1. Why do people assume that the referees (if there were any) really understood the papers and should thus come out and explain it? Most of you have been refereeing papers yourself. Do you read and check every line? That's impossible, and I'm open about this in every report I write. Even if you do think you got it all, does your judgment make the paper correct? We're all just humans and prone to make errors. As an amusing reminder, here's an (incomplete) list of "incomplete proofs": https://en.wikipedia.org/wiki/List_of_incomplete_proofs.

2. What's the matter with statements like the following?
* "well-known to every one at RIMS" (K. Joshi)
* "these German mathematicians" + many more (I. Fesenko)
* "a deep sense of discomfort, or unfamiliarity, with new ways of thinking about familiar mathematical objects" + many more (S. Mochizuki)

Did you all lose your minds? What is this?

3. The papers by Mochizuki consist of building up tons of highly ambiguous language, and when it comes to a proof, it's all obvious from the definitions. Why does anyone actually take this serious? What's comical is that Mochizuki himself complains in his pamphlet that "negative positions concerning IUTch were always discussed in highly non-mathematical terms, i.e., by focusing on various aspects of the situation that were quite far removed from any sort of detailed, well-defined, mathematically substantive content." Yeah, sorry, but how are we supposed to talk about this thing then?

4. Scholze and Stix tried to make some sense out of this and pointed out a specific part they don't understand; see also the comments above. There has been no reply except comments along the lines of point 2 above. So, what? Do you want to force them with a baseball bat to understand it? What are they supposed to do? What do you want?

Mochizuki: If you can't explain your stuff, no one will care, period.

17. **Peter Woit**
April 21, 2020

Jay Watt,
For many of the things you are not getting, I think most mathematicians feel the same way. About point 1 though (referees):

First of all, the standard of refereeing expected for a claimed proof of this kind is much higher than normal. But the reason for demanding an explanation from the editors and referees is that two years ago they were presented by Scholze and Stix with a strong argument about a specific flaw in this proof, as well as the information that Scholze and Stix spent a week discussing this flaw with the author and left convinced the author had no answer for how to fix the proof. In response to the problem identified by Scholze/Stix, the author seems to have made no substantive changes to the argument to fix it (Scholze says the problem is still there).

What's incomprehensible here is that the editors decided to publish the proof anyway, and even held a press conference to promote this. The editors and referees involved in this have a very specific responsibility to the math community that they are not meeting: they need to produce a convincing explanation for why Scholze/Stix are wrong (presumably they have this from the referees, otherwise they would not have decided to publish). Absent that, what we have here is a strong argument that the proof is wrong, met by a press conference saying the editors disagree, but will not say why.

18. **Timothy Chow**
April 21, 2020

Regarding whether this an unprecedented situation, I agree that there are many ways in which it is unprecedented. However, I would say that it is far from unprecedented for a flawed paper (even one solving a major open problem) to be published even when experts have seen a preprint and believe it to be at best incomprehensible. If an author has a strong reputation then mathematicians are typically very leery of saying that a paper is wrong unless they can point to a provably false statement. They have been socialized all their lives that it is taboo to say something definitive unless they can back it up with a rigorous mathematical proof. So if a paper is not even wrong then mathematicians will dance around the issue and generally refrain from delivering a verdict that it should not be published, unless they have formally accepted the task of refereeing the paper. Note, for instance, that Taylor Dupuy has said that he does not think that the Scholze–Stix manuscript is a sufficient reason for rejecting Mochizuki's proof, and he wants to see the final published version before making a final judgment. In general (i.e., setting aside the specifics of the IUTT papers), this is a typical attitude, and leads to quite a number of dubious papers by famous people getting published even though experts know that there are serious and perhaps fatal problems with them.

I think that what's most unprecedented about the current situation is that two mathematicians, who are not referees, have gone public with a major criticism prior to the publication of the article. This is the really unusual part of the story, and it might not have played out this way had there not been a false rumor a couple of years ago about the imminent publication of the paper. Had this rumor not been circulated, and had Mochizuki's papers simply appeared in PRIMS without a prior public announcement, then the situation would not be that different from, say, Hsiang's claimed proof of the Kepler conjecture and the ensuing controversy.

19. **MZ**
April 21, 2020

Jay Watt:

> There has been no reply except comments along the lines of point 2 above.

Not sure this is accurate. The M remark you quote was mentioned in a 2018 Quanta piece—perhaps that is where you are getting it from? Its original source is (apparently) the 2018 report by M on the discussions he had by Scholze & Stix. This report has comments way beyond what you quote in terms of mathematical content.

Also, reading the comments from people who actually interacted with him, it seems that M does engage into detailed mathematical discussions with people who contact him about his work. This way of representing his responses as no-math-content, dismissive commentary seems inaccurate.

As for point-by-point factual summaries of the state of the problem, this [description by D. Roberts] seems to have a more neutral/objective wording than some of the summaries given during the current comment thread:

> In documents released in September 2018, Scholze–Stix claimed the key Lemma~3.12 of Mochizuki's third Inter-Universal Teichmüller Theory (IUTT) paper reduced to a trivial inequality under certain harmless simplifications, invalidating the claimed proof. [. . .] Mochizuki agreed with the conclusion that under the given simplifications the result became trivial, but not that the simplifications were harmless. However, Scholze and Stix were not convinced by the arguments as to why their simplifications drastically altered the theory, and we stand at an impasse.

20. **Peter**
April 21, 2020

Timothy Chow,

I think you're making an interesting point, but the question then becomes: when is a proof "published", i.e. "made public"?
You write "two mathematicians, who are not referees, have gone public with a major criticism prior to the publication of the article." But Peter Scholze is always careful to point out that he's analyzing what is public now, and not the publication in PRIMS. And what is public now, is entirely the responsibility of Mochizuki. This unprecedented situation is created by him, not by these two mathematicians.

21. **Peter Woit**
April 21, 2020

Timothy Chow,
The whole story here is very unusual. Yes, in an alternate universe where Ivan Fesenko hadn't distributed an email claiming the IUT papers had been accepted for publication, which caused me and others to blog about the publication news , which caused Peter Scholze to speak up publicly about the problem, much of this would have taken place only privately before publication, and the public mess would have been, like in the Hsiang case, post-publication.

But that's not what happened, and one reason that it's not what happened is that, unlike Hsiang's proof, the Mochizuki proof received a huge amount of attention from experts from 2012 on, leading most of them to conclude that the proof was incomprehensible. As it became increasingly clear that experts in the subject could not get a comprehensible explanation from Mochizuki (or those around him who claimed to understand the proof), many of them became worried that the journal would publish the proof despite its incomprehensiblity and were debating what to do about this.

It should be emphasized again that at the time of the abortive announcement, what experts were upset about was the unusual prospect of publication of an incomprehensible claimed proof, but what has happened now is much worse than that: publication of a proof the community is convinced is flawed, by editors who are well aware of this.

I don't know the story of the refereeing of the Hsiang paper, but find it hard to believe that editors of the paper were aware of any privately expressed opinion by experts that that the proof wasn't complete and decided to publish anyway. In any case, I don't think comparison to the Hsiang/Kepler conjecture story is very apt. For one thing, the Hsiang proof was not based on claims of a completely new (as in Mochizuki's IUT) approach to the problem. He was following a well-known line of attack. Note that in the skeptical Mathscinet review of the Hsiang paper, you can read

"I think there is hope that Hsiang's strategy will work: at least the main inequalities seem to hold. As far as details are concerned, my opinion is that many of the key statements have no acceptable proofs. Typically, we are given arguments such as "the most critical case is…" followed by a statement that "the same method will imply the general case". The problem with arguments of this kind is not only that they require the reader to redo some pages of calculations, but, notoriously, that they occur at places where we expect difficulties and most frequently it is impossible to see how the same method works in the general case."

In the Mochizuki case, Scholze's claim is not that important details haven't been worked out, but that the whole approach is fundamentally flawed. By the way, if you read the exchange with Scholze you will see that Dupuy does not at all claim there is a proof in the Mochizuki papers, he is just trying to argue the Scholze has not yet rigorously shown that Mochizuki's approach can't possibly work.

22. **Peter Woit**
April 21, 2020

MZ,
I don't think the Roberts quote gives an accurate picture of the argument between Scholze and Mochizuki. I strongly recommend reading Scholze's summary of the problem here

https://www.math.columbia.edu/~woit/wordpress/?p=11709&cpage=1#comment-235940

and if you don't find it convincing, read the entire discussion, linked to in this posting.

What Scholze is claiming is not that "if you simplify the proof it won't work", but that there is a fundamental mathematical issue of principle for why nothing like this kind of proof can work. He explains this issue clearly in the second and third paragraphs of his comment. The later discussion is all about whether these paragraphs give a rigorous argument, or whether maybe Mochizuki has some way (which no one else has been able to understand) around the argument.

23. **Jay Watt**
April 21, 2020

Peter,

you are quite right about what you said about my point 1 (referees). Let me say I'm more surprised by the fact, it seems, that people indeed expect this may be helpful and would lead to anything. If a referee could actually clarify all/some of the issues (or just the specific one raised by Scholze&Stix), then why not do it here, anonymously? I think they can't, and any attempt would likely go along the lines "Well, Mochizuki probably meant (some vague statement)", as all the other discussions went so far. All this is not getting anywhere. It's the nature of the papers and the "theory" that makes it impossible to deal with on a rigorous and verifiable basis. It's an eel.

@MZ: The "deep sense of discomfort" quote is by M, at the end of http://www.kurims.kyoto-u.ac.jp/~motizuki/Rpt2018.pdf. But this whole thing: why all these philosophical meta phrases? Why not focus on the subject? What is this all about?

24. **Timothy Chow**
April 21, 2020

Peter Woit: I agree that there are disanalogies with the Hsiang case. But I do want to point out that it is actually disturbingly common for mathematical papers by well-known people, claiming to solve important problems, to be published even when the editors have received private indications from experts that the papers have serious gaps, or even that the entire approach is fundamentally flawed. It's usually not talked about openly because unless the author admits that there is an irreparable gap, you'll make enemies by making such a claim. I also don't know what happened behind the scenes with the publication of Hsiang's paper, but if the editors privately knew that other experts had serious reservations and decided to publish anyway, it wouldn't have been the first time that that sort of thing happened.

If Mochizuki's papers had been published in, say, 2016, after "only" four years, I don't think the situation would be quite so unprecedented. But yes, the current circumstances are unprecedented.

25. **Timothy Chow**
April 21, 2020

By the way, just now I looked again at Hales's 1994 Intelligencer article about Hsiang's proof. He makes it clear that he presented Hsiang with serious objections several times in the interim between 1990, when Hsiang announced his proof, and 1993, when Hsiang's proof was published. So it seems likely that the editor of the journal was aware, prior to publication, that other experts in the field found the proof unacceptable.

26. **Peter Woit**
April 21, 2020

Jay Watt,
I also find it highly unlikely that any of the referees or anyone the editors consulted post Scholze/Stix had a convincing argument for how the Mochizuki proof overcomes their objections. I do think it's important that they be confronted with a demand to produce such an argument. If it exists, they can vindicate themselves by making it publicly available. If it doesn't, they have two choices: change their decision about publication or double down on unethical behavior, claiming "there is an argument but we have to keep it secret".

27. **anon**
April 22, 2020

I agree with Timothy Chow that incorrect proofs being published, even when concerns have been privately discussed with the editors, isn't _that_ unusual. Also, in mathematics retraction of (well-known to be) faulty papers seems even more difficult than in other disciplines

Of course, the IUT saga has been very unusual or even unique in mathematics because of the huge amount of publicity it has received, and the behaviour of some people surrounding the case. It's definitely strange that besides the author there are several people who vouch (even very, very, fervently) for the proof, yet are completely unable to explain it in any meaningful way.

28. **mgflax**
April 27, 2020

math_jin@ retweeted a report that the papers to be published in P(RIMS) are essentially identical to the versions on M's website, with the exception of a single footnote on the first page.

29. **Nick Maiorino**
April 28, 2020

Hi Peter Woit,

Yesterday, David Roberts on his blog "theHigherGeometer" reported that papers relevant to Mochizuki's Corollary 3.12 are finally beginning to appear on Taylor Dupuy's homepage. See "Dupuy and Hilado's work on unravelling Mochizuki":

https://thehighergeometer.wordpress.com/2020/04/27/dupuy-and-hilados-work-on-unravelling-mochizuki/

30. **JE**
April 30, 2020

The same twitter account mentioned above by mgflax (which may or may not be a source of reliable information) retweeted another message a few days ago identifying one specific mathematician at RIMS who has apparently gone through Mochizuki's papers and is reported as not being convinced of the validity of the proof.

Although this may only count as anecdotal evidence of internal dissent (were it true), it would suggest that not everyone at RIMS fully endorses the belief that the Szpiro conjecture will become a theorem when the papers get published by PRIMS.

31. **Peter Woit**
April 30, 2020

JE,
At this point it's a factual matter that no one other than Mochizuki has come forward publicly with an argument explaining why the proof is correct, despite Scholze's arguments. I assume that those mathematicians at RIMS with any interest in the subject are well aware of this situation, and many if not most are privately drawing the obvious conclusions.

32. **David Roberts**
April 30, 2020

@JE is this 'specific mathematician' Teruhisa Koshikawa?

33. **Peter Woit**
April 30, 2020

David Roberts,
I assume JE is referring to this tweet
https://twitter.com/MugaShohou/status/1253341200054054912

Besides Mochizuki, the others listed there as understanding the proof are Hoshi, Yamashita and Saidi. As far as I know, the documents written by Hoshi (in Japanese) and Yamashita (in English) do not address the problems that Scholze raises, and I am not aware of anything on the topic written by Saidi.

34. **David Roberts**
April 30, 2020

@Peter, that was my guess, too. (I seriously wish that Hoshi's notes were in English, as his other work seems to be very reasonable, as far as I can tell.)

35. **JE**
May 1, 2020

@Peter and David,
Yes, that's the tweet. Peter, you're probably right about the uneasy situation created for some mathematicians at RIMS, especially after Kashiwara's and Tamagawa's appearance at the press conference held in early April to announce the publication, which could have been interpreted as a clear sign of support for Mochizuki's proof from the institution as a whole (Kashiwara was presented as head of the team that examined professor Mochizuki's theory, see e.g. https://www.japantimes.co.jp/news/2020/04/04/national/japanese-mathematician-shinichi-mochizuki/#.XqvfxGgzaUk). As things currently stand there, silence can be eloquent. We already knew that Hoshi, Yamashita and Saidi endorsed the proof, but the fact that one mathematician at RIMS has been publicly reported as not being convinced of it (at this point of the discussion) may be even more eloquent.

36. **David Roberts**
May 3, 2020

Hi Peter, I think it worth including *in the pdf document* a mention that the discussion continued, and give a link back. You mentioned that there was content before the first comment you included, so why not also say the discussion continued? Not everyone reading that document will come to it by a link from your blog post where you mention this. I say this merely from the point of view of having a coherent scholarly record (whatever one's view of the various positions).

37. **Peter Woit**
May 3, 2020

David Roberts,
I was planning on updating the pdf document to a final form, didn't get around to it today until just now. It's a beautiful day here in New York, and earlier a long bike ride seemed more pressing than that particular task.

38. **Timothy Chow**
May 5, 2020

Peter Woit, I noticed that in the PDF document you say that the PRIMS editors have decided that the Mochizuki proof should be deemed correct and complete. Are those the editors' precise words, or is that an inference you're making from their decision to go ahead and publish the proof?

39. **Peter Woit**
May 5, 2020

Timothy Chow,
That's my inference from their decision to publish (reiterated after consideration of the latest discussion with Scholze). I suppose it's possible that the PRIMS editors have an unusual understanding of the role of a mathematics journal and have decided to publish a proof they know to be possibly incorrect or incomplete. If so, perhaps at publication they will include some sort of text explaining such an unusual choice.

Various and Sundry

April 30, 2020
Categories: Uncategorized

- If like most other people you're stuck at home, and having trouble concentrating on the projects you thought the current situation would cause you to finally find the time to complete, one thing you could do is watch a lot of talks about mathematics online. As far as I can tell, mathematicians are doing much better than any other field right now in dealing with this, since they have a wonderful site developed at MIT called mathseminars.org. It contains a fairly comprehensive set of listings of Math seminars now being run online.

  If there's anything similar in the physics community, I'd be interested to hear about it.

- A new book about the problems of fundamental physics has recently appeared, David Lindley's The Dream Universe: How Fundamental Physics Lost its Way. I've been thinking for a while about whether to write about it here, have held off mainly because I felt I didn't have much interesting to say. Today I see that Sabine Hossenfelder has written a review of the book which I mostly agree with, so you should read what she has to say.

  There are a couple places where I significantly disagree with her. For one thing, unlike Hossenfelder, I'm a great fan of Lindley's much earlier book on this topic, his 1993 The End of Physics. This was written a very long time ago, at a time when writing for the public about fundamental physics was uniformly positive about the glories of string theory. Unlike all those books, this one has held up well. Reading it at the time it came out, it was remarkable to me to find someone else seeing the same problems with the field that seemed to me obvious, providing a very helpful indication that "no, I'm not crazy, there really is something wrong going on here."

  It's interesting to read Hossenfelder's take on the way Lindley makes "mathematical abstraction" the villain in this story:

  > The problem in modern physics is not the abundance of mathematical abstraction per se, but that physicists have forgotten mathematical abstraction is a means to an end, not an end unto itself. They may have lost sight of the goal, alright, but that doesn't mean the goal has ceased existing.

  Here is where I definitely part company with Lindley, and to some extent with Hossenfelder. The current problems with fundamental physics have nothing to do with mathematical abstraction, but with the refusal to give up on bad physical ideas that don't work. Thirty-six years ago Witten and many other leaders of the field fell in love not with a mathematical abstraction, but with a bad physical idea: replace fundamental particles with fundamental strings. One reason they fell in love with this idea was that it could be fit together with two other bad ideas they had been dallying with at the time, that there are new forces mixing leptons and quarks (GUTs), and that you can relate bosons and fermions with the square root of translation symmetry (SUSY).

  Unfortunately it seems to me that many theorists have now drawn the wrong conclusion from the sorry story of the last forty-some years, deciding that what they need to do is to stay away from unwholesome mathematics, and stick to the wholesome experimentally observable and testable. But what if the underlying reason you got in a bad relationship with a seriously flawed love interest was that there weren't (and aren't) any experimentally testable ones to be found? Maybe what you need to do is to work on yourself and why you stay in bad relationships: the mathematically abstract love of your life might still be out there.

- Witten yesterday posted a definitely not mathematically abstract paper on the arXiv, Searching for a Black Hole in the Outer Solar System. It's basically a proposal for finding a physical black hole we could then go and get into a relationship with. I can't help thinking the probabilities are that getting into a healthy relationship with a new mathematical abstraction is more likely to work out than this.

