even Maxwell’s theory can seem a bit ‘metaphysical’ in that one may ask *what* is waving. This led to the idea of the ether and its subsequent repudiation. Yet we all feel comfortable with waves, whether classical or quantum, because we can at least imagine them, even if they have some ghostly ontological aspect.)

Things get even more mysterious for me when the commutation relations are applied to the electromagnetic field. How can something that was invented for particles be simply transplanted to the electromagnetic field? You may say that the EM field is ‘made up of’ particles called photons, but there is a difference with, say, the particle in a potential well for which Schrodinger derived his equation. The difference is simply that the ‘classical’ entity with which we begin is, in one case, a particle and, in the other, a wave. How can the same algebraic gimmick (if I might say so) simply apply in both cases? At least, why don’t physicists spend more time wondering about this? Every QED and QFT textbook I have seen simply ‘postulates’ the commutation relations for any pair of ‘conjugate’ variables, according to Lagrangian theory. I don’t deny that this somehow works in a number of cases, but the fact that it does should be profoundly puzzling to physicists. After all, not only is there the particle/wave difference in the classical starting point, but in one case we have a particle in an *external* potential and in the other case we have a *free* plane wave NOT in a potential. Yet the physicists just wave their magic wand and justify this magic by the pretext that it happens to work, as if that were a sufficient excuse! 🙂

Then when it comes to strings or the Planck regime, the questions and puzzles simply increase by orders of magnitude. I think I’ve said enough and you can see where I’m going. I’d like to dispense with algebraic abstractions like commutation relations and get back to good old partial differential equations describing waves that I can visualize evolving in space. If you argue that the commutation relations are in fact always equivalent to PDEs, then why not go to the PDEs directly? And the way I have seen the CRs applied in modern physics papers, in what seems like a mechanical and robotic fashion, makes me wonder if all contact with PDEs (and hence visualizability) has simply been lost, and THIS may be the problem. It may have all degenerated into quantum algebraic mumbo jumbo. Is this something any of you care about? Thanks

May 15, 2005

Hi,

Interesting summary of Bonolis’ article… I’ll try to get a paper
copy.

The story about the conversation between Born, Heisenberg and Hilbert, in which Hilbert pointed out the connection between matrices and eigenvalue problems of partial differential equations, and Born/Heisenberg went away thinking that Hilbert was a very strange old man, is part of the lore of physics. I first heard it from Kurt Gottfried in a course on quantum mechanics at Harvard.

Thomas Larson:

Yeah I saw Lubos meantioning that paper, too. I did not comment because I thought that's just a **joke** that some solid state physicists were trying to **ridicule** their counter part colleagues in super string research.

Certainly if super string simply does not exist, no one can make an experimental device to produce them. But that's not even the point.

We know, super symmetry, if it exists, must exist at an energy scale very high, much higher than the energy accessible by today's accelerators, i.e., above TeV, which corresponds above 1×10^16 degrees temperature.

On the other hand, the Bose-Einstein condensation of heavy metal atoms, as we know it, involves energy scale extremely weak, only at super cold temperature, sub mili degree absolute temperature, can those fermions condense into bosons. Therefore, any interaction withou the slightest amount of energy could easily thaw it out of Bose-Einstein condensation. Ther super symmetry interactions, certainly, is 1×10^20 times higher than that's required energy level to destroy the Bose-Einstein condensation. So such an experimental setting could not have produced anything even if super string theory is all correct.

Quantoken

23. **Thomas Larsson**
May 15, 2005

Note the standard caveats with if's and would's:

"If their idea can be put into practice, it would allow aspects of string theory to be explored in an experiment for the first time."

If arch-angles are produced at the LHC, it would allow aspects of Christianity to be explored in an experiment for the first time.

24. **D R Lunsford**

It appears obvious that when we improve our understanding of nature, it is necessary more and more mental power. In some sense you can explain GR, QFT or ST for public in usual, "cotidiane", terms, but the real understanding is only achieved from the mathematical formulation of those ideas and that math is each time more difficult and abstract.

I could offer you good examples of these topics but since Peter probably would erase my post, you would see my recent work in epsilon-calculus.
Recently, a mathematical research has done some good comments in my ideas on calculus and criticism of Connes, on an recent post (on GR) in a well-known forum. I think that you can find me easily.

It is rather probable that one day nobody can understand new mathematical formalism. In fact, that **fatal epoque** has already arrived to pure math, like some of us probably know.

In general, people has no idea of QM, GR, Strings or others. Since that was a teacher of young people, and some of my friends continue to be. I can say you that people has no best understanding of Newton gravity now that 100 years ago.

26. **Quantoken**
May 13, 2005

Some one said:

"This means that real physics is increasing **abstract** and **simplying** physics for the man on the onminbus is now impossible."

I completely disagree. The whole point of science is try to de-mystify nature and try to simplify and explain nature in ways we human can understand. If science grows more and more complicated and abstract and is detached from the comprehension ability of the people, eventually it will grow to the point that no one in the world understand science any more. Then science is no longer relevant to the development of human society if no one could understand it. I do not think that is the trend.

Back in stone age, nobody even knows how much is 1+1. Back in Newton's time, no one even realize the existence of gravity. But today even an average person knows a little bit of weird stuff of 10 dimentional super strings. And any weird field you publish your paper, there are at least a couple thousand people around the world who would like to read and can understand your stuff.

Science is becoming more accessible to people, not less accessible!

Imagine what will happen if the opposite is true. Einstein's GR was once said to be understood by only 12 people. Now a theory twice complicated and twice as advanced would probaly be understood by 6 people. Continue on and pretty soon the comprehensibility is reduced to zero. And the knowledge will be accessible to not a single living human being any more, zero.

Is that possible? Not at all. As long as science is still part of human culture, it will always remain accessible to at least a portion of the population, and this portion could only grow, not shrink. The information age makes it more likely that a vast majority of population will become very familiar with at least some partucular areas of science.

Quantoken

27. **Juan R.**
May 12, 2005

Like an expert in chemical questions, i can sure you that chemistry newer was reduced to/ explained by physics (either inside or outside of QM, SM, and ST).

I known the usual **(very wrong)** belief of that all of chemistry is already known (e.g. popular claims by Weinberg, Witten, etc). But they are so correct like Newtonian physicists claiming for an understanding of chemical reactions or 19th century physicists claiming for ultimate models of chemical bond based in classical electrodynamics.

For me it is so arrogant the claim by physicists of that all of chemistry is known like the claim by string theorist of that ST is the TOE. Somewhat like Peter considers useful to explain that ST is not a TOE (in fact one cannot predict anything) I consider good to present the current status of chemistry like an autonomous science.

28. **Selrach**
May 12, 2005

Hi Chris W,

Reading your post made me think about my
favourite issue with 21st century Physics.

What is to replace the Hierarchy?

What I mean is that Science upto now has explained the world thus: Geology then Biology then Chemistry then Physics then Mathematics.

However, with Quantum Mechanics, this clear delineation has broken down with superposition effects and with String Theory with mirror symmetries (proven as mathematics!).

So called paradoxes are paradoxes if you try to 'simplify' the problem at a higher Hierarchy level .

This means that real physics is increasing abstract and simplying physics for the man on the onminbus is now impossible.

An amateur mathematician.

29. **robert**
May 12, 2005

It's good to see Schwinger's rehabilitation in a couple of the posts following on from the 'can mathmos do physics and vice versa?' debate. His papers are models of clear exposition, whether they address the quantisation of gravity or the generation of synchrotron radiation, and, where possible, make direct numerical contact with physical reality. As is evident when reading his 'Classical Electrodynamics' text, he felt that the maths should emerge from the physics, rather than the other way round. This is particularly evident in his amazing 'On Angular Momentum' paper, which brings us neatly back to the Gruppenpest question.

Whatever; it is sadly true that those of us raised on Morse and Feshbach find it rather hard to penetrate the hep-th arxiv these days.

30. **Thomas Larsson**
May 12, 2005

Re Einstein's disregard for mathematics. While developing GR, AE did some absolutely marvellous inventions in mathematical technology, namely the summation convention and the idea to put contravariant indices upstairs (though I'm unsure whether this is really due to AE). In my experience, many mathematicians still seem unconfortable with these inventions, 90 years afterwards.

31. **Steve M**
May 12, 2005

Drl,
I recently had a look at old papers of Schwinger's from Physical Review in the 50s. They are an absolute calculational tour de force. He states what he is going to do and derive, then does the stunning calculation in complete detail. No excuses, no handwaving, no waffling, no speculation and no wishful thinking. The stark contrast with many of the modern arxiv papers kind of hits you.

32. **Chris W.**
May 12, 2005

Ben said, "By the way, even though Einstein developed respect for mathematics after laboring over General Relativity, I did read somewhere that later in life he complained that the mathematicians had so transformed (or veiled) his theory that he no longer understood it!"

Actually, I'm quite sure that he said this early in his career, in response to Minkowski's explicitly geometrical formulation of *special* relativity. Notwithstanding his initial misgivings, Minkowski's formulation set the stage (in part) for posing the questions that led to general relativity, ie, as Einstein reconsidered his relativistic theory of space-time measurement in the context of the equivalence principle and what was understood about gravitation prior to 1915.

======================

This is how new mathematical ideas can be so helpful; they can make it possible to state clearly and objectively notions and assertions that experience, physical intuition, ordinary language, and pre-existing mathematics can only motivate and sketch in an incomplete and sometimes contradictory fashion. Nonetheless the crude initial formulations are essential when new and fundamental problems are being confronted. They make it possible to sensibly discuss the problem of what new mathematics is needed for addressing *physical questions*, and why. My feeling about much recent work is that it relies on formal precision and rigor as a comforting and professionally rewarding refuge—a way of avoiding the crucial, difficult (and usually somewhat ill-posed) questions while still demonstrating admirable technical mastery and (perhaps) making contributions of substantial value to mathematicians and mathematical physicists.

In this context, consider Feynman's famous remark:

> If, in some cataclysm, all of scientific knowledge were to be destroyed, and only one sentence passed on to the next generation of creatures, what statement would contain the most information in the fewest words? I believe it is the atomic hypothesis that
>
> *All things are made of atoms—little particles that that move around in perpetual motion, attracting each other when they are a little distance apart, but repelling upon being squeezed into one another.*
>
> In that one sentence, you will see, there is an enormous amount of information about the world, if just a little imagination and thinking are applied.

In quantum field theory and general relativity we seem to have left this simple starting point (and its closely related predecessors) way behind, and modern mathematics has been absolutely essential in doing so. Have we lost something as well? That is, have we obstructed a path to a *lucid* reconsideration of this metaphysical starting point? It seems to me [see comments] that the fundamental issues raised in attempting to develop a theory of quantum gravity make this question more important* than it has been in a very long time.

—-
* In his recent lecture at Perimeter Institute Leslie Ballentine emphasizes what I believe to be a closely related point:

> Einstein's "God" talk was purely metaphorical, like "Mother Nature", or "Father Time". His objection to indeterminism was more serious, but has unfortunately been over-emphasized. [John Stachel has argued that it has also been badly misunderstood. -CW]
> His most powerful criticism of the "Copenhagen" interpretation did not involve determinism/indeterminism.
> Rather, it concerned realism (or *ontology*).

For some time now it has not been clear what physics at the most fundamental level is *about*. What it is about has certainly been clear enough to do much valuable research, up to a point, but I strongly suspect that in certain areas we have reached that point, and must now find a deeper, more lucid, and more unified answer to this basic question.

33. **D R Lunsford**
May 11, 2005

RE Klein – he at once understood the light cone, in fact he invented the theory of "light cones" insofar as projective geometry needs a quadric to become a metric geometry. How wonderful for Klein, in my opinion the Newton of mathematics, to see his program so gloriously realized.

-drl

34. **D R Lunsford**
May 11, 2005

Peter – you should check out Schwinger's book on electrodynamics, based on lecture notes and mostly reviewed by Schwinger himself. This book is one of my prized possessions. You really get a clear idea of how Schwinger did physics, and in this context it's just amazingly to the point.

http://www.amazon.com/exec/obidos/tg/detail/-/0738200565/qid=1115861218/sr=8-2/ref=pd_csp_2/104-0715732-6355125?v=glance&s=books&n=507846

Sorry for the long url.

-drl

35. **Peter**
May 11, 2005

Actually I don't think either Schwinger or Feynman had much use for mathematicians, although Feynman's style was more intuitive and pictorial and Schwinger's more formal.

I've always found Schwinger hard to read, whether or not you know the subject he is writing about, but Feynman can also be hard if you are just learning the subject. His lectures on physics for undergraduates famously baffled most of the students. I've heard that when they both presented their work on QED, people found Schwinger more understandable, since he presented coherent derivations, whereas Feynman seemed to be engaging in repeated leaps of logic. On the other hand, I've also heard about these early calculations that "Feynman made it look like anyone could do it, Schwinger that only he could have done it".

36. **Ben**
May 11, 2005

Hi. I'm an engineer by profession with an interest in physics, but my mathematical knowledge is not deep. Speaking of the overuse of math in physics, I have an impression regarding Schwinger and Feynman, and I am wondering if it is correct. Schwinger was supposed to be one of the most virtuosic mathematical physicists of his day, allegedly capable of calculations nobody else could do or perhaps even understand. Feynman, on the other hand, seems to have taken a relatively 'intuitive' approach to QED, which dispensed with heavy formalisms in favor of the famous Feynman diagrams. Yet, who had the greater impact on physics? It seems quite clear to me that it was Feynman. I suspect that this comparison is almost a cliche among physicists. I did read somewhere that Feynman once referred disparagingly to 'fancy schmancy differential geometry'. By the way, even though Einstein developed respect for mathematics after laboring over General Relativity, I did read somewhere that later in life he complained that the mathematicians had so transformed (or veiled) his theory that he no longer understood it!

37. **Peter Woit**
May 11, 2005

To expand on the previous comment:

Klein's point of view on geometry as being about Lie groups and Riemann's point of view as it being about metrics and curvature were unified by Cartan, who really was the first one to come up with the modern view of geometry, in which the connection on a principal G-bundle plays the central role.

Hilbert was definitely the major figure in mathematics in the early part of the century, since by this time Klein wasn't very active (he retired in 1913). Klein was the one who built up the great school of mathematics at Gottingen, but by the time quantum mechanics came around, he was dead and Hilbert was the leading figure there. Hilbert's influence is due partly to the fact that he worked in an amazingly wide array of mathematical areas, with geometry only one of many.

By 1925, Hilbert was getting old (63). It is Weyl who was really at the height of his powers during those years, and had the most influence on physics during that period.

38. **Walt Pohl**
May 11, 2005

Selrach: Klein's Erlanger programme was done in by changes in mathematical fashion more than anything else. Riemannian geometry simultaneously encompassed Klein's geometries and the classical differential geometry of curves and surfaces, so it has drawn most of the attention. The Erlanger programme just became a special case of highly-symmetric Riemannian manifolds.

DRL: Within mathematics itself, Hilbert is a more influential figure than either Klein or Weyl — probably the most influential figure on mathematics in the twentieth century.

39. **D R Lunsford**
May 11, 2005

Selrach,

In my opinion, there are Klein, Weyl, and a lot of second stringers 🙂

-drl

40. **D R Lunsford**
May 11, 2005

Thomas,

Your comment RE Lie is extremely interesting and exactly to the point.

-drl

41. **Thomas Larsson**
May 11, 2005

DRL, I don't think that one should regard Hilbert's remark as Einstein-bashing, but rather as an observation that mathematical skills and physical intuition are very different things. Of the two, the latter is more important. Your math can be improved if needed, but without an understanding of the physics you don't know which math is needed.

42. **Selrach**
May 11, 2005

Hi drl,

I am not sure that you can compare Klein and Hilbert in that way!

Both were mathematicians who created grand overarching philosophies which have proved influential but flawed. Klein's geometry is group theory (Erlanger program) was shown to be inadequate, when Peano/Weierstrass discovered continous curves which have no derivatives anywhere!

Hilbert's program was of course undone famously by K Godel.

My belief is that they are both great flawed mathematicians!

An amateur mathematician

43. **Thomas Larsson**
May 11, 2005

In my experience, the mathematical knowledge of string theorists is rather lopsided. Many of them are strong in algebraic geometry (which I am not), but it is unclear to what extent algebraic geometry is really needed in physics. Real physics, i.e. GR and SM, can be understood without even knowing about manifolds and bundles. This is obvious, since these theories were discovered before fiber bundles became popular in physics around 1980. If we want to calculate some QCD amplitude, does it really help to know that the gauge potential is a connection on some SU(3) bundle? Some problems, like the Dirac monopole and the Aharonov-Bohm effect, can perhaps be understood better in modern language, but I doubt that neither Dirac, Aharonov nor Bohm knew about it.

A good illustration of the strange selection of well-known math is given by simple Lie algebras of vector fields over the complex numbers. The Cartan-Killing classification in the finite-dimensional case (A_n, B_n, C_n, D_n, E_6, E_7, E_8, F_4, G_2) is common knowledge, but Cartan's classifictation of the infinite-dimensional ones (W_n, S_n, H_n, K_n) is not. Which is strange, because these algebras were well known to Sophus Lie himself, and they play a much more prominent role in physics than do the finite-dimensional ones (except A_1 and A_2).

44. **Juan R.**
May 11, 2005

Famous Feynmann criticism to math-oriented physicists continue to be true.

Some of my colleagues focus on mathematical research and believe that are doing physics when only are providing new mathematical views on old physical problems.

1?) Physics, after math.

Moreover, I believe that in some decades we will find limitations on the use of math for modelling nature.

When i read the GR manual from Wald, I wonder that only after several chapters one begins to see some of physics. What do you think?

45. **Kay**
May 11, 2005

“Einstein … often spoke against abusive use of mathematiccs in physics. Physics, he would say, is essentially a concrete and intuitive science”. “I don’t believe in mathematics”, Einstein is reported to have affirmed before 1910.

Einstein re-articulates here an old and somehow paradoxal intellectual relationship towards the use of language which can be dated back to Platon. It is very funny to read this citation of Einstein because remember that his enemies in Germany dispraised his physics as jewish and abstract. They bashed Einstein and all modern physics with exactly the argument that physics should be concrete and intuitive. The key-term in these philosophical polemics was the concept of “Anschauung” (in orig. german). “Anschauung” cannot be simply translated into “view” or “concept” but it includes a sensual and a contemplative aspect of “watching the true shapes of the ideas” and is not a mere technical reasoning. Remember also that Einstein was an opponent of Bohr/Heisenberg style of positivism which led the classical world of “Anschauung” completely behind and transformed physics into an interface-language for holding a conversation(!) with nature (later it was Prigogine/Spengers who insisted in this “dialog with nature”). This controversy was not less popular in mathematics and the most prominent proponent of positivism/formalism was no one else than David Hilbert.

The role of language in the mindset of “Anschauung” was that of a service. So it was mathematics to the physics-community of that time. Language had no different role than fixing vagueness and making ideas communicable and testable but it had no function of it’s own. The modern mindest is far away from the platonic ideal of “Anschauung” but it comes close to that of investigating language and it’s effects. It’s more Kabbalah than nature mystics.

Regards,
Kay

46. **Fabien Besnard**
May 11, 2005

“I don’t believe in mathematics”, Einstein is reported to have affirmed before 1910.
– p 3.

True, but he changed his mind later.

47. **D R Lunsford**
May 11, 2005

Wow, Einstein bashing even from Hilbert. Jealous I suppose. Of course it’s ridiculous. I read the papers, so I don’t give a fig about Hilbert’s lofty opinion of himself. Notice that one never finds Klein making such comments, and Hilbert was no Klein.

-drl

48. **Thomas Larsson**
May 11, 2005

Some quotes from physics/0504179 :

“Einstein … often spoke against abusive use of mathematiccs in physics. Physics, he would say, is essentially a concrete and intuitive science”. “I don’t believe in mathematics”, Einstein is reported to have affirmed before 1910.
– p 3.

“Every boy in the streets of Goettingen understands more about four-dimensional geometry than Einstein. Yet, … Einstein did the work and not the mathematicians”
– attributed to Hilbert, p 11.

49. **JC**
May 10, 2005

Alejandro,

I got the impression the more “hardcore” mathematically inclined string folks and other theorists seem to be fond of using a lot of “new math”. Papers written by folks of this sort seem to pop up frequently in various journals like J. Math. Phys. or Comm. Math. Phys., and other lesser known journals specializing in “mathematical physics”.

Some of these guys seem to be quite far away and disconnected from experimental data.

50. **Chris W.**
May 10, 2005

On the genesis and significance of Noether’s work in connection with general relativity, see this **review** by Nina Byer (UCLA, 1999).

From Hermann Weyl’s 1935 memorial to her:

“A stormy time of struggle like this one we spent in G?ttingen in the summer of 1933 draws people closely together; thus I have a vivid recollection of these months. Emmy Noether – her courage, her frankness, her unconcern about her own fate, her conciliatory spirit – was in the midst of all the hatred and meanness, despair and sorrow surrounding us, a moral solace.”

(For more, see this page.)

51. **Juan R.**
May 10, 2005

I agree in that in general new physics implies often new math.

The term new math would be taken on a broad sense, e.g. new applications in physics of old mathematical stuff. A example is the formulation of GR by Einstein and based in math done by mathematicians.

For science, the rule is first physics after math. This rule is violated in string M theory, where there is some advance in pure math but few or no advance in physics. This indicates, at least to me, that the entire endeavour is completely wrong. It is not the problem of finding some correction term or some new magical concept solving all problems, we may simply ignore the approach and focus in another theory/-ies.

Quantoken,

There are problems now intractable (but that wiil be solve in a future) and other may be totally intractable to practical effects forever.

One of that intractable forever problems is the formulation of a TOE. It does not exist.

I don't think that "intractability" is the source of time arrow, without a concept of entropy.

Time arrow is based in certain topological effects linked to intimate structure of spacetime. Entropy plays a fundamental role and it is the source for the well-known link between thermodynamics and gravitation.

52.
May 10, 2005

It's easy to let mathematical formalism bury physical insight (or to use it to disguise a lack of physical insight).

Quantoken

There is significant contact between number theory, the Reimann hypothesis and quantum chaos, described in Chapter 11 of Marcus du Sautoy's 'Music of the Primes'. Perhaps it is not so strange that Bombieri's April 1st 1997 announcement of a proof of the RH described a physically motivated analysis that drew on insights from supersymmetric fermionic-bosonic systems – a near absolute zero ensemble of a mixture of anyons and morons.

56. **JC**
May 10, 2005

A lot of the math used in string theory before the 1984 Schwarz anomaly cancellation paper, didn't appear to be much more complicated than the sort of math one comes across in quantum field theory and general relativity. A lot of the "new math" seems to have surfaced quite quickly after Witten started to publish a lot of string papers, especially complex algebraic geometry related stuff like Calabi-Yau manifolds. (Some of it looks like it was carried straight over from supergravity compactification type of problems).

Peter said:
"I think most people are resistant to learning a new abstract formalism unless there is good evidence that it **really does something useful**. One has a limited amount of time and energy, and learning a new formalism can be time-consuming."

Usefulness is really in the eyes of the beholder. Each individual math field is certainly considered some what useful at least to some people, otherwise there would be no one studying them. But out of all of possible math fields, which in principle could be an infinity, those applicable or useful to physics, which must be a finity since we are talking about a finited universe, such math applicable to physics must be a very small portion.

For example number theory is very useful. But it does not seem to be related to physics. What does it do with physics whether all prime numbers lies on a straight line in the Liemann Hyperthesis? Nothing. Similarly the P and NP problem is unrelated to physics, too. Whether there is an efficient way of cracking the RSA encryption would not tell us howto unify gravity and QM.

In mathematics you can surely imagine a 11 dimentional world, and derive tons of seemingly interesting mathematics out of it. You could also imagine what if the world is two dimentional. But it's really not relevant at all. The world is 3+1 D as we know it and there hasn't been any evidence it could be otherwise.

One math branch that interests me is the problem of tractability. Some math problems are seeming intractable. Are those truely intractable by nature, or are they merely due to our shallow knowledge of math in our era? If intractability can be proven as a natural occurance, then apply it to quantum computing, it could explain the emergence of the **time arrow**, without the entropy. In another word, our world could be constructed using a series of **quantum one way hash functions**, so it could only move forward in time but never backwards.

May 10, 2005

I dissent. String or not string, most theoretical physicists are fond of using new mathematics. It is only that their discovery path does not coincide with the one used by mathematicians; so the new math they use come mainly from other theoretical physicists.

59. **ksh95**
May 10, 2005

JC asked Peter:
"…Excluding the string theory crowd, why are some physicists resistant to using "new mathematics"?.."

Ksh95 will answer:

People are resistant to learning new mathematics for the same reasons they are resistant to sticking shards of glass in their eyes. Very painfull, lots of screaming, plenty of cursing…

60. **Peter Woit**
May 10, 2005

Hi JC,
I think most people are resistant to learning a new abstract formalism unless there is good evidence that it really does something useful. One has a limited amount of time and energy, and learning a new formalism can be time-consuming.

Heisenberg et. al. had some good reasons to be dubious about thinking of p and q operators in terms of matrices. It wasn't so clear how useful this was, and in the end Schrodinger ended up showing that representing these operators as differential operators was much more useful than thinking of them as matrices.

For more than twenty years, string theorists have been pushing a long list of proposed abstract formalisms, none of which have gone anywhere in terms of giving any insight into unification. By now, most everyone is pretty dubious whenever they hear about another such proposal.

May 10, 2005

Peter, since I am new on this blog I read now your previous historic post.

The usual presentation of history by physicists is usually wrong and omit important detailed well-proved. Perhaps the most radical manipulation was those of Newton, when recent research has demonstrated that his chemical career was omited…

There are several example of rewritings of history by physicists. This is not so strange for understanding. Think during one instant in string theory and the manipulation of mass media, the neglect of other schools (many laymen still think that string theory is the only approach to QG), and the rewriting of string theory history.

This is also true of usual history for group theory. For a more realistic view I recommend

Foundations of Chemistry 2001, 3, 55?78.

This paper traces the origins of Eugene Wigner?s pioneering application of group theory to quantum physics to his early work in chemistry and crystallography. In the early 1920s, crystallography was the only discipline in which symmetry groups were routinely used. Wigner?s early training in chemistry, and his work in crystallography with Herman Mark and Karl Weissenberg at the Kaiser Wilhelm institute for fiber research in Berlin exposed him to conceptual tools which were absent from the pedagogy available to physicists for many years to come. This both enabled and pushed him to apply the group theoretic approach to quantum physics. It took many years for the approach first introduced by Wigner in the 1920s ? and whose reception by the physicists was initially problematical ? to assume the pivotal place it now holds in physical theory and education. This is but one example that attests to the historic contribution made by the periphery in initiating new types of thought-perspectives and scientific careers.

More data

When Abraham Pais asked Wigner whether the vastly increased complexity of the calculations involved in the transition from three to four particles (in the Schr?dinger equation) marked his first full awareness of the power of group theory, Wigner replied that his first awareness of the power of group theory in facilitating calculations arose out of his work on the lattice structure of rhombic sulfur.

May 10, 2005

Peter,

Excluding the string theory crowd, why are some physicists resistant to using "new mathematics"?

I can perhaps understand why an experimentalist would be resistant to "new mathematics", when most "new math" doesn't really help them much in their day to day research work. I've noticed quite a number of particle phenomenology folks and even some string theorists who are particularly resistant to "new mathematics", unless the "new math" is "forced" upon them by the "experts" in the field (ie. like a Gell-Mann or a Witten).

Real World Strings

May 16, 2005
Categories: Uncategorized

Quite a few people have written in to point out to me a recent paper by some condensed matter physicists about the possibility of trapping a fermionic atomic gas in a vortex inside a Bose-Einstein condensate. As far as I can tell, about the only thing this has in common with superstring models of quantum gravity and elementary particles is that their abstract starts the same way as many superstring abstracts: "Supersymmetric string theory is widely believed to be the most promising candidate for a 'theory of everything'". This article has gotten wide attention in the press and on the internet at Slashdot which informs us that this will "(provide) the first experimental evidence to support superstring theory." At Slashdot you can also read comments from large numbers of confused souls who now believe that experimental confirmation of superstring theory is right around the corner. Obviously this is about as absurd as believing that the existence of my shoelaces provides excellent experimental confirmation of the existence of open strings.

Another weird related phenomenon is the wide-spread idea that violin strings somehow have something to do with superstring theory. For some reason it always seems to be violin strings rather than, say, electric guitar strings. Maybe string theory would be more popular if it would make the connection with a more popular music form. The violinist Jack Liebeck has been going around with physicist Brian Foster, with Liebeck giving concerts in which he "demonstrates superstring concepts on his violin." The performance ends "with a duet for two violins in which lecturer and soloist join forces to illustrate the production of mini Black Holes" at the LHC. I really think an electric guitar would be a lot better for this purpose.

These performances are taking place at dozens of locations around the world, are somehow part of "World Year of Physics 2005", and supposedly educating people about science. They invoke the memory of poor Albert Einstein, implying that he has something to do with superstring theory since he played the violin and searched for a unified theory. Unfortunately Foster and Liebeck don't seem to be coming to New York, although they were at Cornell this past weekend.

Along the same lines, for something truly weird, get a copy of Einstein's Violin: A Conductor's Notes on Music, Physics and Social Change, by Joseph Eger, the music director of the Symphony for United Nations. This book, besides also invoking poor Einstein, goes on in an extremely repetitive fashion about how superstring theory shows that music and fundamental physics are all the same thing. Eger has all sorts of original insights including for instance:

"Science had its heyday during Sputnik and then gradually faded until the eighties, when string theory came to the fore."

"Religious fundamentalists, big business, and politicians, especially of the neo-conservative variety, have been quick to appropriate quantum mechanics and a perversion of the new music to sell their fundamentalist religion, anti-Darwin ideologies, and biological nightmares."

"On this cosmological scale, and since we are postulating that the universe is music and that music expresses and explains the universe, then we can take the next logical step, that music could hold the key to a T. O. E."

Evidently Witten is guilty of at least not discouraging the author, a sin for which I hope he is punished by having to read this book:

"One day in the eighties, driving with Ed to New York from Princeton, he responded to my question about what he was working on by excitedly telling me about string theory and its ten or more dimensions. Bewildered yet emboldened by this brilliant scientist, I tentatively spoke of my theory that the universe is made of music. Half expecting polite derision, he thought for a few seconds and calmly responded affirmatively."

   M.S. El Naschie is of course, the editor of Chaos, Solitons and Fractals. The rest of the gang(not say that they are tainted by association with their boss) are here, http://www.elsevier.com/wps/find/journaleditorialboard.cws_home/967/editorialboard

   In between chuckles, I am extremely disturbed that a reputed publisher would publish stuff that looks like it's excerpted from an anti-Sokal parody. Does Reed Elsevier publish more of these journals?

4. **ksh95**
   May 17, 2005

   …was making fun of the idea of theoretical physics thinking it had something to do with music, in this case a certain sort of popular music performance. If you can't make fun of popular music, what can you make fun of?
   …

   I thought it was the modern-day cyber incarnation of blackface comedy, but after a little research it turns out that "50 cent" is a highly successful rap artist…my fault I guess?

5. **Peter Woit**
   May 17, 2005

   Maybe I've got it wrong, but it seemed to me that whoever wrote that little bit of parody wasn't making fun of anyone disadvantaged or different than them, but was making fun of the idea of theoretical physics thinking it had something to do with music, in this case a certain sort of popular music performance. If you can't make fun of popular music, what can you make fun of?

6. **ksh95**
May 17, 2005

But beware of making fun of any of this. Surely Mr. El Nachie is a member of one disadvantaged group or another, so some commenters here will be offended.

Hmmm, Maybe I'm the only one who doesn't think that "…they're different than me, hahaha…" is funny.

And just for the record. I'm not a disadvantaged minority, gay, deaf, female, christian, or liberal. It just seems to me that the person who looks at different cultures and then proceeds to burst into gut-busting laughter…can't be very intelligent.

Maybe I'm wrong

7. **JC**
May 17, 2005

Just looking at El Naschie's listing of papers on SPIRES, it looks like he published around 56 papers over the last 4 years. This would be around 14 papers per year, or a paper every 3 or 4 weeks! When was the last time a bigshot, like an Ed Witten or John Ellis, published this many single-authored papers in one year?

On the surface it looks like El Naschie is using the journal "Chaos Solitons Fractals" as if it was his own personal "vanity" journal. In the publishing business the publishers with the lowest reputation seem to be the "vanity" publishers, who will publish just about anything for a fee. (These are usually the publishers of last resort for authors who have been turned down by just about every other publisher). Have some journal publishers stooped down to the point of offering "vanity" journals?

May 17, 2005

Hi Kanex,

Thanks for the comment, those are extremely impressive papers. One might wonder how they got published in an Elsevier journal, since such journals are known for their high prices and correspondingly high editorial standards. The journal is online (if you are at an institution that sends big bucks to Elsevier) at http://www.sciencedirect.com/science/journal/09600779

The fact that the editor is named M.S. El Naschie may have something to do with why it publishes all those papers.

But beware of making fun of any of this. Surely Mr. El Nachie is a member of one disadvantaged group or another, so some commenters here will be offended.

11. **Kanex**
May 17, 2005

Hi Peter. I've been reading your blog for a long time and this is my first post 😉

I'd like to share with you some amusing papers. I think they are even better than warren siegel's parodies 😉

This would be just a Green-Schwarz superstring analog? Interesting actually, if it could be done and string methods could prove powerful tools in condensed matter theory and in ongoing questions in qcd. Confusion among people though and again in the press, just like people thought black holes had actually been made at Brookhaven.

There is a definite and well-known connection between music ability and math ability. The pleasure you get from math/physics is just like the pleasure you get from music really. Both are a powerful symbolic language. I myself studied classical guitar in the 80s (and still do)and wanted to do music as as degree but ended up doing theo. phys/math instead (also my family did’nt consider music a “real degree” I remember)

The violin analogy has been used in just about every popular book on string theory: one vibrational mode or note corresponds to an electron, one to a quark etc. A nice enough idea but one that has never actually been made to work, at least with the particles we actually know to exist. Eddie Van Halen’s “Eruption” solo would probably much better describe the production of black holes at the LHC.

PS I see you are back Peter. I was wondering if you had gone off to join the cinema line a week early for the first showing of the new Star Wars film:)

16. **Anonymous**
May 16, 2005

Well, string theory was originally studied to understand strong interactions; what we now call QCD strings. Perhaps the study of Bose-Einstein vortices as a noncritical string is a return of string theory to its physical roots. As a phenomelogical model, the Polyakov action fits in with lattice simulations to a remarkably good accuracy. In fact, Polyakov came up with his action while trying to reformulate Yang-Mills theories using Wilson loops. Perhaps the same thing will hold true for vortices as well.

I think noncritical string theory is worth persuing to understand QCD. The theory where glueballs are closed strings and mesons are open strings with quark flavor Chan-Paton factors. The string network picture of gauge theories certainly adds weight to this idea with the interesting twist that strings can branch.

In fact, string theorists are trying to do the same thing. They are looking at string theory in AdS_5 as a dual description of QCD.

It certainly is plausible that there might be an S-dual description of superconductors and superfluids using vortices based upon noncritical string theory just as some gauge theories admits an S-dual description using monopoles. In fact, I think this has already been done by some theorists working on the Kosterlitz-Thouless phase transition.

The prediction of 26 or 10 dimensions only comes about, I think, if we restrict ourselves to the simplest conformal field theories and insist upon constant dilaton fields, etc..

17. **Ben the Engineer**

JDG and Other Conferences

May 17, 2005
Categories: Uncategorized

This past weekend I was in Cambridge and attended many of the talks at the JDG conference held at Harvard. The conference was nominally in honor of Shiing-Shen Chern, who died late last year, so many speakers made some connection between their work and Chern's, especially his work on Chern classes.

Among the purely mathematical talks I attended was a very clear one by Victor Guillemin on Morse theory and convexity theorems on symplectic manifolds. The material he covered is quite beautiful, but rather old by now. His reason for covering it seemed to be that he has a new book on the topic (with Reyer Sjamaar) called "Convexity Properties of Hamiltonian Group Actions", soon to appear from the AMS in the CRM monograph series, but also available on Sjamaar's website.

Mike Hopkins gave an impressive talk on "Derived Schemes in Stable Homotopy Theory" which was based on very recent work by his student Jacob Lurie. This work involves defining a notion of a scheme which makes sense in the context not of the commutative rings of algebraic geometry, but instead the commutative rings of spectra in stable homotopy theory. It allows a new construction of the tmf (topological modular forms) theory of Miller and Hopkins.

Iz Singer reminisced about taking a class in geometry from Chern at Chicago in 1949, a class which he thought may have been the first one Chern taught in the US. Singer's talk was about "Projective Dirac operators" which have an index which is a fraction. One of the main motivations for Singer's original work with Atiyah on the Atiyah-Singer index theorem was to understand the integrality of the A-hat genus on a spin manifold as coming from the fact that it was an index. On a non-spin manifold the A-hat genus takes on fractional values, and one can use this to prove the non-existence of a spin structure. In work with Mathai and Melrose, pseudo-differential operator techniques are developed that allow one to define a sort of index in these situations where there is no spin (or even spin-c) structure.

There were several talks by physicists, or related to physics. One was by Kefeng Liu, half of which was about some new metrics on moduli space, the other half about some formulae coming out of work on topological strings. For this material, see his talk at last year's Yamabe Conference. Vafa gave a talk on "Topological M-theory", which he motivated by starting with the holomorphic anomaly in the topological string B-model. For quite a while it has been known that you can think of these topological string results as giving a vector in the Hilbert space one gets from quantizing H^3(M), where M is a Calabi-Yau. Topological M-theory is supposed to be something related to topological string theory in much the way the full M-theory is related to the full-string theory, so involves one-dimension higher. Thus it deals with 7-dimensional manifolds and tries to explain some of the phenomena related to topological strings on 6-d Calabi-Yaus in these terms. For more about this, there's a talk by Andrew Neitze on-line that covers some of the same material.

Nikita Nekrasov's talk was about "Z-theory", which is his own name for the same ideas about topological M-theory that Vafa was talking about. He drew a version of the standard picture of the M-theory moduli space, now for Z-theory and with all sorts of mathematical objects attached to the various cusps. Nekrasov gave a similar talk in Nagoya late last year, as well as one at Strings 2004.

While a lot of interesting mathematics has come out of topological strings, the idea that that there is some grandiose unification involving thinking about 7d G2-manifolds seems to me even less promising than the idea of 11d M-theory itself, which for years now seems to have gone nowhere. Just as M-theory has led many physicists to pointless wanderings in 11-dimensions, it now seems to be leading mathematical physics away from rather rich mathematical areas into the complicated geometry of seven dimensions. Undoubtedly this will lead to some new mathematics, but it looks to me like it will be much less interesting than the mathematics emerging from string theory during earlier periods. The interaction between mathematics and physics remains dominated by the ideology of string/M-theory, and this is harming both subjects.

One aspect of the sad state of the interface between math and physics is that virtually no one from the physics department at Harvard seemed to be attending the JDG conference lectures. I'd been expecting to see at least Lubos Motl there, but he was down at Columbia attending a meeting on string cosmology. He reports on the talks here, here, and here, as usual covering very critically a talk on loop quantum gravity, quite uncritically one about the landscape and absurdly baroque constructions that try to make some contact with the standard model. I'm beginning to believe that his "leashing" did have something to do with his criticizing the landscape ideology too vigorously, since he seems to have stopped doing that.

For the latest on the landscape, see a recent talk by Lubos's senior colleague Arkani-Hamed (whom he better not piss off too much) at the PHENO 05: World Year of Phenomenology symposium in Wisconsin, entitled The Landscape and the LHC. Arkani-Hamed's talk begins with the usual strained historical analogy, this time a long and bizarre description of the calculation by Aristarchos of the distance to the sun by the method of parallax. The point of this is highly obscure, but seems to be that since Aristarchos was wrong to find unreasonable the huge distances to the stars implied by the lack of visible parallax, we're wrong to find unreasonable the huge amounts of fine-tuning required by split supersymmetry.

He goes on much like Susskind for quite a while about the glories of the landscape idea, with the twist that supposedly split supersymmetry is "sharply predictive". The only "sharp" predictions he mentions concern a relation between some coupling constants which haven't been observed and likely never will, as well as that there may be a "long-lived" gluino. Not that he actually has a prediction for the mass or lifetime of this gluino.

   May 21, 2005

   Re: Lubos, I'm sticking with the PC violation story. But it's probably also true that he had best not offend his natural and most crucial constituency.

2. **D R Lunsford**
   May 19, 2005

   Back to "projective Dirac operators" this must imply giving up on an agreed upon length scale, so it's making a definite statement about mass (which is really an inhomogenous term in the Dirac equation). And there is an implicit statement about matter currents, or really charges, requiring a coupling that is consistent with no given scale. And so this is a definite statement about charges.

   -drl

3. **Juan R.**
   May 18, 2005

   G2 manifolds are not the true geometry of the universe. They continue to be a standard geometry, even when they are not well-understood still by mathematicians.

   I agree with you, Peter, on that the new folk will not provide any significant contribution to our physical ideas about nature in despite of so-many speculation and grandilocuents claims were posted by Schwartz and company.

4. **fysix**
May 18, 2005

You criticize the talk of Nima Arkani-Hamed at Pheno05 at UW-M . Checking the original paper (hep-th/0405159, title too long 😉 by N. A.-H. and Savas Dimopoulos I would rather say that this kind of “orthogonal” thinking should be welcomed rather than condemned.

5. **D R Lunsford**
May 17, 2005

“In March 2005”

-drl

6. **Carl Brannen**
May 17, 2005

I attended the talk by Arkani-Hamed on the landscape. There were quite a lot of talks having to do with landscapes at the conference.

Based on my observations of the audience, and the questions or lack thereof, I got the impression that most of the attendees were interested in more traditional elementary particle theory and experiments. Gia Dvali also gave a plenary talk on “attractors in Landscape”. To have plenary landscape talks in a phenomenology meeting was a bit silly.

My own talk was a speculation on the nature of the high energy cosmic ray “Centauro” events having to do with Clifford algebra and a hidden dimension.

Carl

7. **Peter Woit**
May 17, 2005

Note that I wasn’t claiming this stuff was related to physics. For one thing I don’t think Singer et.al’s “projective Dirac” operator is anything local. You need to look at their paper to see exactly what it is.

8. **D R Lunsford**
May 17, 2005

“Projective Dirac operators” – wow that implies a lot of questions…

What’s the adjoint? would probably be #1

How does it couple to mass and matter? #2 #3

etc.

String Theory and Theology at the AAAS

May 18, 2005
Categories: Uncategorized

Someone wrote to me today to tell me that Harvard's Nima Arkani-Hamed recently gave a lecture in Washington with the title "String Theory — Can We Test It?". Somehow, I suspect that his lecture didn't really give an honest answer to the question, since it would be hard to fill up an hour-long talk by just saying "No".

Looking into this more carefully, it turns out that the talk was part of a "Dialogue on Science, Ethics and Religion" sponsored by the AAAS. At first I thought it was unusual to see a "Science and Religion" program paid for by anyone but the Templeton Foundation (for more about them, see here and here), but it turns out that they are the first organization listed in the list of those providing financial support for the program. I wouldn't have guessed that the AAAS was in bed with Templeton and running programs on "Science and Religion", but this kind of thing doesn't surprise me anymore.

Arkani-Hamed's talk was entitled: Naturalness versus the Superstring Landscape, or, Why Does The Universe Appear Finely Tuned? (not sure why it was advertised with the "String Theory — Can We Test It?" title). The organizer and "respondent" was James B. Miller, an ordained Presbyterian minister with a Ph. D. in Theology from Marquette University. From the abstract it appears that the talk involved Arkani-Hamed's usual claims that split supersymmetry makes "sharp experimental predictions" for what the LHC will see (he seems to have a rather different notion of what an experimental prediction is than most scientists, much less what a "sharp" one is). He also seems to have implied that the superstring landscape scenario predicts split supersymmetry, something that actually isn't the case, or at least is only true in the sense that the landscape predicts nothing at all, and thus is consistent with anything.

   To place the religious insinuations in context, see this jeremiad by T. M. Moore, former Executive Pastor of Coral Ridge Presbyterian Church (Florida).

   —
   [Thanks to Arun (I think) for tracking this down a few months ago and posting the link in a comment on Preposterous Universe (Sean Carroll's blog).]

2. May 18, 2005

   Here is an explanation. NAH is a champion of a branch of (meta)physics that can be summarized as "everything goes": large extra dimensions, ghosts, supersymmetry without supersymmetry,
   you name it. Indeed, in the absence of experimental data, such nonsensical, loophole-filling ideas cannot be disproved.
   But every human being needs structure: thus he turns to God for guidance. I am sure that ksh95 would provide an eloquent description of this supernatural phenomenon.
   Jean-Paul

Game Over

May 18, 2005
Categories: Uncategorized

Shamit Kachru (described by Lenny Susskind as the "master Rube Goldberg architect") and collaborators have a new paper out this evening on flux compactifications, one that in a rational world should finish off the subject completely. Recall that Kachru is one of the K's responsible for the KKLT construction of these flux compactifications that stabilize all moduli, and for the last couple years debate has raged over whether this sort of construction gives 10^{100}, 10^{500} or even 10^{1000} possible string theory vacuum states.

Susskind, Arkani-Hamed, and other anthropic principle aficionados have argued that the fact that this number is at least 10^{100} is a great triumph because it means that there are so many vacua that at least some will have small enough cosmological constant to be consistent with our existence. But if there are too many, all hope of getting predictions out of string theory disappears. With 10^{1000} vacua, you can find not only the cosmological constant you want, but probably any values of anything particle experimentalists have ever measured or ever will measure, and the theory becomes completely unpredictive.

Even so, the study of these vacua has become more and more popular over the last year or two, with many arguing that, no matter how big the number is, at least it's finite, so you have improved over the standard model, which has continuously tunable parameters. This argument was made in the panel discussion at the Perimeter Institute a month or so ago. Also, a finite number of vacua allows you to study their statistics, by assigning a weight one to each possible vacuum state and getting a probability measure by dividing by the total number. You can then engage in wishful thinking that this probability measure will be peaked about certain values, giving a sort of prediction.

The new paper gives a construction of flux compactifications of type IIA string theory, and in this case the authors find an infinite number of possibilities. This should kill off any hopes of extracting predictions from string theory by counting vacua and doing statistics. The authors try and put a brave face on what has happened, writing:

"we should emphasize that the divergence of the number of SUSY vacua may not be particularly disastrous. A mild cut on the acceptable volume of the extra dimensions will render the number of vacua finite."

but then they go on to puncture their own argument by noting that:

"one can legitimately worry that the conclusions of any statistical argument will be dominated by the precise choice of the cut-off criterion, since the regulated distribution is dominated by vacua with volumes close to the cut-off."

With this new result, the infinitesimally small remaining hope of getting predictions out of the string theory landscape framework has now vanished. It will be interesting to see if this slows down at all the ever-increasing number of string theorists working in this field.

Update: Lubos Motl has some comments about this same paper.

   I said,

   I don't know the level of new students doing PhD and all of that in string theory. Do you know Peter?

   By "level" i mean "the number of"

2. **Juan R.**
   May 22, 2005

   Peter said:

   "No intelligent young person is going to go into this field as long as it is obviously an intellectual disaster area."

   I am not completely sure. Month ago, a joung math student contacted with me for solicintg more information in my open criticism of string theory.

   He was rather misguided in a lot of points. I explained my points, but he remained skeptic. For example, he said that was not true my claim that string theory was substituing the around 20 parameters of SM by more than 10000 new ones. He claimed that Brian Greene's "Elegant" book said that one single parameter was sufficient.

   I explained to him that string equation parameter was valid for "predictions" on 10D, for real 4D one need compactification and all, a priori, predictive power is lost.

   He remained skecptic. He said that if I was saiyng was true, then Brian Greene had said that in his book. !!!!!!

   Some people doing PhD and after leaving the field has contacted to me and agree with my valoration of string theory like a waste of time. I abandoned my string-brane research some time.

   I don't know the level of new students doing PhD and all of that in string theory. Do you know Peter?

3. **Dmitriy**
   May 22, 2005

   Hi Peter,

   What makes me especially nervous, it's the fact that almost everyone looks for physics _beyond_ the Standard Model. Everyone is eager to find its failure. This is nonsense to me. I always thought that a scientist wants to understand nature and I would never expect that he would like to see his model of the world failed. I'm afraid it's all about money.

   May 21, 2005

   Offhand I can't really think of many promising "new" fields that a post-1984 tenured string theorist could possibly defect to, other than maybe conventional *particle/astroparticle phenomenology or some area in condensed matter theory.*

Perhaps we should delete the last twenty years from memory and go back to the way we were then. What kid of things was people doing before the upsurge of string revolutions?

I think we were studying the non abelian anomaly in order to use it somewhere in QCD… was it because the glue? Or something of the chiral limit?

Also for sure there was someone there still thinking about flavour. Well, perhaps only H Fritzsch in Germany.

There was also detectability of new particles via their interaction with nucleus. Witten and Goodman on dark matter for instance. As well as some low-energy theorems for the Higgs boson.

5. **Peter**
May 21, 2005

I certainly agree that the whole string theory phenomenon is due to HEP being a victim of its own success. Until someone does an experiment which disagress with the standard model and gives a clue how to get beyond it, things are going to be very tough.

But this is no excuse for getting stuck in an endless investigation of one speculative idea about going beyond the standard model, one that has clearly failed. It is amazing to see how unwilling people are to abandon an idea they have a lot of time invested in, no matter how clear it is that the idea can't work.

6. **Dmitriy**
May 21, 2005

Hi everyone,

don't you think that all the problems of string theorists are mostly due to overall stagnation of HEP as a field. There is nothing really new found in an experiment (beside maybe the mass of neutrino, which hardly changed anything) and I doubt that anything can be found at LHC beside maybe Higgs. Without experimental data people are just doomed to either leave the field until any intersting data is available or do "math". It's clear that we are way too far from energies when quantum gravity effects can be of any significance. So overall I don't see why string theory approach is better or worse than any other quantum gravity theory.

But even this is not a big problem. What really looks bad is a typical career path that one has to follow to stay in physics. There is no room for mistakes. The competition for a permanent faculty position is so tough that hardly anyone who doesn't have tenure would risk to switch a field just because he thinks that the field is going in a wrong direction. It takes many years to get a certain level of compitence to do anything sensible. I'm afraid we just work too much and don't have much time to think.

7. **Tony Smith**
May 20, 2005

In a comment to his string theory blog "Game Over", Peter says "… string theory … is obviously an intellectual disaster area.".

I am reminded of a story mentioned in another of Peter's blog entries about Hilbert and Heisenberg. According to Thall's History of Quantum Mechanics, at http://mooni.fccj.org/~ethall/quantum/quant.htm :

"… Hilbert suggested to Heisenberg that he find the differential equation that would correspond to his matrix equations. Had he [Hesenberg] taken Hilbert's advice, Heisenberg may have discovered the Schr?dinger equation before Schr?dinger.
When mathematicians proved Heisenberg's matrix mechanics and Schr?dinger's wave mechanics equivalent, Hilbert exclaimed,

"Physics is obviously far too difficult to be left to the physicists …" …".

Since the string theorists seem to be becoming an obstruction to the advance of physics, and since JC said a comment on Peter's blog:

"… Only … scenario … which could possibly cause a huge landslide exodus from string theory, is if the government grant agencies (ie. DOE, NSF, etc …) all decide to stop funding …",

I have a suggestion. Perhaps the black-budget programs of the USA might be expanded to include a well-funded space exploration and colonization program in which a large human colony is sent into space to contact other civilizations on some of the newly discovered extrasolar planetary systems. Since the colonizers will be the ones who form the aliens' first impressions about humans, the colonizers should be only the best and the brightest so that the aliens will be dazzled by the brilliance of humanity. Obviously that means that the ship should carry all the most outstanding superstring theorists, who would be honored to be chosen. In order to impress the aliens even more, the aliens should be deceived into thinking that humanity back on earth included some who were even more brilliant than the best-and-brightest superstring theorists. Therefore, the ship carrying the superstring colonists should be modestly named something like, for example, the B Ark.

Tony Smith

8. **JC**
May 20, 2005

Peter,

Only other scenario I can think of offhand which could possibly cause a huge landslide exodus from string theory, is if the government grant agencies (ie. DOE, NSF, etc …) all decide to stop funding any string theory research.

It would be interesting to see what types of future papers will cite this particular Kachru et. al. paper hep-th/0505160

Offhand I can't really think of many promising "new" fields that a post-1984 tenured string theorist could possibly defect to, other than maybe conventional particle/astroparticle phenomenology or some area in condensed matter theory. I can't really see many string folks suddenly defecting to loop quantum gravity, nor to many of the other camps working on various partisan approaches to "quantum gravity".

9. **Peter Woit**
May 20, 2005

Hi JC,

What's really amazing to me is how string theorists refuse to give up, no matter how bad it gets. At this point it's completely clear that the idea of string theory based unification is dead, but no one seems to be giving up anyway. The attitude is "we're going to keep doing this until someone gives us a new fad to work on", but there is no encouragement at all for anyone to try and find something new. String theorists still will only hire string theorists.

I don't see anything changing unless Witten comes up with something new. Increasingly the people who got tenure pre-1984 and know about something other than string theory are getting old. Those who got tenure post-1984 more and more often don't know about anything except string theory, and have no interest in learning. No intelligent young person is going to go into this field as long as it is obviously an intellectual disaster area.

10. **Thomas Larsson**
    May 20, 2005

    *So I somewhat marvel that people aren't more interested in the old fashioned stringy models or even the more modern brane world stuff. No one has outputed a no go theorem on the small/positive cc for those classes of theories, so why aren't people still looking for whatever *that* may be.*

    I think that no-go theorems more or less exist. If you want to use AdS/CFT, it is certainly a problem if the CC is positive, since that rules out the AdS part. People have tried to invent some kind of dS/CFT, but AFAIU the CFT must then live at temporal negative infinity, which apparently is problematic and usually a discarded possibility.

    Don't forget that there are other problems, too. Without flux compactifications you have at least one unbroken SUSY and unstabilized moduli, i.e. new long-range forces, in disagreement with experiments, right?

11.
    May 20, 2005

    While not defending the Landscape approach to phenomenology, the point is that string theory contains these flux fields, they may be turned on, and so the number of possible supersymmetric vacua is much larger than previously imagined. As far as other approaches are concerned, people use flux vacua to construct brane worlds that are on a more solid theoretical footing, i.e. with all moduli stabilized and with an acceptable final cosmological constant. Once you've found the possibility of turning on flux, you can't pretend that it doesn't exist. What this indicates, to me at least, is that finding a useful (testable) string phenomonology will involve more than finding a proper vacuum, and will most likely involve cosmological dynamics. Finally, Occam's razor is fruitfully applied to starting points (two examples being Einsteins equations or the replacement of particles with strings) and really doesn't apply to solutions (all gravitational solutions in one case or all possible vacua in the other)

12. **Fred**
    May 20, 2005

    What I have never understood about the landscape business. Why exactly do people take flux compactifications so seriously if this is what it outputs, eg an unpredictive mess?

    There are many potential models in String theory, many Brane inspired models and what not. I take it the former is the only one (to date) that has outputed a small and positive CC. However typically the tradition in physics is, if its too messy move on and find something else. Typically (a variant of Occams razor) that turns out to be the simplest and invariably the correct answer (even if nothing has been discovered that fits the bill, we usually assume the universe is governed by simplicity).

    There have been many theories that have been discarded in physics b/c of this premise, even before whatever else replaces *it* has been discovered.

    So I somewhat marvel that people aren't more interested in the old fashioned stringy models or even the more modern brane world stuff. No one has outputed a no go theorem on the small/positive cc for those classes of theories, so why aren't people still looking for whatever *that* may be.

    It seems to me String theory is still alive and well, its just that many of its practioners have abandoned a perfectly sensible attempt at understanding qg, with a weaker phenomenological theory that clearly doesn't cut it.

13.
    May 19, 2005

    I have a theory that Quantoken is a monkey. For proof, look at his typing skillz.

14. **Quantoken**
    May 19, 2005

    Correction.

    I said: "Most of the monkey patents would look like completely garbage. But it's OK. We can eliminate most of them by the **anthropic principle**."

    On a careful thought, I would replace it with **Monkey Principle**. That would also be what I call what string theoretists call anthropic principle. I call it **monkey principle** 🙂

    Quantoken

15. **Quantoken**
    May 19, 2005

    Peter said:
    "Susskind, Arkani-Hamed, and other anthropic principle aficionados have argued that the fact that this number is **at least 10^100** is **a great triumph** because it means that there are so many vacua that at least some will have small enough cosmological constant to be consistent with our existence."

    Hey I would suggest something much better than 10^100 cavuas, I call it **the monkey theory**, a true **theory of every thing**. And this theory is **absolutely correct and permanently safe** from being falsified.

    Very simple, you just allow a monkey to hit a keyboard arbitrarily for a little while, and then repeat again, and try again. The possible number of monkey patents it may come up with is definitely limited, something between 4^4^4 and 6^6^6, which definitely look better than 10^1000 vacuas.

    Most of the monkey patents would look like completely garbage. But it's OK. We can eliminate most of them by the anthropic principle. The correct monkey patents would at least make some sense in English. And certainly, once in a while it may come up with something that reads like "F=MA" or "E=MC^2", which happen to be the correct physics theory.

    What's the odd of a monkey type 6 letters and it happen to be "**E-MC^2**"? It's certainly not zero, and roughly one out of 10^11. That's certainly a much better odd than one in 10^100 vacuas being the correct one!!!

Just allow the money keep typing, it eventually give you all monkey patents that is conceiveable. Any correct and incorrect theories we human can think about in the past and in the future million years, would all eventually come out of the monkey typing machine. Theory of every thing, every theory of thing, every theory of every thing, every every theory of thing, they will all come out with pretty good odds, not just a TOE.

And it is verifiable experimentally!!! Actually as I have demonstrated I can make **"very sharp predictions"** out of this theory. I predicted that "E=MC^2" can come out of it with an odd of roughly 1 in 10^11. It's not observed experimentally yet, but no one will doubt it. It is only that we do not have enough monkeys, (or in another word we do not have enough string theorietists to study all of the 10^100 cavuas).

You see, my monkey theory definitely beats string theories already 🙂

Quantoken

16.
May 19, 2005

there are more (vacua) in heaven and earth than are dreamt of in your philosophy.

17. **Juan R.**
May 19, 2005

JC,

"How fast do you think people will abandon the field?"

I replied to this in another part.

With each new failure of stringy endeavour, string adherents begin a new, more arrogant, folk tale.

The history that i write is not exact but one could say that with the failure of ST like a theory of the strong, they claimed that also was a theory of gravity. With the failure of first versions of "superST", claimed that was also a theory of rest of interactions and particles. With the failure, they claimed that M theory was the theory of everything, from particles or gravity to cosmology, big bang, and other universes newer observed but "living" in some "part". M-theory was also the basis for some eccentric topics like aliens (Kachu), extrasensorial perception, would reformulate QM eliminating its present weird state (Witten), etc.

I think that they will interpret the failure of M theory like a symptom of that the theory was conservative in excess. Probably it was a **theory of more than everything** and that would explain the current failure 🙂

18.
May 19, 2005

String Theory appears to be a toaster. M-theory however, though lacking in real physics, is nonetheless going somewhere.

19. **JC**
May 19, 2005

Peter,

If this is indeed "game over" and string/M-theory is not a mysterious space ship but really a toaster, how fast do you think people will abandon the field?

20. **Anonymous**
May 19, 2005

But these are vacua where SUSY is unbroken, right? Shouldn't one expect infinitely many, since there are moduli spaces of SUSY theories? Isn't what matters the number of non-SUSY vacua?

21. **D R Lunsford**
May 19, 2005

April is the cruelest month, breeding
Didacts out of the dead landscape, mixing
M-ory and D-sire, stirring squareroots with string pain.

22. **Not a Nobel Laureate**
May 19, 2005

Remarkable how much trouble one can get into by taking the simplest object beyond a point, a string and applying the constaints of quantization and relativity.

"This is how String Field ends,
Not with a Bang, but
With a Whimper."

[Sorry T.S. Elliot]

23. **D R Lunsford**
May 18, 2005

The CC is zero. It's an artifact of decoupling of light and gravity.

US HEP News

May 19, 2005
Categories: Uncategorized

The US High Energy Physics Advisory Panel (HEPAP) is meeting in Washington yesterday and today, and some of the presentations are already available on-line. These include one from the DOE Office of High Energy Physics which notes that, given budgetary constraints, the only way significant funds will become available for new projects (including significant work on the proposed ILC linear collider), is by shutting down operations at the Tevatron or PEP-II. The Tevatron is now scheduled to operate until 2009 (at which point it can't compete with the LHC), PEP-II at SLAC until 2008. The DOE is asking the P5 committee to advise about whether or not it might be a good idea to shut these facilities down early, and redirect the funds that are freed up elsewhere.

There are also reports on the status of PEP-II and the Tevatron. PEP-II and other accelerators at SLAC were shut down after an accident last October, only turned back on last month. The plan now is to run the machine steadily until July 2006, with only a one-month break in October. Presumably it's down today, since if you try and connect to the SLAC web-site, you get a message saying that power is out at SLAC due to a tree falling and severing the main power feed to the site.

The Tevatron is doing well this year, recently achieving record luminosity, and its integrated luminosity so far this year is running ahead of even optimistic projections. It seems highly unlikely to me that the P5 committee will suggest shutting it down early.

There's also a report from the ongoing National Academy of Sciences EPP2010 study of the future of US particle physics. Presentations from a meeting earlier this week at Fermilab are now available. These include presentations dealing with what is going on outside the US, including ones from DESY in Germany and KEK in Japan.

The biggest issue facing US particle physics is what to do about the International Linear Collider (ILC) project. In the presentation of Michael Witherell (ex-director of Fermilab), he notes that the world is in a transition from having five major labs running the largest accelerators to possibly only two: CERN with the LHC, and wherever the ILC is sited, if it is built. For US experimental high energy physics to remain a world leader, it is crucial that the ILC be built, and built in the US. Witherell recalls how the US HEP budget has declined by $100-150 million in real dollars over the last few years, but then gives a plan for the future that involves this budget increasing by 4% over inflation every year, something I find hard to believe is going to happen. The EPP2010 site also contains feedback they have received from various members of the community in response to questions about plans for the ILC.

In other experimental HEP news, the Experimental High Energy Physics Job Rumor Mill has been revived, joining the Theoretical Particle Physics Jobs Rumor Mill. Send them both your inside information!

Comments

1. **loser**
   May 21, 2005

   Speaking of pork, and directed to the first comment, the DeLay-Frist wing of the GOP is a lot of heat and flash, but is losing political capital rather quickly and will badly need to do horsetrading just to stay elected next year.

   Consider instead who IS speaker of the house, has been the speaker, and who will probably BE the speaker for the next 3-5 years. And what national accelerator lab is in his district? Hmmmm….

2. **loser**
   May 21, 2005

   Scuttlebutt is that since SLAC's high energy star is falling, BES will move in over the next couple years to completely take over SLAC, with LCLS as the star attraction. So that might accelerate their demise as a HEP lab.

   Fermi is clearly pushing hard to be in a strong position when siting for ILC is decided.

   Also, NANL: guess again. The NIH budget is tapering off now also. Pork is where it's at.

3. May 21, 2005

   Here we are now – entertain us

4. **Not a Nobel Laureate**
   May 19, 2005

   "Witherell recalls how the US HEP budget has declined by $100-150 million in real dollars over the last few years, but then gives a plan for the future that involves this budget increasing by 4% over inflation every year,"

   In your dreams, Mikey, in your dreams.

   That money is going to medical research now as the Boomers begin to confront their mortality.

5. May 19, 2005

   Well, for the ILC to be built in the US, it's clear that for political reasons it would have to be located in Texas, and in particular within one of DeLay's gerrymandered congressional districts, which would conflict with the "linear" requirement.

Stalking the Riemann Hypothesis

May 22, 2005
Categories: Book Reviews

My friend Dan Rockmore has a new book out, entitled Stalking the Riemann Hypothesis, which is quite good. Dan had the misfortune of starting work on this book at the same time as several other people had the idea of a popular book about the Riemann Hypothesis. For better or worse, his has appeared after the others, which came out last year. In solidarity with him, I haven't read the others, so can't directly compare his to theirs.

Dan's book begins with a mixture of history and explanations of the math involved. In the sections having to do with more recent work, he concentrates on one particular approach to proving the Riemann hypothesis, an approach that has interesting relations to physics. This involves an idea that goes back to Hilbert and Polya, that one should look for a quantum mechanical system whose Hamiltonian has eigenvalues given by the Riemann zeta-function zeros. Self-adjointness of the Hamiltonian then corresponds to the Riemann Hypothesis. This conjecture has motivated a lot of the research that Dan describes in detail, including relations to random matrix theory, quantization of chaotic dynamical systems, and much else.

Philosophically, I'm very fond of the idea that quantum mechanics is basically representation theory, and that the way to produce interesting quantum mechanical systems is by using geometric constructions of representations using cohomological or K-theoretic methods. While I'm no expert on the Riemann Hypothesis, my favorite idea about it is that proving it will require a mixture of the Hilbert-Polya search for a quantum mechanical system, together with the cohomological approach that worked in the case of function fields. In that case, the Weil conjectures famously were based on the idea of constructing an appropriate cohomology theory. This was carried through by Grothendieck and others during the fifties and sixties, with Deligne finally using this technique to get a proof in the early seventies.

For the number field case, the most developed conjecture that I know of about what might be the right sort of cohomology theory is due to Christopher Deninger. He has a very interesting recent review article about this, see also his lecture at the 1998 ICM.

Update: For another nice discussion of zeta-functions and the Riemann Hypothesis, see John Baez's latest This Week's Finds.

Update: There's a nice article in the Washington Post about Dan and his book.

3. **Peter Woit**
   May 27, 2005

   I'm not sure exactly what Dan meant by "ill-defined" in this case. The Clay problem is trying to ask for a big breakthrough in what one can rigorously say about the solutions of Navier-Stokes, but since this is hard to define, they give four examples of specific theorems whose proof would count.

   I have looked recently at the de Branges paper. The first version had some intriguing mentions of quantum mechanics and listed Weyl's Group theory and quantum mechanics book as a reference (although the reference didn't correspond to anything in the text). These have been removed, but the rest of the paper looks much the same, although I don't have the old version to compare to.

4. May 27, 2005

   About De Branges proof….you say you tried to read it. Have you read it recently? it seems to be dated April 2005.

5. May 27, 2005

   Peter, you friend says on that post article that navier-stokes is "ill defined". What exactly does he mean by that?

6. May 25, 2005

   Since Riemann Zeta is perhaps the most fundamental function of the complex analysis, it would not be too surprising if conformal invariance would be involved with the proof of Riemann hypothesis.

   It is easy to find support for this intuition. The eigenfunctions of the scaling operator L0=t/dt with t in R+ come as functions
   t-s with eigenvalue given by λ=-s. For integration measure dt one obtains a counterpart of plane wave basis by assuming the complex conformal weight to be s= 1/2+iy implied by Riemann hypothesis. This easy to see by taking u=log(t) so that inner product transforms to an inner product of plane waves exp(iy1u) and exp(-iy2u). Zeros and also linear combinations of zeros of zeta with integer coefficients would define conformal weights for a discrete basis of a Hilbert space. If the real part of the conformal weight differs from 1/2, the functions in question diverge exponentially at the limit when u goes to +∞ or -∞. Obviously Riemann hypothesis is very natural in this context.

My own proposal for the strategy of proving Riemann hypothesis is however based on the idea that Riemann zeta at line Re[s]=1 defines an inner product for eigen functions of a modified operator L0 representing non-Hermitian operator analogous to an annihilation operator and having zeros of zeta as its complex eigen values. These functions define a generalization of coherent state basis rather than that of an orthogonal state basis as in the case of Hilbert-Polya conjecture.

This means that their inner products are non-vanishing and proportional to the values zeta (z1+z2*) and thus proportional to zeta(1+i(y1-y2)) for the eigen values at critical line (note that zeta diverges at s=1 but this is actually not a problem). Riemann hypothesis guarantees the orthogonality of states with conformal weights s=1/2+iy to a negative norm state having a vanishing conformal weight s=0. This condition would exclude non-critical complex zeros and I have proposed a reductio ad absurdum argument for a proof of Riemann hypothesis in the article Pitkänen (2003), *A Strategy for Proving Riemann Hypothesis*, Acta Math. Univ. Comeniae, vol. 72.

The article can be also found at my homepage

The complex conformal weights appearing as linear combinations of imaginary parts of non-trivial zeros of zeta have a key role in TGD. Since physical states must have real conformal weights this gives rise to conformal confinement forcing many particle systems to behave like single quantum coherent units. There are physical motivations for the proposal that dark matter corresponds to a conformally confined quantum coherent phase in which ordinary particles have complex conformal weight.

The gluonic color glass condensate observed in RHIC behaving like liquid rather than quark gluon plasma and having black hole like properties could be one instance of this phase associated with a highly tangled color magnetic flux tube in Hagedorn temperature defining the hadronic analog of black hole with effective gravitational constant corresponding to hadronic length instead of Planck length.

May 24, 2005

A bit like string theory, no?

Not very much, actually. Each of the many ideas floating around about the Riemann Hypothesis is being pursued by a small number of people, which is a quite healthy situation. In particle theory, one speculative idea (string theory) is being pursued by thousands of physicists, and it remains very difficult to get a job doing mathematically based particle theory research unless you are willing to do string theory. And if any speculative idea about the RH had failed as miserably as string theory unification has, it would have been long ago abandoned by everyone involved.

10. **Levi**
May 24, 2005

Two comments:

1/ For mathematically literate readers (e.g. nearly all of the readers of this blog), the best introduction to the Riemann Hypothesis is the book "Riemann's Zeta Function" by H. M. Edwards. Very readable, although you can't zip through it like a novel. And it's a Dover paperback so it's cheep.

2/ The approach Peter mentions is promising, but a lot of smart people have been pursuing it for quite a while without success. A bit like string theory, no? Maybe physicists will have to learn to be as patient as mathematicians.

11. **anon**
May 24, 2005

My guess would be that the proof of the Riemann Hypothesis would rely on something vaguely similar to Deligne's proof of the Weil Conjectures (the last conjecture,R.H. over finite (?) fields) in that some similar mathematics for Deligne's proof would be necc. for the RH. So I'd guess it'd demand a lot of stuff from Grothendieck. OR, something else…

My wild guesses are about as good as anybody else's out there…

Why cast aspersions, Tony? De Branges' paper is there for everyone to see. Download it, and see for yourself if the proof is valid.

13.
May 23, 2005

One of deBranges' former PhD students (Li) immediately posted a paper on the arXiv indicating an error in deBranges' argument.
D. Jerison at MIT read de Branges' paper carefully after his announcement, and if I remember correctly gave a seminar talk about it.
The subsequent lack of interest in the paper has to do with the contents of the paper and de Branges' failure to address or acknowledge the criticisms, not any particular prejudice of "Western" mathematicians (Li is Chinese, and Jerison an American, by the way).

There are certainly people who work publically or privately on the Riemann hypothesis, such as Sarnak, Connes, Cohen, Deninger, not to mention pretty much the entire analytic number theory community. The people other than deBranges who do this, generally manage to remain credible over the years.

Rockmore's book tries too hard to avoid formulas, in my opinion, and is interesting (though not necessarily to the general public) mainly for the academic gossip therein.

14.
May 23, 2005

Silly nitpick: While Wiles announced the proof at Cambridge, his official appointment at the time was at Princeton, not Cambridge as Tony asserted

15. **Peter Woit**
May 23, 2005

Hi Tony,

The situation of Wiles and deBranges is quite different. First of all, the math community didn't work as a team to fix Wiles' proof. He fixed it himself (with some help from his ex-student Richard Taylor, after a team of referees went over the manuscript, and one found the initial error). People would have taken any purported proof of Fermat by Wiles seriously, the fact that he was proving Taniyama-Shimura-Weil just made it more interesting. The significance of Taniyama-Shimura-Weil is that it is part of the "Langlands Conjectures". These are not a fad like string theory, many of them have been rigorously proved, and they give results about number theory that are accessible no other way (e.g. why Fermat is true). They are a set of very deep structural insights into how number fields behave, and there are a huge number of concrete, rigrorous results to back that statement up.

Dan's book doesn't have much at all about deBranges, from what I remember it is one of the others that has quite a bit about him, from a sympathetic point of view. Have you looked at de Branges's manuscript? I can't speak for why others haven't made a major effort to understand it, but I tried and I can tell you why I gave up. I found it completely impossible to follow. The manuscript is not written in anything like a standard mathematical form, with the structure of the argument outlined, together with a proof of each step. From the main manuscript itself, you can't even tell that there is supposed to be a proof of the RH in there. His separate document ("Apology….") has more of an explanation of what he is doing. Maybe if you spent a lot of time trying to read that first, you might have a fighting chance of figuring out what argument he is trying to make.

The case of Wiles is very different. His argument was laid out completely clearly and explicitly, so that anyone who was familiar with the technical tools he used could easily follow what he was doing. And if you weren't familiar with the technical tools, it was explicit what they were, and you could go out and read up on them elsewhere.

I have some sympathy for the idea that de Branges may actually have a proof, or enough of a good idea about one that maybe his ideas could be used to produce a proof. But he hasn't written up what he has in a way that others can understand, unless they are willing to do a huge amount of work to decipher what he is trying to say. There are already various reasons for people to be skeptical about whether he has a proof, and the combination of this with the fact that his manuscript is nearly impossible to follow is what explains the situation here, not any prejudice about Purdue or anything else.

16. **Tony Smith**
May 23, 2005

When I compare the Riemann Hypothesis efforts of de Branges with the Fermat efforts of Wiles, a question arises, and I wonder whether it is dealt with in the book by Rockmore.

According to a PBS interview at http://www.pbs.org/wgbh/nova/proof/wiles.html Wiles said: "… at the end of the summer of 1986 … this friend told me that Ken Ribet had proved a link between Taniyama-Shimura and Fermat's Last Theorem. … I knew that … to prove Fermat's Last Theorem all I had to do was to prove the Taniyama-Shimura conjecture. It meant that my childhood dream was now a respectable thing to work on. … in late May [1993] … Then I told ….[my wife]… I'd solved Fermat's Last Theorem. … I'd missed … an error … completely …".
The Nova interviewer said: "… Eventually, after a year of work, and after inviting the Cambridge mathematician Richard Taylor to work with you on the error, you managed to repair the proof. …".

In a June 10, 2004, blog post at http://www.math.columbia.edu/~woit/blog/archives/2004_06.html Peter said: "… Louis de Branges is a mathematician at Purdue who has had a long history of claiming proofs of the Riemann hypothesis. … de Branges has a checkered history as a mathematician, with several of his claimed proofs of the Riemann hypothesis and other problems turning out to be incorrect. On the other hand, he did produce a correct proof of one well-known problem, the Bieberbach Conjecture. In that case … after he explained his ideas to a group of Russian mathematicians … it became clear that de Branges really did have a proof. It looks like this one may also take some major effort to see what he really has. …".
In a 20 August 2003 review of Sabbagh's book on the Riemann Hypothesis at
http://www.maa.org/reviews/sabbaghRH.html
S. W. Graham says: "… The conventional wisdom is that de Branges' approach will not work …".

My question is:

Why was Wiles's erroneous proof treated sympathetically by the math community, leading it to work as a team to correct the proof, while de Branges's erroneous proof is treated by the math community with hostile skepticism ?

Is it because Wiles was hanging his hat on the fashionable Taniyama-Shimura conjecture ? If so, then another question is to what extent fashion (and social construction a la superstring theory) is a driving force in the mathematics community.

Is it because Wiles was at Cambridge while de Branges is at less-prestigious Purdue ?

Is it because the mathematics community somewhat resents de Branges because his Bierberbach work showed, with the help of USSR mathematicians, that skepticism of the Western mathematics community is fallible ? Since the USSR is gone now, is there really any somewhat independent (of the West) mathematics community that might work on approaches that are ignored by the Western mathematics community ?

In other words, why does the Western mathematics community not undertake a "… major effort to see what he [de Branges] really has …". ?

"..what might be the right sort of cohomology theory"

topos theoretic descent theory

Running Scared

May 23, 2005
Categories: Uncategorized

Last Wednesday night, a paper appeared on the arXiv that spelled very bad news for the whole "Landscape" scenario of how to get physics out of string theory. This paper produced what appears to be an infinite number of possible vacuum states for string theory, ruining hopes for getting predictions out of the Landscape by doing a statistical analysis of vacuum states.

Tonight a new paper by a prominent Landscapeologist (Michael Dine) has appeared. The abstract gives no hint of trouble, claiming evidence of "distinctive predictions for the structure of soft breakings", but the beginning and the end of the paper tell a different story. The second paragraph of the paper admits that the infinite number of states destroys this research program, but deals with this by saying that the author will just ignore the problem for now:

"If this (infinite number of states) is true, many of the ideas discussed in this paper will have to be reconsidered…. the discussion of this paper will be predicated on the assumption that the number of relevant states in the landscape is finite and naive statistical ideas can be applied."

In the paper's conclusion, Dine states:

"There are many ways, as we have indicated, in which the ideas described here might fail. Perhaps the most dramatic is that the landscape may not exist, or alternatively that there might exist infinite numbers of states, whose existence might require signficant rethinking of our basic understanding of string theory and what it might have to do with nature."

I'm looking forward to Dine and others finally getting around to "rethinking what string theory might have to do with nature". It's about time.

   May 30, 2005

   Alejandro,

   I don't know what would be a precise definition of "completeness", with respect to how our brains think.

   One way I've thought of it is how marketing and advertising folks are experts at manipulating people into thinking that they are "incomplete", and that the easiest way to feel "complete" is to buy their products.

2. **Alejandro**
   May 30, 2005

   Beyond the animal fear mechanism -which, btw, happens to be the title of this blog entry-, linguists have pointed out that the repression of some grammatically correct but unnatural phrases could be in the origin of religion. So for instance "you rain", "I died". In western culture, especially the later. This remark is interesting because it asks for some extra steps of sophistication in logic. Deictics must have evolved to be able to point to the speaker, and verbal tenses need be no trivial. Thus, when logic/language evolves to be sophisticated, the pretension of completeness creates a series of conflicts that are usually solved by religion. I do not know if this inability to cope with logical conflicts is a hallmark of modern theorists or just a naive comparison…

   Ah, Tony, here there is a taoist quote for our collection (-:

   "hence they hold that '*what is not*' is no less real than '*what is*'" [Arist. Metaphys. A 4 985b4]

3. **JC**
   May 29, 2005

   Alejandro,

   It's very well understood that for most people, uncertainty produces more anxiety in their minds than in scenarios of certainty. If for no other reason, ideological/fanatical type thinking brings about a sense of certainty to someone's mind (albeit, perhaps a false sense of security). More "certainty" seems to give many people a "peace of mind", even if only at a psychological level. If nothing else, it seems to be largely a psychological coping mechanism to flee away from "danger" in the form of "predators" and/or "barbarians".

   People who are major "control freaks" seem to fall into the pattern of only feeling "secure" in themselves if they have total certainty and control over the things in their lives which they have direct control or access over. Control freaks seem to go ballistic when their sense of self certainty and/or control becomes more uncertain.

   In the case of religion, perhaps the sense of a "god" looking over us and being the ultimate explanation of almost everything in the world, is what gives followers and believers a higher "certainty" outlook in life. Explanations of things happening by random chance and/or "shit happens" at random, doesn't quite have the same "warm fuzzies" feeling as explanations like "god's will".

   I'm not really sure how this would apply to something like string theory, unified field theories, etc … other than perhaps these "theories" produce a false sense of "theoretical" certainty in the minds of the people working on them. (Whether their theories are right in the end, is a completely different question altogether).

4. **Alejandro**
   May 29, 2005

   Yes Tony, this blur betwean creator and created is a hallmark of the approach to religion of a lot of scientists, and probably the only way for them to keep a religion while being productive in science. And this approach is already heretic for most established religions. But I believe that the acting scientist climbs a new step when s/he becomes aware that the scientific study of the description of the world has wiped away any fear of future or death; in such state religion does not have any role to fulfil anymore, and it becomes unnecessary.

   (Incidentally, and as a less ambitious example, I have always though that a reason for physicists to be good at Banking and Finance is that they do not have the same faith in money that economists have.)

Going back to topic, I wonder this view, of Faith as an analgesic against Fear, could be applied to analize String Theory from the positions claimed by Juan R.and JC. We should inquire which Fear are theorists trying to exorcise.

5. **Tony Smith**
May 28, 2005

Alejandro said "… that the continuous application of science and reason drives one towards Epicureim … while Western pre-chemists declared themselves as disciples of Leucipo and Democritus (thus Epicurus?), Eastern pre-chemists declared themselves as disciples of Lao-Tze, and then users of the Taoist inspiration. …".

I tend to agree with Prof. Cooper's course outline for Philosophy 335 on the web at http://www.princeton.edu/~johncoop/Phil335/Phil335.html where it says: "… the two main post-Aristotelian or (as they are more usually called) Hellenistic schools of philosophy, [are] the Epicurean and the Stoic. …", and I tend to agree with Stoicism as described at http://www.geocities.com/Athens/Delphi/8309/philosophical.html where it says: "… What is referred to in Stoic writings as "Zeus" in one place, may be referred to as "Nature" elsewhere. … there is still little distinction between creator and created, or between physical and spiritual. The Stoic worldview is thus closer to that of Daoism, Vedanta or some varieties of Sufism than to orthodox Christianity or Islam. …".

It seems to me that the "reading Nature book" approach has worked well in some instances, such as Einstein's development of special and general relativity, and that such an approach need not necessarily lead to Epicurus, but might as well lead one to Stoicism/Daoism, or also to the Hegelian Dialectical Materialism of the Nagoya school in Japan that motivated Kobayashi and Maskawa in their formulation of a 3-generation model that explains, among other things, CP violation.

Tony Smith

6. **Alejandro**
May 28, 2005

Well, probably the Spinozian/Eistenian view is heretic for most of the established religions. G-d aware scientists have usually tried the "reading Nature book" approach in order to justify their research in the inner works of Nature, but it has not worked very well. It seems that the continuous application of science and reason drives one towards Epicureim, in the sense preached by Lucretius.

Which is not bad, because if the goal of religion is to calm soul anguish and fears, it can be told that acting by Science and Reason also do a good work.

About symbolism, it is interesting that while Western pre-chemists declared themselves as disciples of Leucipo and Democritus (thus Epicurus?), Eastern pre-chemists declared themselves as disciples of Lao-Tze, and then users of the Taoist inspiration.

7. **Tony Smith**
May 28, 2005

If Alejandro is correct in saying: "… Probably the use of "religious" by JC there was implied to mean "based on faith, irrational, inaccessible to human reason"….", then JC's position would be in direct opposition to that of Einstein, to whom "religious" means "… at least to a certain extent, accessible to human reason. …".

Personally, I prefer Einstein's definition, but it may be that many people prefer the definition attributed to JC by Alejandro.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

8. **Alejandro**
May 28, 2005

Probably the use of "religious" by JC there was implied to mean "based on faith, irrational, inaccessible to human reason".