Comments

3. **Sabine Hossenfelder**
   May 1, 2020

   Hi Peter,

   Thanks for the link. You quoted the one paragraph with a typo! Can you make the "end to a means" a "means to an end"? I didn't read the "End of Physics" when it came out but only a few years ago, which may have had an influence on my impression. Yours and Lee's and Jim Baggott's books are all considerably more informative and provide more solid arguments. Lindley's in comparison is rather superficial. But I admit it's somewhat unfair to compare his to books that appeared much later. Best,

   Sabine

4. **Peter Woit**
   May 1, 2020

   Hi Sabine,
   Fixed.

5. **Alessandro Strumia**
   May 1, 2020

   This site aggregates calendars of known physics webinars:
   https://sites.google.com/site/onlinephysicsseminars
   If something is missing, contact organisers (indico or google format only). Furthermore, physics is going to be included here (https://researchseminars.org) and InSpire is starting an analogous initiative. However these do not aggregate automatically.

6. **Jamie Sully**
   May 1, 2020

Hi Peter,
The ‘mathseminars.org’ website has now been expanded to include all of physics and mathematics. It is officially live, as of this afternoon, at:

http://researchseminars.org

The site has good coverage of talks in high-energy theory, but we hope that word will spread quickly to the rest of physics.

Best,
Jamie

7. **Armin**
May 1, 2020

Peter,

Is it possible that your conception of what has gone wrong in terms of “bad physical ideas” is just another way of framing Sabine’s conception in terms of “forgetting that mathematics is a means to an end”?

After all,

1. most of mathematics is not at this time relevant to physics, and is not expected to be.
2. This implies there are plenty of opportunities for physicists to be inspired by pieces of math which entail “bad physical ideas”.
3. But then, falling in love with, and consequently overlooking any red flags as one develops those ideas seems pretty accurately describable as Sabine does.

8. **Peter Woit**
May 1, 2020

Armin,
Mathematics is the language of physics, so you can blame any bad idea on “mathematics”. My disagreement with Hossenfelder is that I dislike her use of that framing of the problem, when what she mainly has in mind are certain specific failed ideas, which I think are more properly thought of as failed physical ideas, nothing to do with the fact that they are formulated in certain mathematical terms.

There is and always has been a strong tradition among physicists of skepticism about use of any type of mathematics beyond what they were trained in. If you go back to the early days of quantum mechanics you can find people complaining about matrices, a little later complaining about group theory (the “gruppenpest”). The failure of string theory has led such people to blame this failure on the use of such mathematics. But what if, absent help from experiment, what is needed for progress is a new idea coming out of mathematics, not out of experiment? Fundamental theoretical physics may be in the process of turning against exactly the tools it needs to get anywhere.

There’s a huge universe of mathematical ideas, most of which won’t be helpful in finding new physics. Those skeptical of the value of abstract math for physics have plenty of good examples to point to where mathematical structures are being invoked that are not of any help in physics. My reading of the history that I’ve seen over the course of my career though is not that the main problem is people getting lost down blind alleys of mathematics, but getting lost down blind alleys of bad ideas about physics. As an example, consider the multiverse. Claiming to explain things with “everything happens” is an awful idea for how to do physics and how to do science, and that’s the problem with it, not whatever mathematical language you choose to dress it up in.

Or, put differently, the problem isn’t with people falling in love with ideas because they find the math attractive. This may be our best hope for new ideas. The problem is not giving up on one’s ideas when they fail.

9. **Armin**
May 2, 2020

Thank you, Peter. I think I understand your perspective better now.

A propos history of physics: One richly informative website with accounts literally from the mouths of those physicists who lived it is https://www.webofstories.com/

10. **Bernhard**
May 2, 2020

Is it me or is that black hole article a bit at odds to Witten’s typical interests?

11. **Peter Woit**
May 2, 2020

Bernhard,
Yes, although Witten has always had wide interests, and his interests fundamentally are more about physics than mathematics. If you want to find a reason for him getting interested in this particular topic, it’s hard to overemphasize how central a topic black holes have become to theorists. Also, Witten has been involved with the Breakthrough Prize organization, which is a Milner/Zuckerberg operation, and they’re the ones behind the Breakthrough Starshot idea.

12. **DB**
May 3, 2020

Bernhard and Peter,
there are a lot of comments on different internet forums that state that Witten has basically given up on trying to find a TOE, and now has focused his attention more on the famous It from Qubit idea.
But he’s not the only one. If you look closely, many top theoretical physicists are directing their research and energies towards the high-tech world. His involvement with the Breakthrough Starshot idea is one of the clues.

13. **Peter Woit**
May 3, 2020

DB,
I don’t think it’s Witten in particular who has given up on trying to find a TOE, this is the attitude of most influential particle theorists. Among string theorists, the majority opinion now appears to be that the “landscape of string vacua” that predicts nothing at all is an indefensible position at the end of a blind alley, and that continued focus on string theory requires other arguments.

14. **DB**

May 3, 2020

Peter,
thanks for the info.
For many of us, it was pretty clear a long time ago that pursuing the search of a final TOE was a complete waste of time, for the simple reason that… it does not exist.
Witten probably saw the light a couple of years ago, as proved in the interview he gave to Graham Farmelo in Princeton. He accepted the landscape idea, which is the dominant position nowadays.
Only a couple of fanatic radical defenders of string theory being the TOE carry on saying that ST will come up with the final, unique solution to the Laws of Nature.
I happen to know a couple of them, one from a small country in Central Europe and the other from the Sates.

I don't know what other arguments string theorists are thinking of focusing on and pursuing, but I'll be very interested if you could tell me what they are.

Thanks!!

15. **Peter Woit**
May 3, 2020

DB,
I don't think that it it's clear that a TOE doesn't exist, although it is clear string theory as currently understood cannot give you one. String theory defenders have the following options:

1. Claim that string theory has succeeded, but because of the landscape can't predict anything. The problem with this is that most other physicists will not take you seriously. At one point I linked here to discussion at a Simons Center talk where Vafa explained just how damaging this has been to the perception of string theory among the public and among other scientists.

2. Claim that there is a problem with the landscape, that string theory as currently understood may be able to make some sort of prediction of something. This is the "swampland" program favored by Vafa. For reasons explained in many places here I don't think this will work. I see no evidence this point of view is getting much traction in the physics community.

3. Claim that the problem is that string theory is too poorly understood to be able to tell if it makes predictions or not, but that it is our "best hope for a TOE", justifying continued work on it. My impression is that this is currently the most common point of view among theorists who call themselves "string theorists". Since there are no viable ideas out there for how to move string theory in the direction of giving a predictive TOE, in practice people in this camp have stopped work on the problem and taken up other things to work on (e.g. it from qubit ideas).

16. **DB**
May 4, 2020

Thanks for your reply Peter.
This will be my last email on this thread, otherwise I will almost monopolize it.

I know about Vafa's swampland idea. As you say, it's going nowhere. Even though it's been out for years now, no top theoretical physicist has followed that road. Just him and his team. It doesn't look promising at all.
On one of the conferences organized to talk about it, I remember Arkani-Hamed said the following:
"QM forces us to split the world into two parts: infinite "observers" and finite "systems", but… neither Gravity nor Cosmology likes this!!!"
And two minutes later, the following:
"This raises the possibility that we are misinterpreting string landscape-
the different regions aren´t "out there", but are different approximate "system/observer" splits of a single object".

I can send you the link of the conference if you want.
So it seems to me that Nima has a hunch that all that swampland and landscape ideas have no traction at all.

I fully agree with what you say that the majority of string theorists now tend to defend point number 3. Actually, the phrase you've noted was said by Witten himself. No wonder the rest follows suit.

The most probable future for string theory, IMO, is going to be that it will be studied as a branch in mathematics.
Is it useful? Yes it is.
Can we fully discard it? No ways.
Has it got future? You bet.
But it does not describe Nature. It is not a unique theory of reality, but maybe something deeper -a set of mathematical principles that can be used to relate all physical theories. A new kind of Calculus, if you like.

Finally, when it comes to a possible TOE, that's where we part our ways.
I don't believe one exists at all. I think it's too much to hope for. And if it does exist, I tend to believe that it will always stay out of reach.

17. **Peter Woit**
May 4, 2020

DB,
There are lots of problems with solving the problem of string theory by announcing that it is just "mathematics", beginning with the problem that one doesn't know what "string theory" actually is. To the extent the words have any meaning, they are as a program to develop a specific sort of fundamental physical theory, not as a specific mathematical construction.

What you quote from Arkani-Hamed seems to me just the kind of off the top of his head speculation about some unknown possible new revolutionary fundamentals of physics replacing quantum mechanics that he likes to indulge in. He and others have gotten pushed into this by the (unacknowledged) failure of their previous research programs. A few years ago, pre-LHC results, in all his talks he put up a slide showing a fork in the road, arguing that in a few years the LHC would tell us whether there was weak-scale new physics providing naturalness or else it was the landscape.

The results are now in: no weak-scale new physics. But instead of now giving talks about how the LHC has proved the landscape picture (which he knows would cause his audience to laugh him out of the lecture hall), instead he is promoting speculation about replacing space, time and QM with something completely different.

18. **DB**
May 4, 2020

Thanks Peter.
To be honest, I never understood Nima's quote very well…

19. **David Hillman**
May 4, 2020

Hi Peter. I was struck by the starkness of your comment that the idea of there being new forces mixing leptons and quarks is a bad idea. It's long seemed to me unlikely, purely from a prejudice towards the simplicity of things (and perhaps this is just one more example of a prejudice that might lead a physicist astray), that the number of protons at the beginning of time would be the same very large number that it is now. Are you saying that this is a bad idea? or are there other ways to avoid proton number conservation besides having a mixing of leptons and quarks? (Similarly, where do you stand on Sakharov's conditions to explain prevalence of matter over antimatter?)

20. **Peter Woit**
May 5, 2020

David Hillman,
I don't see any point to trying to guess based on our prejudices about what the world should be like whether quarks can turn into leptons. Given that we don't see protons decay quickly, that's strong evidence that quarks don't turn into leptons. It makes perfectly good sense to speculate that maybe they do, just at a very low rate, and build experiments underground to look. We did this and found that, at the lowest rate we can probe, doesn't happen. Quarks turning into leptons is not an idea about mathematics, it's an idea about physics, a "bad idea" in the sense that all evidence is that it doesn't work.

I was really trying to make a point about the failure of GUT models. Some people like to point to that failure as a failure driven by mathematics: theorists wrote down a theory based on a large Lie group (SU(5)) that was supposed to be "mathematically beautiful" and that theory failed, so the problem was the use of the Lie group and obsession with mathematical beauty.

But the underlying problem with GUT models is not the mathematics. There are an infinity of different ways you can dress up in mathematical language (eg. an infinite number of choices of groups and representation) a GUT hypothesis which postulates new physics at a new energy scale that allows quarks to turn into leptons. In all of them the "mathematical beauty" of a large symmetry group is cancelled by having to introduce a new complicated and ugly Higgs sector to break the symmetry and explain why we don't see it. What drove the GUT hypothesis was not mathematics but physics (ask Georgi and Glashow…), and its failure is a failure of a physical idea, not of the idea of pursuing mathematical beauty as inspiration for new ideas about fundamental physics.

Some Philosophy of Science

Categories: Uncategorized

Defenders of certain failed speculative theories like to accuse those who point to their failure of being “Popperazzi”, relying on mistaken and naive notions about predictions and falsifiability due to Karl Popper. That’s never been the actual argument for failure, and two excellent pieces have just appeared that explain some of the real issues.

- Sabine Hossenfelder’s latest blog entry is Predictions are overrated, a critique of the naive view that you can evaluate a physical theory simply by the criterion “Does it make predictions?”. She goes over several important aspects of the underlying issues here, making clear this is a complex subject that resists people’s desire for a simple, easy to use criterion for evaluating a scientific theory.
- Over at Aeon, Jim Baggott writes about this under the headline How science fails, focusing on the life and work of philosopher of science Imre Lakatos. I wish I had been aware of the ideas of Lakatos when I wrote a chapter about the complexities of evaluating scientific success or failure in my book *Not Even Wrong*, since he was concerned with exactly the sorts of issues I was grappling with there.

  One of the main ideas of Lakatos is that you should conceptualize the problem in terms of characterizing a research program as “progressive” or “degenerating”. As relevant new experimental and theoretical results come in, is the research program showing progress towards greater explanatory power or is it instead losing explanatory power, for instance by adding new complex features purely to avoid conflict with experiment? One way I like to think of this is that it’s hard to come up with an absolute measure of success of a research program, but you can more easily evaluate the derivative: is some new development positive or negative for the program?

  I don’t think there’s any question but that supersymmetry, GUTs, and string theory are classic examples of degenerating research programs. In 1984-5 there was great hope for a certain idea about how to get a unified theory out of string theory (compactification on Calabi-Yaus), but everything we have learned since then has made this hypothesis one with less and less explanatory power.

  The Lakatos framework has the feature that there is no absolute notion of failure. It always remains possible that the derivative will change: for instance the LHC will find superpartners, or a simple compactification scheme that looks just like the real world will be found. The not so easy question to answer is when to give up on a degenerating research program. I think right now prominent string theorists are taking the attitude that it’s past time to give up work on the idea of string theory unification (and they already have), but not yet time to admit failure publicly (since, you never know, a miracle may happen…).

And now, for something completely different: If you want something more entertaining to read about particle physics, I highly recommend Tommaso Dorigo’s Anomaly! (see review here). The one problem with that book was that it stopped in the middle of the story (end of Tevatron Run 1). He now is making available some chapters (see here and here) he wrote that cover the later, Run 2, part of the story.

   May 5, 2020

   The whole question of what precisely a prediction is, has had a very stimulating analysis in the philosophy of science under the concept of the “empirical content of a theory.” Some hard problems here include the question of the theory dependence of our apparatus, so e.g. if you take a reading on the LHC, you not only need the particle physics, but also the electronics, solid state physics etc. to understand the numbers. I enjoyed the book “Structure and Dynamics of Theories” by Stegmuller (based on the work of Joseph Sneed) who makes sense of this.

2. **Marty Tysanner**
   May 5, 2020

   Another good post is by Stacy McGaugh, Predictive Power in Science. He discusses varying levels of prediction/explanation, with the “gold standard” being *a priori* predictions because they can’t be fudged.

3. **Low Math, Meekly Interacting**
   May 5, 2020

   I simply can’t agree that “predictions” are underrated, unless one is so inclusive as to consider a whole lot of obvious rubbish. Of course the mere ability to make some prediction doesn’t qualify as good science. But the inability to make any prediction is surely enough to disqualify.

   “Explanatory power” is “elegance” with more letters. I doubt there’s a way to really quantify the constituents of hypotheses and of theories in any universally reliable sense, so as to allow us to compute the magical ratio of explanations to assumptions. Sure, some things obviously need to be slashed by Occam’s razor. Other things, it’s not so cut-and-dry. A lot of people have come up with ideas that lacked the desired economy, and had them thinking, rightly, that “there’s gotta be a better way”. But it did the job, at least for a time. That’s perfectly scientific.

   Why can’t it be enough to “work sufficiently accurately to encompass known observations and predict new phenomena, such that it can be accepted provisionally?”

4. **Klavs Hansen**
   May 5, 2020

   LMMI:
   I’m not sure your suggestion “work sufficiently accurately to encompass known observations and predict new phenomena, such that it can be accepted provisionally” is not really what people are asking for. It sounds as if you want consistency with known facts and non-trivial predictions, based on an understanding that by necessity must be provisional as all other science.
   Predictions serve as more than a test of theories, of course. We should not forget that science is done by humans and comes with a huge baggage of sociology. My otherwise extremely diplomatic PhD supervisor had a remark about people who “can explain everything and predict nothing”. Non-trivial predictions that get confirmed demonstrate the hard way that somebody has understood something about the way Nature works.

5. **Sabine Hossenfelder**
   May 5, 2020

   Thanks for the link. Was about to mention Stacy’s post, but I see someone already did!

6. **Daniel Tung**
   May 6, 2020

Sabine seems to embrace only explanatory power and discards prediction power as a criteria of good science. But there is always the problem of how to define good explanation. She mentioned a good explanation should have less assumptions and is able to accommodate more data. This is reasonable, but it is not enough. For example, to certain people the statement "God created everything" seems to be a good explanation. It is also an extremely simple one. The problem with this "explanation" is that the statement itself has no predictive power at all. So both simple non-ad hoc explanatory power and novel successful predictions are necessary for the definition of a good science.

7. **Low Math, Meekly Interacting**
   May 6, 2020

   Klavs: Sure, as long as we can get everyone to agree on what "non-trivial" means. Generally, that's in the same league as "porn", i.e., you know it when you see it. Except when you don't. Obviously it's damn hard to nail down. I tend to like the stock, anodyne "definitions" of the above sort I quoted simply because there's hope they invite enough consensus to get people off of the subject of definitions and move on to the work. I wouldn't claim they're terribly useful as a guide, but as soon as one tries to get more particular there's a whole lot to debate, and little to show for it afterward.

   But for heaven's sake, let's not trivialize the importance of a prediction…at least of the sort we know to be great when we see it.

8. **Klavs Hansen**
   May 6, 2020

   LMMI:
   We don't all need to agree on a definition of the (non-)trivial nature of predictions to appreciate them.
   Just like we don't need to agree on how precisely to define dirty clothes before we agree that laundry is a good invention.

9. **Stephane**
   May 6, 2020

   I think any physicists should at minimum have read the book by Alan F. Chamlers – What Is This Thing Called Science? (4th edition).

   It is also interesting to note, that physics books for students were rewritten after the Second World War and the Sputnik crisis in the US to target more Engineers and so by removing all 'too philosophical chapters'. It is very nicely described in David Kaiser's article: "Turning physicists into quantum mechanics," Physics World (May 2007): 28-33.

10. **Peter Woit**
    May 6, 2020

    All,
    Like progressive and degenerating research programs, there are progressive and degenerating comment threads, and this one is degenerating in the usual way. If you don't have something new and interesting to say that is specifically about the material in the posting, please resist temptation.

11. **Tommaso**
    May 8, 2020

    Hi Peter,

    many thanks for citing my outlet of additional material from Anomaly!

    Concerning Sabine's defense of theory that make failed predictions, I will iterate here what I commented on twitter about it. Since she has been bashing Supersymmetry theorists for quite some time now, precisely because of their failure to make falsifiable predictions and their undeterred insistence on the possible veracity of their theory (with connected attacks to new accelerator physics projects), I mentioned that her latest entry seemed inconsistent. But consistency, so they say, requires you to be as ignorant as you were a year ago….

    Cheers,
    T.