9. **Tony Smith**
May 28, 2005

JC referred to "… the mindset of people working on "unified field theories", resembling religion …" in the derogatory context of "… "physics envy" … "theory" in the social sciences …".
I think that such derogation of "mindset … resembling religion" in working on "unified field theories" is unfortunate and misguided.
For instance, it is well known that Einstein, who worked on "unified field theories", said: "I believe in Spinoza's God who reveals Himself in the orderly harmony of what exists … I have not found a better expression than 'religious' for the trust in the rational nature of reality that is, at least to a certain extent, accessible to human reason. …". Even though Einstein did not succeed in his search for a "unified field theory", he did accomplish some useful things, including general relativity, along the way.

Some other attempts at constructing "unified field theories", such as GUTs, supergravity, and superstring theory may have also failed in that they have not produced a model with the content of gravity plus the standard model, but they have at least been useful as no-go theorems, and the people working on such things (Glashow, Hawking, Witten, et al) vary widely in the extent to which they openly discuss "religion" in the context of their "mindset" with respect to their approaches to physics.

Perhaps it might be useful to distinguish between two different types of "mindset … resembling religion" with respect to physics:
an Einstein-type belief in the existence of a Platonic ideal orderly harmony
and
a cult-like belief in a particular approach that is embraced by a particular powerful bureaucratic social/political instituion, such as the Roman Catholic approach to astronomy hundreds of years ago that led to the burning of Giordano Bruno, and such as the current superstring bureaucracy.

In my opinion, the former (Einstein) view is good constructive motivation, while the latter view is obstructive to progress in physics.

In order to make clear my personal biases with respect to such things, I should say that my personal work, a summary of which is available on the web as a 15 Mb (about 300 pages) pdf web book at http://www.valdostamuseum.org/hamsmith/philophysicsbook/PhiloPhysics.pdf), is an attempt to unify gravity with the standard model and to connect that unified model with things "resembling religion" that have motivated me, including but not limited to the writings of Ibn Arabi, divination systems of IFA, Shinto, and I Ching, Tarot, and the Rig Veda.

Although I think that it would be quite fair to criticize my physics model with respect to objective criteria such as whether or not its calculated results are consistent with experiment and observation, and even with respect to subjective criteria such as whether or not its mathematical structure is perceived by a critic to be elegant or ugly,
I do not think that it would be fair to criticize it (or me) because it is to a large degree motivated by my perception of such things "resembling religion".

In other words, I am opposed to derogation of work on "unified field theories" that is motivated by a "mindset … resembling religion".

    May 28, 2005

    Most “theory” in the social sciences such as economics, finance, etc … isn’t much more than the equivalent of “physics envy”. In some ways it is similar to the mindset of people working on “unified field theories”, resembling religion more than anything else.

    A hardcore Machiavellian type of person will use all kinds of “theory” to justify all kinds of things for their own “political” gain, when they know very well that the “theory” is largely BS for the most part. As far as they’re concerned, the “theory” provides a good “cover story” to justify their schemes, while “hiding” their ulterior movtives.

    JC said:
    “If somebody can predict with 100% certainty how the future is exactly going to unfold, they can easily become a zillionaire with zero risk!”

    I know a way of getting rich with 100% certainty, and with zero risk. Just deposite $1 in your bank and never withdraw it for the first 500 years. You won’t get rich yourself but your offsprings will. At just 5% annual interest rate, you could easily beat Bill Gates when one of your offsprings withdraw the money 500 years later.

Seriously there are surely many ways one can get rich if that's all you want. Most people simply can not do it. Most people can not do simple things like save some money in the bank and keep their books balanced. Hey not even the president of this country can do that. What can you say?

Quantoken

19. **JC**
May 26, 2005

DR Lunsford,

Most financial "prediction" methods aren't much more than the equivalent of "snake oil", or in some cases outright fraud. If somebody can predict with 100% certainty how the future is exactly going to unfold, they can easily become a zillionaire with zero risk! A good test as to whether an economic theory and/or "prediction" is the real deal, is to see whether the author/promoter of it is richer than Bill Gates or Warren Buffet.

20. **D R Lunsford**
May 26, 2005

I thought everything was differential equations.

BTW it's likely that these financial industry predictive techniques will find their way into camcorder stabilization and so on.

21. **JC**
May 26, 2005

ksh95 said,

"BTW. I thought financial mathematics was only differential equations."

You'll probably get a different answer depending on who you ask.

In the case of Enron, former CEO Jeff Skilling jokingly referred to financial math as HFVA "Hypothetical Future Valuation Accounting", which "can add a kazillion dollars to the bottom line."

In principle, the "textbook" derivative securities valuation stuff is largely stochastic differential equations. This should already make things suspicious considering economics Nobel Laureates Myron Scholes and Robert Merton won the economics Nobel Prize in 1997 for the Black-Scholes equation stuff. A year later in 1998, the hedge fund LTCM (Long Term Capital Management) which Scholes and Merton were involved with, collapsed during the Russian ruble default. The Federal Reserve Bank of New York ended up strongarming LTCM's creditors in "bailing out" LTCM and dismissing the management, in order to prevent the credit markets from collapsing if LTCM ended up having to liquidate their portfolio in a "panic selling" manner in order to satisfy margin calls. (The Federal Reserve Bank seems to be very concerned about the credit markets collapsing, while not really paying as much attention to the stock markets).

The Black-Scholes stuff was also behind the "portfolio insurance" strategy which was popular in the 1980's. Some folks blamed the portfolio insurance stuff for really accelerating the downward crash of the stock market on Oct 19, 1987.

For the rest of practical everyday finance, a lot of it doesn't use much calculus for the most part. In principle things can be done without much more than a calculator or excel spreadsheet.

A lot finance seems to resemble religion a lot more than science, especially when it comes to the stock market and other investments.

22. **ksh95**
May 26, 2005

No one is interested in your facts Tony, they just cloud the waters. I think my argument is a perfect example US congressional logic.

Scientists usually predict or postdict experiments. Without experiments theorists are left without guidance and inevitably go off the rails. When theory goes of track the foundations of innovation are shaken. The pillars of capitalism are at stake. At this point the communists take over, terrorism runs rampant, and oil prices sour.

See? It all makes perfect sense.

If we could somehow relate the SSC to gay marriage and social security we may even secure the Super Duper Superconducting Collider (SDSC).

BTW. I thought financial mathematics was only differential equations.

23.
May 26, 2005

Tony Smith wrote: "[…] it is easier for the USA government to see through bullshit supporting a bad experimental project than it is for them to see through bullshit supporting a theoretical program […]"

More likely, the cost of supporting a theoretical program is negligible compared to the cost of building a superconducting supercollider. With a budget deficit in the billions, cutting a few millions on academic wages (such as they are) + pencils and paper won't get you very far. Cutting the largest hardware project ever, now that's something else.

24. **Tony Smith**
May 26, 2005

ksh95 described "… string theory as an object lesson describing what happens when congress kills large projects (the SSC comes to mind) …".

The relevant chronology is:
1984 – Weinberg and other influential physicists announced their support for Schwartz's Superstring theory;
1987 – Reagan announced plans for SSC and Green, Schwartz, and Witten published their 2-volume Superstring book;
1993 – SSC killed early in Clinton Administration
1994 – second superstring revolution (based on dualities etc) began

2005 – superstring theory is still dominant, devouring about 90% of theoretical elementary particle physics funding.

I fail to see how string theory is a consequence of the death of the SSC. It seems to me that the glory days of string theory, during which it became the dominant approach to theoretical physics, coincided with the glory days of the SSC rather than the death of the SSC.
Maybe ksh95 is referring to the fact that the second superstring revolution occurred shortly after the death of the SSC, but it seems to me that to the extent there may be a connection there, it may be that the superstring folks decided that they needed a second revolution to avoid the fate of the SSC, and that they hyped the dualities as the needed revolution.
Perhaps the fact that the SSC was killed off in 1993 while string theory continued to prosper financially is an indication that it is easier for the USA government to see through bullshit supporting a bad experimental project than it is for them to see through bullshit supporting a theoretical program involving mathematics that is even more sophisticated than the math used for financial derivatives etc.

Juan R. Said:

"…String theory has caused more damage to the public image of science that the last 100 scandals…"

The public image of science looks something like; a bunch of nerdy guys in thick glasses and white lab coats running around a lab full of beakers. The overwhelming majority of the public is blissfully unaware of the very existance of string theory…The image of science will be just fine.

If we're smart we'll use string theory as an object lesson describing what happens when congress kills large projects (the SSC comes to mind).

I would recommend pg. 429 from the Carl Rove playbook.

The sky is falling. China and India are passing us in science and we will lose our technological advantage. When that happens the communists will take over and we'll all be speaking Chinese. The only way to preserve our way of life is a new accelerator. It should be the greatest accelerator the world has ever seen because Americans are the greatest people in the world.

We should end with chants of USA…USA…

26. **Juan R.**
May 26, 2005

As said

The only correct ST equation

String theory = Faith

The Faith move mountains, therefore String theory move also mountains. In one or another form it remained with us in several centuries. Always someone in some place claimed that the theory is correct and the he/she has solved his current flaws.

The idea of string theory is correct is so scientific like the idea of that a new planet near Sun is the cause of anomalous orbit of Mercury. It was a hypothesis (beatiful?) but only that.

String theory was a hyphotesis, initially beatiful i believe, but with each new revolution the stuff was more and more uggly, inefective, and unelegant.

String theory has caused more damage to the public image of science that the last 100 scandals (e.g. Pons cold fusion, quantum telekinesy by Uri Geller, etc.) joined.

May 25, 2005

Hobbyists?? I bet that isn't what they tell the people funding them. I bet people like Kachru might even claim they do this kind of thing for a living. If they don't, it's more a time for a change in personel then ever.

As an aside, while in Alaska recently I talked quite a bit with many different people who made a living off fishing, and got to see some of how they worked. In any other circumstance I would consider it a shame to spend so much time on an analogy. Here, however, it seems quite appropriate, given how the mistake you are making in the analogy and the topic seem to be in the same vein.

33. **Barry O'Genesis**
May 25, 2005

If you are a hobby fisher, then you fish to see if there are fish. If you are professional, you have ways of determining whether there are fish before you fish, and you don't sit around a fishing hole that doesn't produce.

I see that you have never talked to a professional fisherman. The ones I know go out every night to try to catch fish, no matter what anyone tells them about the failings of the fisheries industry.

So are these hobby theorists we're discussing, or professionals?

Since 1998, we are all hobbyists . Jeez, guys, we are living at a time when we have one of the most sensational observations of all time, the acceleration of the universe, in front of us, and nobody has a clue as to why it is happening. Do you really think that "People should be trying Something Else" is an adequate response? Tell us what that Something Else *is*, and we'll gladly listen. Meanwhile I suggest that we all go off and try to write some papers. A paper showing how string theory constrains possible cosmological models would be good, even *if* string theory *is* a failure as a unified theory. It's still preferable to "Something Else" theory!

34. **Thomas Larsson**
May 25, 2005

Incidentally, Thomas Larsson, are you a physicist?

At least I once was. I ran out of funding after completing a four-year postdoc a decade ago. But then again, I didn't try very hard to hang around, since at that time I felt that starting a family and having a permanent income was a much higher priority than staying in academia. You can judge for yourself whether I'm still a physicist by looking at hep-th and math-ph.

Incidentally, are *you* a physicist? An anonymous poster doesn't have much credibility.

35.
May 25, 2005

Following the work of Georgi and Glashow on SU(5), there were lots of works in the early 80's on GUTs that became more and more complicated, lost any hope of being experimentally testable. Serious people like Callan, Coleman, Gross and Witten, never got into that.

There was also a lot of work at some point on the so-called technical fine tuning problem. Lots of papers were generated, but no serious person ever worked on it.

I'm afraid, you are right, I don't think Kachru, Arkani-Hamed, Dimopoulos and others that you mention, are of the same calibre as Gross and Witten. I also don't think that any of them would think of himself as being in the same calibre.

The only man in the landscape business that I take seriously as a very talented theoretical physicist is Michael Douglas. His work, at least from the late 80's on low dimensional strings and integrable models is great.

I know that I'm voicing strong opinions, but that's how I feel.

Incidentally, Thomas Larsson, are you a physicist?

36.
May 24, 2005

Actually, Q brings an interesting point. Phenomenology existed in particle physics long before strings. It meant fitting experimental data by simple theoretically-motivated formulas.
The highest point of particle phenomenology was the discovery of Bjorken scaling that led to the present formulation of QCD and last year's Nobel prizes.
The definition of superstring phenomenology is essentially "non-testable hypotheses, inspired by superstring theory, made by physicists who would not be able to compute the Veneziano amplitude".
Jean-Paul

37. **JC**
May 24, 2005

If this string landscape stuff dies a painful death, what is there left to do in string theory besides banging one's head harder and harder on KKLT type stuff or just plain giving up?

38. **Quantoken**
May 24, 2005

Aaron said:
"This is completely absurd. There are more jobs in **phenomenology** than in strings right now. Plenty of string theorists are moving in that direction (and towards astrophysics) to better position themselves for the upcoming job market."

What is absurd is the invention of the English word **phenomenology**, and the creation of a whole profession out of that hype? What exactly is a phenomenologist?

In all other branch of scientif research, you are either a theoretical researcher, or an experimental researcher. Either theory or experiment, or both. There is no third kind. There is no phenomenological biology. No phenomenological chemistry. No solid state phenomenologist, and no phenomenological mathematician.

Why should fundamental physics theory research be an exception and create the weirdness called **phenomenology**. If you start that route, you could also invent super string hypertheologist, or super string speculatologist, or landscapologist, or a bunch of other names. It's all vacuous!

I think that the very fact that they needed to invent a middle ground called phenomenology, reflect the truth that **they really can not make any prediction or connect**

their theory in any way with the reality. Otherwise, like in all other fields, theoretists do the calculation on their theory and make verifiable predictions, and experimenters simply do experiments and verify the prediction, and there is no need for any middle man called phenomenologist.

It remains that even phenomenologists are so far unable to provide any predictions so far. Time to create yet one another middle ground field between experiment and phenomenology, to bridge the wide gap between theoretical fantacy and reality, I guess? 🙂

Quantoken

39. **Aaron**
May 24, 2005

OTOH if you are a young theoretical HEP researcher the choice now is virtually to either work on string theory or get out altogether.

This is completely absurd. There are *more* jobs in phenomenology than in strings right now. Plenty of string theorists are moving in that direction (and towards astrophysics) to better position themselves for the upcoming job market. By my quick count on the rumor mill, there are 5 new string people and 15 or 16 new phenomenologists or astro-types. As we get closer and closer to the LHC turning on, most people expect this ration to tilt even more towards phenomenolgy.

I'm really not sure where this skewed view of the field comes from, but it certainly has little bearing on reality.

"Any bets on what people will be talking about at the Strings 2006 conference?"

Shoe-laces?

41. **Chris W.**
May 24, 2005

Not that it means anything, but the chronology of Enron's rise is rather similar to that of string theory:

> Enron was formed in **1985** by the merger of Houston Natural Gas and InterNorth, engineered by HNG CEO Kenneth Lay. It was originally involved in the transmission and distribution of electricity and gas throughout the United States and the development, construction, and operation of power plants, pipelines, and other infrastructure worldwide.
>
> Enron grew wealthy through its pioneering marketing and promotion of power and communications bandwidth commodities and related risk management derivatives as tradable securities, including exotic items such as weather derivatives.
>
> As a result, Enron was named "America's Most Innovative Company" by Fortune magazine for five consecutive years, from 1996 to 2000. It was on Fortune's "100 Best Companies to Work for in America" list in 2000, and was legendary even among the elite workers of the financial world for the opulence of its offices.

42. **Kyle**
May 24, 2005

If you are a hobby fisher, then you fish to see if there are fish. If you are professional, you have ways of determining whether there are fish before you fish, and you don't sit around a fishing hole that doesn't produce.

So are these hobby theorists we're discussing, or professionals?

43. **Peter Woit**
May 24, 2005

Sorry, but the whole attempt to claim that cosmology will solve the problems of string theory just looks to me like another attempt to evade the undeniable fact that string theory unification has failed. It's only "common sense" that cosmology must be the answer if you start from the idea the string theory must be correct. The Hartle-Hawking stuff of Tye and others shows not the slightest sign at all of leading to anything that looks like the standard model.

If a small number of people want to base their research program on an extremely unpromising speculative idea, that wouldn't be objectionable, but this is being used to support a failed enterprise that dominates particle theory and keeps people from being able to work on other things. When work on a speculative idea is driven by sound scientific considerations, you're right that even if the idea doesn't work out, it may lead to something that does. When it is being driven by sociological reasons, it is very unlikely to lead anywhere interesting.

44. **Barry O'Genesis**
May 24, 2005

"You can put your faith in cosmology or some unknown non-perturbative effects, but this is purely wishful thinking and there isn't a shred of evidence for either hope."

Sure it's wishful thinking. That is what always happens when you embark on a research project and you can't see how it's going to pan out: you hope that something will work, it turns out that it fails in some interesting way, and that leads you in another direction, etc etc etc. This latest Kachru et al paper just shows that the uniform distribution cannot be the right one, something that many people, most loudly Lubos Motl, have suspected for a long time. That just means that we have to work on some kind of Hartle-Hawking gadget to tell us how points in the landscape are selected. Henry Tye and co have done some beautiful work on this, see
http://arxiv.org/abs/hep-th/0505104
Of course one works on such a thing hoping that it will lead somewhere — what's wrong with that? And the idea that cosmology will be relevant to this problem is not "faith", it's just common sense.
You can argue that a lot of people who should know better are working on silly stuff like [insert recent technical work of several famous people *here*] when they should be working on cosmology, and I would agree with that. But to say that there's no evidence that studying cosmology will get us anywhere is like saying that nobody should go fishing unless they have evidence that sufficient numbers of fish exist in the pond. You settle that question by proceeding to fish, not by waiting for somebody else to furnish "evidence".
Bottom line: string theory doesn't work without cosmology, and people are belatedly realizing that. Not very apocalyptic really.

45. **Quantoken**
May 24, 2005

For as long as there is money, there will continue to be super string theory and super string theoretists. Just as astrology has been in exist for thousands of years and will continue to be for some more thousands of years, although it's been long proven none-predictive. There continue to be a market for astrology and some people continue to believe they can predict something in astrology. It's all driven by money and people's fear of the unknowns.

Do you believe those super string researchers have actually been honest to themselves, and actually believed they wer doing scientific research, and never realizes they are researching crackpot theories? I actually don't think they have been honest to themselves in rejecting the notion that string theory is none-predictive.

It's all about money and survival within the circle.

Quantoken

46. **Peter Woit**
May 24, 2005

Meanwhile, back in the real world, there are plenty of string theorists who don't work on the landscape. And in fact don't believe in any of the statistical stuff.

Sure, but, as landscape advocates will point out, you still have to deal with the fact the the theory appears to have an infinite number of vacuum states, and is probably utterly non-predictive. You can put your faith in cosmology or some unknown non-perturbative effects, but this is purely wishful thinking and there isn't a shred of evidence for either hope.

47. **Peter Woit**
May 24, 2005

Any bets on what people will be talking about at the Strings 2006 conference?

I don't know about 2006, but I'm betting a lot of talks at Strings 2005 will start off (OK, after the initial "string theory is the most promising idea for unification") like Dine's, saying something like "We're going to ignore the problem of an infinite number of vacuum states, because that makes everything we're going to talk about useless".

On the Enron analogy: That's great, I've been fascinated by the Enron story, read the recent book and did see the film down at Lincoln Plaza. But I hadn't made the connection to string theory. I have been trying to figure out for years how to sell string theory short. One thing I've done is to try and get string theorists to put their money where their mouth is and enter into a bet with me. For some reason, none of them have taken me up on it.

I've witnessed such phases in theoretical high energy physics before.

I've never seen anything quite like this one, with people from the top institutions in the field embracing outright pseudo-science. And even those leaders of the field who aren't engaging in pseudo-science haven't been willing to step up and criticize what is going on (the only exception I can think of is David Gross).

48. **Thomas Larsson**
May 24, 2005

I've witnessed such phases in theoretical high energy physics before.

Are you old enough to have witnessed the demise of aether theory? Otherwise, exactly which phases are you referring to?

One of their main characteristics is that respectable people don't take part in them at all. Unfortunately, this time, one really good scientist is taking part in this, namely M Douglas, however, everyone that I have regard for is totally silent.

So you have no regard for Susskind, Dimopoulous, Arkani-Hamed, or Kachru?

Btw, Witten has not been totally silent. He has repeatedly been saying that he hopes that current discussion of the string landscape isn't on the right track, but has no convincing counter-arguments. Cf e.g. Peter's post about the recent New Scientist article from April 28:

Witten is referred to as a "string grandee", and quoted as saying about string theory "More work has always given more possibilities – far more than anyone wanted… I hope that current discussion of the string landscape isn't on the right track, but I have no convincing counter-arguments."

49.
May 24, 2005

I've witnessed such phases in theoretical high energy physics before. One of their main characteristics is that respectable people don't take part in them at all. "
What–here? Well I never.

Meanwhile, back in the real world, there are plenty of string theorists who don't work on the landscape. And in fact don't believe in any of the statistical stuff.

52. **Chris Oakley**
May 24, 2005

Stringlover is neglecting to mention one important thing: if you work for Enron and don't like the corporate culture you can always go and work for someone else, doing the same job in a (hopefully) less annoying environment. OTOH if you are a young theoretical HEP researcher the choice now is virtually to either work on string theory or get out altogether. Enron also had the bullshit-defeating requirement to make money, a requirement that few are going to have difficulties understanding. But if the "top" HEP theorists are going round saying that the Landscape is the best thing since sliced bread, few among the general public are going to be able to prove them wrong. No – that is the territory of the has-beens, crackpots and cranks who post here.

53. **Stringlover**
May 24, 2005

Everybody following the progress of string theory must see the excellent documentary "Enron: The Smartest Guys in the Room". The title only gives a hint that it really tells the story of string theory, but the parallels between the Enron phenomenon and string theory are so remarkable that we can only expect string theory to share Enron's fate. It's on at Lincoln Plaza, which is within walking distance of Columbia if you like walking.

Anyway, it all starts off with a great accounting idea called "Mark to Market", in which you assume that the great idea that you have will work just fine, and write down in your accounting books that you already have the profit you expect to make. Great! Record profits straight away – the investors love it.

Step two: Lots of talking directly to the public; press releases, reviews in magazines saying that your company (or theory) is fabulously successful.

Step three: Create a macho atmosphere in which everybody involved in the company (theory) constantly talks about how smart they are. The public love it; everybody agrees that these guys are the most intelligent geniuses ever to walk the Earth. Suggesting that this might not be the case is immoral.

Step four: Make the leaders of the whole project objects of hero worship – they're the smartest guys in the room. Einstein had nothing on them.

Step five: Realise that perhaps some of things that you had earlier announced were sure to work out are not working as well as you had planned. Call another press conference and tell them that everything is working even better than you had hoped. Privately realise that you've staked too much on this to back out now.

Step six: Be aggressive and insulting to people who doubt your claims that your project is the greatest success in history. There was an excellent scene where Jeff Skilling gets asked "How does your company make its profits?", and responds with "If you'd done your homework you'd know how stupid that question is." To another guy who asks "Why is it that every company apart from yours can produce a balance sheet, but with you we just have to trust you?", Jeff calls him an asshole and hangs up.

Step seven: Finally acknowledge that the project is unsustainable. Declare bankruptcy and go to jail.

Well, string theory is up as far as step six, from what I can see. From the string theorists that I know who've moved to Wall Street, I can say that string theorists seem to fit in very well in an Enron-style environment, and have just the right mixture of technical ability, the inclination to soak up ideology and follow glorious leaders to the promised land, and macho insistence that since they're so extraordinarily clever, they could never be wrong, that the future looks quite grim for them.

54. **JC**

Any bets on what people will be talking about at the Strings 2006 conference?

News From SLAC and Elsewhere

May 26, 2005
Categories: Uncategorized

Earlier this week Jonathan Dorfan, the director of SLAC, announced a reorganization of the structure of the laboratory. The new structure involves four divisions, two scientific and two operational. One of the scientific divisions will bring together particle physics and astrophysics. It will be led by Persis Drell who also will be a deputy director of the laboratory, a position previously held by her father, particle theorist Sidney Drell. The other scientific division will be called "Photon Science", which will make use of the SLAC x-ray sources. At the moment SLAC produces intense x-ray beams at the SSRL, using synchrotron radiation from a ring which is a descendent of the original SPEAR electron-positron ring that was crucial in the "November Revolution" of 1974 (and which also provided me with a job one summer).

The main SLAC linac is being turned into a free electron X-ray laser to be called the Linac Coherent Light Source (LCLS), which will be operational in 2009. At that time the plan is for SLAC to be out of the accelerator based high-energy physics business, with the PEP-II collider also shut down. The last fixed target experiment using the linac, E158, recently reported the most accurate measurement of the weak mixing angle at relatively low energies (at LEP it was very accurately measured at the Z pole). This measurement shows the running of the ratio of coupling constants predicted by the renormalization group. For more about this experiment, see an article in the latest Nature magazine.

This week's Science magazine also has an article about particle physics. It reports on the HEPAP meeting mentioned here earlier where a plan to evaluate whether to shut down PEP-II or the Tevatron early was put forward. On a more positive note, the House Appropriations committee has restored some of the cuts in the FY 2006 DOE budget proposed by the White House. The House committe added $22 million to the high energy physics budget, bringing it back to the FY 2005 level (which, accounting for inflation, would still be a cut, but a smaller one).

An article in New Scientist about the same House bill explains that money is being taken away from the ITER international project to build a fusion reactor and used to bring funding for domestic fusion research also back to FY2005 levels. This may have something to do with the fact that the latest news about ITER is that a deal has been reached that will site it in France.

   May 30, 2005

   Quantoken,
   you are just obnoxious. Who talks about He3 from the moon? Deuterium from sea water is what the only sustained controlled fusion ever sparked on earth was using. You seem to think that everone except for yourself is a stupid moron. Some people tend to think the converse.
   Michael

2. **Quantoken**
   May 30, 2005

   Michael saked:

   "getting deuterium out of sea water does not kill the efficiency. Can you imagine that the people who work on fusion science, as well as those who grant billions of $$ funding for it, have checked this first thing?"

   Absolutely not! There is a huge gap between Fundamental research and industry application. Can any of the earlier scientists who were the first one probing the secret of atoms imagine that their research will one day lead to a deadly weapon that could easily wipe out whole cities? No. Did the inventor of pesticides like DDT and 666 realize the scope how his or her invention destroys the environment? Absolutely not.

   How hard or easy it is to extract fusable material from the environment is of absolutely no concern to those doing fusion research, or those grant research funds. So **NO**, they have NOT checked out this "first thing". I would be surprised if you could cite even one paper by thermal fusion research scientists talking about the techniques or cost of mining or extracting He3 from the moon.

   Quantoken

3. **D R Lunsford**
   May 29, 2005

5. **Michael**
   May 29, 2005

   Quantoken,

   getting deuterium out of sea water does not kill the efficiency. Can you imagine that the people who work on fusion science, as well as those who grant billions of $$ funding for it, have checked this first thing? Do you really think that your rambling objections qualify as a contribution? I am afraid the answer to the last question is yes.

   Michael

6. **Quantoken**
   May 29, 2005

You still don't get the most important point I pointed out. The important thing is it may actually cost **MORE** energy to extract and refine the fusable elements, than the amount of energy you can obtain by the fusiom reactor. If that is the case, then it is a useless technology, regardless of the monetary cost.

The energy cost is due to the percentage scarcity of the fusable isotopics like deuterium and He 3. You would have to evaporate tons of sea water just to obtain one gram, or even a few miligram of the scarce isotopics you want. Such refinery process costs huge amount of energy. And that cost can not be reduced beyond a theoretical level no matter how sophisticated your technology might become.

If you disregard of the cost efective factor, sure, we have plenty of alternative energy source we can think about. There are plenty of Hydrogen on Jupiter for example. Just ship some Hydrogen from Jupiter to earth and it will can be used on fuel cells etc. But the energy cost to bring Hydrogen from Jupiter to earth is more than you can get out of it, so it is infeasible. Likewise, there are plenty of methane for you ti mine on Uranus. But it is in-practical.

The only feasible, economical, and environmental alternative energy source, is the **heat from the deep of the earth crust**. Just dig a hole a few KM deep, you let water down and high temperature steam comes up, allowing you to turn it into electricity and other energy form. It's actually nuclear energy since the source of heat is the natural decay of elements in the earth crust, like U238 and U235. That's a huge amount of energy, causing tectonic plate movements, volcanoes, earthquakes and tsunamis.

Quantoken

7. **Michael**
May 29, 2005

What is everyone here talking about? No closer to viability than a long time ago? That is simply wrong. Just a few years ago there's been the first self sustained controlled fusion for several minutes, and it put out a lot more energy than had to be put in.

I realize that science sceptics gather here. But why ignore well known facts?

Michael

8. **M**
May 28, 2005

In response to a couple of comments by Q:

"1.Feasibility. We have spent half a century on this without success. It may take another half century before the technology is finally achieved, and much longer before it becomes an economically viable energy source. The energy crisis will hit far before this becomes successful."

I believe one can make a very convincing argument that the relatively slow progress in fusion research is directly attributable to the lack of any feeling of urgency. If a true energy crisis looms, it is almost certain that enormous resources will be poured into whatever alternatives seem best. That would probably include fusion, but other viable alternatives would get serious attention as well. It is not reasonable to assume the same level of funding as today and then extrapolate more than about five years into the future.

" 2.Usefulness. The fuel used in thermal nuclear fusion, Helium 3, is a scarce resource on earth."

Helium 3 may look good in some ways, but deuterium-tritium as a fuel has a longer history of research and would almost certainly be more practical, if for no other reason than the scarcity of helium-3.

Of course, none of this means that fusion research will actually be practical as a large scale power source, but I wouldn't count it out either. SOMETHING has to eventually take the place of fossil fuels…

M

9. **steve**
May 28, 2005

Actually Mike, Quantoken raises a couple of fair points. With all due respect to the people who have worked on fusion and plasmas physics, we are no nearer a commercial or viable fusion reactor design –or even something for which you get more energy out than you put in–and may not even do so in this century. Its a tough, maybe intractable problem that only nature has solved in the sun and the stars. The political problems don't help either. Still, maybe someday it will work but 200 years is too long to wait.

Sometime this century a massive global energy crisis is going to start to kick in and no-one seems to want to face up to it. I remember once being at the top of the World Trade Centre observation deck (in the good old days before it had jet airliners flying into it) taking in the amazing view and thinking about the colossal amount of energy New York was using up. Not to mention the endless stream of cars. And that is just a tiny part of the US and the world. In the future, just where is all that power going to come from? And demand keeps going up and up.

I still think ITER is worth doing though and the cost is not that great when put in perspective. Yes, there is Helium 3 on the moon but how do you get it even if you could use it? We could not get back to the moon either even if we wanted to. We are not as technically advanced as we might like to think.

10. **Dmitriy**
May 28, 2005

Quantoken,
even if nuclear fusion will become practicle only in 200 years we have to do research now to make it possible in future.
Dmitriy

11. **Michael**
May 28, 2005

Quantoken,
you are underinformed and underexposed. Just keep your stupid ideas to yourself.
Michael

12. **Quantoken**
May 27, 2005

There is absolutely no point in wasting money on ITER or other thermal nuclear fusion research for several reasons:

1.Feasibility. We have spent half a century on this without success. It may take another half century before the technology is finally achieved, and much longer before it becomes an economically viable energy source. The energy crisis will hit far before this becomes successful.

2.Usefulness. The fuel used in thermal nuclear fusion, Helium 3, is a **scarce resource** on earth. Scientists have been telling us the total amount of He 3 stored on earth. That's misleading when you do not talk at the same time **what takes to extract the He 3**. For example He 3 contained in one litre of sea water contain the amount of energy equivalent to one litre gasoline. But to extract the He 3 contained in one litre sea water probably costs energy equivalent to a few hundred litre gasoline. Then it is totally worthless as an energy source even if you do not consider the economical factors.

Or there's plenty of He 3 on the moon, too. But to go to the moon and bring the He 3 back would also cost much more than what it is worth.

3.Cost, cost and cost. That includes econimical cost, environmental cost and resource cost.

Quantoken

Smart People

   Well it seems very condensed.

   -drl

4. **Peter Woit**
   May 29, 2005

   Hi Gentle Skeptic,

   I've posted at various points about some of the topics you suggest (see for instance the third post on the blog near its beginning, and many of the posts about mathematics that I think may have some relevance to physics).

   The questions that are left open by the standard model are few in number and well-known to everyone in the field. Basically the main ones are:

   What is causing electroweak symmetry breaking?

   What explains the pattern of groups, representations and coupling constants of the standard model?

   What about quantum gravity?

   My own best guess about which direction to investigate is laid out in a paper on the arXiv and on my website entitled "Quantum Field Theory and Representation Theory: A Sketch". I've been busy with other things this past academic year, but am again thinking about these topics this summer, and will try and write more of a positive nature about them here in the near future.

   But I really don't want to spend much of my time promoting my own ideas. They're there if you want to read about them (and I hope to write up something more detailed this summer), but I'm not going to repeat them endlessly here. The fundamental problem with particle theory these days is that things are hard and there are few if any good ideas around. But I feel the main reason for this is that all of the intellectual resources of the field are tied up in the failed string theory project. Until this situation changes, it is going to remain unlikely that things will improve.

5. **A_Gentle_Skeptic**
   May 29, 2005

   Peter, your detestation of string theory is almost everywhere in evidence on your blog. Please forgive me for asking, but have you posted somewhere on your blog your own analysis of what are the main questions that physicists ought to be addressing today and what are the promising techniques that they ought to be employing?

   Thanks and best regards…

6. **Anonymous**
   May 29, 2005

   Haha! That fits Lubos Motl perfectly

PITP Showcase Conference

May 29, 2005
Categories: Uncategorized

The Pacific Institute for Theoretical Physics, based at UBC in Vancouver, held a Showcase Conference a couple weeks ago, which was supposed to "celebrate the exciting new developments taking place in theoretical physics". According to the organizers there are lots of exciting new developments in string theory, since six of the invited speakers (Myers, Ooguri, Randall, Schwarz, Shenker, Susskind) spoke on that topic, but no one at all spoke about elementary particle physics. There were also quite a few talks on condensed matter physics.

The talk of John Schwarz consisted mainly of the standard recounting of the history and basics of string theory that anyone who has been to conferences like this has heard a hundred times. This part stopped with Maldacena's work more than 7 years ago. On more recent topics, about the anthropic explanation of the cosmological constant, Schwarz says: "Is there another explanation? I hope so." He ends by putting up a long list of questions about string theory, more or less the same list everyone has had for twenty years now.

Steve Shenker spoke on Emergent Quantum Gravity, with "emergent" the new buzzword of the field. There was a separate workshop on emergence overlapping with the Showcase conference, organized by Phil Anderson and others, with Susskind the only string theorist allowed to speak there. Shenker introduced a new terminology to justify string theory: it is "An algorithmically complete, consistent description of quantum gravity", although he does add the caveat "In certain simple situations (like flat space)". By this I guess he is trying to get around the problem of how to claim that your theory is complete and consistent when you don't know what it is. The idea is that at least you have an algorithm for doing computations. Perhaps he means perturbative string theory, although that is neither consistent nor complete (the expansion in the number of loops diverges). Perhaps he means a non-perturbative formulation like a matrix model, which works in 11 flat dimensions, but then he really should note that he's not talking about quantum gravity in four dimensions, which is what most people care about.

There was an interesting panel discussion on The Theory of Everything?, which was moderated by Steve Shenker. He seemed mainly interested in making the obvious point that string theorists weren't actually claiming that their theory explained anything about, say, biochemistry. The panel was actually balanced between string theory enthusiasts (Shenker, Schwarz, Randall), and skeptics ('t Hooft, Unruh, Wald). Some of Shenker's introductory remarks are inaudible, but he did repeat his claim about the "algorithmically complete" nature of string theory. "t Hooft had some quite interesting comments. He recalled that at a conference back in 1985 he had been the only one who didn't think that twenty years later string theory would have solved all the problems of particle physics, noting that it was now 20 years later, he had been right, everyone else at the conference wrong. He was making the point that string theory now is extremely far from solving any problems in particle theory, and one can't tell if this situation will change in 20, 200 or 2000 years. He tried to say some positive things about string theory, but they were pretty half-hearted. For instance he noted that dualities were very interesting, but they linked one ill-defined theory to another ill-defined theory. He also noted that in its present formulation string theory is only defined on-shell, which he takes as meaning that it doesn't give a true local description of what is going on. He has reasons for being suspicious of people who claim that all one needs is an on-shell theory.

Schwarz attributed the TOE terminology to John Ellis. He said that he feels string theory is very far from explaining anything about elementary particle physics, that it was "almost hopeless to find the right vacuum". He described what landscapeologists are doing in a skeptical tone, but didn't actually criticize this. Answering 't Hooft, he claimed that back in 1985 he and Mike Green were actually more pessimistic than most other people about the prospects for getting quick results out of string theory.

Bill Unruh made the standard criticism that what is wrong with string theory is that string theorists are motivated by beautiful math, not physics. He doesn't seem to have noticed that few string theorists are now doing math, since unfortunately most of them have taken to heart the criticisms of people like him. The failure of string theory has unfortunately reinforced the skepticism of many people like Unruh about the use of math in theoretical physics.

Wald quoted what sounded like a recent description of what string theorists think they are doing, then revealed that his quotes were from the 19th century, and referred not to string theory, but to the popular theory of the time that atoms were vortices in the ether. He deftly made the point that it is quite possible, if not likely, that string theory is just as wrong an idea as the vortex one.

Lisa Randall made some defensive comments about string theory as a guide for future research, even if it turns out not to work. These included the bizarre political analogy that it was wrong to worry about string theory ruining the credibility of physics, because, after all, the bogus WMD business didn't seem to have hurt Bush's credibility.

There were then some questions and comments from the audience. Susskind was in the first row, looking very peevish and defensive. He kept repeating that the field of theoretical physics had "no real choice but to track this down", meaning to investigate the infinite landscape, and that this would take the efforts of many physicists. He explicity worried that funding agencies would not give any grants to anyone working on the landscape, to which Unruh responded that the shoe was really on the other foot, with some NSF panelists refusing to fund anyone who wasn't doing string theory.

The conference web-site also includes an explanation of string theory which claims that in recent years string theory has "evolved very rapidly", that the reason it can't be tested is because of the small distance scales involved, and that it may be testable by observing a "5th force", all of which is a load of nonsense.

Lubos Motl has an interesting post going over all the possible ideas he can think of that might lead to the next superstring revolution. Needless to say, they all sound extremely unpromising to me. Judge for yourself. He also quotes the promotional material for Susskind's book due out late this year. It seems that "the Laws of Physics as we know them today are determined by the requirement that intelligent life is possible".

   Hi Kea,

   I'd be interested to hear more about the formulation of non-standard analysis in the context of topos theory.

2. **Kea**
   June 12, 2005

   "one need more advanced math, like nonstadard analysis or better (epsilon calculus)"

   Hi Juan
   For anyone who is interested: non-standard analysis comes under the umbrella of topos theory

3. **Juan R.**
   June 12, 2005

I was not asking about total area of BH, i was talking about quantum of area (in the spirit of LQG).

Some of my questions were "redundant" because i already know the reply. For example the authors are interpreting incorrectly the "continuum limit". If really one takes the limit of area (or volume) –> 0 one obtains a kind of spacetime Zeno effect and nothing changes in spacetime.

This confussion is usual in quantum gravity, due to false statement of that GR is works with continuum spacetime. This cannot be studied from usual math, one need more advanced math, like nonstadard analysis or better (epsilon calculus). There one discovers that area is newer zero. This is not speculation, is well-proven, even there are experiments that can prove this. Moreover, mathematically one can prove trhat in the limit of area (quantum of) zero there is no Hawking radiation and BH are stationary ones.

In string M-theory, people still believes in differentiable manifolds (like new G2). I will always say that string M-theory is a waste of time because is being developed by – people. It is really interesting that each year string theorists agree with things that i said years ago.

4. **the original anonymous**
   June 11, 2005

   Juan, naturally I cannot speak for the CDT researchers. It is only recently that I have begun to watch this line of research carefully. I want to keep current some of your questions about CDT and perhaps respond (even though not authoritatively)

   You ask about CDT model of BH. This goes to some of the most recent work: a paper by Loll and Dittrich that just appeared, and the PhD thesis of Dittrich which unfortunately is written in German. So far there is almost nothing written about the way the BH should be modeled in CDT.

   I think this new BH research will be prominent at the October conference ("Loops 05") at Potsdam AEI. Dittrich is at AEI and is one of the local organizers, Loll is one of the invited speakers.

   You asked about the area. So far, in what I know of what is published, neither BH area nor entropy have been calculated in CDT.

   So that we do not forget the questions from your earlier post, I will copy some interesting ones of them:

   [[…

   …I have also my doubts about the mathematical machinery for taking the "continuum limit". Or there is continuum spacetime or one can measure quantums of area for example in a BH. Is not clear for me, What do authors say?

   At macroscopic distances, they "claim" for demonstration that geometry is 4D. On other paper, they say

   "Of course, we will never be able to show by computer simulations alone that the effective
   dimension is exactly equal to four. What we are assuming here is that this dimension is
   indeed an integer, because there are no classical theories describing the dynamics of geometries
   of dimensionality 3.9, say."

   Interesting concept of "derivation". It resembles to me the "derivation" of 4D GR from 10D string theory, i.e. when one knows the correct answer first and then modify/adapt the obtained reply from theory to the real, needed, reply.

   Moreover there is available other approaches (i know some very much) that provide outcomes for experiments and can be tested. Is there something about this outside of paper. Experimental data perhaps? Author claim that no check if
   Newton?s inverse square law can be recovered in an appropriate limit. Others have already proved this very important point.

   A dynamically generated scale dependent
   dimension from 2 to 4 is truly exciting news, i agree, but does work it in paper or in reality?

   ****

   And a joke for finish this large post. How many time will be necesary before string theorists claim that this is part of string theory? including the claimed reduction of dimension to short scales

   Posted by: Juan R. at June 9, 2005 07:02 AM]]

5. **the original anonymous**
   June 11, 2005

   I have to laugh, Juan, because it is just as you said here:

   [[You say,

   "But the idea of dimension being around 4 at large scale and declining (more or less continuously) to around 2 at small scale, how could this idea be accommodated in string theory?"

   A priori cannot be accommodated in today string theory, but like there is no string theory, just a big collection of conjeture, hypothesis, beliefs, etc. i wonder if future string theorists will claim that your ideas are really a part of string theory. String theory is great 🙂

   Simply revise the history of field and see like the theory was changing and adapting to new ideas from outside of string community. For example, one or two decades ago LQG was nonsense, one could compute "nothing", was called prerelativistic physics and garbage by string theorists. One decade ago, some (e.g. B. Greene) began to claim that perhaps LQG and string theory both were two sides of same reality. Now several string theorists claim that LQG may be a part of string theory…]]

   and ALREADY a string-believer here at this blog is making ludicrous attempt to imitate the outside result:

   [[String worldsheet has dimension 2, background space has dimension 4. 4->2 is a typical string effect. QED]]

   😀

   I can assure you he is not the real anonymous, only a second-rate imitation anonymous

   This thread may have expired but I will stay around a while in case there is more discussion.

June 10, 2005

Dear "",

"You suggest string theorists like to absorb every interesting idea into their polymorphic theory as a possibility. Or at least this may have been their custom."

It is not my suggestion, it has been claimed by many people including own string theorists.

I can do is quote to string theorist Seiberg who said recently:

"*string theorists are arrogant enough that whatever comes up in their research, they will call it string theory.*"

You say,

"*But the idea of dimension being around 4 at large scale and declining (more or less continuously) to around 2 at small scale, how could this idea be accommodated in string theory?"*

A priori cannot be accommodated in today string theory, but like there is no string theory, just a big collection of conjeture, hypothesis, beliefs, etc. i wonder if future string theorists will claim that your ideas are really a part of string theory. String theory is great 🙂

Simply revise the history of field and see like the theory was changing and adapting to new ideas ***from outside of string community****. For example, one or two decades ago LQG was nonsense, one could compute "nothing", was called prerelativistic physics and garbage by string theorists. One decade ago, some (e.g. B. Greene) began to claim that perhaps LQG and string theory both were two sides of same reality. Now several string theorists claim that LQG may be a part of string theory.*

String theorists are very arrogant and don't love the idea of that anybody is working in more complex, sophisticated, and good theories than them (the most sophisticated that i know is non-criticial string theory in Lindblad form, a formulation totally outside of standard easy string theory. For instance, NCST is a nonunitary formulation violating Schwartz ineffective desires (an unitary theory is simply wrong). Curiosly there is not serious formal theory, just a generalization of usual (Schwartz, Greene, Witten, vafa, etc.) easy string theory to adapt it to theories known in other branches of physics since decades!!!!

The first versions of NCST (the 90s) used an old (really outdated) theoretical formalism developed by known chemist Ilya Prigogine. More recent versions are constructed from standard axiomatic theory developed by mathematical physics community. There six theories computing from different communities: chemists, decoherence physicsts, laser community, astrophysicists, etc.

From canonical theory one can derive all those efforts (decoherence, etc.) from a single advanced theory. The standard axiomatic theory developed by mathematical physics community arise like a simple trivial theory after of four succesive approximations. ***that is the theory used in NCST, therefore we know that is simply a toy model and not the more fundamental theory like people as B. Greene claim.***

8.
June 9, 2005

Juan_R, thanks for your reply! Your joke is also an interesting question:

"How many time will be necesary before string theorists claim that this is part of string theory? including the claimed reduction of dimension to short scales"

I also ask myself this, especially the finding about dimension (as measured by a diffusion process) declining at short scale.

You suggest string theorists like to absorb every interesting idea into their polymorphic theory as a possibility. Or at least this may have been their custom.

But the idea of dimension being around 4 at large scale and declining (more or less continuously) to around 2 at small scale, how could this idea be accommodated in string theory?

You have asked several questions that either I cannot respond to, or would take us rather far from Peter Woit's topic of this "PITP Showcase" conference blog.

I will come back to this if I see that it is not considered out of place.

Interesting posts "anonymous",

if you want talk about triangulations was innecesary your "hey guy that you think about".

If i don't love dynamical triangulations, you would not are hungry… but seeing your special interest in the topic…

****

It is really difficult for me to take seriously works, who authors still "believe" that wavefunction of universe may be a solution of the Wheeler-DeWitt equation

… and continue with Einstein-Hilbert (i wonder like will solve extragalactic problems from it), the use of piecewise Minkowskian geometries (like in "metric"-gravity approaches). It will be interesting that authors can say about "affine" gravity models and computation of astronomical orbits.

In one of papers they compute, wrongly, the wavefunction of the universe (eq 22). Fascinating for one so higghly estimated work (by its authors). The derived effective Euclidean
action is not correct.

The details of the renormalization mechanism (here open) were already solved in other methods (using also discrete structure).

What about the inclusion of matter fields? Are we claiming for a consistent quantum gravity or realistic quantum universes without matter or… only speculating? Will the method work fine with more realistic models?

The phase diagram is really interesting but does work it in paper or in reality?

What about the "fit" of used simulation method with standard QFT? I wait with impatience a rigurous study of this.

I have also my doubts about the mathematical machinery for taking the "continuum limit". Or there is continuum spacetime or one can measure quantums of area for example in a BH. Is not clear for me, What do authors say?

At macroscopic distances, they "claim" for demonstration that geometry is 4D. On other paper, they say

"Of course, we will never be able to show by computer simulations alone that the effective
dimension is exactly equal to four. What we are assuming here is that this dimension is
indeed an integer, because there are no classical theories describing the dynamics of geometries
of dimensionality 3.9, say."

Interesting concept of "derivation". It resembles to me the "derivation" of 4D GR from 10D string theory, i.e. when one knows the correct answer first and then modify/adapt the obtained reply from theory to the real, needed, reply.

Moreover there is available other approaches (i know some very much) that provide outcomes for experiments and can be tested. Is there something about this outside of paper. Experimental data perhaps? Author claim that no check if

June 8, 2005

Who is the person loading us with CDT info?

11.
June 8, 2005

Juan R mentioned Dynamical Triangulations research. Instead of arguing with his notion of its significance and impact, I will post a short reading list for anyone who wants to find out what is going on in that field

Basic papers:

http://arxiv.org/hep-th/0105267
Dynamically triangulating Lorentzian quantum gravity
41 pages, 14 figures
Nucl.Phys. B610 (2001) 347-382

http://arxiv.org/hep-th/0505154
Reconstructing the universe
52 pages, 20 figures
Report-no: SPIN-05/14, ITP-UU-05/18

Abstract: "We provide detailed evidence for the claim that nonperturbative quantum gravity, defined through state sums of causal triangulated geometries, possesses a large-scale limit in which the dimension of spacetime is four and the dynamics of the volume of the universe behaves semiclassically. This is a first step in reconstructing the universe from a dynamical principle at the Planck scale, and at the same time provides a nontrivial consistency check of the method of causal dynamical triangulations. A closer look at the quantum geometry reveals a number of highly nonclassical aspects, including a dynamical reduction of spacetime to two dimensions on short scales and a fractal structure of slices of constant time."

—-

Recent short papers giving new results:

http://arxiv.org/abs/hep-th/0404156
Emergence of a 4D world from causal guantum gravity
11 pages, 3 figures; final version to appear in Phys. Rev. Lett
Phys.Rev.Lett. 93 (2004) 131301

http://arxiv.org/abs/hep-th/0411152
A semiclassical universe from first principles
15 pages, 4 figures
Phys.Lett. B607 (2005) 205-213

http://arxiv.org/abs/hep-th/0505113
Spectral dimension of the universe
10 pages, 1 figure
SPIN-05/05, ITP-UU-05/07

Lecture notes to introduce graduate students to the field

A discrete history of the Lorentzian path integral

R. Loll (U. Utrecht)
38 pages, 16 figures
Lect.Notes Phys. 631 (2003) 137-171

12. **Juan R.**
June 8, 2005

Yes, there has been a lot of discussion on this topic of dynamical triangulations.

Ambjorn, Loll and collaborators have provided some new material for strings theory, more correctly that a theory of membranes may be relevant for a background independent form of string theory.

These triangulations appear to be useful in some models of spacetime foam. I don?t know if are used in LQG. Possibly dynamical triangulations can be a computational approach to some basic aspects of quantum gravity. It is possible that finally it modifies some aspects of particle physics: high-energy behavior, cut-offs, etc. but I don?t wait for some really profound.

Thanks Tony, nice article

13. **Tony Smith**
June 8, 2005

Lee Smolin in an opinion article in the June 2005 isssue of Physics Today (pages 56-57) said in part:
"… In the present system, scientist feel lots of pressure to follow established research programs led by powerful senior scientists. Those who choose to follow their own programs understand that their career prospects will be harmed. …
Those who invent their own research programs … are often undervalued and underappreciated …
Several young string theorists have told me they simply have neither the time nor the freedom to ask their own questions or develop their own ideas. …
young theorists who pursue alternatives to string theory have had great difficulty finding any academic positions in the US. …".

Smolin proposes that "… Scientists should be penalized for doing superficial work that ignores hard problems and rewarded for attacking the longstanding open conjectures …
A research program should not be allowed to become institutionally dominant until supported by convincing scientific proof of the usual kind. …
A foundation or agency could create … fellowships, to go specifically to theorists under 40 who invent their own ideas and programs aimed at solving foundational problems in physics …".

Cynically, Smolin's article could be viewed as an attack on superstring theory and a plea for more funds for his LQG program, especially since he characterizes his Perimeter Institute as having a "… specific mandate … to be a home for independent foundational thinkers …".

Even though Smolin's article may be self-promoting, at least some of its points may have some validity.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

14. **Kea**
June 7, 2005

"Peter, what do you and other posters think about the
theory of dynamical triangulations…"

There has been a lot of discussion on this over at PF lately.

15. **Peter**
June 7, 2005

I'm glad people are working on dynamical triangulations, maybe this will give a viable verion of quantum gravity. But, like LQG, I don't see any way to connect this stuff to particle physics, which limits my interest in it, since my main motivation comes from that direction.

16.
June 7, 2005

Peter what do you and other posters think about the
theory of dynamical triangulations pioneered by
Jans Ambjorn and collaborators . From what I understand this is the third alternative approach
to quantising gravity besides string tehory and LQG.
do you think one can learn particle physics from this approcah?

17. **Juan R.**
June 7, 2005

Scott ,

Far from any interpretation, I simply cite your previous phrase.

?*I would suspect that any chemists who share this view do not trully understand what the implication of QM is*.?

The problem that I remarked is perfectly well known. I see no problem that you can easily find literature in the topic.The most easy violation of QM is to observe that full QM is not used in computational programs in molecular chemistry physics (e.g. Gaussian) only part of QM is used, whereas other part is ignored, when one reintroduces all of QM in the equation one observe that the concept of molecule disappear. This is not so strange since there is no structural aspects in QM, one cannot obtain the description of structures. There is no ?problem? in atomic physics.

In the reference that I provided you can find some easy (at undergraduate level) discussion regarding methyl acetylene, allene, and cyclopropene. See reference cited for more information.

Now you add ?*Also your point has to do with the concept of chemical structure in general whereas I was originally questioning why DNA's incomplete quantum explanation in particulare deserved special attention, which is a seperate issue entirely.* ?

Far from personal interpretation, I read your past post ?*Personally I am not aware that biochemists were having any trouble understanding DNA structure so I see no reason why the laws of physics would need to be changed to accomodate DNA.*?

I simply have pointed that we need change them for accommodate DNA since a pure QM description of DNA does not work. That was my point, only that.

Torbjorn Larsson

Simply I wanted state the stupid elitism in some members of academia.

Thanks by your mention to Baez?s index, we would agree that many string theorists are effectively crackpots.

You are right, these results were eventually published, but in some cases was a question of luck (there are well documented cases), in other occasion the publication was in an obscure journal and only after several decades that work recovered like excellent. Other works are rejected for publication during many decades (e.g. 25 years). All those cases I know are for ?simple? theories in a very specialized subfield of a part of science (e.g. Yukawa Meson theory), modifying only a 1% of accepted mainstream in that field (e.g. physics) and practically nothing in the rest of science (e.g. ecology). Therefore the initial rejection was from a small part of comunity believeing in mainstream.

I ask, what for a revolutionary theory modifying physics, chemistry, biology, etc. at the same time?

Previous editor-in-chief of Nature said that today Newton theory would be rejected for peer-review publication. What about a theory that violates the policies of compartimentalized journals, uses parts of different theories of physics, chemistry, etc., or even do not use "writting style" and "recomendations" (different for chemistry, physics, ecology, medicine, etc.)

Weinberg said that a new theory demonstrating that the concept of field is not fundamental would be a sensation. Imagine a hypotetical rigorous and advanced theory that modifies fields, GR, QM, thermodynamics, chemical kinetics, statistical mechanics, Maxwell EM, etc. Do you really believe that would be published by any editor of usual journals?

My previous use of words ?true? or ?TOE?, of course, was only prose for remarking the point.

About consciousness, I can assure to you that QM is not sufficient. I have no doubt. It is true Gell-Mann discusses an effect connected to specific brain structure, but he use a reformulation of standard QM that when properly improved (Gell-Mann/Hartle is non rigorous in several crucial points) offers to us a new formulation of nature generalizing QM.

18. **JC**
June 7, 2005

Many fanatics and some crackpots completely refuse to answer questions in plain english without any obfuscation and/or waffling. They also frequently get angry whenever hard questions are asked directly to them. Their tactics frequently involves ad hominem attacks against the questioner themselves, instead of answering the hard questions directly.

Perhaps there's some validity to the notion that "the truth hurts" for many people.

19. **D R Lunsford**
June 6, 2005

Meep! 173rd post! 40th prime post!

-drl

20. **Torbjorn Larsson**
June 6, 2005

Still not correct enough:

"distingush" – distinguish

"throw more money in" for experiments, even if new theories have superseeded the first.

21. **Torbjorn Larsson**
June 6, 2005

(Redfaced, again.) Umm, I thought I vetted my last commentary enough. Let's see:

"learn ST" – well, get to know some more about it, more likely.

"everythere" – everywhere.

"statistics" – probability models.

22. **Torbjorn Larsson**
June 6, 2005

Seems like most of the arguments I'm involved in borders to the content of blog and post, so I'm back:

Juan:
Crackpotism – Thanks for the interest! I think it's hard to measure alone due to different arenas (someone may be perfectly normal outside his eccentricity) and the consensus nature. Thomas mentions Baez measurement tool (http://math.ucr.edu/home/baez/crackpot.html) that lets one judge the most common crackpots outhand. But there remains social factors.

Publication – You mention difficulties, but these results were eventually published. I'm not sure what you mean by "true "TOE"" – something outright called "true" or "TOE" will not get published due to the implied crackpotism.

Consciousness – What I argued with Matti was that QM and consciousness cannot be fundamentally connected, if not TGD replaces todays QM. Gell-Mann discusses an effect connected to specific brain structure. If you ask me however if such QM (or ST) is needed to explain consciousness my answer would be 'no' from Occam's razor, in lack of further evidence.

QT:
First, I will offer my apologies for being such an arrogant bastard, whether you noticed it or not. Web posting seems to be an excellent social arena, and apparently while I can spot arrogant behavour in others, I need to put my nose in my own mess to recognise it.

Second, I'm not an "SSTer" or even STer. I'm probably going to try learn some of it though.

Third, on dimensions I didn't make myself very clear. Obviously I can misinterpret a lot, being next to ignorant on string stuff. But one has to distingush between _spacetime_ dimensions and others. ST concludes that it has a finite number of dimensions. Apparently they don't even need to have a geometry. Out of this, somehow, ST has to build spacetime.

So if you say 4 =! 11 or something similar, you are comparing apples and pears. You can't do that. So no contradiction.

Maybe ST has elicited true statements, but if so they were already known. Mostly it is Not Even Wrong – but so are its contenders for QG. I don't think you can call it crackpot – if you do, most will disagree.

However, you raise one very interesting point!!! How long may a theory be alive without any definitive answer?

Obviously, in math, a very long time. (Fermat's theorem, for example.) But I think of math as an internal logic game, very few measurements here. 🙂 Unfortunately, since I'm Baeysian, I think that you must sooner or later measure in statistics. Obviously, everythere else you must, too.

In lack of better measure, let's go for the money! So, I would say that 2-3 generations can be left hanging, since you probably want your children or grandchildren to benefit at least. So I would up your estimate to 3*30 years. After that it can be declared failed, and there is absolutely no use to throw more money in.

23. **Scott**
June 6, 2005

Also your point has to do with the concept of chemical structure in general whereas I was originally questioning why DNA's incomplete quantum explanation in particulare deserved special attention, which is a seperate issue entirely.

24. **Scott**
June 6, 2005

juan,
my point wasn't that the quote showed that they didn't understand QM it was that if I am going to doubt qm's ability to account for DNA I am going to need to see the evidence for myself untill then i am going to assume that it can account for it. I was hoping that someone might give me some details of this controversy as it seems very interesting and very helpfull if true. "the
view that structure is nothing but a metaphor"(and basically a meaningless statement anyways) is only one way to interpret the equations of QM and so that is why I suspected that there may not really be a controversy over this and requested actuall data showing some sort of violation of quantum mechanical principles. Still waiting for some info on this.

25. **Juan R.**

I said

"To list here the extensive research literature in the topic and the different models/proposals (by quantum chemists and molecular physicists) for improving QM would extenuate to me."

Of course, string theorists know nothing of this and string theory is a simple (probably unitary) elementary QM.

This is another of dozens of reasons of that ST has failed like a theory of everything.

The irrelevant attempt, from string theorists, to explain "everything" knowing almost nothing (e.g. what theories are used in other fields or like fit experimental data) is the best example of crackpot that i know.

26. **Juan R.**
June 6, 2005

Scott , the reference you solicited

When chemists disagreed with physicists? idea of that chemical reactions could be explained with classical mechanics. Physicists smile and claimed that didn?t understand the topic 🙂

When chemists disagreed with physicists? idea on that chemistry reactions could not conserve energy. Physicists smile and claimed that didn?t understand the topic, in fact the law of conservation of energy was rejected by top physics journal and published by first time in Annalen fur Chemie 🙂

When chemists disagreed with physicists? idea on that chemical bonds could be explained from classical electromagnetism smile and claimed that didn?t understand the topic. Please remember those childish models proposed by physicists (including several Nobel laureates for Physics like Stark). But chemical model (Lewis) was correct and was based in radical assumptions like the superposition principle BEFORE QM was developed by physicists 🙂

When chemists disagreed with physicists? idea on that all of chemistry could be explained with Schr?dinger equation. Physicists smile and claimed that didn?t understand the topic. Chemists shows that Dirac ideas on relativistic QM and chemistry was completely wrong. It is interesting that whereas many physicists (of course with no idea of chemistry) claim that famous Dirac?s quote is correct, Murray Gell-Mann said that ?of course it was an exaggeration?. I am sure that Gell-Mann thinking is the outcome of his chemical friends that explain to him how things are in reality 🙂

The quote that perturb to you is not from a top research journal is from an basic educative journal.

J. Chem. Educ. 2000, 77, 522?526.

To list here the extensive research literature in the topic and the different models/proposals (by quantum chemists and molecular physicists) for improving QM would extenuate to me.

You irrelevant claim, on that any chemists who share this view do not truly understand what the implication of QM is, would be remember in a future like today we remember the dozens of false claims of physicists from Newtonian ?poque. I?m sorry to say this.

Seeing your writing, especially your note on ?exact explanations? and ?complexity of DNA? suggests to me that you have no idea of the field that I was talking. I suspect that your knowledge of QM is very elementary one, perhaps at mathematical level of last Weinberg QFT manual?

Torbjorn Larsson said

A crackpot is "a person who is regarded as strange, eccentric, or crazy".

Humm!!! Really interesting, that is the definition of Einstein in his last years, when he was searching for a unified theory of fields and was considered an eccentricity (in his own words) caused by his old age.

?But the total risk is small for the really good stuff, so if you have great fears I would suggest that is because you have some other reason to be.?

Almost 35 of works after awarded by a Nobel Prize were rejected for peer review publication, and completely ridiculized by specialists. At least 18 of most cited works of all history of science were initially rejected for peer review publication.

The situation now is still poor due to increase of economic risks in usual journals, Editors prefer reject a good but problematic paper rather than lose one or two points in IF and similar measures.

Some editors simply admit that the true ?TOE? cannot be published in usual journals because editorial and peer-review policies are not good enough.

?I think decoherence and/or consistent histories make consciousness unrelated to QM.?

Murray Gell-Mann (crackpot?) considers that consciousness and other questions of mind modeling may be explained from his consistent histories like a kind of quantum effect amplified by special biomolecular structure of cerebrum cortex.

Perhaps the crackpots are a 90% of those wonderful members of Physics departments. Perhaps those intelligent guys that rejected his quark theory for peer-review publication?

TL said:

"I think common logic tells the rest of us that even if SST isn't successful (Uups, yet) it doesn't contradict."

The only common logic I know says that 4D != 11D. Maybe you SSTers have invented a different set of math in which 4 == 11. You still have not bridged the gap between 4 and 11.

But it is recognized that so far SST has NOT been able to make a single statement that is true about nature, and that can be verified to be true. How many papers have you guys published in 20 years, yet you have NOT made one damn true statement about the nature.

It is about time to call SST a crackpot theory. If you think 20 years is not enough, then I can give you another 20 years, or maybe more. But at the end of day it can not be allowed indefinitely or forever, there needs to be **a finality to this craziness**. Let's call it what it is worthy: a crackpot theory.

Quantoken

28. **Thomas Larsson**
June 6, 2005

Larsson (Are there two Larssons?), can you tell us more about your theory of quantum gravity using projective representations of the diffeomorphism group? You keep mentioning to online but never spell out the details.

Yes, there are two Larssons. It is a quite common Swedish name, meaning the son of Lars (or Lawrence). I'm called so because my great-great grandfather's name was Lars Nilsson.

The most recent reference is hep-th/0504020; further references to published work by myself and others can be found therein. A very similar manuscript will appear as a chapter in a book on quantum gravity, probably scheduled to be released next spring. It has the same publisher as this book.

29. **Scott**
June 5, 2005

kea,
provide a link and i will look at it but i am in the middle of finals and am spending to much time dicking around as is to go find it myself.

anyways back on topic,

I find the fact that Susskind was worried that the landscape might stop being funded is a very good sign.

30. **Torbjorn Larsson**
June 5, 2005

Uups again, thet should be "successful yet".

31. **Torbjorn Larsson**
June 5, 2005

Uups, sorry Peter, I missed your commentary about the content stringency at first. Now, I would like to withdraw with a response to QT, string part of which may be acceptable, otherwise feel free to delete:

QT:

About 3section I think Scott made my point eminently. You could call my argument a retrap. 😉

"For as long as there hasn't been a successful attempt to reduce to 4-D from SST, the SST remains a contradiction to the known 4-D spacetime, and hence remain a crackpot."

I think common logic tells the rest of us that even if SST isn't successful it doesn't contradict.

32. **Torbjorn Larsson**
June 5, 2005

Anonymous:

"Are there two Larssons?"

Yup. I'm the ignorant one (on theoretical physics).

33. **Kea**
June 5, 2005

Scott:"there is no reason the structure of DNA should drive specualation over any other phenomenon that is only roughly described by QM due to its complexity"

At least read the paper referenced below.

34. **Peter**
June 5, 2005

I've been away much of the last week and haven't had time to do much with the weblog. This comment section has unfortunately been taken over by people who want to carry on discussions that have nothing to do with the original posting. Please do this elsewhere, from now on I'll start deleting such postings.

I'll also try and write something later tonight or tomorrow about the workshop where I spent most of last week.

35. **Scott**
June 5, 2005

ok will then can you point to more accurate observations of DNA that contradict current theory? If not there is no reason the structure of DNA should drive specualation over any other phenomenon that is only roughly described by QM due to its complexity.

36. **Kea**
June 5, 2005

Scott: "..check out about this issue somewhat quickly.."

No one said it was easy.

37. **Kea**
June 5, 2005

…which is true but no more then any other structure must be explained by the new physics unless DNA is not adequately accounted for in the old physics…

Let me spell this out: Newtonian mechanics has a perfectly adequate description for the orbit of Mercury, so long as one doesn't look too accurately. The situation here is analogous. Of course we know roughly what DNA is using standard QM. That doesn't necessarily mean that our understanding cannot be improved.

38. **Scott**
June 5, 2005

Quantoken,
read what TL said about trisection again,

"On 3secting angles, of course some angles can be constructed as required, that is known since the Greeks I think. The problem is to 3sect _all_ of them. (Or any randomly chosen one, if you prefer.) You know, most of the time we complain that you don't know, and don't want to learn, basic physics. Now it turns out you don't even know maths…"

he is saying not that you are wrong about being able to do this but that you lack the knowledge that this has been known for a long time(though of course from your wording that is not clear at all) So he was not nor ever did dissagree with your ability to trisect angles and hence did not fall into your "trap"

Kea,
I am in the middle of studying for finals right now, I don't have time to go to the library and find and read 53 pages of this book, if you have some sort link i can check out about this issue somewhat quickly it would be much appreciated. I do not think I am misunderstanding you, you said "As a pragmatist I simply recognise that the structure of DNA appears with tortile tensor categories, and hence must play a role in the new physics", which is true but no more then any other structure mus be explained by the new physics unless DNA is not adequately accounted for in the old physics for which i have seen no evidence.

39. **Kea**
June 5, 2005

"I was looking for something more specific I don't have the time to read through 20 books to find this supposed evidence against QM."

Scott – you appear to have misunderstood. We're not saying anything against QM per se. We're talking about theories of QG which go beyond QM.

40. **Kea**
June 5, 2005

Scott

How about

M.C. Shum
Tortile tensor categories
J. Pure Appl. Alg 93 (1994) 57-110

and references therein.

41. **Quantoken**
June 5, 2005

TL:

You made yourself a **very good example** to illustrate my point when I meantioned trisection angles. Go back and read my original word carefully, especially pay attention to the keyword **"SOME"** which I highlighted. The point is most people fall into such a mentality that they automatically close up at a first sight of something offending to their beliefs, and does not bother to carefully exam the fact. The fact is I have NOT said not a single thing that contradicts the conventional wisdom on trisection angles. But you thought I did and tried to argue with me.

You fall into the trap I set up to prove my point. Isn't it great!!!

Now, about 4-D spacetime and SST. There is no disagreement that macroscopically the spacetime is 4D. There are various attempts to reconcile SST with the 4-D spacetime. None successful or convincing so far.

For as long as there hasn't been a successful attempt to reduce to 4-D from SST, the SST remains a contradiction to the known 4-D spacetime, and hence remain a crackpot. So keep trying and trying harder to show me that you can get nothing but 4-D out of SST, until you do SST remains a crackpot theory!!!!!

As for microscopic scale, one that approaches the discreteness of spacetime. I think the dimentions would be zero, not 11. But I am not not going to discuss it here. The important things is any correct theory must tell us **without ambiguity and without a second guess of possibility** that the macroscopic spacetime is 4-D.

Quantoken

42. **Scott**
June 5, 2005

anon,

I was looking for something more specific I don't have the time to read through 20 books to find this supposed evidence against QM. Thanks anyways though.

43. **Kea**
June 5, 2005

"Every so often, Peter W has to drive all the crackpots out of his comment section, and clearly this thread is ripe for another such cleanup."

Perhaps you could clarify for us: precisely which posters on this thread are crackpots? Am I one? If so, then the lack of mathematical sophistication in your remark hardly makes my knees tremble.

44. **anon**
June 5, 2005

Scott

You could start with the books on the list

http://au.expasy.org/seqanalref/bioinfbo.html

45. **Scott**
June 5, 2005

Juan,

"Most chemists react with complete incredulity to the
view that structure is nothing but a metaphor, pointing out the
seemingly overwhelming evidence for structure that comes from spectroscopic and other structural studies. They suggest that if a deep quantum mechanical analysis reveals molecular structure to be a mathematical artifact, then the fault must lie with present-day quantum mechanics and not with the deeply entrenched chemical notion of structure."

where did this quote come from? I would suspect that any chemists who share this view do not trully understand what the implication of QM is. Show me an actual study with evidence that the observations of DNA can't be explained by QM(not that an exact explanation doesn't exist which it won't due to the complexity of DNA).

46.
June 5, 2005

Larsson (Are there two Larssons?), can you tell us more about your theory of quantum gravity using projective representations of the diffeomorphism group? You keep mentioning to online but never spell out the details.

47. **D R Lunsford**
June 5, 2005

TL – ok thanks.

-drl

48. **Torbjorn Larsson**
June 5, 2005

Damn, I meant reviewing, not refereeing, of course. Sigh, I haven't used my English part of the brain too much lately…

49. **Torbjorn Larsson**
June 5, 2005

QT:

Taking your own advise, please tell us how SST contradict 4D spacetime? AFAIK it doesn't, 4D may emerge and there are proposals how it does.

Nitpick: You can't say that anything is allowed in QG, you mention some restrictions.

On 3secting angles, of course some angles can be constructed as required, that is known since the Greeks I think. The problem is to 3sect _all_ of them. (Or any randomly chosen one, if you prefer.) You know, most of the time we complain that you don't know, and don't want to learn, basic physics. Now it turns out you don't even know maths…

If a guy has spent 27 years to insist on something without much out of it, au contraire, he _is_ totally nuts!!! I hope you will one day understand why…

You should not confuse nut with crackpot.

I know you don't understand the latter concept completely. (Please don't ask me why!) From the above, it seems you don't know how to measure nuttyness, either. But a nut is someone who, however intelligent, is "afflicted with or exhibiting irrationality and mental unsoundness". (Hmm, so me answering you once or twice may not be nuts. 😉 A crackpot is "a person who is regarded as strange, eccentric, or crazy". So you may seem crackpot without being nuts, or you may be nuts without being regarded as crackpot.

Specifically on Matti maybe my claim, in an earlier comment, on the problems with his consciousness claims will prove correct. Crackpot or nut or neither, I cannot however judge alone; at least there must be some consensus in regard of crackpotism, see the definition above.

50. **Torbjorn Larsson**
June 5, 2005

I am hesitant to join a thread that overwhelm my ability to handle all sub-subjects, but it is raining outside and you all seem to have fun. (BTW, is there a theory for the growth of complexity in threads, however complexity is defined? 🙂 My interest stems from merely trying to orient myself shallowly on todays front edge physics, so I am eminently equiped to make a longwinded fool of myself here:

Aaron makes a lot of good points. As I understand it, it has been and will be ever more difficult (expensive and timeconsuming) to make experiments. In lack of definitive experiments, string theory as well as the contenders currently hang out there. Obviously string theory has merits, as Aaron and others point out, and it's not the only theory out there, so the situation is normal.

Some posters seem to think that good science may be put down or will stay buried. I don't agree.

There are some risk that ideas or results will be rejected outhand by mistake or purpose (to close to researchers own products), I know that from my own publishing and refereeing as PhD, alas not on theoretical physics. (Of course, I am biased since the refereeing was a consequence of my own papers being accepted.:-) Or papers may never be read and supported. This is characteristics of filters and of social contexts.

But the total risk is small for the really good stuff, so if you have great fears I would suggest that is because you have some other reason to be.

Chris:
How do you make sense out of "the Laws of Physics are determined by the requirement that the laws of physics are discoverable"? Is it not possible that there are laws of physics that will never be discovered (to become Laws of Physics) or explained? I think Goedel has something to say about that in an even simpler context.

Matti:
I thought the view that QM should have anything to say about consciousness was shown to be a dead horse long ago.

There are still no good definition of consciousness, so how do you measure and experiment?

And when we can do that, there is the matter of QM interpretations, or 'different religions' that I saw someone refer to them as. I think decoherence and/or consistent histories make consciousness unrelated to QM. If that happens, you probably cannot do what you propose to do, unless you can make these interpretations faulty. Honestly, in my consciousness you appear nutty on this. 😉

51. **Quantoken**
June 5, 2005

A Rivero:

Surely there ARE crackpots who claim something that has long been proven wrong, like perpertual motion machine kind of thing. But more often there are alternative theories that were thought to be crackpots because they do not seem to be adhere to the main stream, but they actually adhere to all known and proven physics theories, and they only contradict the unknown and unproven of physics.

For example super string theory is crackpot, because it clearly contradict some known and proven physics, e.g. that **spacetime is proven to be 4-D**. And anything that does not agree with super string is probably NOT crackpot, as long as they have no inconsistency to classical and quantum mechanics and other known physics laws. As in quantum gravity, since it is totally unknwon, anything is allowe so far.

I hereby boudly claim that I find trisection angles is possible for some angles. Reading that most must think that such a claim is a crackpot because it's long proven trisection of angle is impossible. But it is actually possible for **SOME** angles. This is exactly what happens when a paper making some unusual, out of the main stream claims, is submitted. You would probably throw it away the first instance upon seeing the offending keyword trisection angle, but if you spend some time and taking it apart you find the claim actually does not violate any thing that is known so far.

Matti Pitkanen is an interesting guy. I do not think I can agree with his theory. But if a guy spend 27 years to insist on something, unless he is totally nuts he must have thought about something that no one has thought about.

My point is that if any one spend a little bit time study what his stuff is, and picking out just one claim he made which clearly violates one of the known physics law, then he can be called a crackpot. But if **no one** has done such a study, and no one has picked apart even **just one wrong claim** of Matti Pitkanen's, then he deserved no hat called "crackpot", regardless how weird his theory seems to be to the rest of us.

For civilized discussions can we all agree on that? That the word “crackpot” should not be abused as a four letter word used for personal attacks, but rather should be used together with facts and evidences. If you claim Joe is a crackpot, then show one case where Joe makes a claim which contradicts known physics? If you are unable to cite examples, then you should be refrain from using that word.

Quantoken

52. **Alejandro Rivero**
June 5, 2005

Every so often, Peter W has to drive all the crackpots out of his comment section, and clearly this thread is ripe for another such cleanup. But maybe PW should ask himself why his blog is so popular with nuts.

You are from outside academia, are you? Physics departments everywhere in the world constantly receive reports of squares of the circle and trisections of angles, so to say. With the advent of the internet, they also come via email or web; check any other forum on physics, from physicsforums to the forums of the official string-theory website. Bet the MIT librarian could name a complete collection of free books and preprints from nuts. Sci.phys… newsgroups are in the same situation. The internet is working as a publishing media, but it fails to be a research & learning media, and the nuts are always a good excuse for this failure.

?Interesting article here on history of peer review by F. Tipler, including metion of Einstein’s 1905 papers,and how we came to the present system we have today. ?Peer Review. Does it ensure quality or enforce orthodoxy???

I have studied a bit the current scientific publication system, and could offer you dozens of convincing answer. Below two of them:

At least 18 of the articles next identified between the most cited of the history of science (according to the Science Citation Index) were initially rejected by editors and referees of scientific journals.

Nature rejected a Nobel class manuscript from Hideki Yukawa. The Physical Review also rejected similar manuscript in 1937

One of the referees of Physical Review found three ?errors? in Yukawa paper and recommend the reject. Yukawa won the 1949 Nobel Prize in Physics for his prediction of the existence of mesons on the basis of theoretical work on nuclear forces with that same paper.

This does not ensure quality

Thomas Larsson

Locality fails when one works in far from equilibrium situations. This is standard for anyone with a slight knowledge of that field (of course, outside the trivial applications of local QFT).

It is unnecessary the appeal to QG then.

Scott said

Personally I am not aware that biochemists were having any trouble understanding DNA structure so I see no reason why the laws of physics would need to be changed to accommodate DNA.

This contrast broadly with more recent chemical thinking.

?*Most chemists react with complete incredulity to the
view that structure is nothing but a metaphor, pointing out the
seemingly overwhelming evidence for structure that comes from spectroscopic and other structural studies. They suggest that if a deep quantum mechanical analysis reveals molecular structure to be a mathematical artifact, then the fault must lie with present-day quantum mechanics and not with the deeply entrenched chemical notion of structure*.?

I cannot post more data here because Peter would erase but the point is that QM is not sufficient for explaining mind (one even cannot explain DNA). In some restricted sense, Penrose is correct.

54.
June 5, 2005

Every so often, Peter W has to drive all the crackpots out of his comment section, and clearly this thread is ripe for another such cleanup. But maybe PW should ask himself why his blog is so popular with nuts.

In that connection I note that the name of Shamit Kachru regularly gets mentioned contemptuously here. I don’t see what SK has done to deserve such abuse. The truth, of course, is that anyone here, including me, would be delighted to have a publication list one-fifth as impressive as SK’s.

55. **Thomas Larsson**
June 5, 2005

DRL – local frame rotations generate a different group, isomorphic to gauge transformations with gauge group SO(3,1). This has nothing to do with diffeomorphisms, except that the vielbein transforms under both.

A rep is projective if it only holds up to a phase, eg. spinor reps of SO(3), which are in fact proper reps of SU(2). For infinite-dimensional groups, projective reps modify already the Lie algebra, e.g. in 1D the diffeo algebra becomes the Virasoro algebra (which is well known), and in several dimensions we get the multi-dimensional generalization thereof (which is new).

A key insight from CFT is that there are two qualitatively different types of reps; classical reps which act on primary fields (scalar densities), and quantum reps where L_0 is bounded from below. The higher-dimensional generalization of the classical reps act on things like tensor fields, connections, closed forms, etc. In fact, any concept in differential geometry can be formulated in terms of reps of the diffeo group, which is obvious once you think a little bit about it.

Another lesson from CFT is that it is the quantum reps that appear in quantum physics. The only proper (no Virasoro extension) quantum rep is the trivial one, which implies lack of locality. So if we want local general-covariant QFT, we have no choice but to consider projective reps. Considering that 't Hooft allows himself to think about hidden variables to achieve locality, I think that it is a rather big deal.

56. **Matti Pitkanen**
June 5, 2005

Kea's comment:

"I don't like the term 'consciousness' myself, but have a great sympathy for the direction of your work, as a category theorist. I prefer to talk about the Comprehension Scheme, following the work of Lawvere and others on the topos theoretic foundations of mathematics."

Thank your for an interesting and encouraging comment. My own strong conviction is that a real unified theory cannot contain logical contradictions in its basic structure, therefore consciousness. Instead of consciousness one could of course speak about the necessity of constructing theory of quantum measurement by making conscious observer part of the physical universe. Here von Neumann would probably agree.

I do not have any deep understanding about the technicalities of category theory and know only the basic concepts. It is however obvious to me that a systematic "structuralist" thinking is necessary if one really wants to construct anything resembling TOE. In M-theory this aspect seems to be absent. To me category theory seems to be tailor made to say something about consciousness ("Comprehension Scheme"). After all, the contents of consciousness remain hidden somewhat like the "real" structure of objects of category if only morphisms are known. Amazingly non-trivial things can be said about consciousness using only minimal starting assumptions consistent with quantum measurement theory. I have discussed possible applications to TGD in Category Theory, Quantum TGD, and TGD Inspired Theory of Consciousness and Equivalence of Loop Diagrams with Tree Diagrams and Cancellation of Infinities in Quantum TGD.

There were comments about locality somewhere in the thread. Space-time locality is the source of infinities in quantum field theories. If one identifies physical states of the Universe as modes of classical spinor fields in the world of classical worlds (briefly CH), situation changes. Physics is local and classical in CH but non-local at the level of 3-surface since K?hler function as "absolute minimum of Kahler action" is a non-local functional of the three-surface. As a consequence, the standard local divergences of path- and functional integral formalisms do not appear in TGD. This view about physics is almost unavoidable in "structuralist" mind set and I see the result as a demonstration about the problem solving power of this approach.

Matti Pitkanen

57. **Scott**
June 5, 2005

the Laws of Physics as we know them today are determined by the requirement that things we observe are possible.

If this is what you mean when you say you agree with Suskind's statement then yes of course. But this is not what Susskind is implying.

however you say "As a pragmatist I simply recognise that the structure of DNA appears with tortile tensor categories, and hence must play a role in the new physics"

Personally I am not aware that biochemists were having any trouble understanding DNA structure so I see no reason why the laws of physics would need to be changed to accomodate DNA.

58. **Kea**
June 4, 2005

Susskind: "the Laws of Physics as we know them today are determined by the requirement that intelligent life is possible"

The great irony in this quote is that the likes of Penrose, Matti and myself actually like the quote! Only, right out of context. My interpretation of it is completely different from anything resembling the Anthropic Principle. As a pragmatist I simply recognise that the structure of DNA appears with tortile tensor categories, and hence must play a role in the new physics. This is not to say that it is possible to say anything meaningful about the highly derived construct of intelligent life in the foreseeable future. I think that's stupid.

59. **anon**
June 4, 2005

I have a 2005-is-not-1905 experience to tell :

Our HOD copes well in the corporate culture of today. Every 6 months all PhD students have a meeting with the HOD and their supervisors. In one of my meetings it was carefully explained to me that, even if my work was as good as Maxwells no one would take the slightest notice if I did not have a PhD – so I had better put my head down and do what I was told.

60. **Kea**
June 4, 2005

Matti

I don't like the term 'consciousness' myself, but have a great sympathy for the direction of your work, as a category theorist. I prefer to talk about the Comprehension Scheme, following the work of Lawvere and others on the topos theoretic foundations of mathematics.

All the best…

61. **Kea**
June 4, 2005

I am constantly amazed by the number of physicists that seem to think an advance in QG will be made using mathematics with which they are familiar.

62. **Kea**
June 4, 2005

"Although not wishing to defend the custodians of arXiv in any way, it is hard, looking at your web pages, to see why your work is deserving of the term physics. I would see it more as a mathematical tangent that originated in physics…"

So TL, are projective reps of the diffeo group just local bein rotations?

-drl

64. **Thomas Larsson**
June 4, 2005

Gerard t'hooft: …What seems to be missing presently, however, is a clear description of the local nature of its underlying physical laws. …

It is interesting that both 't Hooft and Unruh emphasized locality. 't Hooft himself even seems ready to dismiss quantum mechanics to obtain that goal (Planck-scale determinism). In this connection, it might be worth to recall item 9 in Baez' crackpot list:
9. 10 points for each claim that quantum mechanics is fundamentally misguided (without good evidence).
Actually, IMO the caveat applies, since locality is a very good reason for anything, so 't Hooft misses his 10 points.

He makes his point perhaps even clearer in the video from the same site, where he quotes David Gross saying "There are no local observables in quantum gravity, so forget it". Which of course is true, unless you allow for projective representations of the diffeomorphism group…

65. **Arun**
June 4, 2005

F. Tipler loses me when he suggests that Intelligent Design is a scientific theory and indulges in quote-mining Lynn Margulis against Darwinism (problems in the Darwinism do not open the door for Intelligent design). That suggests to me that he may be quote-mining all the other problems that various scientists have stated they have had in having radical new ideas accepted.

Anyway, in my opinion, let a million flowers bloom, and let there be a good search engine, and let people pick for themselves which ideas they find valuable, worth pursuing, and so on. Scientific respectability is like brand value, it is earned and maintained by providing high quality.

66. **stephen**
June 4, 2005

Thanks for link. It is important to have evidence of what t' hooft was thinking, contrary to other peoples thoughts.

Gerard t'hooft:String theory clearly appears to be strikingly coherent. What seems to be missing presently, however, is a clear description of the local nature of its underlying physical laws. In all circumstances encountered until now, it has been imperative that external fields, in- and outgoing strings and D-branes are required to obey their respective field equations, or lie on their respective mass shells. Thus, only effects due to external perturbations can be computed when these external perturbations obey equations of motion. To me, this implies that we do not understand what the independent degrees of freedom are, and there seems to be no indication that these can be identified. **String theoreticians are right in not allowing themselves to be disturbed by this drawback.** Pg. 79

67. **V**

Concerning ArXiv:
Note that in many countries researchers do not have access to journals, because they are too expensive. The ArXiv is then the only connection to the scientific world. (Well, sometimes we sent them the published version of the paper by e-mail, when asked.) I personally know one researcher who is regularly publishing in PRL and PRD but his university does not have funds to allow him to print the papers on the printer. He is thus reading papers only on the computer for years. This is what I call a real lack of funding.

68.

?Also if you start using terms like "theory of consciousness", then AFAIC you are entering Crackpotsville (that favourite resort of disgruntled academics).?

Well, Matti can speak, study, research, etc. all that want do. There are not prohibited fields. Or perhaps there are? Past Pope recommended to Hawking do not study about Big bang and origin of universe!!

Gell-Mann is also interested in theories of consciousness. He offers talks and is collaborating with biologists, etc. Also Nobel laureate Watson (or was Crick?) did a "theory of consciousness", based in ?memory delay?.

Are Matti, Gell-Mann, Watson, neurobiologists, biochemists, quantum chemists working in anesthesia effects, etc. crackpots?

Sorry – I meant to qualify that. The connection with physics is the thing I think is tenuous.

70. **Thomas Larsson**
June 4, 2005

In my experience, mathematicians are much more open to ideas from outsiders than are theoretical physicists. Once one young string theorist independently made the same key observation that I did, namely that infinite-dimensional constraint algebras generically have quantum anomalies. Alas, he was only interested in this observation as a means to discredit LQG. When he realized that I agreed with him, he became so embarrassed that he declared that canonical quantization is invalid. Not only is this one of the weirdest claims I have even seen, but it is also completely irrelevant, since conformal anomalies also manifest themselves in the path-integral quantization of the Polyakov action.

How open-minded are people if they dismiss their own ideas just because I happen to agree?

mortain said

?Only if you are 'endorsed' by those already able to post on the arXiv.?

That is not true. From my personal correspondence with a physicist that know ArXiv very well

?*If administrators at ArXiv.org sent you a list of endorsers, most likely they would have been people who are strong supporters of string theory. It is probably not advisable to use the names they sent you. As an alternative you can go to the arxiv.org section where you are interested in posting and find papers by scientists which show that they do not necessarily support string theory and look on their abstract to see if they are qualified to endorse papers. If so, you could try sending to them. Perhaps you would have a better chance*.?

and he continues with

?*However, even if they endorse you, this does not guarantee that arxiv.org will allow you to post your paper, since they have a history of disobeying their own rules and have blocked people who have been legitimately endorsed (my own personal experience)*.?

Aaron Bergman said

?I'm just a guy doing fairly mathematical string theory. It's not a surprise I don't know something in phenomenology? But, it's out of my area so I can't really comment much more.?

Reading your comments on ArXiv and Swiss patent clerk. You appear to be ?out of my area? also here. Brian Josephson has studied the topic a bit (see also his letter in *Nature*). You simply are doing ?speculation? favoring your own views.

Probably you know that many administrators of ArXiv are oriented-string researchers. Perhaps would be more easy obtain endorsement and permanency on ArXiv for you 🙂

Please, write a short paper claiming that string theory is completely wrong and a waste of time and attempt again for endorsement and posting :-))

Your comments on that Einstein published his paper in usual journal may be understood in a pure 1905 perspective. He, today, would be rejected for peer-review publication, I am practically sure, I know a bit about editorial guidelines and publication policies.

?If Newton had published his theory today, it would be rejected for peer-review publication because was too ambitious one.?

From previous editor-in-chief of *Nature* journal.

D R Lunsford said

?Unaffiliated Individuals – Scientists, engineers or educators in the US and US citizens may be eligible for support, provided that the individual is not employed by, or affiliated with, an organization??

Also for outside of US? Have you read about rigidity of Spanish science administration system? Probably one of most rigid of the world!

In Spain it's not ?impossible? but more practical to play to Lotto 🙂

Chris Oakley said

We are mixing two different problems: a) if/how foreigners to academy get a fair hearing. b) if/how foreigners to strings -or to the next mainstream- get a fair hearing.

73.
June 4, 2005

1. The arxiv is certainly very useful but also overrated. It is a double-edged sword. This year I needed detailed information on two topics and what I found on the arxiv in each case was pretty much utterly hopeless. Having consulted text books and various paper journals, going back a few years, I found the information I needed in detailed and substantial form. The arxiv is also now chock full of papers that have serious errors or are just superficial waffling and hand waving. I only read arxiv papers that were or are subsequently peer reviewed and published in a real journal. The Wittens and Weinbergs don't need peer review–everyone else does. Incidently, how many Landscape papers for example, would actually make it into Nucl. Phys. B or Phys. Rev. D? I read paper journals and will continue to do so. I would like to see a totally blind and unbiased system of peer review whereby there are no names or affiliations and the reviewers see only the physics content of "a manuscript".

2. I published 4-5 papers in the late 90s, and in my spare time, that had no academic affiliation.
(My stuff is more mathematical physics and math though.) Having a Phd certainly does help however. If your work is good enough or has any substance and it professionally presented, it at least gets a fair hearing. Editors can tell right away whether a manuscript has merit and should be considered or is just crackpot, and whether the author has a formal professional background in the subject. A lot of trained mathematicians and physicists work at companies and their own businesses. They still have a right to publish any ideas they still might have. I've seen published physics papers where the affiliation was a financial institution so maybe the next 'Albert' (male or female) is working at a bank rather than a patent office. My concern with the arxiv and physics publishing in general is that censorship and political motivations replaces fair and unbiased peer review.

74. **Matti Pitkanen**
June 4, 2005

Chris,

your earlier postings have not shown even a slightest indication that you have understood the idea of scientific argument. You produce just arrogant rhetorics typical for people who have never thought a single original thought and for some reason call themselves skeptics. You can perhaps scare some first year student but cannot cheat professionals.

Since you have obviously not yet learned what is the point of scientific discussion, I am willing to give some helpful advice. First ask yourself: do I have really something interesting to say? If the answer is yes, formulate clearly what your claim is. But do not stop here! You must also carefully develop arguments that you believe to justify your claim.

It is never too late,

Matti Pitkanen

75. **Scott**
June 4, 2005

I'm going to have to agree with Aaron, if your paper has any merit if and you are determined enough you can find a proffesor who will give you a chance whether this be your old advisor or anyone else. I would suggest looking outside of string theory for this professor though.

76. **Alejandro Rivero**
June 4, 2005

The funding problem is not about affiliated vs unaffiliated, it is about mainstream vs exploratory research. As I said before (upstream in the thread), even having tenure does not imply funds, at least in the European universities I know. A professor only has a limited fund for education, and zero euros for research. So he must ascribe to a research group, and the research group must send a proposal for funding to different institutions. Individual proposals have not encouraged (ie, they are unlikely to be accepted by the granting institution). And of course a group proposal outside mainstream is also unlikely to be accepted, as it is a huge assignation. Nice catch-22 here.

The way out is that a research group "looks towards other place" when one of their members do exploratory research. This ability to look to other place depends of a lot of factors from seniority of the researcher to his willingness to support the mainstream papers too, and of course of the risk for the prestige of the group (remember that a failure in prestige can imply loss of funding for all the group).

Low profile, not risky, research, is usually supported at the level of local resources even for not affiliated people keeping relationship with the field (as Aaron describes correctly). It is a bit more problematic to support travel and meetings of unaffiliated, but it can be arranged occasionally from minor allowances in the group funding. But at the end there are a group responsible for the funding, remember, and they have a limit in the risk they can take.

Now, beyond travels, chalk and blackboards, imagine the nighmare in *experimental* physics. I know of a (actual, I am not referring to Cavendish) young tenured professor leaving the campus because he foresaw that it was impossible to get funding for a different experiment; one needs to convince all the collaboration to resign from the current research line.

77. **Chris Oakley**
June 4, 2005

Matti,

Although not wishing to defend the custodians of arXiv in any way, it is hard, looking at your web pages, to see why your work is deserving of the term "physics". I would see it more as a "mathematical tangent that originated in physics", a classification that also applies to String theory, LQG, Twistor theory and dozens more ideas that have not, and may never lead to testable predictions. Also if you start using terms like "theory of consciousness", then AFAIC you are entering Crackpotsville (that favourite resort of disgruntled academics).

78. **Matti Pitkanen**
June 4, 2005

I have now worked almost 27 years with Topological GeometroDynamics. I have written four massive online books about TGD giving a detailed documentation of the theory and its applications(about 5000 pages). American Mathematical Society has in its subject classification table a link to my homepage. Penrose refers to my work relating to p-adic physics in US edition of his newest book.

Despite this it has been impossible to get material about TGD to arXiv.org during the last decade. Because TGD challenges the basic materialistic and reductionistic dogmas and is also a quantum theory of consciousness, I cannot expect invitations to physics conferences and the idea about getting some financiation is totally outlandish. I feel disgusting even the thought of forcing people in difficult position by begging for endorsement to arXiv.org. In practice this of course means professional death since no one takes seriously a person who cannot get eprints to arXiv.org.

This situation inspires a small thought experiment. Suppose for a moment that TGD indeed provides the bottle neck ideas necessary to unify the basic interactions. The physical interpretation of TGD was more or less established around 1982, 2 years before the first super string revolution, and collective effort to develop these ideas could have been launched then. On basis of this one can make rough estimates about the financial and human resources wasted during these 20 years as an outcome of my marginalization in physics community in the case that I am right. I am certainly not the only victim of censorhip and one of us might be right. Arrogance costs.

Matti Pitkanen

79. **D R Lunsford**
June 4, 2005

Aaron – getting funding is a challenge, regardless of publishing, if you're not affliliated:

Unaffiliated Individuals – Scientists, engineers or educators in the US and US citizens may be eligible for support, provided that the individual is not employed by, or affiliated with, an organization, and:

** the proposed project is sufficiently meritorious and otherwise complies with the conditions of any applicable proposal-generating document;*
** the proposer has demonstrated the capability and has access to any necessary facilities to carry out the project; and*
** the proposer agrees to fiscal arrangements that, in the opinion of the NSF Division of Grants & Agreements, ensure responsible management of Federal funds. Unaffiliated individuals should contact the appropriate program before preparing a proposal for submission.*

But, it's not impossible.

If you have something worth saying it will worm its way to the surface.

-drl

80. **Aaron Bergman**
June 4, 2005

Aaron, you mean your PhD "thesis adviser", right?
Suppose you are a patent clerk (or any other occupation) in 2005, with no physics PhD, and a BSc or MSc in physics. Do you think your undergraduate tutor or mentor (or anyone else) would endorse you to allow you to post three preprints on the arXiv? You could submit your work to journals, but in this century, how likely are the editors and referees to take your research seriously, when you have no academic affiliation?

If they were good, yeah. Good meaning more than just 'good physics'. They also need to be clear and well-written. If I were to try something like this, here is what I would do. I would pick a junior faculty member and send a polite e-mail noting your background, the problem you think you have solved and the techniques that figure in the solution. Note that you have a clear, publication quality exposition of the idea with lots of formulae and calculations. Say that you're not sure that what you've done is right and that you'd appreciate any advice they could offer. Some people will ignore you, but if you have a short, clear exposition, I'll bet someone will look at it. It might even end up being a graduate student. If they tell you it's wrong, let it go. If they tell you they don't understand it, ask how you can clean up the exposition. If they don't want to say anything else, let it go. Be polite and be willing to accept that you might just be wrong.

Needless to say, this is not how most things of this sort go. The vast majority of people writing from outside of academia have things that are either completely incoherent or you can tell that they are completely nutty in about three lines. And very, very few of them are polite. Remember, capital letters, boldface and exclamation marks are *not* your friends.

81. **mortain**
June 4, 2005

You could submit your work to journals, but in this century, how likely are the editors and referees to take your research seriously, when you have no academic affiliation?

Quantoken: nice comment. It chimes with my own opinion on string theorist TV appearances. Walking on the street is a recurring theme in string theorist/theory documentaries, I believe. I recall Brian Greene sitting in a cafe and wandering around New York in his 'Theory of Everything' (U.K. title) series. That same series did repeat several sequences of CG imagery ad nauseum, especially those squiggly blobs on a grid. At least we weren't treated to a middle-aged man taking a dip!

Then there was that old BBC 'Horizon' documentary which showed Witten walking around a rocky landscape and gazing at the sky. Beautiful scenery, but surely not representative of the common working environment for theoretical physicists, and now perhaps illustrative of the quest of string theorists as they confront a barren Landscape.

82. **Aaron Bergman**
June 4, 2005

Do you really believe this? Wow. Do you mind if I ask you a personal question? How many years of your postgraduate life have you spent working outside academia?

Yes. I believe this. You know why? Because Einstein got his doctorate while outside of academia. He submitted his thesis in 1905, while working as a patent clerk since 1901. Einstein's papers were submitted to journals during that time, too and were accepted.

You know what else? There are people outside of academia publishing papers on the ArXiv (although the name of the person I'm thinking of escapes me right now.)

If you develop a good relationship with your thesis adviser and you write a good paper, you'll get endorsed. That's probably the easiest way to go. Really, being out of academia has nothing to do with anything. Not being a kook is the key.

83. **Kea**
June 3, 2005

Aaron: "This swiss patent clerk would have gotten endorsed by his old adviser and posted to his heart's content."

Do you really believe this? Wow. Do you mind if I ask you a personal question? How many years of your postgraduate life have you spent working outside academia?

84. **Quantoken**

Berry said:
""Even after 20 and more years, my feeling is that we do not understand string theory but that there is every indication that there is something there to understand."

This is the key point, isn't it? Is 20 years a long time or a short time? I would say that it is extremely short."

The first paragraph is a nonsense. Of course if you don't understand something then there is something to be figured out and understood. If you understand it all then there is nothing remaining to be figured out. But that says nothing about the thing you don't understand or whether it is relevant at all to the nature.

It is OK with me that some string theoretists feel they need a couple more 20 years to figure things out. But looks to me many of them have changed their professions to scifi novelists. These days you can not turn on the TV without seeing fancy stringy terminologies flying around, like landscape, bubbles, parallel universe etc etc.

What is that grey-haired Japanese guy who always shows up on TV, talking vividly, with mistery written all over his face? I see him more often than Dubya these days. The other night I was watching the Science Channel. Half of the night was filled with a series string theory programs, from "parallel universe" to "bubble universe" and "unfolding universe" and to "extra dimentions".

Can you believe it? They can talk the whole hours and show tons of colorful amazing computer animations, but at the end of day **they have NOT talked about a single thing that actually had anything to do with nature.** Not a single thing in string theory has been proven to be relevant to the nature in any way shape or form. Whole hours of TV program was filled with scenes of these famous guy writting something on the blackboard or on a piece of paper, typing on a computer keyboard, sitting, standing, sleeping, walking on the street, playing tennis, and swimming. There was a closeup of one of these guys swimming half naked, taken by an underwater camera.

What does it all has anything to do with science? It's ourageous they could propagate to the public in such a misleading way when they really have absolutely nothing to talk about about their research results after 20 year.

Reminds me of politicians who could talk for half an hour none-stop, and when you pick it apart you find that actually not a single thing has been said!

Quantoken

85. **Scott**
June 3, 2005

Peter,
You had me going there for a second. I had to go back to find other posts of Barry's in one of your other blogs, in order to figure out if you were joking or if you were actually complimenting him on a joke.

86. **Peter Woit**
June 3, 2005

Hi Barry,

Thanks for the parody of what string theorists are thinking these days. It was very funny.

87. **Alejandro Rivero**
June 3, 2005

Perhaps there are several "Einteins" in the world, but since they cannot post in ArXiv

ArXiV (and journal editors, generically) is not the problem, it just reflects the community (and note I have been myself censured/blocked some times in the past, sometimes due to content,
sometimes to -editor's opinion- "spamming"). Do you remember these poor guys in each macroconference trying to attract people into their poster? People knows that, beyond the content, the probability of immediate use of any of these posters is very low, and they do not care.

This guy, rejected the invitation because would pay the travel, etc. from his own money.

A related problem is that in most countries even **tenured** teachers do not have direct allowance for research expenses, and they need to get this money not from the university they are, but from external sources.

Of course a single travel is a minor issue, and sometimes I have been lodged in spare rooms of the conference lot, or in family houses. But as years go by, it becomes a real nuissance. So for the dreams of independent research at tenure.

88. **Alejandro Rivero**
June 3, 2005

I'm just a guy doing fairly mathematical string theory. It's not a surprise I don't know something in phenomenology

I acknowledge I was abusing a bit of empirical data by generalising from one guy to the whole community.

Still, it is a pity how divided we have come. Part of the problem is that almost nobody in hep-th (or math-ph) can remember why such or such topic is worthy of study.

Myself I was just a guy studying non commutative geometry and then two years ago some accident launched me to read phenomenologist papers. In the world of hep-ph, closer to experiment, it becomes more evident that in the route to success is not enough "calculation + publication + prediction"; you really need to fit in the mainstream. Following the previous example, another semiempirical formulae as the last year Minakata-Smirnov, which is neutrino related, have got in a short time a higher level of awareness -measured as citations from different authors and countries- that Koide's, which is for charged leptons.

89. **Quantoken**
June 3, 2005

Some one said:
"The arXiv is purportedly "a means for specific communities of scientists to exchange information." **One hundred years after 1905**, a Swiss patent clerk without a PhD in physics would surely have been locked out of the arXiv.

This swiss patent clerk would have gotten endorsed by his old adviser and posted to his heart's content."

I say **absolutely NO** and there is absolutely not a single piece of evidence for it. Notice we are now talking about **A swiss patent clerk in the year 2005**, whose name is most probably not called Einstein, **NOT the 1905 guy** called Einstein.

Can you name just ONE recent ARXIV paper which is authored by an actual real swiss patent clerk with no fame, with no Ph.D. and no academy institution association? Can any one name even just one such paper?

Not a single one I would say!

There is no scientific evidence to suggest that any swiss patent clerks can publish on today's ARXIV, and plenty of evidences to suggest otherwise.

Rememeber Einstein was NOT a famous swiss patent clerk in 1905, he was an **average and no-name patent clerk** back then, and needed to tutor high school students to supplement family income.

Quantoken

90. **Aaron Bergman**
June 3, 2005

Well, I have already made have of my point 🙂 *if nobody knows what papers are.*

I'm just a guy doing fairly mathematical string theory. It's not a surprise I don't know something in phenomenology. I notice that the PRD paper has 104 cites, though, which makes it hard for me to believe that nobody knows what it is. But, it's out of my area so I can't really comment much more.

The arXiv is purportedly "a means for specific communities of scientists to exchange information." One hundred years after 1905, a Swiss patent clerk without a PhD in physics would surely have been locked out of the arXiv.

This swiss patent clerk would have gotten endorsed by his old adviser and posted to his heart's content.

91. **Kostya**
June 3, 2005

For anyone who is interested here is a link to t'Hooft's lectures which he used in his string theory class.
http://www.phys.uu.nl/~thooft/lectures/string.html
It's a very nice introduction with many detailed computations that are usually skipped in most textbooks.

92. **mortain**
June 3, 2005

Peter, hasn't the length of this thread of comments set a record for comments on your blog? I don't recall seeing the number of comments on any of your other blog posts reaching 100. It seems notable and even remarkable.

Juan R., I too thought that the arXiv's 'endorsement system' is a terrible development. Why did they have to change their ways after a decade or so without such a system? They even had more funding directed to them in recent years! "The growth in number of submissions to arXiv necessitates an automated endorsement system" – well, why not use the additional funding to create more personnel positions and not shut out people who take a courageous step into the domain of academic physics? I think their reasons for the endorsement system are utter crap. After all, I don't recall the arXiv being swamped with crank 'preprints', and surely such 'preprints' only ever constituted a small fraction of the total content of the arXiv since its inception.

Yet they claim that "we can continue to offer free and open Web access to all." Yeah, right. Only if you are 'endorsed' by those already able to post on the arXiv. Maybe it has naturally become a mirror of the off-line world of selectivity on the 'it's who you know' basis in secular physics departments. Or a sad reflection on the state of the modern physics community.

The arXiv is purportedly "a means for specific communities of scientists to exchange information." One hundred years after 1905, a Swiss patent clerk without a PhD in physics would surely have been locked out of the arXiv.

93. **Juan R.**
June 3, 2005

Someone said

"Good luck being the next Einstein. If you're good enough to revolutionize the field while working outside of it, then you won't need any of my advice. But, for those of us who aren't as smart as Einstein, there are better paths to take."

Simply stupid and arrogant!!

"And, in the time since Einstein, can you name one physicist who wasn't at a research institution that made a revolutionary contribution?"

Perhaps there are several "Eınteins" in the world, but since they cannot post in ArXiv, as emphasized this year

Covert censorship by the physics preprint archive

by Brian Josephson (Nobel laureate for physics) (has you read his February open letter to community?

nor pay expensive print requirements from their own money for publish in a JCP, etc.

Curiously I know to one guy from outside of official academy that did a paper on nanothermodynamics, and was formally invited by a organizer (who read him) of an international conference on the topic.

This guy, rejected the invitation because would pay the travel, etc. from his own money. No because he could not write a conference. In fact, that guy gave a conference (in marine sciences) being an undergraduate student because its previous institution payed it.

94. **Alejandro**
June 3, 2005

Sorry the duplicate. Peter has put a "blocking system" that confused me; I was attending to a student (ah, exams) and at the same time pressing the "Post" button

🙁

95. **Alejandro Rivero**
June 3, 2005

There are 245 papers under 'Koide' on SPIRES. You're going to have to be a bit more specific.

Well, I have already made have of my point 🙂 if nobody knows what papers are. But the two more recent show the formula and references, so one can start from the references, for instance, of hep-ph/0505028

The earlier references online are Phys.Lett.B120:161,1983 and Phys.Rev.D28:252,1983

I think it is worth echoing some of Aaron's words:

"So, if you want to have fun speculating occasionally, that's cool, but in the meantime you should also publish results that people can point at when they want to hire you. If you want to put in the time and energy that generating a new theory of quantum gravity will probably entail, it's probably a good idea to wait… The point being is that, before you have tenure, and to a lesser extent even afterwards, you have to produce. I'm sorry you find this offensive, but it's just the way things are."

Those are hard words, but in my opinion probably on the mark. I am somewhat of an idealist myself; if it isn't possible to look beyond the horizon, explore some ideas outside the mainstream and feel a passion about gaining understanding and (hopefully) making a real contribution to physics, then physics becomes "a job" and loses much of its appeal. As a grad student myself, I am sympathetic to Scott's and others' point of view. But, as Aaron indicates, you still have to live in a results-oriented society…

As in business, if you aren't producing you are a lot less likely to remain employed, and if you aren't succeeding at some level others are likely to ignore you and your ideas. If a research institution is looking to hire someone or a funding agency is looking at grant proposals, they will want to feel reassured that the people they choose will actually produce something. That is human; who wouldn't think that way? If you had two acquaintances who wanted to borrow money from you, would you rather lend to the one who had a track record of being conscientious and trustworthy or the one whom you knew little or nothing about in terms of their trustworthiness? Institutions and funding agencies have plenty of choices; why not go with the "safest" people? Idealism is good for your (and my) own motivation, but other people would rather take a risk on someone with a track record.

It's a harsh world out there for the seeker of knowledge and understanding for its own sake…

98. **Scott**
June 3, 2005

Barry,

Honestly if we aren't intelegent enough to realize that not all landscapers are adament about the antropic principle or to think that string theorists in general agree with peter that the game is over why would you care what we think as that would obviously make us retarded. Obviously the people doing research in string theory have different oppinions on it then peter.

20 years not long? its only one less then i've been alive. 20 years and still no testable predictions? Maybe you should look back on 20th century physics and see how much things progressed(by which I of course mean more and more predictions being made and verified more experimental results being explained) every 20 years.

"This is what an ambitious student should be aiming to do"

Isn't that what you guys have been trying to do for the last 20 years? Why should all ambitious students tie themselve down to one theory that has gone nowhere(aka made no verified predictions) in 20 years?

99. **Barry O'Genesis**
June 3, 2005

I'm very impressed by Aaron's original contribution to this thread and I would like to underline some of his points, especially for the benefit of any students or prospective students who might be reading this.

Aaron said:

"So, hopefully without sounding horribly condescending, I just want to point out that Peter's blog does not present a good idea about how things are."

This is absolutely correct. I do not see any signs of despair among the string theorists I know, including the landscapers. Maybe they *should* be despairing, but they aren't. So people reading this blog should not come away believing that the "game is over" as a result of Kachru's latest.

"Flux stabilization seems to have, much to the disappointment of many, led to an overabundance of vacua. This has led to a number of different proposals on how to deal with this, including anthropic arguments."

Actually very few landscapers are really convinced anthropoids. The anthropoids are just better at writing popular science books. Also note that not all landscapers are convinced that the landscape is really all that large.

"It is not correct, however, to say that the field is consumed with this. The number of papers that deal with anthropic arguments do not even approach one half or one quarter. Most of us are perfectly happy to go on with our own projects and leave the anthropic stuff to the occasional dinner table argument."

This is true, but by the way it is not so clear that it is such a good thing. I would much rather see more people working on the landscape than on chern-simons theory, for instance….

"Even after 20 and more years, my feeling is that we do not understand string theory but that there is every indication that there is something there to understand."

This is the key point, isn't it? Is 20 years a long time or a short time? I would say that it is extremely short.

"Some argue, then, that there should be research alternatives. There are two answers to that. In terms of quantum gravity, there just aren't that many games out there, and there's not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured."

Another key point. Remember: *every* crackpot out there regards himself as an unjustly neglected iconoclast. By the time you get tenure, or indeed long before that, you should have grown up enough to realize that if you can make some tiny but real contribution to the mainstream you will be doing a lot better than most people.

"But, it's also possible that, as we understand the theory better and better, maybe some of those vacua fall away, or maybe we find universal predictions of the theory that apply for all physically realistic vacua. We'll never know if we don't try."

Exactly. This is what an ambitious student should be aiming to do, not to find a job as a patent clerk who will totally revolutionize physics by means of a simple application of the theory of left pseudo-heaps.

100. **D R Lunsford**
June 3, 2005

Back to the topic sort of,

This is a very good physicky lecture on Clifford algebraicana:

http://arxiv.org/abs/hep-th/0506011

-drl

101. **Aaron Bergman**
June 3, 2005

There are 245 papers under 'Koide' on SPIRES. You're going to have to be a bit more specific.

102. **D R Lunsford**
June 3, 2005

People will pay attention if you can surprise them with something they already know.

-drl

103. **Alejandro Rivero**
June 3, 2005

If you can calculate something people will listen

Not "something" but "almost everything". Look at Koide's work. Published in Phys Rev D and other journals, including a prediction (mass of tau) that was verified exactly (not within one or two sigmas, but just in the gaussian peak) ten years after the publication. But the original interpretation, in the context of preons, needs of a lot more of calculations to jump from "model" to "theory" and, not being mainstream, nobody is going to waste time on it. Nor to try another explanation.

You only get attention if you can calculate AND your calculations are reusable in current work of other people.

104. **D R Lunsford**
June 3, 2005

Ok thanks mike, if you wouldn't mind, could you drop an email telling me what was claimed and what is known?

-drl

105.
June 2, 2005

…and don't forget the free BBQs and afternoon teas.

106.
June 2, 2005

>>Aaah! But that's where you're wrong. I know of a >>number of smart people that have been doing PhDs >>for well over 10 years.

>And getting paid?

One can get by on remarkably little as a student. One can always earn a bit of money tutoring, waitressing or whatever.

107. **Aaron Bergman**
June 2, 2005

Aaah! But that's where you're wrong. I know of a number of smart people that have been doing PhDs for well over 10 years.

And getting paid?

So long as they keep coming up with good ideas that other academics can get credit for, they won't be kicked out.

The "good ideas" being very important there.

108.
June 2, 2005

Aaron: "If he had done that graduate school, there's a good chance they'd have thrown him out if he didn't have some good intermediate results."

Aaah! But that's where you're wrong. I know of a number of smart people that have been doing PhDs for well over 10 years. So long as they keep coming up with good ideas that other academics can get credit for, they won't be kicked out.

109. **Scott**
June 2, 2005

…like the development of relativity instead or…

110. **Scott**
June 2, 2005

well, ok I think I understand your position a little better now. Personally I am not going to worry that much about towing the line after I get a PHD because then I will be able to if nothing else at least publish on arxiv even without a job.

personally,I think that quantum gravity in the end will end up being not as hard as we think, just that the basic ideas that leads to it just hasn't been thought up and explored yet. Also I think it is because people are trying to solve the problem all at once like the development instead of by increments like the developments of quantum mechanics.

111. **Aaron Bergman**
June 2, 2005

so while you think non-tenured can i guess get away with writing some speculative papers(this being a strange definition of speculative that doesn't include stringtheory papers) you think they shouldn't do so.

Speculative in this case meaning outside the mainstream. And, generally, yes, young researchers won't get very far spending their entire time outside the mainstream. The reason why is not that this is somehow transgressive, but that generally you won't accomplish anything. It's easy to speculate vaguely, but it's very, very, very hard to get concrete results, ie, do calculations. Nobody wants to hear your ideas on what quantum gravity should be — everybody has them. If you can calculate something people will listen, but there's a reason that quantum gravity has remained unsolved for fifty years: it ain't easy.

So, if you want to have fun speculating occasionally, that's cool, but in the meantime you should also publish results that people can point at when they want to hire you. If you want to put in the time and energy that generating a new theory of quantum gravity will probably entail, it's probably a good idea to wait. Wiles, once he had tenure, was able to put aside seven years to work out Taniyama-Shimura. If he had done that graduate school, there's a good chance they'd have thrown him out if he didn't have some good intermediate results.

The point being is that, before you have tenure, and to a lesser extent even afterwards, you have to produce. I'm sorry you find this offensive, but it's just the way things are.

112. **Scott**
June 2, 2005

oops that last sentence should have ended in a question mark.

113. **Scott**
June 2, 2005

I didn't say I would be the next einstein my point was the non tenured often are the ones with the revolutionary ideas, I simply took the most extreme example of this that i could think of. Just a reminder of your origninal statement.

"there's not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured."

so while you think non-tenured can i guess get away with writing some speculative papers(this being a strange definition of speculative that doesn't include stringtheory papers) you think they shouldn't do so.

114. **Aaron Bergman**
June 2, 2005

Good luck being the next Einstein. If you're good enough to revolutionize the field while working outside of it, then you won't need any of my advice. But, for those of us who aren't as smart as Einstein, there are better paths to take.

And, in the time since Einstein, can you name one physicist who wasn't at a research institution that made a revolutionary contribution?

Just as another random note, many people seem to have missed the part where I said that one can intersperse the more speculative papers with the mainstream stuff.

115. **Scott**
June 2, 2005

Aaron how about my example(though I didn't state it explicitly and just listed patent clerk as a job where you could still work on physics ideas at the same time) of Einstein who did not even work at a school at all let alone have tenure when he published his 1905 papers.

116.
June 2, 2005

er… "not"="now" in previous posting. I must use the preview button…

117. **Alejandro Rivero**
June 2, 2005

"When I was younger I had ideas but no skills, not I have skills but ideas are scarce". Heard to a tenured teacher time ago. Consider also that the tenure track is very long, some people getting it when they are near 40 years old.

118. **Aaron Bergman**
June 2, 2005

I will leave it to the readers of this blog to decide for themselves to what extent my brief summary is accurate or useful in the context of my comment to this blog, the point of which is:
If 't Hooft had waited for tenure to pursue an approach that his adviser Veltman "could not believe", then the acceptance of the electroweak model would have at best been delayed substantially.

You miss the point. 't Hooft was working in a well established direction. He was working on theories that had been around for years (if in somewhat disrepute for a period). This is exactly the opposite of what I said someone should wait for tenure to work on. Your problem seems to be that Veltman didn't believe that 't Hooft could do it. Fine, but I never said people shouldn't work on things because their advisers don't believe in them (or, more likely in this case, are threatened by them.) Your example is simply inapposite.

(And his current ideas on quantum mechanics are not Bohmian mechanics.)

119.
June 2, 2005

On that 6-sphere paper: While I'm definitely very far from being an expert on the subject, I heard the author (who is, by the way, a physicist) talking about it a month ago, and it seemed to be seriously flawed to me then (even without understanding the details). Of course this means just about nothing, but that was my impression.

120. **mike**
June 2, 2005

The 6-sphere paper was at math.DG/0505634, but has since been withdrawn.

121. **D R Lunsford**
June 2, 2005

Someone mentioned complex structure on 6-sphere – do you have a direct reference?

-drl

122. **D R Lunsford**

PS – kids probably still say "Thank God I'm done with density matrices!"

-drl

123. **D R Lunsford**
June 2, 2005

Peter said "I don't think smart people will go into physics any more…"

Well difficulties didn't stop **you**! You have no faith in these youngsters? It's the same stuff to figure out after all.

-drl

124. **Tony Smith**
June 2, 2005

Aaron seems to disagree with my brief summary of 't Hooft's experience with renormalization of the electroweak model. My summary was primarily based on the following quotes from The Second Creation, by Crease and Mann (Macmillan 1986):
"… Early in 1971, Veltman had a conversation with 't Hooft that he has never forgotten, the interchange went as follows:
M.V.: I do not care what and how, but what we must have is at least one renormalizable theory with massive charged vector bosons, and whether that looks like Nature is of no concern, those are details that will be fixed later by some model freak …
G.'t H.: I can do that.
M.V.: What do you say?
G.'t H.: I can do that.
"And this he could not believe," 't Hooft said years later …
…
To Steven Weinberg, 't Hooft's proof just seemed like hand-waving. Then he heard that his friend … Benjamin Lee … was working on it … Besides lending 't Hooft's work his considerable prestige, Lee spent most of August translating it into a form other theorists could comprehend. "I was really impressed with that," Weinberg recalled …".

I will leave it to the readers of this blog to decide for themselves to what extent my brief summary is accurate or useful in the context of my comment to this blog, the point of which is:
If 't Hooft had waited for tenure to pursue an approach that his adviser Veltman "could not believe", then the acceptance of the electroweak model would have at best been delayed substantially.

In other words, I feel that Aaron's "wait for tenure" prescription is bad for physics, although it may be a good strategy for achieving Aaron's stated primary goal: to get a job.

Tony Smith

125. **dan**
June 1, 2005

is it true that LQG has a good semiclassical limit, a large volume limit with a positive cosmological constant with the kodama state?

126. **Peter**
June 1, 2005

David,

I'm not convinced I'm the one that's confused about the Stony Brook workshop. It's entitled "Geometry of String Vacua", and the scientific description, in toto, reads "A deeper understanding of the geometry of string compacitification has become increasingly important in connecting string theory to the real world, in the context of early universe cosmology as well as collider physics" (by the way, the idea that studying these compactifications has anything to do with collider physics is pretty funny). Among the speakers listed are Denef, Douglas, Kachru, Kashani-Poor and Silverstein, all of whom work on flux compactifications. More of the speakers work in this area than work on topological strings. If this is a workshop mainly devoted to topological strings, why does it need to be advertised as one devoted to physical string backgrounds?

127.
June 1, 2005

Is this the same t'Hooft who had made some, uh, jokes about his former advisor much in the same way that Veltman would have done so about himself?

128. **stephen**

"The problem with landscape studies is….there are an ever increasing number of people studying the Kachru et al Rube Goldberg machines. Stony Brook's yearly workshop on mathematical physics will be devoted to this this summer."

No it won't. It will be devoted, as in the previous two years, to topological string theory. The phrase in the conference description that's confusing you refers to vafa's recent work in this direction.

132. **Juan R.**
June 1, 2005

Aaron said,

No. There just isn't. Go work on inflation. Go work on electroweak symmetry breaking. Go work on dark matter. Go work on large extra dimensions. Go work on baryogenesis. Go work on susy breaking. Nobody, and I mean nobody, is forcing anyone to go into string theory. I don't know where you get this idea that there is only one 'approved topic'. It's just not true.

I am not in the game directly, but heard people like Glasgow, Phil, or Peter claiming the contrary.

I read to Vafa claiming that ST may be present in **any** important physics departament. I heard to physicists claiming by brutal presure for following the last string fad in their laboratories.

I read a string theorist claiming that many string researchers do not believe in it!!

I read to Witten, B. Greene… Greene claims that ST is the only game in the city. An undergraduate student contacted with me saiyng exactly that, there is two options: ST or nothing.

If he is not informed probably will chose an string career.

Several people contacted with me and explained that leaved physics because either one studied ST or one leaved the field. That was said to me by a PhD on string theory now working outside of physics.

That and your posts on LQG, indicate that you may live in a different world. Alice?

133. **Aaron Bergman**
June 1, 2005

The problem with landscape studies is not just the loony-tunes people in high places who have abandoned doing science to promote anthropism. There are an ever increasing number of people studying the Kachru et al Rube Goldberg machines.

All I can do is point to the papers on hep-th. I just skimmed through the 'recent' search and counted a grand total of one paper on the landscape. A search on 'landscape' in the title or abstract gives 31 papers in the past year. 'Flux vacua' gives 37. Hardly a deluge.

The problem with the idea that young physicists should just keep their head down, and work on approved topics until they get tenure is that right now, in fundamental particle theory, there is only one approved topic.

No. There just isn't. Go work on inflation. Go work on electroweak symmetry breaking. Go work on dark matter. Go work on large extra dimensions. Go work on baryogenesis. Go work on susy breaking. Nobody, and I mean nobody, is forcing anyone to go into string theory. I don't know where you get this idea that there is only one 'approved topic'. It's just not true.

I think I've said this three times now. If you don't believe me, go to the [Rumor Mill] and click on the names of people offered jobs to see what they have worked on. It's all there in black and white (and some blue, too).

134. **D R Lunsford**
June 1, 2005

I think kids should spend a lot of time haunting the journal stacks in the local library – oh wait the Internet replaced all that – my bad.

-drl

135. **Peter**
June 1, 2005

My, my, I go away for the day and look what happens here.

This week I'm commuting down to a conference at Rutgers, and today gave a talk there on loop groups and QFT. After the conference is over I'll probably write something here about it.

Some comments on the comments:

I saw the preprint claiming to find a complex structure on the six-sphere. When I get a chance I'll check with an expert to see if this seems like it might be real.

Mortain:

I thought about mentioning Lax's Abel prize, but I don't know Lax, or really anything about his work, so skipped it since I didn't feel I had anything really to say about that.

I've been aware of the "not even wrong" phrase for longer than I can remember, I didn't get it from Veltman. As I sometimes point out, I don't necessarily have anything against speculative ideas that are "not even wrong", many good ideas start out this way. I'm glad you enjoy the non-string theory posts, some of which are about things that are not even wrong, some about things that are right. Actually, string theory is slowly moving out of the "not even wrong" category to the "wrong" category.

I'll stay away from fights about LQG, and just point out that if the number of people doing string theory now was the same as the number doing LQG, I wouldn't have a problem with string theory. And the idea that LQG hype is on anything like the scale of string theory hype is pretty laughable.

A few comments about what Aaron had to say (and I'm glad he's taking the time to give his point of view here):

While we agree string theory is in the doldrums, I don't think the nineties was a "fruitful" period for particle theory. Pick any decade during the past century and I think you can come up with many more important advances than what happened in the nineties. The nineties were the doldrums, what is happening now is much worse.

The problem with landscape studies is not just the loony-tunes people in high places who have abandoned doing science to promote anthropism. There are an ever increasing number of people studying the Kachru et al Rube Goldberg machines. Stony Brook's yearly workshop on mathematical physics will be devoted to this this summer. The infinite landscape provides an infinite number of relatively easy research problems that people can work on, happily thinking that they're on the cutting edge of research. While there are lots of easy problems to work on, none of them have the most remote chance of having anything to do with physics. Sometimes you don't need to do calculations like this to know that the result can't be interesting.

The problem with the idea that young physicists should just keep their head down, and work on approved topics until they get tenure is that right now, in fundamental particle theory, there is only one approved topic. And it's a topic that sensible young people quickly see is highly unappealing and won't ever lead anywhere. So, the danger is that, rather than spend ten years working on what they can tell is a bad idea, smart people just aren't going to go into particle theory anymore. I'm afraid I already see this happening.

136. **Kea**
May 31, 2005

"Work hard on some well-defined problems, write good papers, get your PhD's and only later, when you get tenure should you think about these big problems"

Some of us suspect that t'Hooft also knows perfectly well that anyone who loves Physics enough to think for themselves will probably ignore this advice.

137. **Kea - anonymous**
May 31, 2005

Aaron: "What I'll say is that's just how the world is: you need to get a job."

Hah! Not in my world. What a load of arrogant bullshit you sprout.

138. **jeff**
May 31, 2005

"If 't Hooft had followed Aaron's prescription, he ('t Hooft) would have submissively abandoned his proof and assumed that he was too dumb to even understand how flawed his work must have been."

Funny you should mention this. One of the best advice I've ever gotten was from 'tHooft: At a conference some years ago (when I just started as a grad student) a bunch of us young students were clamouring around the guy to talk to him and someone asked him about his (then recent) work on holography, quantum determinism etc. His said that he was more than happy to speak to us about it but first wanted to know where in our physics careers we were to which the response was "beginning graduate students". His reply was that before he tells us about this stuff he would just like to offer a little advice: work hard on some well-defined problems, write good papers, get your PhD's and only later, when you get tenure should you think about these "big problems".

139.
May 31, 2005

A paper was just posted on math.DG arxiv claiming to construct a complex structure on the 6-dimensional sphere (it was thought not to exist, but nobody could prove that…)

140.
May 31, 2005

Hi
Peter,
you mention,

"whereas I do see some hope that if one better understands the structure of the standard model, one may be able to get to quantum gravity from there."
whereas it maybe possible that the converse is true. i.e., only by trying to study gravity or
thinking of ways to marry gravity with other forces , can one understand the structure of standard model in detail. Heck we
still do not know if GR is the correct classical theory of gravity since it hasn't been tested as accurately as the other 3 forces in strong \
gravity limit. So I don't think there is anything wrong if people are not studying particle phenomenology and instead spending time on trying to unite gravity with quantum mechanics. Maybe
particle phenomenology has reached a limit.
In fact I would argue that there should be more people working on studying and understanding GR in detail, classical alternatives to GR, and other approaches to QG besides string theory and LQG.
In fact there are very few people working on
"gravitation phenomenology" i.e. trying to undderstand various gravitational based experiments such as data from binary pulsar, gravity probe B, lunar laser ranging etc.

141.

May 31, 2005

The problem with waiting until you get tenure is thas after years as a graduate school, years as a postdoc and years as a junior faculty making all sorts of compromises, you gradually and eventually change into becoming "one of them" without even noticing and assuming you are mainstream enough to get tenure, meaning you can act mainstream enough, decades of pretending will eventually get to you before then and you will start to believe…

That is the way the system works. By the time you get tenure, you have been throroughly brainwashed and completely orthodox. See, it's usually the younger generation which forms the leading edge.

142. **Aaron Bergman**
May 31, 2005

The key event leading to the acceptance of the electroweak component of the standard model was 't Hooft's proof of renormalizability. At the time, not only was 't Hooft merely a grad student (certainly not tenured), and his tenured adviser (Veltman) not only did not understand what 't Hooft had done, Veltman did not beleive that his student 't Hooft was correct or even capable of solving such a problem. If 't Hooft had followed Aaron's prescription, he ('t Hooft) would have submissively abandoned his proof and assumed that he was too dumb to even understand how flawed his work must have been.

Hardly. For a history, you can see Weinberg's recollections.

143. **Tony Smith**
May 31, 2005

Aaron said: "… Some argue, then, that there should be research alternatives. There are two answers to that.
In terms of quantum gravity, there just aren't that many games out there, and there's not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured. …
But the second answer to the question is the more important, because it really belies much of the impression that one might get from this blog. The simple fact of the matter is that there are alternatives in high energy to working in strings … phenomenology or cosmology …".

With respect to Aaron's second answer, phenomenology and cosmology are not alternatives in fundamental theoretical physics, and are not in direct competition with superstring theory. Aaron only lists one competitor of superstring theory, that is, LQG, and he dismisses it by saying "… it is fraught with difficulties, not the least of which are the lack of a classical limit and a bizarre quantization procedure which, if applied to a theory like the standard model, gets physically incorrect answers. …".

That leads to Aaron's first answer, which is that a fundamental theoretical physics alternative to superstring theory "… should be left to the tenured …".

The key event leading to the acceptance of the electroweak component of the standard model was 't Hooft's proof of renormalizability. At the time, not only was 't Hooft merely a grad student (certainly not tenured), and his tenured adviser (Veltman) not only did not understand what 't Hooft had done, Veltman did not beleive that his student 't Hooft was correct or even capable of solving such a problem. If 't Hooft had followed Aaron's prescription, he ('t Hooft) would have submissively abandoned his proof and assumed that he was too dumb to even understand how flawed his work must have been.
Fortunately for physics, 't Hooft did not follow Aaron's prescription and maintained the correctness of his work even in the face of his adviser's contrary opinion, and Ben Lee did the hard work necessary to understand 't Hooft's proof and to recommend it to the physics community.
Aaron could say that the key element was the validation by tenured and respected Ben Lee, but the proof by untenured student 't Hooft was also necessary, and would not have happened had 't Hooft followed Aaron's prescription.
When you look at today's world of fundamental theoretical physics, it seems that there are no Ben Lee type people who are willing to work hard to understand anything outside of their own little boxes, and that amost all of their little boxes are superstring boxes.

Tony Smith

May 31, 2005

Aaron Bergman

said ?I don't believe a scattering amplitude has ever been computed in LQG.?

I am not sure of this because I not revised recent literature on the topic. I think that now graviton-graviton scattering amplitudes can be computed from LQG. Still is not that I said in my previous post.

I believe that computation of black hole entropy has ?been done? for black holes far more realistic than from ST.

Hawking radiation, elimination of ultraviolet divergences in QFT, cosmological inflation, unobserved supersymmetry, and others are best explained in LQG. String theory does not explain nothing of that, absence of ultraviolet is still debatable, and supersymmetry is, at best of my knowledge, a crucial piece of the theory, still nobody observed it in laboratory.

?This goes back to Wheeler and possibly before.?

Hum!! I was not speaking about geometrodynamics, I believe.

?Unitarity violations are also an old idea.? Of course!!

?String theory, on the other hand, really is unitary.? This is still debatable, the best **proof** by Schwartz is some like his recent ?I believe that string theory is unitary?.

anonymous

I said

?What if the failure of quantization of GR is on that GR is not correct after all??

Of course I wanted to be provocative. Let me rewritte.

We want quantize GR, are we sure of that GR is correct before our attempts to quantize it?

Penrose is a relativist. He claim that in some test GR is tested at order of 10^12 (I believe) and claim for an adaptation of QM to GR. I ask: are those test completely infallible? Is GR the correct approach to gravitation? Note that I am not talking about possible Planck scale modifications of GR.

Initially, I took as completely true GR and studied its basis. However, a problem of confrontation of symmetries obligated to me to reconsider my thinking.

Sincerely I am not sure still, but I think that GR is not so correct and verified like I thought only a year ago!! The surprising is that some specialists in gravitation think the same. For example in a recent PR-D of last year the author says

?[…]*the correct relativistic gravitational theory may be of a kind not generally considered hitherto*??

At what extension GR is correct or incorrect. I think that first we would study this before claim for quantization.

Quantoken said

?No, no one is a culpable of the stringy failure and no one should be held responsible for the “failure”. Nature is the nature way it is and it would not have changed anything because somethign the researchers have tried or have not tried. If the nature is not 10-D, then it is not 10-D, and you can get a super-Einstein to research string theory, and he would not get anything different. He would not be able to force the nature to become 10-D. Only God can do that.?

I was obviously being provocative. The emphasis was in that string theorist are unable to recognize, still today, that they choose a wrong way that instead of studyng like nature is, they choose obligate to nature to be like they want to be. I was referring to **scientific methodology**

145. **Scott**
May 31, 2005

man this has strayed far from peter’s blog hope he doesn’t mind.

this is the internet people get snarky(i’m not really even sure what that means) rude. My point was that people care about having a job more then they care about following the research paths that inspire them whether it be a new try at QG or any number of the cases of fine tuning and other problems to be explained The only advantage to having a job as far as I can see is being able to form close working relations with the other faculty which is nice don’t get me wrong but I won’t loose the relationships i will make in grad school completely if I don’t get a job, I can still think about physics and try to come up with new ideas even if i am working as a carpentor a schoolteacher a beggar a writer or even a patent clerk. Maybe I won’t come up with anything successful or maybe I will, who knows.

146. **Amused**
May 31, 2005

>What I’ll say is that’s just how the world is: you need to get a job.

Yeah, what is the alternative ? To join the club of crackpots and failed physicists who find their purpose in life in proclaiming failure of what thousands of other, hard working physicists are doing…finding comfort in mutual shoulder padding and the belief, all those others must be wrong.

147. **Aaron Bergman**
May 31, 2005

“your goal after graduate school is to get a job”

I think i understand what happened to particle physics now, thanks.

The temptation to be snarky here is almost irresistible. What I’ll say is that’s just how the world is: you need to get a job.

So, the question is how do people make their decisions on who to hire. They’re not going to give you a postdoc much less tenure based on nothing. You have to be able to show that you can produce real research. Now, you can spend graduate school trying to find a new theory of quantum gravity, but odds are you’ll fail. People have been failing at it for fifty years. It’s hard. And, then, you’ll be stuck with nothing but easy speculation and no job prospects.

What some people do is to work in the wacky stuff while generally doing mainstream stuff. To pick an example, Max Tegmark writes on the interpretaion of quantum mechanics, but if you check out his papers, you can see that the vast majority of his stuff is quite grounded.

What it comes down to is that, in order to succeed, you have to show that you can produce. And the way to do that is to work on tractable problems. But, I wish you luck in whatever you end up trying to do. Maybe you’ll succeed. We all hope someone will, eventually.

148. **Scott**
May 31, 2005

“your goal after graduate school is to get a job”

I think i understand what happened to particle physics now, thanks.

149. **Aaron Bergman**
May 31, 2005

It is arrogance of the highest order to conclude that the failure of string theory to predict means a failure of fundamental physics in general. We do, after all, have all the successful theories developed before string theory came on the scene.

Who’s doing that? In fact, the success of the standard model is precisely an example (if the landscape, god forbid, turns out to be true) of certain generic predictions that hold for all realistic vacua.

150. **Aaron Bergman**
May 31, 2005

While I can’t speak for mortain I can tell you that I didn’t first decide that i wouldn’t go into string theory from this blog, nor does all of my limited knowledge in strings come from it.

I’m not here to recruit anyone. There are more jobs in other fields. If you find them interesting, I highly recommend pursuing them.

I don’t like your assumptions that i am incapable of thinking for myself and was tricked by peter.

I’m not claiming anyone is ‘tricked’. I just recalled my experience about getting an impression of a field from an internet forum and noted that I certainly got a misleading impression.

This I also found rather unappealing:

"there's not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured."

If there is no "game" in physics(particle or cosmology) that attracts me I plan, and already have a couple of spare ideas floating around my head that need development, on making my own "game" or I will fail trying untill someone else makes a "game" i'm interested in, whether the tenured want me to or not.

like chris said just cause this one model of how you think things might work is unpredictive doesn't mean there isn't another model out there that is, me I'm going to keep looking for that next model

I wish you luck because you will need it. The simple fact of the matter is that your goal after graduate school is to get a job, and the way to do that is to write papers that others read and cite. It might not be the ideal way for the world to work, but that's just life. The good news is that, if you can play the game well enough and get tenure, you can do whatever you want. That, after all, is the point of tenure. But until then, it's good to work on the tractable problems and get a record people can look at when application time comes around.

151. **Aaron Bergman**
May 31, 2005

Questions such as corrections to scattering amplitudes (via E-p relationships)

I don't believe a scattering amplitude has ever been computed in LQG

BH entropy (including computation of logarithmic corrections, etc)

LQG has not computed the black hole entropy either. There has not even, to my knowledge, been an identification of a black hole state in the theory.

Hawking radiation, elimination of ultraviolet divergences in QFT, cosmological inflation, unobserved supersymmetry, and others are best explained in LQG;

LQG has next to nothing to say about any of these.

CY is just a "standard" differential manifold. The substitution of macro spacetime by a kind of quantum foam was first introduced in LQG, etc.

This goes back to Wheeler and possibly before.

Even possible violations of unitary were first introduced in LQG and only recently in certain noncommutative geometries in brane theory.

Unitarity violations are also an old idea. String theory, on the other hand, really is unitary.

And this is what I mean by LQG hype….

152. **Scott**
May 31, 2005

Chris,

Thanks for the advice, motivating myself to work on stuff that I'm not really wanting to do is one of my biggests problems my plan is to apply to whichever grad schools will give me the most freedom in my research. Speaking of motivating myself to do things i'm going to go finish my lab write-up.

153. **mortain**
May 31, 2005

Previous comment was a mortain comment; accidentally omitted pseudonym.

154.
May 31, 2005

Yes, anonymous, I am frustrated. I'm glad I'm not the only one. Thank you for your comment on this (it's helped).

To Scott: yes, I think you are entering at a good time, too. Hopefully there will be lots of experimental discoveries soon, leading to new theories and a reshaping of fundamental particle physics. Maybe the LHC is just what we need to oust string theory, perhaps analogously to Michelson-Morley's experiment demolishing the aether. I got my PhD two years ago, by the way. I wish I'd been reading a blog like this as an under-graduate!

Hey, Chris, I did just that… and afterwards got nowhere very fast in physics or in life, sadly.

"What if the failure of quantization of GR is on that GR is not correct after all?" That is a worrying thought, at least for me, Juan R. I suppose the converse, as far as conventional approaches to QG go, is Penrose's kind of view, i.e. that QM requires modification, and not GR. Either way, I find possibilities like these very discomforting. One fact I've never gotten over is that some special materials (whilst in Earth's gravitational field) do not obey GR [see, e.g., Clifford's article in '300 Years of Gravitation']… what's that all about!? Just quantum corrections to GR, or a problem with GR?

Peter, was it Pauli or Veltman-quoting-Pauli who inspired your blog's name? If string theory did die, would you change the name of your blog? I believe that your blog would be no less interesting or worthy if string theory didn't exist. Incidentally, did you notice that Peter Lax won the 2005 Abel Prize this month? I'm almost certain that you made posts about the other previous Abel Prize winners (all three of them), and I wondered if you were planning a post about Lax.

155. **Ed Z**
May 31, 2005

I've been following a lot of the string theory news for years now in the press as well as in the arXiv (with very limited understanding) and by searching the internet for articles and blogs. It seems to me that there are a few camps out there with particularly strong views either in favor of this theory or that theory, and frequently they take their theories and any challenges to their theories quite personally, which I suppose is fine, as long as it contributes to the progress of science.

On the other hand, it seems that the politicization [sp?] that is so prevalent in the US now with the Conservatives and the Liberals squaring off in every possible forum is spilling over into high-energy physics theory. Is this how things were in the early days just before the quantum revolution, or is it somehow different?

To me the picture of an ideal physicist is someone who is deeply interested in understanding how nature works, and does so objectively, and realizes that despite the advances that science has made so far, nature always seems to throw a few curve balls in with every round of pitches, and we have to be prepared for them, if we hope to hit a home run.

156. **Quantoken**
May 31, 2005

Some one said:

"But the culpable of **failure of stringy endeavor** is not Nature, nor Lotto, nor Peter, nor Glasgow, nor Phil, nor… nor this ignorant called Juan R. The problem was the arrogance of string theorists."

No, no one is a culpable of the stringy failure and no one should be held responsible for the "failure". Nature is the nature way it is and it would not have changed anything because somethign the researchers have tried or have not tried. If the nature is not 10-D, then it is not 10-D, and you can get a super-Einstein to research string theory, and he would not get anything different. He would not be able to force the nature to become 10-D. Only God can do that.

Actually I think the word "failure" is not even the correct word to describe the current status of string theory. Failure is the kind of thing that has an outcome dependent on what you do. You do or behave in a correct way you succeed, and you do it a different way you fail. If there is a treasure island out there and you could not find it. It's a failure. But if there is no treasure island to start with, then it's not a failure but simply reality.

The string theory is the later case. It's not a failure. It is simply reality. The reality is the world is 4-D, not 10-D. Plain and simple. And some people can not accept that reality.

Quantoken

157. **Urs**
May 31, 2005

At least Aaron every now and then takes the time to drop a note here whose author is actually familiar with what he is talking about. He should be honored for that.

158. **Chris Oakley**
May 31, 2005

Scott,

Observations like the one I made below (at 05:16) are so obvious that no-one should need to make them. The fact that someone has to is indicative of the groupthink mentality of string theorists. I think that you are right to want to follow your own lights, stringy or not, and I applaud you for it, but my advice – for the sake of your own sanity – is to be prepared to go quietly and gracefully after your Ph.D. if you fail to find like-minded individuals within the establishment who are prepared to support you.

159. **Scott**
May 31, 2005

Wow Aaron way to fuel the fire. While I can't speak for mortain I can tell you that I didn't first decide that i wouldn't go into string theory from this blog, nor does all of my limited knowledge in strings come from it. I first decided that it definately wasn't for me after my freshmen physics seminar course where Schwartz's answers to my questions about predictions and testability were very disatisfying as were the reasons to pursue string theory that he gave(and all the ones i've read of sence then and before for that matter). I don't like your assumptions that i am incapable of thinking for myself and was tricked by peter. This I also found rather unappealing:

"there's not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured."

If there is no "game" in physics(particle or cosmology) that attracts me I plan, and already have a couple of spare ideas floating around my head that need development, on making my own "game" or I will fail trying untill someone else makes a "game" i'm interested in, whether the tenured want me to or not.

like chris said just cause this one model of how you think things might work is unpredictive doesn't mean there isn't another model out there that is, me I'm going to keep looking for that next model.

160. **Juan R.**
May 31, 2005

Aaron Bergman, string theory has not been more successful that LQG.

Questions such as corrections to scattering amplitudes (via E-p relationships) BH entropy (including computation of logarithmic corrections, etc) Hawking radiation, elimination of ultraviolet divergences in QFT, cosmological inflation, unobserved supersymmetry, and others are best explained in LQG; CY is just a "standard" differential manifold. The substitution of macro spacetime by a kind of quantum foam was first introduced in LQG, etc. Even possible violations of unitary were first introduced in LQG and only recently in certain noncommutative geometries in brane theory. The absolute ?success? of LQG over string M hype is brilliant.

One woud also remember that the number of researchers in string M-theory is of the order of 10 times that of LQG practitioners. Therefore, the relative ?success? of LQG is still more impressive.

When Brian Greene claims, in public, that they can ?see? GR in their equations whereas LQG have many problems for obtaining the correct macroscopic limit, he is being no sincere, because one may know first GR for introducing *by hand* the corresponding modifications on original string description for ?convergence?.

Peter said:
?*I do see some hope that if one better understands the structure of the standard model, one may be able to get to quantum gravity from there*.?
I partially agree, but due to inconsistencies between GR and SM, at least one of both would be drastically modificated.

What if the failure of quantization of GR is on that GR is not correct after all?

Some question about this interesting possibility?

dan, string theory is not a quantum theory of gravity. Einstein gravity is 4D and nobody can derive that from 10D action without *ad hoc* assumptions. Moreover, string theory does not introduce an adequate quantum description of spacetime still. Non-commutative M-theory is just in a stopping way.
The description via gravitons is only ?formal? with no macroscopic correspondence and for the unification with particle physics, in the words of Daniel Friedan (now a ?renegade?):

?*At best, for each macroscopic background spacetime in the manifold of possibilities, string theory gives large distance scattering amplitudes that form a caricature of the scattering amplitudes of the standard model of particle physics*.?

Even if one see that the background may be chosen *by hand* previously.

mortain, after of several of my open criticisms to status of string theory, many people contacted with me, including previous string theorists. One of them, did a PhD in string theory and just leave the field (and physics) because insatisfction ith the way of high energy.

If instead of current dictatorial status in the field young people can research in other promising areas outside of string theory garbage, then several youngs promising physicists continue being today physicists and the high energy would today is full of new fascinating ideas.

You would be not angry if the ?best?, ?marvelous?, ?fascinating? ?theory? invented was simply a waste of time. You may be angry with Nature and its ?stupid? choosing of a macro 4D without string or D0-branes.

If string theorists were no crackpot theorists and had not killed other interesting stuff…

If you play to Lotto and you put all your money in a single combination, you can win or you can lose. String theorists were completely sure of that they couldn?t lose, but the ?Casino?, Nature, always win 🙂

But the culpable of failure of stringy endeavor is not Nature, nor Lotto, nor Peter, nor Glasgow, nor Phil, nor… nor this ignorant called Juan R. The problem was the arrogance of string theorists.

Peter, i think also that LQG is not the last word, still the research model chosed has been much more interesting. Supposed success of string theory, like the ?derivation? of BH entropy, are also achieved in LQG with 4D.
If S is the ratio success/publicly for strings and L is for loops then L >> S.

After of many years working in silent, LQGs (especially Smolin) are now playing to publicy of their ideas, this is a deffences attitude against so many papers, talks, and popular books by “stringys” claiming that string theory is the only approach to quantum gravity, which is, sure, completely false.

Moreover, still LQG is open and would introduce interesting ideas for particle physics. Smolin thinks one could see by first time gravity modification to standard model on next generation of accelerators. Note that in LQG
E^2 = m^2 + p^2 + corrections terms

161. **Chris Oakley**
May 31, 2005

In regards to the anthropic principle, there is, unfortunately, a rather depressing prospect. All this nonsense, for all that Peter can throw around words like ‘unscientific’, ‘unpredictive’ and ‘unfalsifiable’, could still just be how the world is. We might just be stuck with it. There could be countless vacua, and we just might live in one of them for no particular reason.

If this is true then in terms of theories that make precise statements about the world in which we live, we are a lot worse off than we were in 1979. What perhaps many will fail to appreciate is that string theory is not a superset of our pre-string view based on quantum mechanics, QFT and GR, but an alternative. The ability to properly reproduce the “old” theories has never been demonstrated. So if this alternative fails to make testable predictions it is not a failure of physics in general, it is just the failure of a particular idea. It is arrogance of the highest order to conclude that the failure of string theory to predict means a failure of fundamental physics in general. We do, after all, have all the successful theories developed *before* string theory came on the scene.

162. **Aaron Bergman**
May 31, 2005

Oh my. What a thread….

Certainly some people should be working on quantum gravity, especially if they are doing it in a non-overhyped way, trying to really seriously understand the technical issues involved. The LQG community appears to be doing this.

LQG is far from underhyped. They’ve had their full page spreads in the Times, Smolin gets quoted pretty much everywhere, and they’ve tiresomely put themselves forward as the great rebels against the overbearing and ignorant hordes of string theorists. Frankly, it’s just as offensive as anything that has ever come out of a string theorist’s mouth.

But that’s not really what I want to say. Judging from the comments, it looks like a lot of prospective physicists are reading this blog. I remember from not so way back when, as an undergraduate, in the days when Usenet mattered, I read sci.physics.research. What I didn’t know, then, was that it gave me a horribly skewed view of the field. When I showed up at graduate school, full of all the questions I thought string theorists had no answers for, I quickly discovered, sometimes to my embarrassment, that they knew all the questions and had good reasons for doing what they were doing.

So, hopefully without sounding horribly condescending, I just want to point out that Peter’s blog does not present a good idea about how things are. Now, I don’t want to lie: there is a sense of the doldrums in the field right now, especially after such a fruitful period as the nineties. Flux stabilization seems to have, much to the disappointment of many, led to an overabundance of vacua. This has led to a number of different proposals on how to deal with this, including anthropic arguments. It is not correct, however, to say that the field is consumed with this. The number of papers that deal with anthropic arguments do not even approach one half or one quarter. Most of us are perfectly happy to go on with our own projects and leave the anthropic stuff to the occasional dinner table argument.

My personal feeling on the subject is that trying to make predictions of the real world based on strings is like playing darts in a pitch black room without knowing which wall the dartboard lies on.

Now, Peter undoubtedly would think of that as a horrible indictment of string theory, but it isn’t. Even after 20 and more years, my feeling is that we do not understand string theory but that there is every indication that there is something there to understand. In the process of seeking that understanding, we have learned much about supersymmetry, nonperturbative gauge, the large-N limit, conformal field theory, gravity in higher dimensions, new scenarios for phenomenology and, not least of all, lots of cool mathematics. So, whatever mythical opportunity cost we may have incurred, I’d hardly say that these were years ill-spent.

Some argue, then, that there should be research alternatives. There are two answers to that. In terms of quantum gravity, there just aren’t that many games out there, and there’s not much market for the sort of speculation that could lead to a new direction — that sort of thing, much like the interpretation of quantum mechanics, should be left to the tenured. LQG is the most widely hyped alternative, but, their own PR aside, it is fraught with difficulties, not the least of which are the lack of a classical limit and a bizarre quantization procedure which, if applied to a theory like the standard model, gets physically incorrect answers. In addition, their claim to compute the black hole entropy relation appears to be quite ephemeral upon close examination. String theory, for all its ills, at least gets that correct. The simple fact of the matter is that no alternative theory of quantum gravity has come close to the success that string theory has had, however minor you may consider that success to be. If you think of yourself as a stubborn iconoclast, unwilling to follow the herd, realize that pretty much everyone who goes into physics is like that. It's hard enough to get a group of physicists to decide where to go out to eat, much less browbeat them into a particular direction of research. There's a reason so many people work on string theory, and it isn't peer pressure.

But the second answer to the question is the more important, because it really belies much of the impression that one might get from this blog. The simple fact of the matter is that there are alternatives in high energy to working in strings, and those alternatives are *more* lucrative as career paths. As a commenter pointed out, LHC is turning on in a few years. This is the golden age of cosmology. Look at hiring patterns: people who do phenomenology or cosmology are being snapped up by the dozens. Lots of string theorists on the market are trying to rapidly broaden their horizons so they can compete for these jobs. So, go work on those things. That's where the excitement is. There's no need for string theory to 'die'; there are plenty of other things to do with plenty of jobs to get.

And, why should it die, really? In regards to the anthropic principle, there is, unfortunately, a rather depressing prospect. All this nonsense, for all that Peter can throw around words like 'unscientific', 'unpredictive' and 'unfalsifiable', could still just be how the world is. We might just be stuck with it. There could be countless vacua, and we just might live in one of them for no particular reason. All the Poppers in the world can't change that. But, it's also possible that, as we understand the theory better and better, maybe some of those vacua fall away, or maybe we find universal predictions of the theory that apply for all physically realistic vacua. We'll never know if we don't try.

I've argued above that string theory has already had a string of successes even if the ultimate goal of a full theory of quantum gravity still lies beyond the horizon. Some people are antsy, to be sure, looking for things to say before the grand accelerator turns on, but, in my view, there are still many problems out there to explore. Once upon a time, in the late eighties and early nineties, people thought string theory was dying, too, but that was just the calm before the storm. Who's to say that now is the time to give up, that, from here, all is hopeless?

Because, really, that's just more hype.

163. **A.**
May 31, 2005

Peter,

if I understand you correctly, you consider string theory interesting and worthwhile because of its connections with QFT dualities, but not as interesting as the hype around it suggests. This is a reasonable point of view which I share, to some extent. I agree that the potential of string theory to give us a unified theory of all interaction has been somewhat overhyped. This is not a unique situation: when people discovered N=8 supergravity, some suggested that it is the final theory of everything, without much evidence. The amount of hype in string theory is about normal and much less than in LQG, imho.

There are at least two reasons that so many people work on string theory (and not, say, on LQG). First, it is very rich and consequently fun. It leads to all kinds of neat theoretical ramifications which make one forget about the original goal (unification). The second reason is that it apparently does provide a consistent theory of quantum gravity, including black holes. No other approach to quantum gravity can boast this. It is true that the matter fields do not quite come out right, but this should not be very important. By studying string theory one has a chance to understand how to describe physics in a space whose metric is fluctuating. This is the point which Witten likes to emphasize, and it is also very reasonable. IMHO, these two factors account for the "unreasonable popularity" of string theory, not the hype.

164.
May 30, 2005

First superstring revolution, second superstring revolution…..

my vote:
Categories and Logic revolution!

165.
May 30, 2005

"Unless, of course, there is a revolution."

Yeah! Let's go!

166.
May 30, 2005

Unless, of course, there is a revolution.

The first superstring revolution

The second superstring revolution

???

167.
May 30, 2005

"Just die, string theory – please! Die, die, die! I've had enough!"

Unfortunately, history runs at a slower pace than a mere human would like! Many of us share your frustration…but I'm not holding my breath.

168.
May 30, 2005

By the way, has anyone sorted out the relation between algebraic holography (Rehren duality) and the Maldecena duality yet?

169.
May 30, 2005

Did someone come up with a generalization of the AdS/cft duality? Any quantum field theory, not just conformal ones?

170. **Peter Woit**
May 30, 2005

It's not really true that I'm not interested in either string theory or LQG. I'm interested in string theory as a possible way of solving QCD, as a source of interesting mathematical ideas, and potential techniques that might be useful elsewhere. I just think the idea of getting a unified theory out of a 10d string or 11d M-theory doesn't work at all and people should recognize that and do other things.

I try and follow what is going on in LQG, also because I hope some of their techniques will be useful. The problem with quantum gravity is that you have no experimental guidance about what you should be looking for and no way to check whether your theory agrees with reality. Maybe this will change. But I'd be a lot more interested in quantum gravity if some way could be found to connect it to particle physics, where we have a huge amount of data. String theory hoped to do that, but it doesn't work.

Certainly some people should be working on quantum gravity, especially if they are doing it in a non-overhyped way, trying to really seriously understand the technical issues involved. The LQG community appears to be doing this. But, personally, I don't have any ideas about how to start from thinking about quantum gravity and get to particle physics, whereas I do see some hope that if one better understands the structure of the standard model, one may be able to get to quantum gravity from there.

What's not healthy about the current situation is how much effort is being put into one research program, especially now that it has failed. People should be trying a wide range of different ideas, starting from what they know best and have good ideas about how to extend in new directions.

Sure, I think ultimately we'll understand the correct relation of quantum theory and GR, but it's impossible to know on what time scale. Right now though, the discouraging indications from both LQG and string theory are that if they produce a consistent theory of quantum gravity, it will be one that isn't testable (Lee Smolin has some claims that contradict this) and doesn't connect up usefully with particle physics. At the PITP conference, I think Shenker was claiming that, by holography, every QFT is also a theory of quantum gravity. If that's true, you have a solution of the problem of quantizing gravity which is really a Pyrrhic victory.

171.
May 30, 2005

Peter , you mentioned that you are not interested
in either string theory or Loop quantum gravity. My question is which approach according to you will lead to the correct quantum theory of gravity?
also do you support research in quantum gravity
(i.e. non-string approaches to QG)?
also do you think that one day we shall find the correct quantum theory of gravity?

172. **Scott**
May 30, 2005

mortain,

As another person planning on going into theoretical particle physics, I like to look at the positive aspects of the situation today. By the time I get a Phd the LHC will have been up and running for a year or two(still an undergrad right now) and if there are interesting observations I will be entering the field at very interesting time, and if there are no interesting observations it is still a good bet that many will stop working on string theory and there will still be a wealth of new ideas that should have been thought of by now to tinker with. Personally I am really glad I am entering the field now instead of say any other time in the past 20 years.

173. **Peter Woit**
May 30, 2005

Hi Dan,

Sorry, but the idea of getting the structure of the standard model out of wormholes sounds like a complete pipe-dream to me.

The problem with perturbative string theory is that the loop expansion is divergent. So, while (conjecturally) you may be able to get finite answers for the contributions of n-loop superstring amplitudes to graviton scattering, you can't sum the series. String theorists like to say this isn't a problem, since the same thing happens in QFT where the perturbation series is only an asymptotic series. But, at least for non-abelian gauge theory QFTs, you have a well-defined non-perturbative definition of the theory, which seems to give finite results. Even conjecturally, the closest thing to this in string theory is something like Matrix theory, but that only works in some non-physical cases like flat 11d spacetime.

174. **dan**
May 30, 2005

thanks for replying Peter,

yes i am well aware of lubos anti-lqg crusade, though he does come "out of the closet" and admits he's spent "hundreds" of hours studying the subject.

john baez does hold out the hope that particles could be modeled on space-time wormholes through the fabric of space-time (as opposed to strings), though lqg is still in its infancy.

i am curious as to what you think of string theory as a quantum theory of gravity? string theory does allow calculations of s-matrix scattering for gravitons

175. **Peter Woit**
May 30, 2005

I believe Veltman's attitude towards string theory is much more negative than 't Hooft's. See the last few sentences in his book about particle physics, explaining why he hasn't mentioned string theory (or supersymmetry):

"They are figments of the theoretical imagination. To quote Pauli: they are not even wrong. They have no place here."

176. **mortain**
May 30, 2005

Just die, string theory – please! Die, die, die! I've had enough!

My apologies for such an unscholarly outburst. [Please note my outburst is not aimed at string theorists.] After reading recent posts by Peter about how ludicrous string theory already is (and is becoming), particularly about what should be recognized as the death blow to the 'landscape', I just couldn't contain myself. I agree with yourself, Peter, and always have. Juan R., I applaud you.

Damn string theory for being around at the time when I had hoped to begin a career in theoretical particle physics! Bad timing indeed; as if things, especially the availability of employment, weren't difficult enough already in theoretical physics!

I think Unruh's response to Susskind's claim regarding string theory funding extends to every Western nation engaged in physics research… perhaps to every nation engaged in physics research worldwide, such is the prevalence of string theory and its hype. Wizened senior theoretical particle physicists: just keep on sapping that funding for string theory – only you know it makes sense!

By the way, Peter, do you know what 't Hooft's former collaborator/supervisor, Veltman, thinks of string theory? I vaguely recall a post-lecture question about string theory being put to Veltman at a conference, but I cannot remember his answer (though I doubt it was as detailed as 't Hooft's public remarks).

Also, Peter, why should string theory's motivational 'qualities' concerning non-perturbative QFT be considered a success? String 'theory' seems to have motivated a lot of nonsense since its inception. As you point out, if more people had been working on non-perturbative QFT in the first place, and not on string theory, the progress already achieved to date would surely have been made, or made several times over, without the influence of string theory.

So… please, I beseech ye, just do the decent thing, string theory, and die. Forthwith, consign thyself to history!

May 30, 2005

Hi Dan,

I wasn't thinking about LQG when writing about Lubos. He's very much skeptical about it. My own opinion is that it's a promising way of dealing with quantum gravity. But personally my main interest is not in quantum gravity, but in particle physics, and unfortunately LQG doesn't seem to have anything to say about this.

A.,

I've followed 't Hooft's public remarks about string theory carefully and corresponded about it with him. His own words should speak for themselves, but my interpretation of them is as follows:

1. He doesn't believe that string theory based unification is anywhere near explaining anything about the standard model. He explicitly says he was a skeptic about this in 1985 and now feels he has been proven right. He refers to the need for a completely new idea in this area.

2. He's interested in quantum gravity, and interested in what string theory has to say about that.

3. I think his words about dualities were carefully chosen. They have definitely led to interesting relations between QFTs and AdS/CFT is important progress towards finding a string dual of QCD, but precisely because 't Hooft has worked hard on large N, he's aware of how limited this progress is. 't Hooft is also a careful worker, taking great pains to be very precise about what he is doing. I suspect the very hazy nature of a lot of the string theory duality stuff, and the lack of a fundamental understanding of what the theory is and where the dualities come from, bothers him.

As for the progress in QFT due to string theorists that you mention. Witten has certainly contributed a huge amount to understanding non-perturbative QFT, but most of this has had little or nothing to do with string theory. String theory has motivated some progress in non-perturbative QFT, and this remains the best reason to keep doing string theory. In this area it's not a complete failure, like it is as an idea about unification. But I still think that if one-tenth the amount of work on string theory had gone into work on non-perturbative QFT itself, there would have been even more progress in this area.

178. **Alejandro**
May 30, 2005

CrisW says:
if Susskind's conjecture was reformulated as "the Laws of Physics are determined by the requirement that the laws of physics are discoverable," then I think it would stand a fighting chance of being fruitful,

Yep, I could buy it. Perhaps even "speakable" or "measurable" instead "discoverable", which is very broad.

179. **Fyodor**
May 30, 2005

"How exactly are Laughlin's "emergence" ideas very harmful to science in comparison to string theory, besides being a bit on the loony side?"

Homework exercise: write an essay for the Templeton Foundation explaining how Intelligent Design *is* after all scientific, once one takes into account the "emergent" nature of physical laws….[no money for this one I fear, because I bet that somebody has done it already…] Only in California. I hope.

String theory has its faults, but I have not seen a string theory paper anywhere near as downright kooky as Chapline's Laughlin-inspired twaddle about black holes. True I have heard string theorists say some silly things about GR. But nothing on that level. The tone of Chapline's stuff is frankly irrational: you pansies with your differential geometry — here, let me show you how a real condensed matter *man* handles a little problem like that!

By the way, I am impressed by Peter's ability to divine Leonard Susskind's emotional state by studying the bumps on LS' bald pate. Technology updates phrenology.

180. **Juan R.**
May 30, 2005

That is, like said in 2003 and repeat to the beginnig of this 2005, string theory is a waste of time.

The basic equation i said in March 3, 2005

Arrogance + wrong physics + elementary math = fiasco

All supposed experimental indirect verification in acellerators, and cosmology (beatiful cosmic strings "explaining" dark matter), etc. all of that proven to be wrong.

The supposed predictive power of string theory and its "only parameter" diluyed in the fact of that Nature is, at least macroscopically, four dimensional. Nature may be stupid after all!

From the hypotetical TOE to the real TON "Theory of Nothing"

I said that string theory was not a scientific hypothesis.
Now many of string theorists agree with desesperatly claims as "physicists may have to rethink what it means for a theory to explain experimental data". It sound somewhat as given that string theory does not agree with basic underpinnings of scientific method, we would change the method for adapting it to our nonscientific "Credo"

In recent years string leader Jim Gates like to use the term our “kind of a church”

Many string theorists have arrogantly ignored, furiously attacked (e.g. during decades claimed that LQG was wrong), or misunderstood other interesting approaches to quantum gravity.

On recent years Witten searched a link wth twistors, Vafa proposed that perhaps LQG (in past times a “heresy” for string theorists) could be a part of string theory, etc.

From the supposed leading of string theory durcing all of 20th century claimed in past years to the recent increasing number of canceling of lectures on the topic, halt publication of new undergraduate textbook on the topic; canceling of post-docs, summer programs, and conferences, etc.

Only five or six years ago, string theorists were claiming in public that the apparent 4D (“postulated” in standard model) was a consequence of string theory. What success!!

Recent work is less promising, as admited by Witten this year

“That’s a big problem that has to be explained. As of now, string theorists have no explanation of why there are three large dimensions as well as time, and the other dimensions are microscopic.”

Another of claims of string theorist was that string theory was the most fundamental and sophisticated theory newer imaginated. The math involved in string theory was imppresive and the concepts completely revolutionary ones.

We agree in that part of geometrical side of string theory is very advanced but in other parts string theory was always archaic, as stated from many people from many different fields: general relativity, advanced quantum mechanics, thermal fields, chaos, etc.

Even without experimental verification one already knew that, for instance, Schwartz superstring action was not the most fundamental approach to nature. But, and this is an very important point, string theorists have a general misunderstanding of that is being done in other fields of science. It is very arrogant claim that your theory is a TOE and explains ALL to most fundamental level, when you do not know equations, concepts used in other fields.

It is not so strange that one can obtain current string M-theory only after of many asumptions and simplications.

181. **JC**
May 30, 2005

Fyodor,

How exactly are Laughlin’s “emergence” ideas very harmful to science in comparison to string theory, besides being a bit on the loony side?

If not many people are really taking Laughlin, Anderson, etc … seriously about their “emergence” ideas as a “unified field theory”, then how harmful are they? How much more “dangerous” are they compared to the crowds who follow quantum gravity in general?

182. **Fyodor**
May 30, 2005

Peter, it is very clear that the “emergence” bullshit being propagated by Laughlin and co is infinitely more harmful to the cause of science and reason than string theory could ever be. I suggest that you direct your ire in that direction. It’s obvious that this whole field is generated by the gargantuan chips that fools like Laughlin have on their shoulders because anything beyond special relativity is also beyond their comprehension. He and Anderson are living proof that even Nobel prizewinners can let their personal resentments overcome their professional judgement — indeed, in Laughlin’s case, their residuum of common sense.

183. **A.**
May 30, 2005

Peter,

you say that ‘t Hooft’s positive remarks about string theory were “half-hearted”. I wonder how
you determined this. Perhaps this statement is simply a reflection of your anti-string bias. Why could ‘t Hooft not be genuinely excited about various dualities between gauge theories, or between gauge theory and string theory,
as in AdS/CFT? After all, he was the first to propose that in the large-N limit Yang-Mills theory
can be described in terms of strings. AdS/CFT makes this very concrete. (It also proves that superstrings are permanently part of theoretical physics, since they describe the strong-coupling limit of a very interesting QFT in 4d). String theory also enabled us to find or better understand many highly nontrivial dualities between QFT, by reducing them to geometric “dualities” or to the well-understood T-duality. Any QFT-lover would do well to study string theory.