12. **Peter Woit**
    May 8, 2020

    Hi Tommaso,
    Since Sabine hasn't been writing editorials for the New York Times arguing for shutting down the future of what I and my colleagues do, I can afford to be more charitable. I think her criticism was of the naive idea that you can easily tell good from bad theory by use of the identification "makes predictions=good theory". Unfortunately it's not so easy, and that's one reason I decided to write a whole book about the problem of evaluating SUSY/GUTs/string theory, instead of a paragraph saying "no predictions" (lots of people never read the book, just a review or two, and so are convinced that the content of that book is nothing but that kind of paragraph).

    In the SUSY case, many of the prominent theorists involved decided pre-LHC to stick their necks out and claim to have a specific prediction falsifiable at the LHC (weak scale SUSY). This was quite unusual. Thanks to you and your colleagues, science progressed, with heads chopped off and their previous owners reduced to the behavior of proverbial chickens with a similar experience. This hasn't stopped some of them from continuing to award each other $3 million prizes, but has very seriously damaged their credibility and influence. So, yes, it would have been a good idea for Sabine to acknowledge that sometimes the naive model does work (and we desperately need more of that…)

13. **Lee Brown**
    May 19, 2020

    Regarding "I don't think there's any question but that supersymmetry, GUTs, and string theory are classic examples of degenerating research programs. "

    Do you think that the attempt to use supersymmetric particles to explain the supposed anomalous events recorded in the ANITA project are legitimate, or simply an attempt to resuscitate supersymmetry?

    Popularly written about here : https://www.livescience.com/63692-standard-model-broken-supersymmetry-new-physics.html
    Referring to this preprint: https://arxiv.org/pdf/1809.09615.pdf

    I would like your thoughts Prof. Woit, as it is beyond my ability to judge.

14. **Peter Woit**
    May 19, 2020

Lee Brown,

The great thing about SUSY is that you can explain any weird event or two using it, but no one takes this kind of activity seriously. Those 2018 media claims were bad enough, but the coverage of ANITA has now completely jumped the shark: the NY Post today has this

https://nypost.com/2020/05/19/nasa-finds-evidence-of-parallel-universe-where-time-runs-backward-report/

"In a scenario straight out of "The Twilight Zone," a group of NASA scientists working on an experiment in Antarctica have detected evidence of a parallel universe — where the rules of physics are the opposite of our own, according to a report."

There doesn't appear to be anything new here, I can't figure out what idiot told the press about "evidence for a parallel universe". If I had any association with ANITA, I'd be suing the Post for defamation.

This kind of nonsense really should just be ignored, I'm only commenting on this because one needs a little bit of comic relief these days.

15. **Blake Stacey**
May 21, 2020

There's a CNET story ("No, NASA didn't find evidence of a parallel universe where time runs backward") that suggests the NY Post cribbed from the un-paywalled portion of a New Scientist story from April:

https://www.cnet.com/news/nasa-did-not-find-evidence-of-a-parallel-universe-where-time-runs-backwards/

My guess is that PI has a pretty well-funded PR staff.

16. **Willie Storage**
May 25, 2020

Sabine has admirably defeated a straw man without even giving the standard lines from the likes of Paul Thagard ("falsifiability provides no criterion for rejecting astrology as pseudoscience") that usually accompany "disproofs of Popper." She doesn't seem to have read Lakatos carefully, and possibly not even Popper. Arguments defending explanatory power over predictive success have all the problems that led Popper to see a clear difference between the predictive theory of Einstein and the explanatory-only theories of Freud, Adler, and Marx. Popper saw making correct predictions as possibly more of a vice than a virtue; it is very wrong to pin predictive success on Popper. Astrology makes many true predictions, but they are not bold. Popper admired bold predictions (falsifiable on that basis, not merely trivially falsifiable) for all the reasons that philosophical Bayesians do; without the theory the prediction should be utterly surprising, with the theory, less so. Eddington's experiment was his exemplar for this. Of course science seeks good explanations, but with no element of refutability, theory choice based on explanatory power descends into pure relativism.

17. **Art**
May 26, 2020

I note that the price of "Anomaly!" no longer is one. Looking forward to reading it.

Final Fourier Analysis Notes

May 18, 2020
Categories: Uncategorized

Our semester here at Columbia is finally over, and I've put the lecture notes on Fourier analysis that I wrote up in one document here. A previous blog posting explained the origin of the notes: they cover the second half of this semester's course, from the point at which the course became an online course due to the COVID-19 situation.

Not much blogging going on here, mainly since everyone staying home seems to have kept news of much interest to a minimum.

Comments

1. **Sami**
   May 19, 2020

   Great notes and thank you for making them public.

2. **DB**
   May 19, 2020

   Peter,
   this upcoming event might be pretty interesting.

   https://conference.ippp.dur.ac.uk/event/906/

3. **Geoffrey Dixon**
   May 20, 2020

   Correct me if this is way off:
   > The Fourier transform is possible because the 1-sphere is parallelizable;
   > What is known about generalizing concept to the 3- and 7-spheres?

4. **Justin B Glick**
   May 20, 2020

   I thought you could use a good laugh during these troubled times. Unfortunately, the article doesn't seem to be in jest.

   https://www.google.com/amp/s/whdh.com/news/nasa-uncovers-evidence-of-bizarre-parallel-universe-where-physics-time-operate-in-reverse/amp/

5. **Peter Woit**
   May 21, 2020

   Justin B. Glick,
   See
   https://www.math.columbia.edu/~woit/wordpress/?p=11747#comment-236286

   Geoffrey Dixon,

   It's not S^1 being parallelizable (all 1-manifolds are parallelizable…) that makes Fourier analysis work, it's that S^1 is a group (rotations of the plane). S^3 is also a group (SU(2) or Sp(1), unit quaternions if you prefer). There is an analogy of Fourier analysis in this case (like for any compact Lie group). Abstractly
   $$Functions(G)=\sum_{irreps\ V} V\otimes V^* =\sum_{irreps\ V} End(V)$$
   Or, in the case of SU(2):
   $$Functions(S^3)=\sum_{n=0}^{\infty}(\text{matrix elements of}(n+1)\times(n+1) \text{matrices})$$
   This says that any function on G can be expanded in matrix elements of irreducible representations, e.g. any function on S^3 can be expanded in matrix elements of the spin 0,1/2,1, etc. representations (these matrix elements depend on the group element, so are functions on the group).

   If your group is commutative, all irreducible representations are one-dimensional, and you get an expansion in these (as character functions on the group). For instance, the $e^{in\theta}$ for S^1.

   S^7 isn't a group, so this won't work.

6. **Peter Orland**
   May 21, 2020

   Hi Peter,

   But the group property is not necessary for orthogonal expansions to exist…

   Spherical harmonics on S^2, expansions in terms of orthogonal polynomials, Bessel functions. Orthogonality and completeness are all proved (despite there not being a Peter-Weyl/Plancherel theorem, which you have for groups). Granted that some (but I think not all) of these are obtained by reducing from a group to a lower-dimensional manifold.

   Not trying to be snarky here, just mentioning something that appears relevant. Maybe calling an expansion into orthogonal functions "Fourier" depends on the group property (since it is an expansion into group characters) of the manifold. That would make the term purely a matter of semantics. Beyond that, I'm not sure how it is important.

7. **Peter Orland**
   May 21, 2020

   For example, the symmetry group of S^7 is SO(7) or $spin(7)$. There are certainly spherical harmonics, respecting this group symmetry, on S^7.

8. **Peter Woit**
May 21, 2020

Hi Peter,

Yes, there are various other generalizations. There are bases of orthonormal functions of various kinds without an obvious group theory origin. For a pair of Lie groups G, H, you can think of functions on G/H as the subspace of functions on G that are right invariant under H. This is how you get spherical harmonics: think of S^2 as $SU(2)/U(1)$, functions on S^2 as functions on S^3 right invariant under the $U(1)$ action. In terms of the decomposition I wrote above into a sum over spins of $V\otimes V^*$, the $U(1)$ acts on one of these, with invariant piece one-dimensional for integral spin, zero for non-integral spin. So, the sum is over all integral spin representations, and this is exactly the decomposition of functions on S^2 into spherical harmonics.

While S^7 is not a Lie group (and G/H in general is not parallelizable), S^7 does have an amazing ("unparalleled" by any other example) variety of different geometries, thought of as different identifications with a G/H.

$$S^7=Spin (5)/Spin(3)=Spin(6)/SU(3)=Spin(7)/G_2=Spin(8)/Spin(7)$$

(you might want to think of $Spin(5)$ as $Sp(2)$, $Spin(6)$ as $SU(4)$).

9. **DB**
May 21, 2020

This might be entertaining for just over 40 mins.
The first part has some interesting aspects.
There are a couple of questions at the end, one re the landscape…

https://www.youtube.com/watch?v=GC2mqMmfW6o

10. **Peter Orland**
May 21, 2020

Your comments on S^7 are fascinating (I knew about S^2), but I guess I was making the point that there also exist complete sets of orthogonal functions on manifolds in all sorts of situations; even with no symmetry (by which I mean no Killing vector at almost every point).

I suppose I could have made my earlier point clearer by not citing examples of manifolds with symmetry.

11. **Peter Orland**
May 21, 2020

…but what seems clear is that when there IS symmetry, constructing orthogonal families of functions becomes an easier algebraic problem (with all kinds of beautiful aspects), rather than a hard and ugly analytic problem. Maybe that is the real point.

12. **Geoffrey Dixon**
May 22, 2020

I found an 8 year old introductory text on Spherical Harmonics in q Dimensions (Frye and Efthimiou). It claims there is scant literature on this topic, so something at this level is probably great for someone who has taught advanced analysis, but not by preference, and decades ago. I name no names.

13. **David Reed**
May 22, 2020

The group property is needed for convolution.

14. **Peter Orland**
May 23, 2020

Spherical harmonics in any dimension are quite adequately discussed in the book by Hochstadt on Mathematical Physics.

15. **Geoffrey Dixon**
May 23, 2020

Peter O: Hochstadt is mentioned in the text of Frye & Efthimiou. They say it is more advanced and definitive. I wonder if I own the thing – down in the Bat Cave. For the time being, given how unlikely it is at his point that it will help me crystallize my intuition, I'll continue perusing F&E in a desultory way.

Oral Histories

May 24, 2020
Categories: Uncategorized

I recently ran across a recent interview with Mary K. Gaillard, which encouraged me to look again at the AIP's oral histories site. For a review of her autobiographical book, see here.

She has the following comments on the current state of HEP theory:

> **Zierler:**
>
> What do you see as the future of theoretical physics? Where is the field headed?
>
> **Gaillard:**
>
> Well, I think it's headed towards insanity by itself. I mean, no, if we don't have experiments, people can let their imaginations run wild, and invent anything without it being verified or disproven. So I think it—I mean, if we want to understand more about what happens at higher energies, we have to have higher energy colliders. I don't think—well, cosmology is tied to particle physics, and that's probably something from—I mean, there is a lot of data coming from cosmology. And there is some data that will be coming from very low energy precision physics. But I don't think that theory by itself—it needs to be kept in line by experiments.
>
> …
>
> **Zierler:**
>
> And so what advice do you have sort of globally for people entering the field in terms of the kinds of things they should study, and the way they should study those things?
>
> **Gaillard:**
>
> That's a —actually, I often advise people to go into astro-particle physics just because I think that it has more promise of getting data because I don't—I mean, I strongly believe you can't go forward without good data, and unless—well, of course, if they do have another generation of colliders, that would be great. I just don't know if that's going to happen…

Another very recent interview I found interesting was that of Vipul Periwal. Periwal arrived as a Ph.D. student at Princeton around the time I was on my way out, starting his career right about when string theory hit in late 1984. He worked as a string theorist for quite a few years, ending up in a tenure-track faculty position at Princeton, but then left the HEP field completely, starting a new career in biology. Here are some extracts from his interview:

> **Zierler:**
>
> And what was David 's research at this point? What was he pursuing?
>
> **Periwal:**
>
> String theory. He was just 100 percent in string theory. Right? They just did the heterotic string, and so everyone was — every seminar at Princeton at that time was all string theory. It was all string theory. Curt was working on it, David was working on it. Edward was working on it. Larry Yaffe was probably the only person — no, two people, Larry Yaffe and Ian Affleck were not doing string theory. Not that they couldn't, but they just would not do it.
>
> …
>
> **Zierler:**
>
> So you mean, despite at this point all of the work on string theory, there were still existential questions about what string theory was, that remained to be answered?
>
> **Periwal:**
>
> There still are.
>
> **Zierler:**
>
> Yeah.
>
> **Periwal:**
>
> No one has ever figured out what is string theory. I mean, if you go ask all the eminent string theorists, none of them can answer for you this one simple question. Can you show me a consistent string theory, where supersymmetry is broken?
>
> …
>
> **Zierler:**
>
> Was it good for your research? Was it a good time for you ?
>
> **Periwal:**
>
> I don't think I did particularly interesting research. I did — I mean, I did okay, but I'm not particularly proud of anything I did there, except for one little paper I wrote, in which — see, this is called the contrarian part — is I showed — people were very excited about the large N limit, so I took this toy model, and I showed that in the large N limit, it actually produced something nonanalytic, as in like, you could not, in any order of 1 over an expansions, ever see what the answer was that was exact at N equals infinity. So, in other words, it was to me a cautionary tale. Like, you think you're doing large N and then getting an intuition for finite N. But here's this very simple model where you can do the calculation exactly, and you can do all your 1 over N expansion as far as you want, and it'll never tell you about what's going to happen at N equals infinity. But you know, it's a — at this point, string theory was already at that time pretty much a sociological thing.
>
> **Zierler:**

What do you mean “sociological”?

Periwal:

So, it’s something that was borne home to me gradually, that there’s no experimental proof. Like, are you a good physicist or a bad physicist? Who’s going to tell? How do you know? Right?

Zierler:

Yeah.

Periwal:

I mean, I’d go and give a talk somewhere, and I remember this very clearly. I went and gave a talk at SUNY Stony Brook, what’s now called, I guess, Stony Brook University. And at the end of the talk, I was talking to one of the faculty there who’d invited me. And he said, “So, what does XYZ think of this work?” And I was just taken aback. I was like, wait, you’re a physicist. I’m a physicist. Why do we need to know what XYZ thinks of this?

Zierler:

Yeah.

Periwal:

Right? That’s what I mean by sociology.

Zierler:

I see. It’s as much about what a certain group of peers thinks about the theory.

Periwal:

Yeah, and this really perturbed me. As far as I was concerned, after the string perturbation theory diverges thing, I was not interested in doing perturbative calculations. So, what the solution was that people did was: okay, we’ll work on various supersymmetric theories where there is no higher contribution, and under the assumption that there is supersymmetry, you can use holomorphicity to deduce things from the structure of the fact that there’s so much supersymmetry. And this really bothered me, as in okay, there’s this really amazingly beautiful structure, and lots of very pretty mathematical results that are coming out — mathematical results that are suggested by these correlations. But I just don’t get — as a physicist, I don’t to want to have to worry about, “What does XYZ think about what I’m doing?”

Zierler:

Yeah, because you’re pursuing a truth, and it’s either true or it’s not. It doesn’t really matter what other people think about it.

Periwal:

Right. I really don’t care. I mean, no matter how much I respect — and I do — Edward, or David, or whoever, I really don’t need to know what they think about my work. Right? I just — anyhow —

Zierler:

How does that attitude serve you in an academic setting, though? Right?

Periwal:

It doesn’t.

Zierler:

How does that attitude affect you in terms of tenure considerations and things like that?

Periwal:

Yeah, so when I was — no, so I actually — I mean, when I was — well, I have no — I’m really stupid sociologically, as in, I have no instinct for self-preservation. So, I could see I had role models in front of me of how people with tenure…

Zierler:

Succeeded.

Periwal:

…succeed, not just getting tenure at Princeton, but getting tenure at very good places after Princeton, too. And I paid zero attention to all this. So, while I was at Princeton, I tried doing some lattice gauge theory.

With this attitude, it’s not surprising that in Periwal didn’t get tenure at Princeton. He didn’t soon get job offers elsewhere in HEP theory, and decided in 2001 better to try another field than keep going in the one he was in. The interview ends with:

Zierler:

Alright. So, really, the last question. What does the big breakthrough moment look like for you? How would you conceptualize this in terms of putting all of this together? What does that big breakthrough look like?

Periwal:

If I could make a prediction that was clinically testable, that would make me very happy.

Zierler:

Do you think you'll get there? It's the thing that motivates you.

Periwal:

Yeah. I want — you know, I said this once. We had someone visiting when I was managing the physics seminar at Princeton once, as an assistant professor. So, this guy asked me, "So, Vipul, what are you working on?" And I was very jaundiced at that time about making a prediction. So, I said, "Well, lattice gauge theory," which, you know, nobody at Princeton did lattice gauge theory. You were all supposed to be doing string theory. I said, "Yeah, I want a number before I die." People are looking at me like, "What kind of lunatic is this?" But you know, a number. That would be nice.

Looking through the old interviews, I found one of very personal interest, that of [Gerald Pearson], who worked with my grandfather Gaylon Ford at Bell Labs. Some of his stories mentioned work with my grandfather (whose main expertise was in the design and construction of vacuum tubes) at Bell Labs during the 1930s. During this period both studied at Columbia, where my grandfather got a master's degree in physics.

Pearson:

Gaylon Ford worked with Johnson. When Kelly was head of the tube department, he worked in that area. And then they had a big shakeup after which the job was no longer available. Much against his desires, he came over to work with us.

…

Hoddeson:

In 1938 you were moved over from Johnson's group into Becker's. In fact, you and Sears seem to have changed places.

Pearson:

Before that took place, I remember Johnson called me into his office one day and he wanted to know if I would like to work on… well, Buckley had sent a memorandum asking for temperature regulators for buried cable. Johnson wanted to know if I would like to work in this area. Of course, no one likes to change their jobs but I said, "Fine" and we agreed that I would spend a portion of my time on this problem and that's where thermistors came from. This continued on and it was very successful. Then it was decided that the work fit in better with Becker's area than it did with Johnson's. And, well you asked me about Ford. He was the one who was brought from the tube shop to work on this. And then he later went to work on something else.

Hoddeson:

Let's see if we can date that time. Ford wasn't working with you yet. Ford is here with you in 1934. But this move didn't take place until '38.

Pearson:

Yes, that's what I was saying. He first came over to work on change of resistance with temperature. And he was working with a sulfide compound. And then, let's see, what happened to him. He went someplace else and Johnson called me into his office and asked me if I would like to carry on Ford's work and we agreed that I should do it part time and still work on noise. But I said I didn't want to work with sulphur, it smelled too bad. I said if I work in that area, I'm going to use some other materials. So I made a study of that. First I worked on boron and then on a combination of oxides. A lot of my patents are on such materials and devices. These devices are still used today in the buried cable system as volume regulators.