I cannot resist noting that in the last 15 years there was a lot of progress in understanding nonperturbative QFT, and essentially all of it was achieved by people whom you would call “string theorists”, people like Witten, Seiberg, Vafa, etc.

184. **Chris W.**
May 30, 2005

..or to put it another way, such solutions look like *simulations*, based not on insight, but on sheer mathematical cleverness, with the promise that the results will ultimately justify the convoluted means. After all, Ptolemy’s account of celestial motions was of great practical use for centuries, and was overthrown by observations that were of little practical import but remained inexplicable in his system. Appearances might have been preserved with further refinement, but with explanation and not merely calculation as a goal, the effort began to seem pointless and futile.

185. **dan**
May 30, 2005

Peter,
In the link you provided to lubos’ website, “the next superstring revolution” he does cite loop quantum gravity, which he admits he’s spent “hundreds of hours on” as a possible basis for another superstring revolution. so when you suggest none of these directions seems promising, do you also believe LQG is a dead-end? that would be surprising to me, as you have posted Lee Smolin’s responses to string theorists on several occassions

-Dan

186. **JC**
May 30, 2005

At times one wonders whether something looking more and more like “spaghetti”, that something doesn’t look quite “right” about it. With more and more “epicycles” added in, it starts to look more and more like something that would impress Rube Goldberg.

If one has ever tried to figure out all of Enron’s accounting and obfuscation, it looks like the equivalent of “Rube Goldberg-ism” in the financial world. At times one wonders whether string theory, the old aether theory, and the many “unified field theories” over the years, are the scientific versions of “Rube Goldberg-ism”. Things look more and more complicated and more “spaghetti”-like.

187. **Chris W.**
May 29, 2005

See the **Conclusion** of this interesting new paper from John Stachel and Mihaela Iftime, posted on Friday.

188.
May 29, 2005

Well, your blog is one of the most widely visited physics blogs. You definitely ARE having an effect.

189. **Peter**
May 29, 2005

I don’t know exactly what effect I’m having, but the increasing number of physicists willing to speak out about what is going on, and the increasing amount of skeptical press may be having some effect.

As far as the landscape goes, I think I’m in a solid majority, with even most string theorists thinking that it is not science. Recall that even Lubos Motl and I agree about this, and David Gross has spoken out forcefully and publicly on the topic. It was interesting to see that Susskind has started worrying that the NSF and DOE will start refusing to fund landscape studies. I suspect a sizable number of people on the panels evaluating particle theory grants may soon start (or have already started) giving low marks to proposals to do landscape research.

190.
May 29, 2005

Is it possible that they are being so defensive because people like you are being so vocal in their dissent?

191. **Chris W.**
May 29, 2005

Regarding the last paragraph, if Susskind’s conjecture was reformulated as “*the Laws of Physics are determined by the requirement that the laws of physics are discoverable*,” then I think it would stand a fighting chance of being fruitful, although not by itself. Consider carefully what is implicit in the reformulated assertion.

Rutgers Workshop

June 5, 2005
Categories: Uncategorized

I spent most of last week commuting down to Rutgers to participate in a workshop on "Groups and Algebras in M-theory", organized by Lisa Carbone. Lisa was a student of Hyman Bass's here at Columbia some years back, and in recent years has been working on Kac-Moody groups and algebras over finite fields.

Much is known about one special class of Kac-Moody algebras, the so-called affine Lie algebras. These are basically Lie algebras associated to loop groups, with a central extension. The study of the representation theory of these algebras is closely connected to quantum field theory in 2d space-time dimensions, and my first talk was about this topic. For more details about this, from the point of view I was taking, see the remarkable book by Pressley and Segal called "Loop Groups", lecture notes from 1985 by Goddard and Olive at the Erice Summer School and Srni Winter school (see Int. J. Mod. Phys. A1:303, 1986), and Witten's paper "Quantum Field Theory, Grassmanians and Algebraic Curves" in Communications in Mathematical Physics, 113 (1988) 529-600.

An elaboration of these ideas in one direction leads to the concept of a "Vertex Operator Algebra" (first introduced by Richard Borcherds), and the study of these was pioneered by Jim Lepowsky, who also participated in the workshop, together with his ex-student and now Rutgers faculty member Yi-Zhi Huang. Several other current and ex-students of Lepowsky and Huang were also there and gave talks. For more about vertex operator algebras, see the recent short review by Lepowsky, or the materials on Huang's web-site. A VOA is essentially the same thing that Beilinson and Drinfeld call a chiral algebra, and these have applications in the geometric Langlands program.

What Lisa is really interested in is the non-affine case, where relatively little is known. Non-affine Kac-Moody algebras and groups seem to have no known tractable realizations, and many basic questions about both the algebras and the groups, as well as their representations, remain open. In recent years several of these algebras have been conjectured to have something to do with M-theory, most notably E_{11}, and the study of this connection has been the main focus of the work of Peter West, who gave a series of talks at the Rutgers workshop. For some more about this, see his recent papers, especially one on The Symmetry of M-theories. West's graduate student P. P. Cook also has a weblog, and recently wrote a posting explaining a bit about this topic.

Greg Moore was at many of the talks and kept the speakers honest. He gave a fast-pace talk covering some older work, roughly the same material as in his paper with Jeff Harvey entitled Algebras, BPS States and Strings. I gave a second talk explaining a bit about my point of view on the Freed-Hopkins-Teleman theorem and its relation to representation theory and QFT.

After the talks Thursday afternoon there was a discussion section on what is going on with string theory, supersymmetry, and mathematics. No one was willing to defend work on the "Landscape" and I was surprised to find myself pretty much in agreement with quite a few people there about the way string theory has been pursued in recent years. On the whole the mathematicians are kind of bemused by the whole string theory controversy. The subject has certainly led to some very interesting and important mathematics, and they are happy to concentrate on that, although interested to hear about the controversy surrounding string theory in physics.

Comments

1. **Matti Pitkanen**
   June 9, 2005

   Thank you for Thomas Larsson for a hint to look Segal's book. I will do it when I visit Helsinki.

   The Dynkin diagrams of simply laced algebras appear also in the Jones inlusions of hyper-finite type II1 factors of von Neumann algebras (see also the article V. Jones (2003), *In and around the origin of quantum groups*, arXiv:math.OA/0309199) and there are reasons to believe that minimal conformal theories with simply laced quantum groups with few exceptions correspond to Jones indices M:N1 factor. There are good reasons to hope that conformal field theory structure is in some sense an inherent feature of this kind of geometry. E10 and E11 seem to represent steps in this direction.

   In TGD framework the counterpart for this group is infinite-dimensional group of generalized canonical symmetries of δ M4+×CP2: the conformal structure is inherited from δ M4+. An interpretation as a Kac-Moody group obtained by localizing canonical transformations of S2×CP2 localized with respect to the radial lightlike coordinate of M4+ is in question.

   Peter: "If one could find a simple symmetry principle underlying M-theory"

   Stone duality for higher descent

3. **D R Lunsford**
   June 8, 2005

   AR – I've never seen any explanation even of how gauge invariance as a main principle is supposed to emerge from ST. (Not that I really care 🙂 I saw a half-hearted attempt to pull the QED Lagrangian from such and so string confuguration but it was a real stretch, so to speak.

   -drl

4. **Peter Woit**
   June 8, 2005

   Mike,

   Glad you like the blog!

   Alejandro,

   If one could find a simple symmetry principle underlying M-theory, that would be very interesting, and make the whole idea much more well-defined and potentially useful. But I'm not really convinced by any of the attempts so far. Up to you to see what you think from West and other's papers. As they say, we report, you decide….

5. **Alejandro Rivero**

June 8, 2005

Is this post insinuating that "The Symmetry of M-theories" could be the next superstring revolution if it is explicitly approved and explained by some superstring boss?

6. **Michael Crowley**
June 8, 2005

Hi,
I just wanted to say thank you for this blog. I discovered it while Googling on the Penrose book "Road to Reality"–a book I am enjoying tremendously but am having an extremely difficult time with. I am a lay person but find this discussion incredibly fascinating and am desperately trying to learn enough math and physics to follow these discussions. It's probably hopeless : –). But thank you for this blog.

Sincerely,
Mike Crowley

7. **Thomas Larsson**
June 8, 2005

Matti, this is a good point. I had forgotten that the vertex operator construction of Frenkel-Kac and Segal only works for level 1 reps of simply-laced algebras (ADE). I think that Pressley-Segal has a chapter about vertex operators towards the end of their book, but they call them blips for some reason.

8. **CW**
June 7, 2005

In this connection see this new preprint by H. Nicolai:

> The purpose of this article is to highlight the fascinating, but only very incompletely understood relation between Einstein's theory and its generalizations on the one hand, and the theory of indefinite, and in particular hyperbolic, *Kac Moody* algebras on the other. The elucidation of this link could lead to yet another revolution in our understanding of Einstein's theory and attempts to quantize it.

(..link from **It's equal but it's different**.)

9. **Matti Pitkanen**
June 7, 2005

It would be interesting to known whether vertex operator construction exists for non-simply laced algebras, in particular G_2. Goddard and Olive proposed such a construction for all of them except G_2. I failed to find any definite answer to this question from web.

Matti Pitkanen

10. **Thomas Larsson**
June 7, 2005

That's Richard Borcherds, of course. Sorry.

11. **Thomas Larsson**
June 7, 2005

Robert Borcherds has done great things on Moonshine and Monsters, but he is too young to have introduced vertex operators. I think there is a difference between vertex operator algebras and more general vertex algebras, though. Maybe he had something to do with the latter.

According to Goddard's and Olive's IJMPA review, vertex operators were first introduced by the first generation of string theorists, refs 71,89,90,91: Fubini and Veneziano (1970), Nambu (1969), Fubini, Gordon and Veneziano (1969), Gervais (1970), although very similar things were already done by Skyrme (1961). Vertex operators were first applied to affine Kac-Moody algebras in refs 95,72,65: for SU(N) by Halpern (1975), and in the general case by Frenkel and Kac (1980) and Segal (1981).

Incidentally, the multi-dimensional Virasoro algebra, which I claim is the correct quantum constraint algebra of general-covariant theories, was first constructed as a vertex operator algebra by Eswara Rao and Moody, *Vertex representations for n-toroidal Lie algebras and a generalization of the Virasoro algebras*. Comm. in Math. Phys., 159 (1994) 239-264. It might be noted that Bob Moody is rather well known, e.g. as a coinventor of Kac-Moody algebras.

12. **Peter Woit**
June 6, 2005

I didn't really intend to make any claims about who was responsible for the idea of a VOA, just to comment on who was at the workshop. I had thought of mentioning Borcherd's work, since several talks referred to it. To avoid confusion, I'll rewrite the post slightly, adding a reference to Borcherds.

13.
June 6, 2005

Such silly revisionism. Vertex algebras were invented by Richard Borcherds; its hardly convincing to claim that it is a different notion when you add a Virasoro and the word "operator" in between "vertex" and "algebra"…

(Mind you, with a Fields' medal, he really doesnt need protecting.)

Future of Fermilab

June 9, 2005
Categories: Uncategorized

Nature this week has an editorial about Fermilab entitled All or Nothing at Fermilab associated with a news article Fermilab: High-risk physics. The article and editorial are about the fundamental problem facing Fermilab: in a few years the high energy frontier will move to the LHC at CERN, with many physicists leaving Fermilab. The future of the lab remains up in the air, as the only viable plan for a new high-energy accelerator is the ILC project, and this would require massive new funding which is still quite uncertain. While SLAC has diversified into X-ray physics, Fermilab remains committed to operating at the highest energies. Many people worry that if the ILC is not funded or delayed for many years, Fermilab will be in a difficult position, and a prime target for budget cuts.

This week the lab is hosting the annual "User's Meeting". Presentations about current and future activities at Fermilab are available on-line.

Comments

1. **Tony Smith**
June 9, 2005

The Nature Editorial abstract at
http://www.nature.com/nature/journal/v435/n7043/full/435713a.html
says in part "… If Fermilab builds the ILC, it will regain its position at the forefront of international science; failure could lead to staff reductions and intellectual atrophy. … the Large Hadron Collider (LHC) [is] due to enter service in 2008. …".

If Fermilab succeeds in getting the ILC, then it may be prosperous for many years.
However, if Fermilab's ILC efforts fail, Fermilab has only 2005-2008 of lifetime left before obsolescence.

In the latter event, there is in my opinion a way for Fermilab to go out in glory instead of dying with a whimper: consider non-consensus interpretations of existing Fermilab data.

The Fermilab T-quark data show 3 peaks at (roughly):
130-150 GeV (low)
160-190 GeV (middle – containing the usual consensus 173 GeV value)
200-240 GeV (high)

These values of T-quark masses can be seen in terms of a plot of the Higgs mass vs. the T-quark mass with vacuum stability and triviality boundary lines show, as done by Froggatt in http://xxx.lanl.gov/abs/hep-ph/0307138

A simple Nambu-Jona-Lainio model gives a 145 GeV T-quark, consistent with the low value. (See Yamawaki in http://xxx.lanl.gov/abs/hep-ph/9603293)
The corresponding point on the Froggatt diagram is well within the usual region with respect to triviality and vacuum stability.

An 8-dimensional Kaluza-Klein Nambu-Jona-Lasinio model gives a 172-175 GeV T-quark, consistent with the middle (and usual consensus) model.
The 8-dim Kaluza-Klein is similar to the model of Batakis in Class. Quantum Grav. 3 (1986) L99-L105, in which the compact 4 dimensions are CP2.
The corresponding point on the Froggatt diagram is on the vacuum stability line, possibly indicating that it is on the line between a 4-dim vacuum and an 8-dim vacuum, in which case the T-quark data might be used to study the higher Kaluza-Klein dimensions.

A Bardeen-Hill-Lindner model, similar to a gauged Nambu-Jona-Lasinio and four-Fermi model, gives a 218 GeV T-quark, consistent with the high value. (See Hashimoto, Tanabashi, and Yamawaki in http://xxx.lanl.gov/abs/hep-ph/0311165)
The corresponding point on the Froggatt diagram is the critical point at which the usual region is intersected by both the triviality boundary and the vacuum stability boundary.

How I view this stuff, with some pictures, are in a pdf file at http://www.valdostamuseum.org/hamsmith/YamawakiNJL.pdf which is a pdf version of my web page at http://www.valdostamuseum.org/hamsmith/Yamawaki.html

Roughly, it seems to me that further analysis of existing Fermilab data in the regions of all three peaks might give important insights into the mutual interactions of the T-quark, the Higgs, and the Vacuum, possibly shedding light on many important questions such as the origin of mass and possible higher Kaluza-Klein dimensions, all in terms of experiments that can be (and some of which have already been) done with realistic technology.

Please note that the above is only one proposal for how further analysis of existing Fermilab data might produce interesting physics insights that may or may not be seen at LHC, depending on how LHC selects its data by triggers, cuts, etc., and how LHC analyzes its data.
However, it is an example of how Fermilab might get some interesting and important results over the next few years even if the ILC is never built.

Tony Smith

Why No “New Einstein”?

June 9, 2005
Categories: Uncategorized

Lee Smolin has a piece in the latest Physics Today entitled Why no “new Einstein”?. Unfortunately it’s only available to Physics Today subscribers, although Lee tells me he will see if he can put it on-line on his web-page. Tony Smith previously mentioned this in a comment to an earlier posting.

The problem Lee addresses seems to me to be an extremely important one. Pretty much every knowledgeable particle theorist that I talk to these days, string theorist and non-string theorist, agrees that current ideas about how to go beyond the standard model are not working very well. Everyone hopes that some big new idea will come along and show the way forward, with people often wistfully speaking about how maybe some bright post-doc out there may be at this very moment working on the needed new idea. The problem with this is that what is needed is probably something quite different than any of the current popular research programs, and finding it may be difficult enough to require someone’s concerted effort over quite a few years. If this is so, it’s very hard to see how anyone on the standard career path in the US is going to be able to do this. A young post-doc here generally only has a couple years in between needing to apply for new jobs, and if he or she were to devote those years to working hard on a very speculative new idea, this would most likely be suicidal for their career.

Some will argue that young theorists should just try and work on speculative ideas in their spare time, spending enough time working on currently fashionable topics such as string theory to impress people enough to ultimately get a permanent job, at which point they can work more seriously on their speculative idea. The problem with this is that getting up to speed and participating in the latest trendy research in string theory is a very demanding task, one that isn’t likely to leave much time or energy for other projects. In addition, it’s not at all clear that being willing to work hard on an obviously failed research program like string theory is consistent with having the intelligence and drive needed to do something really new. Instead of working on string theory, a young theorist could try and work on one of the other popular topics such as cosmology or phenomenology, but these are very different subjects than fundamental work in quantum field theory. A young theorist would be more likely to be able to find the necessary time if he or she went to work as a night-time security guard.

Lee makes several excellent proposals about how to restructure the way hiring is done to encourage young people who want to try something new. I hope he has some success in getting the powers-that-be to realize what a serious problem the field is facing and take some of the actions he suggests.

Two completely unrelated topics:

Lubos Motl has a posting about the Harvard Commencement, where it seems they’re giving Witten an honorary degree (Columbia already did this in 1996). He also writes about a new web-site for the Sidneyfest, the conference in Sidney Coleman’s honor that was discussed here and on many other weblogs. The new web-site includes copies of letters to Coleman from people who couldn’t attend the conference. In one of them Greg Moore recalls and reproduces Coleman’s proof from the late eighties that string theory is the unique theory of nature.

For something pretty weird, see this from the latest Notices of the AMS. There’s more about the activities of its author on Robert Helling’s weblog. The new issue of the Notices also contains an article about the 2006 NSF budget request for mathematics.

Update: Lubos Motl has his own comments on Smolin’s article, together with a link to some site where someone seems to have posted the article without attribution.

Comments

1. **Peter**
   June 15, 2005

   Good idea, I’d been thinking of doing that.

   I have been deleting some comments, but am trying to err on the side of letting people say what the want to say.

2.
   June 15, 2005

   Peter,

   Could you put the text of Lee Smolin’s reply letter in your next blog entry? It is buried
   here among the postings of loonies and
   it deserves to be more widely known (at
   least parts of it) as it helps to understand
   his position and motives better. If that is
   impossible, can you at least remove the
   two postings right after that letter that are
   stupid, offensive and simply indecent.

3.
   June 15, 2005

   What’s wrong with anomalies? Sure, it turns first class constraints into second class constraints, but Dirac showed us how to deal with that.

4. **Juan R.**
   June 15, 2005

   Well, I agree with **Ruadhan**

   Now it is a usual popular claim that Witten is the new Einstein or even the new Newton.

   Sincerely, that is stupid. I?m sorry but Witten is not a 10% of a Feynman, regarding to physics.

   Dan said

   1- “there is no current experimental data that clearly goes beyond the SM and GR.” This is not true. There is experiments and data. SM was designed for typical accelerator physics experiments, if one continue to test it one probably fin nothing. Apply the SM to a molecule, for example, and after we will talk about that.

Has you computed the total orbit of Mercury using full GR (including non radial components)? Orbit programs use only some GR effects in perihelion and light deflection but ignore time delays in the computation of orbit. Why?

2- "theories that go beyond SM and GR such as ss/m-theory make predictions (10D-SUSY) that are not currently testable." Incorrect again. Alternatives to GR are doing predictions about the future Gravity Prove B, alternatives to SM also can be verified in molecular experiments. There are proposals in literature for verifying the SM several orders of magnitude more exact that usual tests.

3- "there is no experimental evidence to guide theory." False again, there are dozens and dozens of current anomalies in data that guide to us to new theoretical frameworks. For example, certain anomalies in tomahawk data arise from new forces do not predicted by QED.

In a recent Physical Review D:

"*may reflect departures from both Newtonian gravity and GR on galactic and larger scales. Now alternatives to GR are traditionally required to possess an Newtonian limit for small velocities and potentials… also raises the possibility that the correct relativistic gravitational theory may be of a kind not considered hitherto*."

A "new" einstein will make predictions like the universe is **not** 10D and SUSY, I am practically sure.

"same can be said for other approaches, such as LQG-volume and area operators." This is false; the existence of a quantum of volume and area can be proved. In fact, it has been theoretically proven that no existence of quantum invalidates some well-known experimental data. I mean an indirect verification of the quantum not one direct test (at least i don't know any), somewhat like curved spacetimes in GR are not directly measured but compatible with many data.

5. **dan**
June 15, 2005

I am not entirely certain how physics can benefit from a "new" einstein since the original einstein made specific predictions that were soon testable,einstein attempted to explain discrepiences with experimental results and known physics of his time, a new einstein would have the following problems

1- there is no current experimental data that clearly goes beyond the SM and GR and

2- theories that go beyond SM and GR such as ss/m-theory make predictions (10D-SUSY) that are not currently testable.

3- there is no experimental evidence to guide theory.

if a "new" einstein makes predictions like the universe is 10D and SUSY — there would be no way to confirm it.

(same can be said for other approaches, such as LQG-volume and area operators).

so i don't entirely understand smolin's point. maybe the "new" einstein is alive and publishing and his name is witten, but we don't have the technology to test witten's theories.

6. **Thomas Larsson**
June 14, 2005

Dear Lee,

Let me emphasize that I am not a string theorist – on the contrary, over the last years I have had strong disagreements with Lubos and others, especially over the role of diff anomalies. While initially a statistical physicist, the success of CFT made me interested in Lie algebras, where I discovered how to generalize the Virasoro algebra beyond 1D and developed its representation theory, together with mathematicians like Moody, Rao, Berman and Billig. In particular, the Virasoro algebra in 4D is the anomalous form of the algebra of 4-diffeomorphisms, which is the constraint algebra of GR in covariant formulations (in non-covariant canonical quantization the constraint algebra is modified).

So when I speak about diff anomalies, I do it as someone who has developed new mathematics which has not been absorbed by the physics community. You may wish to keep that in mind.

As to the issue of anomalies, i.e. the claim that we ignore the established knowledge that ?INFINITE-DIMENSIONAL CONSTRAINT ALGEBRAS generically acquire anomalies on the quantum level…? is simply false. It is contradicted by rigorous existence and uniqueness theorems in LQG.

Whereas I claim that this is true, it is not at all generally accepted. On the contrary, it is widely asserted that there are no pure gravitational anomalies in 4D, see e.g. Weinberg's QT of F II, ch 22. Nevertheless, the constraint algebra of GR contains many subalgebras isomorphic to the infinite conformal symmetry in 2D, generated by vector fields of the form f(z) d/dz, where e.g. z = x^0 + ix^1 or z = x^2 + ix^3. Upon Fock quantization, these conformal subalgebras will in general acquire anomalies for the usual reason, making the whole shebang anomalous.

The reason why these anomalies cannot be seen in conventional field theory is that the relevant cocycles are functionals of the observer's trajectory in spacetime. Unless this trajectory is introduced and quantized in conjunction with the fields, the relevant anomalies cannot be formulated. This is IMO the crucial obstruction to the quantization of gravity.

1) The approach to quantization of constrained systems is different in string theory and LQG. The former approach depends on a gauge fixing that refers to a fixed background metric. It results in the construction of a Fock space. The latter is background independent and involves no background metric, no gauge fixing and results in a state space unitarily inequivalent to a Fock space.

2) There is a body of rigorous results that support each kinds of quantization. Hence it cannot be a question of which is correct mathematically. Both are correct, within their contexts. It is a question only of which construction is appropriate for which theories and which describes nature.

Conventional quantization has turned out to describe nature in other contexts. I think this is a good reason to believe that it is the correct approach. In particular, CFT has been successfully applied to 2D condensed matter, where conformal anomalies have been measured experimentally. This is of course a different context and not directly relevant, but this fact has shaped my basic instinct that anomalies are very real things which cannot depend on the quantization method used.

3) The treatment of constraints in string theory depends on certain technical features of 1+1 dimensional theories, particularly the fact that there is a gauge in which L_0 plays the role of a Hamiltonian and therefore should, in that gauge, be quantized so as to have a positive spectrum. The anomalies are not generic, as asserted above, rather they depend on the additional condition that L_0 should be a positive operator.

Yes, this is the crucial point. In any physical theory, there should be some positive operator which can be interpreted as a Hamiltonian; there is a physical requirement that energy be bounded from below. Of course, in GR there is a Hamiltonian constraint rather than a genuine Hamiltonian. This is another reason to introduce the observer's trajectory; you can define a genuine Hamiltonian as the operator that translates the fields relative to the observer.

Anyway, in all applications of Lie algebras to physics so far, the reps have been of lowest-weight type. At least for finite-dimensional Lie algebras, all unitary irreps are of this type.

There are other reps of Diff(S^1) that are non-anomalous but in which L_0 is not positive.

If you consider the restriction to the algebra of polynomial vector fields, generated by L_m with m >= -1, then all irreps have a vacuum vector (or are dual to such a rep).

So a choice is made in the standard quantization of string theory, which his motivated by the physics. This does not mean it is the right choice for all physical theories.

OK. I disagree.

4) Conversely the existence and uniqueness theorems which support the LQG quantization work only in 2+1 dimensions and above for the reason that gauge fields don?t have local degrees of freedom in 1+1 dimensions. The existence theorems tell us that there are quantizations in 2+1 and higher of diffeo invariant gauge theories that have unitary, anomaly free realizations of diffeo invariance. The uniqueness theorem tells us that the resulting state space we use in LQG is unique.

Contrary to string theorists, I claim that anomaly freedom is not a necessary requirement. To illustrate this point, let me again use the bosonic string as an example and quote from GSW, subsection 2.4: 'Classical free string theory can be consistently formulated for any spacetime dimension, but quantization with a ghost-free spectrum requires D less than or equal to 26. […] In the special case of D=26 and a=1 the spectrum is entirely tranverse, with many decoupled zero-norm states.'

Thus, D=26 is special, but D less than 26 is not ruled out by consistency requirements. It is only in 26D that it is possible to pass to the reduced Hilbert space by imposing the physical state condition L_m|phys)=0, but when D less than 26 this is not necessary, because the full, unreduced Hilbert space is already positive-definite.

Thus, my position is that some diff and gauge anomalies are good, making it possible to break diff and gauge symmetry on the quantum level, such as the string in D less than 26 illustrates. This does not mean that all gauge anomalies are good, of course. On the contrary, I recently gave a simple algebraic argument why conventional gauge anomalies, due to chiral fermions and proportional to the third Casimir, indeed are inconsistent. This argument does not apply to observer-dependent anomalies, which are proportional to the second Casimir.

The idea that diff and gauge anomalies may be consistent is of course very controversial.

With regard to the non-standard quantization, in which holonomies, but not local field operators are well defined, it is of course true that when applied to standard systems this leads to inequivalent results. ?This apparently leads to unphysical consequences, such as an unbounded spectrum for the harmonic oscillator.? But, give me a break, do you really think someone is proposing to replace the standard quantization of the harmonic oscillator with the alternative one? What is being proposed is that the quantization used in LQG is well suited to the quantization of diffeo invariant gauge theories.
In case it is not obvious, let me emphasize that harmonic oscillators are not relevent here, and can play no role in a background independent quantum theory, precisely because the division of a field into harmonic modes requires a fixed background metric. Thus, the physics of the problem REQUIRES an alternative quantization.

Sorry, but here I flatly disagree. I find it very disturbing that LQG methods yield the wrong result for the harmonic oscillator.

I am frankly puzzled why someone who claims to know the literature well would throw up examples like the harmonic oscillator up in this context. I can try to understand their point of view, but it certainly reads as if they either are choosing to ignore the basic point, which is that background independent quantizations cannot use fock space, or they are looking to make debating points to impress ignorant outsiders.

I agree that a diff invariant quantization of gravity cannot use Fock space, and I am convinced that such a quantization does not exist. However, a diff *covariant* Fock space quantization of gravity may very well exist. By this I mean a quantization in analogy with the string for D less than 26: the unreduced Hilbert space is consistent in itself, and diffeomorphisms are promoted to a genuine but anomalous symmetry acting on the full Hilbert space.

A step in this direction was taken in hep-th/0504020. Sure, there are problems: the (manifestly covariant) regularization has not quite been removed, no invariant inner product has been found, and no hard predictions have been extracted. But there is a Hamiltonian which is bounded from below in the regularized theories, the analogous construction for the harmonic oscillator has a spectrum bounded from below (it is not quite right, and I discuss why), and infinities cancel best (though not quite, so I am doing something wrong) in 4D. Most importantly, since phase space variables are promoted to operators in the usual way, this is genuine quantization, which is witnessed by the presence of anomalies.

Finally, I didn't express myself very well on the sociological issues. I agree with you about the problems with string theory, and I did not mean that funding to LQG should be stopped. However, given what I feel is a major problem (the harmonic oscillator spectrum), and that LQG already is the second biggest player in QG, I cannot really think that it is badly underfunded at present levels.

7.
June 14, 2005

Indeed, string theorists truely are legends in their own minds.

8. **Ruadhan**
June 14, 2005

Thomas Larsson said:
>It would be very wrong to dismiss string theorists as misguided fools or corrupt villains. There might be exceptions, but many of them are among the smartest physicists on this planet.

I smell moral pressure from string theorists on this issue. It is considered immoral to say that string theorists aren't superhuman geniuses. Let me say this: I have met and talked to many of them, and they seem to me to be no more intelligent on average than a typical mathematician or theoretical physicist. Just as it is OK to exaggerate how bad Hitler or Saddam Hussein were, for example by saying that they ate babies, it is OK to exaggerate how clever string theorists are. A person who says that Saddam didn't eat babies can be attacked for being a Saddam-sympathizer, and a person who dares to say that all of this "string theorists are all geniuses" talk is mere propaganda can be attacked for claiming to be more intelligent than string theorists, which nobody is entitled to do unless they know more than all the string theorists about heteroskedastic fibrations over David-Letterman manifolds.

String theorists aren't the smartest guys on the planet. They're just enmeshed in a macho culture where they have to claim to be super-geniuses, and they can conceal their mediocrity behind a cloak of gibberish which one must become a string theorist to see through.

Lee said:
>Then, because of the possibility that quantum computers could break codes, there has been a lot of support for the last few years. And a lot of progress has been made, both experimentally and theoretically on aspects of foundations of QM.

It seems to me that any progress that has been made has been in the realm of taking the previously existing understanding of QM and applying it to new systems. People have talked about qubits and Shor's algorithm and quantum registers and have demonstrated quantum teleportation, but these are all straightforward applications of the previously known and well-understood formalism of quantum mechanics.
I think that this is no more indicative of progress being made on the foundations of quantum mechanics than the successful factorization of a large number constitutes progress on the foundations of arithmetic.

An example of a genuine non-trivial thing that quantum mechanics says is the following:
Suppose there are N experiments with the following properties:
1. Each experiment has only two possible results.
2. If we perform the same experiment twice, then we get the same result.
3. If we know in advance with certainty that a particular experiment will give a particular result, then the probabilities of the possible results for all other experiments are 50%.

Then N is less than or equal to three.

Nobody has ever attempted to address questions like why this should be true. Instead, it seems that the quantum computation people have agreed amongst themselves that they like the many-worlds interpretation and have left the foundations there.

11. **Lee Smolin**
June 14, 2005

Dear Peter and colleagues,

I am grateful for the attention given to my essay. I only want to emphasize a few points here. The main thing is that the essay is carefully written. It does not advocate more funds to LQG or any other program. It explicitly advocates more support and positions for young, ambitious theorists pursuing their own research programs who are unaffiliated with any larger program. Several proposals are made for how to accomplish this. I would hope that the focus of the discussion could be on these proposals.

-String theory is criticized in the essay mainly because it is currently sociologically dominant, and so subject to the problems mentioned. It was necessary to do so as many readers of physics today will be unfortunately unaware that there are any problems with string theory, or any viable alternatives. Anyone with a long enough memory will know that the sociological issues in high energy theory predate string theory, and have hurt physics in the past, i.e. in the case of S-Matrix theory.

-I hope I don?t have to say that I am not anti-string theory. My current last paper on the ArXiv is a technical paper in string theory, and I have 14 more in past years, plus 8 papers on related topics such as the landscape. I wouldn?t have written these papers if I didn?t think there was a good chance string theory is relevant to nature. The fact that someone like me who contributes sometimes, but not exclusively, to string theory, is not considered ?a string theorist? is part of the sociological problems my essay criticizes. Similarly, the fact that one can elicit angry responses, and be called ?anti-string? for carefully and correctly recounting the actual status of various conjectures is a sign of an unhealthy sociology. No one calls someone anti-LQG or anti-QCD when they do a similarly honest summary of what is known and not known in those fields.

-I would claim that the sociological issues mentioned in the essay have hurt string theory even more than they have hurt the alternative programs, because they greatly limit the range of ideas worked on, and because people with a lot of imagination and intellectual independence are either selected out or choose themselves to work within communities which are more friendly to diversity and imagination. As a result, key issues such as the question of a background dependent formulation, or perturbative finiteness, don?t get a lot of attention, in spite of their centrality for the whole program.

-I was grateful that someone noted the range of subjects at the LQG meetings. This was not planned, it is a natural outcome of the more open and curious atmosphere among people who work on the subject. We don?t believe we should have a meeting without inviting people from alternative and rival programs to report to us what they are doing, as well as to serve as critics. At the meeting in Marseille last May we even invited a persistent critic of LQG-Ted Jacobson-an early contributor who is now very critical of the subject-to give a talk to lay out his criticisms. I think it would be very good for string theory if the organizers of their meetings took a similar attitude.

-Someone asked for a blanket term for LQG, CDT, causal sets etc. We use background independent approaches to quantum gravity. There is a lot of interchange of ideas, techniques and people among these programs, and many of us have contributed to more than one. There is a very different intellectual climate, in which diversity, creativity and independence are strongly encouraged.

-Someone is asking for what is ?LQG proper?? But the fact is that a lot of different things are now going on roughly under the name of or related to LQG. After all, this is now a community of > 100 people and there is no orthodoxy and no one trying to control what people work on. We agree generally on what has been achieved and what problems remain open, but not much beyond that. There is a healthy variety of approaches and attitudes towards the open problems. If there is one thing we all agree on it is that no approach is likely to achieve the right theory that is not background independent at its foundations. Come to the meeting and see what is happening.

-While the point of my essay was not to advocate more funding to any particular direction, if you ask me I will of course say that I think that people working on background independent approaches to quantum gravity deserve much more support. Among them are Loll and Freidel, that I am glad someone mentioned, but there are many others.

-I did not, as Lubos implies, advocate funding a large number of people who do nothing but think about the foundations of quantum theory. What I do advocate is much more support for the kind of person who might be inclined to work on foundational issues. These are deep and independent thinkers who believe that the road to progress in physics is confronting the hard problems directly. But there is no need to argue about whether more funding for foundations of quantum mechanics would be fruitful. The experiment has been done. For decades there was no support at all, and slow progress. Then, because of the possibility that quantum computers could break codes, there has been a lot of support for the last few years. And a lot of progress has been made, both experimentally and theoretically on aspects of foundations of QM.

-Although this essay was not written to advocate LQG, since it is attacked in response I should try to clear some things up. Someone asks for an accounting of the present status of the field. I among others, have given one in hep-th/0408048, shortly to be updated.

As to the issue of anomalies, i.e. the claim that we ignore the established knowledge that ?INFINITE-DIMENSIONAL CONSTRAINT ALGEBRAS generically acquire anomalies on the quantum level…? is simply false. It is contradicted by rigorous existence and uniqueness theorems in LQG. As a few people do nevertheless take this seriously let me start from a point we can agree about and see if we can clear this up for good. I would hope we can all agree that:

1) The approach to quantization of constrained systems is different in string theory and LQG. The former approach depends on a gauge fixing that refers to a fixed background metric. It results in the construction of a Fock space. The latter is background independent and involves no background metric, no gauge fixing and results in a state space unitarily inequivalent to a Fock space.

2) There is a body of rigorous results that support each kinds of quantization. Hence it cannot be a question of which is correct mathematically. Both are correct, within their contexts. It is a question only of which construction is appropriate for which theories and which describes nature.

3) The treatment of constraints in string theory depends on certain technical features of 1+1 dimensional theories, particularly the fact that there is a gauge in which L_0 plays the role of a Hamiltonian and therefore should, in that gauge, be quantized so as to have a positive spectrum. The anomalies are not generic, as asserted above, rather they depend on the additional condition that L_0 should be a positive operator. There are other reps of Diff(S^1) that are non-anomalous but in which L_0 is not positive. So a choice is made in the standard quantization of string theory, which his motivated by the physics. This does not mean it is the right choice for all physical theories.

4) Conversely the existence and uniqueness theorems which support the LQG quantization work only in 2+1 dimensions and above for the reason that gauge fields don?t have local degrees of freedom in 1+1 dimensions. The existence theorems tell us that there are quantizations in 2+1 and higher of diffeo invariant gauge theories that have unitary, anomaly free realizations of diffeo invariance. The uniqueness theorem tells us that the resulting state space we use in LQG is unique.

5) Now it is true that Starodubstev and Thiemann have found it an interesting exercise to apply the LQG techniques to free string theory. Not surprisingly they get a theory that is unitarily inequivalent to the usual one. This does not mean that the usual quantization of string theory is wrong, nor does it mean that the LQG techniques are wrong when applied to other problems, where the existence and uniqueness theorems together with a large number of results prove their worth. All we learn is that the two quantizations are inequivalent, which was to have been expected.

6) With regard to the non-standard quantization, in which holonomies, but not local field operators are well defined, it is of course true that when applied to standard systems this leads to inequivalent results. ?This apparently leads to unphysical consequences, such as an unbounded spectrum for the harmonic oscillator.? But, give me a break, do you really think someone is proposing to replace the standard quantization of the harmonic oscillator with the alternative one? What is being proposed is that the quantization used in LQG is well suited to the quantization of diffeo invariant gauge theories.

In case it is not obvious, let me emphasize that harmonic oscillators are not relevent here, and can play no role in a background independent quantum theory, precisely because the division of a field into harmonic modes requires a fixed background metric. Thus, the physics of the problem REQUIRES an alternative quantization.

The detailed motivation is, I think, well argued in the papers, and are supported by the results as well as the existence and uniqueness theorems. First, is well known that a complete coordinatization of the gauge invariant configuration space for a non-Abelian gauge theory requires the holonomies. Second, using them gives rise to the unitary non-anomolous reps of the spatial diffeomorphisms.

Nor is anyone proposing using non-seperable Hilbert spaces for the full theory, the point is that when one mods out by the piecewise smooth spatial diffeos one is left with a seperable Hilbert space.

I am frankly puzzled why someone who claims to know the literature well would throw up examples like the harmonic oscillator up in this context. I can try to understand their point of view, but it certainly reads as if they either are choosing to ignore the basic point, which is that background independent quantizations cannot use fock space, or they are looking to make debating points to impress ignorant outsiders. They must know comments like this are not going to influence experts, because they are, after all, taken from our own papers, written precisely because we wanted to clarify the difference between the new and standard quantizations and the limits of the applicability of each.

With regard to the sociology of the string-loop division, ?Roughly speaking, string theorists are fundamentally particle theorists with a strong understanding of quantum theory, whereas loop people are gravitists with a background in GR?, this is a myth. Rovelli, myself and many other people in LQG were trained as particle physicists, myself at Harvard in the late 70?s. Most of the physical motivation for LQG comes directly from ideas about formulating gauge theories in terms of loops that were studied by Polyakov, Wilson, Migdal, Mandelstam, Neilsen and others. LQG is squarely an outgrowth of their intellectual tradition. The only thing we added was to correctly treat the diffeomorphism invariance exactly in the quantum theory. This led to new results just as the exact treatment of gauge invariance in lattice gauge theory led to new results. I would claim that we made progress in LQG precisely because we had a very good grounding in QFT.

String theory, as it is practiced, makes much more contact with the general relativity tradition, especially the once discredited tradition of extending general relativity to add dimensions and degrees of freedom in the search for a unified field theory. You are much more likely to read a paper which studies solutions to a generalizationsof the Einstein equations, with hbar=0, by a string theorist than by someone working on a background independent approach to quantum gravity.

This of course does not mean that string theory is wrong. But I believe it does mean that by enforcing a narrowly restrictive notion of what constitutes good work, the community of string theorists has hampered progress in string theory by excluding from consideration the lessons learned by attempts to do what string theory must do eventually if it is to be a real theory: which is to find a background independent formulation of a quantum theory of spacetime.

12. **Curious**
June 14, 2005

Well said, M. I think that we have reached the
common ground, and the discussion was
useful. A revolution can start with a new Einstein —
or with less imaginative new Plank and Bohr —
or nonimaginative new Rutherford and Michelson. Eihter outcome is fine and useful
to physics. What is needed is a large
pool of technically savvy receptive people
who can carry it out when it finally starts.
Thanks to string theory we have this pool.
You may not like the theory but it keeps
able people busy and sharpens their skills;
it is superb mental gymnastics and it will
be useful in the end. Some diversification
would not hurt, but in all probability people
will end up exploring not one but several
dead ends. They will also stop understanding
each other completely, just like LQG and string people. Groupthink will not be breached; there will be more insular groups.
But that's nor here nor there.

M is also right that the best way to bring the true revolution about is, yes, to revise
the fundamental assumptions. My own prejudice which I share with Einstein is that GR is not the correct classical
theory of gravitation (and that is why it is so
difficult to quantize). Experimental verification

of GR is still a work in progress; we can wait.
It will all sort out in the end.

Thank you, M, for your contribution to this discussion, and thank you, Peter, for bringing the subject up.

13. **mortain**
June 14, 2005

In addition to the traits listed below as contributing to Einstein's success, wouldn't it be pertinent to also add that he – like many other pioneers and lone wolves, such as Newton, Wiles and Perelman – had the time to pursue problems which interested him? Unlike Newton's day and Einstein's day, perhaps the only way to ensure that one has the time to work on (and eventually solve) outstanding, significant problems in any subject in our era is to make the time for oneself. Einstein may have had time to theorize at the patent office. Newton had free time forced upon him by an outbreak of bubonic plague. As Peter asserted, it may take seven years to solve a major academic problem – but this would surely require full-time work upon it. Wiles may be an exception, but then again he was aware of the problem he wanted to solve from a young age.

Furthermore, I thought Einstein only graduated from the modern equivalent of a technical college with a diploma, and never went to anything approaching a graduate school.

June 14, 2005

Thomas Larson: "It would be very wrong to dismiss string theorists as misguided fools or corrupt villains. There might be exceptions, but many of them are among the smartest physicists on this planet"

BUT the SMARTEST physicists CAN ALSO BE completely misguided fools. In another thread some one said: "…that it was pity the Creator had not taken advice". The reason the **Creator** did not take advice was the pity fact that smart people like Edward Witten wasn't born yet to give the **Creator** some advices how the universe should be created and how many dimentions it should have.

Seriously, the nature is the way the nature is and you can not treak the nature to fit your theoretical model no matter how smart you could be. If the universe is not 10-D, Edward Witten can not turn it into 10-D no matter how hard he tried. The pity things is at the end of day it may very well turn out all wrong and Edward Witten's would have wasted some of the most intelligent minds on this planet in vain.

BTW, Einstein was never super smart or super intelligent. He was average in lots of aspects. But one thing that makes him great is he could **think outside the confinement of the box**, and he pick apart common ideas that other people took for granted, and find that these ideas were really not meant to be taken for granted, and he happened to be correct!

Quantoken

…seem quite promising to me, e.g. dynamical triangulations. My comments referred to LQG proper. The papers I have looked at may be a few years old, but there has hardly been any changes in the fundaments since then.

Posted by: Thomas Larsson at June 14, 2005 03:16 AM

We obviously need better terminology, Thomas. Who is it that you are referring to when you say "LQG-people"? What current research to you mean when you say "more money to LQG"?

However, the suggested cure, which more or less explicitly reads more money to LQG, is problematic since many people feel that the LQG people are ignoring well-established facts.

Posted by: Thomas Larsson at June 12, 2005 06:13 AM

Two places–Hermann Nicolai's department at AEI and Smolin's Perimeter Institute–are centers where there are a lot of LQG people. I am not sure there is anyone at either place doing what you would call "LQG proper".

Perhaps it would give some substance to your comments, so I could better tell what you mean, if you would name some persons at AEI or PI who have posted "LQG proper" work on arxiv in the past year.

Since I hold you in high regard, I am quite curious to know what specific recent papers, say by AEI or PI people, you would pick to typify "LQG proper". This would typify the kind of research for which Smolin's essay, in your view, "more or less explicitly" advocates more funding.

16. **Thomas Larsson**
June 14, 2005

To the anonymous poster (Marcus?):

I have not said that LQG should be deprived of money. However, it is the second best funded approach to quantum gravity, and it has recently been well advertised in the press.

I think I have a reasonably good ideas what loop people are up to. There are several research programs present at Loops 2005, some of which seem quite promising to me, e.g. dynamical triangulations. My comments referred to LQG proper. The papers I have looked at may be a few years old, but there has hardly been any changes in the fundaments since then.

After the Loops meets Strings conference at AEI Potsdam, several string theorists have examined LQG closely from their viewpoint, Nicolai et al. but also Helling-Policastro and spr comments by Urs Schreiber. Although there might be some Schadenfreude in these papers, I believe that the critique voiced therein is serious and seriously meant, and it should not be dismissed easily. In particular, the second paper compares conventional and LQG quantization. To quantize in the usual sense, we start from some phase space and replace the q's and p's by operators and Poisson brackets by commutators. However, the q's and p's do not exist as proper operators in LQG (not both of them anyway), but only in exponentiated form. This apparently leads to unphysical consequences, such as an unbounded spectrum for the harmonic oscillator.

It would be very wrong to dismiss string theorists as misguided fools or corrupt villains. There might be exceptions, but many of them are among the smartest physicists on this planet (though I may have made some hasty comments sounding differently in the heat of debate). I have even found myself in agreement with Lubos Motl a lot recently (on physics, my opinions about politics are uninteresting). It is really only when he makes these weird statements about string theory, like it is immensely successful, predicts the standard model, and is already proven correct, that I disagree, and he has not made so many claims of that nature recently.

Roughly speaking, string theorists are fundamentally particle theorists with a strong understanding of quantum theory, whereas loop people are gravitists with a background in GR. So when string theorists say that LQG is quantum theory only in a weak sense, I think one should listen.

The importance of diffeomorphism group in GR is hardly in question, whether you call it general covariance, diff invariance or background independence. In fact, the lack of background independence is often used as an argument against string theory.

Perhaps I am barking up the wrong tree, but at least I have found my own tree to bark at. In a time when genuinely new ideas are scarce, this is at least something.

M said:

[2] the key problem is that we are making flawed assumptions about the form (or ingredients) of a more fundamental theory, in which case the failure is one of imagination or insight rather than effort.

M, let's look more closely at your second cause which you call "[2]" and consider the possibility that it is especially operative in the US. I will explain but first look at this example of a paper by someone at Lyon (FR) and two people at Cambridge (UK)

http://arxiv.org/gr-qc/0506067

For context, glance at the abstracts of the four papers Laurent Freidel has written this year.

http://arxiv.org/find/grp_physics/1/au:+Freidel/0/1/0/all/0/1

I would say that the scientific establishments that support this are able to take general relativity seriously and pursue, with some of their resources, the idea that one should FIRST get a quantum spacetime geometry, a background independent, nonperturbative quantum gravity, and then, when one has quantum spacetime dynamics on a continuum, which will be a mathematically new continuum, THEN one can build on that a new field theory and a new standard model. So the program is to get a RELATIVISTIC QUANTUM PHYSICS but not special relativistic like earlier quantum field theory, not merely built on Minkowski space, but the real thing: a GENERAL relativistic quantum physics built on a continuum with no prior commitment to some fixed geometry.

For whatever reason that agenda seems to be understood by the establishments outside US and people like Freidel can work in Canada, Germany, France, UK.

Let us suppose that a scientific establishment which only knows to go directly for the UNIFIED THEORY therefore SCREWS UP because it is incapable of supporting work like Freidel's, because it only knows to try for a more fundamental theory in the way that STRING TRIED, on manifolds with a prior fixed metric, or on Minkowski space. We can entertain the idea that this kind of establishment screws up because of a flawed vision: because it DOES NOT TAKE SERIOUSLY the 1915 lesson of General Relativity of gravity as geometry. Because of this limited vision it is unable to support people like Laurent Freidel doing spin foam + matter, and people like Renate Loll doing CDT computer simulations of quantum universe. So Loll has to be at Utrecht (at Gerard 't Hooft's institute) and Freidel has to be in Canada or France, and his co-authors have to be at Cambridge UK and Loll's co-authors have to be at Copenhagen and Potsdam and Krakow Poland.

BECAUSE THEY AND THEIR LIKE CANNOT WORK IN THE USA because the establishment people cannot imagine to quantize Gen Rel FIRST and get a quantum spacetime dynamics and THEN on that new continuum to build a unified theory—-a relativistic quantum physics.

That is how I see your "cause [2]". there is no mystery about good ideas, progress towards a more fundamental theory is going WELL at the moment, there have been surprising developments in the past couple of years. But the US is somewhat retarded about noticing and lacks the preparation to hop on the bus. So Smolin essay is pointing out not that he or his postdocs are unhappy (they can always go back to Europe or find jobs in Canada) He is pointing out to US academics that the US is falling behind in theoretical physics (in quantum gravity and other branches that matter, not string theory)

The reason Smolin would say to diversify the programs in US departments, and to tune the support system more towards resourceful mentally independent people is NOT so that the fundamental problems of physics will be solved (that view is a bit US-centered, if necessary they really can do without us, if the US stays stuck on string there still are other establishments smart enough about placing their bets with young people who can eventually make whatever new physics is needed).

The purpose of doing what Smolin suggests and diversifying programs in US departments and institutes etc, and tuning the support system more for individuals IS SO THE US CAN CATCH
UP.

Well that is my take on it, M. At least for tonight.

June 13, 2005

Anonymous wrote:

Maybe by tinkering with the support system you can get more people who are intellectually independent, resourceful, inventive, motivated to solve fundamental problems, and who take seriously (possibly conflicting) well-established physical principles.

I don't know whether there is a clear answer to the question of whether an improved "support system" will lead to an influx of the kinds of new ideas that are needed. It certainly seems clear (to me at least) that a friendlier intellectual and funding environment will bring greater diversity, but whether this diversity actually accomplishes the desired goal of reinvigorating fundamental theoretical physics with productive new directions is much less clear. After all, the problem seems less one of "not enough new ideas" as one of "not enough productive new ideas."

A key question is what is the origin of the shortage of ideas today. Perhaps it is because

[1] the key problems are *hard*, and so the only failure (if it is to be called that) is insufficient effort;

or maybe it is because

[2] the key problem is that we are making flawed assumptions about the form (or ingredients) of a more fundamental theory, in which case the failure is one of imagination or insight rather than effort.

It seems impossible at this point to really know which of these (or maybe some an entirely different cause) is where the greatest problems lie. It seems clear that since the standard model solidified, many very smart people have attacked the problems from a (admittedly limited) number of angles, and thus far none has resulted in anything that looks like a genuine success. If explanation [1] is correct, then I would agree with Curious when he says,

Whether a testable physical theory is the result of tinkering of many or a protean tour de force by a single genius is of little importance.

Chris Oakley seems to concur when he says,

I would therefore advocate the relatively unambitious program of examining weaknessness in existing theories, or in one's understanding of existing theories and seeing if one can patch these up in any way.

Certainly it is hard to argue with the statement that as long as you stick close to what is known your effort is less likely to be wasted! But whether that will be enough to break the logjam is an entirely different question…

On the other hand, if explanation [2] is right then maybe it will take an original thinker to take the first steps. Once that is done, I believe there are enough very capable and willing physicists to flesh out a new theory, much as was done during the development of quantum mechanics or the standard model. In this sense, such an original physicist *would* resemble an artist of exceptional ability — an ability to see past what seems self-evident with the necessary insight to capture the essence of what is needed.

Personally, I think that some of explanation [2] is valid. Given the enormous effort by many people of very high caliber over a long time, pursuing a number of different paths, it seems to me that some significant assumptions are being made that aren't quite right. I would certainly argue that the theoretical edifice that has been empirically verified thus far will remain intact at least in the form of effective theories; one can't argue with success, and the successes of the standard model and GR, for example, are pretty evident. But it seems quite possible that some of the assumptions that went into the construction of these key theories were not entirely right or fundamental, and it is our mostly unquestioning assumption of the necessity of those assumptions that could now be keeping us from making significant new progress toward what will be an eventual new theory. This is speculation, of course. And even if it is correct it does not mean it would take another Einstein to take the first key steps.

19. **Chris Oakley**
June 13, 2005

I think Curious's comments are quite apropos. One reason why the inventors of quantum mechanics and relativity disappeared from view in the latter half of the 20th century was that they were looking for another revolution. Unfortunately for them, quantum mechanics and special relativity turned out to be pretty good, and not in any obvious need of revolutionising. And – whether the practitioners admit it or not – overambition has also been the bane of string theory. Try to do too much and you will end up doing nothing. And if they say, "At least we showed that XYZ cannot be made into a physical theory", one should simply point out that the universe of theories that do not work is potentially infinite, and creating new rays within it not an especially good use of one's time.

I would therefore advocate the relatively unambitious program of examining weaknessness in existing theories, or in one's understanding of existing theories and seeing if one can patch these up in any way. It may *sound* boring, but at least one is morely likely to have something to show for it.

20. **Alejandro Rivero**
June 13, 2005

And I think what M says he "doesn't buy into" boils down to the essay TITLE.
Yep, the title is misleading. One must notice that Smolin has suffered more pression about the concept of "New Einstein" because a popular magazine charged him with such title, some years ago. As I told before I had preferred "a new Sommerfeld" or something so.

21. **Curious**
June 13, 2005

I risk to repeat myself, but I would like to answer M and also once again turn the
discussion to two inter-related topics: (a) are any
administrative or reorganizational actions
on the part of physics community
like those advocated by Smolin
would lead to the emergence of a new Einstein? and (b) Do we need this new Einstein?

We all know that none of Smolin's suggestions will bring a new Einstein to
existence. Useful as his advice may be
in improving the climate in which the research
is done, there is no guarantee that such a
climate would help to bring this peculiar goal about.
Neither it will help to make people more
open to radical ideas, as that would require changing the human nature. Only a great crisis in physics
(say, nothing but SM from LHC) would do that.
Nobody and nothing stays in a way of creativity of today's generation of theorists: no gurus,
no cliques, no government policies, nothing.
It is all in the head. Independent thinkers
will overcome any pressure and any obscurity,
if their theories are correct. The best way
to bring Einstein is perhaps to cut federal
support completely; then only dedicated
people will remain and we will be back to the era of gentlemen scientists (when there was explosive development of science and true opennes to ideas); but I am not suggesting
that. The resistance does not matter.
Both quantum mechanics
and SR met tremendous resistance at
first. Did that stop Bohr or Heisenberg or Dirac? No, it did not. Just take my word, when the
correct theory emerges it will take us all by
storm, no matter what and who gets which grants
and how much, what cliques currently exist,
what opinion Witten has, etc. That happened
before and it will happen again.

M correctly points to the fact that highly talented, original thinkers make great advances in mathematics, music, etc. That whole new vistas can be opened by such people.

Symphonies and certain mathematical constructions would not emerge without them, ever. True.

But physics is not mathematics. Nor is it
artistry. Whether a testable physical theory
is the result of tinkering of many or a protean
tour de force by a single genius is of little importance. Quantum mechanics has been
developed in many small steps. So is QFT.
So is analytical mechanics. Laplace, Hamilton
etc were not Newtons or Einsteins but they
did a great job w/o which there would not be
Maxwells and Einsteins. I am not advocating team
work and doing TOE by a committee of
mediocrities. My point is different. We do not
need a new Einstein. We need 10 Schwingers, 5 Bethes, 6 Heisenbergs, 3 Bohrs, 7 Wigners, 4 Weyls and an occasional Landau. You can change this formula however you like. That would do, believe me, if these
people will pursue their interests with open minds. Please, do not wait for this new Einstein to appear and solve all the problems.
In physics, you do not have to be a genius to
do the work of a genius. Forget about the violin and the high moral ground; not needed for job.
You can do it too, just try.

22. **John Rennie**
June 13, 2005

Since we've mentioned physical intuition, can anyone tell me the physical interpretation of local gauge symmetry. Such Googling as I've done has failed to find anything beyond a comment (I'm afraid I forget the source) that "it represents hidden degrees of freedom in the theory".
Given how central the concept is to field theories I'm a bit surprised how much it is glossed over. Maybe the next Einstein could start by asking what physical mechanism is responsible …

23.
June 13, 2005

Thomas Larsson offered a nice concise argument here which I will try to respond to.

[[…For almost five years, I have publicly said that string theorists are barking up the wrong tree. Why should I now be afraid of saying that the much smaller LQG community is doing the same thing (a different tree, admittedly, but still wrong)? Basically I'm using the same argument. Diff anomalies simply must be relevant to the quantization of gravity, because GR has many constraint subalgebras isomorphic to infinite conformal symmetry in 2D, any the lesson from string theory is that these subalgebras generically have anomalies. And no, I certainly don't think that people at Loops 2005 neither appreciate diff anomalies nor know very much about them.

Posted by: Thomas Larsson at June 12, 2005 02:58 PM]]

"saying that the much smaller LQG community is doing":

Thomas, I do not think you know what the much smaller LQG is doing. I keep a casual watch on the literature and would say that those not involved with cosmology are mostly doing path integral-type stuff. You seem to think that your discussion of constraint algebra is relevant, but it is not clear why.

"Diff[eomorphism] anomalies simply must be relevant to the quantization of gravity, because GR has many constraint subalgebras isomorphic to infinite…"

Are you SURE that diffeomorphisms MUST be relevant? One center of interest in the LQG community is an approach where there is no differentiable manifold representing spacetime. No differentiable manifold means no diffeomorphisms. No diffeomorphisms means no anomalies.
In this approach (CDT) the continuum is approximated by piecewise linear manifolds. The behavior of the continuum is described in the limit as the size of the triangulation goes to zero, and the continuum in the limit is neither smooth nor of the same dimensionality at all scales.

It is not obvious why "diffeomorphism anomalies must be relevant to the quantization of gravity", especially in path integral approaches, or in approaches where there are no constraint algebras, or where there are no diffeomorphisms.

Since it is not obvious, perhaps you would like to give a detailed explanation.

Thomas you say Smolin's essay is "problematical" because following its results would result in more support for LQG people (doing whatever LQG people do these days).

You argue that these LQG people should not get more money because they do not know some things you know about diffeomorphism anomalies.

I get the impression that you do not know who the LQG people are or what they are working on. I have seen you sometimes citing some older papers of Thomas Thiemann and Abhay Ashtekar, papers which do not seem at all typical of either Ashtekar's current work or the research going on in the LQG community.

Maybe you should actually GO to the Loops 05 conference this October and see who actually are these people and what actually are their researches towards which you are making the blanket statement they should not get additional funding.

Then you might have a different idea of who is barking up what wrong tree. It might be you 🙂

24.
June 13, 2005

to return to the topic of Smolin's essay, M made a point on 11 June that I don't think got enough consideration

[[…

It seems to me that certain aspects of Einstein's personality are quite important to his ability to achieve the impact that he did. In my opinion the combination of several key traits was crucial:

1. Excellent physical intuition.
2. Great respect for established results. This characteristic strongly distinguishes serious scientists from crackpots.
3. Willingness to pursue an independent direction, but only when it was apparent to him that the conventional approach was inadequate.

4. Inwardly directed and motivated. He didn't let others decide for him what he should be working on or what approach was correct.
5. Tenacity. He didn't give up on problems he was interested in, neither because they were hard nor because others didn't buy into his program.

As for the connection with Smolin's article…

I think all of the above characteristics (and others) were very important to his success. I also think it is clear they came from inside him as an individual and were not the product of an especially nurturing environment or support system. None of his best work was done while he was at the IAS at Princeton, although at the IAS his environment offered an environment much closer to what Smolin advocates than the environment where he did his best work.

So, I guess I don't really buy into that part of Smolin's thesis that states "the system" shoulders much of the blame for "no new Einstein." If and when someone like Einstein comes along, he or she will succeed primary due to internal motivations and traits, not because Smolin's proposals have been put into place. Groupthink in physics departments and within funding agencies, hiring decisions based on having a clean record of "correct" research endeavors, and funding decisions based on their compatibility with fashionable research programs and directions are cancerous and harmful to the progress of physics, I agree. But do they prevent the appearance of a new Einstein? I really doubt it; I don't think obstacles in the system can stop someone like that…

Posted by: M at June 11, 2005 10:36 PM]]
****
My comment on M's post is
I would say that Smolin's essay has two distinct messages:

A. Diversify the theoretical research programs represented in departments, institutes, at conferences (incidentally giving young researchers more choice and better information about alternative lines of theoretical investigation). Arguments could be used similar to those applicable in the case of monopoly power and the suppression of economic competition.

B. Reallocate support more towards the individual researcher (with choice left open) and less by program. Perhaps this would mean longer-term postdoc fellowships awarded NOT on the basis of the pre-established program to which the recipient is indentured, but instead on personal criteria that allow more scope in the choice and invention of research goals.

And I think what M says he "doesn't buy into" boils down to the essay TITLE. And if so, I strongly agree. Part A, diversify programs with more competition between rival approaches, does not have any obvious connection with Albert Einstein in 1905.
Einstein is not a symbolic or informative example relevant to that.

Nor is his life a very good argument for Part B, says M, because Einstein represented a rare combination of intellectual and moral qualities which you can't get by tinkering with the system.

Maybe by tinkering with the support system you can get more people who are intellectually independent, resourceful, inventive, motivated to solve fundamental problems, and who take seriously (possibly conflicting) well-established physical principles. Maybe you can get more ordinary-caliber serious creative people, which would be great! Those people are not necessarily new Einsteins though. I am all for Part B of Smolin program. But the identification with Einstein seems corny.

25. **Kea**
June 12, 2005

Is that you, Marcus?

26.
June 12, 2005

Dan, you ask:
[[…let us suppose string theories' open problems continue to remain open, and that LQG is able to show it has a semiclassical limit in agreement with GR.
Would you predict a mass exodus from strings to loops? or is academia such that strings will remain dominant, and LQG marginal?]]

I take LQG broadly defined as "What LQG-people are doing" and as what will be the main focus at the Loop 05 conference. The Loop conference will feature CDT as one of its main attractions. For an idea of where it stands on "SEMICLASSICAL LIMIT" see this paper

http://arxiv.org/abs/hep-th/0411152
A semiclassical universe from first principles

For additional detail on this and other developments see this one:

http://arxiv.org/hep-th/0505154
Reconstructing the universe

Other basic CDT papers:

http://arxiv.org/abs/hep-th/0404156
Emergence of a 4D world from causal quantum gravity

http://arxiv.org/abs/hep-th/0505113
Spectral dimension of the universe

http://arxiv.org/abs/gr-qc/0506035
Counting a black hole in Lorentzian product triangulations

http://arxiv.org/hep-th/0105267
Dynamically triangulating Lorentzian quantum gravity

In this approach spacetime is not modeled by anything with a differential structure or smooth coordinates. For instance the largescale dimension can be 4D and the dimension decline continuously down to near 2D at very small scale. This is not what one expects with, for example, a differentiable manifold where the dimension must be a whole number corresponding to the number of coordinate functions.

this year we are beginning to see a shift of LQG-people's interest towards CDT. Actually it began around May 2004 with the Marseille LQG conference. this is a movement of interest within the general (broadly interpreted) LQG field. You speak of
an "exodus" from string but from my point of view this does not seem to matter as much as the shift of interest and resources inside LQG.

Dan you said:

[[I was thinking of spin network formulation, although one of Lubos' criticism is that there is no clear connection between the Hamiltonian formulation and spin networks. Is there are clear connection between canonical quantization and causal sets or dynamic triangulation?…]]

You may mean "spin foams" and not spin network since spin networks are basic to canonical-LQG (the formulation that requires a Hamiltonian constraint). Spin networks form the basis of the kinematic state space of vintage LQG.

On the other hand spin foams is a path integral approach and fortunately they are not equivalent. Lubos is quite correct that there is no clear connection! However this is hardly a criticism.
It just illustrates that the broad field of LQG contains several different approaches to quantum gravity.

Are their "clear connections" from spin foams to causal sets to dynamical triangulations? ABSOLUTELY NOT! It is just that similar skills and intuition apply and similar concerns and problems are important. And the same people (LQG-people) easily cross over and work on the various differnt approaches.
And the different approaches show up at the same conferences.

Vague connections yes. Formal logical provable connections no.

I should enter a disclaimer. I watch research in this field with considerable interest, as it is currently progressing rapidly and is exciting. But I am not an expert and dont do research in it. If I was to go into any kind of LQG (broad sense) research it would be CDT, without question. Very new so basically can get in at ground floor.

dan you say:
[[do you know what the current research in LQG is on the Kodama state, which according to Lee Smolin
http://arxiv.org/abs/hep-th/0209079,
has a good semiclassical limit with a positive cosmological constant. I am aware Witten has argued the state is unphysical.
http://arxiv.org/abs/gr-qc/0306083%5D%5D

these are old papers, a fair amount has been written about Kodama since then. probably arxiv search engine can find it. recent papers by Stephon Alexander and two people at UBC. use arxiv search to track them down.

27. **Peter**
June 12, 2005

Hi Dan,

I don't think that many string theorists will abandon string theory for LQG, even if everyone agrees that LQG has the right classical limit. For one thing, the whole landscape story shows that many string theorists would rather abandon doing science than abandon string theory. For another, many string theorists are, like me, basically particle theorists, and would take the attitude, that if LQG works it just means there are two ways to do quantum gravity, but since the string theory way is supposed to explain particle physics, it is better and they will keep doing it.

28. **dan**
June 12, 2005

Hello Pete,
short of a no-go theorem, I suppose the work on the semiclassical limit could continue on for an indefinite time. i agree with you though that the current commitment to string theory research is out of proportion to string theory's tangible physical results.

Based on Smolin's analysis of academia, let us suppose string theories' open problems continue to remain open, and that LQG is able to show it has a semiclassical limit in agreement with GR.

Would you predict a mass exodus from strings to loops? or is academia such that strings will remain dominant, and LQG marginal?

Hello At,

I was thinking of spin network formulation, although one of Lubos' criticism is that there is no clear connection between the Hamiltonian formulation and spin networks. Is there are clear connection between canonical quantization and causal sets or dynamic triangulation?

As for the spin network, do you know what the current research in LQG is on the Kodama state, which according to Lee Smolin
http://arxiv.org/abs/hep-th/0209079,
has a good semiclassical limit with a positive cosmological constant. I am aware Witten has argued the state is unphysical.
http://arxiv.org/abs/gr-qc/0306083

i know Smolin was workign on a paper in response to Witten, which John Baez pointed out, but what has become of this?

29.
June 12, 2005

Dan, here is the list of non-string QG topics selected for the October
"Loops 05" conference
http://loops05.aei.mpg.de/

Background Independent Algebraic QFT
Causal Sets
Dynamical Triangulations
Loop Quantum Gravity
Non-perturbative Path Integrals

It is not always clear how inclusively the term "LQG" is being used. Ten years ago LQG referred to a CANONICAL QUANTIZATION approach to GR, in which dynamics was to be implemented through the Hamiltonian constraint. In the mid-to-late 1990s LQG researchers experienced difficulty with the Hamiltonian and in particular with the associated constraint algebra. Largely on this account, many if not most LQG people moved over to path integral approaches including SPIN FOAMS, CAUSAL SETS, and DYNAMICAL TRIANGULATIONS.

Today, very few LQG are actively pursuing canonical quantization of GR. An exception is Thomas Thiemann at AEI who has something called the Master Constraint program.

There is a LQG program developed by Gambini and Pullin which looks somewhat like canonical LQG, but which has no constraint algebra and no Hamiltonian constraint. Its Hamiltonian is a discrete time-evolution operator.

Anyway we have a confusing abuse of language here. Almost everybody seems to use “LQG” as a blanket term for the non-string, mostly path integral, approaches to QG. There is no other widely recognized blanket term for what LQG people do!

But then some people, it would seem Thomas Larsson is a case of this, proceed to talk about the “LQG” in a much narrower sense, as if it were the canonical quantization program of the 1990s that has already been described in several books—the approach that encountered difficulty realizing Hamiltonian constraint dynamics.

Now I am wondering which “LQG” you mean, dan? Here is what you said:

[[..How many years are you willing to give “LQG” and its attempt to recover the classical limit before you deem it a failure? and if it is unable to find such a limit within a specified time period, would it be fair to say that LQG is as failed a project as string/m-theory.

Posted by: dan at June 12, 2005 03:08 PM]]

The non-string QG approach that many people would consider closest to “recovering the classical limit” would be CDT, I suppose (causal dynam. triang.) That was invented in 1998 (the year the first two CDT papers were published). It first produced a 4D spacetime in computer simulations in 2004. Smolin, who seems to represent “LQG people” for many of us, recently co-authored a CDT paper. There are indications that CDT will be one of the main points of discussion at Loops 05. I cannot say for certain that CDT has NOT “recovered the classical limit”.
Perhaps I could fetch some links to recent CDT papers and you could decide for yourself.

30. **Peter Woit**
June 12, 2005

Hi Dan,

First of all, unlike the case of string theory, I haven’t spent much time following the debates and arguments over LQG, so I don’t want to make any pronouncements about either its success or its failure. I’ve explained why elsewhere, basically it’s because I’m fundamentally a particle theorist. String theory has failed because it is now clear it can’t explain anything about unification in particle theory. LQG has never tried.

In the current situation, where there are no successful ideas about going beyond the standard model, everything people work on is not a success, and thus has experienced some degree of failure. This doesn’t mean people shouldn’t work on these ideas, maybe the failures can be overcome. But the amount of effort that has gone into string theory unification has been staggering, and has provided huge amounts of evidence that the idea can’t ever work. The effort going into LQG has been much more modest, and, although it hasn’t completely achieved its goals, it’s not implausible that with more work some new ideas will be found. I don’t think one can say the same about string theory any more.

If those working on LQG don’t make any progress during the next 5-10 years, and it really is true that they can’t get out GR in a the classical limit, I suspect most people working in the field will move on to something else. If instead they attract thousands of physicists to work on the idea, and have dozens of conferences each year, some with 500 theorists in attendance, if I’m still around I’ll be spending a lot of time complaining about their behavior.

31. **dan**
June 12, 2005

Hi Peter,
I do have a question for you,

I am sympathetic to your claim that String/M theory is currently a “failed” project.

What I wonder is whether you think LQG is a “failed” project as it has been unable to reproduce GR.

How many years are you willing to give “LQG” and its attempt to recover the classical limit befre you deem it a failure? and if it is unable to find such a limit within a specified time period, would it be fair to say that LQG is as failed a project as string/m-theory.

32. **Thomas Larsson**
June 12, 2005

Of course Smolin asks for a redistribution of funds from string theory to LQG. After bemoaning the string theory dominance, he complains how difficult it is to find positions for young people in technicolor, preon models, dynamical triangulations, causal sets, and LQG. How can this be construed otherwise than as a call for redistribution of funds from string theory to these areas, in particular LQG?

String theory surely has problems – there is no theory, no predictions and no experimental support. But this does not imply that large amount of funding should go to research aiming at disproving QM, GR or the standard model. OK, LQG does not aim at disproving QM, but claiming that anomalies can be arbitrarily dialled to zero by a new wonderful quantization method is not far from it. The existence of anomalies does certainly not depend on the quantization method; conformal anomalies arise also in the path-integral quantization of the bosonic string, in the form of Schwarzian derivatives that appear in the transformation law of the measure. Again, they only cancel in 26D.

In this connection it might be worth mentioning that I was originally trained in statistical physics, where stringy mathematics (read CFT) plays a fundamental role. Unless the situation in HEP, the application of CFT to 2D statphys is a success story, and it has be experimentally verified beyond reasonable doubt. In particular, the central charge has been measured, at least in computer simulations, and it has been found to agree with the non-zero CFT prediction. From this perspective, the idea that conformal anomalies can generically be avoided is absolute nonsense.

For almost five years, I have publicly said that string theorists are barking up the wrong tree. Why should I now be afraid of saying that the much smaller LQG community is doing the same thing (a different tree, admittedly, but still wrong)? Basically I’m using the same argument. Diff anomalies simply must be relevant to the quantization of gravity, because GR has many constraint subalgebras isomorphic to infinite conformal symmetry in 2D, any the lesson from string theory is that these subalgebras generically have anomalies. And no, I certainly don’t think that people at Loops 2005 neither appreciate diff anomalies nor know very much about them.

Implicit in section 5 of Nicolai et al. is a suggestion for a research programme: quantize GR in a similar way as the Polyakov action is quantized in bosonic string theory. This is more or less what I have tried to do for 15 years, and at the very least some of the mathematics – the anomalies and many representations – is now firmly understood. However, in my view this is strong evidence *against* string theory – if previously overlooked mathematics allows GR in 4D to be quantized, there is really no need for extended objects in 10 or 11D.

Thomas Larsson faults Smolin's essay as follows:
[[… the suggested cure, which more or less explicitly reads more money to LQG, is problematic since many people feel that the LQG people are ignoring well-established facts.

Posted by: Thomas Larsson at June 12, 2005 06:13 AM]]

that is, in Larsson's view, Smolin's article is problematic because it advocates more money for LQG people
and LQG people ignore a well-established fact about constraint algebras which Larsson has discussed on several occasions.

1. the main thrust of the article is not advocacy of specific research lines. however several are mentioned (foundations of QM, technicolor, preons, QG phenomenology, causal sets, dynam. triangulations, Loop)

Loop (in the narrow canonical sense, or even the broadly inclusive sense) is not given priority in Smolin's list. It is hard to see how Larsson can criticize the essay for special pleading or favoritism.

2. In Larsson's view it would be problematical for unnamed "LQG people" to get more research funds. Who are "LQG people". A good working definition would be those who are organizing and speaking at the October Loops 05 conference at the Albert Einstein Institute
http://loops05.aei.mpg.de/index_files/Home.html

This link gives the topics to be covered at the conference.

This other link lists the invited speakers:
More about the programme
http://loops05.aei.mpg.de/index_files/Programme.html

Since you are accusing people of being ignorant of well-established facts, Thomas, which of these invited speakers to Loops 05 do you say are ignorant of well-established facts? I am just curious. Do you know any of them and have you talked with them to be sure that they are ignorant as you say?

I think maybe some were never ignorant of what you say and maybe some could have been ignorant perhaps a couple of years ago and may have learned something since then. But personally I don't know. You are making the blanket claim about the ignorance at present time of a group of people—-so that Smolin's essay is problematical if it leads to them being given more research funding—-and so I guess it is up to you to substantiate it.

34. **Quantoken**
June 12, 2005

It's worth noting that my discoveries must be ground shaking for figured out the strong and weak coupling constant. The exact moment I click the mouse on the "publish" button it triggered a 5.6 richter scale earthquake. No kidding.

35.
June 12, 2005

Thomas Larsson, it would help if you and indeed all of us (myself included) would look more objectively at what the Smolin essay actually says. I have used caps to emphasize relevant parts. Notice that most of what Smolin is talking about has little connection with what you are talking about (alleged ignorance of unnamed Loop people concerning anomalies and "infinite dimensional constraint algebras")

[[Alternatives to strings

More worrisome, young theorists who pursue alternatives to string theory have had great difficulty finding any academic positions in the US. This is true of those who pursue alternative programs in particle physics, like TECHNICOLOR and PREON models, and also true of those who pursue alternative approaches to quantum gravity, such as DYNAMICAL TRIANGULATIONS, CAUSAL SETS, AND LOOP QUANTUM GRAVITY. These subjects are all pursued much more vigorously outside the US, because leading researchers in these areas are drawn to leave US universities by offers of very good opportunities elsewhere.

One approach barely represented in the US is QUANTUM GRAVITY PHENOMENOLOGY, which studies how to test quantum gravity theories experimentally by means of high-energy astrophysics experiments such as the Gamma Ray Large Area Space Telescope and the Pierre Auger Observatory. The experiments are supported in the US, but most theorists who are developing the relevant phenomenology are outside the US.

Other examples show the hazards of too much concentration of resources on a few areas, to the exclusion of others. For decades, the FOUNDATIONS OF QUANTUM MECHANICS got virtually no support in the US; it was believed to be a direction without promise. In the last 10 years the fast-moving field of quantum information has shown that important experimental and theoretical results about foundations of quantum mechanics were always there for the finding…]]

The approach to quantum gravity which he mentions first, Ambjorn Jurkiewicz Loll CDT ("dynam. triangulations"), is a path integral approach that has nothing to do with "infinite dimensional constraint algebras".

Indeed if he is to be accused of special pleading, much of what Smolin mentions in the short passage about specific non-string lines of research do not involve "infinite dimensional constraint algebras".

However, you say:
[[… the suggested cure, which more or less explicitly reads more money to LQG, is problematic since many people feel that the LQG people are IGNORING WELL-ESTABLISHED FACTS.

Most of modern string theory – M-theory, AdS/CFT, flux compactifications, anthropic principle – is arguably built on loose sand, but some string theory insights are here to stay. LQG, and even more so the LQG string, violate probably the most fundamental insight of string theory: that INFINITE-DIMENSIONAL CONSTRAINT ALGEBRAS generically acquire anomalies on the quantum level…
…
…
Posted by: Thomas Larsson at June 12, 2005 06:13 AM]]

It has been pointed out here at Peter's blog, by Smolin himself in fact, that much of the work by LQG-people in the past 10 years has been in the path integral direction—spin foams and the like. This has not involved "infinite dimensional constraint algebras" or any constraint algebras at all.

I thought Smolin effectively answered Hermann Nicolai's
"outsider's view" article in his letter posted here, by pointing out that Nicolai's view of LQG research was overly narrow or else some 10 or 15 years out of date. Nicolai's view of Loop-and-related research has changed radically since that article, judging from the list of topics and speakers for the October "Loops 05" conference which Nicolai's institute is hosting.

I think if you take another look at your own post here, of 12 June, you will see that it is not Smolin who is self-serving and trotting out his own favorite hobbyhorse.

36. **Torbjorn Larsson**
June 12, 2005

Curious:

"GR, basically, hindered the progress in physics as much as it fostered it. Its own creator was not satisfied with this theory and its general validity has not been shown experimentally to this day."

I think this is incorrect. I seem to remember that you need GR, not only SR, to construct and maintain GPS satellite systems. Also, I think all the serious contenders have been shown wrong already. If I am mistaken I hope someone more knowledgeable will correct me.

37. **Alejandro Rivero**
June 12, 2005

A related question in some comments here is "Why a new Einstein", but it seems that most bloggers are driven by General Relativity. IE we want a new Einstein to unify the four forces. So we discuss about LQG (not rare in a thread about Smolin), fundamental strings, etc.

I a humbler way, let me suggest that a new Einstein taming the strong force could give already enough advance for some years: to be able to calculate particle masses *and effective coupling constants* (and from it, decay widths and branches) for all the hadronic interactions. I wonder how many of the support for strings comes still from the hope of being able to solve this particular point, independently of higher hopes.

38. **Juan R.**
June 12, 2005

Peter, i repeat my previous question for you if you have time for reply it.

would be more effective if you could post your comments in string theory (e.g. in Landscape stuff) directly like an attachment to each ArXiv preprint instead of here? That model did already exist in the CPS preprint (unfortunately closed) and worked very well, because one could see the preprint and in the same html page comments/discussion by people.

39. **Juan R.**
June 12, 2005

I agree with several, practically the whole, of Smolin's points and proposals.

Four additional comments:

1) I believe that Smolin article is, at some extension, a reclaim for attracting more people to "nonstandard" quantum gravity research like LQG. There is around 10 times more people working in strings, branes.

2) The real problem is about money. Past science was less expensive and moreover great advances were done by people with his/her own money. Today many parts of science are really expensive and one need funding or a "Templeton" grant :-). Money implies control of it and control implies directed research and directed research implies the control by mainstream. Less popular research programs are in the last part of the list for obtaining funding. That is a natural outcome of current scientific "democracy". History shows that in general questions mainstream knowledge is good, but in radical answers, mainstream is just wrong (remember revolutions of past begining in Newton).

3) A real Einstein, if any today, would not follow current popular research programs. Because a real Einstein (or Newton) would choose elegant, powerful approaches instead of irrelevant theories and ugly programs. A point is sure to me. Today Einstein would not follow current approaches to quantum gravity. **None** of them is really profound, several are ugly, and many of them are simply wrong.

4) Where is Wally (i.e. Lubos Motl)? I claim that the first "Einstein-like grant" was given to him for developing his impresive knowledge and physical intuition in quantum, gravity and other topics. All of we would favouring this plea. It is simple, if we leave to him study topic freely, he (great genious) choose the wrong way. The rest of people simply would follow the contrary way and the advance of science in next decades, would be impresive :-0.

40. **Thomas Larsson**
June 12, 2005

M wrote some posts ago
It seems to me that certain aspects of Einstein's personality are quite important to his ability to achieve the impact that he did. In my opinion the combination of several key traits was crucial:
…
2. Great respect for established results. This characteristic strongly distinguishes serious scientists from crackpots.
…

This is the crucial point, isn't it. It is easy to agree with Smolin's description of today's problems in physics, with string theory's experimentally unmotivated dominance. However, the suggested cure, which more or less explicitly reads more money to LQG, is problematic since many people feel that the LQG people are ignoring well-established facts.

Most of modern string theory – M-theory, AdS/CFT, flux compactifications, anthropic principle – is arguably built on loose sand, but some string theory insights are here to stay. LQG, and even more so the [LQG string](), violate probably the most fundamental insight of string theory: that infinite-dimensional constraint algebras generically acquire anomalies on the quantum level.

It is generally accepted that constraint algebras, like the infinite conformal symmetry of the bosonic string, must be anomaly free. (My opinions in this matter differ and are controversial, although IMO well-founded.) However, the fundamental observation is not really that the conformal anomaly cancels in 26D, but that it generically (D != 26) does not cancel. It is thus no surprise that string theorists (and not only them) reacted strongly when the LQG people claimed that it is possible to quantize the bosonic string without an anomaly for any D. For a detailed argument, see the [critical review of LQG]() by Nicolai et al., especially Section 5, Constraint algebra.

Thus, given that many people think that LQG is fundamentally misguided, it is hard to feel that it is really under-funded at the present level.

Incidentlly, my own work can be regarded as an attempt to treat GR along the same lines that string theorists treat the Polyakov action. This is evidently much harder (otherwise someone else would already have succeeded), but I find it rather striking that at least the relevant anomalies have been found, together with large classes of representations.

41. **Scott**
June 12, 2005

um my first sentence of my last post should have ended with "without Einstein" however curious seems to have made that point in a much clearer way then i did/ would have if i had finished the sentence.

42. **M**
June 12, 2005

Hi Curious,

I may be mistaken in my impression, but it seems like you are missing the main point of Smolin's article, based on what you wrote:

"It has been implicit in your discussion as well as in Smolin's paper that we desperately need new Einsteins to advance physics. The whole controversy then centers on how to get these proto-Einsteins out of obscurity, with or without the violin."

I didn't see that implicit assumption in Smolin's article. I doubt that his objective was to convince the world that we need a new Einstein to save us from our theoretical morass and lead us to a bright future (with the rest of the article then proceeding to explain how we should clear the roadblocks so this can happen).

It seemed to me that Smolin was using Einstein as a symbol for independent and creative thinkers who could (hopefully) make significant progress on really vexing problems. He proceeded to outline some systematic, serious impediments within "the system" and gave suggestions for making changes that would reduce them and nurture new approaches. He may be right. But it seems to me that someone like Einstein would find a way to work on the really difficult problems and get his or her work noticed even with the theoretical climate of today.

As an aside, is it controversial with you that there is a real need today for significant new ideas in fundamental theoretical physics, or that major advances are usually initiated by a small number of people? You seemed to imply that a team effort is a reasonable substitute for exceptional individual talent when you wrote,

"Except for GR I cannot think of any of Einstein's theories that would not be suggested by others 5-10-15 years later. … The task that was carried by a single person in 1905 could have been carried by several lesser minds w/o much loss for science."

Obviously it is impossible to disprove your statement, but there are many examples of activities where a team or committee of lesser minds is no match for exceptional thinking by a single individual. For example, think about difficult mathematical problems that have resisted long efforts by others until a single person with the requisite insight or creativity came along. Think about especially great works of visual art, literature or music. Can a team of excellent architects create a design that is equal or nearly equal to that of a truly exceptional architect? Would you feel as confortable fighting a battle (military or corporate) that is being led by a committee of excellent strategists as you would one that is led by a truly exceptional strategic thinker? (It also seems worth noting that Einstein played a very key role in the development of quantum mechanics; read Pais' biography if you doubt this. It is questionable that things would have turned out as they did in the 1920s without his help. Among "all those geniuses in the 1920s," most were working out consequences and difficulties in the new quantum theory, a much easier task than coming up with a new theory in the first place.)

43. **Scott**
June 12, 2005

Curious,
It is hard to understand cause and effect properly, were other people finally thinking new ideas because einstein broke the grip of the old ideas with his SR explanation of the photoelectric effect and brownian motion, or would have poincare finnally make the leap (actually i don't think he ever did either despite of or maybe because of einstein) to SR, and then maybe someone like bohr or heisenberg might have explained the photoelectric effect. The point is the field is in desperate need of some new people(don't get hung up on the "einsteins") to get the ball moving towards a new physics by making revolutionary steps toward the reconcilation of QM and GR as well as properly explain things like "dark matter" and "dark energy" among other things. It is these people who may not be quite the timesaver that einstein that need to be recognized and encouraged instead of pushed out of the field by its institutionalism. To do this we need to be able to recognize these thinkers better by changing arxiv and getting universities ect to diversify their speculation.

Also I would like to remind you that seeing as GR and QM have not yet been reconciled yet it would be foolish to assume the GR has somehow held physics back.

"He worked hard on these problems. And so should you"
yep, I am going to do that as soon as my summer starts. Speaking of which I am going to go finish up my labwritups so that I can start working on it.

44. **Curious**
June 12, 2005

It has been implicit in your discussion as well
as in Smolin's paper that we desperately need new
Einsteins to advance physics. The whole controversy then centers on how to get these proto-Einsteins out of obscurity, with or without the violin. I beg to differ. Except for GR I cannot think of any of Einstein's theories
that would not be suggested by others 5-10-15 years
later. He was, basically, a terrific time saver, most of the time. It is preposterous to suggest that w/o Einstein there will be no BE statistics, or photons, or statistical fluctuation & Brownian motion theories, or special
relativity – to name just a few topics. Think of all these geniuses in the 1920s; they did that and more. One thing
I am not certain about is GR. I do not think that
such a theory would be advanced without Einstein,
but it might have been better for physics if it weren't in the end; after 1930 nobody would even think about
suggesting a nonquantum, purely classical theory of
gravity. GR, basically, hindered the progress in physics as much as it fostered it. Its own creator was not satisfied with this theory and its general validity has not been shown experimentally to this day.

I think that we do not need new Einsteins. The task that was carried by a single person in 1905 could have been carried by several lesser minds w/o much loss for science. Perhaps, we just need to think a bit like Einstein and look at old problems with fresh eyes. One can hope that a
new Einstein will come and clear the slate for you.
Or one can look for new ideas w/o counting on that.

Surely, the second coming of A.Einstein would be helpful. However, delegating the responsibility to find new things to others is not dignified. Who
and what prevents YOU from seeing the obvious? Funding agencies? Peer opinion? Latest fads? Stop fooling yourself. Getting new ideas has always been difficult. It is YOU yourself. And I am no better than you.

Einstein did not write papers in the 50s that he
needs a new Newton to help him out of his TOE problems. He worked hard on these problems. And so should you. Enough of this new Einstein nonsense.

45. **Scott**
June 11, 2005

M,
Anonymous was the one trying to shut down an avenue of discussion, if he wanted smolins proposal's discussed, he should do more then say hey lets talk about these I think they are good instead of saying hey smolin said this I think this about it. Granted he did put some thoughts on it such as its good but all he said was I think these are good suggestion but I would like this suggestion checked out and think this other suggestion should be done carefully. Not knowing the answer to his one question and seeing nothing else to talk about I choose to explain why I thought my comments on changes to the arxiv and other comments about why were on topic in the fact they further the thinking in the question Smolin is attempting to answer thus in a way critiqueing for the points if overlooks if you need to look at it that way to justify the thread drift. So lets get the story straight anonomyous was trying to limit the direction of thought about why no new Einstein solely to discussing Smolins points and forcing us all to think(or at least restict our conversation) along only those lines, allowing no others. Do you see the parrallel? That parrallel to the main reason cited for their being no new Einstien was what i found so hilarious, i am sorry if it came off as insulting but it was really funny too me, i actualy did laugh out loud about it(granted I was really sleep deprived at the time). As far as I know Peter only gets worried about the thread going off topic when posters pet theories get brought up and discussed to much which hasn't happened in this thread.

That being said I think you are dead on with your description of his personality and how this would lead to his success even despite our current institutional problems. But what about the "miniEinsteins" those who are very similar to einstein and capable of thinking of revolutionary ideas but without as strong a drive to do so despite the institutional problems we have. Why should, many others who made creative and revolutionary ideas didn't have to succeed despite this. In that sense we should still try out these suggestions and Juan and my suggestions about changing the arxiv for better communication in order to facilitate these individuals. Of course all of this is mute if a genuinely "new einstein" in the sence you are speaking of blasts on to the scene as such an event would lead to a more revolutionary thinking among others as well as break the institutional hold. Personally I have odds on the real deal showing up and making this discussion mute, but just in case…(of course this just type of waiting for an "Einstein" really brings back my messianic complex comment)

46. **M**
June 11, 2005

As a follow-up to the anonymous poster:

"Let's not distract ourselves with details about the personality of Albert Einstein and his symbolic life experiences. Maybe there is hope of a generational shift and qualitative improvement in US research institutions."

It seems to me that certain aspects of Einstein's personality are quite important to his ability to achieve the impact that he did. In my opinion the combination of several key traits was crucial:

1. Excellent physical intuition.
2. Great respect for established results. This characteristic strongly distinguishes serious scientists from crackpots.
3. Willingness to pursue an independent direction, but only when it was apparent to him that the conventional approach was inadequate.
4. Inwardly directed and motivated. He didn't let others decide for him what he should be working on or what approach was correct.
5. Tenacity. He didn't give up on problems he was interested in, neither because they were hard nor because others didn't buy into his program.

As for the connection with Smolin's article…

I think all of the above characteristics (and others) were very important to his success. I also think it is clear they came from inside him as an individual and were not the product of an especially nurturing environment or support system. None of his best work was done while he was at the IAS at Princeton, although at the IAS his environment offered an environment much closer to what Smolin advocates than the environment where he did his best work.

So, I guess I don't really buy into that part of Smolin's thesis that states "the system" shoulders much of the blame for "no new Einstein." If and when someone like Einstein comes along, he or she will succeed primary due to internal motivations and traits, not because Smolin's proposals have been put into place. Groupthink in physics departments and within funding agencies, hiring decisions based on having a clean record of "correct" research endeavors, and funding decisions based on their compatibility with fashionable research programs and directions are cancerous and harmful to the progress of physics, I agree. But do they prevent the appearance of a new Einstein? I really doubt it; I don't think obstacles in the system can stop someone like that…

47. **M**
June 11, 2005

Scott wrote:

"No one is objecting to his suggestions here this indicates we all agree, and so we moved onto discussion about other things to incourage revolutionary thinkers and better ways to recognized them and their ideas in the arxiv."

I don't think anyone appointed you as spokesperson for what everyone else thinks. Peter's topic was Lee's article, 'Why No "New Einstein"?' It seems quite inappropriate to try to shut down discussion on that in favor of steering discussion to less on-topic areas (and in an insulting manner, at that). Recall Peter's explicit requests on a number of occasions to maintain discussion on the particular topic; that the anonomous poster was trying to do this is to be encouraged rather than disparaged.

48. **Scott**
June 11, 2005

anonymous,

No one is objecting to his suggestions here this indicates we all agree, and so we moved onto discussion about other things to incourage revolutionary thinkers and better ways to recognized them and their ideas in the arxiv. Personally I find the fact that you are simply wanting to simply discuss Smolins proposals instead of having us think of more proplems and proposals, is in the context of this topic extremely hillarious, I'll leave it to you to figure out why.

49.
June 11, 2005

I continue hoping for some discussion of these three substantive proposals of Smolin

quote from June "Physics Today"

To prevent overinvestment in speculatative directions that may end up as dead ends, departments should ensure that different points of view about unsolved problems, and rival research programs, are represented on their faculties.

Research groups should seek out people who pursue rival approaches, and include them as postdocs, students, and visitors. Conferences in one research program should be encouraged, by those funding them, to invite speakers from rival programs. Instructors should encourage students to learn about competing approaches to unsolved problems, so that the students are equipped to choose for themselves the most promising directions as their careers advance.

Funding agencies and foundations should take steps to see that at every level scientists are encouraged to freely explore and develop all viable proposals to solve deep and difficult problems. Funding should go to individual scientists for individual thought and not to research programs. A research program should not be allowed to become institutionally dominant until supported by convincing scientific proof of the usual kind. Before such proof is demonstrated, alternative and rival approaches should receive encouragement to ensure that the progress of science is not stalled by overinvestment in a direction that turns out to be wrong.

—-end quote—

Does anyone doubt that these three of Smolin's proposals should be put into effect? Could some governing body in NSF adopt them as resolutions, or is that too much to ask? Could someone with an agenda like Smolin's be appointed to a position within NSF from which leverage can be applied to the major physics departments and the relevant agencies and people at various levels. If that is too much to expect, then why, exactly, is it so?

If the US scientific establishment has reached a point at which such proposals actually need to be made (instead of being implemented per custom in normal academic practice) then can anyone here offer any objection to their adoption?

Let's not distract ourselves with details about the personality of Albert Einstein and his symbolic life experiences. Maybe there is hope of a generational shift and qualitative improvement in US research institutions.

50.
June 11, 2005

[[I thought this was about why their was no "new Einstein," silly me. Adding to Smolin and Peters comments on why this is…

Posted by: Scott at June 11, 2005 11:14 AM]]

Of course you are welcome to think that. Please allow me to suppose something different. I suppose that the headline question of "why no new Einstein" is essentially just good journalism.

It gets attention, dramatizes the issues, and I suppose energizes people by involving them in emulation fantasy.

One could also as "why no new Feynman" or "why no new Kepler".

but allow me to suppose that this is simply a journalistic hook and that the substance of what he is talking about is as follows:

1. he claims (dont know if true) that creative independent-minded talent that you would earlier have expected to stay in US is going to places like Europe and Canada.

this could be, e.g., a talented young European, proven innovator, who comes to US for postdoc and then instead of moving on to faculty at Columbia or Princeton (as he or she might have done in years past) goes back to Utrecht or Potsdam.

I dont know what statistics Smolin is talking about. he is saying US theory establishment is now COMPARATIVELY LESS ATTRACTIVE to bold ingenious workers and that the lucky ones are LEAVING. Maybe he is wrong. and maybe he is right. It needs to be checked.

2. He is saying that to make the US more attractive again, to foster and keep these people, certain re-diversification should be done by

a. department chairs, hiring committees, tenure review
b. research institute directors, conference organizers,
c. NSF committees, foundations that fund conferences, fellowships, etc.

This diversification is more along the lines of having SEVERAL RIVAL programs or theoretical approaches represented in the department, or the research institute. One of the best examples of this is the Albert Einstein Institute at Potsdam which has several quantum gravity approaches being pursued.

3. He may also be saying loosen the institutional grip which vested research programs have on theory in major departments, at least to the extent they turn the inventive young person into a brain-slave. But in my private estimation this should be with some care, if at all, since if applied heedlessly it could damage the coherence of valuable efforts.

In any case I think it is sentimental nonsense to think that one is going to find some policy change that will produce people that will be recognizably similar to those whom we revere as heros and saviours, "new Einsteins", or Keplers, or Feynmans or whatever. A practical objective would be to make US research institutions once more attractive to talented independent minds, if necessary by breaking the monopoly power of overgrown programs.

51. **Juan R.**
June 11, 2005

Quantoken now i am understand some of your topics.

You said "The real Einstein did not go to graduate school either." I think that he was.

"They can write to some of the most famous physicists at the time and very likely they will get some respose and discussion."

You also can. I say this by own experience. I have talked with leader physicists in several disciplines inclusding several Nobel laureates like Prigogine (for discussing about thermodynamics), Weinberg (for discussing about QFT), etc.

Almost all of my mails were read and correctly replied, including formulas, references, etc.

When i began to talk with Prigogine i clearly say to him that i was undergraduate, but my mansucripts were interesting for him and contacted to a post-PhD of his group with me and both collaborate in a hot thermodynamical topic.

I see that if your work is minimally serious, it is read by people with interest and comments/suggestions received.

On Edward Witten I can say nothing.

52. **Juan R.**
June 11, 2005

Quantoken,

I have hard often that Einstein was not studied and therefore any can do a revolution in science without go to the university.

I don't know if it is your case (i didn't understand well your post), but I thought that Einstein was a graduate (physicist) with good experience in scientific research. Moreover, I think he was did a PhD in a molecular hot topic. Am I wrong?

53. **garrett**
June 11, 2005

In talking about the arxiv, I said that it was "(mostly) open." I think this is pretty much the best way to go, with an automated, and hence near zero cost, system to screen out obvious cranks. A system of endorsements, with a very broad base of endorsers, does a good job of this. However, I think it's bad when the arxiv administrators mess with this submission criteria by hand — deleting articles or restricting endorsed posters, based solely on their opinions. It's bad because this sort of judgement should be carried out by the community, as the next step. By deleting articles or censoring posts, the reviewers are overstepping their bounds and potentially killing good and maybe even groundbreaking articles based on their opinions. This has unfortunately happened several times, to Tony Smith and Brian Josephson and others, and it's just not the administrator's place. If they take great pains to establish a good and fair system, the administrators should realize that in messing with it by hand they're doing something wrong — they're practicing exactly the kind of heavy handed censorship that an open forum is supposed to prevent.

54. **Scott**
June 11, 2005

I thought this was about why their was no "new Einstein," sill me. Adding to Smolin and Peters comments on why this is as well as discussing additional changes besides the general diversification ideas are in no way offtopic.

55.
June 11, 2005

this blog discussion is supposed to be about Smolin's proposals?

Here are 3 of them. they seem totally uncontroversial to me: no brainers. Any disagreement?
quote Smolin

To prevent overinvestment in speculatative directions that may end up as dead ends, departments should ensure that different points of view about unsolved problems, and rival research programs, are represented on their faculties.

Research groups should seek out people who pursue rival approaches, and include them as postdocs, students, and visitors. Conferences in one research program should be encouraged, by those funding them, to invite speakers from rival programs. Instructors should encourage students to learn about competing approaches to unsolved problems, so that the students are equipped to choose for themselves the most promising directions as their careers advance.

Funding agencies and foundations should take steps to see that at every level scientists are encouraged to freely explore and develop all viable proposals to solve deep and difficult problems. Funding should go to individual scientists for individual thought and not to research programs. A research program should not be allowed to become institutionally dominant until supported by convincing scientific proof of the usual kind. Before such proof is demonstrated, alternative and rival approaches should receive encouragement to ensure that the progress of science is not stalled by overinvestment in a direction that turns out to be wrong.

—-end quote—

Wasn't "portfolio diversification" in the theory section of a department approved and fairly common practice a few academic generations back? Isn't it still far from rare in major universities outside the US?

56. **Quantoken**
June 11, 2005

Scott said:
"One reason, there are no new einsteins is that many may quit before even finishing gradschool."

Please note: The real Einstein did not go to graduate school either. He finished colleage as an average and could not find a job for two years. Then only with some help from some one influential he got the job of a patent clerk.

The big difference is at Einstein's time science was still the activity of a small elite group, not a massive modern industry. As an average Joe, Einstein **and his friends** can access the academy easily: They can read the most advanced science journals and can underdstand and discuss the stuff. They can also submit papers and it is more likely than not that they can get their papers published. They can write to some of the most famous physicists at the time and very likely they will get some respose and discussion.

But all that is no longer possible today since science has grown into a huge huge massive full fleged modern industry. The kind of communication Einstein enjoyed is no longer possible, despite the availability of the internet.

Just try to think about a new Einstein, who is a college graduate, but who miraculously get it all figured out, write to Edward Witten, telling him Sir you are wrong, don't waste any more of your time studying super string theory, bla bla bla? What kind of response do you expect?

Now think about the real Einstein living today, and there hasn't been SR and GR yet, But QM and SST have been fully developed today. So the establishments includes the classical Newtonian mechanics, QM, SST, and the Universe was a static model, and of course the spacetime is absolute. Assuming that's what we got today.

Now this guy called Einstein, who nobody knows, comes forward in the year 2005, and tell everybody: It's all wrong, Newton got it wrong, there is no absolute spacetime, bla bla. I have a whole set of new theories which describes the experimental evidences better than the Newton Mechanics. And the universe could not be static at all. Depend on the critical density, **either all stars will fly away, or one day the sky will collapse on us**. Not only that, my new theory (GR) is also **incompatible with QM**, so I believe that QM could also be wrong or at least it is not a complete theory, bla bla bla. Would any one take him seriously? This guy doesn't even have a Ph.D., thank God, why would any one even bother to read his paper?

Think about that, wouldn't you say that Einstein was lucky to be born in 1879, not in 1979?

57. **Scott**

June 11, 2005

One reason, there are no new einsteins is that many may quit before even finishing gradschool. The amount of stuff needed to learn to catch up on the physics of today is alot longer then in einsteins day and someone of einseins character may not like having to spend all of this time learning what their school's say to learn instead of following wherever their thoughts bring them. My roomate quit school earlier this year for among other things. Would he have been a "new einsein" i don't know he definately loved thinking about physics and is smart as hell. I personally almost decided to quit this semester for the same reasons, and even though I didn't my constant thinking about things from how to get america cheap health insurance or getting rid of political parties, to thinking about fundamental problems in physics the reconciliation of GR and QM or the missing antimatter in the universe ect almost caused me to fail despite my decision to the contrary.

Another factor is the impression gotten that from most of the methods used today is that figuring out the new physics will take crazy mathematics skills and large research programs(ST and LQG) to work through and that there is no place for individual creative input that they could make despite not being a genius as far as mathematics is concerned. The only way for the creative individual to think otherwise is if they have a severe messianic complex like me. Luckily that is a common complex for smart people who can think up new ideas however it often gives them to much overconfidence in their particular ideas which can lead to crackpotism if the individual is not carefull.

58. **Scott**
June 11, 2005

Juan I like the idea of an open forum to talk about the paper in question, but a couple of points. Also a conveniant multiple ranking system to replace the how much is it cited model.

by which i mean seperate ranking for different categories such as:

scienceness,revolutionary/proggression of standard ideasness,effect on own workness(this one is measures the same thing that citations does but by person instead of by person weighted by papers),ect

then you would be able to see the number of people that gave each rating in each category as well as being able to sperate who(by category such as HEP and sub categories like string theorists) gave which ratings.

Also I would suggest having a seperate forum for pointing out actuall mathematical type errors.

59. **Juan R.**
June 11, 2005

Simply to say an important detail that i forgot!!

My old example of why a minimum review in science is needed, is based in a joung guy that a year ago claimed to be the new Einstein in certain science forum.

Some formulas of his "revolutionary" theory appear in the project page. You can value by yourself, why minimum review is needed. I wonder if Smolin proposal for detecting new Einsteins can effectively detect real geniouses from charlatans. I think that is possible but an really expensive task.

Probably from each 100000 hoaxes one find a single new Einstein. I agree with Smolin and think that humanity would waste time and money in this class of projects.

Only a last question, who will decide what is Einsteinian-like and what is hoaxers-like scientific work?

60. **Juan R.**
June 11, 2005

Below link don't work (i think that is a bug with preview buttom).

The link is Gonz?lez-?lvarez reply to "Science without denominations"

I think that current misunderstanding about string theory from outsiders would be eliminated if the system of publication was open with open discussion.
Any nonspecialist could simply read the criticism to string theory and see that the real status of string theory is not that of "Elegant Universe" by Brian Greene.

Students could obtain a good idea of that is being done in each field, if that field is open to debate and choose future careers.

I openly invite to any to discuss the future model of scientific publication and submit comments.

61. **Juan R.**
June 11, 2005

Garrett,

Your suggestion is exactly the posted by Shagaev, peer review may be substituted by open forum at journals pages. As said, I cannot post the page of project for reformulation of publication system here because Peter?s blog offers an error with the link; it is a Russian page and blog cgi says that is not "adequate" (?).

From Gonz?lez-?lvarez reply to "Science without denominations" you can link to Shagaev own suggestions in the page of the project for new model of publication.

I think that zero review is bad for science, and my specific proposal adds a minimum review process. It is compatible with some proposals at last 01 conference in electronic publishing. I added in the project page an example of why minimum review (split between adequate and inadequate) is necessary. The final validity of adequate papers will be based in open discussion within community.

I think that many anti-string theory (like Peter) would love i) an elimination of censure in some anti-string papers, ii) possibility for open forum of submitted papers. Now, one can see last papers in string fad in ArXiv and after one become here to read interesting comments.

Peter, a question for you, would be more effective if you could post your comments in string theory (e.g. in Landscape stuff) directly like an attachment to each ArXiv preprint instead of here? That model did already exist in the CPS preprint (unfortunately closed) and worked very well, because one could see the preprint and in the same html page comments/discussion by people.

Garrett on your *If your stuff is decent, you should be able to find an endorsement*." I did extensive comments in this. An expertise in ArXiv said to me that usually ArXiv administrators provide to you a list of endorsers pro string theory and is best ignore it and search for others endorsers. Moreover, even if your work is finally endorsed and accepted, administrators (pro string theory) can erase it without explaining to you why, and violating own ArXiv policies.

62. **D R Lunsford**
June 10, 2005

JE – is that a whine? Just put it out there.

-drl

63. **garrett**
June 10, 2005

I like the publishing model of the physics arxiv, as propounded by Paul Ginsparg. I think, instead of the peer review process, it's best if researchers post to a (mostly) open forum, and have their work rated collaboratively by the community. Right now citations act as this collaborative rating. The arxiv, as some point out, is not completely open, but I haven't encountered a problem with its barriers, as I usually have some affiliation or another with academic institutions. If your stuff is decent, you should be able to find an endorsement. It may be the case that I'm academically shooting myself in the foot by not publishing through traditional journals, but I like to make the future happen by embracing it.

Quantoken and J.E. — I always like reading good new stuff. But I can't comment on it unless it's out there to be seen.

64. **Quantoken**
June 10, 2005

Me, too! I am interested in seeing what J.E. has, although I will be quite skeptical.

garrett, how do you manage to get anything published at all? I don't think it's possible. Not that I have tried. I haven't, I am holding off publication of my research until I can figure it all out. But I am on a right track to getting pretty close to solve some of the most puzzling fundamental physics problems. So close that I no longer even bother to discuss my ideas on my own BLOG any more.

Quantoken

65. **Chris Oakley**
June 10, 2005

J.E.-

I would certainly be interested in your paper. Why not post a PDF version on your web site, or something?

66. **garrett**
June 10, 2005

I liked Smolin's article. Probably because, though no Einstein, I do fit Smolin's criteria for a young researcher on the fringe — working on hard fundamental problems, with only a few articles published because I thought they were good. And I've got a lot of good stuff I'm working on. But it's tough, and lonely, doing this all on my own. I looked at the web page for PI, thinking it might be a cool place to go spend some time, but it looks like it too is dominated by string theorists. I'd love if some other options were to open up, but I suspect Smolin's "modest proposal" for change will go over with the establishment about as well as Jonathon Swift's.

67. **Alejandro Rivero**
June 10, 2005

I agree with Aaron and Chris. Journals and ArXiV (that, btw, seems to be more relaxed this semester) policies are symptoms, not the cause.

As I told in Lubos's blog, my read of (/into?/) Smolin's article is a request for anarchy in modern science, opposed to the Order of "group thinking". Tony likes to speak of the "Golden Bars of Consensus". Consensus is a part of every assembly, of course, but it must be counterweighted by Initiative.

68. **Alejandro Rivero**
June 10, 2005

Read "The Dawning of Gauge Theory" by Lochlainn O'Raifeartaigh for a real happy shot of pure physics in contrast to all this bitching.

I was gonna send him email, but unfortunately he's dead. What is it about the Irish and Italians that makes them such great geometers? Catholicism?

Guinnes. I remember O'Raifeartaigh vividly describing us the smell of Dublin streets in the morning coming some days of the week, depending of the brewery works, and how the citizens were able to decide from it the best day to go out for a beer.

69. **J.E.**
June 10, 2005

Well, I'm no new Einstein for sure, only a theoretical physicist who works and lives as a translator. But in case it can help explain the current lack of new ideas in the field, let me say that several years ago I took the challenge of trying to remove infinities from QFT (specially from QED, which is where they first appeared), as I felt pretty uncomfortable with them during my student years (not to speak of renormalization). By realizing that something was missing and by introducing minor changes into the standard QED approach, I managed to reproduce all cross section values and to compute the electron MMA at third order with about the same accuracy as the standard value (and without any need for renormalization). Once the task was completed and the paper was prepared, I realized that I had no apetite to fail or succeed to publish it, gain recognition or anything like that. Why bother to face critics and indulge into endless discussions instead of turning my efforts into another problem which I felt more appealing?

70. **Juan R.**
June 10, 2005

Mike Crowley said

"Or perhaps breakthrough ideas were written about in a paper decades ago but never noticed."

There are well documented cases of breakthrough ideas ignored during decades and finally aknowledged like great. For example, Onsager Nobel Prize.

I think that situation now is poor with a order of 10^2 journals in a specific field. Nobody can read all. I suspect that really someone good idea is hidden in a non-top journal. Perhaps some great idea that permits to me solve some of unsolved problems that i am working now with few success:

71. **Peter Woit**
June 10, 2005

Perelman had no “departmental elders” to answer to. As far as I know he was essentially working outside the academic system in Russia, supporting himself on his savings.

Wiles was tenured at Princeton, and had made his reputation based on earlier work. Someone I know who saw one of his grant applications from that period claimed that although Wiles wasn’t explicitly saying so, reading between the lines you could tell that he was trying to prove Taniyama-Shimura-Weil. He was one of relatively few people with a strong enough reputation that he could be pretty sure he could get a grant based mostly just on his reputation, without having to give away what he was up to.

I’ve always thought the funniest part of the Wiles story was that near the end of his work on this problem, he scheduled an advanced graduate course, in which he went over in great detail one of the more obscure technical parts of the proof. The only one in the audience in on why he was doing this was Nick Katz, so slowly all the other students drifted away, since the course just seemed pointless and obscure to them. The funny thing is that this was normal enough for the Princeton math department that no one noticed anything unusual was going on.

72. **mortain**
June 10, 2005

Fantastic post, Peter. I’ve always tried to read everything Smolin writes (and also Rovelli). Once I was fortunate enough to meet Smolin in person, which despite the extremely high risk of intellectual embarrassment (at the time, I was a grad student), was like bathing in neural fireworks. Smolin opened up more new intellectual horizons for me in 15 minutes than innumerable string theory discussions ever did.

Still, no “new Einstein”? When it comes to gravity, perhaps we should be asking why there is no ‘new Newton’. If Einstein and Newton are on a par as regards their understanding of a force as elusive as gravitation, we might be better off reserving optimism for the 2160’s.

Seven years of intensive hard work seems like a small price to pay for relative immortality. It’s got to be worth it. But if so, why don’t more people try to solve the big problems? Anyway, just what did Wiles and Perelman do to satisfy their departmental elders that they were doing what mathematicians ‘usually’ do whilst patiently conquering major unsolved problems? Does any one remember?

73. **Mike Crowley**
June 10, 2005

One thought that sends shivers up my spine that there may indeed be another Einstein–or several–out there who simply cannot get the attention of the scientific community. Or perhaps breakthrough ideas were written about in a paper decades ago but never noticed.

Another thought–and I could be way off base here–is that a breakthrough of some sort might come from another discipline altogether, from dynamic systems or complexity (?). The interdisciplinary approach of complexity seems to have encouraged some new ideas in other fields.

Lastly, perhaps there is a possibility for “lone wolves” who have a limitless passion for physics (and intensely want answers) but, because they do not particularly care one way or the other whether they are accepted into the community of science, and have not been indoctrinated to think in terms of what is professionally acceptable or too risky, have nothing to lose by considering unconventional theories. These would most likely have to be individuals who are not dependent upon the scientific community itself for survival. But then the problem becomes one of being heard or taken seriously.

One hope I have is that the desire to know the truth about the origin of the universe, what came before, how the universe operates and why we are here would be so strong that it would eventually override the superficial considerations that might be obstructing new and better ideas. Discovering this and other blogs has been a true revelation because I had no idea until recently that these controversies existed.

74. **Juan R.**
June 10, 2005

I did comments in that, see references. See data extracted from papers, science citation index and own experience of Nobel laureates, whic work was rejected many times for peer review publication.

Scott, you forget that photoelectric articles was based in some ideas already thought for others, and a few of luck for the publication.

You forget that GR was rejected by Nobel commite like “speculation without many importance”.

75. **Chris Oakley**
June 10, 2005

I agree with Arun. ArXiv and the journals just reflect the attitudes and prejudices of the clique who decide the worthwhile research topics. With a few notable exceptions the rule is that if ArXiv do not want your papers then probably no-one will want to hire you either. This is not cause and effect: it is just two sides of the same coin.

76. **Arun**
June 10, 2005

Re: arxiv, and rejection policies – I don’t think an Einstein thought, oh, there is a journal that will accept my papers, so I’ll think revolutionary thoughts. arxiv problems are a symptom of a conformist culture, not the cause of such a culture.

77. **Scott**
June 10, 2005

your forgetting the explanation of the photoelectric effect as well. One of Einstiens greatest accomplishments and the his 1905 paper he thought was most revolutionary. Einsteins claim over poincare has mainly to do with the clear new conceptual breaks in his paper and his production of the Lorentz’s math from the two postulates that physics is the same in all reference flames and the speed of light is always c.

http://www-groups.dcs.st-and.ac.uk/~history/HistTopics/Special_relativity.html

78. **Juan R.**
June 10, 2005

Why no new Einstein? I did some comments about this in the past in this blog (e.g. last PITP Showcase Conference and in other sites.

Recently, Nobel laureate Laureate Brian Josephson critiqued the rejection model in ArXiv and in his web page claimed that today revolutionary ideas such as those by Einstein or Yang-Mills would be not considered for community. In the case of Einstein, he would find difficulties due to his lack of official affiliation.

Several editors, scientists (including several Nobel laureates), official science organizations, etc. are claiming in the last decade that current organization and publication system of science is the source of its clear stopping, without great advances or revolutions.

The problems are:

– **Oriented research**. Newer in the past the greatest achievement were obtained from rigid oriented research, specially Nobel laureated works. Nobel achievements are an elegant mixture of talent more luck.

– **Archaic publication systems favoring old ideas**. Usual peer review is the confrontation of your manuscript with established ideas. Referees are the guardians of standard knowledge. If your work is = establishment + small addition will be published. If your work breaks establishment at a great extension then will be rejected.

– **A rigid hierarchic (military?) organization**, where young promising science students are used like ?brain extension? by senior tenured scientists for working in the ? stupid? projects of later. It is really frustrating for a young scientist to work personally in some interesting (revolutionary) theme, comment with his chief and this say that your work is ?either wrong or uninteresting? (curiously highly respected specialists in the topic say, ?I like your approach? and similar after reading manuscripts). Peter did interesting comments relating high-energy physics in his legendary (physics/0102051).

June 9, 2005

No new Einsteins? What does it matter? No one listens to their elders anyway.

-drl

82. **Peter Woit**
June 9, 2005

Hi Eric,

I was also thinking of Wiles and Perelman who are interesting evidence that it takes about 7 years to make progress on a big problem. Wiles did it after he had tenure at Princeton so could do what he wanted, Perelman by saving his money earned from several years of jobs in the states, and living cheaply in Russia.

Hi Tony,

I wasn't thinking of Vilenkin, but rather a college friend (not Eric….) who advocated this as a way of getting intellectual work done.

83. **Tony Smith**
June 9, 2005

Peter, you said "…A young theorist would be more likely to be able to find the necessary time if they went to work as a night-time security guard. …".

Were you thinking of Alexander Vilenkin, about whom a February 1996 Discover Magazine article by David H. Freedman on the web at
http://www.gradewinner.com/p/articles/mi_m1511/is_n2_v17/ai_17808131
says in part:
"… Vilenkin's fascination with cosmology dates back to high school in the Ukraine … few professors at the university could do anything to satisfy Vilenkin's curiosity about cosmology; his frustration grew worse when he was rejected by Soviet graduate schools. … Unable to get work as a physicist,[Vilenkin] took a job as a night watchman in a zoo and set about doing cosmology on his own. After being allowed to emigrate in 1976, he came across an advertisement for the graduate program in physics at the State University of New York at Buffalo. He had better luck getting accepted in Buffalo than in the Ukraine, and he whipped through the Ph.D. program in just one year. Eventually he landed a job at Tufts …".

Tony Smith

Multiverse, String Theory and Templeton

June 10, 2005
Categories: Uncategorized

A couple months ago when I was shocked to realize how close to reality my April Fool's parody had been, I'd unsuccessfully tried to find out some more information about the Templeton conference at Stanford that Mark Trodden had mentioned here. There's now something about it on the Templeton website. It was part of Templeton's Humble Approach Initiative which has as its goal "to bring about the discovery of new spiritual information."

The conference was called Multiverse and String Theory: Toward Ultimate Explanations in Cosmology, and brought together various landscapeologists (including most of the Stanford theory group). One of the other participants was the Rev. Dr. Rodney Holder, an Anglican priest who believes that science supports Christian belief, and that "modern cosmology has reinvigorated the traditional argument for the existence of God from design". He has written an article on miracles that won an award from the Templeton Foundation, and has a new book out entitled God, the Multiverse and Everything: Modern Cosmology and the Argument From Design, which argues for Intelligent Design.

Comments

1. **Tony Smith**
   June 15, 2005

   Peter, thanks very much for your honest statement that you are opposed to "… right-wing extremists …" such as Templeton who you view as "… mixing fundamentalist religion and politics in a dangerous way …".

   Although I cannot prove it by a rigorous poll or such, it is my opinion that most (probably almost all) of the academic landscape/superstringers have similar views.

   Assuming for the purpose of discussion here that such is the case, it raises the questions:
   Why would academic landscape/superstringers try to jump into bed with Templeton?
   Is their current 90% of the usual theoretical physics funding not enough for them?

   The obvious answers are that 90% is not enough and they want further funds so badly that they will sell their souls to get it.

   Why is 90% not enough?

   Probably because the system is designed to produce landscape/superstring PhDs each year at an exponential rate (if the number of PhDs produced is proportional to the number of current faculty, and the new PhDs become faculty), and the usual funding does not have corresponding exponential growth.

   Therefore, even 100% of conventional funding would not be enough to satisfy the exponentially growing landscape/superstring appetite.

   The resulting greed explains such superstringer actions as:
   selling their souls for Templeton money;
   and
   Witten's attempt (through Griffiths) a few years ago to grab Piet Hut's IAS post.
   With respect to the latter, see an 11 October 2000 statement by Richard Muller at http://muller.lbl.gov/pages/MullerStatement.html saying: "… I am very sad to see the lawsuit between the Institute for Advanced Study and Piet Hut … the Institute for Advanced Study … is doing enormous damage to itself by attempting to terminate him. …".
   and a Science magazine article by Constance Holden, dated 27 October 2000, at http://www.sns.ias.edu/~piet/lawsuit/science.html that says: "… Hut dismisses the negative job assessments, saying that there has been no formal evaluation of his work and that the visiting committee had little regard for his field of computational physics. He says the problem started with a 1993 dispute with string theorist Ed Witten over Hut's desire to buy an expensive supercomputer. Witten has declined to comment. …".

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

   PS – The links about Piet Hut above were roughly contemporary with the events around the year 2000, and may no longer be live links.

   June 14, 2005

   Hi "",
   I have not a machine for knowing that people is thinking when say phrases. I cannot know that Einstein mean when asked

   "Had God any choice in the creation of the world?"

   A joke? Perhaps a redundant question (Einstein was determinist)? I don?t know. He also said that time was an illusion, but in the last years of his life, he appeared to sustain a different view. I simply don?t know. If he was living now I could ask to him, but I cannot do it.

   I wonder is that scientist are discussing about things that science cannot say nothing and the hot debate here.

   Was Universe created by God:

   – Yes. It is possible

   – No. It is possible

   Science cannot say nothing. Therefore Rodney Holder's claims are undecible according to logical calculus. I cannot see serious problems with that (when my above opinion is explained). Quoted above Holder's claims are not antiscience, but some people here is anxious.

What **IS** antiscience is the mainstream belief of that SM or GR are explained by experiment. That is a great **MISTAKE**

After of several replies, manuscripts, sci posts, etc. still nobody has demonstrated to me that SM and GR are correct.

In SM the supposed proofs of my contenders (e.g. Weinberg) usually don't pass of the elementary stuff S-matrix theorems (many are wrong when one study the details).

In GR, nobody (including of course active workers as Carlip, Ehlers, Will…) has demonstrated rigorously that GR even fits to solar system data.

4. June 13, 2005

   Had I been present at the creation, I would have given some useful hints for the better ordering of the universe. [1]

   Note [1].
   Carlyle says, in his "History of Frederick the Great," book ii. chap. vii. that this saying of Alphonso about Ptolemy's astronomy, "that it seemed a crank machine; that it was pity the Creator had not taken advice," is still remembered by mankind,-this and no other of his many sayings.

5. **Arun**
   June 13, 2005

   Did you know "Although much of the public controversy over intelligent design has focused on the application of design to biology, it's important to remember that design theory itself reaches well beyond biology, and that some of the strongest evidence for design comes from such fields as physics, astronomy, and cosmology."

   Brought to you by the Discovery Institute.

   🙂

6. **Quantoken**
   June 13, 2005

   "Had God any choice in the creation of the world?"

   Probably the god had no choice on a lot of things that is needed to create this world. For example mathematics rules. For a very specific example, the numerical value of PI, 3.14159265…., you can list all the decimal digits of PI to infinity and it is a sequence that contains infinite amount of information, more than what the whoole universe can register and hold. But once you lay down the definition what PI is, all of its digits are **completely fixed**, even the god is powerless to alter even one digit of PI out of the infinite number of digits! You can not create a universe in which the PI is even slightly different from ours!!!!

   On other things, maybe it's just a matter of the way our thinking works. For example Newton's second law. It is actually just a Newton's second convention. Because that Newton's second law/convention actually **gives the definition** what is force. Without a definition of what is force, you can not lay out a relationship how force is related to other quantities. The same equation, F=MA, can not serve on two purposes simutaneously, one to give a definition what is force, one to define the relationship between force and mass and acceleration.

   So in that sense, force is really just a necessity of human thinking, not a necessity for how things works in this universe. The god could well create the universe using just mass, spacetime and movements, with no reference whatsoever to the notion of force.

   Now the question is, the 4-D spacetime, is it by choice or is it **a mandatory like PI is**? If it is mandated, then, certainly, only 4-D universe is possible, and the 11-D super string theory is not going any where.

   Quantoken

7. June 13, 2005

   Juan, I like your posts. But I think Einstein was being cute when he said

   "Had God any choice in the creation of the world?"

   Different ethnics have different funnies. English humor is not easily explained to French wit.

   It is utterly charming how Einstein put it, but it is not, I think, about God or choice.

   It is about the logical and mathematical form of physical laws. Can they only be of this form (but maybe with different constants?)

   If only Immanuel Kant had been a jew as well as a german he could have been more provocative and amusing and we might all have benefited.

8. **Juan R.**
   June 13, 2005

   In "A man's ethical behavior should be based effectually on sympathy, education, and social ties and needs; no religious basis is necessary. Man would indeed be in a poor way if he had to be restrained by fear of punishment and hope of reward after death."
   [Albert Einstein, "Religion and Science", New York Times Magazine, 9 November 1930]

   Einstein was talking about usual religion.

   Regarding

   "Religion without science is blind. Science without religion is lame."

   i simply don't know if he was talking about religion, in general, or about his own view of "religion" (phylosophy).

   I think that Einstein would not agree with many Templeton questions but, in some sense, he asked about "antrophic" questions in his famous query

   "Had God any choice in the creation of the world?"

Sorry Scott, I cannot post a link to that here. I follow rigorous Peter Woit's guidelines in what can be posted and what cannot be.

9.
June 13, 2005

I was glad to see Scott's quote of Einstein:
[[It was, of course, a lie what you read about my religious convictions, a lie which is being systematically repeated. I do not believe in a personal God and I have never denied this but have expressed it clearly. If something is in me which can be called religious then it is the unbounded admiration for the structure of the world so far as our science can reveal it.]]

I looked for the source and found something about the quote in
http://en.wikiquote.org/wiki/Albert_Einstein

Wiki says it comes from:
Letter to an atheist (1954); Albert Einstein: The Human Side (1981) edited by Helen Dukas and Banesh Hoffman, Princeton University Press

Must add agreement and approval for the distinction Scott draws between Einstein's view and Templeton's. Judging from the quote of Sir John, that gentleman wishes people to acknowledge an "intimate", actively interfering Creator-person, an idea I find mildly disgusting. The thought of an affectionate busybody transgressing laws of nature for personal reasons is something of comedown from the unqualified admiration for physical law expressed in Einstein's letter.

10. **Scott**
June 13, 2005

"It was, of course, a lie what you read about my religious convictions, a lie which is being systematically repeated. I do not believe in a personal God and I have never denied this but have expressed it clearly. If something is in me which can be called religious then it is the unbounded admiration for the structure of the world so far as our science can reveal it." -Einstein

"From a theological perspective it is indeed tempting to see this remarkable self-organizing tendency … of the cosmos … as an expression of the intimate nature of the Creator's activity and identification with our universe." -Templeton

Peter has already pointed out the difference of their views but I thought I would pick another more blunt quote of Einstein's to really drive it home. Templeton talks of the universes principles being an expression of the creator's "activity and identification" with the universe while Einsein is simply in awe of the nature of the world and for lack of a better word that awe can be termed religous. These are in no way the same thing and in no way indicative that Einsein would approove of templeton's actions. God was simply Einsteins word for order/harmony/ect in physical law.

"Religion without science is blind. Science without religion is lame"

knowing what Einstein considered religous, "a feeling of awe at the scheme that is manifested in the material universe," this means the second part indicates that the life of science is sucked out if you have no awe for the principles that define the universe.

"Phys. Rev. on a generalization of S-matrix theory to chemical dynamics for example? (Molecules are not in the infinite past and scatter to the infinite future :-)"

I for one would appreciate a link to that.

11. **Juan R.**
June 13, 2005

I said,

"*It is really interesting that Einstein would not have approved research in quantum field theory. It is well-known that his valuation of quantum field theory (QED) was more radical than Dirac own one*."

Peter said,

"*The situation of quantum field theory at the present time is very different than it was more than fifty years ago back during Einstein's lifetime.*

Similarly the threats to the scientific enterprise are different. Whether or not he would have approved of a lot of the Templeton verbiage…"

I posted extensive quotes of Einstein and his own ideas about physics and religion. You are open to interpret words of others in your own benefit, but his phrase "*Religion without science is blind. Science without religion is lame*." is simple and clear for understanding.

It is also clear that Einstein hated relativistic quantum field theory (as said his words were "hard") and when results of experiments show ?coincidence? at eleven (?) figure he remained impassible. Why? Eccentricity of an old man? Of course, no. Einstein was not an engineer, he was a physicist a pure physicists searching ?true? and ?elegance?.

He knew that relativistic quantum field theory (then QED) was an ugly subject (**and still is**). The words of Peter are not true. The situation of quantum field theory (e.g. QED) at the present time is the **SAME** than it was more than fifty years ago back during Einstein's lifetime.

There are two types of physicists: ?real? (authentic) physicists and ?engineers? (most of particle physicists). Unfortunately, a deep understanding of nature cannot be achieved from relativistic quantum field theory (a theory that does not work in molecular chemistry as is well-known) Would I post here a recent Phys. Rev. on a generalization of S-matrix theory to chemical dynamics for example? (Molecules are not in the infinite past and scatter to the infinite future 🙂

From a guy called Dirac

… When one tried to solve it, one always obtained divergent integrals… Rules for discarding the infinities [(renormalization) have been developed]. Most physicists are very satisfied with this situation. They argue that if one has rules for doing calculations and the results agree with observation, that is all that one requires. But it is not all that one requires. One requires a single comprehensive theory applying to all physical phenomena. Not one theory for dealing with non-relativistic effects and a separate disjoint theory for dealing with certain relativistic effects. Furthermore, the theory has to be based on sound mathematics, in which one neglects only quantities that are small. One is not allowed to neglect infinitely large quantities. The renormalization idea would be sensible only if it was applied with finite renormalization factors, not infinite ones. For these reasons I find the present quantum electrodynamics quite unsatisfactory. One ought not to be complacent about its faults. The agreement with observation is presumably a coincidence, just like the original calculation of the hydrogen spectrum with Bohr orbits. Such coincidences are no reason for turning a blind eye to the faults of a theory. Quantum electrodynamics … was built up from physical ideas that were not correctly incorporated into the theory and it has no sound mathematical foundation. One must seek a new relativistic quantum mechanics and one?s prime concern must be to base it on sound mathematics.?

When one studies QFT seriously, one knows **WHAT** is computed and **WHAT** is ignored. When one seriously studies quantum field theory onw know **WHY** quantum field theory being wrong offers the correct answer to scattering experiments and wrong answers in other questions.

As said in other posts in this blog, one would not take seriously Weinberg manual 🙂

12. **Peter**
June 12, 2005

Hi Tony,

Here are some clarifications about what I think.

First of all about politics: there are plenty of other blogs on the web with similar politics to mine, so I've tried to stay away from political topics. But, like a lot of people, I'm very unhappy about what I see happening to this country as its politics is taken over by right-wing extremists. One of them is John Templeton Jr., president of the Templeton foundation and chairman of "Let Freedom Ring", a right-wing political organization. These people are mixing fundamentalist religion and politics in a dangerous way. See for example:
http://www.newsmax.com/archives/articles/2004/6/26/111715.shtml
I don't think it is a coincidence that they also are trying to inject religion into science and to promote pseudo-science.

Sure, the main sources of funding of string/M-theory remain universities and government grants, and this is the biggest problem. But I think it is remarkable and worth making a fuss about that leaders of the field of particle theory are getting in bed with foundations run by people whose agenda in life is promoting extreme right-wing politics and trying to increase the influence of religion over all of American life, science included.

13. **eli**
June 12, 2005

Peter,

1. I apologize for placing comments on GR that did not directly pertain to the discussion that you have in mind.

2. However, it is the cosmological consequences of GR with its insistence on dark matter, energy and other mysteries that gave fodder to Templeton foundation and the like cults. These people did not get their agendas from the Bible. They've got it from the popular press that, in turn, reflects the current state of cosmology. The best way to deal with the problem is to seek for physical theories that do not invoke the forces of darkness.

Once more, please, accept my apology for bespotting your blog.

14. **Tony Smith**
June 12, 2005

Peter, you say that you are opposed to "… the unholy alliance of a well-financed right-wing organization and string-theory/multiverse pseudoscience …".

You choice of words puzzles me. "unholy" indicates a religious judgment. "right-wing" indicates a political judgment.

If "superstring/multiverse pseudoscience" does indeed threaten to bring about what Feynman called "a degeneration of ideas" that causes "vigourous philosophy …[to]… disappear", and I agree with you that such a threat is real and serious, then it seems to me
that ANY funding of "superstring/multiverse pseudoscience" enhances that threat,
and it is irrelevant whether the funding comes from "unholy" or "holy" sources or from "right-wing" or "left-wing" sources.
In fact, I would guess that the most serious problem is not that "unholy" "right-wing" Templeton money might go to "superstring/multiverse pseudoscience", but
that 90% of the academic (predominantly left-wing) and government (holy or not, I don't know) funding for theoretical physics might continue to go to superstring theory and that superstring theory might morph entirely into "superstring/multiverse pseudoscience", thus leading to Feynman's "degeneration of ideas".

15. **Peter Woit**
June 12, 2005

The situation of quantum field theory at the present time is very different than it was more than fifty years ago back during Einstein's lifetime.

Similarly the threats to the scientific enterprise are different. Whether or not he would have approved of a lot of the Templeton verbiage, I think he would have recognized the threat to what he held most dear embodied in the unholy alliance of a well-financed right-wing organization and string-theory/multiverse pseudoscience.

16. **Juan R.**
June 12, 2005

It is really interesting that Einstein would not have approved research in quantum field theory. It is well-known that his valoration of quantum field theory (QED) was more radical than Dirac own one.

17. **Juan R.**
June 12, 2005

"If it is one of the goals of religions to liberate maknind as far as possible from the bondage of egocentric cravings, desires, and fears, scientific reasoning can aid religion in another sense. Although it is true that it is the goal of science to discover (the) rules which permit the association and foretelling of facts, this is not its only aim. It also seeks to reduce the connections discovered to the smallest possible number of mutually independent conceptual elements. It is in this striving after the rational unification of the manifold that it encounters its greatest successes, even though it is precisely this attempt which causes it to run the greatest risk of falling a prey to illusion. But whoever has undergone the intense experience of successful advances made in this domain, is moved by the profound reverence for the rationality made manifest in existence. By way of the understanding he achieves a far reaching emancipation from the shackles of personal hopes and desires, and thereby attains that humble attitude of mind toward the grandeur of reason, incarnate in existence, and which, in its profoundest depths, is inaccessible to man. This attitude, however, appears to me to be religious in the highest sense of the word. And so it seems to me that science not only purifies the religious imulse of the dross of its anthropomorphism but also contibutes to a religious spiritualisation of our understanding of life."

[Albert Einstein, "Science, Philosophy, and Religion, A Symposium", published by the Conference on Science, Philosophy and Religion in Their Relation to the Democratic Way of Life, Inc., New York, 1941]

18. **Juan R.**

22. **Tony Smith**
June 12, 2005

Peter, you said "… Look not at what the Templeton people say (which is relatively innocuous), but at what they do. …".

OK, and when I do, I see things like providing publicity and support for things like landscape and failure to fund things like Smolin's suggested Einstein fellowships that might actually advance our understanding of physics (and, therefore, from an Einstein/Spinoza viewpoint, God/religion), so I see your point and agree with you.

If the superstring/landscape people prevail, then I think that we will indeed be entering an era of what Feynman called "…a degeneration of ideas, just like the degeneration that great explorers feel is occurring when tourists begin moving in …" and "… it gets very dull … the vigorous philosophy … will … disappear …".

June 12, 2005

Please stop posting comments here about whether or not General Relativity is correct. This has nothing at all to do with the topic of the posting. Please stop using this weblog as a forum for this kind of discussion and do this elsewhere. I'm deleting all the comments about this.

24. **Peter**
June 12, 2005

Hi Tony,

First of all I read that quote differently, not as saying "Creator=Universe", but as saying whoever the Creator is, he/she/it "identifies" with the Universe and its problems, i.e. she/he/it feels our pain or something, is not detached, but remains involved on a day-to-day basis. But much of this religion/sciences stuff is all so ill-defined that you can make pretty much what you want out of it.

That's not what's objectionable. Look not at what the Templeton people say (which is relatively innocuous), but at what they do. They explicitly refuse to support serious science, and instead fund an incredible array of attempts to inject religion into scientific practice. In theoretical physics, they aren't ever going to fund serious research into quantum field theory, mathematics related to quantum field theory, or any serious work of the sort Einstein would have approved of. Instead they are heavily funding the one part of the field that most people consider dangerous pseudo-science and a serious threat to the whole concept of what it means to do science. I don't think this is a coincidence.

25. **Tony Smith**
June 11, 2005

Peter, you said "… Templeton and the intelligent designers believe there is some sort of intelligent "Creator" out there… who continues to intervene in the universe and the affairs of humans …".

Is that consistent with the plain meaning of the Templeton quote about "… the Creator's … identification with our universe …" ?

If Templeton says Creator = universe, then isn't that more consistent with Einstein/Spinoza, or pantheism, than with a human-father-type external Creator/God who built our universe as our playhouse and might from time to time punish us if we don't play nice in our playhouse ?

Further, Templeton's quote about "remarkable self-organizing tendency" seems to me to be far more consistent with Einstein's "rational nature of reality" than with the landscape view "that there is no mathematical reason for … fundamental facts about physics".

Templeton's actual words still seem to me to be pretty much consistent with the Einstein view.
Do you think that it is possible that Templeton himself is reasonable but that some people who purport to follow Templeton, and to try to get money from him, are not so reasonable ?

For instance, those known as fundamentalist Christians seem to me to insist that only their religious path is the correct one and that those who fail to follow that path will suffer in eternal literal hell,
while the web page at http://www.templeton.org/sir_john_templeton/index.asp indicates that Templeton himself "espouse[s] a non-literal view of heaven and hell" and "a multi-faith framework of … the diversity of gifts within the major religions of the world," … including "Buddhism, Christianity, Confucianism, Hinduism, Islam, Jainism, Judaism, Sikhism, Taoism, Zen and Zoroastrianism.".

Perhaps your disagreement is not so much with Templeton himself, but with some who purport to be his followers and try to get his money ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

26. **Peter Woit**
June 11, 2005

Hi Tony,

I think the two quotes you give represent quite different views. Einstein is emphasizing the "the rational nature of reality", that with hard work we can discover and understand the deep mathematical structures that govern how the world works. As far as I know he had no interest in "anthropic" explanations, or any sort of belief that the universe is designed the way it is in order to make human life possible. He didn't place human beings and their concerns at the center of things.

Templeton and the intelligent designers believe there is some sort of intelligent "Creator" out there who has set up the universe to produce human beings, one who continues to intervene in the universe and the affairs of humans. I don't think Einstein believed anything like this. The intelligent designers, together with the anthropic landscapeologists, are happy with the idea that the explanation for many fundamental facts about physics is that there is no deep mathematical reason for them, they just are the way they are because they make our existence possible. I think Einstein would have found this completely noxious, and most serious theoretical physicists still feel this way.

27. **Tony Smith**
June 11, 2005

From a Templeton web page at http://www.templeton.org/science_and_religion/index.asp :
"… From a theological perspective it is indeed tempting to see this remarkable self-organizing tendency … of the cosmos … as an expression of the intimate nature of the Creator's activity and identification with our universe.
– Sir John Marks Templeton …".

Einstein said:
"I believe in Spinoza's God who reveals Himself in the orderly harmony of what exists … I have not found a better expression than 'religious' for the trust in the rational nature of reality that is, at least to a certain extent, accessible to human reason. …".

I don't see much if any difference between the views stated above by Templeton and Einstein.
Also, I don't see much if any difference between Templeton's phrase "self-organizing tendency" and the usual meaning of the term "evolution".

So: Why can't we all just get along ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

28. **Nathan**
June 11, 2005

The fact that there is even a "debate" on teaching Intelligent Design angers me.

29. **Tony Smith**
June 11, 2005

There have been some comments mentioning Feynman's 1965 book The Character of Physical Law. Here are some relevant excerpts from that book:
"… The age in which we live is the age in which we are discovering the fundamental laws of nature, and that day will never come again. It is very exciting … but that excitement will have to go. … in the future either … all the laws become known … or … experiments get … more and more expensive, so that you get 99.9 percent of the phenomena … and it gets slower and slower and more and more uninteresting …
… ultimately, if it turns out that all is known, or it gets very dull, the vigorous philosophy … will … disappear … There will be a degeneration of ideas, just like the degeneration that great explorers feel is occurring when tourists begin moving in …".

To me, it seems that since GR plus the standard model does describe nature pretty well, and each advance in collider energy only produces data that is substantially consistent with GR plus the standard model, that superstring theory is a clear example of what Feynman called "a degeneration of ideas".

In my view, the only realistic way to get out of the degenerative rut of superstring theory is to try to construct a new model that embraces and extends GR plus the standard model. The same Feynman book gives his prescription for constructing such a new model:
"… 'guess – compute consequences – compare with experiment' … When you get it right, it is obvious that it is right … because … more comes out than goes in …
… we need … imagination in a terrible strait-jacket. We have to find a new view of he world that has to agree with everything that is known, but disagree in its predictions somewhere … and in that disagreement it must agree with nature. If you can find any other view of the world which agrees over the entire range where things have already been observed, but disagrees somewhere else, you have made a great discovery. …".

In my opinion, superstring theory fails to meet Feynman's criteria because it is not constructed by his 'guess – compute consequences – compare with experiment' method.

I feel Feynman's method can lead to a more fundamental unification of GR plus the standard model, and that my work is an example, because I constructed my model using Feynman's 'guess – compute consequences – compare with experiment' method, and every time I found a flaw in my construction, I found that the flaw was correctable and that each correction produced more and better results, so that as of now my model is in pretty good agreement with all accepted experimental observations, with one exception: the T-quark mass, which is the disagreement required by Feynman's criteria. My view about the T-quark mass is set out in my comment on Peter's 9 June 2005 blog entry about the "Future of Fermilab", so I will not repeat it here.

Tony Smith

30. **Juan R.**
June 11, 2005

It was said,

“Feynman hinted at the end of his 1965 BBC lectures, The Character of Physical Law, that when a radical revision occurs next it may be quite different from what is wanted by today’s practitioners.”

Humm, it sounds like “string theory is not the Final formulation” since ST is just modified QFT and its practitioners use just traditional physics like S-matrix, Hilbert-Fock space, wavefunctions, armonic strings, reductionism, etc.

31.
June 10, 2005

Joao: they have to turn out speculations because they work in theoretical physics. John Horgan’s claim in “The End of Science” (1997) that science has ended, just because there is the big bang and standard model, pushes them into stringy multiverses.

If Horgan is right, even in just the sociology of physics, then the enlightenment really is over. We then have to dig deep in the history to discover what happens when the lights go out in science.

Everyone who claimed that the elegant theory of phlogiston was rubbish was laughed off stage. Dead end science claims it is right because it fiddles its theory to fit all the facts. You can’t debunk it. You cannot get anyone to listen to a radical, simpler and more accurate approach.

Feynman hinted at the end of his 1965 BBC lectures, The Character of Physical Law, that when a radical revision occurs next it may be quite different from what is wanted by today’s practitioners. He referred to an influx of tourists, the silly guys on the outside always making silly comments. To him, it would be tragic for tourists to pollute prestine mountains by looking for easier paths to the top.

32. **Jo?o Carlos**
June 10, 2005

Those ID people are pathetic: they lack the science to “prove” their creeds, and lack the faith to believe their creeds without “scientific proof”.
Bad “science” and worse “religon”…

Response From Smolin

June 15, 2005
Categories: Uncategorized

Lee Smolin wrote an interesting responses to comments in the comment section of my posting about his [Physics Today piece entitled "Why No New Einstein?"](). I'm reposting it here.

"Dear Peter and colleagues,

I am grateful for the attention given to my essay. I only want to emphasize a few points here. The main thing is that the essay is carefully written. It does not advocate more funds to LQG or any other program. It explicitly advocates more support and positions for young, ambitious theorists pursuing their own research programs who are unaffiliated with any larger program. Several proposals are made for how to accomplish this. I would hope that the focus of the discussion could be on these proposals.

-String theory is criticized in the essay mainly because it is currently sociologically dominant, and so subject to the problems mentioned. It was necessary to do so as many readers of physics today will be unfortunately unaware that there are any problems with string theory, or any viable alternatives. Anyone with a long enough memory will know that the sociological issues in high energy theory predate string theory, and have hurt physics in the past, i.e. in the case of S-Matrix theory.

-I hope I don?t have to say that I am not anti-string theory. My current last paper on the ArXiv is a technical paper in string theory, and I have 14 more in past years, plus 8 papers on related topics such as the landscape. I wouldn?t have written these papers if I didn?t think there was a good chance string theory is relevant to nature. The fact that someone like me who contributes sometimes, but not exclusively, to string theory, is not considered ?a string theorist? is part of the sociological problems my essay criticizes. Similarly, the fact that one can elicit angry responses, and be called ?anti-string? for carefully and correctly recounting the actual status of various conjectures is a sign of an unhealthy sociology. No one calls someone anti-LQG or anti-QCD when they do a similarly honest summary of what is known and not known in those fields.

-I would claim that the sociological issues mentioned in the essay have hurt string theory even more than they have hurt the alternative programs, because they greatly limit the range of ideas worked on, and because people with a lot of imagination and intellectual independence are either selected out or choose themselves to work within communities which are more friendly to diversity and imagination. As a result, key issues such as the question of a background dependent formulation, or perturbative finiteness, don?t get a lot of attention, in spite of their centrality for the whole program.

-I was grateful that someone noted the range of subjects at the LQG meetings. This was not planned, it is a natural outcome of the more open and curious atmosphere among people who work on the subject. We don?t believe we should have a meeting without inviting people from alternative and rival programs to report to us what they are doing, as well as to serve as critics. At the meeting in Marseille last May we even invited a persistent critic of LQG-Ted Jacobson-an early contributor who is now very critical of the subject-to give a talk to lay out his criticisms. I think it would be very good for string theory if the organizers of their meetings took a similar attitude.

-Someone asked for a blanket term for LQG, CDT, causal sets etc. We use background independent approaches to quantum gravity. There is a lot of interchange of ideas, techniques and people among these programs, and many of us have contributed to more than one. There is a very different intellectual climate, in which diversity, creativity and independence are strongly encouraged.

-Someone is asking for what is ?LQG proper?? But the fact is that a lot of different things are now going on roughly under the name of or related to LQG. After all, this is now a community of > 100 people and there is no orthodoxy and no one trying to control what people work on. We agree generally on what has been achieved and what problems remain open, but not much beyond that. There is a healthy variety of approaches and attitudes towards the open problems. If there is one thing we all agree on it is that no approach is likely to achieve the right theory that is not background independent at its foundations. Come to the meeting and see what is happening.

-While the point of my essay was not to advocate more funding to any particular direction, if you ask me I will of course say that I think that people working on background independent approaches to quantum gravity deserve much more support. Among them are Loll and Freidel, that I am glad someone mentioned, but there are many others.

-I did not, as Lubos implies, advocate funding a large number of people who do nothing but think about the foundations of quantum theory. What I do advocate is much more support for the kind of person who might be inclined to work on foundational issues. These are deep and independent thinkers who believe that the road to progress in physics is confronting the hard problems directly. But there is no need to argue about whether more funding for foundations of quantum mechanics would be fruitful. The experiment has been done. For decades there was no support at all, and slow progress. Then, because of the possibility that quantum computers could break codes, there has been a lot of support for the last few years. And a lot of progress has been made, both experimentally and theoretically on aspects of foundations of QM.

-Although this essay was not written to advocate LQG, since it is attacked in response I should try to clear some things up. Someone asks for an accounting of the present status of the field. I among others, have given one in hep-th/0408048, shortly to be updated.

As to the issue of anomalies, i.e. the claim that we ignore the established knowledge that ?INFINITE-DIMENSIONAL CONSTRAINT ALGEBRAS generically acquire anomalies on the quantum level…? is simply false. It is contradicted by rigorous existence and uniqueness theorems in LQG. As a few people do nevertheless take this seriously let me start from a point we can agree about and see if we can clear this up for good. I would hope we can all agree that:

1) The approach to quantization of constrained systems is different in string theory and LQG. The former approach depends on a gauge fixing that refers to a fixed background metric. It results in the construction of a Fock space. The latter is background independent and involves no background metric, no gauge fixing and results in a state space unitarily inequivalent to a Fock space.

2) There is a body of rigorous results that support each kinds of quantization. Hence it cannot be a question of which is correct mathematically. Both are correct, within their contexts. It is a question only of which construction is appropriate for which theories and which describes nature.

3) The treatment of constraints in string theory depends on certain technical features of 1+1 dimensional theories, particularly the fact that there is a gauge in which L_0 plays the role of a Hamiltonian and therefore should, in that gauge, be quantized so as to have a positive spectrum. The anomalies are not generic, as asserted above, rather they depend on the additional condition that L_0 should be a positive operator. There are other reps of Diff(S^1) that are non-anomalous but in which L_0 is not positive. So a choice is made in the standard quantization of string theory, which his motivated by the physics. This does not mean it is the right choice for all physical theories.

4) Conversely the existence and uniqueness theorems which support the LQG quantization work only in 2+1 dimensions and above for the reason that gauge fields don?t have local degrees of freedom in 1+1 dimensions. The existence theorems tell us that there are quantizations in 2+1 and higher of diffeo invariant gauge theories that have unitary, anomaly free realizations of diffeo invariance. The uniqueness theorem tells us that the resulting state space we use in LQG is unique.

5) Now it is true that Starodubstev and Thiemann have found it an interesting exercise to apply the LQG techniques to free string theory. Not surprisingly they get a theory that is unitarily inequivalent to the usual one. This does not mean that the usual quantization of string theory is wrong, nor does it mean that the LQG techniques are wrong when applied to other problems, where the existence and uniqueness theorems together with a large number of results prove their worth. All we learn is that the two quantizations are inequivalent, which was to have been expected.

6) With regard to the non-standard quantization, in which holonomies, but not local field operators are well defined, it is of course true that when applied to standard systems this leads to inequivalent results. ?This apparently leads to unphysical consequences, such as an unbounded spectrum for the harmonic oscillator.? But, give me a break, do you

really think someone is proposing to replace the standard quantization of the harmonic oscillator with the alternative one? What is being proposed is that the quantization used in LQG is well suited to the quantization of diffeo invariant gauge theories.

In case it is not obvious, let me emphasize that harmonic oscillators are not relevent here, and can play no role in a background independent quantum theory, precisely because the division of a field into harmonic modes requires a fixed background metric. Thus, the physics of the problem REQUIRES an alternative quantization.

The detailed motivation is, I think, well argued in the papers, and are supported by the results as well as the existence and uniqueness theorems. First, is well known that a complete coordinatization of the gauge invariant configuration space for a non-Abelian gauge theory requires the holonomies. Second, using them gives rise to the unitary non-anomolous reps of the spatial diffeomorphisms.

Nor is anyone proposing using non-seperable Hilbert spaces for the full theory, the point is that when one mods out by the piecewise smooth spatial diffeos one is left with a seperable Hilbert space.

I am frankly puzzled why someone who claims to know the literature well would throw up examples like the harmonic oscillator up in this context. I can try to understand their point of view, but it certainly reads as if they either are choosing to ignore the basic point, which is that background independent quantizations cannot use fock space, or they are looking to make debating points to impress ignorant outsiders. They must know comments like this are not going to influence experts, because they are, after all, taken from our own papers, written precisely because we wanted to clarify the difference between the new and standard quantizations and the limits of the applicability of each.

With regard to the sociology of the string-loop division, ?Roughly speaking, string theorists are fundamentally particle theorists with a strong understanding of quantum theory, whereas loop people are gravitists with a background in GR?, this is a myth. Rovelli, myself and many other people in LQG were trained as particle physicists, myself at Harvard in the late 70?s. Most of the physical motivation for LQG comes directly from ideas about formulating gauge theories in terms of loops that were studied by Polyakov, Wilson, Migdal, Mandelstam, Neilsen and others. LQG is squarely an outgrowth of their intellectual tradition. The only thing we added was to correctly treat the diffeomorphism invariance exactly in the quantum theory. This led to new results just as the exact treatment of gauge invariance in lattice gauge theory led to new results. I would claim that we made progress in LQG precisely because we had a very good grounding in QFT.

String theory, as it is practiced, makes much more contact with the general relativity tradition, especially the once discredited tradition of extending general relativity to add dimensions and degrees of freedom in the search for a unified field theory. You are much more likely to read a paper which studies solutions to a generalizationsof the Einstein equations, with hbar=0, by a string theorist than by someone working on a background independent approach to quantum gravity.

This of course does not mean that string theory is wrong. But I believe it does mean that by enforcing a narrowly restrictive notion of what constitutes good work, the community of string theorists has hampered progress in string theory by excluding from consideration the lessons learned by attempts to do what string theory must do eventually if it is to be a real theory: which is to find a background independent formulation of a quantum theory of spacetime.”

Comments

   June 21, 2005

   Actually, I wasn’t talking about spatial diffeos, but rather the group of 4-diffeos, which is the full constraint algebra in covariant formulations. The Dirac algebra is an artefact of the foliation of spacetime which nobody likes, but phase space is intrinsically a covariant concept. This observation apparently goes back to Lagrange and has been emphasized e.g. by Witten, Ashtekar and Rovelli. My suggestion for how one can use cohomological methods to construct the covariant phase space and use it for quantization can be found on the arxiv.

   The reps do not depend on a reference metric or foliation. They do, however, depend on a privileged curve, which I call the observer’s trajectory. The key idea is to expand all fields around it before quantization. The trajectory is not a background structure, however, because must be quantized together with the fields.

   I recently tried to initiate a discussion about this on spr. Since I have already abused Peter’s hospitality by promoting my own ideas, maybe the discussion should be moved.

   June 21, 2005

   Re the last comment, on recovering ordinary QFT from LQG, let me stress again that there are explicit known semiclassical states, and ordinary QFT is recovered at long wavelengths by studying excitations of them. Hence, we know that the physics of flat, or DeSitter spacetime is in the theory.

   The problem is to go beyond these results to
   i) show that the ground state, subject to some appropriate boundary or asymptotic conditions, is such a state, ii) show whether classical spacetime emerges from a generic physical state and iii) show whether lorentz invariance is preserved, broken or deformed by Planck scale corrections in the ground state, and hence predict what should be seen in AUGER, GLAST, ICECUBE and other upcoming experiments.

   In recent papers, Freidel et al show how deformed Poincare invariance arises as the limit of LQG coupled to matter in 2+1. See also hep-th/0501091 for an admittedly heuristic argument that this is true also in 3+1.

   For these see sections 4.4 and 5 of hep-th/0408048 and the references provided there.

   As to whether it might be easier to obtain certain results in a different formulation with anomalous reps of the spatial diffeo’s, perhaps, and this could be worth trying, but only if one does not put in what is to be shown, which would be the case if those reps are constructed with reference to a background metric.

   June 19, 2005

   “But surely, the new quantization should in some way resemble a Fock type quantization in the limiting case where there is a classical metric. So some limit of the new quantization should recover the familiar harmonic oscillator.”

   Well isn’t thats the big unanswered question though in LQG, that they can’t seem to recover minkowski space? In many ways it makes sense if you think about it, the anomalous reps constrain ones freedom considerably, whereas the generic formalism they use doesn’t contain that structure, or rather it subsumes it so completely it washes it out. Finding a mechanism to retrieve that as some sort of limit strikes me as a *hard* problem in asymptotic behaviour. Everyone who does QG knows how hard that can be, in one guise or another.

   June 19, 2005

The results are very preliminary. I don't think it's in anyone's best interest to make sweeping pronouncements.

good caution. I will try to avoid doing that

5. **Aaron Bergman**
June 19, 2005

thank you Aaron, your words are partially reassuring. I remember the parameters which they discuss tuning—-essentially G (or the inverse kappa) and an asymmetry parameter Delta (or the related alpha) which intuitively tells the "squatness" of 4-simplex (its foreshortening of timelike edges).

Those are the parameters are inputs to the model. They don't tune them so much as describe the phase diagram of their model in the plane of those two parameters. They find one phase which seems to describe a macroscopic universe.

This is a different issue than the continuum limit where, as you take the spacing to zero, you tune various parameters to achieve a phase transition.

Also, I never said that the continuum limit of this theory (if such a thing exists) is something like only lives on S^3 x S^1. Who knows what will happen. They have some interesting ideas on the effective dimension as a function of length scales, but this doesn't necessarily mean some bizarre spacetime topology. Rather, it could describe some sort of fuzzy graviton, or something else. Beats me.

It's not even clear that these models describe anything really. The results are very preliminary. I don't think it's in anyone's best interest to make sweeping pronouncements.

June 19, 2005

Aaron:*You can't just take the lattice size to zero to get a continuum limit. Things are generally more complicated than that and involve tuning various couplings so as to achieve a phase transition in the limit. Ambjorn et al comment on this on pp. 12-3.*

thank you Aaron, your words are partially reassuring. I remember the parameters which they discuss tuning—-essentially G (or the inverse kappa) and an asymmetry parameter Delta (or the related alpha) which intuitively tells the "squatness" of 4-simplex (its foreshortening of timelike edges).

but I am still not fully confident that even with the correct tuning of the parameters for a "continuum limit" —obtained by computing the path integral for simplexes of size 'a' repeatedly as 'a' goes to zero—-I am still not confident that in the limit there is a continuum with topology of R x S3

Or, as you say, S1 x S3, since they sometimes make it periodic so it fits in the computer and replace R by the circle S1, in which case what we are talking about may really be S1xS3.

I appreciate the clarification, but I still have a suspicion that the spacetime of Renate Loll is not topologically either S1xS3 or RxS3 but may instead be a mathematical novelty.

(my doubts arose partly because the dimension varies with scale and tends to be quite a bit less than 4 at close quarters)

7. **Aaron Bergman**
June 19, 2005

the basic CDT spacetime is the set R x S3, but I am not sure that the topology is R x S3. In fact I am unsure how to define the topology on it, except as the cumulative effect of many histories, or in other words as a somewhat uncertain topology.

The topology of each element in their path integral is always the same, usually S^1 x S^3.

the CDT continuum is constructed as the limit of PL 4-manifolds as the size of the simplex goes to zero. Any PL 4-manifold is a topological 4-manifold. In this case each of the approximating PL 4-manifolds is topologically R x S3.

You can't just take the lattice size to zero to get a continuum limit. Things are generally more complicated than that and involve tuning various couplings so as to achieve a phase transition in the limit. Ambjorn *et al* comment on this on pp. 12-3.

Chris W: *From Quantum general relativity and the classification of smooth manifolds (Hendryk Pfeiffer):*

…The diffeomorphism invariance of the classical observables then implies in the language of the triangulations that all physical quantities computed from the path integral, are independent of which triangulation is chosen. The discrete formulation on some particular triangulation therefore amounts to a complete fixing of the gauge freedom under space-time diffeomorphisms…

(I'll leave it at that. It's been raining in Vermont for several days. I've spent a good portion of the past 36 hours whitewater kayaking, and could use a good night's sleep.)

—
Chris, that was a very interesting paper by Hendryk Pfeiffer. I have a glaring point of mathematical ignorance that perhaps you might help me with.

the basic CDT spacetime is the set R x S3, but I am not sure that the topology is R x S3. In fact I am unsure how to define the topology on it, except as the cumulative effect of many histories, or in other words as a somewhat uncertain topology.

the CDT continuum is constructed as the limit of PL 4-manifolds as the size of the simplex goes to zero. Any PL 4-manifold is a topological 4-manifold. In this case each of the approximating PL 4-manifolds is topologically R x S3.

But I am not sure in what sense, if at all, the limit of such things has to be a topological 4-manifold. This is Hendryk Pfeiffer's term—-locally homeomorphic to R4. In a topological 4-manifold, as Pfeiffer says, the transition (i.e. coordinate change) functions are C0 continuous but not necessarily differentiable.

So I am not sure that Pfeiffers paper would apply to the CDT spacetime, for instance.

BTW I notice he posted the first version 21 April 2004. A couple of weeks later Pfeiffer was at the "Loops 04" conference that Carlo Rovelli organized at Marseille, and talked about it. On the second day of the conference, Tuesday 4 May, Renate Loll gave a talk on CDT in the morning and Hendryk Pfeiffer spoke that afternoon. It would have been an appropriate time to ask this kind of question, I suppose.

There may be some embarrassingly obvious answer to my doubts about this. If you are aware of one please let me know after you have rested up from kayaking.

9. June 19, 2005

this is not intended to elicit a response from Lee Smolin (if he happens to be still reading the thread) but simply to acknowledge that I stand corrected by him on the subject of LQG and spin foams spacetime discrete structure. Accordingly I remain undecided on how to view the CDT lack of discreteness declared by Loll et al for instance on page 2 of hep-th/0505113. They say their probing by Monte Carlo-style simulation has so far not uncovered evidence of “fundamental discreteness…[or]…a minimal length scale.”

1. I can, on the one hand, set aside notions of reconciliation and consider LQG and CDT to be incompatible models, each consistent and supporting calculation, of quantum spacetime dynamics. Presumably, each is able to make testable predictions (though CDT is at a somewhat earlier stage of its development) and empirical observation will eventually distinguish between them.

2. On the other hand, I can surmise that Loll et al have not probed sufficiently and that further computer simulation or analysis might uncover discrete spacetime structure in their model. For instance, if I understand correctly, no one yet has constructed an operator in CDT corresponding to an observer measuring a physical area or volume. If this is eventually done, further along in CDT development, I cannot see how to rule out the possibility that such an operator have discrete spectrum. Thus some discrete structure might appear at a later stage.

sorry for misstating Smolin’s role in PI, back a ways in this thread—he cleared that up

10. **Juan R.**
June 19, 2005

Some remarks,

For the history of early “eigenvolumes” and the use of quantums of volume (in the same sense that quantums of energy) see

Length Scale for the Constant Pressure Ensemble: Application to Small Systems and Relation to Einstein Fluctuation Theory. J. Phys. Chem. 1996, 100, 422-432.

One can prove that those “quantum of volume” and related to quantum of area of standard BH. One can also prove that in the limit quantumA –> 0 the BH is stationary (constant total A).

You have claimed in several articles that departures from standard (string theory)

E^2 = p^2 + m^2

predicted from LQG could be “directly” verified in the next generation of acellerators (2007?). Have you considered an “indirect” verification of quantum of volume at macroscopic scales? I am working in that.

What is the status of Lorentz invariance and frame independence in today LQG?

You claim a consistent classical limit. Can LQG obtain departures from GR at the extragalactical scale (e.g. TF law for anomalous galaxies)?

11. **Juan R.**
June 19, 2005

Lee Smolin,

Regarding discrete structure of spacetime, i think that can be proved indirectly with usual experiment.

In fact, some well proven mathematical theorems show that if area and volume are really zero one obtains wrong answers for macroscopic questions. It is an usual error to believe that classical gravitation is based in a pure diferential manifold. It is a error conected with some wrong asumptions of usual calculus (non standard analysis and hiperreal numbers solve that partially)

I can prove that if quantum of area –> 0 then there is no Hawking radiation, there is no dissipative effects at astro or cosmo scale, etc. Therefore there is quantum sure!

The quantum of area/volume is related to departures from standard (string theory)

E^2 = p^2 + m^2

Moreover, the existence of quantum of volume is needed in the computation of partition functions, since that many standard computed PF have dimension of volume. That is well known. In fact the first “quantums” of volume were named eigenvolumes by Guggenheim.

I think that you are not replied M query. I am sure that one cannot obtain a pure consistent classical state from LQG, due to mathematical incongruencies. Someone derived GR from LQG?

I am not talking about obtain certain spectra that like how. The same situation arises in usual limits of QM. Somewhat like one need “decoherence” effects (h^2 terms to Schrodinguer like in standard Calderia-Legget equation) we need add news terms to usual LQG. This also solves the old problem of time in HQG; Wald recent proposal is unnecesary.

“So the attitude is rather different from other approaches. Some string theorists admit they do not know what string theory is, but they nevertheless are sure it is right.”

Great!!! One day Witten admits that nobody know that is really string or M theory, and another day he claims that it beatiful and elegant!

12. **Thomas Larsson**
June 19, 2005

Lee: I realize that what I wrote could be construed as a personal attack, and I apologize for that. My excuse is that I feel a great sense of frustration for not being noticed (by physicists, mathematicians were always much more open-minded). I started to work on multi-dimensional generalizations of the Virasoro algebra back in 1987 and published the first paper in 1989. Although not not explicitly stated, it was always obvious to me that this algebra must have applications to quantum gravity, for the same reason that the ordinary Virasoro algebra is relevant to string theory.

My funding ran out in 1993, which made sense at that time because my program was stuck. But after the key obstacle was removed by Rao and Moody a few years later, it was possible to develop a representation theory, which may be regarded as the quantum analogue of tensor calculus (tensor fields carry classical reps of the diffeo group). It was totally obvious to me that this must be to quantum gravity like tensor calculus is to classical gravity, i.e. very important. The complete lack of interest was extremely frustrating in that situation.

Thus, I behaved nicely throughout the 1990s, and it didn't do me any good. After more than a decade, one can start to lose patience. I only started to receive feedback after I criticized string theory in math-ph/0103013 (from a quite original viewpoint). This taught me that being nice is something that the physics community simply does not award. So be it.

Given my present age and family situation, I am not really personally interested in funding anymore; not unless it comes in the form of a permanent position in Stockholm without teaching duties anyway. But I would very much like to see an influx of people thinking along these lines, because I believe it is a promising idea, but I myself am stuck at this time.

On a different note, I think that your proposals have some serious problems. In what way would your Einstein fellowships differ from a MacArthur genius grant except that string theorists are excluded? Who would decide who should get these grants – you, Ed Witten or maybe Lubos Motl? It seems to me that funding must ultimately be decided by tenured professors, i.e. the same people who decide about funding today. Finally, should a paper like hep-th/0412325 be regarded as string theory or not?

13. **Arun**
June 19, 2005

" So long as the resulting theory is well defined, I don?t see the force of an argument from a priori grounds. that experience shows Fock type quantizations must be right in all cases because they only work when there is a fixed background metric, while the whole point of the new quantization is that it provides an answer to the question of how to construct a well defined QFT in the absence of any background metric."

But surely, the new quantization should in some way resemble a Fock type quantization in the limiting case where there is a classical metric. So some limit of the new quantization should recover the familiar harmonic oscillator.

14. **Kea**

June 18, 2005

From **Quantum general relativity and the classification of smooth manifolds** (Hendryk Pfeiffer):

> This suggests that the path integral of general relativity in d ≤ 5 + 1 admits a discrete formulation on such triangulations. General relativity in d ≤ 5 + 1 is therefore related to what we call a PL-QFT, i.e. a TQFT based of piecewise-linear manifolds. In particular, a path integral quantization of general relativity in d ≤ 5 + 1 is related to the construction of invariants of piecewise-linear manifolds. From the classification results, we will see that this is most interesting and in fact an unsolved problem in topology, precisely if d = 3 + 1. It is the decision to take the diffeomorphism gauge symmetry seriously which singles out d = 3+1 this way.
>
> The diffeomorphism invariance of the classical observables then implies in the language of the triangulations that all physical quantities computed from the path integral, are independent of which triangulation is chosen. *The discrete formulation on some particular triangulation therefore amounts to a complete fixing of the gauge freedom under space-time diffeomorphisms. The relevant triangulations can furthermore be characterized by abstract combinatorial data, and the condition of equivalence of triangulations can be stated as a local criterion, in terms of so-called Pachner moves*. [emphasis added] ?Local? here means that only a few neighbouring simplices of the triangulation are involved in each step. A comparison of Pachner moves with the block-spin or coarse graining renormalization group transformations in Wilson?s language reveals what renormalization means for theories with dynamical geometry for which there exists no a priori background geometry with which we could compare the dynamical scale of the theory.
>
> —

16. **Lee Smolin**
June 18, 2005

Thanks again for all the insightful comments. Perhaps I can add something to a few of the threads of discussion.