   May 25, 2020

   Hi Peter,

   the interview with Periwal is spot-on right. I was a postdoc in HEP during the 00's and I had very much the same experience and the same attitude as Periwal – not to pay attention to the sociological aspect of the game (which sure enough ended my academic career). I think, though, that what Periwal describes goes much deeper than just string theory. During my career I came in close contact with other fields like loop quantum gravity and noncommutative geometry, and what I encountered there was the same sociological structures – a very hierarchic system, where it is critical for your future prospects to be accepted by the few people "on top".

   Its depressing, because the incentive structures in academia are in a way upside-down: you get rewarded for being a conformist and punished for being original. You build a career by sticking to mainstream and you kill a career by trying out ideas outside of mainstream. As long as the incentive structures are not fixed I am not sure that things will really change.

   The only place that I encountered a fundamentally different culture was in mathematical physics, among people doing axiomatic and algebraic quantum field theory. There I found a much less hierarchic culture where people were more open to new ideas. In fact, very much the same attitude that I have encountered among mathematicians.

   My field of research is an intersection between mathematics and physics and thus I have often given talks to mixed audiences. To me it is striking how different mathematicians and physicist react to new ideas. In my experience the mathematicians – and also mathematically oriented physicists – are much more willing to consider new ideas. Thus I completely agree with your view that HEP should look towards mathematics in order to learn how to deal with a situation where we have less experimental data to work from.

   – and by the way, it is possible to do research outside of academia. I don't think that people should necessarily waste their time in a system that is broken.

   Best, Jesper

2. **Tess**
   May 27, 2020

   I find the "it's sociological" comment really amusing, thought I'm not sure what it's trying to imply about sociology. From sociology, there's a subfield called Legitimation Code Theory, which talks about how knowledge is structured and related systems of power. The shift he refers to, from dealing with the research claims and evidence as written to asking "what does a particular expert think of this?" can be described within LCT as a change from a knowledge code to a knower code, where the authority of the speaker determines the perceived legitimacy of what is said.

3. **Robert Wilson**
May 28, 2020

Jesper,
I think you are right to point to the culture of mathematics as a good example of how progress can be made. In mathematics, people reject new ideas *after* considering them carefully, rather than before. Some years ago, there was a very interesting announcement of a proof that all finite projective planes have prime-power order. I won't embarrass the author of this paper, who was and is a well-respected mathematician, by giving further details, but I found this announcement surprising, so I immediately got hold of the paper and starting reading it. I organised a seminar series in which I explained the argument. Not until week 3 or 4 did I find the crucial error, buried deep in a double induction, where one of the indices had slipped by 1, thus bringing the whole house of cards tumbling down. It would have been easy for me to reject the result as implausible without reading it, as seems to happen all the time in physics, but that is not the culture in mathematics. It would have been easy to say, there's a mistake on page 1, the whole thing is rubbish, but that is not the culture of mathematics. The important thing is to engage with the argument, and to find not any old mistake – that is easy – but to find the crucial mistake which cannot be patched up. If experts do this kind of work before passing judgement, then the subject is in safe hands. If they pass judgement before doing this work, it is not.

4. **Thomas Van Riet**
May 28, 2020

Concerning: "No one has ever figured out what is string theory. I mean, if you go ask all the eminent string theorists, none of them can answer for you this one simple question. Can you show me a consistent string theory, where supersymmetry is broken?"

That is not about the 'what' really. Rather about the 'how' to break SUSY. At which scale etc,…. Let me be clear that dynamical SUSY-breaking in QFT is also a nightmare (ironically string theory, through AdS/CFT, has given us insight in this issue) . Are we all negative about QFT because of that? I mean, imagine we could break SUSY like 123 and pull as many 4D EFTs out of our stringy hat as we wanted ("old school landscape reasoning") people would have complained we cannot predict anything more than what QFT can. Once we start realizing that finding consistent non-SUSY 4D vacua is actually highly involved and constraining ("Swampland viewpoint"), we seem to be criticized for not yet having described the universe and everything within. So I wonder: is research on fundamental interactions only free of attacks once we solve all problems at once? I expect that this is not possible and that any healthy approach to a "theory of everything" is one that makes us confront ourselves with our limited knowledge of mathematics. String theory seems to make that clear to us. There is no reason, I can think off, to be less excited about strings, than we were 20 years ago. On the contrary, we have only seen striking ideas like holography emerge.

5. **Peter Woit**
May 28, 2020

Thomas van Riet,
Periwal was a Princeton faculty member specializing in string theory, with his field of expertise non-perturbative string theory. He's undeniably right that "No one has ever figured out what string theory is." Do you disagree with that? The "SUSY breaking" reference was clearly just to rule out certain specific non-physical cases with a lot of SUSY where someone could point to a conjectural definition.

As for whether there's a good reason to be less excited about string theory than 20 years ago, you might want to consider asking all the IAS physics faculty why they've stopped working on string theory…

6. **Thomas Van Riet**
May 29, 2020

Dear Peter

We must be reading different arxivs? To my knowledge they have continued working on it. It is certainly true that the hep-th community has gone in many spin-off directions inspired by string theory ideas (SYK being one). But no, stringy research is alive and kicking.

7. **Peter Woit**
May 29, 2020

Thomas Van Riet,
I notice you didn't answer my question, assume you agree that "No one has ever figured out what string theory is." is an accurate statement. As you are well aware, the SYK model is a quantum mechanics model that has nothing to do with string theory. Yes, string theory "inspired" work on SYK, because its failure caused string theorists to stop thinking about strings and try and find something different and more promising to work on.

The Week's Anti-Hype

May 27, 2020
Categories: Uncategorized

I never thought I would see this happen: a university PR department correcting media hype about its research. You might have noticed this comment here a week ago, about a flurry of media hype about neutrinos and parallel universes. A new CNN story does a good job of explaining where the nonsense came from. The main offender was New Scientist, which got the parallel universe business somehow from Neil Turok and from here.

The ANITA scientists and their institution's PR people were not exactly blameless, having participated in a 2018 publicity campaign to promote the idea that they had discovered not a parallel universe, but supersymmetry. They reported an observation here, which led to lots of dubious speculative theory papers, such as this one about staus. The University of Hawaii in December 2018 put out a press release announcing that UH professor's Antarctica discovery may herald new model of physics. One can find all sorts of stories from this period about how this was evidence for supersymmetry, see for instance here, or here.

It's great to see that the University of Hawaii has tried to do something at least about the latest "parallel universe" nonsense, putting out last week a press release entitled Media incorrectly connects UH research to parallel universe theory. CNN quotes a statement from NASA (I haven't seen a public source for this), which includes:

> Tabloids have misleadingly connected NASA and Gorham's experimental work, which identified some anomalies in the data, to a theory proposed by outside physicists not connected to the work. Gorham believes there are more plausible, easier explanations to the anomalies.

The public understanding of fundamental physics research and the credibility of the subject have suffered a huge amount of damage over the past few decades, due to the overwhelming amount of misleading, self-serving BS about parallel universes and failed speculative ideas put out by physicists, university PR departments and the journalists who mistakenly take them seriously. I hope this latest is the beginning of a new trend of people in all these categories starting to fight hype, not spread it.

Comments

1. **Warren Siegel**
   May 27, 2020

   An antiuniverse preceding our universe (Turok) isn't what's usually meant by a parallel universe.

2. **Peter Woit**
   May 27, 2020

   Warren Siegel,

   I could have sworn one of the news stories I saw explained that this was a "perpendicular" universe, but can't now find that.

3. **David Roberts**
   May 27, 2020

   There's a new paper in Nature about measuring the cosmic baryon density using FRBs, that is being reported in Australian ABC News as finding a whole lot of 'missing matter' in the universe (maybe some local pride breaking through: Australian telescopes and astronomers were involved). It's not terrible, the headline is a bit more sensational than the rest of the article.

4. **anon**
   May 28, 2020

   Missing baryonic matter is like water on Mars: I've lost count how many times I have seen press releases claiming that it has been found for the first time.

5. **Jens**
   May 28, 2020

   Doesn't string theory provide a natural explanation for hype/anti-hype asymmetry?

6. **Peter Woit**
   May 28, 2020

   David Roberts/Anon,
   I don't want to get into discussions here of claims about things like the significance of observations of fast radio bursts, simply because I'm incompetent to evaluate this or to even competently moderate a discussion of it. People who want to engage in public discussion of scientific issues need to pay close attention to the difference between what they have some expertise in and what they don't. This means avoiding weighing in on issues you don't have expertise in. It also though means that, since there are often few experts on a particular issue, those that are experts have an obligation to "If you see something, say something".

   On the issue of "parallel universes", there has been a massive failure over the years, with an overwhelming quantity of BS rarely if ever challenged by those who understand that it is BS. This press release is encouraging, I hope we'll see this become a regular practice. If your research is misrepresented in the press, go to your institution's PR people and put them to work.

   Jens,

   Yes, string theory does explain hype/antihype asymmetry, but it's not a natural explanation, since it involves fine-tuning by those involved.

An Advertisement for Representation Theory

June 9, 2020
Categories: Uncategorized

There's a new article at Quanta today promoting representation theory, Kevin Hartnett's The 'Useless' Perspective that Transformed Mathematics. Representation theory is a central, unifying theme in modern mathematics, one that deserves a lot more attention than it usually gets, with undergraduate math majors often not exposed to the subject at all. My book on quantum mechanics is very much based on the idea that the subject is best understood in terms of representation theory. Unfortunately, physics students typically get even less exposure to representation theory than math students.

While I think the article is a great idea, and well-worth reading, I do have two quibbles, one minor and one major. The minor quibble is that one example given of a group, the real numbers with multiplication, is not quite right: you need to remove the element 0, since it has no inverse. If the group law is the additive one, then the real number line with nothing removed truly is a group.

The major quibble is with the theme of the article that a group representation can be thought of as a simplification of something more complicated, the group itself. This is a good way of thinking about one aspect of the use of representation theory in number theory, where representations provide a tractable way to get at the much more complicated structure of the absolute Galois group of a number field. The talk by Geordie Williamson linked to in the article (slides here) explains this well, but Williamson also gets right the more general context, where the group can be easy to understand, the representations complicated. For a simple example of this, in the case of the circle group S^1 the group is very easy to understand, its representation theory (the theory of Fourier series) is much more complicated (and much more interesting).

As Williamson explains, a good way to think about what is going on is that representation theory does simplify something by linearizing it, but it's not the group, it's a group action. When people talk about the importance of the study of "symmetry" in mathematics, physics, and elsewhere, they often make the mistake of only paying attention to the symmetry groups. The structure you actually have is not just a group (the abstract "symmetries"), but an action of that group on some other object, the thing that has symmetries. When you talk about "rotational symmetry" you have a rotation group, but also something else: the thing that is getting rotated. Representation theory is the linearization of this situation, often achieved by going from the group action on an object to the corresponding group action on some version of functions on the object. Once linearized, the group action becomes a problem in linear algebra, with the group elements represented as matrices, which act on the vectors of the linearization.

To further add to the confusion, "symmetry" is often described in popular accounts as meaning "invariance". In typical examples given, "invariance" just means that you have a group action, since the group is taking elements of the set to other elements of the set (e.g. rotations not of an arbitrary object, but of a sphere). In representation theory, you have a different notion of invariance. For instance, for the representation of rotations on functions on the sphere, the constant functions are a one-dimensional invariant subspace, giving a trivial representation. But, there are lots of more interesting invariant subspaces of higher dimensions. These are the irreducible representations on the sets of spherical harmonics.

1. **I**
   June 9, 2020

   As an expert on this topic, at least with regards to QM, could you give your opinion on the most important texts/papers in the field?

2. **Peter Woit**
   June 9, 2020

   I,
   The fascinating thing about representation theory is that it is a unifying theme, appearing centrally in very different areas of mathematics. In each such area there's a huge literature and many different textbooks, so I can't come up with a short list, and I don't know of a book that provides a single overview of the many different areas of the subject.

3. **nikita**
   June 10, 2020

   It's strange they used Burnside as an exemplary representation theory sceptic. He founded it together with Frobenius.

4. **Robert Wilson**
   June 10, 2020

   As a popular article explaining representation theory to non-mathematicians, it does a reasonably good job. To a professional representation-theorist, however, it jars in a couple of places. "Mathematicians aim to avoid grappling with the full complexity of a group; instead they gain a sense of its properties by looking at how it behaves when converted into the stripped-down format of linear transformations" is wrong on so many levels. Physicists may behave like this, but mathematicians do not: we strip away the inessentials of linear transformations in order to study the stripped-down abstract group, not the other way around. It is true that to study a group it is often essential to study its representations: but this makes things more complicated, not less. It is also true that applications of group theory almost always involve representations: the group itself is usually too abstract for this purpose, without the mediation of representation theory.

5. **Robert Wilson**
   June 10, 2020

   nikita,
   You are absolutely right. What about Burnside's p^a.q^b theorem? The quintessential example of a theorem in group theory that until relatively recently could *only* be proved using representation theory, and not by group theory alone. In the very early days of representation theory in the second half of the 1890s it might have seemed as though the subject was too abstruse to be useful, but this point of view very rapidly became obsolete.

6. **John Baez**
   June 10, 2020

   I explain how Burnside changed his attitude toward group representation theory here.

7. **Sam Hopkins**
   June 11, 2020

   When people say "representation theory is a central, unifying theme in modern mathematics" I wonder to what extent they really mean that the objects to which representation theory can usefully be applied (say, simple Lie groups and all their offshoots) are central. It seems there is still a bit of mystery as to why representation theory is so effective for understanding these kind of algebraic objects and their actions. Certainly Williamson's work (and the work of his forebears like Lusztig, etc.) explores the boundary of representation theory's effective reach.

8. **Thomas Larsson**
   June 12, 2020

   As an undergraduate, and also later, I didn't understand the point with groups and representation theory. I took courses and could follow the steps, but it didn't seem very important to me. As a graduate student, I specialized critical phenomena and fractals, in particular in 2D because that was where progress was made. This was in the mid 1980s, when CFT came around, which I noticed but didn't understand.

   Then when preparing for my dissertation, I read the NPB paper by Dotsenko and Fateev, and it suddenly clicked. I realized that what I had studied in grad school could be explained in terms of the representation theory of the Virasoro algebra. This was a complete eye-opener and changed forever how I viewed physics, for better or worse.

9. **Albert**
   June 12, 2020

   Regarding your first quibble, the apparently trivial example of the multiplicative real numbers as a group, i.e. the reals w/0 zero, is actually kind of useful
   for understanding the difference between GL(2, C) and GL(2,R). The multiplicative complexes and reals are of course GL(1, C) and GL(1,R) and for both 1 and 2 dimensions, the
   complex groups are connected while the real ones have two connected components, with positive and negative determinant, the former a normal subgroup of index 2. I had never understood this very well, and realized only recently that the explanations are the same. Since the exponential function takes addition to multiplication, the Lie algebra (i.e. the additive group of all matrices) is mapped to the positive determinant matrices GL^+(2,R); note that indeed
   det(exp(A))= exp(trace(A))), so the image must have positive determinant. Further, to show the image is pathwise connected
   you can linearly interpolate in the Lie algebra and push that forward to a path in the image.
   (You can't directly linearly interpolate in the group since you might pass through something with determinant 0).

10. **Robert Wilson**
    June 17, 2020

    Geordie Williamson contacted me personally to point out that he is quoted out of context in this article, and in his lecture he discusses Burnside's change of heart in depth.

Feynman Lectures on the Strong Interactions

June 15, 2020
Categories: Uncategorized

Available at the arXiv this evening is something quite fascinating. Jim Cline has posted course notes from Feynman's last course, given in 1987-88 on QCD. There are also some audio files of a few of the lectures available here. The course was interrupted by Feynman's final illness, with the last lecture given just a couple weeks before Feynman's death in February of 1988. There's an introduction to the notes by Cline in which he explains more about the course and how the notes came to be.

The course was given over thirty years ago, and many textbooks have appeared since then, but it seems to me this has held up well as an excellent place for a student to go to learn the subject.

Comments

1. **Peter Orland**
   June 16, 2020

   There seems to be a lot of overlap with the course I took from RPF ten years earlier. Definitely a rewarding experience.

2. **Doug McDonald**
   June 17, 2020

   I read most of the piece.

   I would say that, more than a place for a beginner to go, it is the place for the
   non-beginner, non-really-expert to go to for interesting physical insights, especially ones not currently mainstream teaching fodder.

   Glashow, whom I saw in person for a whole semester, was like that too … but the big difference is that Feynman's insights hold up to post-lecture study as not being as empty handywavy as Glashow's. I, a chemist (!), could and did see through them.

HEP Theory Job Situation

June 17, 2020
Categories: Uncategorized

Way back in the 1980s and 1990s I was, for obvious personal reasons, paying close attention to the job situation for young HEP theorists. They were not good at all: way more talented young theorists than jobs, many if not most Ph.D.s who wanted to continue in the field unhappily spending many years in various postdocs before giving up and doing something else. By the later part of the 1990s I had found a satisfying permanent position in math, so this problem seemed much less interesting. When I was writing "Not Even Wrong" I did spend quite a bit of time gathering numbers to try and quantify the problem, and wrote about them in the book.

Since then I haven't paid a lot of attention to the HEP theory job situation, hoped that it might have gotten a bit better as the wave of physicists hired during the 1960s hit retirement age, opening up some permanent positions. Today someone sent me a [link to a personal statement on Facebook] (sorry, but you need to login to a Facebook account to see this) from a young theorist ([Angnis Schmidt-May]) who has recently decided to leave the field, for reasons that she explains. These include:

> We are put in competition with each other from day one, and only very few of us will be given prestigious positions in the end. Most of us never see a permanent contract, keep jumping from place to place and eventually need to find a second career after having sacrificed our entire 20s and 30s to academia. After having made it through the worst part of this and more or less securing my career, it still made me sick to see young physicists entering this spiral. I felt terrible about encouraging them to continue on this path because it is impossible to tell who will make it in the end and who will end up miserable with regrets…
>
> Science itself is severely suffering from the poor working conditions and lack of genuine career prospects. I personally found it extremely hard to focus on the science while constantly being worried about the duration and location of my next contract. #PublishOrPerish. Interactions with and among colleagues are often dominated by the drive to "show off". Very few people focus on removing misunderstandings or ask honest questions in order to fill their knowledge gaps. The general atmosphere is dominated by doubt instead of trust. We constantly need to outshine our peers. Better to demonstrate superficial knowledge of broad subjects than to focus on the details of a deep problem. Your next result needs to be "groundbreaking", otherwise you're out of a job. But produce it and have it published at least one year before your contract ends because that's when you need to apply for a new one. Science has become a show…
>
> I see absolutely no chance that any of the above will change any time soon.

She also makes important points about the personal cost of this system:

> During the last 10 years, I was forced to constantly move around, losing contact to people who meant a lot to me and not being able to establish new lasting relationships.

Sadly, it seems pretty much nothing at all has changed in the last 30-40 years, and I continue to believe this is one reason the subject has been intellectually stagnant during this period. About the only positive suggestion I can make for anyone who wants to try and do anything about this is to take a look at the analogous job situation in mathematics. My knowledge of this is mostly anecdotal, but my impression is that while, like most academic fields, the career path for a new math Ph.D. is not easy, the situation is not at all as bad as the one in HEP theory described above.

Completely Off-Topic: Xenon1T has reported [new results] today. This seems to me unlikely to be new physics (extraordinary claims require extraordinary evidence), so if you want to follow this story, you should be [consulting Jester], not me.

Comments

1. **Warren Siegel**
   June 17, 2020

   That's show business.

2. **Mark**
   June 17, 2020

   Not really a hep theory problem is it? Pretty much every academic field suffers from this problem – too many talented PhD, hardly any permanent jobs.

3. **Sabine Hossenfelder**
   June 17, 2020

   Very sad 🙁 I was on her PhD committee in Stockholm. Alas, I know exactly what she is talking about.

   And let me add that at the age of 43 I am still sitting on a temporary contract and am worried to run out of funding every other year or so.

4. **Peter Woit**
   June 17, 2020

   Mark,
   Yes, it's a general problem in academia, but to different degrees in different fields. About 20 years ago I was looking very closely at whatever data there was, and the problem in HEP theory was worse than in almost any other subject. I haven't looked at recent data, can just say that the situation in mathematics seems to me much better than in HEP theory. In particular the sad description here of the competitive environment doesn't sound like what I've seen going on in mathematics.

5. **Geoffrey Dixon**
   June 17, 2020

   Small advice from someone who fought the gnawing doubt for decades, then took steps to adjust to reality and break free:

   > If you want to do mathematics, or mathematical/theoretical physics, then do it. An institution is not necessary in most cases – just time.
   > Find something other than science that you can be passionate about, and which has the potential to provide a living.

   For me it was animation, then interactive animation, and finally a job I enjoyed creating interactive online apps that required a mathematical background. During all that time I continued working on mathematics and physics, albeit with less time. I gave talks at conferences. I retired with not too many worries.

   I was lucky, maybe, but being able to apply mathematics and physics to the real world will never not be needed.

Can your ego take the surrender? Is it surrender? Is academia what you grew up thinking it would be? Angnis discovered it is not, and she is correct.

6. **Low Math, Meekly Interacting**
   June 17, 2020

   This isn't at all unique to HEP theory, though the problem may be more/most acute in that field. The process of recruitment is fundamentally dishonest. The incentive to maintain a steady supply of cheap labor is irresistible. Research U.'s accept and produce far too many PhD's, indoctrinated and trained only for academia, with few provisions for those who can't hack it, for whatever reason. If there were any motivation to train talented people adequately for the more diversified needs of a real-world workforce, things could be much better, but there simply isn't. The needs of the institution (i.e. the grant and publications numbers game) are overriding. One needs to at least be made aware of the reality going in, but the system is far from self-policing.

7. **Peter Woit**
   June 17, 2020

   LMMI,
   Yes it's a general problem, but I do think it is much worse in HEP theory, and the damage the problem has done to the subject is unusual.

   I did do a few minutes research to see if I could get info about other fields. One thing that quickly turned up is detailed data on Philosophy Ph.D.s maintained here:
   http://placementdata.com:8182/phd-programs-running-tally
   One might think of a philosophy Ph.D. as the quintessential useless humanities degree that would make one unemployable, but the top programs often have 60-70% of their graduates getting academic positions of some sort, 25-40% getting academic positions in departments with Ph.D. programs. I'd be curious to see similar numbers for HEP theory, suspect they would be quite a bit lower.

   The humanities model is different than that in the sciences, in that they tend to not have postdocs, you can get a tenure-track job when you get your degree. Arguably this is a much better system than the HEP physics one, avoiding the brutal personal cost to many of having to spend years moving around and not putting down roots.

   The mathematics model is again different, somewhere in between, with both fewer research postdocs and fewer tenure-track jobs available to new Ph.Ds. A typical career path would be a single "postdoc" involving teaching, then a tenure-track job. I'd be very curious to know if there are numbers available comparable to the philosophy ones.

8. **Art**
   June 17, 2020

   She's leaving after "more or less securing" her career? I don't get it. Why not stay in place and work to improve things? (I refuse to open a Facebook account.)

9. **GM**
   June 17, 2020

   It is the same situation in pretty much all other disciplines, but in some of them it is even more messed up because many people would actually be perfectly OK with not being a tenured professor while in the same time the progress of science would greatly benefit from their accumulated expertise (experimental fields in the life sciences and chemistry immediately come to mind). Those people now just get thrown out of the system, and it is not even the case that they can just go to industry, R&D in biotech, pharma and the chemical industry has been increasingly either outsourced or just shut down altogether.

   But if there were permanent positions in which such people could just keep doing their research even if there is no tenure and teaching involved, that would first, keep them happy doing what they love to do, and second, help move science forward. What was all that specialized training for, after all?

   Sounds like a win-win, doesn't it?

   Except that in that sort of system proper wages would have to be paid and that people in such positions would probably not be working 14-hour days if they have families and kids.

   It is much better for the selfish short-term interest of research institutions, and, let's face it, also for the senior scientists who did manage to win the rat race, to have the current system, in which junior scientists spend two decades in a state of constant uncertainty that forces them to work those 14-hour days while being paid between a third and a half of what they would be otherwise, indefinitely delaying starting a family, etc.

   Sounds exploitative? It is.

   It is also a very good mechanism of control on a broader level, because it means that nobody in their right mind will rock the boat until they get tenure, but by that point they have been thoroughly vetted and domesticated and will likely never do so after that either.

   In the USSR a lot of the dissidents came exactly from the ranks of scientists.

   There was certainly a lot to oppose about what unfolded in the US over the last five decades but it has not in fact been meaningfully opposed. Much of the general population was driven to destitution, through mechanisms quite analogous to those in place to exploit junior scientists in academia. And now with the coronavirus we see that for the people on top, the general population is physically expendable too, in numbers in the millions, as long as this serves their selfish economic interests.

   The truth is that scientists not only did not say much to oppose that process, they in fact often supported it. Because when you constantly have to worry about the future and you can be thrown out at any moment, you, first, don't have the time to think about larger issues, and second, it is just not advisable to stick your neck out.

10. **Peter Woit**
    June 17, 2020

    Art,
    She does address this at some length, note the
    "I see absolutely no chance that any of the above will change any time soon."
    She has found a rewarding opportunity to work in a much better environment outside HEP theory. Why should she continue to work in a toxic environment, where everyone takes the attitude "this is how it always has been, nothing can be done"?

    The problem with this kind of environment is not just that good people can't find a permanent place in it, but that many of the best of those who can have other opportunities and leave.

11. **Chris Oakley**
    June 17, 2020

Sabine,

Just in case you are not aware of this, rubbishing most of what is going on in theoretical physics is not the best strategy for getting a permanent job in academia.

But you do it so well that if I was rich enough to have my own institute, you'd be hired straight away.

12. **Peter Woit**
June 17, 2020

GM (and others),
I'd like to insist that people stick to discussing the problems of HEP theory, rather than the inexhaustible question of the more general problems of other fields and the sad state of our society in general. For other fields, which ones provide a model for HEP theory to look to for something better?

I'd love to see some relevant data, but at least for those parts of academic mathematics I'm most aware of, the situation is much better, with full-time junior positions paid fairly well, with some hopes for finding a good permanent job (the adjunct teaching business is where people are mistreated).

13. **LK2**
June 17, 2020

I got a permanent position with a lot of luck. I find very hard to advise a young scientist to pursue this career. Moreover, I see a lot of bright phds leaving academia straight away nowadays. Why? Because industry is hiring physicists and giving them very interesting problems (mainly datascience). We are living in times where some industry problems are more exciting and advanced wrt what we do in a physics dept (quantum computing, machine learning, …). My take on hep theory or phds in general? Reduce the phd positions drastically or state clearly at the beginning what to expect if after graduation one wants to try to pursue a research career. Honestly, after many years in academia, I wish I had abandoned after the phd. Today's fundamental physics research is show-off and fake-grants writing just to "do stuff". Good luck to all the academia job seekers, K.

14. **zzz**
June 17, 2020

>rubbishing most of what is going on in theoretical physics is not the best strategy for getting a permanent job in academia.

"most" is not HEP

15. **Maciej**
June 17, 2020

Although I sympathise with the HEP community because I used to work in the field (not anymore) I don't really see where the problem is. HEP community hasn't produced any new (i.e. beyond the Standard Model) meaningful, testable theory for decades now. Most research papers are still about Susy, Strings, Loops – which are either ruled out already, provide no predictions or are not testable.
Even layman politicians will notice that there is no point in investing much in that area. Clearly many bright researchers will not secure jobs, little of them will. This was always the case, maybe now even more than ever. But I think it is adequate to the fact that there has been literally nothing new for decades.

If someone is complaining about not securing the job due to extreme competition, maybe it is time to change the field. There are plenty of topics that are well funded and equally challenging: quantum computing, artificial intelligence/machine learning, quantitative biology, quantitative finance et.c.

16. **Peter Woit**
June 17, 2020

Maciej,
My impression is that the job situation is somewhat better now than it was back in the 70s, the time of huge breakthroughs in the field as the Standard Model came together. There's no evidence that bad intellectual health in HEP theory causes a bad job situation, but I think it's quite possible that a bad job situation has helped contribute to bad intellectual health.

17. **Edward M Measure**
June 17, 2020

Does it make sense to control the number of PhD's awarded? The number of Postdocs? Or are these cures worse than the disease?

Right now there are excellent job opportunities for physicists, including those with just a BS, in software engineering and data science. For less stress and more job security, they can, if skilled, make 3 or more times as much as they would as a tenure track assistant prof. And the problems might be more interesting.

18. **William Connolley**
June 18, 2020

> We are put in competition with each other from day one, and only very few of us will be given prestigious positions in the end… We constantly need to outshine our peers.

Whilst this is obviously stressful for individuals, it isn't clear it is a problem for the field. Putting people in competition and rewarding only the best sounds like a plausible strategy. I'm not saying it is nice, or fair, or even deliberate, I'm only talking about the overall good of scientific progress. You could perhaps argue that the lack of progress disproves this idea, but then again maybe the work is just very hard. On the other hand, ASM addresses this by saying that the stress makes it hard to do science; I'm not sure that's fully convincing. And of course there's short-term pressure for flashy results, but you get that most everywhere.

19. **Angnis**
June 18, 2020

Dear Peter,

thank you so much for drawing attention to my FB post. I would like to emphasize that, originally, this post was intended only for my family and friends but then some people asked me to make it public so they could share it. I honestly did not expect that it would reach this far but now I am really glad that it did.

From the comments above, I understand that some of your followers are wondering about why I did not stay in academia in order to improve the situation. In fact, this was the hardest part in making the decision to leave. In my last years as a group leader I did my very best to improve the work environment for my team. Unfortunately, I constantly had to justify my actions and decisions to other colleagues. Paying attention to the well-being of my employees, I witnessed severe difficulties to handle family emergencies due to institutional restrictions, mental breakdowns due to stress and even harrassment in the work place. There was no system in place to help me handle these situations and when I tried to talk about this to other professors they always defended the status quo of academia. The only people who shared my point of view were younger and not in influential positions. Most of them were afraid to drive a change because they feared that this would affect their career prospects. In the end it felt too hard to deal with this on my own.

I truly loved physics and my research topic. I never wanted to do anything else and I am sure I would still be there if the environment had been different.

I decided to leave when I got offered a challenging role in a tech startup that tries to truly make a change, not only in its industry but in all of society. (Since some people asked me on FB: you can see what I do now on http://www.ceretai.com) My new team has a mission, we care for each other and for society as a whole. We reflect on our well-being at work on an every-day basis. And, in case your followers are wondering, we get things done without unhealthy pressure and are pioneering a new business area within artificial intelligence.

All the best,

Angnis

20. **Peter Woit**
June 18, 2020

Angnis,
Thanks for your comments. Good luck with the new career path!

My own experience with the work environment for young theorists is from long ago and far away from that of Angnis, but maybe things are not that different now. What struck me most about the environment was not any pressure from senior people, but their general lack of any interest in the lives or activities of their younger colleagues. My impression was that for most senior people, having a lot of grad students and postdocs around was important in order to have a viable research operation going and they had generalized goodwill towards them, but the fact of the matter was that these were people who weren't going to be around the field for long, so not worth paying much attention to. This was very different than the attitude in experiments, where the young were the ones getting the work done, so close attention to them needed to be paid.

21. **Peter Woit**
June 18, 2020

Edward M. Measure,
The reason nothing has changed in 40 years is that no one is going to fund a large increase in the number of permanent positions, so the only way to get to a healthier ratio of young theorists to permanent jobs would be to reduce the number of postdocs and grad students. No theory group wants to reduce the size of its grad student population: for one thing, if the did they university would likely cut permanent positions for theorists. There is a good case to be made for moving resources from postdoc positions to longer-term ones, I've never understood why that possibility hasn't gotten more consideration.

Non-academic job opportunities are pretty good now, but it's always been the case that theorists could generally find such work. I think a lot of senior people in the field take the attitude that it's fine to train lots of young people to do HEP theory, even though there are no jobs for them, because they can find other work. To the extent young people enter the field with the attitude "I know this won't lead to a permanent career, but I'll enjoy learning about his and working on it for a few years", that wouldn't be so unhealthy, but that mostly is not what is going on.

22. **Dmitrii**
June 18, 2020

Peter,

I know corona-virus is a once-in-a-lifetime event, but this year conveys an absolutely horrible impression for the job market situation in Math too.

My advisor told me early on that there would be a hiring freeze for 20-21 applications, so no postdocs for me (and he was right!). He suggested that I might consider deferring till 21-22, but he expects a surge in job market candidates during that year (precisely because of those people who decide to defer).

It is hard to tell at this point, but I expect that the effect of the pandemic on the financing of STEM-fields will be felt for a long-long time, so the market will further squeeze.

23. **Peter Woit**
June 18, 2020

Dimitrii,
You're quite right, the COVID disaster has caused a huge problem for grad students and postdocs who need to go on the job market, in math, physics and most fields. Columbia, like many places, has a hiring freeze in place. I know there is some effort, here and elsewhere, to extend funding for some graduate students because of the situation. This would be an excellent time for foundations like the Simons Foundation to step up and provide funding for students and postdocs who are victims of bad timing.

It's also true that the future is highly uncertain, with the long-term effects of this on university finances and hiring worrisome. Good luck and much sympathy to you and others facing this.

24. **Dmitrii**
June 18, 2020

Peter,

Thank you for the kind words.

Let me mention one more thing with regards to your claims about the relatively healthy situation in math compared to HEP: I heard from multiple senior people that to get a tenure-track from an R1 university a postdoc needs to be publishing about 1 paper every 6 month (of course, this is just an average not taking into account the quality of the paper, which might vary drastically). Given my level of talent, that would likely force me to spend my postdoc years on relatively shallow projects. Such incentives certainly lead to a deterioration of the field, much along the lines of what you describe about HEP.

One some level that is fair that only the most-talented (who can publish big results in a relatively short span of time) stay in the academia. On the other hand, I recall that Peter Higgs said in his interview that he wouldn't have done what he had done in the current publish or perish atmosphere.

I obviously do not have any solutions to offer, I am just sharing my frustration. It makes me sad that I will most likely have to abandon my dream of working as a scientist in favor of a less-stressful and more fulfilling job. It is not even the issue that theorists can get much higher salary in tech, as I am sure most academics do not work on their craft for the money. It is indeed the constant feeling that there is an impenetrable barrier between a young scientist and a tenured faculty member and that they control your fate to a ridiculously high degree (with a wide variety of malpractices coming with this control, such as nepotism, cronyism, discrimination, etc.).

Somebody made a remark above that probably one cannot work in science under such amounts of stress. I have certainly experienced that during this year, where my health (both mental and physical) just started giving up from the increased teaching load because of classes moving on-line, news about the job market, news about the plans of bringing back on-line teaching in the fall, your mentors worrying about their own problems and a general feeling of helplessness. I don't know for sure, but I suspect these problems do not manifest themselves to the same degree in other jobs available to people with such level of skill and education.

25. **David Roberts**
June 18, 2020

On the note of a hiring freeze, my department (mathematics, covering pure/applied/stats) was advertising positions that were empty when the university implemented a blanket hiring freeze. We have permanent people retiring/moving on this year, and we still can't fill *their* positions, even though it's cost-neutral (or even will save money). We are cutting subjects we would normally teach to even just maintain a sensible workload. Hiring ECRs is a looong way down the list.

26. **Peter Woit**
June 18, 2020

(All: after some Googling, I figured out that the "ECR" David Roberts is referring to is an "Early Career Researcher").

Dmitrii,
My comments about math being in better shape than physics shouldn't be taken as implying that the situation of academic jobs for young math researchers is an easy one, just that the situation in theoretical physics is significantly worse. And, in both fields, even those who end up successfully with a permanent position are put through years of stressful uncertainty and difficult relocations, of a sort those in non-academic positions generally don't have to put up with. Of course this is much worse than normal this year.

In math like in all of academia, hiring can involve a lot of unfairness and not necessarily reward the best work. I should say though that in all my years in the math department at Columbia, I've seen a lot of hiring decisions being made, and almost always felt that they were being made honestly and as fairly as possible. Especially in recent years, this has been very competitive. Like most places, the main in some sense unfair criterion is that people want to hire others working in areas close to their own, doing things they recognize and understand. Within this constraint, I haven't seen much emphasis on counting papers or citations, rather people want to see that a candidate has done some piece of work that impresses them. It is true that everyone's own expertise is limited, so there's a lot of reliance on letters from experts in the candidate's field.

27. **Robert**
June 22, 2020

Of course, I would love it, if people knew well before their 40's birthday what their long term job perspective would be (and for myself it luckily worked out, I have a permanent non-professor position in a strong physics department, so maybe my view is biased).

But that said and as I have already commented on FB, I don't think it's a fair portrait of the post doc years to paint them as only suffering to secure a tenured position. That would be horrible and everybody who perceives it like this should better leave today and find something more rewarding (luckily enough such positions exist for many HEP people). When I was a grad student and later a post-doc, I went to the office not because it was required of me for my career path, but because I enjoyed so much what I was doing! I could do what I liked most and was even paid for it. So I don't think it is a waste of time, even if you leave academia/physics/maths eventually. Even with the slightest quantitative understanding, you should realise that the number of PhD supervised by one professor means that not everybody will end up being a professor if the system is at least somewhat stationary. So that should not be your (only) motivation. You should do it for yourself and while doing it acquire quite a few skills that will also help you later in your non-academic career (which most people do since the jobs they end up in were mostly not available to them right after graduation).

Yes, moving to another country every two years building up a new social environment is really tough (and not well compatible with forming a family for example) but for a few years, it can still be worthwhile as long as you get enough out of it (in the present and not only in a hypothetical future).