-On LQG and discrete structure. First, do we agree that even though electrons move in space the spectrum of the hydrogen atom being discrete means that quantum mechanics of the atom has discrete structure? In a very similar sense, since all the geometric observables including volume, area (and yes length) have discrete spectra, corresponding to a discrete basis (of diffeo classes of embeddings of labeled graphs) then the quantum geometry of space has become discrete. The key point is that the discreteness scale-roughly L_Planck, cannot be taken to zero, otherwise black hole entropy comes out wrong, and semiclassical states do not correspond to classical metrics.

-But it is true that if you derive a version of LQG from a strict quantization of GR, there is a fixed background, which is the bare differential manifold. There is no background metric but there is a background topology and differential structure, defining the diffeo classes of embeddings of the spin networks.

-Hence, Markopoulou followed by Freidel and others, proposed dropping the embedding and basing the theory just on combinatorial spin networks. These models are then discrete in a stronger sense. There are some advantages to this (reformulation in terms of a matrix model, cleaner relation to causal sets) but one can non longer claim the theory is a precise result of a quantization of GR. Both frameworks, with and without embeddings, continue to be studied.

-The discreteness of length was shown in T. Thiemann, gr-qc/9606092, J.Math.Phys. 39 (1998) 3372-3392. Angles also have disrete spectra: S. Major, Class.\ Quant.\

Grav.\ {\bf 16}, 3859 (1999) gr-qc/9905019; gr-qc/0101032.

-On spin foam models and discreteness. There are several different spin foam models under study. In all of them a history is a discrete labeled combinatorics structure (for example branched 2-complex.) In some of them the label sets are continuous because they come from the rep theory of Lorentz or Poincare and areas are not discrete. But these have not been shown to correspond to evolution amplitudes for canonical states. Others (Reisenberger, Markopoulou, etc) do give evolution amplitudes for spin networks and have discrete areas.

– M asks, is there a suitable correspondence principle where known physics can be recovered? The answer is yes. There are several results that show that excitations of certain LQG states reproduce, for momenta small in Planck units, the spectra of conventional QFT?s including gravitons, photons etc on flat space or de Sitter spacetime. Some are cited in section 4.4 of my review hep-th/0408048. See also hep-th/0501091. See recent papers by Freidel, Livine and others that show in full detail how standard Feynman perturbation theory emerges from a spin foam model for gravity coupled to matter in 2+1 when G_Newton goes to zero.

As to what people in non-string approaches to quantum gravity are doing, I agree, why not look at the conferences? Here are some recent ones, some with talks available.

http://www.cpt.univ-mrs.fr/%7Erovelli/program2.html
http://www.ws2004.ift.uni.wroc.pl/flash.html
(talks at: http://www.ws2004.ift.uni.wroc.pl/html.html)
http://www.perimeterinstitute.ca/activities/scientific/PI-WORK-2/

-Several of the comments ask, why quantize as in LQG? Why not quantize with another approach (such as one that uses anomalous reps?)

I do not see how there can be an apriori reason to prefer one quantization scheme over another one. Our job is to construct candidate quantum theories of gravity, compare their results and learn from them. In LQG there are existence and uniqueness theorems that prove that the approach exists, and theorems that guarantee uv finiteness. Thus, the approach leads to a structure that mathematically exists and within which computations can be done. Many computations have been done.

We are thus no longer at a stage where it is interesting to ask why do or why not do questions. There are now a different class of questions which include: Does the theory make predictions? How do they compare with experiment? What properties have been shown? What remains to be shown? There are certainly several key open issues to discuss, and we are not shy to discuss them.

No one is claiming that we know LQG is the right theory of nature. We are claiming that it is a well developed approach, that gives an apparently consistent answer to what we think is a necessary question, which is how to construct a diffeo invariant QFT in the absence of a fixed background metric. This gives a rich arena with many open problems and many things to do either to understand it better, make predictions, or as a jumping off point for the invention and study of new theories.

So the attitude is rather different from other approaches. Some string theorists admit they do not know what string theory is, but they nevertheless are sure it is right. In LQG we study well defined theories, which have many good properties, but most of us feel no need to ?believe in them? pending experimental confirmation.

So our attitude is if someone like Thomas Larsson has a different approach that?s great. We know what its like to be starting something new other people don?t understand or support, and we will support you, so long as you don?t waste your and our time attacking us on a priori grounds. We suggest you should try to develop your ideas to at least the point where we can compare the results.

For example, someone asks, ?What's wrong with anomalies? Sure, it turns first class constraints into second class constraints, but Dirac showed us how to deal with that.? Fine, we only insist that this is not the only way. The LQG results and theorems show that you can find diffeomorphism invariant states through a different procedure, involving only first class constraints, which is

a. Construct a kinematical Hilbert space, which is a rep of a Poisson algebra that coordinatizes the phase space, which carries a unitary and non-anomalous rep of the spatial diffeo?s.

b. Use that non-anomalous unitary rep to construct explicitly another Hilbert space, which is the space of diffeomorphism invariant states.

c. Compute many observables of interest representing diffeo invariant classical quantities as finite operators on this space, leading to predictions of physical interest, an ultraviolet finite theory etc.

There are by now so many rigorous results supporting this construction that the burden of proof is on the other side: given that this procedure works and leads to a well defined finite physical theory, why not explore its consequences as a possible quantum theory of gravity?

So when Urs says, ?It seems to me that the reason to drop weak continuity in the quantization of gravity in 3+1 dimensions is that it makes an otherwise intractable problem tractable – but possibly at the cost of having oversimplified a hard problem,? fine, but lets discuss the results. Does this lead to a space of states with enough physical states and with a well defined dynamics? YES. Are some states interpretable as semiclassical states? YES. Does that dynamics have all the properties we require for a quantum theory of gravity? YES to some questions such as uv finiteness, other questions are still open, such as a proof that the ground state is semiclassical.

-Aaron says, ?It is, in fact, a radically different approach to quantization that, when applied to current theories, gives experimentally incorrect answers.? Thomas Larsson argues that ?I find it very disturbing that LQG methods yield the wrong result for the harmonic oscillator.? I don?t understand the logic of their arguments at all. Yes, it is a different quantization, i.e. one based on representations of the algebra of Wilson loops and electric flux?s rather than local field operators. Yes, it is unitarily inequivalent to Fock space. That is good, as Fock space knows about a particular fixed background metric. If a background independent Hilbert space, which quantizes the whole space of metrics, were unitarily equivalent to a Fock space based on a single fixed metric, something would be wrong.

The claim is precisely that this is a new class of QFT?s which is available to quantize diffeo invariant gauge theories in 2+1 dimensions and above, and which has novel features and leads to novel results. So long as the resulting theory is well defined, I don?t see the force of an argument from a priori grounds. that experience shows Fock type quantizations must be right in all cases because they only work when there is a fixed background metric, while the whole point of the new quantization is that it provides an answer to the question of how to construct a well defined QFT in the absence of any background metric.

-If you still want to have an argument on a priori grounds as to why representations of non-canonical algebras will be required to have a background independent quantum theory of gravity, please go back to the papers of Chris Isham from the late 70?s and 80?s where he made a detailed and convincing case for this. These papers, together with the work of Polyakov, Wilson, Midgal etc on formulating quantum gauge theories directly in terms of Wislon loops were the major motivation for LQG. What we did was construct the non-canonical algebras Isham called for from Wilson loops. Also, please note that lattice gauge theory is not based on Fock space.

-Finally, I am not a director of PI, just one of the scientists, so PI is very far from ?Smolin?s institute?. Also, when I am defending LQG I try to discuss the whole research program, not my own personal work, which departs in some papers quite a bit from that of many of my friends.

17.
June 17, 2005

Chris, another thought in connection with what you said earlier:

It should be mentioned that at least some string theorists seem to have a particular antipathy to conjectures about a possible discrete substructure for spacetime, which often play a role in alternative approaches to quantum gravity.

Your reference is a bit vague, but you may have heard TALK about a discrete structure of spacetime in canonical-LQG.
In fact the model of spacetime used in that approach is a differentiable manifold, as is the LQG model of 3D space. The basic variables and observables of that theory are constructed on this smooth manifold (not on a lattice or set of discrete points, a mistaken impression easy to get.)

As canonical-LQG theory develops, the spectra of the area and volume operators turn out to be discrete. This means that even though space and spacetime are represented by smooth continuums, when one comes to actually measure some physical area or volume the outcomes of measurement must in theory be confined to a discrete set, which can be calculated in planck units. (The points in the set are very close together, on the order of a planck unit area or unit volume apart, but they are nevertheless separate points). I find this puzzling, and can't say I quite understand how observation of area and volume can have discrete spectrum. But that is how it turns out.

Not so with length. In canonical-LQG the operator corresponding to measuring a length, if I remember correctly, has not as yet been shown to have discrete spectrum.

Popular accounts of canonical-LQG ordinarily make much of the discrete spectra of area and volume. So also do non-technical survey articles by LQG pioneers such as Ashtekar and Rovelli. That is understandable (the discrete spectra of certain measurement operators are very interesting and have far-reaching consequences) but how far one wants to go towards interpreting that as spacetime's "discrete structure" is a somewhat matter of taste.

Since the late 1990s the interest of QG researchers has shifted noticeably away from canonical-LQG towards the spin foam approach, whether rightly or wrongly remains to be seen. In the spin foam approach, AFAIK, there is so far no proof that area and volume operators have discrete spectrum.

In my non-expert judgment as an observer, if you put together CDT (e.g. Loll et al) research with Spin Foams (e.g. Freidel et al) you'd get at least 60 percent of current work on spacetime dynamics. And therein would be no discrete spacetime, nor even discrete spectra of area and volume!

But some of the remaining percentage of the work would be canonical-LQG with its discrete spectra albeit constructed on a smooth continuum.

I don't have statistics on this, only an impression from following the literature, and I am excluding quantum cosmology research (e.g. Bojowald et al) where the model has only a finite number of degrees of freedom. This is a quantum analog of the usual Friedmann equation of classical cosmology—quantum cosmology is symmetry-reduced so it can deal with a finite number of parameters instead of a whole spacetime geometry. Several of the operators in loop quantum cosmology have discrete spectra.

In short, the situation is complicated and it is not at all clear that "QGATS" (quantum gravity alternatives to string) research is moving in the direction you suggest, namely "discrete substructure of spacetime". Nor is it clear what discrete substructure means, in general.

Probably those you mention as expressing their "particular antipathy" can safely be ignored since they could well be saying more than they actually know about non-string QG. It is no use arguing with them, I should guess, about discreteness, or Lubos Motl's "aether", or anything else, for in my experience the antipaths can always find more reasons for antipathy.

June 17, 2005

[Chris W. at June 17, 2005 12:36 PM]:
It should be mentioned that at least some string theorists seem to have a particular antipathy to conjectures about a possible discrete substructure for spacetime, which often play a role in alternative approaches to quantum gravity.

"often play a role" is vague, Chris, and could be misleading. Aaron Bergman just brought up recent work of Ambjorn and Loll that interested him. This is a prominent example of QG alternatives to string. There is no discrete structure or any suggestion of a minimal length. Here is a quote

http://arxiv.org/hep-th/0505113
Spectral Dimension of the Universe

—quote from page 2—
We have recently begun an analysis of the microscopic properties of these quantum spacetimes. As in previous work, their geometry can be probed in a rather direct manner through Monte Carlo simulations and measurements. **At small scales, it exhibits neither fundamental discreteness nor indication of a minimal length scale**.
—end quote—

Chris, I urge you to keep abreast of the research in QG alternatives to string, which is moving rapidly and does not accord with common "hearsay" that one may get from string experts. I hope you are not relying on hearsay.

The paper which Aaron gave a link to, also recent and by the same authors, is
http://arxiv.org/hep-th/0505154
Reconstructing the Universe

It would be a good place to get firsthand impressions about this particular non-string development (called CDT, causal dynamical triangulations)

Chris, you say:
Lubos Motl has suggested that such ideas are tantamount to misguided attempts to resurrect the classical aether in the context of quantum gravity.

I suspect if we were to go through on a case by case basis we would find that you have received a number of erroneous impressions from Lubos Motl.

19. **Thomas Larsson**
June 17, 2005

Anonymous June 17, 2005 10:16 AM:

It is clear that some of us attach more significance to the harmonic oscillator than you and Smolin do. Fine. But let us at least agree that the Helling-Policastro result deserves to be widely known, just as the fact that string theory is not background independent is well known. Then people can make up their own minds.

20. **Chris W.**
June 17, 2005

It should be mentioned that at least some string theorists seem to have a particular antipathy to conjectures about a possible discrete substructure for spacetime, which often play a role in alternative approaches to quantum gravity. Lubos Motl has suggested that such ideas are tantamount to misguided attempts to resurrect the classical aether in the context of quantum gravity.

It would be interesting to read a thoughtful exposition of the philosophical presuppositions underlying the string theory program (or programs). I haven't come across one so far, and given the impatience of many string and particle theorists with philosophical discussion of any kind I don't really expect to see one any time soon.

This intersects in my mind with the issue of how to evaluate and *interpret* quantization methods. Here again is a subject for which thoughtful philosophical discussion could be most illuminating. One might wonder why the formulation of a quantum theory should depend on "quantizing" a classical prototype at all. A key notion appears (to me) to be that in our currently accepted understanding of quantum theories, discreteness is a feature of *certain* solutions, and does not really reside in the fundamental assumptions shared by quantum theories in general. Indeed, quantum field theory is supposed to largely explain the origin of the discrete substructure of matter that was taken as a given* in 19th century and early 20th century physics.

—
(* ..with notable exceptions, of course.)

June 17, 2005

I did not yet get an answer to my question to Urs Schreiber and Robert Helling about rival lines of QG research alternative to string (which I will call "QGATS" for lack of a better term).

So I will repeat the question, just to be clear what i am asking.

The people contributing here (including the string experts Urs Schreiber and Robert Helling) seem to mean several different things by "LQG", so that confusion gets into this thread of discussion very easily.

I would like to know what Schreiber and Helling would identify as the currently active lines of research that are QUANTUM GRAVITY ALTERNATIVES TO STRING.

Which people would you gentlemen say are leading QGATS researchers? What papers have been posted recently, say in the past twelve months, that are significant QGATS papers?

It would be very helpful to know who you think leading people are, especially the younger crop just getting established.

It would be useful to have some specific arXiv numbers of research articles posted in the past twelve months that could serve to typify for us what you think are the main rival directions to string.

[Posted by: at June 16, 2005 01:24 PM]

I am grateful to Aaron Bergman for his brief response, with link to a paper by Renate Loll and her co-authors Ambjorn and Jurkiewicz.

But it is unfortunate that Urs and Robert have not yet replied (or perhaps they will choose never to reply to this question.)
I will explain why I think it is unfortunate.

The discussion of the issues raised in Smolin "New Einstein" essay is clouded by people naively equating
Smolin = LQG = QGATS
So people in this thread dismiss Smolin's call for more program diversity in US instutions, including QG rivals to string, as self-serving. They assume it would simply result in more support for LQG *whatever that is* (none of our critics seem to have an accurate idea of Smolin's research interests, or what should be called LQG, or what the range is of rival alternative lines of research).

What is even more unfortunately misleading is an oversimplification often suggested by posts like those of Schreiber and Helling:

QGATS = LQG = Thomas Thiemann's January 2004 paper.

Whether or not this is intentional, it has seemed to me that as soon as the possibility is raised that money or attention might be reallocated from string to some alternative QG lines of research, we immediately begin to hear references Thiemann's Loop-String paper. 🙂

22.
June 16, 2005

I can't believe the way people are falling all over themselves over this Smolin guy. Why not read Thomas Larsson?…
Posted by: D R Lunsford at June 16, 2005 09:49 PM

That is an interesting question, drl. I think the answer in part is that Smolin is a leader in "Quantum Gravity Alternatives to String" research. Call it "QGATS" if you like acronyms 🙂
the older term "LQG" is no longer sufficiently inclusive or adequately descriptive.

"QGATS", or whatever you want to call it, is now a hot group of research lines. Postings on arXiv have been increasing sharply over the past 2 or 3 years, while string-related postings (and citation standings) have stagnated or declined.

Smolin's institute (PI) is one of the few places in the world where there is a rough balance between research in string and Quantum Gravity alternatives.

Two other places I can think of are Hermann Nicolai's branch of Max Planck Institute (AEI-Potsdam) and it seems now also Gerard 't Hooft's institute at Utrecht.

Interesting things are happening at all these places. And they are the exception—only a handful of such institutes worldwide. So Smolin is not only a leader in an interesting area, "QGATS" :-), but he is also playing in an interesting league. Accordingly, it is not unusual for someone in touch with current developments in theoretical physics to take note of Smolin's point of view.

June 16, 2005

From Juan:

You can continue erasing my posts Peter, since that your "arguments" (to say) for erasing them is not consistent i continue to post here because information is important. If your argument is simply "i erase because i want do it", then please explicit it in "your" blog philosophy. I don't post my last three or four erased posts, simply the later of minutes ago (with minor modifications). (This was followed by a reposting of a comment that Peter had apparently previously deleted.)

Juan,

Your insistence on violating Peter's guidelines bothers me a lot, and probably many others as well. This blog is Peter's project, something that takes some of his precious time to build and maintain, and willfully violating his requests and standards so that you can push your own views, your own idea of what is important, is simply improper. A blog is not an unmoderated public forum; it is not your given "right" to say whatever you want just because you personally think it is important. If you think certain things need to be said, then find another forum (e.g., sci.physics.* Usenet groups) where you can raise and discuss those issues. It is important to remember we are all guests here, and should treat the host (in this case, Peter) with the same respect we would want to be treated with if we were the host or hostess.

It should be clear that explicitly violating Peter's guidelines for keeping comments on topic does not impress others. More likely, it gives you more the appearance of a crank, and makes it much less likely that others will take you seriously. It gives the appearance of a guest who acts rudely to the host or hostess; even worse, the guest apparently complains loudly when the host protests their rude behavior.

So please, Juan, respect Peter's repeated requests to keep posts on the topic. For an umoderated environment, take advantage of the Usenet groups.

25.
June 16, 2005

Aaron: *Speaking for myself, I find the recent results of Ambjorn et al intriguing, although I don't claim to understand them all that well right now.*

Since the link you gave in your post is

Reconstructing the universe

you might also be interested by another recent paper by one of the same authors
http://arxiv.org/gr-qc/0506035
Counting a black hole in Lorentzian product triangulations>

26. **Alejandro Rivero**
June 16, 2005

Hmm Aaron I can imagine in three minutes three arguments to relate d=2 and d=4 in the context of quantum gravity.

– That the curvature tensor is basically a 2-dimensional object,

– That path integrals have the custom of having fractal dimension two.

– That Polyakov action in NonCommutative geometry comes from the four dimensional integration of a two dimensional object (NCG integrates via dixmier trace, you can do strange things).

-that a string has worldsurface d=2

(did I said three arguments? Well, the last one does not score)

27.
June 16, 2005

Aaron, I just saw your post about the work by Ambjorn, Jurkiewicz and Loll. I don't have time to change my own post, which follows, to accord with yours but I agree—find the Dynamical Triangulations work intriguing.

It is to be one of the main topics at the Loops 05 conference at AEI in October, and Renate Loll is on the invited speakers list.

—-what I was going to post before I saw Aaron's was this—
it seems to me that as a first approximation a good map of the current active research in QUANTUM GRAVITY ALTERNATIVES TO STRING is given by the non-string topics posted at the "Loops 05" conference website

http://loops05.aei.mpg.de/

Background Independent Algebraic QFT
Causal Sets
Dynamical Triangulations
Loop Quantum Gravity
Non-perturbative Path Integrals

A representative list of researchers would be the list of invited speakers for that conference, which has been posted although the conference is still several months away.
http://loops05.aei.mpg.de/index_files/Programme.html

I think that the underlying concern shown by several of the posters here is with MONEY. Does string get to keep it or does it have to share some with its rivals? Therefore we cannot afford to be vague about who the rivals are. Funding for young researchers is an especially important topic in this thread and in the earlier "New Einsteins" thread. Thanks to Smolin for bringing issues of support allocation for young theory people (grad students, postdocs, young faculty) to the fore.

Because rival research lines are at issue, we must be clear about what the main QGAS efforts are. If we include some non-string QG in the physics department of a US university, what kind of research would it be? Name some papers from the past twelve months. Name some young researchers featured in the Loops 05 list of invited speakers.

28. **Aaron Bergman**
June 16, 2005

Speaking for myself, I find the recent results of Ambjorn *et al* intriguing, although I don't claim to understand them all that well right now.

30. **Urs Schreiber**
June 16, 2005

Hi Ummm,

OK, I am not 100% sure what your point is, now.

Fact is that in many discussions about that anomaly issue people get confused by the fact that in string theory there is a gravitational theory on parameter space and one on target space.

In the context of what has become known as the 'LQG-string' one is concerned exclusively with the issue of the quantum gravity theory on parameter space. All background dependence of string theory is a red herring for this particular discussion.

Which of course does not mean that there is nothing to discuss concerning the quantization of the target space gravity theory. But that's not the issue of the 'LQG-string'.

Best,
Urs

31. **Ummm**
June 16, 2005

Hi Urs,

I am in agreement that the worldsheet theory is not background dependent. My point is that when an LQG enthusiast gets a bug up their bum about background dependence, they're talking about strings as perturbation theory against a particular space-time. It's not necessary to be too technical about this.

32. **Peter**
June 16, 2005

To Juan and others:

Do not post here attempts to carry on a discussion about alternatives to GR, QM, etc. This is not a general physics discussion forum. Please do this somewhere else. I will continue to delete all such posts.

33. **Urs Schreiber**
June 16, 2005

Hi Ummm,

no, the issue I commented on is the quantization of the worldsheet theory and how its LQG-like quantization relates to the standard one. This is 2D gravity coupled to scalar fields and it is irrelevant for its discussion whether you want interpret these scalar fields as embedding fields into a target space or not.

So, if it helps, you can forget about the idea of fundamental strings for the moment and just consider the quantization of 2D gravity coupled to scalar fields. This is well understood. In the standard formalism, which uses weakly continuous representations of operators, the ADM constraint algebra of this gravitational system always has an anomaly.

34. **Thomas Larsson**
June 16, 2005

The Thomas mentioned in Robert's post is Thiemann, not me. Also, I am pretty sure that Stone-von Neumann only applies to QM with finitely many degrees of freedom, so it might not be directly relevant to gravity.

35. June 16, 2005

Ummm, the fixed background that Smolin refers to is the target space-time, fixing this is part of the definition of the CFT. Surely you realize that this is an important open problem?

36. **Urs Schreiber**
June 16, 2005

Concerning the different approach towards anomalies in the LQG-like quantization of the string and the ordinary quantization, Lee Smolin wrote:

> The approach to quantization of constrained systems is different in string theory and LQG. The former approach depends on a gauge fixing that refers to a fixed background metric.

I guess this refers to the quantization of the Polyakov action after the conformal gauge has been fixed. It is worth pointing out that precisely the same constraint algebra is obtained by taking the Nambu-Goto action or the Polyakov action, regarding them as (background free) gravity on the worldsheet coupled to scalar fields on the worldsheet and compute the ADM constraints of these. One finds a Hamiltonian constraint L + bar L and a diffeomorphisms constraint L – bar L. No gauge has to be fixed at any time.

(This can easily be checked. The calculation is for instance given in Henneaux's old lecture notes on string theory.)

So the quantization of the string is precisely about the quantization of a background independent gravitational system in two dimensions. And any weakly continuous quantization of the resulting constraint algebra does feature an anomaly.

The resason that 'oscillators' make an appearance in this background free quantization is merely due to the special property of the constraint algebra in 2D to have structure constants instead of structure functions. This makes Fourier decomposition in parameter space a useful tool.

It seems to me that the reason to drop weak continuity in the quantization of gravity in 3+1 dimensions is that it makes an otherwise intractable problem tractable – but possibly at the cost of having oversimplified a hard problem.

37. **Robert**
June 16, 2005

As Lee goes into some details, I would like to mention our preprint hep-th/0409182 where we discuss Thomas' approach to the quantization of the string (and also the harmonic oscillator).

There, the upshot is, that the GNS-state of Thomas is not (weakly) continious, a property that is up to discussion but I consider quite suspicious. In the case of the oscillator it leads to a state that is that of an oscillator coupled to a heat bath of infinite temperature. This does not look too promising.

Furthermore, (although this argument might not be rigorous) this treatment suggests to me, that his state is not only independant of diffeomorphisms but also under any map that maps spacetime points bijectively (pointwise, not necessarily even continious) and thus produces a theory that only sees space-time as a set of points and forget completely even about topology.

As I understand, the reason to take such drastic steps are taken is the misconception that one should start from state that is invariant under diffeomorphisms. However, there is no physical motivation for this: It is enough to start with a state that is covariant, i.e. a state in which the action of diffeomorphisms is defined as operators in the corresponding hilbert space. The usual Fock quantization provides exactly this and due to the Stone von Neumann theorem is the only one that does this continiously.

At least in the classical theory, GR is diffeomorphism invariant but any solution (i.e. metric) sponaneously breaks this invariance to the isometry group of that space-time (which is generically trivial). So all the classical states are not invariant but only covariant.

38. **Alejandro Rivero**
June 15, 2005

I can not see the problem with the harmonic oscillator. Well, first of all, I missed the preprint number where such problem is discussed. I didn't know that LQG was already able to support and quantise another force fields jointly with gravity. But in anycase, given that an harmonic oscillator force is not included as one of the forces in the Standard Model, I am happy if it can not be supported under LQG. I would be even happier if the unique supported forces where SU(3)xSU(2)xU(1).

39. **Aaron Bergman**
June 15, 2005

The point about LQG is not that it's wrong — after all, experiment is the ultimate arbiter of that — but that is not a conservative approach to quantum gravity as is often claimed. It is, in fact, a radically different approach to quantization that, when applied to current theories, gives experimentally incorrect answers.

40. **M**
June 15, 2005

Thomas Larsson gave a detailed response to Lee's post in the previous thread. Since it is more likely to elicit a response in this thread than the earlier one, I think it is worth repeating it in full. I will add my own comment at the end, in agreement with one of Thomas' comments.

* _ * _ * _ * _ * _ * _ * _ * _ *

Dear Lee,

Let me emphasize that I am not a string theorist – on the contrary, over the last years I have had strong disagreements with Lubos and others, especially over the role of diff anomalies. While initially a statistical physicist, the success of CFT made me interested in Lie algebras, where I discovered how to generalize the Virasoro algebra beyond 1D and developed its representation theory, together with mathematicians like Moody, Rao, Berman and Billig. In particular, the Virasoro algebra in 4D is the anomalous form of the algebra of 4-diffeomorphisms, which is the constraint algebra of GR in covariant formulations (in non-covariant canonical quantization the constraint algebra is modified).

So when I speak about diff anomalies, I do it as someone who has developed new mathematics which has not been absorbed by the physics community. You may wish to keep that in mind.

As to the issue of anomalies, i.e. the claim that we ignore the established knowledge that ?INFINITE-DIMENSIONAL CONSTRAINT ALGEBRAS generically acquire anomalies on the quantum level…? is simply false. It is contradicted by rigorous existence and uniqueness theorems in LQG.

Whereas I claim that this is true, it is not at all generally accepted. On the contrary, it is widely asserted that there are no pure gravitational anomalies in 4D, see e.g. Weinberg's QT of F II, ch 22. Nevertheless, the constraint algebra of GR contains many subalgebras isomorphic to the infinite conformal symmetry in 2D, generated by vector fields of the form f(z) d/dz, where e.g. z = x^0 + ix^1 or z = x^2 + ix^3. Upon Fock quantization, these conformal subalgebras will in general acquire anomalies for the usual reason, making the whole shebang anomalous.

The reason why these anomalies cannot be seen in conventional field theory is that the relevant cocycles are functionals of the observer's trajectory in spacetime. Unless this trajectory is introduced and quantized in conjunction with the fields, the relevant anomalies cannot be formulated. This is IMO the crucial obstruction to the quantization of gravity.

1) The approach to quantization of constrained systems is different in string theory and LQG. The former approach depends on a gauge fixing that refers to a fixed background metric. It results in the construction of a Fock space. The latter is background independent and involves no background metric, no gauge fixing and results in a state space unitarily inequivalent to a Fock space.

2) There is a body of rigorous results that support each kinds of quantization. Hence it cannot be a question of which is correct mathematically. Both are correct, within *their contexts. It is a question only of which construction is appropriate for which theories and which describes nature.*

Conventional quantization has turned out to describe nature in other contexts. I think this is a good reason to believe that it is the correct approach. In particular, CFT has been successfully applied to 2D condensed matter, where conformal anomalies have been measured experimentally. This is of course a different context and not directly relevant, but this fact has shaped my basic instinct that anomalies are very real things which cannot depend on the quantization method used.

3) The treatment of constraints in string theory depends on certain technical features of 1+1 dimensional theories, particularly the fact that there is a gauge in which L_0 plays the role of a Hamiltonian and therefore should, in that gauge, be quantized so as to have a positive spectrum. The anomalies are not generic, as asserted above, rather they depend on the additional condition that L_0 should be a positive operator.

Yes, this is the crucial point. In any physical theory, there should be some positive operator which can be interpreted as a Hamiltonian; there is a physical requirement that energy be bounded from below. Of course, in GR there is a Hamiltonian constraint rather than a genuine Hamiltonian. This is another reason to introduce the observer's trajectory; you can define a genuine Hamiltonian as the operator that translates the fields relative to the observer.

Anyway, in all applications of Lie algebras to physics so far, the reps have been of lowest-weight type. At least for finite-dimensional Lie algebras, all unitary irreps are of this type.

There are other reps of Diff(S^1) that are non-anomalous but in which L_0 is not positive.

If you consider the restriction to the algebra of polynomial vector fields, generated by L_m with m >= -1, then all irreps have a vacuum vector (or are dual to such a rep).

So a choice is made in the standard quantization of string theory, which his motivated by the physics. This does not mean it is the right choice for all physical theories.

OK. I disagree.

4) Conversely the existence and uniqueness theorems which support the LQG quantization work only in 2+1 dimensions and above for the reason that gauge fields don?t have local degrees of freedom in 1+1 dimensions. The existence theorems tell us that there are quantizations in 2+1 and higher of diffeo invariant gauge theories that have unitary, anomaly free realizations of diffeo invariance. The uniqueness theorem tells us that the resulting state space we use in LQG is unique.

Contrary to string theorists, I claim that anomaly freedom is not a necessary requirement. To illustrate this point, let me again use the bosonic string as an example and quote from GSW, subsection 2.4: 'Classical free string theory can be consistently formulated for any spacetime dimension, but quantization with a ghost-free spectrum requires D less than or equal to 26. […] In the special case of D=26 and a=1 the spectrum is entirely tranverse, with many decoupled zero-norm states.'

Thus, D=26 is special, but D less than 26 is not ruled out by consistency requirements. It is only in 26D that it is possible to pass to the reduced Hilbert space by imposing the physical state condition L_m|phys)=0, but when D less than 26 this is not necessary, because the full, unreduced Hilbert space is already positive-definite.

Thus, my position is that some diff and gauge anomalies are good, making it possible to break diff and gauge symmetry on the quantum level, such as the string in D less than 26 illustrates. This does not mean that all gauge anomalies are good, of course. On the contrary, I recently gave a simple algebraic argument why conventional gauge anomalies, due to chiral fermions and proportional to the third Casimir, indeed are inconsistent. This argument does not apply to observer-dependent anomalies, which are proportional to the second Casimir.

The idea that diff and gauge anomalies may be consistent is of course very controversial.

With regard to the non-standard quantization, in which holonomies, but not local field operators are well defined, it is of course true that when applied to standard systems this leads to inequivalent results. ?This apparently leads to unphysical consequences, such as an unbounded spectrum for the harmonic oscillator.? But, give me a break, do you really think someone is proposing to replace the standard quantization of the harmonic oscillator with the alternative one? What is being proposed is that the quantization used in LQG is well suited to the quantization of diffeo invariant gauge theories.
In case it is not obvious, let me emphasize that harmonic oscillators are not relevent here, and can play no role in a background independent quantum theory, precisely because the division of a field into harmonic modes requires a fixed background metric. Thus, the physics of the problem REQUIRES an alternative quantization.

Sorry, but here I flatly disagree. I find it very disturbing that LQG methods yield the wrong result for the harmonic oscillator.

I am frankly puzzled why someone who claims to know the literature well would throw up examples like the harmonic oscillator up in this context. I can try to understand their point of view, but it certainly reads as if they either are choosing to ignore the basic point, which is that background independent quantizations cannot use fock space, or they are looking to make debating points to impress ignorant outsiders.

I agree that a diff invariant quantization of gravity cannot use Fock space, and I am convinced that such a quantization does not exist. However, a diff covariant Fock space quantization of gravity may very well exist. By this I mean a quantization in analogy with the string for D less than 26: the unreduced Hilbert space is consistent in itself, and diffeomorphisms are promoted to a genuine but anomalous symmetry acting on the full Hilbert space.

A step in this direction was taken in hep-th/0504020. Sure, there are problems: the (manifestly covariant) regularization has not quite been removed, no invariant inner product has been found, and no hard predictions have been extracted. But there is a Hamiltonian which is bounded from below in the regularized theories, the analogous construction for the harmonic oscillator has a spectrum bounded from below (it is not quite right, and I discuss why), and infinities cancel best (though not quite, so I am doing something wrong) in 4D. Most importantly, since phase space variables are promoted to operators in the usual way, this is genuine quantization, which is witnessed by the presence of anomalies.

Finally, I didn't express myself very well on the sociological issues. I agree with you about the problems with string theory, and I did not mean that funding to LQG should be stopped. However, given what I feel is a major problem (the harmonic oscillator spectrum), and that LQG already is the second biggest player in QG, I cannot really think that it is badly underfunded at present levels.

Posted by Thomas Larsson at June 14, 2005 10:44 PM

* _ * _ * _ * _ * _ * _ * _ * _ *

I am not at all qualified to comment on either Lee's or Thomas' statements. However, like Thomas, it bothers me a lot that LQG apparently cannot reproduce the known spectrum for the harmonic oscillator in some limit where it should. Historically it has been a requirement for a new theory to reduce to an established earlier theory in the limit of the earlier theory's applicability, as, say in the well known example that quantum theory gives the classical result in the limit hbar->0, or GR gives the Newtonian result in the flat space limit. Why should LQG be exempt from such a consistency check? Given that there aren't too many ways to test a theory of quantum gravity, it seems like a failure here should be taken very seriously. It seems like Lee is a little too dismissive when he says,

But, give me a break, do you really think someone is proposing to replace the standard quantization of the harmonic oscillator with the alternative one? What is being proposed is that the quantization used in LQG is well suited to the quantization of diffeo invariant gauge theories.

But then again, this is just the perspective of one who has only superficial knowledge about LQG…

this is quite possibly a trivial sidecomment but I want to mention a consideration from the standpoint of a "physics watcher" which is that I also benefit from the range of quantumgravity research options that gradstudents and postdocs have at AEI-Potsdam and Perimeter/Waterloo.

when a US grad student who has only the choice string or nothing chooses a research topic this does not tell me anything, I am watching a stock market where investors have only one choice or very limited choice. so I do not benefit from watching his or her behavior.

but by contrast I watch the career of, for instance, Bianca Dittrich at the Albert Einstein Institute with great interest
BECAUSE HERE IS AN INTELLIGENT HIGHLY MOTIVATED PERSON ON THE GROUND who is free to make choices between, say, Thiemann's Master Constraint canonical approach and Loll's Triangulation approach (which are on radically different mathematical ground).

I think a lot can be learned by watching intelligent gamblers, or intelligent investors investing precious capital (young research time).

So to me it is very exciting to watch Dittrich's career because the system she is in gives her choice of programs—-Hermann Nicolai directs AEI "Unified Theories and Quantum Gravity" division in a way that is VERY DIFFERENT FROM VAFA'S HARVARD. Wow, is it different! Nicolai branch of AEI has string but also LQC with bojowald, and canonical-LQG with thiemann and also dynamical triangulations work and a lot of other stuff. If you are there, or at 't Hooft"s Utrecht institute, or at Perimeter in Canada then you really have some interesting options. So to me it is more informative to watch what the postdocs do in those places.

And this is not just pure frivolity on my part, I really think you get scientifically valuable information by giving graduate students exposure to various things and a choice of radically different rival approaches, because the scientific enterprise benefits from their special perspective of what attracts them to devote their careers to. We all benefit from their intuitive hunches of what will pay off.

Let us hope that this does not make Artem Starodubtsev and Etera Livine and all of them self conscious knowing that bystanders get a clue of what is happening by seeing what they do.

Quantum gravity is at an intensely exciting stage and a LOT is happening. Onlookers can be glad for the instututes that are run with several alternate programs, and also (in my experience as an observer) they tend to be where the progress is being made.

Suspicious Dualities

June 15, 2005
Categories: Uncategorized

These days some of the strongest criticisms of what is going on in string theory are coming from Lubos Motl's weblog. His latest post asks what would have happened if currently fashionable ideas about string theory had appeared in the sixties before the standard model. They would have led to claims that many things about particle physics were inherently unpredictable, or dependent on the details of the earliest moments of the big bang. But when the standard model appeared in 1973, it made a wide range of detailed predictions of this type.

He also makes some remarkable statements about string dualities:

"Virtually all conjectured non-supersymmetric dualities (except a few exceptions in the topological context) are suspicious, and even those that are true may be true only because we define one of the sides to be dual to the other – while other equally consistent definitions may exist, too."

and claims that in the mid-90s Tom Banks described how research on string dualities was being done as follows:

"If you can't show that a conjectured duality is wrong in 5 minutes, it must be correct."

Funny, I'd always suspected that was what they were doing, but I'd never have dared to suggest it. And by the way, I'm wondering if Jacques Distler has given up on string theory. It's been several months since he's written anything about strings, and a month since he's written anything at all.

Comments

1. **Torbjorn Larsson**
   June 17, 2005

   Sure. But Lubos says "Although string theorists are obviously capable to study any of these things, …"
   which I criticize; as hubris if you like.

2.
   June 17, 2005

   I kow that Lubos did not have this in mind, is is awfukky lowbrow

   Harsh, but just.
   🙂

3. **Torbjorn Larsson**
   June 16, 2005

   I don't believe I did that! awfu*ll*y of course, my fingers slipped.

4. **Torbjorn Larsson**
   June 16, 2005

   "We need to define what string theory is *not*…"

   I kow that Lubos did not have this in mind, is is awfukky lowbrow :-), but there is a constraint of sorts right here, in his model of theories:

   "… construct a bound state of these electrons called the feminist …"

   There is no obvious one-to-one correspondence between different brain constructions and states (ie male and female) to feminist actions.

   So we should really know to stop here. (Apart from that nerve interactions are through ions, transmitter substances, reinforced/inhibited couplings and growth/death, so electrons should not describe them.)

5. **Peter Woit**
   June 16, 2005

   I've been moving to a new apartment today, so have been away from e-mail and just recently came into the office. I've deleted some of the more egregiously off-topic posts just now, so if you're wondering what that discussion is about, to some extent it's about posts that are no longer there.

   M has it right about why I don't just let anyone post anything they want to. To put it in more personal terms: I want this weblog and its comment section to be something that I'd actually like to read. In the past when I've let people post whatever they want, the comment section has degenerated into something I found not worth reading. When this happens, I assume that many other sensible people will decide the comment section here is worthless, and stop reading it or writing in to it. I'm not going to let that happen.

6. **Kostya**
   June 16, 2005

   Dear Peter,
   Why do you let crackpots to post on your blog?
   I guess it's amusing to read their comments but it gets kind of annoying at the end of the day.
   Lubos, please don't waste you time answering to their stupid comments.

7. **M**
   June 16, 2005

   From Quantoken:

Not only Peter will delete any thing about alternative ideas, he will also delete arguments against those alternative ideas he deletes just as well. He is against string theory. But basically he is only interested in arguments either for or against string theory, and for or against LQG, and nothing else.

I have not noticed Peter selectively deleting comments just because they weren't about string theory or LQG. I have seen him repeatedly request that people keep their comments related to the topic at hand. People who post comments that push their own particular flavor of a "theory" that supposedly explains all kinds of wonderful things that standard theory does not are usually not adhering to Peter's guidelines, and thankfully he is not overly shy about removing such comments.

If you want to see how free-for-all physics discussion forums operate, visit any of the unmoderated Usenet physics groups, like sci.physics.relativity for example. A relatively small number of people actually try to hold intelligent discussions, but the great majority of the traffic consists of discussions of nonsensical alternative "theories," insults, and off-topic items. In an unmoderated public forum, it just doesn't seem to happen that intelligent discussion of carefully thought out alternative ideas will take place over any length of time. Turkeys flock together, and the turkeys will be attracted to a forum where "alternative theories" can be discussed like fruit flies are attracted to a piece of overly ripe fruit (especially if they think serious scientists might read their stuff).

I really hope Peter continues to hold standards for keeping comments on-topic. It is really nice to have a few forums where people can discuss serious physics without the clutter of unsubstantiated (or poorly supported) claims posing as an alternative theory. It think Peter already errs on the side of keeping comments that are at best marginal, although some people whose comments were deleted would probably disagree. Perhaps he will occasionally have a topic where discussions of far out ideas will be on-topic, and then there would be no need to suppress even the nonsense.

Finally, I think that anyone who carefully thinks through an alternative idea and plays by the rules that all serious physicists play by — and that means making quantitative predictions, having predictions that agree with known empirical results, and not making unsubstantiated wild claims — can expect a respectful hearing by at least some people. Peter has said more than once that occasional references to personal web pages that discuss alternative ideas are fine; he just doesn't want to have people filling the comment section with that kind of stuff. For those who want to stimulate a more vigorous discussion of their ideas, take it to the unmoderated physics groups on Usenet and it will probably generate some traffic there.

8. **Lubo? Motl**
June 16, 2005

Quantoken, your comments are irrelevant because you know nothing about the subtle questions that are discussed.

It's just trivially true that the 1/2 BPS sector of type IIB string theory on AdS5 x S5 is equivalent to Quantum Hall System.

http://arxiv.org/abs/hep-th/0505129

A natural question is whether this can be extended to similar systems used in condensed matter, and it is a technical question that can't be ultimately answered by your passionate guesswork.

9. **Lubo? Motl**
June 16, 2005

"Fascist and antif*ist" – have not you wondered that this is an oxymoron?

10. **Quantoken**
June 16, 2005

Lubos meantioned that he had done some research relating "Fractional Quantum Hall Effect and string theory"

It is absolutely ridiculous for a string theoretist to even waste one second thinking about the connection between the two subjects. There are as unrelated as trying to use Euler's law to try to forecast the weather. They belong to completely different domains. The FQHE is problem of manybody of quantum theory in condensed matter physics, and problem that has been well studied and well understood, and does not need any external explanations. There is no physical fractional charge whatsoever.

Quantoken

11.
June 16, 2005

Fascist and antifeminist

"The crudest approximations will be enough for this calculation because the physical object under investigation is pretty simple"

12. **Lubos Motl**
June 16, 2005

Well, I can't deny that our two blogs have a significant overlap in the readership, but one may still argue that my blog is being read by many serious people, and even many of those who read both of these blogs have very different reasons why they read one as opposed to the other.

My comment comparing the situation of theoretical particle/string physics to biodiversity climate science was not predominantly about the anthropic principle although I mentioned some anthropic examples. Let me say more examples what I had in mind – something related to my recent research that seems increasingly less attractive:

Fractional Quantum Hall Effect and string theory.

Non-singlet states in various matrix models.

Calogero models and string theory.

And so forth. One may propose many dualities between string theory and these conventional theories and constructions and their generalizations. But do we really believe that these connections are deep? Is there a reason why string theory should be helpful or illuminate either of these things? It has illuminated Calabi-Yau manifolds, for example, but it does not mean that the success can be extended anywhere.

As far as I know, string theory has not given new insights about the FQHE and my bet is that it won't give any in the near future.

I personally doubt that string theory is deeply connected with all these (and other) things, and even the speculative idea that it *is* connected is not attractive to me in any deep way. String theory should be a theory of everything, but not everything in this sense. I would find it more rational and satisfactory if string theory showed that some of these otherwise nice things – like the Calogero model – can't have any relation with the most fundamental laws. We need to define what string theory is *not*, and undoubtedly some of the things that string theory is not have been proposed as examples what string theory *is*.

Of course, any idea can be embedded in string theory, including feminist social theory. Take a Calabi-Yau space, heterotic strings, compactify, discover electrons, construct a bound state of these electrons called the feminist, let it evolve, and decode the brain hologram. The crudest approximations will be enough for this calculation because the physical object under investigation is pretty simple, and what you will get is feminist social theory.

But in this example, the theory is not connected to the characteristic stringy phenomena. Although string theorists are obviously capable to study any of these things, I doubt whether we should pretend that it is a part of string theory.

13.
June 16, 2005

Lubos' posts in this blog are legendary ones.

Many of us know to him and his fascist style.

14.
June 16, 2005

"what your low-brow blog and its low-brow readers enjoy"

"- (Lubos). You and you readers are stupid."

Hmm, it appears to be true then that, no matter how
smart you are, how righteous your cause is or how
strong your arguements are, in the end it'll come
down to namecalling!

15. **Arun**
June 16, 2005

I postulate a (Peter blog) (Lubos blog) duality and can confirm it in 5 minutes 🙂

16. **Juan R.**
June 16, 2005

– (Lubos). You and you readers are stupid.

– (Peter). Thanks for the clarifications.

Great!

17.
June 16, 2005

From the perspective of time, all discoveries seem trivial. The "duality revolution" was certainly a big step. However, one can ask what is the true physical origin of various dualities and why they work so beautifully for superstrings while not much can be done without supersymmetry. In my opinion, dualities have no dynamical content. All what they represent are very strong constraints imposed by supersymmetry, and they hold only in BPS (and almost-BPS) sectors. Same thing about AdS/CFT: when two structures have the same symmetry, you will certainly find some matching observables.
In non-supersymmetric theories, BPS-like configurations — instantons play some minor role
but the important dynamical effects like confinement have a different origin.
If you agree, then here is no point in talking about non-supersymmetric dualities. We are stuck with very difficult dynamical problems, like in QCD. I am curious what others think about it…
Jean-Paul

18. **Mike Ros**
June 15, 2005

I have the impression that a sizeable fraction of Peter's readers are also Lubos' readers

I anticipate that it works both ways; I always read both.

19. **Torbjorn Larsson**
June 15, 2005

It is worse; Lubos included himself. May I suggest Vicodins? 😉

20. **Just another low-brow reader**
June 15, 2005

From Lubos:

… or about simple-minded destruction of string theory which is what your low-brow blog and its low-brow readers enjoy.

As one of Peter's blog readers, this would make me low-brow. But I also read Lubos' blog, so I guess that makes me one of his low-brow readers too. In fact, I have the impression that a sizeable fraction of Peter's readers are also Lubos' readers, so does this mean that Lubos' blog is therefore infested by low-brow readers? Such a deep, difficult question almost makes my head hurt.

Lubos can be so *endearing* sometimes…

21. **Peter**
June 15, 2005

Hi Lubos,

Thanks for the clarifications. I thought from the context of my post and yours it was clear that your gedanken experiment referred to the whole anthropic principle line of thinking.

I don't want to discourage people from thinking about anything, but I do want to discourage them from thinking about one particular thing (string/M-theory based unification in 10/11 dimensions) since, despite twenty years of effort, it has failed completely and has now led a sizable part of the community off into pseudo-science. It would be good for physics if people thought more about other things than this, just about any other things…

22. **Lubo? Motl**
June 15, 2005

Dear Peter,

what you have not understood is that the rule "if you can't rule it out in 5 minutes, it's true" has really worked in all the important cases during the duality revolution, and in some cases it also worked afterwards.

Non-supersymmetric dualities have never been a part of the basic established structure of string theory. For example, type 0A is, in some sense, dual to M-theory on a Scherk-Schwarz circle. Except that such a statement is physically unverifiable because in order to connect the two limits, one has to go through spacetime that is completely unstable.

A more modern example is the description of non-SUSY configurations obtained by adding things such as anti D3-branes to supersymmetric AdS spaces; it's questionable whether these configurations may be seen in the dual boundary CFT.

My gedanken experiment about the 1970s was not about putting the whole string theory as we know it to the test – or about simple-minded destruction of string theory which is what your low-brow blog and its low-brow readers enjoy. It was about checking ideas how to go beyond the current state of affairs. Unfortunately, you're extraordinarily capable to distort statements and facts in such a way that you want to discourage as many people as possible from thinking about anything.

All the best
Lubos

Bogdanovs Gain a New Supporter

June 18, 2005
Categories: Uncategorized

If you didn't follow this a couple years ago, you can read John Baez's detailed description of the Bogdanoff Affair. For more about my dealings with them, see here., here, and here. If you want to read their stuff, go to the website of the Mathematical Center of Riemannian Cosmology which purports to be in Latvia.

In brief, the Bogdanovs are two brothers in France with a TV show who got Ph. D.s based on work which on the whole was complete nonsense. I'm not surprised that they managed to get Ph. D.s, and one of them was failed on his first attempt. It's not unusual in academia to be faced with having to decide what to do with students who seem to be enthusiastic and work hard, but don't perform at an acceptable level. There are lots of reasons to just pass them with the lowest possible grade (for one thing, this gets rid of them). One of my colleagues refers to this as the "infinitely elastic C-minus".

What was disturbing about the Bogdanov story was that they managed to get papers published in six refereed journals, some of which were quite respectable. Some of these papers were essentially identical. After this story became public, the editorial board of one of the journals (Classical and Quantum Gravity) issued a statement saying that the paper they published shouldn't have been accepted, and that they were taking (undisclosed) steps to change their refereeing process so this wouldn't happen again. This seemed to me strong evidence that there is so much nonsense now in the theoretical physics literature that the refereeing system has broken down. Many referees are now either unwilling or unable to identify nonsense when they see it.

I had discussions about this with quite a few physicists at the time, and many of them took the position that this wasn't such a big deal. Their attitude was roughly that "So what if these guys managed to get something nonsensical past some lazy referees? Everyone in the community can tell that what they wrote is nonsense and just ignores it. It's not true that we can no longer tell nonsense from serious work". I became somewhat convinced that I was being too harsh on string theorists and others when I thought that they had completely lost the ability to identify nonsense. Maybe the only scandal here was the laziness of referees, not the infection of the whole subject by nonsense to the point where lots of people can't tell the difference. Well, I just changed my mind, clearly at least some string theorists can't.

I feel somewhat constrained in what I can say about the details of this, due to the fact that someone I've been in contact with tells me of being threatened with a lawsuit by the Bogdanovs for having criticized them publicly. I'm also not about to engage in discussion of the details of their nonsense, which is what they, like all crackpots, really want. It's just a complete waste of time.

Comments

1. **Peter Woit**
   June 20, 2005

   Funny, that last comment came from an internet address that looks a lot like the ones of Roland Schwartz and Prof. L. Yang…..

   The idea that topological gravity has something to do with the full quantum gravity is a reasonable conjecture and isn't due to the Bogdanovs. I'm sure people will keep working on it.

2. **Me**
   June 20, 2005

   From my point of view, one must leave to time and history the care to decide wether this fields of research was effectively killed by Bogdanovs.

   I will rather say, on the contrary, that it was born from Bogdanovs.

3. June 20, 2005

   In his criticism of LQG Lubos states, "It assumes the metric tensor is a good variable at all distances and is the only relevent variable…it even assumes Einstein equations are more or less exact at the Planckian regime…these assumptions are challenged in a general enough theory of QG, for example all models that emerge from string theory…assumptions that have no theoretical or experimental justification".

   I agreed with these statements actually, but how come he now thinks it is ok perhaps if the above variable "the metric" has signature fluctuations in the Planckian regime, a la Bogdanov, and is a viable variable in this regime?

   Even if you think TQFT has something deep to say about the initial singularity of spacetime(and who knows)the Bogdanovs have effectively killed this as a respectable research direction.

4. June 20, 2005

   BTW the first place where Lubos signed "lumo (leashed)" was his blog entry commenting on
   http://arxiv.org/abs/hep-th/0504221
   Dijkgraaf, Gopakumar, Ooguri, and Vafa
   Baby Universes in String Theory

   that was on April 30 and in the preceding segment of that day's blog he had said "Unfortunately, I currently do not enjoy the freedom to tell you what I think about these things."

   I tend to view Lubos protestations of tolerance for the Boganoff article as an ironical reproach to somebody who told him to ease up and stop the vitreolic attacks on other stuff. It puts him in position to say, well you told me not to be so ferocious so you must favor relaxing the intellectual standards applied to scholarship, so look what happens! I will just (to spite you) go and approve of the Bogdanoffs on the same basis that I tolerate specious research by [unnamed].

   Yeah that is a tortured overinterpretation, and who cares about the adventures of Lubos melodrama, except he is entertaining sometimes. Anyway I dont take his apparent acceptance of the Bog paper at face value, it is a travesty just like the Bogs (or so I tend to suspect)

5. June 20, 2005

It’s interesting that Lubos is pushing “not complete nonsense” as the new standard for scientific publication, at least for certain types of physics. Of course for, say climate science, he expects a level of rigor exceeding pure mathematics literature.

I can’t help but notice a parallel with certain defenders of Bush administration foreign policy who have adopted “not as bad as Saddam” as the new standard for acceptable moral behavior.

6. June 20, 2005

on the other hand, Dijkgraaf is an eminently sensible choice).

a propos Dijkgraaf, he is one of the invited speakers on the programme of Loops 05 conference in October
loops05.aei.mpg.de/index_files/Programme.html

since Dijkgraaf’s public lecture in July is about black holes and time, I was reminded of his recent paper

http://arxiv.org/abs/hep-th/0504221
Baby Universes in String Theory

Abstract: “We argue that the holographic description of four-dimensional BPS black holes naturally includes multi-center solutions … This provides a concrete realization, within string theory, of effects that can be interpreted as the creation of baby universes…”

in that context I cannot imagine what he could mean by his jazzy phrase “the end of time” except that continuation through a black hole implies a branching of time which could be said to dispose of the classical single-track unitary-evolution notion and thus be “the end” of time as we have thought of it up til now. I certainly agree Dijkgraaf is a great choice (maybe “eminently sensible” could be supplemented to read “inspired” 🙂

7. **Peter Woit**
June 20, 2005

I’d noticed that too. It speaks volumes that the organizers of this conference feel that Susskind’s pseudo-scientific nonsense is worthy of being half of the public face of string theory (on the other hand, Dijkgraaf is an eminently sensible choice).

I wouldn’t read too much into the lack of a definite program for the conference. Scheduling such a program is always difficult, with all sorts of last minute changes.

8. June 20, 2005

this may or may not bear on the general topic of attention-seeking and marginal science
please erase if insufficiently topical

The schedule posted for Strings 05 is still (as of Monday 20 June) almost blank, but it now lists a Leonard Susskind public lecture and two other events.

http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/program.html

Public Talks
Saturday July 16, 2-5p.m.
Robbert Dijkgraaf U. Amsterdam
“Strings, Black Holes, and the End of Space and Time”

Leonard Susskind Stanford U.
“Cosmic Landscape: String Theory and the Illusion of Intelligent Design”

Panel discussion: The Next Superstring Revolution
Tuesday, July 12, 19:00-21:00

the conference goes July 11-16, so is only 3 weeks away. It seems curiously suspenseful on the part of the Toronto organizers that the posted schedule of talks is mostly blank (no regular talks shown, only the two public lectures.) Maybe we can take it as providential sign that Susskind’s title mentions the illusion of intelligence in connection with string theory (kidding)

9. **Mike**
June 20, 2005

I apologize if this is somewhat off topic (please delete if it does not belong), but every day I learn something new here. Matti Pitkanen wrote: “In some other summary brothers identify Big Bang singularity with a point rather than singularity analogous to the boundary of future light cone: this mistake of course appears again and again in popular literature.”

Exactly! Until recently everything I have learned has come from popular literature and that is how we are told to “visualize” the Big Bang. For someone who is not a mathematician or physicist, where do we turn for a more accurate understanding of these issues? Something more advanced than popular books (Kaku) but not as complex as the text books by Polchinski, Zwiebach, Zee, etc.., which are presented as introductions but are too complicated for someone without an advanced understanding of math.

I’m trying to work my way through Penrose’s new book and almost threw in the towel on the chapters on Manifolds and Symmetry Groups. It’s very frustrating. In the introduction he nonchalantly advises readers to feel free to skip the math. 1) I don’t want to skip the math and 2) It’s ALL math.

10. **Fyodor**
June 20, 2005

Between that demonstration of ignorance and Lubos’s new one, I think it is at least safe to say that on the whole string theorists don’t even know what a TQFT is.

Yeah, PW, people who don’t really understand things ought to abstain from commenting on them, don’t you agree? I also find that there are way too many people who engage in heated denunciations of certain theories and yet have absolutely nothing to suggest as alternatives. That, too, is rather feeble, is it not?

11. June 20, 2005

“1.These brothers are surely intelligent. They got an IQ of 200.”

That only comes out to 100 each, assuming it’s evenly split. Nothing to brag about.

12. **Fabien Besnard**
June 20, 2005

Peter,

>What to do about this is a hard problem.

to this I answer : a national anonymous competition. In France this is the way the “grandes ?coles” recruit their students and it put them way ahead universities. The problem is that now it is criticized also (for one thing because this system is very different from what is done everywhere else in the world).
I am not saying that this system should be considered as perfect : it selects people with very peculiar qualities. Nevertheless I do believe it is the less unfair, and I think it should be used along with more traditional academic systems in a balanced way.

Regards.

13. **Matti Pitkanen**
June 20, 2005

I would be happy if the discussion about Bogdanov affair could be based on real arguments rather than uneducated crackpot guesses and unjustified non-sense claims so familiar also from earlier discussions.

Thanks for Lubos for seeing the trouble for performing a real analysis of one of papers. I looked the reports about the thesis of G. Bogdanov and found that Majid gave a positive statement saying that the work was original. Brothers emphasize that they are mathematicians, not physicists. By looking the abstracts of their papers, one gets the impression that also their understanding of Riemannian geometry could be better.

For instance, look just the abstract of THERMAL EQUILIBRIUM AND KMS CONDITION AT THE PLANCK SCALE

Considering the expected thermal equilibrium characterizing the physics at the Planck scale, it is here stated, for the first time, that, as a system, the space-time at the Planck scale must be considered as subject to the Kubo-Martin-Schwinger (KMS) condition. Consequently, in the interior of the KMS strip, i.e. from the scale ℬ = 0 to the scale ℬ = ℓplanck, the fourth coordinate g44 must be considered as complex, the two real poles being ℬ = 0 and ℬ = ℓplanck. This means that within the limits of the KMS strip, the Lorentzian and the Euclidean metric are in a “quantum superposition state” (or coupled), this entailing a “unification” (or coupling) between the topological (Euclidean) and the physical (Lorentzian) states of space-time.

Brothers seem to have a rather vague view about Riemannian geometry (“the fourth coordinate g44 must be considered as complex”). Could a real mathematician really write something like this without feeling a deep pain in his guts.

In some other summary brothers identify Big Bang singularity with a point rather than singularity analogous to the boundary of future light cone: this mistake of course appears again and again in popular literature. Taking into account what brothers propose, this mistake looks strange since singularity is very much like the boundary of the future lightcone and by its metric 2-dimensionality is indeed an excellent candidate for serving as a seat of conformal (and thus also topological) field theory.

I see nothing crackpottish in idea about possibility of Euclidian and Lorentzian signatures. If space-time is identified as a 4-surface (or brane) this is an unavoidable prediction with deep implications. The idea that pre-Planck era corresponds to TQFT is also interesting. Personally I would rather view it as a phase during which the analogs of long cosmic strings dominate and string models become a good approximation.

Matti Pitkanen

14. **Peter Woit**
June 19, 2005

Hi Deane,

I agree that through grade inflation and passing students who don’t perform acceptably the value of undergraduate degrees has been seriously debased. To a lesser degree the same has been true of graduate degrees. What to do about this is a hard problem.

In the Bogdanov case I still think the root of the problem is the failure of the refereeing system. If you look at their theses, Grichka’s is not egregiously non-sensical, and his committee passed him with the lowest grade, which was not unreasonable. Igor’s was nonsense, and his committee did the right thing the first time and failed him. My understanding was that he was told that if he could get his work published in refereed journals, he could come back for a second try. If the referees had done their job correctly, there would have been no problem.

Another unusual part of this story is that the person who agreed to supervise their work was Moshe Flato, and he died unexpectedly before their theses were completed. It’s quite possible that had he lived he would not have allowed Igor to submit such a thesis. Moshe was a wonderful, generous and extravagant man, one whom I was quite fond of, having enjoyed meeting and talking to him on half a dozen occasions or so over the years. I suspect his generosity was what led him to take on the Bogdanovs, but had he lived his devotion to good science probably would have kept something like Igor’s thesis from getting approved.

June 19, 2005

Quote:
It’s not unusual in academia to be faced with having to decide what to do with students who seem to be enthusiastic and work hard, but don’t perform at an acceptable level. There are lots of reasons to just pass them with the lowest possible grade (for one thing, this gets rid of them). One of my colleagues refers to this as the “infinitely elastic C-minus”.

Peter,

It’s about time that we professors recgnize the damage we do to ourselves and our community by doing this. It’s certainly an expedient action, but it does tremendous damage to our credibility.

It is an open secret in many places (Wall Street, for example) that a degree in mathematics— undergraduate, masters, or doctorate—even from a good school, tells you absolutely nothing about a person’s ability to use mathematics. The Bogdanov affair is only a particularly public example of something happens quite often. Is this really how we want it to be?

16. **JC**
June 19, 2005

Some folks completely refuse to believe they're wrong, regardless of how many times they're hit over the head with a stick?

17.
June 19, 2005

quantoken, do you ever tire of being wrong?

18. **Quantoken**
June 19, 2005

Peter:

It was easy to call the other side logically incoherent or complete idiot or things like that when they have published something that you can not make sense of. But consider that:

1.These brothers are surely intelligent. They got an IQ of 200. Admittedly they have practiced and trained for it (well, you can say that for virtually all student exams, as well). But Peter or any one try to get an IQ test score of 200. I bet you can't. I can't. No one I know can.

2.They clearly have spent a lot of time, energy working on the stuff. As Lubos said, all the formulas and equations they cited are correct. And they make correct references to names of people and all that.

If they have better intelligence than you, and have spent **10 years** to come up with the ideas. And you have spent **10 minutes** reading their stuff and could not understand it. The more plausible case is they may really have some good ideas that you are simply not capable to appreciate, versus the other possibility that they are complete idiot with 0 IQ, and that their brain can not think coherently.

Althought scientifically, all those are still nonsense regardless how the logic works. If you can not explain anything in nature, your theory is still worthless as far as science is concerned. This has nothing to do with intelligence.

Quantoken

19. **Peter Woit**
June 19, 2005

Quantoken,

There is a difference between the Bogdanov papers and most of the string/M-theory literature. A more or less typical paper on hep-th these days starts from a set of assumptions about string/M-theory, then goes on to make various arguments and do various calculations based on the assumptions. Most of the time these arguments and calculations make sense, if you accept the assumptions. The problem is that the assumptions are incoherent and don't really make sense.

As an example, consider the Douglas et. al. statistical counting arguments and calculations. You can definitely follow the logic of their argument and calculations, even though the starting point, a mish-mash of ideas about string theory, branes and the anthropic principle, is completely incoherent and there is no rational reason to believe that any prediction about physics can ever be derived from it.

The Bogdanov papers are different. There are huge leaps of logic from one sentence to the next, clear examples of misunderstandings of basic ideas by the authors, etc. The problem isn't their assumptions, but that they can't construct a coherent argument and don't understand the technical tools they are using. This makes their papers look a lot like Sokal's hoax paper, except that their papers aren't (intentionally) funny.

I don't think I'd have any problem winning a court case against the Bogdanovs (for one thing, I think I have strong cause for legal action against them since they published an intentionally mistranslated version of my words). But getting involved in something like that would be a huge waste of time. And now the fact that a Harvard faculty member is going around claiming that their papers make sense and are of value would make the whole thing much more difficult.

Similarly, I'm not going to waste time pointing out all the problems with the Bogdanov's manuscripts. This has been done elsewhere, by John Baez and others. When people like the Bogdanovs publish papers containing wrong arguments and leaps of logic, what they most want is for someone more knowledgeable than them to take their ideas seriously and devote time to figuring out exactly what is wrong with their arguments and thinking hard about whether or not their logical gaps can be filled in. They're lazy, convinced they are geniuses because of their vague conjectural ideas, and hoping that someone else will do the hard work necessary to turn their incoherent conjectures into something that makes sense. In this case I don't believe it is possible to do this, and any time spent on showing this would be completely a waste.

20. **Fabien Besnard**
June 19, 2005

Hello.
I think a clarification is needed here. The brothers have been harshly criticized for a very precise reason : in their last book they misquoted some people (including Peter Woit) as if they supported them, or at least as if they thought the brothers' work were meaningful. I first pointed this (here), then a french journalist talked about it and the brothers suited him, I just can't imagine for what motive. I don't know if the procedure is still on its way.

I agree with Peter that talking about this affair now only serve the brothers' commercial interests, so I won't make any further comment.
Best regards.

21. **steve**
June 19, 2005

As far as I know, complaints from readers about the paper started coming in to the Editorial board of J. Classical and Quantum Gravity before the whole affair blew up, which is unusual. If the brothers are going to start sueing people now for criticising them then any sympathy that I (and other people) might have had for them is gone because this is a good way to help kill science and open scientific debate. However, I don't see how they could realistically expect to sue someone in this way. I imagine though (or hope) that it is the 'crackpot' or 'fraud' label they don't like and not impersonal criticisms of the work itself. This could probably be considered defamation of character and grounds for a lawsuit.

Even if there are seeds of really good ideas in their papers (which there might be) there is such a stigma attached to this whole affair now that no-one is going to continue with or explore the questions they address using the methods they suggest, even if that person(s) could develop or improve the whole approach. Do you think any career-minded person(s) is ever going to write a paper with both "topological field theory" and "initial singularity" or "KMS states" in the title and have the brothers' papers in their reference list? Anyone doing such a thing is going to be instantly labelled crackpot. Also, I doubt any journal (esp CQG) or even the arxiv would accept it. Not that I am saying this is right but this is just the way things are.

22. **Quantoken**
June 19, 2005

Peter said:
“I feel somewhat constrained in what I can say about the details of this, due to the fact that someone I’ve been in contact with tells me of being **threatened with a lawsuit** by the Bogdanovs for having criticized them publicly. I’m also not about to engage in discussion of the details of their nonsense, which is what they, like all crackpots, really want. It’s just a complete waste of time.”

You repeated that several times. Are you really this weak-nerved that you really take such threat seriously? If they sue then let them sue. I do not see you have anything to lose just for being actually sued.

Frankly I do not see any ground for a legitimate law suit just because you discuss and criticize the content of their paper. On the contrary, the fact that you repeatly call them crackpots, without discussing any of the facts that leads you to do so, could well be used as a ground for suing you for defamation.

So just for the purpose of avoiding being sued, you should start criticizing and analysing about their papers in more details, instead of just blanketly accusing them to be crackpots.

Quantoken

23. **Quantoken**
June 19, 2005

Peter:

I do not think Lubos become a supporter of the brother just because he made some comments that looks fair, reasonable and balanced. He made some good points that the brother’s papers raised some important questions. A paper could be well worth publishing even if just for asking the important right question along.

On the other side I do not understand why you have to **single out** these brothers for some harsh criticism, at an era that 99% of academic papers can already be accorded the same evaluation: nonsense and worthless.

The whole super string business is already nonsense since it does not explain a single thing we observe in nature. Does it make the brothers’ paper more nonsense than nonsense just because the presentation of their ideas does not seem very coherent to you? Or if they present the same idea, but in a more logically coherent and more readable ways, then you would not consider it nonsense in that case? **Why pick on unimportant details if the fundation of the whole thing of the whole field is already wrong and none-scientific, regardless of the mathematical details**?

The whole thing started when some one thought the brothers pulled a hoax, and it should end when the brothers point out that it was not a hoax. There is nothing especially wrong or especially bad in the paper of the brothers **comparing with the quality of the rest of academic papers**. The brothers even excelled in asking important questions and provided novel ideas, something that Lubos praised rightfully!!!

The important matter in the status of the affair, is the fact that nowadays in the field of theoretical physics research, it is no longer possible to distinguish between a serious paper, or a hoax. You could no longer tell if some one is dead serious or if he is joking around. That is the status of affair today.

Now, my own evaluation of the brother’s work: The whole idea is total nonsense to start with, regardless of the details. But that would also apply to many of other academic papers I see. So the brothers do not deserve any harsher criticism than the rest.

Quantoken

24.
June 19, 2005

I personally don’t find the paper terribly valuable, but I insist that its vagueness and strangeness is comparable to the vagueness and strangeness of other works about equally difficult and unknown subjects.

such as, for example?

25. **Lubo? Motl**
June 19, 2005

Well, I don’t need to comment on the description “a new supporter of Bogdanovs’ brother” because Peter Woit is obviously the only person here who thinks that this description is anything else than a stupid and childish exaggerated game.

The paper is not a complete nonsense. It is a mathematically detailed clarification of a vague but intriguing idea about a very difficult subject of the initial singularity of the Universe. It is a paper whose details have been improved for 7 months or so, to say the least, to satisfy the real physicists much more than at the beginning. And the local fragments of the paper now mostly reflect the correct definitions of the mathematical concepts and their basic relations.

If Peter Woit thinks that most sentences of the paper are wrong or that the paper has no idea, then it only shows that Peter Woit is uncapable to understand any paper published after 1900.

I personally don’t find the paper terribly valuable, but I insist that its vagueness and strangeness is comparable to the vagueness and strangeness of other works about equally difficult and unknown subjects.

26. **A Scott Crawford**
June 19, 2005

In all fairness, there is a problem evaluating any number of categories of doctorial level physics research, as advanced work commonly delivers raw data based on apparatus that lack a standardized metrology or operation.

The most obvious example of this is “quantum computing” work with ion traps. Because there’s not a high enough degree of consistancy (over 90%) between apparatus performance in different labs, there’s still not an established frequency standard for the time being. (I’m over simplifying). Thus only a casual review of claims or results out of a given lab are possible, strict confirmation and verification will only be possible a couple of years from now. Should doctorates be withheld in the meantime? Of course not.

Yet it's quite obvious that given the number of labs, and the wide spread of resulting research that's been published using standard equipment, that everyone cannot possibly be representing their work accurately (to put it gently). I think it's probably safe to assume that a large number of phd's given for quantum computing (ion trap) research are gifts, pure and simple. So what? By the time the dust settles (so to speak), the frauds will have moved on, the public won't know or care, and no fuss will be made by the physicists and engineers that know.

Just because it's clear there must be some frauds, there's no practical way to determine the genius from the cranks as of yet, so there's little one can do. And because one genius is worth ten cranks, the best course of action is to hold ones nose and wait. If its genius it'll persist.

27. **Juan R.**
June 19, 2005

Sincerely, I am not sure if it is a Lubos trick.

Often one revise literature that is really wrong but contain one or two ideas really interesting that one would investigate in deep.

How could i know if Lubos is talking seriously or simply doing a joke?

Instead of title of this blog

Bogdanovs Gain a New Supporter

i would prefer

Does Bogdanovs Gain a New PARTIAL Supporter?

28. **Juan R.**
June 19, 2005

"Lubos deleted one of my comments about this on his blog, so I won't bother writing there, but will comment here. It's true that I did accuse him of joining the crackpots, and he has every right to delete things he considers personal attacks, but given his general style of dealing with people he disagrees with, this is kind of funny."

Also is funny your erasing of my past post here!!

29.
June 19, 2005

As a post doc, at a leading university, in the 80's, I was witness to at least one PhD thesis on string theory that was refereed by well known people and approved by them, while those who actually knew something about how these theses produced realized that there was nothing new in them, and that at least one was plagiarized.

The problem at the time, was that the subject was developing very fast, there were very few experts with sufficient overview to referee every thesis, and almost all senior people simply had no clue.

I was also witness to how some leading string theorists with physics background, were totally taken by younger ones who used the jargon of algebraic geometry so heavily that no onen could tell if anything they said made sense, but one thought "It must make sense, because it's highly unlikely that someone can make all this up". Not true.

I realized already at that time that it's entirely possible that someone can master the jargon of a highly technical subject and manage to produce papers that get published in leading journals, while these papers have no content whatsoever.

I would be very happy to give detailed examples with names, but I don't want Peter Woit to be hit with legal action.

Another problem that I noticed is that, if any starts to make waves or to question the authorship and/or content of a paper by a PhD student and/or young researcher, people around him, and particularly his supervisor may not like that at all, and the person who questions things ends up being the bad guy. People just don't want this kind of headache. They want students to graduate and go away.

30.
June 18, 2005

Speaking of LQG, Lee Smolin posted a new response this morning in the topic, "Response From Smolin."

31. **quantumhobby**
June 18, 2005

Peter wrote:

One of the reasons why I like to read this blog is that Peter does not pull any punches. I had a few professors in college who gave me 'C's that I probably didn't deserve. I used to think they were just being generous — now I know the truth. 🙂

32. **Wolfgang**
June 18, 2005

> You have written simplicial gravity
> papers yourself
Indeed. I am one among the many who failed
to solve the puzzle (so far).
At this point I hope that somebody will find
the solution and do not care who will find it,
Lubos, Renate or anybody else.
But I would expect that some new experimental
evidence will be needed as guidance.

33.
June 18, 2005

Lubos attacked the CDT approach several month ago.
You can follow this link
http://yolanda3.dynalias.org/tsm/tsm02.html#20041218
for (one of) the discussions about it.

Wolfgang Beirl! You have written simplicial gravity papers yourself, if I remember. I visited your family website quite some time ago, an attractive picture of life in Bahamas.

Thanks for the link.

I wonder if Lubos will use similar arguments the next time he attacks CDT, or if he will try different.

34. **Wolfgang**
June 18, 2005

Just one more remark.
Quantization of 2+1 gravity is possible
without super-strings and Regge-Ponzano
is an example of lattice gravity in 3d.

So, whenever Lubos rides a general attack against
LQG, CDT or other non-string approaches, check
first whether his argument distinguishes between
3d and 4d (the ones I heard from him usually do
not).
If not the argument cannot be valid …

35. **Wolfgang**
June 18, 2005

Dear "",

Lubos attacked the CDT approach several month ago.
You can follow this link
http://yolanda3.dynalias.org/tsm/tsm02.html#20041218
for (one of) the discussions about it.

36.
June 18, 2005

Hi Aaron,
I remember your mentioning Ambjorn et al CDT as an interesting quantum gravity rival to string, in the other thread.
I guess in any research line there are some who are generous towards rival efforts (and permit themselves to be sincerely interested in them) and there are others who habitually attack or condescend. I value the former a lot.

my simplified model of Lubos is that whenever he talks about quantum gravity alternatives to string he will tend to attack whatever he sees as the most dangerous threat to string prestige. (clearly unfair to Lubos and an oversimplification, he would not be so amusing if he were predictable, but that's my model)

So I am expecting Lubos to attack CDT presently, because I see it as the most threatening from his standpoint. I would not be surprised if he were getting into position.

BTW one of the CDT leaders is a woman named Renate Loll, as you doubtless know since you've read one or more of her papers. Apparently she and Ambjorn invented the approach in 1998—their first CDT papers are from then.

37. **Aaron Bergman**
June 18, 2005

I think it is at least safe to say that on the whole string theorists don't even know what a TQFT is.

Nice of you to generalize from two examples.

38.
June 18, 2005

Lubos refers to Majid as "One of the co-fathers of quantum groups". With all due respect, that's plain silly, and shows how little he knows about the subject and how inclined he is to hyperbole.

39. **Peter Woit**
June 18, 2005

Lubos deleted one of my comments about this on his blog, so I won't bother writing there, but will comment here. It's true that I did accuse him of joining the crackpots, and he has every right to delete things he considers personal attacks, but given his general style of dealing with people he disagrees with, this is kind of funny.

One point I made in my comment is that Lubos's claim that "this is one of the punch lines that shows that they're either pretty smart or someone helped them: the observables are replaced by homology cycles on the moduli space of gravitational instantons" is ridiculous. That homology classes on a moduli space are the observables is nothing but the definition of this kind of TQFT. He's impressed that they can repeat the definition????

When this all happend in 2002, another string theorist circulated e-mail to his colleagues attacking John Baez and demonstrating an impressive lack of understanding of TQFT (he believed that a TQFT doesn't depend on the Lagrangian). Between that demonstration of ignorance and Lubos's new one, I think it is at least safe to say that on the whole string theorists don't even know what a TQFT is.

40.
June 18, 2005

Alejandro: *It is a trick, isn't it?*

same thought occurred to me, on first reading Lubos post.
setting up to go thru the motions of applying similar criteria to
some serious work that he wants to discredit
but I would not have voiced my misapprehension
(thinking it too mistrustful on my part) except
that you mentioned it. Yes, it could be a "set up".

41. **Alejandro**
June 18, 2005

It is a trick, isn't it?

Various Math and Physics Links

June 21, 2005
Categories: Uncategorized

Here's a collection of interesting things I've run across recently:

A website devoted to Hermann Weyl. The author is a religious sort, but of the good kind.

A movie taken at the 1927 Solvay conference. It is on the website for "The End of the Certain World", which is a biography of Max Born. I've read the book and some of it is interesting, but I have little sympathy for one of its themes, that Born felt he didn't receive enough recognition for his work (he got his Nobel Prize in 1954, long after many other Nobel prizes were given for quantum mechanics). Frankly I think any physicist like Born who had the incredible luck to be at Gottingen in 1925-26 should have spent the rest of his life thanking his lucky stars and not complaining about his career.

Harvard mathematical physicist Arthur Jaffe has a website. In particular the site has some interesting expository papers, including an autobiographical memoir about the IHES in the early 60s, a survey of constructive quantum field theory, and a work in progress, an introduction to quantum field theory from a rigorous point of view.

There's a recent lecture by Eric Zaslow on Physics and Mathematics which he gives the supremely ugly name of Physmatics.

Some of the lectures from String Phenomenology 2005 in Munich last week are on-line. Lots of talks about flux vacua and the landscape, nothing that seems to have the remotest connection to physics. For a report from the conference, see Robert Helling's weblog.

The talks from a conference held at Potsdam in April on Geometry and Physics after 100 years of Einstein's Relativity are available.

The Bonn Arbeitstagung is a summer conference that was started by Friedrich Hirzebruch in the late fifties, and which often has been the site of announcements of important developments in mathematics. The 2005 Arbeitstagung ended last week and notes from the talks are on-line.

   June 23, 2005

   Nice collectin, thanks. 🙂

3. **Peter Woit**
   June 23, 2005

   Hi Tony,

   Those stories are in the book. Born's complaints weren't so much about his problems fleeing the Nazis as that Heisenberg got a Nobel prize early on and he didn't until much later. I guess he thought the first prize for QM should have recognized the Born/Heisenberg/Jordan work, not just Heisenberg. One problem with this is that Jordan was a Nazi, and the Nobel committee wasn't enthusiastic about recognizing him.

4. **Tony Smith**
   June 23, 2005

   Peter, you say that you "… have little sympathy for one of its themes, that Born felt he didn't receive enough recognition for his work …".
   I have heard (no scholarly references, just gossip) that Born was as you indicated, somewhat insecure and feeling unappreciated, and that he felt such an insecure chord of emotion when he arrived (fleeing Hitler) at the Cambridge train station. One of the buildings most visible from the station was a movie theater whose marquee showed the movie title "Born to be Hanged".

   Further, he expected that he would stay in Cambridge as a professor there, and when he realized that Cambridge was only a first stop at which those fleeing Hitler were sorted out and matched up with available positions, he felt yet another chord of emotional insecurity and feeling unappreciated.

   (Maybe all that is in the book, but I have not read it, and I don't know.)

   Tony Smith

   Did I miss something or you can tell it from the bright of his eyes?

6. **Nat Whilk**
   June 22, 2005

   It would make more sense for the author to have a pair of sites.

   With any luck, it will be trichinella.

7. **robert**
   June 22, 2005

   Thanks for that Peter – the Solvay ‘home movie’ made my day.

8. **D R Lunsford**
   June 22, 2005

   “Physmatics” – utter idiocy. How can people write such drivel with a straight face?

   The Weyl site is nice, but vastly understates his influence, and somewhat misrepresents his work on gauge invariance.

   The Solvay movie was great! You can see that Dirac was rather genial as a youngster, while Pauli seems to have always been a five-foot scowl. Ehrenfest seems almost giddy – no evidence of his impending suicide.

   -drl

9. **Levi**
   June 21, 2005

   I always appreciate it when you post such links. I bookmarked the Jaffe site. The Weyl site is certainly a strange combination of things though. It would make more sense for the author to have a pair of sites.

10,500 vacua!

June 26, 2005
Categories: Uncategorized

According to today's New York Times, "string theory allows for a vast number – 10,500 – of possible 'worlds' wth different self-consistent sets of laws and constants." If 10,500 is "vast", I wonder what 10^{500} is? I also wonder how long it will take for the news to get through that actually this number is infinite, which is somewhat bigger than "vast".

The Times piece is an extract from a recent Scientific American article on variable constants of nature. It also includes the standard claim that M-theory is "the best candidate for a theory of everything", but perhaps an editor is editorializing by pairing this with the news from an astrologer that Saturn is going from Cancer to Leo and Mars is in Taurus. At least the astrologer is able to make predictions: "Many born during this summer of '05 … will impact the world greatly in years to come."

1. **Kea**
   July 4, 2005

   "Lubos Motl and I would imagine pretty much everyone who works on string-m-theory (i.e witten randall susskind) would disagree with you"

   Somehow I don't think so.

2. **dan**
   July 4, 2005

   "This simply isn't possible. Nature is far more sublime than this simplistic and overly classical view."

   lubos motl and i would imagine pretty much everyone who works on string-m-theory (i.e witten randall susskind) would disagree with you. obviously if the world as it exists in itself is NOT 11D SUSY then all the *physics* work on string-m theory is a waste, but at present we have no way of knowing/testing for that. of course the same can be said of non-SUSY spin networks/spin foam.

3. **Kea**
   July 3, 2005

   "what if the world as it exists is 11-dimensional SUSY and our world is one example of an actual Calabi-Yau manifold of 10^500 possible examples"

   This simply isn't possible. Nature is far more sublime than this simplistic and overly classical view.

4. **dan**
   July 3, 2005

   here's a what-if question i have for anti-stringy

   — what if the world as it exist is 11-dimensional SUSY and our world is one example of an actual kalabi-yau manifold of 10^500 possible examples, and that particles are 1-D strings vibrating in 11D as described by the mathematics of string theory.

   wouldn't this scenario justify continued research into string theory for as long as there is physics?

   of course, i've read lubos motl's objections to LQG on his website, and the same what-if applies there (what-if space-time is only 4d non-SUSY, and is described on the planck scales as discrete spin networks would justify continued research into LQG despite its current difficulties)

5. July 3, 2005

   quoted

6. **Alejandro Rivero**

   Phys.Lett.B149:351-356,1984 is sometimes quotes as the initial commentary on axions in string field theory.