28. **Robert**
June 22, 2020

Ah, and what I forgot: Choosing research topics (in plural hopefully) your of course should do what you are really interested in and where you can contribute. But you should be aware that if you mainly focus on niche problems that's quite a bet as you will later need to convince people that are supposed to hire you that what you achieved is interesting (taking into account their own reference frame for "interesting"). I am not saying, don't do it an only follow the stampede, but your results in your area should be well visible from without that area if your peer group in you area is not so big.

29. **theoreticalminimum**
June 22, 2020

Robert,
I see that you are the manager of a masters degree programme (the TMP) in Munich. The TMP website features a page of all those (~300) who have written a thesis in the programme. Maybe you could create a sort of wiki and invite all those who have graduated from the programme to share a brief of their timeline since graduating from the programme, I think this could help those students considering joining the programme have an idea what those who've graduated from it have gone on to do (e.g. TMP 'xx (advisor:) -> PhD (year completed: … ; advisor: … ; institution: …) -> n Postdoc's (institutions) -> etc.). I can see how such a huge database can be helpful to those condering applying to the programme, and later thinking of where they could go after completing the programme.

30. **Robert**
June 25, 2020

theoreticalminimum I agree that this would be something nice to have. Unfortunately, Organization of this program is essentially a one man (me) show and tracking everybody over the years is a considerable amount of work (I try to have a current email address of the alumni and even that is difficult over longer periods of time as those are often tied to institutions and this is what the original post is about; I decided to get my own domain exactly at the point when I started my first postdoc and I had to email everybody in my address book that mail email address was about to change once more from being hosted at my graduate school to my new university). What I can say is that after graduating from this master program (Americans: here in Europe, MSc is really a separate degree before you start your PhD research and not part of grad school or even the drop out of grad school option) almost everybody who intends to do a PhD — the vast majority — finds a good position to do so and the other usually don't because they have found something "better" in industry. On the other end, roughly 10 years after we had the first graduates from our program (we started with 7 students in 2007 who graduated two years later) we start seeing the first ones in permanent or tenure track (type) positions.

HEP News

June 18, 2020
Categories: Experimental HEP News

The CERN Council is meeting today and tomorrow, and should approve the long-awaited 2020 update of the European Strategy for Particle Physics. There will be a live webcast of the open part of the Council meeting on Friday.

My understanding is that the most difficult and contentious decision, that of how and whether to go forward with a new energy frontier collider, has been put off until 2026, when there will be a new update. In the meantime, design work will emphasize studies for the leading contender: a new large circular electron-positron machine. Studies of a linear collider design (CLIC) will continue at a reduced rate. New work will begin on the possibility of a muon collider, as well as other advanced accelerator technologies that might someday be usable.

There will be some move in the direction of the US program, which has abandoned the energy frontier, including more participation in the US and Japanese neutrino programs. A "scientific diversity program", Physics Beyond Colliders, will receive new support. This program will try and come up with new experiments that don't require a new energy frontier machine. For more about it, see this CERN report and this article in Nature.

In other news from CERN, work on the LHC should start resuming this summer, with the ongoing LS2 extended by a few months because of the COVID shutdown, so beams back in the LHC late next summer. There likely will be no significant new data coming from the LHC during 2021. The extended shutdown may provide the time for magnet quench training needed to bring the machine to its design energy of 7 TeV/beam.

Update: The CERN strategy report is here, also see here, here and a press release here. There is press coverage here, here and here.

The headline news is that this backs the FCC plan: a 100km new ring, first run as an electron-positron collider, then as a much higher energy proton-proton collider. There are however a whole bunch of very significant caveats:

- No plan for how to finance this very expensive proposal.
- The press release mentions a construction start timescale of "less than 10 years after the full exploitation of the HL-LHC, which is expected to complete operations in 2038". This is twenty years or so away, a very long time.
- The main near-term goal mentioned is work on designing the magnets needed for the proton-proton machine, to know by 2026 whether a pp machine is feasible. If the design of appropriate magnets with an acceptable cost for the pp machine is not possible, the implication is that there would be no point in building the large ring and ee machine.
- The main competitor to the FCC plan, CLIC, is not at all canceled, but work will continue on it.
- A new project to try and design a muon collider will be funded, with a planned 2026 decision about whether to move forward on a test facility for that. The technology for this still does not exist (muons decay very quickly…) but if such a collider were feasible, it would be much smaller and likely much cheaper than something like the FCC project.

So, those who want to argue one way or another about whether it's a good idea to spend a lot of money on building a new collider should rest assured that the future holds many, many more years in which to conduct such arguments…

Update: I find it very frustrating to see that the online discussion of this is dominated by a pointless argument about whether, as reported, CERN should be going ahead and spending more than \$20 billion or so on a new machine. THEY ARE NOT DOING THIS. What has happened is that, after a lot of work, they have identified the best possible way forward at the energy frontier (the FCC proposal) and decided not to go ahead with it now but to keep studying it and the required technologies. If the cost of this proposal had been a few billion dollars, they likely would have tried to come up with a plan to allocate much of the over billion \$/year CERN budget in future years to the project and start construction. Instead, for the next six years they are allocating .1 – .2% of the CERN budget to further studies of the proposal. Those who have been loudly complaining that this is too expensive a proposal for the HEP community to afford should declare victory, not go to war over this.

Update: The CERN press release has been changed, with "construction" starting within ten years after 2038 changed to "operation" starting within ten years after 2038. This makes more sense, the earlier version seemed absurdly far in the future. My understanding is that the current plan is essentially to put off to 2026 a decision about going ahead with FCC. By 2027 the HL-LHC will be in place, freeing up some money for a new project, possibly the FCC. A 2027 start to FCC construction would allow a start of operations within ten years after the 2038 HL-LHC end date.

Update: Adrian Cho at Science magazine has a report on this that gets it right, headlined European physicists boldly take small step toward 100-kilometer-long atom smasher. It includes the crucial:

> However, CERN Director-General Fabiola Gianotti emphasizes that no commitment has been made to build a new mammoth collider, which could cost $20 billion. "There is no recommendation for the implementation of any project," she says. "This is coming in a few years."

Comments

1. **DB**
   June 19, 2020

   … so we will have many, many more years of Arkani-Hamed spending a lot of time talking about this issue.

2. **Peter Woit**
   June 19, 2020

   DB,
   Arkani-Hamed seems to have turned into a mathematical physicist searching for a replacement for quantum mechanics and GR, so maybe he won't be talking about this so much. He was involved in the Chinese version of this kind of proposal, it may be that will be the one that has some hope of happening in our lifetimes, so attention will move to that. I have no idea what its prospects are.

   On the CERN front though, arguments about this are effectively now moot until 2026, since there's no plan for them to do anything other than to continue to study the possibilities until then.

3. **DB**
   June 19, 2020

   Yes Peter,

Nima has moved over to other things. His ideas about all his "hedrons" seem very interesting, but only time will tell if he's on the right track. No other top theoretical physicist seems to be following that road. So patience is going to be of the utmost importance here.
He was considered to become the director of that Chinese collider, but I'm not sure if that will come to pass either. As you know, the world economy is heading towards a great reset, and I guess that something like that huge collider might well be hanging in the balance at the moment.

And yes, sure. Re the CERN, 2026 is the new date to be paying attention to. The HEP world is moving very slowly, as expected. No surprises there.

4. **vmarko**
June 19, 2020

Any mention of the Chinese collider in the CERN report?

🙂
Marko

5. **Peter Woit**
June 19, 2020

vmarko,
The existence of the CEPC proposal is mentioned, as well as the fact that it's similar to the FCC proposal. Another good reason to put off a decision on FCC to 2026 or so is to see what the Chinese will do. If they go ahead with CEPC, I doubt anyone in Europe will want to try and raise the money for a second similar project.

6. **Gianni**
June 20, 2020

Peter, the quoted report on 'Physics Beyond Colliders' (on arxiv) states on page 7

"more questions than ever remain open."

The report provides exactly three questions: dark matter, dark energy and the baryon-antybaryon asymmetry in the universe.

These three questions are then summed up by stating that there is "exceedingly convincing evidence that there must be Physics Beyond the Standard Model". (All this is on page 7.)

It seems hard to imagine that these three arguments will be sufficient to build a new machine. The arguments are much weaker (but also much more honest!) than they were before the building of the LHC.

We are indeed in an unprecedented situation in high-energy physics: many researchers and possibly little to discover. The situation is extremely difficult to manage, especially for policy makers. I think it is essential to acknowledge this difficulty. There do not seem to be easy solutions. A careful approach, like that of CERN, seems appropriate.

7. **I**
June 20, 2020

One reason to build a collider after the LHC is the massive loss of technical experience and knowledge needed to make one. But it seems plausible that alternative projects listed in the report, and elsewhere, would foster the same expertise. Do you (dis)agree Peter?

8. **Peter Woit**
June 20, 2020

Gianni,
I think the new strategy document does get the main physics case right: the Higgs field remains a central mystery of fundamental physics. The LHC has done a lot to study it, but a Higgs factory able to study it in much greater depth is the logical next step for the field. The problem is whether there's an affordable way to do this, or whether we should just give up, decide that it's not worth it to find out more about this fundamental aspect of reality. I wrote about this in detail here
https://www.math.columbia.edu/~woit/wordpress/?p=10768

The FCC proposal seems to me an honest attempt to lay out what the best way forward is, but the scale and expense of it is highly problematic. The fact that there was no decision to actually move forward on the project, that the decision is being put off for another 6 years, seems to me an acknowledgement of this.

I,
Yes, there's a good case being made that one reason to not completely give up and stop research at the energy frontier is that once you do this, it will be hard to impossible to restart, since all the people with relevant expertise will be gone. Ideally, some smaller scale, less expensive projects can be found to keep the field active. There's clearly a lot of hope in some quarters that for instance a muon collider project will turn out to be feasible. That would use current expertise, while requiring also the development of new technology and solution of new problems.

9. **tulpoeid**
June 21, 2020

"THEY ARE NOT DOING THIS. After a lot of work, they have identified the best possible way forward at the energy frontier and decided not to go ahead with it now."

After reading the press release that's the impression I got. Then, the next day I read some media headlines and articles and was surprised to see that I had completely misunderstood CERN's statement. Eventually the quoted clarification just made me feel better about my wits, and once more totally pessimistic about how science is reported these days. (Can't we get even things like this straight anymore?) (Can it be that the relevant articles were written ahead of time based on rumours and then nobody noticed the difference?)

10. **tulpoeid**
June 21, 2020

Gianni,
this report is for the opposite of "building a new machine". It's a program literally for physics beyond colliders; so the arguments might be differently weighted than for the case for a new collider.

11. **Gianni**

June 21, 2020

Peter,

It seems to me personally that a high price is worth investing for the final theory, and surely 20 000 million. But still I remain worried. The Nature paper you quote, based on the CERN report arxiv.org/abs/1901.09966, presents eleven options for physics beyond the standard model. They also claim that this represents the *phenomenology* of *all possible* extensions to the standard model. The options are based

– on dark photons,

– on light dark matter particles,

– on millicharged particles,

– on Higgs-mixed scalars,

– on heavy neutral leptons,

– on axion-like particles.

Do we really think that there is a chance to find something on these fronts? I must admit that I am sceptical. In my view, the first question to settle is: are we looking everywhere possible? Or more specifically: did the authors miss some option?

12. **Peter Woit**
June 21, 2020

Gianni,
Sorry, tulpoied is right, I missed that you were referring to that "Physics Beyond Colliders" report, which is about non energy frontier possibilities. These are much much cheaper, may make sense to do them even though quite unlikely they'll find something. There may very well be quite a few other such possibilities beyond the ones they mention.

tulpoied,
I think this is somewhat CERN's fault: they emphasized the decision to concentrate on the FCC proposal, hoping I think to generate enthusiasm about it, with the fact that they hadn't actually made the decision to go ahead with this (and had no idea how to pay for it…) deemphasized. The journalists writing articles were likely writing them based on early access to an embargoed version of the press release.

One thing that makes much clearer what is going on is the detailed spending plans in CERN's proposed new medium term budget plan for the next 5-6 years, but I don't think this is a public document right now.

13. **Geoffrey Dixon**
June 21, 2020

Not that my opinion fucking matters, but Gianni's skeptical list of places to search is very telling:
– on dark photons,
– on light dark matter particles,
– on millicharged particles,
– on Higgs-mixed scalars,
– on heavy neutral leptons,
– on axion-like particles.
Every one of these entails shoehorning unimaginative dross into a theoretical architecture to which the mainstream has been addicted for decades – since Dirac and Feynman – and in none of these cases -NONE – should any of these chewing gum fixes succeed to any limited extent – will the community of theorists loudly proclaim: of course, this was inevitable. I know you won't publish this rant, but this is why I'm strongly opposed to building another collider anywhere, whatever technological expertise we may lose in waiting. The lack of imagination behind the proposed endeavor is staggering. Gianni was being far too polite in casting shade on his list of suspect motivations.

14. **Amitabh Lath**
June 21, 2020

If you are not at the energy frontier, you are doing chemistry….not that there is anything wrong with that. That was the advice of an eminent theorist when I was considering different subfields of (experimental) particle physics. He was not wrong. If we don't build the FCC (or CEPC) the field will still do good work, map out the higgs potential, measure the neutrino mixing angles, etc. But it will not be frontier physics.

I do not think $20 billion over a couple of decades is such a big deal, especially when you think about how much will come back into the economy as jobs and taxes. Sabine Hossenfelder has an article in Scientific American arguing against the next collider. The sub heading is: "the money could be better spent researching threats like climate change and emerging viruses" which frankly is the most naive thing I have ever read. Does she really think national and international economies work like that? How much of a bump did non-high-energy fields get when the SSC got cancelled?

15. **Peter Woit**
June 21, 2020

Amit,
I basically agree with you, although I see "mapping out the Higgs potential" (in the sense of measuring Higgs self-interactions) as energy frontier physics, one of the reasons for an FCC-ee and FCC-hh.

I also think the way numbers are being thrown around is problematic. I can't find where the "20 billion euro" number came from. The numbers I have seen are 10 billion dollars for the FCC-ee, another 17 billion for the later FCC-hh. As they have been for the past couple years, people are loudly arguing about numbers in a way completely disconnected from the crucial questions of exactly what those numbers would buy and how they would be raised. The immediate question to me seems to be "can 10 billion dollars be raised to pay for a tunnel + FCC-ee?" Until there's a plan on the table for how to do that, the argument is too disconnected from reality to be worth having.

16. **Niclas**
June 22, 2020

Carlo Rubbia has been arguing strongly for the muon option here in Europe. He says it is very realistic and basically the technology can be worked out. Assuming the

Chinese go the FCC route then a muon factory could be good for CERN with a lot of opportunity for discovery.

17. **Peter Woit**
June 22, 2020

Geoffrey Dixon,
You're making the same mistake I originally did. That list of things to look for that Gianni refers to is from the "Physics Beyond Colliders" report, written by the group looking into possible projects other than a new collider. I agree this is an extremely unlikely and sad list of things to look for, but it's what the future of the field looks like if you don't build a new collider, not a list of what you could look for with a new collider.

18. **Geoffrey Dixon**
June 22, 2020

Feeling less cranky now. I agree that Sabine's suggestion that the money could be more fruitfully spent making the planet able to support more humans is unrealistic. And although I am not immune to the occasional bout of dudgeon regarding trends in high energy physics, as regards its place among all the things humanity gets up to, it is – relatively speaking – an idyllic oasis. A shining city on a hill, as it were … and keeping it shining, and keeping physicists employed in pursuit of some lofty (preferably not misdirected – but even if misdirected) goal … that to me provides some solace, and quiets the inner Thanos. As to Sabine's suggestion, I am reminded of JFK's moon speech ("and do the other things"), and although JFK evidently didn't really care about getting to the moon, it was a good speech, and relevant to this discussion. WTF, build it (or them), for if we do not, we lessen our reason for existing.

19. **Peter Woit**
June 22, 2020

Niclas,

Here's my prediction for the future (assuming no new developments from theory or experiment changing the HEP landscape). In 2026-7 CERN will decide to go ahead with a muon collider test facility. The cost of this will eat up the available funds (100 million or so dollars/year) freed up by the ending of HL-LHC construction expenses. The FCC project will remain a goal for the future, with studies continuing, but no plausible funding plan.

By the way, Alessandro Strumia has a negative piece about the FCC as a guest post here
http://backreaction.blogspot.com/2020/06/guest-post-who-needs-giant-new-collider.html
As he himself points out, he has personal reasons for not being a fan of CERN, so you might want to take that into account when reading him. His point of view I think is not uncommon though among theorists, many of whom have decided they're pretty sure there will be no new physics at FCC-accessible energies.

My advice remains that one should not be paying attention to what theorists think about this, given the sad history of theorists promoting the LHC as a machine that would produce SUSY particles and black holes. They were completely wrong about this, could very well be completely wrong again with the no new physics prejudice. If the experimentalists and machine builders are able to get behind a viable project, that should be supported.

20. **Gianni**
June 22, 2020

Yes, the list from "Physics Beyond Colliders" is indeed for low-energy experiments. I searched for a similarly long report on physics with a new collider, but could not find one. Does anybody know a long report from CERN with arguments in favor of the 100TeV machine or with a list of experiments to be done with it?

21. **Amitabh Lath**
June 23, 2020

Peter, it is not sensible to talk about the cost of a mega project like a new collider as if it were an off-the-shelf item like a new microscope. A lot of the money will come with strings about where it will be spent. A lot of it will be "in kind" esp. manpower and software from developing countries. These should be considered infrastructure and/or stimulus spending.

Let's say the FCC gets power supplies and digitizers from CAEN. This is the Italian/INFN contribution. The understanding is that CAEN will build design and manufacturing facilities in a depressed region in the south. The hope is the technicians and engineers spark a tech boom. The Italian govt. is not simply writing a check.

The effect is even bigger in developing economies, think of Pakistan designing and building the CMS tracker alignment and barrel yoke, or India supplying superconducting corrector magnets and precision positioning jacks for the LHC.

We need large, ambitious, technically difficult projects to strive towards. It keeps us from turning into navel-gazers concerned only about our own conveniences. JFK understood that of course.

22. **Alessandro Strumia**
June 23, 2020

Actually I was not much interested in staying at CERN precisely because high-energy physics, as we knew it, is over. No new physics at LHC and no new collider in the next decades makes big change unavoidable.

23. **Low Math, Meekly Interacting**
June 23, 2020

What I am struck by most is the temporal scale. If the FCC is ever built, a significant fraction of the scientists involved in planning it (and taxpayers paying for the effort) will never live to see it completed. The EU could dissolve in the interim. Western Civilization may be obsolete before its finished. The Great Pyramid of Khufu is a mid-scale capital improvement by comparison.

Increasingly I'm in the sustainability camp. Maybe building a muon collider is not feasible, but it seems like a more worthwhile bet. I want humanity to explore the energy frontier, and I don't need to be persuaded to support it. But my faith in the durability of the institutions needed to see such a project to a fruitful completion has been severely shaken in the past few years. New technology might be the answer.

24. **A reader**
June 23, 2020

To Alessandro Strumia: "because high-energy physics, as we knew it, is over." With all due respect, is yours a scientific statement? Confidence level? Please do not let your personal hate, your personal agenda and your sour grapes help destroy HEP. The same applies to Sabine Hossenfelder. As a humble physicist, and a long term reader of this blog, I completely agree with Peter Woit's view: "If the experimentalists and machine builders are able to get behind a viable project, that should be supported."

25. **Peter Woit**
June 24, 2020

Amit,
It's exactly because the sources of financing for a new collider will be a complicated story that I don't think now is a fruitful time for arguments over that financing. Because people don't have anything specific to argue about, what you end up getting is "we shouldn't build a new collider, no matter how little the cost", and "we should build a new collider, not matter how much it costs" arguments, which seem to me disconnected from reality.

26. **Alessandro Strumia**
June 24, 2020

Dear reader, I would like to see a 100 TeV pp collider, but we reached the point where the usual "positive" view backfires and repels people like Sabine. You worry about people who discuss problems, I worry about problems. For example, do you expect that creative smart young students will enter a field that might produce discoveries with 10K authors when they will be near retirement, unless everything stops earlier?

27. **A reader**
June 25, 2020

Dear Alessandro Strumia, Sabine Hossenfelder is 1 (one) very talkative physicist with access to mainstream media platforms she very much enjoys using to support her personal views. Not all, but some of what she says sounds ideological, absolute views accompanied by (sometimes understandable) rage. I have read Peter Woit's blog for longer than a decade, so I know where that rage comes from and I can understand it. But hers are opinions, and when they are about the future I can't see confidence levels attached to them. I'm not that old, but I am definitely too old to like ideology. I much prefer sane pragmatism.
One of my best teachers, a very good man, old school, he taught us the basics of QFT, his view, I completely agree with, was that EXPERIMENTAL HEP is like an epic endeavour undertaken by an extremely large orchestra. It is astonishing that mankind (mankind!) managed to pull it off (more than once!). Think about the whole history of EXPERIMENTAL HEP. The women and the men whose commitment made all those GIANT achievements possible. I mean, we descend from apes! Much is dysfunctional with HEP THEORY, but why this eagerness to destroy ALL HEP? ALL!?!?
And to reply to your question, yes, I do believe there are still creative smart young students around who are romantic enough to be willing to be part of this epic and dedicate decades of their lives to it. Much of our world is grotesque cynicism and despair. I still remember the intense thrill to be part of a large collaboration at FNAL as a summer trainee, for a very short time, a couple of months, a long time ago, as a 3rd-year undergrad. There was some very special atmosphere there, so special I can still remember it vividly 20 years later, and that "magic" I believe it was that there was some epic going on there. So yes, I do think there are still creative smart young students willing to be part of some epic, in this very ugly time in human history, even if that epic is going to take 40 years of their lives. Just be upfront, state it clearly to them with honesty and without lies.

28. **Alessandro Strumia**
June 25, 2020

Dear reader, FNAL now left the high-energy frontier, because higher energy needs more money until it's no longer sustainable. I remember a similar atmosphere once upon a time in CERN: Soviet-style buildings and first-class physicists. They now got Renzo Piano building, but the epic is over. Buffalo Bill's show is no longer Wild West.

29. **Amitabh Lath**
June 25, 2020

Alessandro Strumia, as Peter concurs above, money is not the issue. The world economy is fully capable of building multiple energy frontier machines. Nor is the interest of young students: every year we get applications from amazing students and can only accept a fraction of them. Of course some turn out to be impatient and want earth-shattering discoveries now dammit! and show no interest in staying. But a core group realize they are part of an epic slog that is generations long.

Think of the bevy of e+e- machines in the 80's that failed to find the top. Were they failures? Of course not. Nature placed her secrets as she wished, not so humanity could make a new discovery every decade.

30. **Gianni**
June 27, 2020

Peter and all,

This is what I found searching. The CERN paper "FCC Physics Opportunities", published in Eur. Phys. J. C 79, 474 (2019), written by hundreds of authors, defines three aims of the FCC: (1) the search for unexpected phenomena around the Higgs and the electroweak gauge bosons, (2) the search for new particles, including dark matter, and (3) the search for "tiny deviations" (they call its this way themselves) from the standard model.

In my opinion, the real question seems to be: will the FCC just confirm the standard model or will it find something new?

We need to be very honest about answering it. Are we reasonably sure that there is something new to be discovered at higher energies? Would we put our hands into fire for our own answer?

31. **Alessandro Strumia**
June 27, 2020

Dear Amitabh, now we are a few years after the LHC peak of interest, and we still have work to do. If nothing new is discovered, the issue I mention will develop in due time.

32. **Peter Woit**
June 27, 2020

Gianni,
This is the heart of the problem: there is no strong theoretical argument for new physics accessible to a new collider, and that's why you are seeing some theorists arguing against building one. The counter-argument is that you do science by testing theoretical arguments, not by just accepting them. An analogy some people are making is that, pre-1998 and to this day, there was and is no good theoretical argument for a non-zero CC. So, why go look for one?

What makes the collider issue difficult is the high cost. If looking for a non-zero CC cost over ten billion dollars, I bet it would never have been done. I don't think it makes sense to decide not to build a collider just because theorists don't expect it to find something new. Deciding not to build such a thing will be a decision to give up on this fundamental field of science with a long and distinguished history, because it's not worth the expense to test the theory at this new higher energy scale. This is a question of values and I come down on the side of those who think it's worth the likely expense. I also though think this debate over values is a sterile one until there's a definite plan for how to pay for this on the table.

33. **Paolo**
June 27, 2020

From the ITER & SSC lesson, 10 years -> 20 years and \$ 20 billions -> \$ 40 billions; some peoples do live in alternative reality.

34. **Peter Woit**
June 27, 2020

Paolo,
My impression is that CERN has a fairly good track record for completing large projects at more or less the projected time and cost. In any case, even in your bad case scenario, the fundamental problem "where are you going to find 2 billion/year?" doesn't change, just goes on for more years…

35. **Peter Shor**
July 3, 2020

Delaying the decision is clearly the correct decision. Suppose that in the next ten years, evidence emerges for interesting new physics somewhere in the neutrino sector, which could only be investigated with some kind of $5 billion neutrino factory (this is, of course, wild speculation). Then if CERN had already committed to the FCC, the neutrino factory would likely end up being built elsewhere, and CERN would be spending tens of billions to be in the rearguard of new discoveries in HEP physics.

36. **LK2**
July 8, 2020

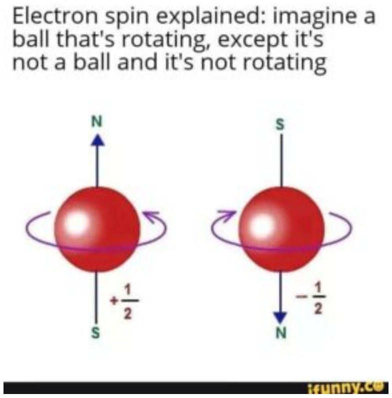
I was hit by the "reader" comment about the magical atmosphere at FNAL at the Tevatron times. It was really true and I also lived that as a student. There you had the feeling that something was really going on. As a person who stayed in exp. particle physics, I see this feeling completely lost in gigantic collaborations, endless meetings, true work done only by students while the others are sitting in meetings discussing budgets, schedules, reports. That's the way it is now, fine: I just decided to work on smaller scale experiments for having more fun. I still would love to see a new energy frontier project launched in the future: as physicists, we have to chart uncharted territory. What P. Shor says is also very relevant: better carefully look at the direction before committing. The muon collider option at least would be a big novelty also from the technological point of view. And handling dense muon beams can be useful also for a neutrino program!

What is “Spin”?

July 23, 2020
Categories: Uncategorized

The explanation for the lack of blogging here the past month is mostly that I haven’t seen any news worth blogging about. It took only a little bit of self-control to not do things like make snarky comments about recent conferences on string theory and quantum gravity.

Today I noticed a discussion on Twitter of the perennial question about what “spin” means in quantum theory, with some of the tweets included this highly appropriate meme:



I thought it might be worth while to make a stab at explaining what “spin” really is. For a much more detailed version, I wrote a book. But this post is much shorter…

Picking a particular point and a particular direction (say the z-direction), the angular momentum J_z is defined to be the “generator” of rotations about that point, around the z-axis. This means that when you do such a rotation by an angle θ, for any observable (function of position and momentum) F
$$\frac{dF}{d\theta}|_{\theta=0}=\{F, J_z\}$$
where the bracket is the Poisson bracket. A short calculation shows
$$J_z=r_xp_y-r_yp_x$$
which is often given as the definition. J_z is itself an observable, which you can say is the angular momentum about the z-axis of a point particle with x,y coordinates of its position and momentum given by r_x,r_y,p_x,p_y. In classical physics J_z can take on any values.

In quantum mechanics, observables are operators acting on states, and J_z becomes the operator $\widehat{J}_z$ which (with an additional factor of $-i$ to get unitary transformations) generates rotations on states. This means (using units such that $\hbar=1$)
$$\frac{d}{d\theta}\ket{\psi(\theta)}=-i\widehat J_z \ket{\psi(\theta)}$$
You can solve this differential equation and see that if you rotate a state by an angle θ about the z axis, you get
$$\ket{\psi(\theta)}=e^{-i{\widehat J}_z\theta}\ket{\psi(0)}$$
States that are eigenvectors of ${\widehat J}_z$ are supposed to be the ones with a well-defined value of the classical observable J_z, given by the eigenvalue.

One finds experimentally that the observed values of J_z are given by
$$\frac{n}{2}$$
Unlike the classical case, as expected this number is quantized (that’s why they call it quantum mechanics…), but the factor of 2 is unexpected. Since a rotation by 2π should bring the state back to itself, one expects that
$$e^{-iJ_z2\pi}=1$$
so J_z should be an integer. If one finds a state with $J_z=\frac{1}{2}$, rotating it by an angle 2π changes its sign. This is weird, but the sign of a state isn’t itself something you can measure.

Looking more closely at the operator $\widehat{J}_z$ for quantum systems, one finds that for some states it has exactly the same relation to position and momentum as in classical physics
$$\widehat{J}_z=\widehat{r}_x\widehat{p}_y-\widehat{r}_y\widehat{p}_x$$
When states are given by a wavefunction depending on spatial coordinates, one can show that this is just the expected action by infinitesimal rotation of the spatial coordinates. In this case rotation by 2π doesn’t change the state, and J_z has integral (not half-integral) values.

For many quantum systems though, there is an extra term:
$$\widehat{J}_z=\widehat{r}_x\widehat{p}_y-\widehat{r}_y\widehat{p}_x+\widehat{S}_z$$
and it is this extra term $\widehat {S}_z$ that is the “spin” observable. When states are given by wavefunctions, what the equation above is telling you is that when you act on a state by a rotation, you get not just the expected induced action from the rotation on spatial coordinates, but also an extra term. A natural guess is that, as in the meme, a point particle is really a ball of some new stuff, with $\widehat {S}_z$ the effective extra term caused by the positions and momenta of the new stuff.

For an elementary particle such as an electron, experimentally one finds that $\widehat S_z$ has eigenvalues $\pm 1/2$, which explains why one sees half-integral quantization. As the meme says, there is no viable physical model of rotating stuff that would give this result. Something very different is going on.

So far I’ve stuck to talking about rotations about the z-axis, but one also should consider rotations about other axes. The problem is that more sophisticated mathematics is needed, since the generators of rotations around different axes don’t commute (doing the rotations in the opposite order gives a different result). The mathematics needed is that of the representation theory of the rotation group $SO(3)$ and its double-cover $SU(2)$. From this representation theory one learns that the only consistent possibilities are given by putting together copies of a “spin n/2” representation for $n=0,1,2,\cdots$. These are $n+1$-dimensional vector spaces, on which $\widehat{S}_z$ acts with eigenvalues
$$\frac{-n}{2}, \frac{-n +2}{2},\cdots,\frac{n-2}{2},\frac{n}{2}$$
The case $n=0$ is that of $\widehat{S}_z=0$, and the simplest non-trivial case is the $n=1$ case which gives $\widehat{S}_z$ for the electron.

So, the “spin 1/2” characteristic of the electron is something completely new, unrelated to anything in classical mechanics. If you describe the electron by a wavefunction, it will take values not in the complex numbers, but in pairs of complex numbers, with rotations acting on the pairs by the spin-1/2 representation (also known as the “spinor” representation). Besides the non-classical physical behavior, the geometry is also non-classical, with the spinor representation something that cannot be described by the usual formalism of vectors and tensors.

Another reason I haven’t been writing much on the blog this past month is that I’ve been working on writing up something about twistors. I’ll write about twistors in detail here when this is done, but one thing they do is give a picture of space-time geometry in which spinors are fundamental, not vectors. A fundamental idea of twistor theory is that a point in space-time is a complex two-plane inside complex four-space. In twistor theory the answer to the question of where the spinor degree of freedom at a point comes from is tautological: the two complex dimensional spinor degree of freedom at a point IS the point.

Bonus link for those who have gotten this far. A presentation by CERN director Fabiola Gianotti, which comes off a bit differently than news reports saying CERN is going ahead with FCC. On page 5

- Strategy gives a direction for future collider(s) at CERN (FCC). Prudent: feasibility study first.
- Intensified accelerator R&D to prepare alternatives if FCC feasibility study fails.
- No consensus in European community on which type of Higgs factory(linear or circular).

Page 9 lists three "first priorities" for the feasibility study:

- find funds for the tunnel
- no show-stoppers for ~100 km tunnel in Geneva region
- magnet technology ; how to minimise environmental impact

Comments

1. **Prof. David A. Edwards**
July 23, 2020

In order to help motivate my calculus students I often show how calculus can be used in sports; this actually often works. In particular, I often describe the motion of a curve ball in baseball. The configuration space of a baseball is R^3xSO(3) and its associated phase space is T*(R^3xSO(3)) (the cotangent bundle of R^3xSO(3)). SO(3) is too complicated to describe to Freshman. So, instead, I use a simpler, though adequate, model of a baseball as a point particle with extra spin angular momentum. Now the phase space is T*(R^3)xS^2. The dynamical equations can now be set up and numerically solved and graphed on a graphing calculator. One can then watch the ball curve! The phase space (S^2,v) (use the canonical area 2-form v obtained by thinking of S^2 as the standard unit sphere in R^3) is not the cotangent bundle of any configuration space. For any s in R+, T*(R^3)x(S^2, s*v) provides a classical phase space of a point particle of spin s. Using Geometric Quantization (see: http://www.amazon.com/Geometric-Quantization-Oxford-Mathematical-Monographs/dp/0198502702/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1219711387&sr=8-1), one can quantize this phase space for s satisfying appropriate integrality conditions and obtain the usual quantum theory of spinning particles. For all s one can deformation quantize (see: http://www.amazon.com/Deformation-Quantization-Mathematicians-Mathematiques-Irma-Lecture/dp/311017247X/ref=sr_1_1?ie=UTF8&s=books&qid=1219711918&sr=1-1
) this phase space and get something that is probably also interesting!

Thus, Pauli was wrong! There are reasonable classical limits of spinning point particles.

July 24, 2020

Hi Peter,
listening to David Gross giving the final lecture on Strings 2020, it seems clear that he has surrendered to the fact that there are certain parameters that might not be calculable, and that they are just an "accident". He might have come to the conclusion that his "never, never, never, never surrender" idea is wrong, and that things are tilting towards the anthropic principle/landscape idea. It might be worth of a comment… snarky or not.

And Witten's answer to Vafa on the 40th and 41st minute on the latter's talk re the completeness hypothesis might be willing of another comment too.

I think both comments seem to point in the same direction, that things are getting pretty murky when it comes to try and find a unique theory of the vacuum that describes our world.

3. **Arnold Neumaier**
July 24, 2020

"the "spin 1/2" characteristic of the electron is something completely new, unrelated to anything in classical mechanics"

Spin is not as quantum mechanical as you make it appear here. Indeed, the coadjoined orbits of the Poincare group provide phase spaces (Poisson manifolds) for classical particles with spin – for positive mass a 2-parameter family parameterized by mass m and continuous spin s. Upon quantization, the coadjoined orbits turn into irreducible unitary representations, and the spin gets quantized in the same way as angular momentum gets quantized when quantizing its representation on the sphere. Nothing more than geometric quantization is involved.

4. **Peter Woit**
July 24, 2020

David Edwards/Arnold Neumaier,
I'm a big fan of geometric quantization, but
1. It's not the best way to understand the spinor degree of freedom.
2. The relation to classical physics is in the limit of large spin, with spin 1/2 the opposite limit, maximally non-classical.

5. **Peter Woit**
July 24, 2020

DB,
To be blunt, I think the current situation with relating string theory to the real world is that most string theorists have simply given up. About the only active area in string theory that even tries is the Swampland business, which hardly anyone takes seriously. Given this situation, there's no longer any science here worth trying to have a serious discussion about, all that remains is the sad sociological question of why people are still promoting string theory as our best hope for a unified theory. But, that's also a tired subject, which I don't want to encourage here unless someone actually has something new to say about this.

6. **John Goldman**
July 24, 2020

Dear Peter,

Thank you for the clear explanation of spin 1/2 behaviour.

Whilst you are considering the twistor geometric implications could you please put your mind to what additional extension is needed to give rise to the 3 neutrino types?
Could a point in space-time be more than a complex 2-plane?
How about a 3-sphere?

7. **Manuel del Río Rodríguez**
July 24, 2020

Dear professor:

My name is Manuel del Rio and I am an avid and enthusiastic follower of your blog and your work. Good to have you back, even if nothing of late tickled your fancy! As you mention your book: it is in my top 5 of books I really want to be able to read in the future (right now, it is hopelessly out of my range; I am a Humanities person and English teacher for adults here in Spain, and have just started an online math degree which will have to progress very slowly -work and son must take priority-).

Even though it will probably have to wait a decade to be read, I will be buying it in the next months. Are you planning a second edition any time soon (incorporating the errata you mention in your page?)? If that were the case, I would wait for the purchase until it is out.

Best greetings

Manuel

8. **Chris Austin**
July 25, 2020

Perhaps the following historical question might be on topic for this post.

-i times the Pauli matrices gives a representation of Hamilton's quaternions. After struggling for a long time to find a generalization of the complex numbers, Sir William Rowan Hamilton suddenly thought of quaternions during a walk in 1843, and he famously scratched his inspiration on a bridge near Dublin. I had assumed that what he scratched on the bridge was something like -i times the Pauli matrices, but in fact what he wrote was $i^2 = j^2 = k^2 = i j k = -1$.