7. June 30, 2005

   thanks for the correction, you were right. it now looks to me like 5 landscape talks

   Frederik Denef, Rutgers University
   Constructions and distributions of string vacua (review talk)

   Michael Dine, Santa Cruz Insitute for Particle Physics
   Branches of the Landscape

   Michael Douglas, I.H.E.S., Rutgers University
   Is the number of string vacua finite?

   Shamit Kachru, SLAC, Stanford University
   A classical type IIA landscape

   Fernando Quevedo,University of Cambridge
   Exponentially large extra dimensions and soft supersymmetry breaking in type IIB flux compactifications

   Plus add to that Susskind's which is one of the two public lectures, to get an overall idea of what sort of showing.

8. **Peter Woit**
June 29, 2005

Well, presumably Denef will be talking about the landscape since that is what he has been working on. And Quevedo's work is also part of the KKLT program, see http://www.arxiv.org/abs/hep-th/0505252

The only other talks related to particle physics unification are Arkani-Hamed's and de Roeck's. de Roeck isn't even a string theorist and presumably will have nothing to say about string theory. Unless Arkani Hamed has figured out some way of using string theory to say what will happen at the LHC, his also won't be about string theory.

So, the only talks that actually involve the idea of using string theory for particle physics unification are the landscape ones. Possible exceptions are Witten, depending on what he has to say about string theory axions, and Yau, who presumably is talking about non-Kahler backgrounds, something which would really make the number of backgrounds infinite…

Looks to me like string theorists have de facto given up on using string theory to do particle physics unification, with the only people still pursuing this the crazies lost in the landscape.

9.
June 29, 2005

in String 05 programme the title of Arkani-Hamed's talk has been posted as about the state of "HEP in year 2010", so not explicitly about landscape but more about impact of future experimental results, presumably.

so now I count 36 titles and only 3 are explicitly about landscape.

I think I counted 44 speakers, with 8 titles "TBA" and so 36 titles listed and only 1/12 of them about landscape.

of course there is the hoopla public lecture by Leonard Susskind with a title to whet the itch of religious curiosity, but that is in the media window of string, which I think is different from the talks.

10. **D R Lunsford**
June 29, 2005

Dear F. Uckoff,

What do you find remotely interesting? There isn't a single idea in the entire lot. It's the pounding of hammers on a steel plate.

-drl

11.
June 28, 2005

To continue the "content analysis" of Strings 05 lineup, the breakdown could be that, while a few are in Landscape, many of the others are in Escape

in other words, to avoid thinking about basic problems, which are a headache, think about black holery/cosmology instead, or read Lord of the Rings.

I counted only three titles about Landscape (out of the 35 titles listed so far)

Michael Dine, Santa Cruz Insitute for Particle Physics
Branches of the Landscape

Michael Douglas, I.H.E.S., Rutgers University
Is the number of string vacua finite?

Shamit Kachru, SLAC, Stanford University
A classical type IIA landscape

admittedly there are the 8 remaining TBA talks, some of which could turn into landscape, like

Nima Arkani-Hamed, Harvard
TBA

12. **Peter Woit**
June 28, 2005

I don't know Douglas personally, and I wasn't accusing him of "making up" stuff he doesn't believe in. I have no reason to believe that he is cynically saying one thing and believing another.

But, you can read about the last time I saw him in person here. I think the fact that he is pursuing a research program that has no plausible hope of ever producing a prediction of anything means that he is doing pure pseudo-science, and the fact that many others are joining him in this is extremely disturbing. And I don't think this is a minority opinion in the physics community. I've found very few string theorists willing to defend what Douglas is up to. People like David Gross and Lubos Motl have made their views about this publicly known, and many, many others privately feel the same way.

Douglas is not the only one whose utter refusal to acknowledge the failure of the string theory has led him to work on things that make absolutely no sense. He, Susskind, and others though, have gone beyond just the standard string theorist's wishful thinking and have completely abandoned the usual norms of what it means to do science.

13. **Kyle**
June 28, 2005

That's funny, I read "Well, Douglas has to either come up with a reason for the number to be finite…" to mean that there has recently been an argument that the number is actually infinite, and he'll have to have a better argument to make his case.

That seems less like a strong acusation and more like common sense to me.

14. **Chris Oakley**

June 28, 2005

I'm not sure about that, Fyodor. Cosmology is more a topic of conversation for those participating in the use of banned substances rather than an exact science.

15. **Fyodor Uckoff**
June 28, 2005

"they are all bullshit nevertheless"

What struck me about the list of titles was how interesting many of them look. Unlike the dreary drivel that is posted here whenever PW goes on holiday and the lunatics take over the asylum.

16. **D R Lunsford**
June 28, 2005

Good point, _____. Those papers are not about string theory, but they are all bullshit nevertheless. Getting shed of strings will not solve very much.

-drl

17. **M**
June 28, 2005

Many people who read what you said will read it as: "Oh, of course he will MAKE UP SOMETHING rather than admit what he did was a failure." I think this is a very strong accusation, and if it is not one you want to make, you should be more careful.

I agree this would be a strong accusation, if that were what Peter is implying. It is certainly possible interpret his words that way, but such an interpretation would itself be a form of accusation that Peter is carelessly assuming Douglas has less-than-noble motives. Implied accusations can work both ways…

Assuming that Douglas will probably prefer a rationalization over admitting his program is wrong just seems like a recognition of common human nature — if you have invested a lot of time, energy and professional "capital" into a program, it can be very hard to admit to yourself that it was a mistake, and usually even harder to say it to others. It is very human to believe and rationalize what one wants to believe, and recognizing that is a far cry from implying questionable ethics. And so far, Douglas hasn't seemed to openly question the idea of statistically "analyzing" the landscape, at least that I have heard…

18.
June 27, 2005

that other anonymous said*Many people who read what you said will read it as: "Oh, of course he will MAKE UP SOMETHING rather than admit what he did was a failure." I think this is a very strong accusation…*
heh heh now we have an argument amongst the nameless, because I think what other anonymous says sounds silly. Landscape is speculative mush, so IMO there is no chance for someone to distort findings. no way can one impute reprehensible scholarly misconduct to anybody.
Mike Douglas seems to me (on admittedly very little clues) to be a totally nice sincere person and I attribute to him scholarly integrity in spades, but the whole thing is so iffy that how could he NOT look on the bright side and emphasize reasons to hope it's finite.

19.
June 27, 2005

"Well, Douglas has to either come up with a reason for the number to be finite, or admit that the research program he has promoted heavily for the last couple years is a complete failure. I'm guessing he'll go for the first alternative."

May I ask if you know Douglas in person? Or, more to the point, what you think of his academic integrity? Do you think he honestly explores and says what he thinks is true, or do you think even when he thinks something doesn't work, he spins things in a way that would make string theory good?

Many people who read what you said will read it as: "Oh, of course he will MAKE UP SOMETHING rather than admit what he did was a failure." I think this is a very strong accusation, and if it is not one you want to make, you should be more careful.

20. **Torbjorn Larsson**
June 27, 2005

Nitpicks: "good we are halfway there" – is of course correct in orders of magnitude if they started out at ~ 1 watt (not Watts; see SI measures).

21.
June 27, 2005

I did some "content analysis" (simple counting) of the titles of the talks on the String 05 program. 43 speakers were listed but 8 titles were TBA leaving 35 titles of talks.

Of these 35, a rather large number seemed to be about cosmology, or about black holes/rings. So I counted those up and they came to 14.

In other words 40 percent of the scheduled talks were about black holes or some cosmic topic. Many had appealing titles like Strominger "Fun with Black Holes" and Tye "Wavefunction of the Universe". In case anyone might be interested, here are those 14 titles:

Melanie Becker,University of Maryland
M-theory Cosmology

Iosif Bena, UCLA
Geometric Transitions, Black Rings and Black Hole Microstates

Atish Dabholkar,Tata Institute of Fundamental Research
Going Beyond Bekenstein & Hawking Exact and Asymptotic Degeneracies of Small Black Holes

Henriette Elvang,UC Santa Barbara
Black rings

Gary Horowitz, University of California Santa Barbara
A new endpoint for Hawking evaporation

Renata Kallosh, Stanford
String cosmology and the index of the Dirac operator

Per Kraus, UCLA
Attractors, Anomalies, and Black Hole Entropy

Joseph Polchinski , KITP, UCSB
Update on cosmic strings

Ashoke Sen, Harish-Chandra Research Institute
Extremal black holes in higher derivative gravity

Eva Silverstein, SLAC, Stanford University
The Tachyon at the End of the Universe

Andrew Strominger, Harvard
Fun with Black Holes

Henry Tye, Cornell
Wavefunction of the Universe

Erik Verlinde, ITF, Universiteit van Amsterdam
A Matrix Big Bang

Bernard de Wit, Institue for Theoretical Physics & Spinoza Institute, Utrecht University
Supersymmetric Black Hole Partition Functions

Here is the full list:
http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/speakers.html

I suppose the above count could be meaningless, or it may simply confirm what has already been said as regards shifting emphasis in string research.

22.
June 27, 2005

Quantoken wrote: "God is not capable ot doing that, since he created just one universe"

You know this for a fact? 🙂

23. **Quatoken**
June 27, 2005

Anonymous said "I can only assume that everyone at the New York times is **mathematically illiterate** and don't know what 10^500 actually means"

Most people ARE mathematically illiterate in failing to appreciate how big 10^500 actually is, that include any one who may believe there is a difference between 10^500 and infinity. 10^500 is a finite number in strict mathematical sense, but for all practicality purpose that is physically meaningful, 10^500 IS an infinity, and there is physics difference between the two.

To appreciate how big the number is, let say we just do a simple enumeration and simply list all the 10^500 vacuas, each entry costs one English letter to list. How big will the entry book be, will it be larger than the Encyclopedia Britannica?

The answer is the total quantum information the whole universe can register is merely 10^120. So even if we turn the whole universe into a huge quantum memory chip, it is 10^380 times short of just to enumerate the list of possible vacuas. It would take 10^380 universes just to do that. Even the almighty God is not capable ot doing that, since he created just one universe.

So string theory ceased to have any remote connection to science once up to 10^500 different vacuas were proposed to be possibly "exist". Go to the other 10^380 universe to research it. Our universe is simply **pitifully too small** to allow the kind of crap like 10^500 vacuas.

Quantoken

24.
June 27, 2005

10,500 is a lot of vacua! I can only assume that everyone at the New York times is mathematically illiterate and don't know what 10^500 actually means! Would not surprise me in this day and age.
I remember hearing about a some idiot senator commenting on a 'star wars' laser system. He was told they had a system that currently operates at 10^4 Watts or something like that but for actual defence purposes would have to be 10^8 Watts (don't know the exact numbers), to which he replied, "good we are halfway there". Don't know if this anecdote is true but it probably is.

25. **Peter Woit**
June 27, 2005

Well, Douglas has to either come up with a reason for the number to be finite, or admit that the research program he has promoted heavily for the last couple years is a complete failure. I'm guessing he'll go for the first alternative.

But from everything I've heard, he makes the number of vacua finite by introducing a cut-off, and one expects things then to depend strongly on the cut-off. The interesting question will be whether he has a plausible argument for cut-off independence.

Also note that a couple years ago the big question he and others were pursuing was "how many vacua?": if the number was 10^100 that was good, if 10^500 that was bad (no predictions possible). Now he seems to have given up on that and is worrying about finiteness. I predict that at Strings 2007 he'll speak about "Is the number of string vacua countably or uncountably infinite?"

26.
June 27, 2005

Douglas is going to give a talk called

Is the number of string vacua finite?

The word I hear is that the answer is going to be, effectively, *yes*.

27.
June 27, 2005

I now see there is a list of the titles of the talks here:

http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/speakers.html

the other link gives the schedule:
http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/program.html

28.
June 26, 2005

The tentative programme schedule for July 11-16 "Strings 05" has now been posted. However so far it just gives the speakers' names without titles of talks:

http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/program.html

29. **FineStructure**
June 26, 2005

I wonder when people would realize the difference between 10,500 and 10^500. I wonder which of the prediction would turn out to be correct. I predict none

30.
June 26, 2005

Poor english. The word "fanatic" does not necessarily mean crackpot. I would call anyone who has spent a considerable amount of time on a particular subject a fanatic.

31. **JC**
June 26, 2005

I've always wondered what makes a particular topic attractive to fanatics, whether it's astrology, Marxism, Ayn Rand, string theory, supply-side economics, evangelical Christianity, extreme Islam, etc … The only common feature I can think of in these particular topics of interest to fanatics, is that they all seem to promise and/or portray a precise worldview "vision" of some sort. It's as if the particular topic's "doctrine" is portrayed as a concise map to a "promised land" of some sort, whether metaphorically or literally.

In the real world, most things seem to be a lot more uncertain and messy to deal with. ("Utopia" is rarely ever found in this world). Fanatics in general don't seem to be attracted to things which cannot be viewed in a "black and white" manner. They don't seem to like subjects which requires one to view things in "shades of grey".

Awhile ago I read Eric Hoffer's book "The True Believer – Thoughts on the Nature of Mass Movements", which discusses the mindset of fanatics and the dynamics of the mass movements they run.

Witten on CNN

June 28, 2005
Categories: Uncategorized

Via David Goss and Lubos Motl, the news that CNN's Candy Crowley has a piece about Witten. Unlike Lee Smolin's Why No "New Einstein"? piece, CNN more or less identifies Witten as the new Einstein. Witten is quoted as giving the following rather defensive statement about string theory: "I just think too many nice things have happened in string theory for it to be all wrong… Humans do not understand it very well, but I just don't believe there is a big cosmic conspiracy that created this incredible thing that has nothing to do with the real world." He's kind of defending against a straw man, since virtually no one is saying string theory is "all wrong" or "has nothing to do with the real world". It quite possibly can provide some sort of dual description of QCD, and that is what much research in string theory these days is aiming for. On the other hand, the conjecture that you can make a unified TOE using string/M-theory in 11 dimensions at this point shows every evidence of being all wrong.

Comments

1. **D R Lunsford**
   July 4, 2005

   Having mass means having a rest frame. In such a case the idea of "left" and "right" neutrinos disappears, and so any Lagrangian built only on (1+y5), which projects out the heretofore unphysical right-handed neutrinos, is going to be wrong. So I assume one adds in some terms in (1-y5) which go to zero with the neutrino mass. But then the mass has suffered from "scope creep". It's complicated.

   -drl

2. **dan**
   July 3, 2005

   i've wondered if neutrinos have mass, does this imply velocity can change if forces act on it?

   "GUTS, both SUSY and non-SUSY, only achieve "unification" by introducing a whole new very problematic Higgs sector to break the new unification symmetries they introduce. This has never been very convincing."

   i am aware that GUT's make predictions like proton decay that have not been verified. Do you think the strong nuclear force can be unified with the electro-weak force if you find the higgs sector to be unconvincing?

3. **Juan R.**
   July 2, 2005

   The situation with string M-theory is specially simple.

   All, exactly all physics, predicted in the past by string theorists was wrong. This indicate, at least to me, the profound misunderstanding of nature that they have.

   Initially, I studied string M-theory, including very recent material like stwing or non-commutative M(atrix) theory. All was wrong, and often the math involved simply ridiculous.

   Seiberg-Witten paper in non-commutative geometry and string theory is very simplistic from a mathematical point of view (specially when one already worked with the non commutative star products in the phase space representation of quantum mechanics). Thus, I remained perplexed of the low level of string literature (when compared with popular claims on books and conferences). In many aspects, string theory is outdated. This is claimed in many published papers and conferences. For example, in the last conference Quantum future, Claus Kiefer and Erich Joos said

   "*this is even true for tentative frameworks such as GUT theories or superstring theory. Although the latter may seem 'exotic' in some of its aspects (containing D-branes, many spacetime dimensions, etc.), it is very traditional in the sense of the quantum theoretical formalism employed*."

   Very traditional may be read "outdated" regarding, for instance, sophisticated experiments with fullerenes.

   I am astonished that the self-proclamed ultra-advanced NC string theory (a radical modification of usual string theory in fixed background/cosmologies) used, in the last decade, advanced math developed in other fields of science by Prigogine and the Brussels School in the **60s**. The delay of the ?ultra advanced? theory is of most than 30 years for a supposed "profound" theory that, in the words of Brian Greene, is providing us the most basic understanding of nature! This is, obviously, false, simply propaganda.

   The same situation arises in recent TFD Dp-brane theory. Today, string theorists are very excited with the new formalism (was unknown for them), but people that developed TFD in the past (were not string theorists) now are developing TFD II. Again, string M-theory is outdated.

   What is correct in string theory (like a TOE)?

   Simply nothing!! It is a waste of time.

   Of course, the claim of that string theory quantizes gravity or predicts GR is false propaganda.

   String theorists are well known due to their falsification of true. This is the reason of this blog.

   For example, in his Elegant Universe, Brian Greene explained to many people that the observed 4D geometry of universe was explained from string considerations or that the concept of pointlike particles was substituted by the concept of strings, for example.

   Curiously, he forgot to comment to public that string is an approximation and that the only known formulation of M-theory is a quantum mechanics of pointlike particles (D0-branes).

   Ok, but can string theorists explain why universe look like 4D? According to Brian Greene popular book, that was explained by Brandenberger y Vafa.

   To the question

   – If these extra dimensions exist, does string theory offer any explanation of why there are apparently three space dimensions larger than the rest?

Witten recently replied

– That’s a big problem that has to be explained. As of now, string theorists have no explanation of why there are three large dimensions as well as time, and the other dimensions are microscopic.

4. **Peter Woit**
July 2, 2005

There’s very strong evidence at least for neutrino oscillations, and I don’t think there’s any known way to explain this withough giving neutrinos mass.

The argument that the neutralino could be a dark matter candidate is the kind of thing that I had in mind in saying the arguments for supersymmetry are very weak. For one thing, you have no idea what the mass of a neutralino in these theories is, choosing it to solve the dark matter problem just looks to me like wishful thinking.

GUTS, both SUSY and non-SUSY, only achieve “unification” by introducing a whole new very problematic Higgs sector to break the new unification symmetries they introduce. This has never been very convincing.

5. **dan**
July 1, 2005

thanks for answering some of my questions. as for SUSY, it’s been said the strongest candidate for cold dark matter is a SUSY-photon/higgs boson called the neuatralino.

the standard model does not yet unify electro-weak with the strong nuclear force, and most such unification scenarios predict proton decay and magentic monopoles. it’s my understanding that non-SUSY unification scenarios predict unobserved short half-lives of protons, so what is left is SUSY-unification scenarios of the standard model.

by the way, do you think neutrinos have rest mass?

6. **D R Lunsford**
July 1, 2005

Strange. Fourth order equaitions fill me with horror, although you can see how the string guys with a world tube have to deal with the sort of things ruled by 4th order equations in elasticity. So this must be why anyone would even consider it. Weyl’s theory in 4d died from 4th-orderness. Again, it’s like mangling some colossal Scrabble Lagrangian so that it churns up something resembling QED.

7. **Peter Woit**
July 1, 2005

Hi Danny,

R^2 theories do have fourth-order equations of motion in the metric variables, thus problems with unitarity and causality. Some people (e.g. Hawking) at times have claimed that maybe these can be dealt with. More positively, these theories are renormalizable.

All known approaches to quantum gravity have one problem or other.

8. **Peter Woit**
July 1, 2005

The standard model isn’t a theory of everything, in particular it isn’t a theory of cosmology. It’s a theory of what particles and fields there are and how they interact (excluding gravity). As for the specific questions you ask:

matter/antimatter asymmetry: where this came from is a cosmological question. In conventional cosmological models, you can take advantage of various features of the standard model (CP violation, electro-weak symmetry breaking) to get mechanisms that produce this asymmetry. Whether within such cosmological models these mechanisms are sufficient to produce the observed amount of asymmetry I believe is still an open question.

particle masses: this is perhaps the main weakness of the standard model. You have to put these numbers in by hand, whereas you would like the theory to predict them.

magnetic monopoles: there are no stable, finite energy magnetic monopoles in the standard model. This agrees perfectly well with the fact that they aren’t observed.

dark matter: again this is a question of cosmology and astrophysics. There is no particle in the standard model whose abundance in standard cosmological models would explain what dark matter is. Maybe there’s a new particle not known to the standard model, maybe something else is causing this.

dark energy: you can set the vacuum energy to whatever you want in the standard model, including the observed cosmological value. The vacuum energy has the same status as particle masses in the standard model, it’s an undetermined parameter.

SUSY: there’s no good reason to extend the standard model to a supersymmetric version. The positive arguments about what this buys you are weak, and supersymmetric models are much more complicated, have a hundred or more extra undetemined parameters, and a host of other problems.

9. **dan**
July 1, 2005

Peter, when you speak of the standard model working so well, how does it explain the matter/antimatter asymetry? does it predict masses? why are there no magnetic monopoles? what is dark matter? what is dark energy? do you think the standard model needs to incorporate SUSY?

10. **D R Lunsford**
July 1, 2005

Peter, what are R^2 theories? Aren’t those fourth order in some context (and so loaded with unphysical solutions)?

-drl

11. **Kyle**
June 30, 2005

“This said, String Theory in it’s various forms and sects is a very useful theoretical tool,”

I’ll ask the question on everyone’s mind:

Useful for what?

12. **pseudo string fan**
June 30, 2005

Hi Chris,

Is it true that the LHC (Large Hadron Collider) will be used to find the super-symmetric particles that string theory has proposed?

A little background about me: I am a physics graduate in Hong Kong. String thoery appears too profound to me. But I am interested in its latest development.

13. **Chris Oakley**
June 30, 2005

Do String theories contribute? Yes. Isn't that enough?

No it isn't, and if I had known 25 years ago that the majority of particle "physicists" were apt to go on this quasi-religious quest just because Ed Witten told them to, I would have gone into molecular biology instead.

There is no, repeat, no experimental evidence to support string theory or even to suggest that it might be a promising idea.

14. **A Scott Crawford**
June 30, 2005

Juan,

I had to knock on wood to ward off the bad mojo that comes from slandering Newton! When it came to understanding the universe Newton was wise enough to defer to "angels" as a viable force when pressed;)

This said, String Theory in it's various forms and sects is a very useful theoretical tool, and I think those who'd pooh pooh them for their inability to be all things to all people are missing the point. There's an infinite variety of ways to view collections of data gathered across the spectrum of experimental apparatus, but there's very few ways to accurately identify generally observed trends for future practical refinement and advance of our total body of scientific understanding. Do String theories contribute? Yes. Isn't that enough?

15. **Chris Oakley**
June 29, 2005

Penrose seems to think highly of something called Twistor Theory.

This is a bit like saying "the pope seems to think highly of a religion called Catholicism".

16. **Peter Woit**
June 29, 2005

No, I don't want to elaborate on this. There have already been long discussions about this here, see for instance Lee Smolin's response I posted on June 15, 2005, as well as his exchange here with Larry Yaffe (August 19 and August 22, 2004).

In general my impression is that neither LQG nor string theory has yet given a completely satisfactory theory of quantum gravity. But the LQG program tends to work with well-defined concepts so you can at least see exactly what their problems are, whereas the string theory arguments often involve very ill-defined concepts and loads of wishful thinking.

17.
June 29, 2005

"…although arguably at least one of them (LQG) does a better job of it than string theory…"

Can you elaborate on the ways you think that this is true?

18. **Mike Crowley**
June 29, 2005

Hi Pseudo String Fan,

Your question is one I was asking myself two months ago. I'm not a scientist, just an interested layperson. The thing that helped me grasp some of the issues involved was reading Roger Penrose's chapters on String Theory in his book "Road to Reality." He deals with some of the difficulties with grand unification, and while I can't pretend I understood every word I did digest enough to recognize that there's more to the story than we get from a book like Michio Kaku's "Parallel Worlds." For me at least it was a real wake up call.

Penrose seems to think highly of something called Twistor Theory. He also includes a chapter on Loop Quantum Gravity and other potential avenues of pursuit.

Mike

19. **Peter Woit**
June 29, 2005

Hi pseudo string fan,

Despite what you might hear in some places, string theory doesn't actually now provide a consistent unification of quantum theory and gravity. The string perturbation series is divergent and no one knows what non-perturbative theory it is supposedly asymptotic to.

There are quite a few other attempts to unify quantum theory and gravity, none of them completely satisfactory, although arguably at least one of them (LQG) does a better job of it than string theory. Some of them are:

1. Loop quantum gravity

2. R^2 theories

3. “Induced gravity”

4. Various versions of triangulated or lattice gravity

5. Topological quantum gravity

and there are probably others…

20. **Peter Woit**
June 29, 2005

Hi Robert,

I voted yes on the CNN poll. Modulo the standard caveats about what one means by a “theory of everything”, I do believe that sooner or later we’ll have a theory that ties up the remaining loose ends of the standard model. Personally I think the fact that the standard model works so well means we’re actually rather close to what Weinberg calls a “final theory”. We might even be there now if so much of the effort of the last twenty years hadn’t been wasted…

21. **pseudo string fan**
June 29, 2005

If you don’t do string theory, with what theories can you bring general relativity and quantum mechanics together?

22.
June 29, 2005

I just wish Michio Kaku would calm down a bit.

23. **Robert**
June 29, 2005

So Peter, did you participate in the poll on the CNN web page?

24. **Juan R.**
June 29, 2005

String theory is, in the words of its more popular practitioners, the Final Theory: **the Last True**.

It was not designed like a dual representation of QCD, like an attempt to perturbatively quantize gravity alone or like a generator of mathematical ideas, it was studied, extended, thought in some High Schools, and popularized to public like the Final theory: the Theory Of Everything.

String theory is wrong; it has failed for explaining everything. It has failed for quantize gravity (perturbative series is not well defined and nonperturbative regime is unknown), it cannot explain GR (contrary to popular Witten claims string theory does not predict gravity, really string theory is adapted to previously known gravity), etc.

I partially agree with the idea of Witten like a new Einstein. Of course, the contribution of Witten to physics is irrelevant (Murray Gell-Mann advanced physics 10 times more than Witten). But I agree in that the emphasis of Witten on “his” string theory sound like the emphasis of Einstein in his unified field theory. Einstein didn?t understand other best theories developed in his time and Witten is doing the same error now.

String, stwing, M-theory, and all that stuff are a waste of time. *Since that their research is based in irrelevant mathematical formalisms and outdated concepts*. String M-theorists (here and thereafter SMt) are so arrogant that with a superfitial mathematical knowledge of other fields of science, they claim for a Theory Of Everything. *The list of outdated concepts and irrelevant mathematical formalisms is greater than number of estimated vacua* (-:

– Usual quantization of the classical bosonic string violates cosmological boundaries. (I wait that SMts will recognize this error before 2050 :-).

– The spacetime used (CY, G2, etc.) do not account for the non-differential character of stochastic processes. It will be funny like string theorists will attempt to model spacetime-foam noisy contributions to a triple D0-brane collision. I wait to see his faces then!

– In the usual unitary vectors space of string mathematics the L-product of two elements is not defined. Only in the L-space the relation *I+(rs)I+(tu) = I+(ru)delta(st)* is defined. No similar product relation exists in the H-space (dimension n) because L-space (dimension nn) is more general. That is, the supposed TOE cannot explain, for instance, Ernst?s work in NMR (that received the Nobel prize) 🙂

– The fixed background S-matrix is, undoubtedly, a funny caricature of real-word processes. There are dozens of well-known papers on the topic and even a new branch of string theory developed!

– Vector states used in the standard spectral decomposition of strings (branes) are of course valid only in the limit *T* –> 0. This was known for decades in other fields of science like plasma physics (quark-gluon plasma). Only the last 5 years, after of three decades of totally wrong research and funny claims, SMts fixed this sound error and developed the very recent Dp-branes theory with the (~) operators, which only work in the linear regime. Far from eq. one cannot use the tilde (~) operators due to well-known presence of dynamical bubbles coupling spacetime events. Of course, all this advanced mathematical stuff was/is ignored by leading researchers like Witten, Greene, Vafa, Schwartz, etc. Witten, the great genius, the great theoretician, the new “Einstein”, did **NONE** contribution to recent doubled space Dp-branes theory. *In fact, his great mind did not know the problem with the use of standard states because he like other string theorists study the topics just superficially*. He is a great string theorist sure 🙂

– String theorists still claim for the derivation of an unitary theory, whereas people in other experimentally proved theories are working with LPS theory in Gelfand triplets. The theorems used are outside of the simple and outdated string mathematics, and one needs a lot of recent mathematical work in rigged spaces and involutive Banach algebra of bounded operators. These non C*-algebras are, of course, ignored by SMTs and their irrelevant TOE. It is impossible to explain recent models for neutral Kaons and its counterparts in higher-flavor-generations from the basic mathematical framework of string, M theory. Concretely the models developed in the last decade by Sudarshan (e.g. generalizing the LOY model) does not fit to string M-theory because are more general.

– Non-critical string theory is more advanced that usual critical (Witten-Schwartz-Vafa-Greene-etc.) one in fixed backgrounds but again irrelevant for a TOE. The most advanced formulation today in non-critical theory simply use ?Lindblad?like? operators (which is only valid if one take the zero limit of the correlation functions for the different vacua) to take into account quantum transitions between different critical string vacua. Moreover, the non-critical string theory has unsolved problems. One can show (with the aid of mathematical methods unknown for SMts and still don’t applied to noncritical formulation) that non-critical string theory formulation is just a shadow to more consistent and generalized theories.

M-theory is "*the best candidate for a theory of everything*", sound like that old claim of "*all universe is understood from Newton mechanics*".

All of us know how accurate was the claim 🙂

25. **D R Lunsford**
June 29, 2005

String theory is wrong because it utterly fails inside its context. Likewise, Weyl's theory is a total failure, notwithstanding Weyl 1929 where phase is made the cuckold of gauge (see O'Rafairtaigh). Failure in physics means insufficiency to the expected context. On this level, string theory is an absolute failure.

-drl

26. **Peter Woit**
June 28, 2005

Not sure what your simple SPIRES search is, but looking at the SPIRES list of most heavily cited papers in 2004, the top 5 string theory ones are

1. Maldacena on AdS/CFT 446 citations
2. Witten on AdS/CFT 258 citations
3. Seiberg-Witten on non-commutative geometry and string theory 231 citations
4. Gubser, Klebanov and Polyakov on Ads/CFT 225 citations
5. KKLT paper 190 citations

Only 5. has anything directly to do with getting a unified theory out of string theory. We can argue about what use 3 is, but 1, 2, and 4, are about AdS/CFT, an explicit relationship between a 4d QFT closely related to QCD and a 5d string theory dual to it, something which has nothing to so with string theory as a unified theory.

27. **Ohne**
June 28, 2005

"It quite possibly can provide some sort of dual description of QCD, and that is what much research in string theory these days is aiming for."

By much I guess you mean about four percent, as a simple SPIRES search can verify?

New Top Quark Mass?

June 28, 2005
Categories: Uncategorized

There's an article in the Chronicle of Higher Education about the Quantum Diaries Webloggers. It points out that since this project is organized by the high energy physics labs, it "presents a sanitized version of life in high-energy physics", with one of the participants quoted as saying "None of us wants to be responsible for saying anything negative." Well at least there is one weblog dealing with high-energy physics where things are not sanitized….

From Gordon Watts, one of the Quantum Diaries webloggers, I learned about the Tevatron Connection Program, which brings together theorists and people from the CDF and D0 experiments at the Tevatron. It seems to me that new results on the top mass were first made public this past weekend at this conference (see here and here). The latest combined CDF/D0 result is ("pending final CDF/DO review"):

top quark mass = 174.3 +/- 3.4 Gev

compare to the previous result using Run I data of

top quark mass = 178.0 +/- 4.3 Gev

In the standard model, the new top quark mass implies a value for the Higgs mass of 94 +54/-35 Gev. Note that much of this range is excluded by the LEP result that the Higgs mass must be above 114 Gev. In the minimal supersymmetric standard model with this top quark mass, getting the Higgs mass above 114 Gev requires making the superpartner of the top quite heavy, introducing a certain amount of fine-tuning into the theory. For more about this, see a posting by Jacques Distler.

   Why is the matrix so large in the first place, here as opposed to elsewhere

   Because you can't do local updates. For the gluon action, you're locally updating the gauge field. So at any point, you only need to know the nearest neighbours. Whereas with the quarks, you've "done" the path integral, so it cares about every gluon field, at every point.

   Put more simply, you're not updateing the "quark field at point x" you're computing the entire effect of the quark field at once.

   Also, it seems to me if you get good precision in the higher mass calculation, the scaling would naively appear to be linear in the eigenvalues.

   The compute time scals as the inverse. And the physical chiral limit is determined by Chiral PT, which shows that the extrapolation is not linear.

   Which again, computing power seems to have vastly superceded since I first heard about Lattice QCD (Moore's law et al). So, obviously it cannot be linear, what exactly big O() is it?

   For a fixed volume compute time scales roughly as the inverse 6th power of the lattice spacing, times the inverse of the lightest pion mass. 4 powers of the lattice spacing are just the number of points on the grid. One is critical slowing of the gluon update algorithm, and the remaing mass*spacing is the slowing of the quark matrix inversion.

   In "real life" it's even worse than this. But this sums it up pretty well.

2. **Fred**
   July 5, 2005

   "So you end up having to compute the determinant of a very large matrix."

   Yea I never quite understood this. Why is the matrix so large in the first place, here as opposed to elsewhere (where other lqcd calculations seem to be so reliable). Is it merely b/c of the smallness of the lattice spacing necessary that leads to such huge matrices? Also, it seems to me if you get good precision in the higher mass calculation, the scaling would naively appear to be linear in the eigenvalues. Which again, computing power seems to have vastly superceded since I first heard about Lattice QCD (Moore's law et al). So, obviously it cannot be linear, what exactly big O() is it?

3. **Matthew**
   July 4, 2005

   What exactly is the nature of the problem in getting the up/down mass light enough?

   Okay, in lattice QCD you write the fermion action as

   S = \bar{\psi} M \psi

   where M is some huge (but finite and totally well defined) matrix that depends on the gauge fields. Now you can't really do grassman variables on the computer, so instead you perform the path integral over the fermions exactly, which gives you

   det(M)

   So you end up having to compute the determinant of a very large matrix. The major cost of doing this is computing the inverse of M. The cost of the algorithim you use to compute the inverse (conjugate gradiant) goes like the inverse of the smallest eigenvalue. And the smallest eigenvalue of the matrix M is the quark mass. So as you take the quark mass smaller and smaller, the cost of your simulation goes through the roof.

   If one is calculating the meson and/or baryon spectrum with heavier quarks (ie. charm, bottom, etc …), is it reasonable to treat them non-relativisticly?

For the bottom quarks the answer is yes. A non-relativistic effective theory is what we use. For the charm it's somewhat less clear. The charm is "heavy" but it's not quite "heavy enough" to let you trust non-relativistic expansions in the same way you trust them for the b quark.

It still worries me if the calculation is about mass splittings instead of absolute.

That is entirely due to the fact that the chiral perturbation theory for the absolute masses still needs doing. The simulations don't care one way or the other. The omega mass was computed, see the paper by Davies and Bernard.

Indeed it is already a bit regrettable the need to recourse to chiral extrapolation there. In some sense, we are not testing QCD anymore but QCD plus the effective theory we are expected to fit to.

I disagree. Chiral perturbation theory, just like heavy quark effective theory, is a consquence of QCD. Using fits based on chiral perturbation theory is a test of full QCD.

Or is the neutral pion one of these problematic low mass objects?

That I don't know actually. One rarely makes a distinction between the charged and neutral pions.

The \eta' is hard though, I know that.

4. **Alejandro Rivero**
July 2, 2005

You tune the 4 bare quark masses (up and down are degenerate, and you ignore the top) and the bare lattice spacing to reproduce 5 experimental numbers

Hmm I have taken a look to the paper; the small error in 5 experimental numbers (plus the four ones "exact" from tuning) are impressive, really more impressive than quenched approximations. It still worries me if the calculation is about mass splittings instead of absolute.

The light quark masses are the key problem in the modern simulations.

Indeed it is already a bit regrettable the need to recourse to chiral extrapolation there. In some sense, we are not testing QCD anymore but QCD plus the effective theory we are expected to fit to.

Acutally calculating meson masses is easy.

In surprises me that also the width for QCD-stable objects seems to be easy to calculate. In particular for the pseudoscalar, this means that the chiral anomaly is handled correctly, does it? Or is the neutral pion one of these problematic low mass objects?

5. **JC**
July 1, 2005

Matt,

What exactly is the nature of the problem in getting the up/down mass light enough?

If one is calculating the meson and/or baryon spectrum with heavier quarks (ie. charm, bottom, etc …), is it reasonable to treat them non-relativisticly? One would guess that mesons and/or baryons with light quarks would have to be treated relativistically.

6. **Matthew**
July 1, 2005

The results of quenching QCD, I dont know if it is a cause of optimism or the contrary. It seems a bit of everything goes.

Modern large scale simulations are unquenched. The paper I mentioned is an unquenched calculation.

Hmm but, besides a fundamental mass, how many free parameters do you need

You tune the 4 bare quark masses (up and down are degenerate, and you ignore the top) and the bare lattice spacing to reproduce 5 experimental numbers. That's it, there are no "free parameters" beyond that. This is not a model.

Are the tuned values published elshewhere?

Yes, you'd have to dig a bit through the references. The papers by the MILC people (Bernard et. al.) are the relevent ones for light mesons.

could you inform us of which other groups are obtaining sucessful predictions for the hadronic spectrum?

Well, every group does the meson spectrum to some degree, if only to fix parameters. Large scale calculations are being done by the CP-PACS group, see hep-lat/0409124 for example. It's not clear if they will be able to get to light enough quark masses though.

The light quark masses are the key problem in the modern simulations. That's where the difficulty is, getting the up/down mass light enough. Acutally calculating meson masses is easy.

7. **Alejandro Rivero**
July 1, 2005

The results of quenching QCD, I dont know if it is a cause of optimism or the contrary. It seems a bit of everything goes. After all, also the purely kinematical cross section of e+ e- —> muons is within a ten percent of the QED prediction, isnt it?

*3 * mass_cascade – mass_nucleon*

agrees with experiment at the few percent level. The paper hep-lat/0304004 has some other things. We've computed a few other light hadron quantities since then, the \Omega mass, for example.

Hmm but, besides a fundamental mass, how many free parameters do you need, and how sensitive the results are to veriations of these parameters? In 0304004, all the quark masses are tuned to reproduce the most important mass predictions (Are the tuned values published elshewhere?).

And now you are here, I wonder… could you inform us of which other groups are obtaining sucessful predictions for the hadronic spectrum?

8. **Matthew**
June 30, 2005

Regarding Lattice QCD,

The CP-PACS group reproducde the light hadron spectrum to within around 10% using quenched (i.e. not entirely physical) lattice QCD in the mid-nineties. There's a plot of this, which is what you probably saw in Wilczek's talk. For modern full QCD simulations we're not quite at the full hadron spectrum, but some things are done. In order to reduce systematic errors one often computes mass differences, for example, the combination

3 * mass_cascade – mass_nucleon

agrees with experiment at the few percent level. The paper hep-lat/0304004 has some other things. We've computed a few other light hadron quantities since then, the \Omega mass, for example.

It's better in the heavy quark sector. Apart from a couple of lingering problems, the charm and bottom meson spectrum has been totally computed, and agrees with experiments. There are also calculations of various decay constants and form factors, which are a bit harder than masses.

My opinion, I think it is fair to say that the meson spectra has not been calculated.

You're wrong, as even a cursory glance at the lattice liturature would show.

Note also we are speaking of unstable particles, so the "pole mass" spectra includes both mass and decay width

Many particles are stable, for example, you can get very clean pion masses. You are correct that unstable particles (such as the \rho) are harder, but it can be done.

Montecarlo errors are high, finite size effects etc

Actually, those errors are fairly well under control for spectrum calculations. What really bites you is discretization errors, and errors in the chiral extrapolations.

Of course, when you try to do harder things (glueball masses, K \to (2,3)\pi) statistics and finite volume are much worse. But for meson masses, it's pretty well under control.

9. **Peter Woit**
June 29, 2005

Hi JC,

I believe the calculation Robert mentions for K a Calabi-Yau gives a simple result: the low mass particles are massless and supersymmetry is unbroken. For obvious reasons this result is not heavily promoted.

A problem he doesn't mention is how to give dynamics to the moduli parameters for the compactification manifold. Naively the effective action doesn't depend on them so you end up with massless scalars, less naively you can believe in fixing them a la KKLT, then you have the landscape to deal with.

10. **JC**
June 29, 2005

Robert,

I'm familiar with what the string people do to obtain an effective action of the sort you have described. What I'm skeptical about concerning this particular effective action procedure, is that I have never seen anybody producing a convincing calculation of the quark and lepton masses in this manner which agrees with the experimental data.

Also what criteria is used to select the K in the 10K spacetime product R^4 x K, besides just trying out many different K's (ie. a torus, K3, Calabi-Yau, etc … which may or may not break some of the SUSY)? With 10^100 or more possible Calabi-Yau's (depending on who you ask), what criteria is used to choose one besides trying out every single one in an exhuastive manner? What would happen if 10^20 or 10^30 of the possible Calabi-Yau's all produce similar quark and lepton mass spectrums to within the experimental error bars? (Though it would be very impressive if exactly ONE Calabi-Yau actually could produce the correct quark and lepton mass spectrum, with all other Calabi-Yau's excluded).

11. **Peter Woit**
June 29, 2005

For the record, Tony Smith points out to me that his prediction for the neutrino mass and mixing angles are at:

http://www.valdostamuseum.org/hamsmith/snucalc.html#asno

and he also has predictions for the top quark and other quark masses at his web site.

I don't have any objections to people posting here a simple link to their predictions of this kind, but keep in mind that I don't want this weblog to be used as a forum for discussing the details of these arguments.

12. **Matti Pitkanen**
June 29, 2005

p-Adic thermodynamics for super-Virasoro generator L_0 taking essentially the role of mass squared operator provides an alternative view about elementary particle and hadron mass spectra explaining fundamental mass scales number theoretically. Also CKM matrix can be deduced to a high degree from number theoretic constraints. Since the possible Higgs contributes only a small shift to fermion masses, the production cross section for Higgs can be by a factor of order 1/100 lower than in standard model.

The five chapters in the second part of “TGD and p-Adic Numbers” contain the detailed calculations.

Matti Pitkanen

13. **Alejandro Rivero**
June 29, 2005

My opinion, I think it is fair to say that the meson spectra has not been calculated. Note also we are speaking of unstable particles, so the “pole mass” spectra includes both mass and decay width. But even mass alone, from QCD plus lattice, is not really got. Montecarlo errors are high, finite size effects etc.

14. **Robert**
June 29, 2005

Tony Smith can also compute the mass of a proton. And this at tree level. Which is remarkable for a composite object in a strongly coupled theory. Or numerology.

Seriously, it is much more convincing to argue that the mass scale of the proton is given by the QCD scale (where the running coupling is of order unity). This gives at least the right ballpark. Anything more precise requires really hard work.

Re particle masses from string theory: This comes from the effective action. Assume you have a massless scalar field in 10D. It obeys some wave equation like Box phi = 0. If your 10D space-time is the product of R^4 x K for some compact six manifold K, you can look for solutions of the Schroedinger type equation Laplacian psi = k psi on K. For such an eigenvalue k make take the original phi to be phi = psi(K) x f(R^4) where I indicated the dependance on the coordinates in parenthesis. Then the above wave equation implies that in R^4, f obeys the Klein Gordon equation for mass squared m^2 = k.

This works not only for scalar fields and thus once you know the K and the spectrum of the Laplacian on it, you know the masses of particles in 4D. The problem to identify the correct K for the real world remains.

15. **D R Lunsford**
June 29, 2005

Tony Smith can calculate particle masses as ratios of volumes of (homogeneous symmetric) spaces. (But, I can’t get him to write down an integral I can do.)

He says the top quark is something like 138 GeV.

-drl

16. **JC**
June 28, 2005

Peter,

I vaguely remember in the 80’s some people making claims of attempting (in principle) to calculate various “particle” masses using string theory. So far I haven’t seen any convincing results of anybody being able to do this successfully. I could never get anybody to explain precisely how to get these “particle” masses. Hopefully they weren’t referring directly to the Regge trajectories stuff from the late 60’s/early 70’s, which don’t seem to be very convincing.

17. **Peter Woit**
June 28, 2005

Hi JC,

I don’t have any references at hand, but I’ve certainly seen papers and talks (e.g. Wilczek’s at the Sidneyfest) where people have shown the results of impressive lattice qauge theory calculations of the masses of these states that come out correct to within the errors expected in the Monte-Carlo calculations. The size of the errors I vaguely recall as being in the range of at most a few percent.

So the fact that you can compute these hadronic masses from first principles makes numerology of them pretty pointless. Of course no one knows how to calculate quark masses from first principles, so there’s lots of room for speculation there. But please don’t do that here….

18. **JC**
June 28, 2005

Peter,

(Slightly offtopic).

Have the lattice gauge researchers been able to calculate the spectrum for any meson and/or baryon families yet, with a precision that makes it possible to compare with the experimental data? If this is possible to do, I would guess it would possibly shut-up most of the people who look at the “numerology” particle masses.

19. **Peter Woit**
June 28, 2005

The difference between the old 178 number and the new 174 number is not statistically significant. It’s very hard to measure this mass accurately since you have to accurately measure the energy contained in a jet. Please spare us further numerology involving quark or lepton masses, since these have all been at least approximately known for a while. Now if someone has a plausible prediction of the Higgs mass or absolute neutrino masses, they should get that on the record since during the next few years these things may finally get measured.

20. **Quantoken**
June 28, 2005

Peter:
Any comment on the fact that a certain John Martin predicted the 174GeV figure correctly one year ago? He made a very good point that the electron mass is a very important fundamental mass unit. That is in line with my assertion in QUITAR that electron mass equals to alpha times the fundamental mass unit, which is about 70MeV.

Quantoken

Latest on Poincare

June 29, 2005
Categories: Uncategorized

The status of Perelman's proof of the Poincare conjecture is still somewhat confusing. For some background see a previous posting and a later follow-up. Last week the ICTP in Trieste issued a press release entitled Poincare Conjecture Solved, which states that Perelman's proof "has been confirmed by an international group of mathematicians whose findings were presented to participants at a conference" at the ICTP. The conference was a summer school, and the press release goes on to claim that "The 60 participants, more than half from the developing world, reaffirmed the approving judgement of the mathematicians."

If you look at the write-ups of the talks, the only relevant thing in print is in the lecture notes of Carlo Sinestrati where he states "The details of the proof are still being checked by the experts in the field; however, the main ideas of the papers are by now widely understood." So, it's not clear who exactly is supposedly now willing to vouch for Perelman's proof, and the comment that the students at the school "reaffirmed" that it is a proof is kind of silly, given the difficulties involved.

There's a month-long summer school going on right now at MSRI in Berkeley, sponsored by the Clay Mathematics Institute. Many relevant materials are available at the web-site of the summer school. As far as I know, none of the experts there is yet quite willing to claim that a complete proof using Perelman's techniques has been written down and checked, although they do seem to be getting close to this point.

Not Nobel laureate said,

"*Aside from the various theoretical dead ends, a more fundamental problem with string theory is that it operates at an energy scale many orders of magnitude beyond what is measurable today. Thus it's non-testable, hence meta-physical*."

This is one of popular miths of string M-theory.
It, like almost all of popular claims on string M-theory, is simply false.

String theory is perfectly testable. The first version of string theory was tested in the strong force regime and abandoned.

The introduction of 26D was forced because the unobserved tachions predicted by 4D version of the bosonic theory.

The next version (+ fermions) were also (un-)tested, for example so many times was claimed the inminent discover of supersimmetry and the first verification of supersimmetric string theory by crackpots!

In cosmological issues, string M-theory has been also tested. A complete failure in the words of Krauss, possibly the poor theory of history of physics according to Woit (discrepancy with experimental data is around 50 orders of magnitude).

The attemtp to explain inflaction and dark matter from string theory also has failed. Regarding cosmological brane theory, the recognized specialist Linde showed that "popular" (i.e. string theory is marvellous, string theory solves the most difficult open problems, etc. etc.) papers by string theorists were completely wrong and predicted the contrary to observed "inflationary" data.

Moreover, it is often ignored that before to explain NEW physics, string theory may explain known physics. In this simple, elementary, step, string M theory does not explain nothing already known. In fact, even the derivation of GR from string theory is based in heuristic reasoning and ad hoc hyphotesis.

It can be shown that string M-theory is incompatible with known experimental data.
The incompatibility with certain statistical mechanics data has forced to some string theorists to develop the so-called non critical approach that violate basic principles of usual "critical" string theory.

The incompatibility with thermal phenomena has forced to abandon all of standard Hilbert-Fock quantization of branes in favor of the new doubled space approach (so-called tilde operators) and the new thermal states of TFD-Dp-brane theory.

In the past, the "derivation" (not in the rigorous sense of term) of GR from 10D superstring action was one of main popular claims of string community. Curiously, now physicists and astronomers maintain doubts in the validity of GR at cosmological scales and well-known modifications like MOND, AQUAL, etc. are being studied and tested. Since that string theory claims just small-scale modifications for GR, one may see that also here string theory is a failure here. For example, string theory is incompatible with standard TF law.

From unitary Schwartz string action one cannot explain experimental data which IS explained by Lindblad semigroups axiomatic theory.
Etc, etc, etc.

All i am saying is standard, it is not speculation. For example, TF law is the basis for one of standard methods in gauging distance in spiral galaxies, Fourier thecniques in L-space (string theory and standard (e.g. Weinberg manual) QFT both work only with H-space) received Nobel Prize for chemistry in 1991, etc. specialists in quantum mechanics have said in many occasions that string theory is not fundamental (see me previous post on Witten for a quote extracted from the conference Quantum Future. It is well-known that true specialists (i.e. people that has really advanced the field) in quantum theory durely critiqued last Witten claims on the generalization of quantum mechanics from M-theory. In fath, it is aknowledged by many recognized specialists in the field that Witten (with no contribution to the field) misunderstands quantum mechanics.

The last year, a Nobel laureate (Freeman J. Dyson) did a similar criticism to Brian Greene in his review of book the Fabric of Cosmos. Dyson reacts atonished to Greene string interpretation of quantum mechanics saying "He rejects [standard view] without any serious discussion". Dyson ignores that IS precisely string theory literature: no serious discussion, only speculation, conjetures, bad math, superfitial insight, etc.

This is the reason why i claim that string theory is wrong like a TOE. It is amazing that questions that i said some years ago (then i was ridiculized) begin to be supported by string theorists now.

In fact, i said in the past that string theory was rather standard (simple) and people ridiculized. In fact, one guy contacted with Lubos Motl and this "hiring" to me.

Fortunately, after of his Nobel Prize, David Gross has said a phrase very similar to i said two years ago: that string theory is not revolutionary.

The guy said to Lubos Motl 🙂

****
If all i am saying about failure of string theory to explain known data is standard, why do string theorists ignore it?

Because are arrogant people and think that understand things when have only a superfitial knowledge of things.

For example some of them are very excited with TFD generalization of brane theory. TFD theory was know decades ago. Now we are working in more geernla stuff TFD II, NESOM-TFD, etc.

Other example, the most recent and radical modification of NC string theory posted in ArXiv by Nanopoulos uses mathematical tools in projected dynamics mathematics developed by Brushels School in the 60s but abandoned by the own School in favor of the recent LPS formalism in Gelfand triplets in the 90s!!!

It is more, not only again string ideas are outdated, even copying the interesting work done by others (e.g. Prigogine), they copy incorrectly!!

For example, the equation (10) of arXiv:hep-th/9403133 is simply wrong for anyone with a minimum insight in generalizations of quantum mechanics (e.e. Solvays conferences, etc.)
Note, i contacted with Nanopoulos for explaining it but he ignored to me, now i does not explain to him that almost of next sections of that and other papers are misleading. It is waste of time contact with string theorists.

My criticism to that preprint is correct, in fact it is supported by one of members of the School, prof. Gonzalo Ordo?ez from Ilya Prigogine institute on Texas that i contacted for verifying.

Matti said:

Batakis introduces electroweak structure more or less by hand without noticing that CP_2 spinor connection possesses naturally electroweak gauge group as holonomy group

I think this latter is Finkelstein and Jauch's (and Speiser and Schiminovich's) quaternion quantum mechanics. This theory also had a rationale for the Higgs mechanism other than expediency.

-drl

3. **Not a Nobel Laureate**
July 4, 2005

Aside from the various theoretical dead ends, a more fundamental problem with string theory is that it operates at an energy scale many orders of magnitude beyond what is measurable today. Thus it's non-testable, hence meta-physical. Having said that, the same can be said about LQG, spin foams and any other theories whose predictions, if they even make any, lie outside the energies attainable at the Tevatron and the LHC or perhaps astrophysically observable.

"Pure reason" has never been a productive form of scientific enquiry.

4. **Matti Pitkanen**
July 3, 2005

Tony Smith mentioned in his posting the paper of Batakis about H=M^4×CP_2 Kaluza-Klein theory. We had a discussion about the paper with Tony for a couple of months ago.

Batakis introduces electroweak structure more or less by hand without noticing that CP_2 spinor connection possesses naturally electroweak gauge group as holonomy group. The problems of KK scenario become obvious when one looks for the spectrum of Dirac operator in H.

a) The two chiralities of H-spinors allow an identification as quark and lepton type spinors when one couples leptons/quarks to n=1/n=3 multiple of Kahler gauge potential of CP_2. The holonomy group U(2)_ew has a natural identification as electroweak gauge group. Separate conservation of lepton and baryon numbers is predicted.

b) The problems are that only right-handed covariantly constant neutrino is massless whereas other states have mass scale defined by CP_2 size. Also the correlation between color and ew quantum numbers for the spinor modes is wrong: only right-handed neutrino corresponds to color singlet. Thus Kaluza-Klein type theory as a limit of something more general is out of question.

Batakis does not notice that CP_2 already unifies color and electroweak symmetries. If one considers space-time as a 4-surface in H and induces spinor structure to the space-time surface (bundle induction is mentioned in the 20 first pages of any text book about bundles and means in recent case projecting of the gamma matrices of H to space-time surface), one obtains electroweak gauge field as classical gauge fields inheriting their dynamics from the dynamics of space-time as 4-surface. Color gauge potentials can be identified as projections of Killing vectors of color isometries.

From this it is a long way to a generalization of string model predicting correctly the massless sector of the theory and mass spectrum of elementary particles and hadrons. A profound generalization of conformal symmetries is needed and emerges naturally when one formulates quantum theory as a theory of free classical spinor fields in the "world of classical worlds" consisting of 3-surfaces in H and endowed with Kähler geometry. The spectrum of Dirac operator and mass calculations see the five chapters in the second part of p-Adic TGD.

Matti Pitkanen

July 3, 2005

Thank-you, Peter. I think I've got it.

6. **Peter Woit**
July 3, 2005

Hi Curious,

I think I mostly agree with you, but a few comments.

The string theory community IS wasting time. They are sitting around waiting for someone else to come up with a new idea. Sure, if someone comes up with a wonderful, compelling new idea with lots of evidence for it, they'll take it up. But as you say, they've set the bar very high. The present situation allows them to get jobs, awards, grants, etc, etc, based on worthless work on string theory, but not for work on other ideas (unless these ideas are quickly successful). I still think that if people start publicly acknowledging that string theory has failed, this will pull the plug on this unhealthy situation. If people can't get a grant proposal to do string theory funded, but have to try and come up with something else, this would have a huge positive effect.

The leaders of the string theory community are well aware that if they start publicly talking about how badly things are going, they're quickly going to get into this kind of trouble. I think that's why many of them will privately agree that string theory is in bad shape, but say very different things publicly. I hope to have some role in not letting them get away with this.

I agree with your three ideas of things to do, and am trying to do them. I hope that reading this weblog will help students think independently. A lot of what I have to say is aimed at them. I also do try and identify and point to new work that might be promising. Unfortunately it's rather discouraging how little of this there is from my point of view. I personally think that a deeper mathematical understanding of the standard model is what is needed for progress, but virtually no one is working on this. The interaction between particle theory and mathematics has narrowed down in recent years to virtually just topological string theory and enumerative problems involving Calabi-Yau 3-folds. This work is interesting, but it is mathematically very narrow.

7. **Tony Smith**
July 3, 2005

Curious said "… I have had several occasions to discuss your blog with our (U Chicago) string theorists — and they read it and they agree with it, and then they ignore it. … The best alternative ideas around are not good enough to recruit string theorists. That is not the result of their obstinacy. These alternative ideas are simply not good enough, period. …".

I disagree, and here is a concrete example of a model that unifies gravity and the standard model and is (afaik) ignored by the conventional string theory community.

N. A. Batakis, in Class. Quantum Grav. 3 (1986) L99-L105, wrote a paper entitled Extra gauge field structure uncovered in the Kaluza-Klein framework. In it Batakis said: "… In a standard Kaluza-Klein framework, M4 x CP2 allows the classical unified description of an SU(3) gauge field with gravity. … the construction of an additional SU(2) x U(1) gauge field structure is uncovered. The construction involves a properly modified 'gravitoweak connection' and supplies a mechanism analogous but not redundant to the Kaluza-Klein ansatz … As a result, M4 x CP2 could conceivably accommodate the classical limit of a fully unified theory for the fundamental interactions and matter fields. …".

If Curious is correct, then I would think that his U. Chicago string theorists would see the Batakis paper as a "spark to inflame" them into developing and completing the work of Batakis.

If, on the other hand, Peter is correct, then those string theorists would feel threatened by a competing non-string (not even LQG) theory and dismiss it without careful evaluation, perhaps even attacking anyone who is seriously interested in it.

I am curious to see what reaction the string theory colleagues of Curious might have to the Batakis paper.

July 2, 2005

Peter,

I do not want to distract you with endless arguments going to and fro etc
inasmuch as I think we are on the same side of the issue. Thereof I'll comment on only one point of
your answer; it is a very important point — to you. The question is how to stop the wastage of
time on ST; that's what we both chiefly want.

You say that you deeply care for the field and you cannot just sit back and see how it disintegrates and how young people become demoralized. I know you do feel the pain. So do I. But critisizing ST in the way you do it – and you do a jolly good job of it – it just does not work. You are convincing the wrong people; those that do not waste time anyway.
I have had several
occasions to discuss your blog with our (U Chicago) string theorists — and they read it and they agree with it, and then they ignore it. It is too late in the game for your arguments to work on them.
One cannot turn a tide on a completely negative message. I do not say that YOU have to be positive about something. But someone better be; otherwise ST is unstoppable. You are trying to combat a belief system using rational arguments against it; that is as futile as Sean's struggle against creationists. Painful as it is to watch the wastage of effort by first-class minds, the only way to stop it is to be creative; that's where we all collectively failed.The best alternative ideas around are not good enough to recruit string theorists. That is not
the result of their obstinacy. These alternative
ideas are simply not good enough, period.

I do not believe in great men visions either but
even more am I sceptical of
the "fertile soil" model of which you and Smolin equally partake. The community of German physicists from which Heisenberg emerged was not at all like a healthy community. It was more like a viper's nest,
with duelling schools, less then enthusiastic welcome of radical ideas, and a community riddled by mutual distrust, anti-semitism, and typically German professorial anti-everything. The community that you have in mind did exist but it was initially marginal and had
not more than 20-30 people at any time. It is always possible to
create such a mini-community of like-minded people inside a larger hostile community.
The power of Heisenberg was not that he had roots
in some healthy worldwide community; initially, there was tremendous opposition to QM. It was the truth of his ideas; it is the truth that won the people against their worst selves. ST does not strangle new thought; this thought is simply not there.

We can only do three things to stop ST:
(i) generate this new all-winning idea by ourselves (ii) foster independent thinking in our students and
(iii) spot this new idea and champion it when it emerges. I cannot think of anything else that might work towards the goal.

You look at the ST community and see people wasting their time on a dud. I see it as a barrier this new idea has to jump over;

it is a mighty high barrier and it works as an excellent
obstacle w/o which the race is meaningless and a perfect deterrent to bad ideas. The ST community is also a potential pool of people that will be able to develop and complete this new idea when its time finally comes. This community is not wasting time,
it is waiting for a spark to inflame.

Perhaps, all of the above is not really news to you and you have heard such arguments many a time. By no means I suggest that you should stop what you are doing; you would not listen anyway. All that I am asking from you is to think once in a while: Are the means that I chose helping to bring about the goal that I chose? If the means are not helpful, another tactics is needed.

I enjoy reading your honest, principled, and intellectually challenging blog but it mainly
serves to vent the frustration; it does not go to the root of
the problem and it does not suggest a winning strategy. Nobody ever became healthy by
a realization of one's sickness, using your analogy. We need a diagnosis, a treatment plan and medicine — if not a cure. You offer a death sentence to a terminally ill patient. Is that enough?

9. **Tony Smith**
July 2, 2005

Curious asked "… Could it be that people rage against the ST because the dominance of this admittedly failed programme painfully reminds them their own failure to produce a great new idea? …".

I don't think so. I think that the rage is directed at the massive publicity campaign to present conventional superstring theory as the only possible program for unification of gravity and the standard model.

For example, the 1 July 2005 issue of Science listed the 25 most important questions in Science today. About the number 5 question, Can the Laws of Physics Be Unified?, Charles Seife wrote:
"… Gravity clashes with quantum theory so badly that nobody has come up with a convincing way to build a single theory that includes all the particles, the strong and electroweak forces, and gravity all in one big bundle. But physicists do have some leads. Perhaps the most promising is superstring theory. Superstring theory has a large following because it provides a way to unify everything into one large theory with a single symmetry?
SO(32) for one branch of superstring theory, for example
?but it requires a universe with 10 or 11 dimensions, scads of undetected particles, and a lot of intellectual baggage that might never be verifiable. It may be that there are dozens of unified theories, only one of which is correct, but scientists may never have the means to determine which. Or it may be that the struggle to unify all the forces and particles is a fool?s quest. …".

It seems to me that Seife and Science are saying that conventional superstring theory, their "most promising" approach, may or may not produce a unique unified theory, but if it fails to do so, then "the struggle to unify all the forces and particles is a fool's quest".

In other words, anyone who pursues any approach other than conventional superstring theory is characterized as a "fool".

That attitude, which is prevalent not only in the scientific media such as Science, but also in the popular media and in the culture of conventional superstring theorists themselves, is where my rage is directed.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Just for the record, the number 1 question listed by Science was What Is the Universe Made Of?, as to which Charles Seife wrote:
"… Ordinary matter and exotic, unknown particles together make up only about 30% of the stuff in the universe; the rest is this mysterious antigravity force known as dark energy … at the moment, the nature of dark energy is arguably the murkiest question in physics?and the one that, when answered, may shed the most light. …".
Thankfully, Seife's article did not present conventional superstring theory as the "most promising" answer to that question, but I have little doubt that members of the conventional superstring community will declare that their theory is the "most promising" approach to an answer.

10. **Peter Woit**
July 2, 2005

Hi Curious,

I've got no idea by what you mean in claiming that Hilbert's research program dominates mathematics. Hilbert was a very broad mathematician, and did a wide variety of things. Some of the areas he worked in that were most identifiable with him are relatively unpopular now (e.g. the formalist approach to foundations of mathematics). Mathematicians work on a wide variety of problems, from a variety of points of view, and they've been making real progress (e.g. the Wiles proof of Fermat, the possible proof of Poincare using ideas of Hamilton and Perelman). A lot of what they do is unproductive, but the field is healthy. Theoretical physicists could learn a lot from this, and not just possibly useful mathematical ideas.

I don't think I'm criticizing string theory in order to find out what's wrong with it. In the end, that's very simple: it abandons the successful core mathematical concepts at the foundation of the standard model and adopts an extremely speculative and not very promising alternative, one that has now conclusively failed. From the beginning of the fad in 1984, it was clear to me and to many other people that string theory wasn't an obviously promising idea. It predicted nothing and there were clear reasons for this.

In 1984 it wasn't unreasonable to work on string theory. The theory was not very well understood and one could hope that further work on it would show a way around its problems. In 2005 the situation is very different. It is completely unreasonable to now believe that these problems can be overcome. Current attempts to create a unified theory out of string theory are both mind-boggling ugly and utter failures.

I won't disagree with you or anyone else who tries to argue that I should devote more of my time to working on positive alternatives and less to criticizing the current situation. Maybe this is right. But I find what has happened to the field I care deeply about extremely disturbing. Each year it has gone from bad to worse, and is increasingly dominated by pseudo-scientific garbage, heavily promoted to the public. I don't find myself able to ignore this.

I'm not a big fan of the "great man" view of science, the idea that progress depends on one brilliant person. More commonly, scientific progress comes from a community of people working on promising ideas. When Heisenberg came up with quantum mechanics he didn't do this all by himself. He was part of a healthy community in which many people were trying many different things. The theoretical physics community is not healthy. It is sick and has been getting sicker. When you're sick, the first thing you need to do is acknowledge this, then figure out what you need to do to get better.

11. **Curious**
July 2, 2005

Peter,

Thank-you for your thoughtful remarks. I've been reading
this blog for some time and I still cannot determine what exactly is your problem with the ST:
you give so many different reasons and none of these various reasons look entirely
convincing, hence your need to repeat yourself time and time again, in order to convince yourself and others. I have a hunch that you have started this blog to find out precisely that — what is the problem with the ST as a programme, at the deepest level — something that you intuitively feel — and you write this blog for yourself — not for the benefit of the others. You suggest various answers to this one question, but these answers do not fully satisfy you. And so is the case with your readers, many of whom are string theorists. They read your blog, they agree, and then keep on doing what they are doing. If the answer were right, they would stop doing ST and start doing something else.

I do not know what that right answer is. You have to find it out for yourself and, please, keep on trying; it is important.

One thing I am sure of is that the problem with the ST is not that it is a fad or that it dominates HEP or that it is unprecedented in physics or mathematics or that it is unpredictive or plain wrong. The problem is US.

Hilbert's research program had dominated and still
dominates mathematics to a much greater extent than
string theory dominates high energy physics. It was viewed as a passing fad by many leading
mathematicians at the turn of the 20th century. It was
enormously sucessful, several excesses aside. Its
success is not and was not self-evident, as it does not logically follow from any rational argument; it is one man's vision. By all criteria it was a fad. It could've been a misguided fad as well. Fad or no
fad, tangible results started to stream out immediately
and still do. There was no time lag between the
promise of a wonderland and the result.

The news about the string theory is not that a certain fad dominates a certain field but how unproductive that fad turned out to be. Perhaps, one's man intuition
is not enough for physics. Or maybe we listened to the wrong man.

I believe that it is entirely appropriate for a fad to dominate the field, and it happended repeatedly, in both physics and mathematics. But most of these previous fads were productive and that's why we do not call these fads "fads" anymore. For lack of better ideas and guiding experimental results,
ST manages to dominate the field without the benefit of being productive.

And yet still, if every string theorist
will read this blog and agree that ST is not even wrong that would not change the situation one bit, because it is unclear what's right. The dominance of ST is not the result of groupthink or worldwide conspirancy as some people believe. It is the looming, annoying testimony to
OUR failure to come up with better ideas
and decisive experiments. The problem is US not THEM. Never before physicists were unable to come up with a good idea for such a long time — and that is certainly not the fault of the ST community.

Could it be that people rage against the ST because the dominance of this admittedly failed programme painfully reminds them their own failure to produce a great new idea? My feeling is that at the bottom, that's the right answer, and it is very sad and disconcerting.

12. **Peter Woit**
July 2, 2005

While physics and math, like all human endeavor, have always experienced a certain number of misguided fads, I think the superstring theory story is without parallel. In physics the closest analog I can think of is the craze for S-matrix theory during the 60s, but that only lasted a decade or so.

No one research program has ever dominated mathematics the way string theory dominates particle theory. The excessively formal style of Bourbaki is more an issue of bad pedagogy and exposition than bad research. While the members of Bourbaki were writing the very formal Bourbaki textbooks, they also were doing a wide range of different wonderful mathematics research. Take a look at the Bourbaki seminar writeups during the fifties and sixties. There's all sorts of exciting new mathematics there, being written up often in an accessible way, with very little evidence of bad effects of too much formalism.

13. **Walt Pohl**
July 2, 2005

Curious: Your comments about axiomization are not true. Axiomization is not as big a deal now as it was in the early twentieth century mainly because it was so successful: the current foundations are adequate for most purposes. Foundational matters still arise, though. For example, a long-open problem in abelian group theory (the Whitehead problem) has turned out to be independent of the usual axioms of set theory (ZFC).

Foundational techniques are beginning to be used to settle purely mathematical questions. There are some results in analysis whose only known proof requires "nonstandard analysis". Model theory was used to prove the Mordell conjecture in the function field case.

14. **Kea**
July 1, 2005

Curious: "…axiomatization of mathematics peaked in
popularity in the first half of the century and
then faded out."

Actually, this isn't true. The field simply evolved into something qualitatively new. Foundations of Mathematics is a big subject today. And as much as String theory bugs me, I have a terrible feeling that history will look at Strings in a similar light. A lot of the maths of M-theory has to be important to physics, as Witten says. The fact that what wins out might not have anything to do with M-theory from certain points of view doesn't alter the fact that detailed arguments connecting the old ideas to the new will inevitably turn up. And all history will see is another turning tide in the ocean – not the swirl of water washing over into the tiny lagoon at the end of the beach.

15. **Curious**
July 1, 2005

Peter then Tony asks an interesting question:
has it ever been an analog of superstring theory in mathematics? Perhaps, they mean:
was there a school of thought that captured a lot of attention, hype and effort and produced very or relatively little after many years of persistent study? The answer is

surely, yes,
though we may disagree on details. Say,
axiomatization of mathematics peaked in
popularity in the first half of the century and
then faded out. It is crushingly boring and
not a very good way to come with interesting
math. Another program, N. Bourbaki used to be as influential as Witten, but few people still care. One can come with more examples.

Observe also that in mathematics the logic
proof stands on its own; there is no emprical
input. By contrast no physical theory is self-
consistent or logically complete. We accept
these theories not because these theories are
rigorous (they may be actually highly dubious)
but because they work. Such a situation is
acceptable for any physical theories because
their difficulties are delegated to a yet
unknown more general theory. However,
such a situation is not acceptable for a TOE;
it should be as consistent as a mathematical
proof. I think that the problem with the string
theory is exactly that: it aspires to be what
no physical theory had ever been: a domain
of pure logic and mathematics, with acceptance criteria peculiar to these fields.
It cannot live to that self-imposed standard.
There could be in this sence no analog of the string
theory in mathematics: the complete analog would
be a mathematical theory that needs a
physical experiment to decide the truth of
the theorem. So far, even computer experiments are not exactly welcome.

16. **Peter Woit**
June 30, 2005

Hi Tony,

The huge groups and large sums of money necessary to do some kinds of experiments have certainly had a bureaucratic effect on some areas of experimental physics, but this doesn't really explain what has been going on in particle theory, where large groups aren't needed.

Particle theory is much, much, much more faddish than mathematics, and attitudes are very different. To oversimplify, in mathematics someone who quickly publishes a not really great paper on what seems to be the hottest topic would generally be thought of as someone shallow, unwilling to take the time to become a real expert in something and do some serious work. In particle theory, someone who doesn't jump on the latest fad is often thought of as an intellectual lightweight who isn't smart enough to quickly absorb something new and work on it.

The roots of this attitude in particle theory come from the days when experiments were producing unexpected new results. The most ambitious people would then jump into trying to explain them. The problem now is that there haven't been any especially new unexpected experimental results in particle physics for a long time, so this kind of attitude has become dysfunctional. Mathematicians have never had experiments to feed them new clues as to what to think about, so they have a tradition of people spreading out and digging in for much longer term research projects.

17. **Tony Smith**
June 30, 2005

Peter, you say "… The way the particle theory community has refused to acknowledge …[that]… over the last 20 years a huge amount of evidence has accumulated that, as an idea for unification … Superstring theory … doesn't work … is something that has no analog I can think of in mathematics.

What is the relevant difference between the math and physics communities?

First, it seems to me that superstring theory is not the only example in which the physics community refuses to recognize obvious failure.
For example, huge amounts of money and manpower have been spent over several decades on magnetic confinement fusion machines. At first, it was worth exploring (like superstrings in 1984), but now, decades later, even though it is clear to any reasonable person that magnetic confinement fusion is not going to be a significant source of energy, the ITER project is getting under way.
For another example, it was clear to any reasonable scientist that the International Space Station would not produce results that would come close to justifying its costs, but it was built anyway.

Those projects (superstring theory, ITER, ISS) all have something in common: they are in fact promoted by growth-seeking bureaucracies.

It seems to me that a distinguishing factor between physics and math is that
the physics community has evolved into a group of bureaucracies that use committee/consensus to enforce uniformity of thought because they feel that any independent thought threatens the fundamental bureaucratic goal of growth,
while
the math community is a lot of individuals, with uniformity of thought being enforced primarily by relatively objective standards of logical proof.

In my opinion, it is no accident that the last big success in theoretical particle physics was the Standard Model of the 1970s, which roughly coincided in time with the rise of large collaborative physics institutions like Fermilab and SLAC.
It also may be no accident that the last big experimental particle physics success was Fermilab's taking of data about the T-quark, and that the most significant data was taken over a decade ago, during its first run.

On the other hand, the math community has continued to make substantial advances, such as Wiles's proof of Fermat and Perelman's possible proof of 3-dim Poincare. Both of those advances were made by individuals, not large collaborations. It may be that collaborations are necessary to validate their work, but the initial work was by individual initiative.

Maybe the problem with physics is its current sociological structure, something that Burton Richter (former SLAC director) tried to point out in his paper at http://xxx.lanl.gov/abs/hep-ex/0001012 in which he said "… In the 500-strong collaborations of today, we … have a bureaucratic overlay to the science with committees that decide on … speakers, paper publications, etc. The participating scientists are imprisoned by golden bars of consensus …”.

Perhaps particle physics might advance more if it loosens the golden bars of consensus, and allows 1000 flowers to bloom (and perhaps lets committees be evaluators rather than enforcers of consensus thought).
It seems to me that astrophysics has come closer to following that path, as it has been successful by taking interesting data such as WMAP and not attempting to enforce any consensus interpretation of the data (being tolerant of interpretations of dark energy and dark matter ranging from conventional cosmological constant dark energy to MOND and many others).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

18. **Peter Woit**
June 30, 2005

Perelman is kind of a special case since the problem is that he hasn’t actually written down a proof, just an outline. Turning his outline into a real proof is a lot of work, especially since he is using some techniques few people are familiar with. The classification of finite groups proof is very long, but at least supposedly all the details are there.

I know people have been working on shorter versions of the four-color and finite group classification theorems, not sure what the status is. For another related story, there’s the claimed proof by Hales of the Kepler conjecture. This one involves both issues of computer calculations and such a complex argument that there have been problems getting it refereed.

19. **DMS**
June 30, 2005

The classification theorem for finite simple groups is likely to remain impossible for any one individual to verify. Perelman’s proof should be ‘easier’ since it requires verification of new mathematical tools.

Also, is there a proof of the Four-Colour theorem that does not need computers??

Seems like proof in the strict traditional sense is not always possible.

What do you think?

20. **Peter Woit**
June 30, 2005

Quantoken,

First of all, stop submitting large numbers of comments, this is not a forum set up for you to go on and on. I’ve deleted all except the first one.

About your points: there’s never any absolute logical certainty of the validity of a proof of the complexity of the one Perelman has outlined. But if several people who really have a lot of experience dealing with the techniques involved put in the time necessary to go over the proof with a skeptical eye and announce that they are convinced by it, it’s extremely likely that the proof is valid. But you don’t have to take their word for it, that’s the whole point of the culture of mathematics. The mathematics community historically won’t recognize a proof until it is written down in sufficient detail to allow anyone who wants to to check it.

How well a proof is checked is a function of how much people care about the result. There are lots of proofs in the literature that are probably invalid if looked at carefully, but no one does this because hardly anyone cares about the result. For things like the Wiles proof of Fermat and this proof, the result is so important that you can be sure the proofs will be carefully checked. The whole process is also to some degree self-correcting. If a mistaken argument gets into the literature, and if it is an important one, other people will sooner or later try and use it to do other things, and if it is wrong it will give them wrong results which will ultimately be noticed.

21. **Peter Woit**
June 30, 2005

Hi Tony,

The smooth 4d Poincare conjecture is still open, no significant progress that I know of.

I think the way mathematics deals with conjectures like 3d Poincare and the way physics has dealt with superstring theory are completely different. Over the years lots of good evidence accumulated for 3d Poincare: all attempts to construct spaces that violated it failed, it was shown to be equivalent to other conjectures about topology for which there was significant evidence, and, as Morgan points out, it fit into a larger web of conjectures for which there was a lot of evidence.

So, the general assumption has been that the conjecture is true, but that new mathematical ideas were needed to prove it. It seems that, together with Hamilton’s work, Perelman has come up with these ideas. But still, until there is a complete proof written down and experts have gone over it and vetted it (under normal circumstances this would happen in a formal refereeing process before publication), mathematicians are not going to be comfortable saying there is a proof. From experience they know that a plausible sounding outline of a proof and a proof with the details worked out are two different things. Until you work out the details you can’t be sure a subtle problem has been missed (e.g. for instance recall the problem with the initial proof of Fermat by Wiles).

Superstring theory in 1984 was just a somewhat wild conjecture with little evidence to back it up. At the time you could argue it was an idea worth working on, but over the last 20 years a huge amount of evidence has accumulated that, as an idea for unification it doesn’t work. The way the particle theory community has refused to acknowledge this is something that has no analog I can think of in mathematics.

22. **Quantoken**
June 30, 2005

Interesting.

“and the press release goes on to claim that “The 60 participants, more than half from the developing world, **reaffirmed** the approving judgement of the mathematicians.”…”

Peter raised a good point on how these 60 guys supposed to **“reaffirm”** the judgements of the mathematicians? By what? Maybe by their faith or confidence in the authority and credibility represented by the hats these mathematicians wear? If they have not spent 5 years trying to rigorously check every single step of the logic in Perelman’s proof, they probably have run it through a spell checker to make sure it contains no English grammar error. Maybe that’s what they mean “reaffirm”.

Suppose Perelman is already a well known and well established guy, He is the No.1 guy in math, and he made this unusual claim that he proved the Poincare Conjesture just today. And the proof is 1000 pages long and extremely hard to read and go through? How does the No.2 guy in math supposed to believe in this No.1 guy? He has two choices:

1.He believes it because he trusts the No.1 guy and because of the authority power that the No.1 guy is smarter than him and whatever No.1 says must be true, and he is not going to waste time questioning the No.1 guy.

2.He question it until he can convince himself that the logic really works. So he need to spend time, tremendous amount of time, maybe several years, 5, 10 years? Rigurously going through every step. After exhaustive search, he could not find a single logical fraud that could render the original proof invalid. Thus the No.2 guy claim to the world that he has gone through the No.1 guy's proof, and he discovered nothing wrong. Thus the proof is valid.

But certainly there is always the possibility that despite of the honest effort No.2 put in, he might still have missed something. Or even the remote possibility that No.2 gets a little bit lazy after spend one year going through 2/3 of the paper. How are we supposed to know that is the case or not. How are we even supposed to know that No.1 wasn't being dishonest and he took the first approach since he was lazy.

So that is the question the next guy in line, No.3, has to ask and answer. Does he believe in No.1 and No.2? And just like No.1, he has two choices, either he believes in No.1 and No.2 by faith and confidence, and save himself some time. Or the No.3 has to do the hard work and going through the whole rigorously thing himself. Being less smart than No.1 and No.2, it would be even harder and take him more time if he wishes to go through the whole thing himself. So there is an even better chance No.3 gets lazy and become dishonest, and just make the "re-affirmation" claim before he finish reading 1/2 of the paper.

And what about the No. N guy, after all the previous N-1 guys claimed the proof was valid? Would he choose to nod his head with the rest of the gang. Or would he want to become the first child who point out the fact that the emperor could actually be naked, and all previous N-2 guys are all just blindly follow their trust in the judgement of the "smart guys" before them?

That's an interesting philosophy question. And one that really worth thinking about, in the light that 60 physicist all collectively choose the first approach, i.e., "re-affirm" purely based on their faith in their math colleagues, instead of actually spend time proof reading the actual proof. And I bet 99.9% of mathematicians, 99.999% of the physicists community, and 99.999999% of the human population, would all very likely put their faith in the top 3 math guys and "re-affirm", instead of wasting their own time in trying to figure out the thing themselves. And I guess Peter, me myself, all readers of this blog, are all probably belong to this majority group like the 60 physicists.

Now are we really so sure the emperor is not naked?

There are two kinds of believe systems, One, faith based, you believe therefore you believe. That we call religion. Another, you believe based on evidences and based on rigorous logic and reasoning, that's science.

Unfortunately when it comes to extremely difficult math or physics problems, virtually in-accessible to the majority of people even in the field, evidence based religions system could be easily replaced by faith based believe system.

What happens a couple hundred years down the road. When the most difficult math problems become so difficult that no human being can resolve them and we have to just trust the proof spitted out of the printer from a super computer. Will we then become a civilization with a religion that worship machines? And science cease to exist? Will that happen eventually?

Peter, you cited in an earlier post Morgan's paper at http://www.ams.org/bull/2005-42-01/S0273-0979-04-01045-6/S0273-0979-04-01045-6.pdf
In that paper, Morgan said: "… After Thurston?s work, notwithstanding the fact that it has no direct bearing on the Poincare Conjecture, a consensus developed that the Poincare Conjecture (and the Geometrization Conjecture) were true. Paradoxically, subsuming the Poincare Conjecture into a broader conjecture and then giving evidence, independent from the Poincare Conjecture, for the broader conjecture led to a firmer belief in the Poincare Conjecture. …".
That is a fascinating commentary on the process of acceptance of conjectures within the mathematics community.

Can you comment on comparing that process of acceptance of the 3-dim Poincare Conjecture by the math community with the process of acceptance of superstring theory as the only possible Theory of Everything by the physics community?

Also, what is the status of the smooth Poincare conjecture in 4 dimensions?
I may be out of touch, but if I recall correctly as of a few years ago it was still unsolved, and Donaldson and Kronheimer say in their book The Geometry of Four-Manifolds (Oxford 1990): "… Smale's h-cobordism theorem: if X and Y are h-cobordant then they are diffeomorphic … breaks down in four dimensions … ". Also, Milnor's paper at http://www.math.sunysb.edu/~jack/PREPRINTS/poi-04a.pdf (updated June 2004) says "… In particular, if M4 is a homotopy sphere, then … M4 is homeomorphic to S4 . It should be noted that the piecewise linear or differentiable theories in dimension 4 are much more difficult. It is not known whether every smooth homotopy 4-sphere is diffeomorphic to S4 … As one indication of the complications, Freedman showed, using Donaldson's work, that R4 admits uncountably many inequivalent differentiable structures. …".
Has the smooth Poincare conjecture in 4 dimensions been solved, or has significant progress been made?

Renaissance Technologies

July 1, 2005
Categories: Uncategorized

Via [Steve Hsu](), the news from the Wall Street Journal is that Renaissance Technologies is about to launch a new hedge fund that could end up managing $100 billion, 10% of the total managed by all hedge funds today.

Renaissance Technologies is run by mathematician Jim Simons, perhaps the most successful hedge fund manager ever. His current Medallion hedge fund manages $5 billion, and his personal net worth is estimated to be about $2.5 billion. Renaissance employs many Ph.D. mathematicians and other scientists, but is quite secretive about their investment strategies. If you ask people who are working there about what they are doing, you get answers like "I could tell you, but then I'd have to kill you."

Simons was an undergraduate at MIT, got his Ph.D. from Berkeley in 1961, then was a junior faculty member at MIT and Harvard. He worked for a while at the Institute for Defense Analyses in Princeton, but was fired over criticism of the Vietnam War. He then went to SUNY Stony Brook, where as chair he built up a great math department, one especially strong in geometry. His work with Chern in the early seventies led to an extension of Chern-Weil theory involving "Chern-Simons forms", which have been of great importance in physics.

During the seventies he started trading currencies and commodities with his own money, leaving Stony Brook in 1978 to form his own investment fund. Over the years he has been generous to the mathematics community, supporting MSRI, the IAS, the Stony Brook and MIT math departments, and many conferences and workshops. I have no idea what his long term plans are for his current billions or the additional ones his new hedge fund may generate, but if even a fraction of them end up financing pure math research, this could have a very dramatic effect.

   Hi Anonymous,

   Thanks for your well thought out comment regarding free markets and central planning. Before commenting on some of your specific points, some clarification is appropriate. In my initial comment about free markets vs. central planning, in an effort to try to avoid the kind of misunderstanding that seems to have occurred, I mentioned early on that

   First, I agree that overall, free markets are much preferable to centrally planned economies, and probably for similar reasons to yours.

   Given that, you will hopefully agree that I will give an emphatic "No" to answer your question,

   So, just to make sure that I got you right: states, i.e. the entities which use theft and slavery to start and run wars, are inherently good; companies, which offer goods on a free market for voluntary exchange, are inherently bad. Did I get that quite right?

   I think my agreement with you on various other points in the past should support my disagreement of your assessment of my overall view. You may have gotten your impression from examples I gave to support the idea that there are times when "central planning" can have overall positive results (sometimes unintentionally!). Generally I try to avoid holding more extreme views since they are usually the product of ideological thinking rather than well thought-out arguments, and to cast free markets vs. central planning is "always good" vs. "always bad" seems somewhat extreme…

   Overall, I think there *can* be a role for regulation or outside intervention in at least three general conditions:

   1. Abusive practices create an unfair advantage for an individual or company. Examples are laws against bribery or racketeering, some regulation of insider trading, and regulations against some kinds of monopolistic practices (e.g., blatantly predatory pricing).

   2. Laws and regulations to prevent indentured servitude or abusive working conditions.

   3. Seeding or nurturing of basic science research, or even new basic technologies that are speculative or have very start up costs without any positive return on investment in an agreeable time frame. This is probably the most controversial area, and I will try to defend it below.

   In a truly free market, government would not take action in any of the above areas. Hopefully we can both agree that government intervention in at least the first two areas above is justified by significant actual abuses that have occurred in the past, even if we disagree on how much government action is appropriate.

   Now, on to some specific points you made.

   This is essentially Marx' old argument for how free market capitalism would abolish itself. It has a couple of big holes in it.

   I wasn't thinking about Marx at all when I made the comment, and I don't think that his agreement or disagreement with it has anything to do with whether the argument is correct. Marx probably thought periodic bathing was a good idea too; I doubt anyone will stop bathing because Marx thought that. 🙂

   One boils down to the difficulty of precisely defining "the market in X".

   This isn't something I had thought about, but I agree with your argument here. I would probably call much of it "market segmentation" rather than "different markets," but I don't know if this is purely a matter of semantics or not. The kind of monopolies I am concerned about are the ones relating to basic needs, where a monopoly has a lock on a very important market and there are no available alternatives, whether it is a scarce resource, a distribution channel, or a manufactured product. On the other hand, many markets are probably not prone to monopoly; for example, trees grow in a lot of places, one company could probably never own a sizable fraction of all the farm land, and you can always drive a basic car if you don't want to pay for a high end sports car.

   As new technologies emerge, old ones are abandoned, and even if a monopolist had managed to establish itself in the context of the old technology, it is very rarely able to retain its position – or even just to survive – when the technology changes… Xerox and IBM are two examples which I particularly like…

   Here I will both agree and disagree, but in different ways. I disagree because this only works in many cases if the market is sufficiently free. A new competitor must be able to establish itself enough to become a serious competitor, and new technology won't necessarily allow that if the established monopolist can use predatory pricing to prevent the new competitor from making a profit, or if the monopolist closes distribution channels to the hopeful competitor by using its market power. Probably most importantly, there is nothing to prevent a monopolist from seeing the need to adapt to the technological change by adopting the new technology itself and then proceeding to use anticompetitive practices to put the new competitor out of business before raising prices again. The reason this works is that adoption of new technology is rarely immediate, so the monopolist can use its power to buy time while adapting to the change.

The way I see it, your argument about technological change is primarily valid if (1) the monopolist is incompetent and refuses to adapt to maintain dominance; or (2) another company with a lot of resources and clout decides to enter the monopolist's market. I admit to grossly oversimplifying things by completely ignoring international trade, and that probably throws into question a lot of what I am arguing since a monopolist can't exert much control in a country where it has little presence. But the international market is even less free than the US market, so I think it is hard to fully take that into account. And wage disparity won't be permanent in the presence of a free market.

If monopolists are effective in using the above anti-competitive practices, it seems safe to say that there will be less and less interest by investors in funding a new company that will compete primarily on the basis of new technology. I think Microsoft is an excellent example — venture capitalists tend to steer clear of funding companies that will compete with Microsoft, one reason being that Microsoft has been very good at incorporating new ideas and thus depriving the new competitor of a market.

Finally, I think the examples you gave of how new technologies can end monopolies don't really support your argument too well. They are great examples of how companies can lose dominance or markets can dramatically change due to new technology, but they all happened in a relatively free market. If IBM hadn't been restrained by the US government in the 1960s to 1980s, I think there would be a lot more mainframe usage today. (As far as Xerox goes, their inability to make money from great new technologies they invented outside their core market is legendary; that says more about their incompetence than anything else). Finally, a lot of the new technologies and markets are offshoots of earlier ones, and they probably wouldn't exist if the earlier ones hadn't established themselves. I don't think you can come up with good supporting arguments for your position that apply to a truly free market, because as far as I know there is no history of that kind of free market existing, at least in "modern" times. It is just "belief" on your part…

*No, a government monopolist will squeeze much harder, in the absence of *any* counterforce.*

I was thinking of the Soviet Union when commenting that a government monopolist will probably not be as inclined to try to extract the maximum possible price for goods. Basic goods were often cheap; it's just that their supply was limited or nonexistent (a different problem). I was not trying to use that as an argument in favor of central planning…

I think this has gotten long enough. I want to respond to some of your other points, especially where you tried to argue that among my examples of government involvement, none actually had an overall positive economic benefit. (At least that seemed to be what you were claiming.) Some of my examples were better than others (the farming one is probably questionable), but I think you are extremely optimistic to think that the aircraft, electronics or communications industries, for example, would be anything close to what they are now if the government hadn't supported their development and acted as a large, reliable customer while the technologies established themselves and costs declined. But I admit that is speculation.

Anyway, thanks for taking the time to reply to my past comments. I am definitely learning from it, and it is getting me to think more about these issues.

   July 13, 2005

   But seriously, your definition, and the subsequent extinction of "planned economy" species only proofs, from the point of view of evolution theory, that planned economies had a disadvantage in the niche of "XXth century countries".

   Darwin's theory does not have a concept of progress, just extinction.

3. **Alejandro**
   July 13, 2005

   I am imagining the sexual intercourse of two countries… well, mitosis seems a more frequent process.

   Hi Anonymous,

   Thank you for your well reasoned reply to my comments about the Ren Tech stragegy. I really appreciate your informed comments — I am learning from them, and trying to learn something and test/modify my views is my motivation for putting some energy into this topic.

At this point it seems like our views are not really in conflict, at least in matters that are well understood. Just a couple of comments about what you wrote:

What actually seems to happen is that the competing technical systems quickly start pre-empting and therefore neutralizing each other, as noted above. Even if this weren't the case, it's hard to see how regulation could help.

I think JC mentioned something about this neutralization early on. It certainly makes sense; one could probably predict this would happen. If this is indeed how things play out, then there probably wouldn't be important, negative long term consequences, meaning that this kind of trading didn't offer significant new efficiencies (i.e., that it was a short term tactical move borne of opportunity).

If, on the other hand, the trading strategy has meaningful negative consequences then I believe regulators will try to step in and "fix" it. Note that I am not arguing that they *should* step in, nor that such an attempt would be successful (as you noted). On the other hand, I am not an absolutist; I think *some* kinds of regulation do more good than harm, so I don't have an opinion at this point. But whatever I (or you) may think, if there is enough disruption and it is perceived as negative, then I am confident that regulators will *try* to clamp down.

I agree that the kinds of regulation that you mentioned, such as limits on trades, computer based trading and limits on trading volume would be either ineffective or counterproductive. However, as Maynard mentioned a little while back, "friction" could be introduced into the system to decrease that attractiveness of quick, low profit trades, for example a tax on certain kinds of transactions (at a minimum this would eliminate the benefit of using multiple brokers). Please note that I am *not* advocating taxation of this sort, but mention it only as an example of the many different tools a creative regulator could use. We'll see how it all plays out…

A.R. wrote:
Please let me apologise

No need to apologise.

A.R. wrote:
pricing mechanisms depend on availability, and that any market system, willing to have exchange prices, must restrict availability by using ownership. The

same applies, intriguingly, in Estate regulated economies, except that ownership is not exercised by individuals.

I agree, prices depend on availability; if you don't want to run into scarcity and oversupply problems, there's no way around that. The problem when trying to dictate prices, rather than letting the market find them on its own, is that you are trying to perform and enormously complicated optimization task. You don't have all the relevant data to do it; if you did have all the data it would overwhelm you; and if it somehow didn't overwhelm you, you would just end up finding the same optimal price point set by the market. So what was the point of all that work, then?

A.R. wrote:
I fail to see how Spanish America was a *internal* colonisation.

Before they became independent countries, the Spanish, Portuguese (and Dutch, and French, and British) colonies in the Americas were run as territories of the respective coloniser, remember? And for a long time, they pretty much plodded along according to the usual European model of the time, with kings, aristocrats and priests running the show. The US got rolling only after it threw tea, taxes and Britons back into the Atlantic and decided to start doing things its own way. And not a minute too soon, I say!

A.R. wrote:
As for "evolution=confrontation", I am pretty sure this is not a theory of evolution as applied by the biologists

Watch countries, economies and social systems evolve, interact with their environment and compete with each other over historical timescales (centuries, millennia). How does this process differ from that of biological organisms evolving, interacting with their environment and competing with each other? (Now that you got me started, what does in fact, prevent a country from being considered a biological organism in its own right?)

M wrote:
I am not aware of any truly free market in any developed, industrialized country

I must unfortunately agree. Such is the state of our world that we must choose among the lesser among evils. 🙁

M wrote:
a truly free market, i.e. a completely unregulated one, is in a kind of unstable equilibrium. Left alone, some competitors will emerge as the strongest, and monopolies form because there is nothing to prevent the most powerful from becoming powerful enough to completely dominate their market.

This is essentially Marx' old argument for how free market capitalism would abolish itself. It has a couple of big holes in it.

One boils down to the difficulty of precisely defining "the market in X". A silly example: is there just one market in cars, or do Ferraris and SEATs really trade on separate markets? Methinks they are really separate, and guess what – the people who make the world's best sport and luxury vehicles turn out to be really bad at competing in the low end mass market, where they get handily beaten not only by Seat but by a whole bunch of Japanese (and other) manufacturers (behind the various corporate logos, it's all FIAT, sometimes spelled out as Failed Italian Attempt at Transportation… which is just plain wrong, at least if your name happens to be Schumacher). Markets stratify and specialize, and competition tends to reward those who concentrate on one segment. Even then, it's rarely the case that a single company completely dominates its segment for long.

The second big hole has to do with the last two words in the previous paragraph: "for long". Schumpeter coined the phrase "creative destruction" to describe the effects of technological development on companies. As new technologies emerge, old ones are abandoned, and even if a monopolist had managed to establish itself in the context of the old technology, it is very rarely able to retain its position – or even just to survive – when the technology changes. When you get a little bit older you start realising that the average time period involved – the duration of a dominating position – is really quite short. You start thinking about it, and you can rattle off one company after the other which totally dominated its market when you were a child or a teenager, and now it's gone – along with the market! Are you old enough to remember mechanical watches from world-renowned Swiss manufacturers (what were they even called?), mechanical calculators (Facit), typewriters (Olivetti), Polaroid instant cameras, Xerox copiers, IBM mainframes?

Xerox and IBM are two examples which I particularly like, because of all their irony: the Palo Alto Research Center run by Xerox developed the mouse & GUI computer interface which we all take for granted these days. Apple "borrowed" it, using it first in a clumsy contraption called "Lisa" (after Job's daughter, I think – or was it

Wozniak's?) which bombed in the market, but which was followed by the (need i say it?) wildly successful Mac line. All the while Xerox kept churning out paper copiers, eventually waking up in reconstruction as the market for paper copiers was largely killed by digital documents stored, processed and viewed on (and occasionally printed from) computers with mouse & GUI interfaces – their own technology! Meanwhile, IBM – king of corporate computing – outsourced the task of developing an operating system for its newfangled personal office computer to a two-bit startup calling itself Microsloth or something… and in so doing created the largest computer market in history, only to be pushed out of the hardware business by Dell and other low cost manufacturers (do you even remember the time when those were called "clone makers"?), while MS took over the software business (but for how much longer?). Did you ever notice when IBM recently sold off the last remnants of its PC business to a Chinese outfit? Probably less so than Apple's announcement that they are finally dropping IBM's processors in favour of Intel's. What IBM does these days? Mainly "services", which to a large extent seems to be about keeping those old mainframes running at the premises of die-hard corporate customers.

It's not easy being a dominatic actor these days… not to mention a monopolist, which strictly speaking is something else, a company which isn't allowed to have competitors (typically by political mandate, as in the common cases of tobacco, alcohol and telecommunications), rather than one which is just very good at beating them in the market (which must mean it's doing something right in the eyes of the consumers, or they would indeed favour the competition).

Now, I'll give you this much: it's conceivable that technologically mature markets, where little further development is possible, may fall in the hands of a dominating company, that such a company may abuse its dominating position in various ways, and that the lack of creative destruction due to the lack of technological competition will cement this dominating position for a long time. I agree that such extraordinary circumstances may call for extraordinary measures, presumably the breaking up of the company in smaller independent units, as was done in the US with Standard Oil and with Bell. But such cases are truly few and far between, and even the two big, historical ones which I just mentioned are often taken as examples of the questionable wisdom of such imposed breakups. Were they really necessary, or would technology have done its job soon enough? Were they really not politically motivated, a la Lukoil? Were ties between baby oils and baby bells really severed, behind the scenes? And what was the net impact on the national economy? There's plenty of material for debate there.

M continued:
Society suffers as these monopolies extract the maximum price their markets will bear without collapsing. Innovation suffers because as long as the monopolist has a captive market there is little external economic pressure to improve efficiency.

I most definitely disagree. The first sentence in the above quote describes a situation of extreme economic duress for the customers, who will therefore be extremely motivated to innovate their way out of their dependence on the monopolist.

M. hoped that:
A government monopolist is probably not going to squeeze the consumer as hard either.

No, a government monopolist will squeeze much harder, in the absence of *any* counterforce. When the same people who run the businesses are the ones who run the schools, the media, the courts and the government, exactly where are you going to turn? And if there's nowhere to turn, why would they not squeeze you as hard as they can? Out of the goodness of their hearts?

M asked:
Was their inefficiency and ineffectiveness at meeting consumer needs due to the fact that the businesses were monopolies (and hence had little motivation to improve), or was it primarily attributable just to their central planning?

How can there be competition without a free market? How can there be central planning with a free market? You can have one or the other, but not both.

M opined:
China seems to maintain a significant amount of central economic planning while gradually freeing its markets by moving away from government monopolies and toward privately owned businesses.

No. China maintains a political dictatorship, i.e. one party rule, state control over the media, censorship, jailing and execution of dissidents, but has been dismantling state run businesses and letting private ones run pretty much undisturbed as long as they make money and nothing else (i.e. trouble, as in free media). It's not the first time the world sees this kind of mix between steel-fisted political dictatorship and pretty free market economics; another releatively recent example which comes to mind is Chile under Pinochet. As far as the economy is concerned, it's not more centrally planned than the US.

M then really made my day by reminding us all that:
The aircraft and electronics industries were extensively funded and nurtured to maturity due to their usefulness for war.

Yes. States with lots of resources – ultimately always derived from taxation, known as theft when any other entity engages in it – always do that, plow those resources down into military expenditures of one kind or another. After relieving their citizenry of the means needed to develop and build the weapons, they draft – a practice known as slavery when any other entity engages in it – their sons (and occasionally daughters) and send them out to kill other expendable young people like themselves using said weapons. I guess that's why you assumed, a little while ago, that those who run state monopolies are inherently good and won't squeeze as hard as private "monopolists", correct?

So, just to make sure that I got you right: states, i.e. the entities which use theft and slavery to start and run wars, are inherently good; companies, which offer goods on a free market for voluntary exchange, are inherently bad. Did I get that quite right?

M claimed:
The Internet was originally a military project.

You are persumably thinking of ARPA-net, just one of the many – mostly academic – networks which grew independently and then fused into the Internet as we know it today. What made it into a mass phenomenon, hence relevant, was (1) the WWW, which as we all know was originally dreamed up at CERN (on European tax money, I'll hand you that much) and (2) the mass availability of PCs, for which we can thank Xerox, Apple, IBM, MS, Dell et.al., in various degrees (see above).

M claimed:
The space industry would probably not exist yet without government funding.

My guess, which is at least as good as yours, is that communication, earth resource and weather satellites – all most commercially viable – would be orbiting the earth now even if not one dime of tax money had ever gone into politically motivated moonwalks and other such nonsense, which historically absorbed most of the funds thrown into the "space" bin. I agree we would most probably not have those amazing videos of astronauts playing golf on the moon. The loss!

M claimed:
The railroad industry was given a significant push due to government grants in the 19th century.

The thought which never seems to enter the mind of those talking about "government grants" is that the money in question came from somewhere – and no, it wan't from the government, it was from something known as taxes. So, let's see; first the government relieves workers and companies of their money, then (after taking its "own" ample cut) it hands some of that money back in various ways. That makes the government the giver of all good things? Let's imagine the unimaginable, that companies and workers had been allowed to keep their money to do things like – oh, I don't know, invest in railways, perhaps? Do you seriously believe that profitable activities wouldn’t be undertaken without the “aid” (actually, it should be properly called interference) of the government?

M continued:
Government funding of the intrastate and interstate highway systems involved huge outlays of funds

Same illogic as for railroads.

M reached new highs with this:
Central planning has been important in maintaining the health of the farming industry, for example in price supports to prevent boom and bust cycles.

Surely even you are aware that the farming “industry” in both the US and the EU is an unmitigated scandal, living off subsidies and protected by trade barriers against third world countries, all amounting to far more money being poured on fat Western farmers than what goes in “aid” to starving ones in the third world, the whole revolting state-run business resulting in Western consumers (yes, the same ones who finance the farm subsidies with their tax money) paying far more than they would in a free market for products which could be imported cheaply from people who are literally dying for a chance to sell their crops?

The “health” of the US, EU (and to some extent Japanese) farming industry is nothing but. Farming is – or rather, should be – a business like all others. If it can’t be run profitably, it shouldn’t be run at all. Those “healthy” farms which you are looking at zombies. The sooner they are put to rest for good, the less further damage they will do.

M continued:
The Federal Reserve Board uses its power over the credit markets to try to keep things stable

The artificially low interest rates dictated by the Federal Reserve Board (which, needless to say, should not be allowed to dictate any interest rates at all – there is no reason why the optimal price for borrowing money shouldn’t be set freely by the market, no matter what the duration of the loan) have created a whole series of bubbles, too long to even start rattling it off here. If you really believe the current situation is stable, I suggest that, as a first step, you peek at a chart over total US debt.

M then surprised me with:
and many would say that currently its policy of maintaining artifically low interest rates continues to encourage unnaturally rapid price increases in many housing markets.

Yes, that’s the most well-advertised of the current Fed-induced bubbles. I thought you were talking about stability?

M correctly summed up thusly:
All in all, I think one could make a good argument that even the US has significant elements of central planning

I must unfortunately agree.

M then again lost me with:
and that overall it has been to the good of the economy and society

The US is great because it’s less regulated and central planned, i.e. more free, than most other countries. The US could be far greater still if it really lived up to the spirit of what got it started in the first place: that little tax revolt known as the Boston Tea Party.

M wrote:
there is something about the use of blind, automated trading, based only on recent activity without regard to any kind of fundamentals, that bothers me

There, now you put your foot right in the ever-raging debate between fundamental and technical traders. 🙂

Most technicians would probably tell you that all available information is already priced into to market, so studying fundamentals is just a laborious and error-prone way of finding out what you can learn immediately from the price and volume charts. The fundamentalists would counter this by asking: ah, but what information can there be in a chart if every trader just looks at market action and nobody bothers to analyze the fundamentals any longer? My (obvious) answer is that, sooner or later, such behaviour will result in a bubble, with financial markets detaching themselves from the realities of the underlying real economy and taking on a brief but spectacular life all of their own.

But, and here we come full circle, if you study the past behaviour of markets – as you must, if you want to be a technical trader – you can’t avoid learning about the existence of bubbles. In fact, you’ll get to know all kinds of interesting historical examples (tulip mania, South Sea Bubble, DJI ~1929, NDX ~2000…). If you are hard core enough, you will even find technical bubble signatures like the log-periodic oscillations of Sornette et.al.; but what you’ll defintely learn is the necessity of always keeping a watchful eye at least on a few fundamental indicators like price over earnings growth. Not to trade on from day to day – that’s futile – but at the very least as rough cuts to keep you out of the worst trouble, and more generally to give you a sense of overall direction over the longer term.

Now, I don’t know what RenTech is doing – I guess nobody outside the company does, or is allowed to tell, at least – but if they are half as successful as claimed, I find it extremely hard to believe that they are not throwing fundamentals into the longer term part of their statistical analysis.

M continued:
This, in a sense, is indeed an efficiency improvement, although it is only of benefit to Ren. Tech’s clients rather than the investment community as a whole.

It’s so tempting to quip “what’s good for RenTech is good for the markets”, but as long as they don’t pay me to do that, I’ll try to take a broader view.

So, let’s remember who’s at the other side of trades entered by speculators. Another speculator? That’s one possibility. In that case, each individual trade may be a zero-sum game between speculators, but the sum of all those trades provides much of the previously mentioned liquidity and price discovery.

Consider for instance the passage of Dennis through the Mexican Gulf. Last Friday, nobody could tell for sure whether the oil rigs and ports in the region would be hit, and if so how badly, and what the consequences would be for oil production and availability.

Companies which depend on a steady flow of oil were looking at a risk. Now, the first thing which you want to do when dealing with a risk is quantify it. That means answering the question: how bad can it get? The activities of speculators in the oil futures markets provided an educated answer to that question, based on weather reports and publically available information about the daily volume of oil produced and off-loaded in the Gulf, the positions and repair status of oil rigs and ports, the safety measures (like taking personnel off platforms and suspending port operations) of companies in the region and so on. This amounted to a pretty sophisticated analysis, performed in real time in a distributed fashion by a large number of independent agents, all acting in – and sharply motivated by – their own self-interest. The consensus emerging from this operation, weighted by degree of conviction (a good measure of analysis effort spent) and speculative resources (a good measure of analysis resources) could be looked up as it evolved, tick by tick, by anyone with nternet access. That’s a pretty good societal service.

But returning to the question of who's at the other side of the trade: the other major possibility, if it isn't a speculator, is that it's a commercial trying to insure against a risk, a.k.a. a hedger. That's the second thing you want to do when dealing with a risk: after
you've quantified it, if you determine that circumstances call for it, you buy insurance against it. Last Friday, if you were a commercial depending on the price of oil for your operations, you could have bought insurance against supply disruptions in the form of oil futures or call options. The counterpart would have been a speculator, willing to take on the risk in exchange for the prospect of a profit.

And here we find the answer to your question: if this speculator is successful, it's because it has good risk management and analysis. From your point of view as a commercial seeking insurance, good risk management means that your counterpart won't go bust and prove unable to pay you when it's time to close the trade; good analysis means that it can take on larger volumes and offer you a better price than other speculators, who are less confident about the future direction of oil prices. Remember, when a commercial goes to the futures or options market to buy insurance, the speculators have to bid for the commercial's business.

M correctly observed:
it seems the game now starts to change. Trading activity is now influenced by the same trading considerations as before, but an additional influence also starts to become important: the behavior of the automated trading systems themselves

True. It's often observed by technical traders that once an indicator becomes widely known and used, its efficiency declines rapidly, as everybody starts pre-empting its signals. To the extent that trading is a zero-sum game between speculators, this inevitably kills the profitability of the indicator, since all traders can't possibly make money from it at the same time. The same reasoning applies when you employ statistical analysis to find patterns in past market action. You may not know the explicit form of the indicator(s) being used by your speculating counterparts, but if you can deduce how they'll respond to future moves, that's close enough. You'll still have neutralized their advantage. So off they go to the drawing board (or, more likely, to the computer) to cook up something new.

And so do you.

I believe biology has plenty of behaviours and physical characteristics evolved in such a manner, with predators and preys, or even males and females of the same species successively adapting to each other's adaptations in previous rounds.

M continued:
Over time, if blind, automated trading systems become the norm (as they would in an unregulated environment if they are more efficient than older systems), then I would expect an important shift in the rationality of affected kinds of speculative activity.

What actually seems to happen is that the competing technical systems quickly start pre-empting and therefore neutralizing each other, as noted above.

Even if this weren't the case, it's hard to see how regulation could help. Are we going to prohibit thinking up new trading strategies? How would such regulation be enforced? Prohibit computer-based trading? Bye bye NASDAQ – and just about every modern exchange in the world (even the last few strongholds of open outcry run electronic trading networks and will probably be fully screen based in a a few more years). Impose a limit on the number or speed of trades? Just sign up with more brokers, trade through more exchanges or make larger block trades (the latter really bad news for anyone wishing to see smooth, liquid, continuous market action). Impose a limit on daily volatility? Done already, after the crash of 1987 – automated trading systems were conveniently blamed, so automatic circuit breakers were put in place which would prevent a repeat performance (and proved pretty useless in 2000 and 2001; all they did was protact the agony rather than have it all go down in one full swoop).

Ultimately, I just don't see with what *right* a third party could come in and impose such regulations on the participants in a free
market. Those who want to trade a market do, those who don't want to don't; those who want to start up a new market with their own rules can do so, too (and do, like the bunch of ECNs for stock trading which started up in the late 90s; the flavor of the day seems to be emission rights trading).

Dear anonymous,

Please let me apologise by the translation problem in the word "value", and blame myself with Machado: "Solo un necio confunde valor con precio". It seems to me, and this was my whole point, that pricing mechanisms depend on availability, and that any market system, willing to have exchange prices, must restrict availability by using ownership. The same applies, intriguingly, in Estate regulated economies, except that ownership is not exercised by individuals.

I fail to see how Spanish America was a *internal* colonisation. As for Siberian, as you say, there is a component lacking: the willingness to go there and to stay there.

Of course I do not like the old Spanish (et al) system of imposed values. Your suggestion surprised me, and it shows that I did not got to make myself clear in the previous posting.

As for "evolution=confrontation", I am pretty sure this is not a theory of evolution as applied by the biologists. Discussion could be perhaps a bit off from the blog entry topic, economy+physics.

Hi Anonymous,

You wrote:

There is a system of resource allocation which is theoretically understood and empirically known to work very, very well: the free market. There is an alternative system of resource allocation which is theoretically understood and empirically known not to work well at all, leading to all sorts of imbalances (scarcities of needed goods and surpluses of unwanted ones) and typically collapsing after a few decades: central planning.

First, I agree that overall, free markets are much preferable to centrally planned economies, and probably for similar reasons to yours. However, I am not aware of any truly free market in any developed, industrialized country, even though the U.S. probably comes as close to that "ideal" as any.

I enclosed "ideal" in quotation marks because I think it is hard to argue that a truly free market is desirable for society as a whole, just as a centrally planned economy (the other extreme) is not desirable. From what I understand, a truly free market, i.e. a completely unregulated one, is in a kind of unstable equilibrium. Left alone, some competitors will emerge as the strongest, and monopolies form because there is nothing to prevent the most powerful from becoming powerful enough to completely dominate their market. At the point of monopoly the market is no longer free; the central planners aren't in government, but they are in the company headquarters. Society suffers as these monopolies extract the maximum price their markets will bear without collapsing. Innovation suffers because as long as the monopolist has a captive market there is little external economic pressure to improve efficiency. And so on. I don't think any of this is very controversial; it seems to be the way things have gone in times past when there was little regulation. I also imagine that you would favor government regulation to keep it from happening, provided it is kept to the minimum necessary to keep the markets as free as possible.

The centrally planned economy you mentioned most prominently, the Soviet Union, is interesting because it also had government ownership of production. Thus, according to my understanding the government was also the monopolist in all key markets, which may be worse than having the different monopolists that emerge in a truly free market, but if so it seems more a matter of degree. (A government monopolist is probably not going to squeeze the consumer as hard either.) So an interesting question arises: Was their inefficiency and ineffectiveness at meeting consumer needs due to the fact that the businesses were monopolies (and hence had little motivation to improve), or was it primarily attributable just to their central planning?

Also interestingly, China seems to maintain a significant amount of central economic planning while gradually freeing its markets by moving away from government monopolies and toward privately owned businesses. Since it continues to grow at a strong rate and is emerging as increasingly powerful on the world stage, it seems their example argues more against monopolies than central planning as the primary economic evil. But since giving up their monopolies means the government has less direct control, it may be hard to distinguish between the two.

Even in the United States, government involvement has interfered with the natural course of free markets, but at least sometimes it has had very positive economic consequences. For example, consider the aircraft, space, electronics, railroad and automobile industries in the United States, which have been extremely important economically; at different times at least the automobile and electronics industries have been the single largest manufacturing employers in the US. The aircraft and electronics industries were extensively funded and nurtured to maturity due to their usefulness for war. The Internet was originally a military project. The space industry would probably not exist yet without government funding. The railroad industry was given a significant push due to government grants in the 19th century. Government funding of the intrastate and interstate highway systems involved huge outlays of funds and made the automobile more desirable. Central planning has been important in maintaining the health of the farming industry, for example in price supports to prevent boom and bust cycles. The Federal Reserve Board uses its power over the credit markets to try to keep things stable, and many would say that currently its policy of maintaining artifically low interest rates continues to encourage unnaturally rapid price increases in many housing markets. All in all, I think one could make a good argument that even the US has significant elements of central planning and that overall it has been to the good of the economy and society.

July 12, 2005

Hi Anonymous,

Well, am finally getting around to responding to you about your last comment in the discussion about computer-based trading of the kind Ren Tech seems to use, and whether it contributes any additional value to society or is just opportunistic. You seemed to take the view that it contributes new value in terms of improved efficiency:

Just like technological competition between car manufacturers results in better cars for their customers, techonological competition between speculators results in better risk reduction, liquidity and price discovery for theirs (i.e. the "respectable" market participants).

You may be right, but there is something about the use of blind, automated trading, based only on recent activity without regard to any kind of fundamentals, that bothers me. Recall that I agree speculators provide an important service. I also agree with you that efficiency improvements are important; they improve productivity. If an automobile manufacturer introduces significant efficiency improvements, competitors will notice and introduce their own improvements or probably lose market share. Similarly, if a large investment management firm produces superior returns due to rapid, automated trading systems, then its competitors will take notice and either introduce their own similar efficiencies or suffer competitive loss.

Where I think the efficiency argument starts to break down is as follows. If the comment by "R" is indicative, i.e.,

RenTech has a large historical database of stock market price movements. The price movements have a lot of random noise, but also significant signals. The job is to identify the signals…

then the trading strategy includes analyzing historical indicators together with current activity and then making trades accordingly. This, in a sense, is indeed an efficiency improvement, although it is only of benefit to Ren. Tech's clients rather than the investment community as a whole. Assuming they maintain superior returns, others can be expected to employ similar tactics. However, it seems the game now starts to change. Trading activity is now influenced by the same trading considerations as before, but an additional influence also starts to become important: the behavior of the automated trading systems themselves. Historical data and analyses don't fully reflect the trading patterns of these computer systems; trades by them are done for different reasons than the historical ones. So the trading systems must adapt to this new trading force; automated trading systems must factor in the activity of competing automated trading systems. Over time, if blind, automated trading systems become the norm (as they would in an unregulated environment if they are more efficient than older systems), then I would expect an important shift in the rationality of affected kinds of speculative activity. Trading activity may become less comprehensible to human traders, since blind, automated trading is at least one step removed from the historical forces that drive speculation (e.g., natural disasters, changes in political climate, changes in economic indicators).

Left unchecked by regulation, I can imagine several kinds of undesirable consequences. Having rapid, automated trading as a significant force in speculative markets could make these markets less stable. People may be relatively slow, but this slowness can improve stability; significantly reducing this time by automation reduces feedback. Second, if having an automated trading system is the price of entry into some speculative markets, smaller investors except for the very brightest will probably be driven out. It is hard to see how the resulting concentration of power would be a good thing. Finally, if the nature of speculative trading changes significantly enough, it seems it will be less effective in providing its historical value to the economy.

I guess I'm saying that I don't see more than a superficial parallel between traditional efficiency improvements (e.g., in car manufacturing) where economic benefits are fairly clear, and efficiency improvements in speculative trading due to technical data driven automated trading. If the hazards I mentioned become reality then I would expect regulators to step in. If none of those hazards became important then it would probably be because the automated trading systems weren't all that effective after all. Either way, I still don't see how the enconomy as a whole will benefit from them; it still seems more like opportunism than additional value to society.

A.R. wrote:
proving that a system/theory/whatever is incorrect does not prove that an alternative id./id./id is correct.

No, but pitting alternative systems against each other under varying conditions and seeing which one does better is a perfectly valid way to find out which one works best (biologists know the concept well as "evolution"). By now, only somebody incredibly (read willingly) ignorant of history could claim other than this kind of competitive stress test has been done many, many times over, always with the same result: planned economies fail (typically killing millions in the process), free market economies thrive.

A.R. also wrote:
As for free markets, the problem to me is not freedom, but market. In the sense of valuation, because I feel that the methods to impose value upon objects are defective.

This statement shows that your problem is very much freedom. Freedom means that each individual chooses for him- or herself what constitutes value, and acts accordingly. There is no such thing as "methods to impose value" in a free market, only methods to peacefully achieve mutual, voluntary agreement on the correct *price* of X in terms of Y (and vice versa), leading to the optimal availability of *both*. If you value X more than Y, you give som Y in exchange for some X. If you value Y more than X, you give some X in exchange for some Y. Free market economies don't impose preferences and values.

Imposing values, i.e. telling others what they should like and dislike, want and not want, demand and abhor – that's the business of dictatorships, which centrally planned economies must inevitably be.

It's obvious from your statements that your real reason to dislike free market economies is that they extract the fair price for the things which *you* value – let's venture a guess, time to think about physics. It would be much nicer to get all that time for free, wouldn't it? Except there is no such thing as a free lunch. If you don't pay for it, somebody else has to do so instead.

That's what imposing values ultimately means: forcing others to pay for what you, not they, want. No longer voluntary agreements, a.k.a. trade, but brute force. That's what you are advocating.

A.R. also wrote:
internal colonisation -go go west- was really a very special prerrogative of the USA

No dear, it wasn't. The medieval kingdoms of Spain and Portugal, incidentally societies much more in line with your preferences of imposed values, had the same prerogative in Latin America, and see how well that served them. Or if you'd prefer to talk about the Soviet Union, there was plenty of internal colonisation going on there too. Of course, those invaluable Siberian oil fields were not exactly created by voluntary workers, now were they?

15. **Alejandro Rivero**
July 11, 2005

Note that proving that a system/theory/whatever is incorrect does not prove that an alternative id./id./id is correct. I believe this has been already argued in this blog when discussing about Quantum Gravity (or in physicsforums?) and I do not see apropiate to repeat all of it.

As for free markets, the problem to me is not freedom, but market. In the sense of valuation, because I feel that the methods to impose value upon objects are defective. Time ago I dreamt of developing a "Physics of Ownership" by studying first valueless, scale invariant, markets as if they were fixed points, and then taking value -either via private or public retention, er, ownership- as a perturbation, analysing relevant and irrelevant parameters etc.

(PS: internal colonisation -go go west- was really a very special prerrogative of the USA, and it distorts the whole perspective)

16.
July 11, 2005

Bah! To this day, even after the loss of the oil-rich, former Soviet republics in the south, Russia remains one of the planet's largest oil producers and exporters. The Soviet Union of old controlled one sixth of Earth's surface and was essentially self-sufficient in natural resources – or would have been, had it not been utterly unable to manage its natural wealth due to its dysfunctional central planning system of waste and corruption.

So much for oil.

As for colonisation, it was certainly neither invented by nor a prerogative of free market economies. Historically, every kingdom and empire which had the capacity to engage in that practice did so, right up to the last one of them, the former Soviet Empire, whose adventures in South East Asia, Africa and Latin America surely aren't unknown to you. But needless to say, even that couldn't save its fundamentally flawed system.

17. **Alejandro Rivero**
July 10, 2005

There is a system of resource allocation which is theoretically understood and empirically known to work very, very well: the free market.

I deny any scientific meaning to "empirically" above. Such empirical source was not under controlled conditions, and a blank experiment does not exist. Most free markets economies have enjoyed an external resource inflow from external (EU) or internal (US) colonisation process, and this inflow could cause the delusion of efficiency.

Additionally, the availability of oil during the XXth century, sometimes becoming almost a free energy source, cast doubts about the equilibrium state.

18.
July 9, 2005

There is a system of resource allocation which is theoretically understood and empirically known to work very, very well: the free market.

There is an alternative system of resource allocation which is theoretically understood and empirically known not to work well at all, leading to all sorts of imbalances (scarcities of needed goods and surpluses of unwanted ones) and typically collapsing after a few decades: central planning.

So, you have a plate of good food and a plate of poison. Which mix of the two are you suggesting is optimal? 50% food and 50% poison? 90% food and 10% poison?

In a free market, the allocation between "planners" (i.e. investors, speculators, traders and what have you) and producers of other goods is self-regulated by it just like the allocation between producers of any set of goods. Supply goes where there is demand to support it, or it will quickly be starved out and move on to other businesses.

In a planned economy, even just a "partially" planned one like European social democracies, allocation decisions are made by politicians and bureocrats, i.e. people who have neither the analytic capabilities nor the information necessary to make sensible decisions, who are not constrained by the feedback mechanisms which make free markets self-correcting and whose own self-interest always calls for one thing only: steal more, spend more.

In one word, poison.

19. **Maynard Handley**
July 8, 2005

What good does trading provide?

In a certain sense the financial markets are the world's planning department; they sift through various proposals for how to invest money and choose those that appear to be most likely to generate profit. This is very obvious in the case of venture capitalists, it is somewhat more roundabout in the case of buying stock at the NYSE and thereby "voting" for or against Apple computer.

Now one can levy at least two different types of criticism against this activity.
* The first is generic "anti-money" sort of criticism, saying things like "the value of a new product is more (eg perhaps some medicine) or less (a newer bigger SUV) than just how much money it will make". There's probably validity to this argument, but beyond this overall agreement, people seem unable to make useful progress on either how to measure this beyond-money value, or how to construct a society (based on real human beings subject to all the corruption and evil of real human beings) to put into

place these "beyond-money" ideas. So I find this line of criticism rather sterile.
* A second line of criticism is to accept the necessity of the current system, but to quibble with details of it. The drugs vs SUVs issue can be tinkered with using taxes and CAFE standards, for example. Specifically, nnow, the issue is, yes these people are doing useful work in planning how the world should invest its money BUT
(a) don't reach a limit in terms of the value of this planning? Having 1% (to pick a number) of the world's brain power spent on the task may be worthwhile, but perhaps the extra 1% spent taking this to 2% of the world's brain power is better spent on making the things we've already planned to do work better?
(b) isn't most of the energy thrown at the problem actually involved in a zero sum game of attacking other participants in this space, meaning that reducing the amount of effort (brain power and computational power) thrown at the problem even by a factor of 10 would lead to precious little difference in the actual planning outcomes?
I personally think both of these are perfectly valid criticisms, and I think society would be better off acting on them. For example small amounts of friction thrown into the system (transaction taxes, higher income taxes etc) would, IMHO, have pretty much zero influence on the actual outcomes for society, but would reduce the value of the exercise for many participants, thereby encouraging them to go off and do something more useful for society.
(Naturally, of course, those in power would disagree with this claim. As always, use some common sense and ask yourself "cui bono"?)

These ideas are explored at great length in Doug Henwood's book _Wall Street_, available for download at
http://www.wallstreetthebook.com/

20. **r**
July 7, 2005

Since I have known a few experimental physicists who have gone to RenTech, I thought a few late comments might be in order. But – warning – I have also heard a few math/physics and Wall Street talks, so I might be confusing some of these talks with some of the private RenTech discussions, or with discussions with others who know the RenTech people.

RenTech has a large historical database of stock market price movements. The price movements have a lot of random noise, but also significant signals. The job is to identify the signals. It seems the technical people, who come from a variety of backgrounds and thus have different perspectives on how one identifies signals, basically are running an ongoing research project in which they put proposed signals into the model, and then test these against the historical data.

I know little about the details of what they do. They do mention signing confidentiality agreements. From either them or others I recall terms like scale invaiance, Wigner random matrix theory, and Markovian statistics. My impression was that they just tend to be a little smarter / faster than other people, rather than being simply contrarian. But a friend's impression was that they are simply better at hedging their risks, as opposed to really finding signals. So draw your own conclusions from this.

21. **Alex R**
July 5, 2005

M wrote: *The contrarian approach can evidently be successful if properly used, but one needs to be intelligent about it. … For example, I observe that nobody is building portable compact disc players with vacuum tube circuitry, but I also predict that if you decide to act contrary to this "majority opinion" and start building vacuum tube-based CD players that you won't make billions of dollars from it.* 🙂

While I, too, have problems with "contrarianism" as an investment philosophy (for example: what happens when *everyone* is trying to be contrarian?), I can't resist pointing out that even your off-the-cuff "observation" about vacuum-tube based CD-players is incorrect. (OK, strictly speaking, I don't know how many of these are portable, and I doubt anyone is making billions of dollars in this market, but the market is there.)

The point here is not so much that one should be contrary for the sake of being contrary, but that many people make unquestioned assumptions about things based on conventional wisdom or common knowledge, and that it can pay to *discover* what those unquestioned assumptions are (often the hardest part!) and to *question* the conventional wisdom they are based on.

22.
July 5, 2005

Yeah, right.

23. **Arun**

There are too many errors in the previous to correct on a blog devoted to Not Even Wrong physics theories. So I'll say no more.

24.
July 4, 2005

Arun wrote:

"Profit is the market economy's measure of the value of the good being provided" is simply wrong.

No. It depends on how you interpret "good being provided". Using your implied interpretation, the statement would be technically correct if it said "added value" instead of just "value". If you separate out "the good being provided" as what's added by the provider, and the rest of it (e.g. materials required to produce it) as just being passed along, the "added" is implied and the statement is technically correct as is.

Not that any of this silly marking of words is of any relevance to the point made.

Arun also wrote:
Secondly, there would be lot of profits being made by some traders if the USA had fifty currencies instead of one. The economic benefit of having one currency however outweighs all these profits.

Perhaps. So what? Given any set of currencies, it's better to have speculators trading them freely than not having speculators trading them freely. That's the point.

Arun the illogically added:
Similarly, it is not at all obvious that speculators are doing something useful

First of all, there is no similarity between the arguments; and secondly, it's quite obvious that speculators are indeed doing something useful, as previously pointed out. And, I may add, they are doing it of their own free will, with their own money, coercing nobody into trading with them – so what's your problem, exactly?

Arun continued:
or whether they are simply living off an inefficiency of the market economy

Elementary knowledge of economics would tell you that it's exactly the process of "living off inefficiencies", a.k.a. arbitrage, that minimizes those inefficiencies.

Wherfeafter Arun surprisingly did admit that:
The market economy is simply an optimizing machine.

The best one there is. And incidentally the only moral one, since it's the only one based on participants acting out of free mutual consent for mutual benefit. What more could you possibly ask for?

Is conventional superstring theory analogous to a dead-end speculative bubble ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

26. **Arun**
July 4, 2005

"Profit is the market economy's measure of the value of the good being provided" is simply wrong. The market economy's value for a good being provided is the price of the good. The value of a United Airlines flight is the same as the value of an equivalent Southwest Airlines flight – that is why the ticket prices cannot be substantially different. That one company makes a profit while the other is in bankruptcy is a measure of the different costs incurred by the respective airlines, and not a difference in the value of the good to the market economy.

Secondly, there would be lot of profits being made by some traders if the USA had fifty currencies instead of one. The economic benefit of having one currency however outweighs all these profits. As a matter of fact, the market economy is ***more efficient*** by having one currency instead of fifty. Similarly, it is not at all obvious that speculators are doing something useful, or whether they are simply living off an inefficiency of the market economy similar to that of having fifty currencies.

The market economy will also yield efficiences and profits in the sale of slaves or narcotics just as well as in derivatives. The market economy is simply an optimizing machine. The economic activity, profits, etc., or making hte optimizing machinery work better are not a justification for what we ought to or ought not to trade in, or whether some forms of trading have any social value or not.

27.
July 4, 2005

The improvement of speculative trading methods (e.g. by automation and more refined statistical analysis) means by definition that the speculator's business becomes more profitable. Profit is the market economy's measure of the value of the good being provided. Hence, the improvement of speculative trading methods increases the speculator's value to the economy.

See it like this: a bad (i.e. unsuccessful) speculator doesn't survive as a speculator for long, and can therefore not keep providing the aforementioned valuable services (risk reduction, liquidity, price discovery) to others. A successful speculator can; a more successful speculator can do it more, and more efficiently.

Just like technological competition between car manufacturers results in better cars for their customers, techonological competition between speculators results in better risk reduction, liquidity and price discovery for theirs (i.e. the "respectable" market participants).

28. **M**
July 4, 2005

Hi Dick and Anonymous,

Actually, I wasn't thinking about speculators in general, just the kind of rapid, computer-based trading systems such as what Sean mentioned Renaissance uses. I fully agree with you that speculators play a valuable role in the economy, provided it is not excessive (and speculative activity is likewise important in other fields like science or art, notwithstanding the many, inevitable dead ends).

On the other hand, my understanding is that this kind of computer-based speculative trading does not provide a service that didn't already exist — market makers of various kinds already have established their niches and seem to have efficiently performed their services to the markets for some time now. Thus, it seems that automated, proprietary trading systems that offer superior returns to a single investment company's customers do not provide a similar benefit to the economy as a whole, unless of course that company is the sole occupant of its niche. Without providing new value, the net effect of this strategy on the overall economy would basically be to redistribute existing wealth rather than create new wealth. This seems more like opportunism, and I don't see that as something to admire…

29. **carl**
July 4, 2005

As far as physicists being impressed by money, I recall an invited talk by S. Thorpe at a particle physics seminar on the subject of how he made $93 million.

That would have been about 1984 or 85. I read his book on black jack, so after this many years I can't recall if his talk included that subject, or was entirely on how he was making money based on options pricing.

Carl

30. **Andreas**
July 3, 2005

Of course, there are societal benefits to expect from speculators if society itself is perceived as a market. While many intelligent and respectable individuals indeed see society as a great market place, such a perception is a bizarre delusion of human reality. Unfortunately, this distorted vision leads global society into crisis.

31.
July 3, 2005

There are several well known answers to the question of market speculation's societal value.

1) Speculators assume financial risks in exchange for future returns (hopefully). Those risks don't come out of the blue; they come from the balance books of people who

do not want or can not afford them. By taking over those risks, speculators perform a service.

2) The presence of speculators in the market makes ir more liquid, improving its ability to accomodate long term investors and commercial operators when they need to perform market operations in the course of their respectable business.

3) Closely related to point 2: speculators improve the market's ability to function as a price discovery mechanism, i.e. a way to determine the current value of an asset you hold. If you are a commercial company or long term investor, you feel a lot happier knowing not only that there are many buyers and sellers of the stuff on your books, but also knowing at what price they are willing to trade right now, not a week or a month ago.

So yes, unlike string theorists (just to pick a random example) speculators perform very useful services for the economy and therefore for society as a whole.

32. **Dick Thompson**
July 3, 2005

M, you said

… The Code actually does the buying and selling, much faster than a human ever could. And it doesn't know, or care, what it is buying or selling; all it knows are the statistics of past performance.

The question that comes to mind is, where the value to society in that? No value is being produced except to those who invested in Rennaisance or work there (at least that I can see), and even there, such a strategy basically seems like a zero sum game.

The value that arbitrageurs, hedgers and such provide to the generality is making a market. Providing opportunities for others to buy and sell where they might not otherwise have had the opportunity. The fact that the code can do this at blinding speed is all to the good.

33. **Arun**
July 3, 2005

M, I too wonder. If there is, e.g., social value in trading currencies, currency futures, hedging against currency rate fluctuations, then the US could do itself great good by letting each state have its own currency, creating so much more opportunity to play these games. The Euro was then a step backwards and so on.

34. **M**
July 3, 2005

Regarding my earlier question about differences in viewpoint between physicists/mathematicians and the population as a whole in the respect/awe given to those who have accumulated great wealth:

It seems like most people who gave an opinion don't see a lot of difference between those who are highly educated in analytical fields like physics and mathematics and the general population when it comes to views about great wealth. There is good food for thought in the responses, at least for me. I especially liked Andreas' thoughts about the limited correlation between wisdom and intellect/education, and how that might limit significant differences from the general population; it makes sense to me.

I also agree with Walt that having $2.5 billion would eliminate the need to worry about income, potentially freeing up time to do physics or mathematics. But I think this potential is kind of an illusion. If you have that much money and you are like most people, your wealth is going to have a major impact on what you do with your time. If you are conscientious you will try to manage your money carefully, which takes time; even if you let others do the managing, you will still need to pay attention, and it seems like that would interfere with creativity. If you are more carefree, you will spend a lot of that money freely, and that too will be a distraction from intense, creative thought. Either way, it seems like great wealth would be more of a hindrance than a help to doing good physics or math.

However, I do agree that financial *independence* is desirable for doing good work for its own sake. Worries about money kill creativity and lead people to direct their energies to meet practical demands, like career growth or just getting by. As Peter and others have repeatedly pointed out, the need to follow what is popular just to survive is not healthy for science.

But… How much money is needed for that independence? Billions? Hardly — it is hard to see how anyone could productively use more than $100 million or so for their own needs. That would buy a *very* nice house, a yacht, maybe a private island, and leave plenty of money left over to live comfortably. I guess that is part of the reason I would naively hope that highly educated, analytical people might have less envy or awe of billionaires than the general population — they could see that beyond a certain point there is little practical advantage to having more wealth. Beyond that point, it seems like its main benefit is to keep score, to have bragging rights to making the most dough. It seems like there is no place for worrying about being in the really big financial leagues if a person loves science, the attainment of knowledge and understanding, and who strives to make a contribution there. (I am omitting philanthropy as a major issue. It is great when wealthy people spread it around, but I can't imagine that very many people become wealthy just so they can be philanthropists.)

Something Sean said about a strategy of Rennaisance Technologies disturbs me at another level:

…The Code actually does the buying and selling, much faster than a human ever could. And it doesn't know, or care, what it is buying or selling; all it knows are the statistics of past performance.

The question that comes to mind is, where the value to society in that? No value is being produced except to those who invested in Rennaisance or work there (at least that I can see), and even there, such a strategy basically seems like a zero sum game. Because there is no new value, wealth is merely being redistributed rather than created. Society as a whole does not benefit; only the names of the winners and losers change. I guess I don't see what is admirable about playing games like that, and even if the players are rich I feel differently about them than those who become wealthy by making society richer as a whole due to their efforts. (I'm referring to the movers and shakers, not the people who are just trying to make a living at what they do well.) This is in contrast to those who build businesses that create new markets, or long term investors who allow companies to grow and become strong, even if it's partly at the expense of weaker companies that will probably wither later anyway. Regardless of whether they are doing it to earn bragging rights, at least society gains value in the process. And if they make some serious money in the process, that's fine with me.

I wonder if I am in a small minority in these views…

35. **Chris Oakley**
July 2, 2005

Mathematics should be an extension of common sense rather than a replacement. This is something that most people wowed by mathematics PhD's in finance don't seem to appreciate.

The LTCM disaster was just maths/physics PhDs doing dumb things, the sort of dumb things that no-one who didn't have a cocky belief that he was smarter than everyone else would do.

And all Joe Jett was doing was arbitraging the internal accounting system. It was so ridiculously simple that Kidder/Peabody should have been, and probably were ashamed of themselves for allowing it to happen.

36. **Andreas**
July 2, 2005

M,

to realize that envy for wealth (i.e., economic power) and wealth worship are pointless requires a certain level of personal wisdom. Wisdom, however, is usually uncorrelated with intellect or education, much in the same manner as technology is uncorrelated with culture. Hence, I expect any highly educated individual in the analytic fields be as much susceptible to money as anybody else. For instance, I think of mathematicians like John Nash, De Branges and, surely, Jim Simons.

37.
July 2, 2005

In order to be a success at anything or make huge amounts of money you have to love what you do; in fact, love it so much that it's not actually a job. A lot of physics and math people are like that, myself included. I can relate to the guy who said he worked in a financial institution and hated it. I tried to get into financial math at one point since people I knew were doing it and wanting to go in that direction. I just found it incredibly boring. I am not saying it is boring–some people will get really into it and that's fine–but for me personally I could'nt do that stuff no matter how much I was being paid. I find it really soulless.

I was also under the impression though that the financial world is more wary of math and physics types due to a number of high-profile disasters in the 90s involving "rocket scientist" types,
like the LTCM meltdown and the Joseph Jett/Kidder Peabody affair.

38.
July 1, 2005

Yeah, unless the $2.5 billion and the people you hire to help manage it end up running your life and taking up most of your time. Some people can handle that kind of wealth and remain creative and happy, and some can't. I'm sure Simons took plenty of time figuring out where he fell in that spectrum.

39. **Walt Pohl**
July 1, 2005

M: I think it's an ordinary human impulse, not something that requires special explanation. Even if you only care about mathematics or physics, you could do more of either with 2.5 billion dollars than you could without.

40.
July 1, 2005

"Are people who are highly educated in analytical fields like physics and mathematics similarly susceptible to the wealth envy or wealth worship?"

Of course, some are and some aren't. When I was younger, at the insistence of my supposedly intelligent family and friends, I got a job at a financial institution dealing in the fixed interest derivatives market. I worked with another mathematically trained individual. I started on $40 000 a year. I estimate that he was on about $500 000 a year. He made the company lots of money. I hated every minute of it. I lasted a year and a half – I don't know how. I left on the dot of 5 o'clock every day, and the only people I was friendly with were the secretary and a woman in accounts. I'm guessing that I was the only technical staff member that was ever expected to actually stay for the one month after I gave notice, because they had no doubts whatsoever that I wasn't simply moving to another investment firm.

Now I'm a little older, and probably no wiser, but I don't let people boss me around any more. I know many in Maths and Physics like myself. Then again, the guy in the office next to me is currently applying for jobs in banks. It takes all types to make the world….

41. **Quantoken**
July 1, 2005

Mr. M:

Doing something other than what majority of the gang is doing is ONLY a necessary condition for success, NOT a sufficient condition. Clearly if you follow the gang and do identical things the end result could only be failure, not success.

Now you ask why not build vacuum tube based CD players, just because no one else does? Well if you look around this world there are too many of this kind of hyperthetical "no body else does" things to enumerate. You could not try all of them.

Actually vacuum tubes are still being used today as **advanced technology**. The largest vacuum tube is 25 miles long and burned underground in Geneva. They are still building it and it's called LHC. It's very different from your TV tube, certainly, but it is a vacuum tube nevertheless and it works on the same physics principle with allow particles to travel in the vacuum and electromagnetic fields are used to accelerate them and bend them. You might ask maybe you can build an accelerator without the vacuum tube, just like you can build a CD player without vacuum tube.

Quantoken

42. **JC**
July 1, 2005

M,

The first "group" in your categorization would perhaps fit into the background of somebody like an Einstein and/or Paul Erdos. Only other people I can think of who could possibly fit into a similar type of categorization (albeit in a different field), would perhaps be people who take a vow of poverty and enter the clergy.

43. **M**
July 1, 2005

This topic has the potential to generate a lot of interesting comments, so I hope Peter will relax his standards a bit for being "on topic" and let well thought out comments remain. It appears that the financial industry is an important employer of physicists and mathematicians, so this seems like a useful topic.

I have what is more of a sociological question about perceptions of mathematicians and physicists about wealth and wealth creation, if anyone knows. The basic question: Are people who are highly educated in analytical fields like physics and mathematics similarly susceptible to the "wealth envy" or "wealth worship" that the general population seems to have? For example, Peter's mention of Jim Simons as managing a $5 billion fund and having $2.5 billion in personal wealth would undoubtedly evoke awe in a very sizable fraction of the population, regardless of whether he donated any of it for increasing human knowledge. Would physicists and mathematicians have that same awe in similar proportions?

If mathematicians and physicists are similarly awed, a secondary question is, "Why?"

I can speak with more understanding of physicists, but perhaps the comments apply equally well to mathematicians. On the one hand, many of us are attracted to physics for idealistic reasons. We want to make a contribution to human knowledge, and hopefully make society better as a result. We also like the challenge of difficult problems and enjoy the excitement of making discoveries or gaining insight. Perhaps a relatively small subset of this group is driven by a deep need to understand and make sense of the physical world; this goes beyond just doing something that is fun and interesting. Certainly the route to becoming a physicist involves a lot of hard work, and hopefully most realize that in the end there is little likelihood of becoming fabulously wealthy, and hopefully most realize that employment in the field is definitely not guaranteed.

There also seems to be another fraction who see physics and mathematics as very challenging fields that are beyond the ability of most of the population to become active participants. Thus, by entering these fields they can not only do something they are good at but they can (perhaps unconsciously) also impress others by their mental acuity, thus gaining respect (and maybe even some awe) of others.

I guess I would expect the second "group" to be more likely to have great respect for a very wealthy person, simply because these people place some premium on success according to traditional societal standards. But what of the first group?

44. **M**
July 1, 2005

From Quantoken:

The secret is do the EXACT OPPOSITE thing of what other people would be doing. Make sure you are always the minority. That way, you make money?

The contrarian approach can evidently be successful if properly used, but one needs to be intelligent about it. Just because you're in the minority doesn't mean you'll make money, just as the early bird doesn't always get the worm (especially if the worm starts roaming around *after* the bird has hunted for its meal). For example, I observe that nobody is building portable compact disc players with vacuum tube circuitry, but I also predict that if you decide to act contrary to this "majority opinion" and start building vacuum tube-based CD players that you won't make billions of dollars from it. 🙂

45. **Dick Thompson**
July 1, 2005

The contrarian strategy is natural for a hedge fund like Renaissance because the idea of a hedge is to invest in something that will pay off if the main investments go sour. I saw the word commodities pop up in these comments. Hedging commodities is a big deal. For example if you are a technology industry with a need for gold in your processes, then you will want to hedge against price swings in gold. You will play around with futures, other metals, things that historically go up when gold goes down and vice versa.

46. **JC**
July 1, 2005

– Sean,

Sounds like an exercise in "data mining". The biggest problem is determining whether a correlation in a data set is just spurious (and meaningless) or if there's a genuine causality with particular "events". Many spurious correlations seem to come and go in a "fly by night" manner.

– Quantoken,

This is better known as the strategy of being a "contrarian". Though being a contrarian isn't always the easiest strategy either, especially if one is into short selling overvalued stocks.

47. **Sean**
July 1, 2005

I visited Renaissance once to give a colloquium. A fun place, full of smart ex-scientists making boatloads of money. The basic idea is to have a computer program ("The Code") look at past performance of various commodities, and use that info to guess what will happen next. The Code actually does the buying and selling, much faster than a human ever could. And it doesn't know, or care, what it is buying or selling; all it knows are the statistics of past performance.

Of course, going from past performance to future behavior is highly nontrivial. That's what they aren't able to talk about. Some day almost all trading will be done by dueling algorithms (or is that already true?).

48. **Quantoken**
July 1, 2005

Oh no, Chris Oakley. "Buy low, sell high" is NOT the secret. It is not followable, most times the market will force you or allure you to do exactly the opposite thing, because market can not be forecasted, without future forecast, you really don't know what is high and what is low.

OK, here is the real secret. I do not need to kill you. But I bet majority of the audience here would not be able to follow it, except for a few lucky ones. Ready?

The secret is do the **EXACT OPPOSITE** thing of what other people would be doing. Make sure you are always the minority. That way, you make money?

Why? Because no system could support a model where the majority of people, 99%, becomes billionares, and only a minority, 1%, go bankrupt. **The only plausible model that's sustainable is one where 99% of people lose money and 1% becomes billionaire**.

So if you see 99% of people doing the same thing and the other 1% doing the opposite, you can bet that 99% is a losing deal and you should join the 1%.

The slogan is be crazy and be different from an average person.

Quantoken

49. **Chris Oakley**
July 1, 2005

Actually I know the strategy that Simons is following. I am going to share it with readers of this blog, but if I discover that anyone has leaked it to any outsiders, then I will personally come round and kill them.

Are you ready?

OK – here it is: *Buy low, sell high*

50. **JC**
July 1, 2005

The fund's MO isn't that surprising. It's very well understood that as soon as "everybody" in the financial world knows about a particular trading strategy, its effectiveness at producing "above average returns" on investment greatly diminishes.

Various and Sundry

July 6, 2005
Categories: Uncategorized

One of the big experimental HEP conferences, the Lepton-Photon Symposium, has just ended and many of the talks are on-line. This is the 22nd of these conferences which happen every two years. New data from the Tevatron about the top quark was discussed, and a paper with the new top quark mass results has been released.

There's a new web-site with news about the LHC.

Last month there was an Einstein Symposium in Alexandria, and presentations are on-line. They're for the general public so pretty content-free, but it is interesting to see what Witten's latest view of string theory is: "I'd like to believe — but of course I don't know — that string theory is on the right track…" Michio Kaku begins his presentation with advertisements for his books, then tells the audience that testing string theory would require creating a "baby universe", that "Mind of God = music resonating through 11 dimensional hyperspace" and that the standard model is "supremely ugly" (which strikes me as something supremely stupid to say).

If you can't wait for next week's Strings 2005 in Toronto, there's a summer school on strings going on at Perimeter, and a meeting in Crete that just ended, along with many more string conferences to come. The one series of talks I won't be able to make it to, but would love to hear would be Graeme Segal's talks in Oporto on 2d QFT.

The DOE has just announced the award of seven new Outstanding Junior Investigator grants in high-energy theory and experiment, one of which is going to Lubos Motl.

Comments

   July 13, 2005

   OK – so to answer Arun's original question [is there a purely Quantum Field Theoretical treatment of the hydrogen atom], the answer is "No",

   Not to be combative, but I pointed you to one, effective field theory methods. Indeed this is the *sane* QFT treatment, since you have things in the problem you can treat exactly.

   Put another way, it doesn't make much sense to restrict your "pure" QFT treatment of the proton to

   S = \bar\psi (Dslash – m) \psi

   as your action. You know you're in the non-relativistic limit, it makes sense to use that fact to the maximum.

2. **Chris Oakley**
   July 13, 2005

   OK – so to answer Arun's original question [is there a purely Quantum Field Theoretical treatment of the hydrogen atom], the answer is "No", you're better off with your undergraduate text books.

3. **Peter Woit**
   July 13, 2005

   There's very good evidence that asymptotically free theories like QCD are non-trivial in the continuum limit. If you ignore fermions, the lattice Monte-Carlo calculations work quite well. There's a mass gap and the extrapolation ot zero lattice spacing and infinite volume look fine. Non-asymptotically free theories like QED are the ones that appear to have a problem in the contiuum limit, since they are becoming strongly coupled at the cutoff scale.

4. **Chris Oakley**
   July 13, 2005

   The notion that any RQFT becomes free in the limit of lattice spacing going to zero ties in with other results, Haag's theorem in particular. People seem to be prepared to do the most amazing things, such as abandoning special relativity, to avoid accepting this.

5. **Peter Woit**
   July 13, 2005

   You can certainly formulate QED on a lattice, and even do perturbative calculations (although they're a lot harder since your regularization is not Lorentz invariant). The lattice technique that doesn't work well for QED is that of Monte-Carlo computer calculations on a finite lattice. These work best in theories with a mass gap, since finite-size effects will go away for lattices much bigger than the inverse of this mass.

   As far as I know, no one has really understood what happens non-perturbatively to QED, whether regularized by a lattice or by any other method. By analogy with phi^4 theory, the fact that it's not asymptotically free suggests that no matter how you try and take the continuum limit, you'll end up with a non-interacting theory. Whether this or something more interesting happens is not known as far as I'm aware, but I haven't followed work in this area, maybe more is known.

6. **Matthew**
   July 13, 2005

   Is this not just saying that lattice techniques simply do not work for QED?

   No, it's saying you have to be careful.

7. **Chris Oakley**
   July 13, 2005

   …at finite lattice spacing QED confines just like QCD. It has been demonstrated (numerically at least, I don't think it's been proven) that QED has a phase transition as the spacing goes to zero, which takes it to a non-confining phase.

Is this not just saying that lattice techniques simply do not work for QED?

8. **Matthew**
July 13, 2005

It may be worth listing out the highest-precision tests of each sector of the Standard Model and of General Relativity.

QED — electron g-2
Electroweak — LEP precision data
QCD — Running of \alpha_s or evolution of structure functions
GR — Hulse Taylor Binary pulsar timing data

For the electroweak theory, I'm not really sure there's a single "showstopper" number. But the LEP data as a whole is impressive confirmation of the standard model.

For QCD, you can measure \alpha_s in a number of different experiments, and run each value to a common scale. The fact that they all agree when run to this scale is strong evidence for QCD.

There's also the evolution of structure functions in deep inelastic scattering (i.e. deviations from Bjorken scaling). This is impressive evidence, but I'm not sure if it relies on any "non-QCD" input.

9. **Matthew**
July 13, 2005

In regard to the the first two: no doubt, but this is not actually a quantum field theoretical treatment of bound states. It is more like saying, "If we could do bound states in QFT, then we would expect the following".

It's an effective field theory analysis. It's more rigorous than just guesswork, it's a systematic expansion. These are used all over modern particle physics.

It's as field theoretical as using a Schwinger-Dyson or Bethe-Salpeter type approach, just different.

In regard to lattices, is it actually feasible to do lattice gauge theory for QED in the same way as one does it for QCD (& I am talking about QFT rather than QM) – ?

Yes, but there are some subtlties peculier to QED. The major one is that at finite lattice spacing QED confines just like QCD. It has been demonstrated (numercially at least, I don't think it's been proven) that QED has a phase transition as the spacing goes to zero, which takes it to a non-confining phase.

From a practical standpoint, I'm not sure how hard this makes it to do QED on a lattice. People do do it though.

IIRC there was some interest in 2+1 dimensional QED in the condensed matter community.

10. **Arun**
July 13, 2005

It may be worth listing out the highest-precision tests of each sector of the Standard Model and of General Relativity.

11. **Chris Oakley**
July 12, 2005

Hi Matthew,

In regard to the the first two: no doubt, but this is not actually a quantum field theoretical treatment of bound states. It is more like saying, "If we could do bound states in QFT, then we would expect the following".

In regard to lattices, is it actually feasible to do lattice gauge theory for QED in the same way as one does it for QCD (& I am talking about QFT rather than QM) – ?

12. **Matthew**
July 12, 2005

The usual answer is that one uses the Bethe-Salpeter equation to do bound states in QFT, but one has to ignore the infinities detonating all over the place, an inconvenience not present in the first-quantised treatment of the one-electron atom.

You can also use a non-relativistic effective theory (NRQED) properly matched to relativistic QED. The Lamb shift has been done this way.

Also, no-one has ever satisfactorily answered my question as to how a technique that only covers scattering processes can be used for bound states anyway.

There are a few techniques. The effective field theory analysis is probably the clearest. For an example of what you can do with this approach there's http://arxiv.org/abs/hep-ph/0003277.

Then of course there is Lattice Gauge Theory. The last time I enquired – relatively recently – I was told that no-one has used the technique to calculate the Hydrogen atom. I am surprised at this as I would have thought it would provide a useful check, especially as they obviously do not balk at the much harder problem of q-qbar bound states.

It's not a terribly useful check since lattice QCD is much more complicated than lattice QED. You can do the H atom using (numerical) path integrals in Quantum mechanics though. That's a fun undergraduate level excercise. However, lattice field theory is not a precision tool. You could easily do the H atom, and get 5/10% accurate results. To get a ppm/b determination of the lamb shift would be very hard.

13. **Alejandro Rivero**
July 11, 2005

Some of these checks are to ten digit accuracy

Well, as I have remarked in other places, by using quenched QED and some experimental data an efriend and myself got to fit -or to fake- six or seven of these same digits in hep-ph/0503104. I guess the real value of QFT is about the generality of its application, and not about a particular, experiment driven, quantity.

14. July 11, 2005

James, the problem with QCD is essentially asymptotic freedom; as momenta grow smaller and distances larger, the coouplings between quarks grow *stronger*. So you can use the well-developed techniques of perturbation theory to compute the outcomes of processes where quarks are banged into each other at very high energy, but the "perturbations" grow too large to handle that way when you try to compute the behaviour of quarks assembling into stable, bound states involving small average momentum transfers. (And as if that weren't bad enough, existing techniques for handling bound states in QFT are quite unsatisfactory; I have little doubt that good progress on that front would open up whole new frontiers for detailed parton model building – now there's something *useful* for all those talented mathematica physicists now slaving away at strings to look at!)

Not being able to use perturbation theory means having to solve a much, much harder problem; in practice you can only do it numerically, with lattice techniques, and then you run into all sorts of technical problems, starting from hardware limitations (a 4-dimensional lattice eats up memory and CPU time very quickly as you increase its size – double the linear size and you get 2^4=16 more points – and ideally you want to be able to take the limit of zero lattice spacing…).

Pentaquarks are such a non-perturbative, and therefore computationally (but maybe not conceptually, depending on how you want to draw the line between the two) hard problem. The 10-digit-precision claims which you quote on the other hand are from realms amenable to perturbation theory.

15. **James Graber**
July 11, 2005

Peter Woit wrote, in response to my comment, ?It's just bizarre to talk about "how unpredictive the standard model" is.? Once again Peter, thank you for your response. Well Peter, you know this stuff and I don?t, so I?m just going to have to take our word for it, or spend years studying it. And I have heard and read that ten digit accuracy claim many times. That?s why the inability to predict or even agree on the interpretation or even existence of whole classes of particles at this late date seems so bizarre to me. Once again thank you.
Jim Graber

16. **Peter**
July 10, 2005

It's just bizarre to talk about "how unpredictive the standard model" is. It makes an infinity of predictions, and every single one that experimentalists have been able to check comes out correctly within experimental errors. Some of these checks are to ten digit accuracy. It's probably the most predictive of all scientific theories known to man. Every particle physics experiment done during the last 30 years has generated reams of data exactly predicted by the standard model. Pick any experimental high energy physics conference, look at the data reported and its precise agreement with standard model predictions.

You seem to not understand the difference between not being able to predict everything (standard model) and not being able to predict anything (string theory). There are some things the standard model inherently can't predict, like fermion mass matrices, others it can predict in principle, but our calculational methods are not good enough to extract the answer. If the standard model predicted everything and we knew how to extract every prediction, high energy physics would just close up shop.

If you want to understand which things the standard model inherently can predict and which it can't, that's not very hard, just learn exactly what the theory is. If you want to understand which things are easy to calculate and which are hard, you have to spend some time really understanding what the known calculational methods are in QFT, and what are their limitations. This takes some serious work.

But it's just completely absurd to claim that there's any similarity between string theory and the standard model from the point of view of predictivity.

17. **James Graber**
July 10, 2005

Peter,
Thank you for your response to my comment. I was not trying to imply that neutrinos were directly related to pentaquarks. My main point is the surprising (to me, at least) lack of predictivity of the standard model. Not being an expert on either the standard model or on string theory, I am continually surprised at how unpredictive both of them are. I will leave criticism of string theory to you and others. I realize that the standard model is not ?not even wrong? because with solid evidence of neutrino oscillations, and thus indirect but solid evidence for neutrino masses, ?everyone? agreed that the standard model needed to be changed and expanded.

(By the way, I was somewhat astounded at how long acceptance of this change took, but that?s a different issue. I am also amazed at the apparent preference for Majorana over Dirac masses. No majorana particles are yet known, so why should neutrinos be Majorana? Of course, it would be cool if they were, but it would seem like Dirac is a much more likely bet.)

And also, people think that by accurately measuring the top quark mass, they can partly predict the Higgs mass. But on the other hand, the pentaquark or the tetraquark can exist or not and the standard model seems fine either way. This seems very unpredictive to me. I have wondered about this for some time. My comment was triggered not just by the recent press release concerning Jlab?s failure to confirm the pentaquark, but also by hep-ph/0507025 which I just happened to read. In addition to your response, another anonymous poster also suggested the reason for this lack of predictivity was the difficulty of solving QCD. I can accept that, but I still wonder why some predictions are possible and others are not. It makes the standard model seem much shakier than it is usually presented as being.
Jim Graber

18. **Arun**
July 10, 2005

Chris,

Thanks! Do you think we can count this as one of the "mass of unsolved problems" that physicists have left behind "in a pursuit of an *a priori* vision of what a simple world would look like" ?

-Arun

19. **Chris Oakley**
July 10, 2005

Hi Arun,

The usual answer is that one uses the Bethe-Salpeter equation to do bound states in QFT, but one has to ignore the infinities detonating all over the place, an inconvenience not present in the first-quantised treatment of the one-electron atom. Also, no-one has ever satisfactorily answered my question as to how a technique that only covers scattering processes can be used for bound states anyway. Then of course there is Lattice Gauge Theory. The last time I enquired – relatively recently – I was told that no-one has used the technique to calculate the Hydrogen atom. I am surprised at this as I would have thought it would provide a useful check, especially as they obviously do not balk at the much harder problem of q-qbar bound states.

Question born of ignorance: is there a purely Quantum Field Theoretical treatment of the hydrogen atom?

21. **Peter Woit**
July 10, 2005

Neutrinos have nothing to do with pentaquarks. For no obvious reason you're conflating two of the unsatisfactory aspects of the standard model: the fact that it doesn't predict fermion mass matrices, and the fact that one doesn't know how to exactly solve QCD. If one could exactly solve QCD in the infrared, this should tell you whether or not pentaquark states exist and what their properties are.

Actually this will be a good test of the idea of using string theory to solve QCD. If anyone ever comes up with a workable string theory dual to QCD, it should predict what happens with pentaquarks.

Jim Graber wrote:
Why can?t the theoreticians even agree on a prediction?

Because non-perturbative QCD is pretty damn hard to solve? (And no, while I'm certainly no expert, I very much doubt that neutrinos, whether massive or not, can be relevant to pentaquarks.)

Perhaps this ?Various and Sundry? thread is a good place to enter this question, which I have been wanting to ask for some time.

The pentaquark has been searched for for over twenty years. Recently, the pentaquark seems to have reappeared and then disappeared, but other weird particles, or particles with weird decay modes are still being seen. The arxiv is full of conflicting explanations for these particles, mostly based on the standard model. Of course, the old standard model, 321Z with _Zero neutrino masses has just been replaced with two competing new standard models, 321M with _Majorana neutrino masses and 321D with _Dirac neutrino masses. So does any of these models predict the pentaquark or not? It seems that the standard model of particle physics (SMOPP or just SM) is almost as non predictive as string theory (ST) at least as far as pentaquarks are concerned. Or maybe it does predict the pentaquark (albeit broader than the recent mirage) and is just plain wrong.

The experimentalists once again seem to be converging on the position that the pentaquark does not exist at any significant level. Why can?t the theoreticians even agree on a prediction? Or is the absence of pentaquarks and tetraquarks some kind of ?superselection rule? to be axiomatically included in the SMOPP?

"To the men and women who create the accelerators, the detectors and the experiments from which the concepts of particle physics spring."

Ah yes, it's in "Concepts of Particle Physics" (Volume II, at least), by Kurt Gottfried & Victor F. Weisskopf. Not so recent though (1986). I remember being struck by that dedication, many years ago, as quite paternalizing for all its political correctness. It's nice to see that I evidently wasn't the only one.

Joseph Schwartz in *The Creative Moment : How Science made itself alien to Modern Culture*. Please, oh please shoot the following down.

"In the late Victorian period Planck was an unusual physicist. Physics then was like biology today, with theorists being objects of scorn for their lack of contact with experimental realities. Other physicists from the period who today are known for their theoretical work were skilled experimenters. Gustav Kirchoff (1824-1887) is known now for his theoretical contributions to heat radiation and the analysis of electrical circuits and not for his experimental work with George Bunsen on optical spectra. Maxwell, famous today for his partial differential equations of the electromagnetic field, was professor of *experimental* physics at Cambridge. H.A. Lorentz, the first theoretical physicist in Holland, was an active experimentalist doing work in optical spectra. Max Born, one of the leading pioneers of quantum theory, was an expert in experimental optics.

And Einstein, known as the foremost theoretician of all time, was experienced in laboratory techniques and interested in technology. With the Habicht brothers he patented a precision volt meter in 1914. In the 1920s, in collaboration with aerodynamicist Rudolf Goldschmidt, he invented a hearing aid. With the Dutch firm, N. V. Nederlandsche Technische Handelsmaatschappy he held a patent for a gyrocompass. And with Leo Szilard he patented several refrigerating devices designed to reduce the noise levels of existing commercial machines.

But today the physics community is deeply divided between the theorists and the experimenters. {resulting in a two class system, with theorists at the center and experimentalists circling around them}

Sensitive theoreticians have been careful to soothe ruffled feathers by making it a point to acknowledge the role played by experimental work. A recent textbook concentrating on theoretical developments is dedicated to the experimentalists, "the men and women who create the accelerators, the detectors and the experiments from which the concepts of particle physics spring".

Although these words are a much-needed acknowledgement of the fundamental source of physics in observation, they nevertheless confirm the existence of inequality. Their unavoidably patronizing connotations are reminiscent of the dedications made by male professionals of all kinds to their wives and secretaries…..

The potentially explosive tensions caused by the inequality between experimental and theoretical physicists are kept within bounds by an exceptionally strong belief in inherited intelligence. Experimental physicists accept second-class status because they feel they are not as bright as theorists. Theorists take their superiority for granted as due recognition of superior intelligence. Physics meetings are famous for their stilted, tense atmospheres as each person is afraid of asking a “stupid” question. Even informal contacts can be dominated by a competitive proving of who understands more of a subject under discussion.

{As a result of the necessarily industrial size undertaking that experimental particle physics has become} “theorists have become an elite within an elite with little or no accountability to an outside audience. There is the occasional theoretical briefing “to the experimentalists”, but in the main, theoreticians have, not unnaturally, become ingrown in their approach to physics.

…Theorists today are so divorced from real experience of nature they have no unconsciously absorbed perceptual knowledge to draw upon. Everything they know has been learned from books. And the understandings based on this secondhand knowledge have inevitably been derivative and second-rate.

—

“Once one believes that spin is a consequence of the Dirac equation, it is only a short step to try to make physics out of the thin air of mathematical guesswork….

{Previously}

“Dirac, perhaps because of his engineering training, was one of the few physicists who remained clear about where things came from. In 1962, Thomas Kuhn…spoke to Dirac about his life and work. Among other things, Kuhn was interested in how Dirac came to write down his equation for a relativistic electron with spin.

Dirac said: “I was playing around with equations and I found that Pauli’s matrices were quite a nice thing to play with. It needed quite an effort to make the further generalization (from 2×2) to 4×4 matrices, but that work did come about from playing about with the three dimensional scalar product.”

Kuhn said: “Was it a surprise that what came out were spin terms?”

Dirac said: “No, I don’t think so. Because one had the Pauli matrices in it [to begin with.” }

…what students of the 1950s were not taught was the understanding of James Franck, one of the leading experimentalists of the 1920s: “What one doesn’t put into the equation will not finally be given by the mathematics”. In its place, students absorbed a theoretical sensibility inspired, not by an attempt to understand, express, and describe, or in Bohr’s word, communicate real physical experience, but by spectacular deductions from a few well-chosen equations.…

{resumes} “The patterns of thinking that now dominate theoretical physics approach the classical definition of autistic thinking: thought that is solely determined by the subject’s wishes and fantasies without reference to the environment or to realistic considerations of space and time”.

About strings 2005, any clue about these axions from Witten? Are they still related to a possible two-higgs doublet (remember it is also my bet 🙂 ?

27. **D R Lunsford**
July 8, 2005

LM has never had a single idea about physics that amounted to pouring piss from a boot, and our wonderful, wonderful academic structure rewards him this way. THAT is why string theory, a vile and idiotic lie, has managed to slough itself along for 20 years, leaving a shiny trail behind it.

While I like Chris’s interpretation, I suspect that what Kaku had is mind was that in 1968 what was discovered was not a theory, but a formula for amplitudes. Only later was it understood that these amplitudes come from a (first-quantized) string theory. The continuing hope is that the current (inconsistent and unable to reproduce physics) version of string theory is an approximation to some wonderful but yet to be discovered M-theory.

Does anyone know what Kaku meant by “String theory has been moving backwards”

I presume that what he means is that the more they work on it, the more that they realise that it is not going to be of any use as a physical theory.

July 8, 2005

Hi,

Does anyone know what Kaku meant by “String theory has been moving backwards” in his PowerPoint statement

= String theory has been moving backwards, since it was accidentally discovered in 1968.
?

July 8, 2005

currently accepted

is not different of the typical forms to request funds in some project, where you are basically asked what are you to discover, and when. I call this part of science, very botanic-wise, the “classification” side. The (also botanic) counterpart, “exploration”, is always more problematic. Smolin article on “New Einstein” was about this, wasn’t it?

I’m tempted to delete the previous comment, but am leaving it since I think that, if accurate, it is interesting to see that the editor of PRL is resorting to an indefensible argument in dealing with nonsense submitted to him (although the “…” may hide a more defensible argument). Please discuss this with the author of this comment on his weblog, not here. I'll be deleting any further comments about this.

Editor of Physical Review Letters says

Sent: 02/01/03 17:47
Subject: Your_manuscript LZ8276 Cook
MECHANISM OF GRAVITY
Physical Review Letters does not, in general, publish papers on alternatives to currently accepted theories ? Yours sincerely, Stanley G. Brown, Editor, Physical Review Letters

Now, why has this nice genuine guy still not published his personally endorsed proof of what is a ?currently accepted? prediction for the strength of gravity? Will he ever do so?

?String theory has the remarkable property of predicting gravity?: false claim by Edward Witten in the April 1996 issue of Physics Today, repudiated by Roger Penrose on page 896 of his book Road to Reality, 1994: ?in addition to the dimensionality issue, the string theory approach is (so far, in almost all respects) restricted to being merely a perturbation theory?. String theory does not predict for the strength constant of gravity, G! However, the Physical Review Letters editor still ?believes in? Edward Witten and Physics Today.