It would be nice to think that Hamilton discovered something like the Pauli matrices 177 years ago. But on skimming through nineteenth century textbooks on quaternions, such as those available on gutenberg.org, no trace of a 2-dimensional representation of the quaternions, or any matrix representation of the quaternions, ever seems to show up.

Élie Cartan constructed the spinor representations of the orthogonal groups in his 1913 paper that constructed, in the sense of their weight spaces, all the irreducible linear representations of the simple compact Lie algebras, (Bulletin de la S. M. F., tome 41 (1913), p. 53-96). The results for the Lie algebras of type B_l, i.e. SO(2l+1), are in section VI, starting on page 69. The weights for the spin representation of B_l are on page 70. An actual matrix form of the spin representation of B_l might be given implicitly in section XV, on page 86. For $l=1$, it looks as though X_1 there might be $(1/2)(\sigma_1 + i \sigma_2)$, X_{-1} might be $(1/2)(\sigma_1 – i \sigma_2)$, and Y_1 might be σ_3. But there does not seem to be any special discussion of the case $l=1$, or its relation to quaternions.

So for practical purposes, was the 2-dimensional representation of Hamilton's quaternions actually unknown, until Pauli presented the Pauli matrices, in his paper "Zur Quantenmechanik des magnetischen Elektrons," Zeitschrift für Physik, 43, 601–623, 1927?

9. **Peter Woit**
July 26, 2020

John Goldman,
Unfortunately at this point I don't know of a way to get generations out of twistor geometry.

10. **Peter Woit**
July 26, 2020

Manuel del Rio Rodriguez,
I'll be writing more about this here in coming months, but this year I'm teaching again the year-long course the book was based on. While doing this I'd like to revise and expand parts of the book, as well as make more minor improvements. I don't think there will be big changes in the first part of the book during the fall semester, but I hope to make major changes in the second half, when I'm teaching in the spring semester.

11. **Geoffrey Dixon**
July 26, 2020

Chris Austin, your comment intimates that Hamilton fell short in not achieving Pauli, when in fact the opposite is true. Pauli spinors are 2×1 complex matrices. The Pauli algebra, C(2), is isomorphic to the complexified quaternion algebra, the spinors of which are SU(2) doublets of Pauli spinors … so, had Pauli allowed Hamilton to inspire his work we may have had electro-weak U(1)xSU(2) theory a couple decades earlier than we did.

12. **Peter Woit**
July 26, 2020

Chris Austin/Geoffrey Dixon,
The fact that the complexification of the quaternion algebra over the reals is the algebra of two by two complex matrices is something I'm sure Hamilton (and other algebraists later on) knew. But I think he was interested in quaternions as a remarkable real algebra, so not much interested in its obvious complex representations.

My own point of view is that physicists have a big blind spot in that they are used to just throwing in complex coefficients whenever convenient, so always work in a complexification and are blind to the fact that there may be multiple real forms of whatever algebra they're working with. See my "two pet peeves" posting

https://www.math.columbia.edu/~woit/wordpress/?p=9222

I do think that removing this blind spot may help in better understanding the structure of fundamental physics, but there will be a lot, lot more needed to do this than keeping straight this simple example.

13. **Doug McDonald**
July 27, 2020

Speaking of lack of blogging, a couple of questions. Recently talk of the seriously suspect (bottom bins are even more suspect!) Xenon-axions experiment stuff is going around.

But we are supposed to be hearing from reliable, likely real, important (positive or negative, clarifying or muddying), results on neutrinos from several places, and muon g-2 experiments from Fermibab. We heard a bit on muon theory, very muddying.

Yet I see nothing blogged. Are there rumors or better? Even rumors of being bogged down whether for technical, analysis, or virus reasons?

14. **Peter Woit**
July 27, 2020

    Doug McDonald,
    Sorry, but while I would love there to be some exciting experimental HEP news (or even a good rumor) to blog about, I haven't heard any recently. Likely the COVID lockdown has impacted constructing and operating experiments, but people should still be able to analyze pre-COVID data from home…

15. **Edward M Measure**
July 27, 2020

    You had me at non-spinning, non-sphere, but is the bottom line that despite the non-classical behavior of the wave function, it otherwise acts just like additional angular momentum?

16. **Peter Woit**
July 27, 2020

    Edward M. Measure,
    To try and clarify the bottom line, yes, if you define
    "angular momentum = observable that generates rotations"
    Then, angular momentum can have two different sources
    1. Effect of rotating $\vec{x}$ in $\Psi (\vec{x})$. This is the angular momentum you are used to, cause by "stuff moving around", it's "orbital angular momentum", formula $$\vec{L}=\vec{x}\times \vec{p}$$
    in its classical and quantum versions.
    2. Ψ may take values in a vector space on which rotations act non-trivially. Then when you rotate a wave function, you get a second contribution from this, the "spin angular momentum". In the case of spin-half, Ψ takes values in $\mathbf C^2$, the spinors, and rotations act on the spinors (in a new way unlike the normal action of rotation on vectors and tensors, including the fact that it is a double-cover of the rotation group that acts, the usual rotations act only up to minus-sign problems).

17. **Babak**
July 27, 2020

    Hi Peter,

    I enjoyed your post.

    I'm just curious to know what do you think about the recent conference at the Perimeter Institute?

    Thanks.

18. **Peter Woit**
July 27, 2020

    Babak,
    I don't want to start a discussion of quantum gravity here. For one thing, I don't think there is anything new to say, and this has been true for quite a while. If you want an overview of the state of the subject I'd recommend looking at Nicolai's talk. It seemed to me rather discouraging, with nothing like a promising new idea. The current philosophy that appears to be dominant is that quantum gravity is "emergent". But Nicolai asks the right question: emergent from WHAT? And that's a question with no good answer. He asks for experimental evidence to help with the situation, but gives no reason to believe such evidence will ever be available.

19. **Cleon Teunissen**
July 28, 2020

    Peter woit,
    you write about an entity that is represented in spinor form:

    "If one finds a state with J_z = 1/2, rotating it by an angle 2*pi changes its sign. This is weird, but the sign of a state isn't itself something you can measure."

    I think among the sources I've read you are the first one to write _explicitly_: "the sign of a state isn't itself something you can measure".

    (Many sources state the following about entities represented in spinor form: "In order to return this object to the same state you have to turn it through 720 degrees." without mentioning whether that is _observable_.)

    I assume the spinor representation offers the most economical way (in mathematical sense) to reproduce the observed atomic spectrum energy levels.

    Let me make a comparison: in electronic engineering it is common to move the mathematical representation to complex number space, so that the equations are not in the form of sines and cosines, but exponential functions, allowing much more efficient manipulation of occurences of phase shift. It's a trade-off, you introduce imaginary voltage and imaginary current, and you get more efficient manipulation, but at the end of the computation you have to convert back to observables: measured voltage and measured current

    Is it possible at all to interpret the spinor representation in a similar way? That is, that it is an economical representation, but at the expense of introducing an _unobservable_ property ("a state with J_z = 1/2, rotating it by an angle 2*pi changes its sign")

    The Einstein-De Haas effect
    As is well known, the Einstein-De Haas effect drives home the point: if you manipulate the spin angular momentum of a sufficiently large population you can obtain exchange of a macroscopic amount of angular momentum.
    https://www.youtube.com/watch?v=qFkW0PHhXcY

    That is: I think it's worth emphasizing:
    quantummechanical spin angular momentum doesn't have a classical counterpart, but not in the sense that it only exists in some confined environment. Exchange with macroscopic objects can be elicited.

20. **Robert Wilson**
July 29, 2020

Chris Austin/Geoffrey Dixon/Peter Woit,
I agree that using quaternions rather than Pauli matrices makes the concept of spin understandable in a more elegant way. “Throwing in” complex numbers does obscure some of the issues. But there is more than one way of throwing in complex numbers. From quaternions/SU(2) one can either go the Pauli route, and end up with SL(2,C), or the Glashow-Weinberg-Salam route, and end up with U(2), often erroneously described as U(1) x SU(2). More clarity on the difference between these methods of throwing in complex numbers, and the underlying reasons for them, would certainly help me to understand what is going on.

21. **Hermann Nicolai**
July 29, 2020

Dear Peter,

thank you for advertizing my talk at QG2020. It was, however, not meant to be discouraging at all! It is just that (as my father, a medical doctor, used to say) “diagnosis must precede therapy”. And part of the diagnosis is that low energy SUSY is clinically dead, that the multiverse program is unlikely to get anywhere, and (for the “non-string approaches”) that explaining this or that particular feature of (say) the CMB is by far not enough, especially if you cannot clearly discriminate your explanation from other competing ones (after all, it might just be dust…). Last but not least divergences between different approaches are still so substantial that hope for a “grand syntesis” is far away. So the PI people did a great job in bringing together all these viewpoints and making the proponents talk to one another, and from that point of view the conference was a great success.

In the end it will only work if everything fits together, and a key element of this is explaining how the standard model (as is!) can emerge from a Planck scale theory. On this we have some ideas of our own (see my last two slides), but I did not want to overly emphasize this as (1) we might well be wrong, and (2) it is not the main purpose of an overview talk to push one’s own pet ideas.

Best regards,

Hermann

22. **martibal**
July 29, 2020

Regarding the explanation of why the standard model is as it is, I noticed than neither in the opening talk by Nicolai nor the closing one by Jacobson there is any mention of Connes and al approach to the SM using noncommutative geometry, although there have been various developments in the last years.

This might well be because this is not a theory of quantum gravity, and so it was not strictly in the scope of the conference. However this is a bit surprising because there are some people working on that topic at PI.
Is this approach to the SM so much “out of the radar” for physicist ? (I am asking without polemical intention, I am genuinely interested in understanding why it seems so much ignored ?).

23. **Peter Woit**
July 29, 2020

Cleon Teunissen,
The comment that the minus sign for spin causes no immediate problem because it is a sign of a wave-function, not of an observable certainly isn’t original to me. Discussing this gets into the interpretational issue of the physical significance of the wave-function, which is a discussion I very much don’t want to start again here.

On the analogy to solving real-valued problems with complex numbers: what’s going on there essentially is that, given a problem with a real-valued solution, you can ask for complex solutions, allowing use of the properties of complex numbers, making finding solutions easier. If you find a complex solution, you have found two solutions to your original problem (the real and imaginary parts), although one may be zero.

What’s happening with spinors is different. There is a serious question about whether it’s best to describe them in terms of real numbers, complex numbers, or quaternions, but the underlying fact is that there is a new and different spin-1/2 degree of freedom, which is undeniably there. It’s not something you are introducing just for calculational convenience.

24. **Peter Woit**
July 29, 2020

martibal and all,
I’m glad to have pointed those interested to Nicolai’s interesting review, and happy that he added comments here, but, as usual, I don’t want to start here an open-ended discussion of the state of speculative ideas, whether about non-commutative geometry or anything else.

25. **Peter Orland**
July 30, 2020

I expect you already know this, Peter, but there is also a classical version of spin-1/2. It’s a little subtler than integer angular momentum, but works just as well. This a charge on a sphere in the presence of a static monopole. This yields a Wess-Zumino action for the unit vector (or element of S^2), and upon quantization, this vector’s components become the Pauli matrices. A more general model (due to Tamm) is a charge anywhere in R^3, in the presence of a static monopole at the origin (which has wave functions which change sign under a rotation).

There is even a nice relativistic generalization. This is a slightly more complicated Wess-Zumino term, depending on two unit vectors in R^4, one of which is parallel to the four velocity, and the other which is orthogonal to the first (so the configuration space is $S^3\times S^3/U(1)$. This gives Dirac fermions after quantization (in Euclidean space. To get to Minkowski space, the S^3’s must be replaced by hyperboloids). One vector is the velocity divided by its norm. When quantized, this vector’s components become the Dirac gamma matrices. The other unit vector’s components become the rho matrices.

26. **Peter Woit**
July 30, 2020

Thanks Peter,
That’s a interesting physical variant of the general idea of taking S^2 as phase space and quantizing, but using the monopole to give the quantization line bundle.

I realized there’s another way to think of this, to argue that the spin-1/2 degree of freedom is what you get when you look not at classical mechanics, but at pseudo-classical mechanics (your phase space variables are anti-commuting) in the simplest non-trivial (d=3) case. I wrote up the details of this in chapter 30 and 31 of the book on QM (http://www.math.columbia.edu/~woit/QMbook/qmbook.pdf).

27. **Chris Regan**
August 7, 2020

Hi Peter,

Are you sure that geometric quantization isn't the best way to understand the spinor degree of freedom? It seems like a good way to go, based on a lower-dimensional example. Quantize space with a honeycomb lattice, and spin 1/2 pops right out. See this paper in Physical Review Letters: https://arxiv.org/abs/1003.3715.

28. **Peter Woit**
August 7, 2020

Chris Regan,
There are lots of ways to get a spinor degree of freedom out of a much more complicated structure. But spinors are really an extremely simple story about two by two matrices. What I'd like to advertise is this simplicity. If you want the simplest possible way to explain where spinors come from, twistor geometry is very compelling, giving spinors tautologically (a point in space time is exactly the spinor space).

Yesterday's Hype

August 1, 2020
Categories: This Week's Hype

Every summer CERN runs a summer student programme, designed to bring in a group of students to participate in scientific activities at CERN and provide lectures for them about the basics and latest state of the field of high energy physics. Because of the COVID situation, this summer they have not been able to bring students in, but are providing instructional lectures and Q and A's. This year's sessions are based on having students follow materials from last year's lectures, followed by a Q and A to answer their questions.

One of the topics the students are presented is What is String Theory?, and you can watch the 2019 video or look at the slides. Timo Weigand's presentation can be accurately described as pure, unadulterated hype, with not a hint of the existence of any significant problem with ideas presented. In the Q and A yesterday, Weigand did come up with a new piece of "evidence for string theory": it "predicts" no continuous spin representations.

I can't begin to understand why anyone thinks it's all right for CERN to subject impressionable students to this kind of thing. Someone, not me, should be complaining to the organizers and to CERN management.

This is unfortunately now an all too common example of what passes for "Sci Comm" in much of the field of fundamental physics: endless repetition of old discredited arguments in favor of a failed theory, coupled with pretending not to know about what is wrong with these arguments. The field that was once one of the greatest examples of the power of the human mind and the strength of the scientific method has become something very different and quite dangerous: all-too-visible ammunition for those who want to make the case that scientists are as deluded and tribalistic as anyone else, so not to be trusted.

Comments

1. **Gianni**
   August 1, 2020

   When I was a summer student at CERN in the 1980s, the lectures for the students were completely professional. This year, Weigand's last slide, with his summary, states: "String theory is a maximally economic quantum theory of gravity, gauge interactions and matter." A theory that adds 7 spatial dimensions and adds supersymmetry seems to give the impression that maybe it might just not be maximally economic. Weigand also writes on the same slide: "Assumption of stringlike nature of particles leads to calculable theory without UV divergences." What a pity that he had no time to explain the way to calculate elementary particle masses and coupling constants in this calculable theory. Possibly the margin on the slides was too narrow to write the calculation down?

2. **Peter Woit**
   August 1, 2020

   Gianni,
   The "maximally economic" description also struck me. It's kind of like listening to our current President: hard to figure out whether the no-relation-to-reality claims you're hearing are intentionally dishonest or just delusional.

3. **Sabine Hossenfelder**
   August 2, 2020

   Students aren't remotely as impressionable as you seem to think. Indeed, the most encouraging feedback I have gotten after the publication of my book came from students complaining that they are being taught useless nonsense. The kids, I think, will be alright. Trouble is, if we wait for them to grow up, we'll see 20 more years of time wasted on failed theories.

   This is why I think the key factor to change is public pressure. The hurdle here is that few people feel qualified to comment on what is going on in the foundations of physics. So, science communication (like you do) matters a big deal by explaining to non-experts just what is happening, why it's a problem, and why they need to call bullshit on it.

4. **Alessandro Strumia**
   August 2, 2020

   I heard various misunderstandings while playing soccer with summer students. The most bizarre, around 2015, was their firm belief that CERN had planned LHC run1 for discovering the Higgs, and LHC run2 for discovering SUSY/new physics.

5. **Peter Woit**
   August 2, 2020

   Sabine Hossenfelder,
   It's not that I think most students believe this kind of hype, although I think it does have some effect of encouraging smarter students not to enter the field, credulous ones to enter it.
   The most serious problem with this is the same problem with having a country's leader every day say things that are clearly untrue. It's not that most people start believing the untrue things, it's that the fact that he's doing it is an announcement that truth no longer matters. Instead, what matters is what's convenient for those in power, and everyone needs to now accommodate to that reality.

6. **Peter Woit**
   August 2, 2020

   Alessandro Strumia,
   Every so often I take a look at what people were saying at various stages in the LHC history. Just happened to look at this, from 2011
   https://www.math.columbia.edu/~woit/wordpress/?p=3492
   You come off well

   "Privately, a lot of people think that the situation is not good for SUSY," says Alessandro Strumia

   Arkani-Hamed at the time was furiously back-pedaling from his 2005 claim that the SUSY question would be settled after one year of LHC data. John Ellis was saying that he would abandon SUSY if it hadn't shown up by late 2012. You're right that around this time the pre-LHC storyline that "SUSY will be easy to see, the Higgs coming much later" had already started to be inverted, with Arkani-Hamed then changing his tune to "it will take until around 2020 to know about SUSY".

7. **Low Math, Meekly Interacting**
   August 2, 2020

   It's not possible to do science indefinitely without empirical checks. If HEP is a victim of its own success, it's not hard to see why. What physicists have achieved in the past century or so is nothing short of staggering. Who wouldn't be irrationally inspired by what the human mind can achieve. But we're wired to believe, and no one ought never to assume striving for brilliance and rationality is enough. Trusting in the strength of other minds is a comfort we instinctively seek, and a luxury we can never afford. Unfortunately, that may mean setting aside the grandest objectives for the foreseeable future, and being content with only the answers nature will yield in the present. I imagine it's difficult to maintain that level of discipline and restraint when it makes one an apostate and forces them to leave the fold.

   Harder still to take the notion seriously, perhaps, when lesser minds such as mine have the chutzpah to chime in with advice. But the lessons of history are clear enough that genius isn't necessary. Lacking it may even be protective. One can never forget they're only human.

8. **Peter Woit**
   August 2, 2020

   LMMI,
   I'm afraid that what has happened is that the "string theory" community has already taken your advice, setting aside actually working on unification as hopeless until something new comes from experiment.

   The problem is not just that they've given up, but that they have coupled this with an argument designed to avoid admitting that this giving up is a failure. The currently promoted ideology is that, whatever it is, "string theory" is not a failed idea, but is our "best hope", and that this "best hope" has shown that the problem is hopeless (the landscape), so everyone should give up.

9. **martibal**
   August 2, 2020

   @Sabine: some students may think they are taught bullshit, but not all of them, at least not the master students. How could they be aware of this anyway ? This propaganda comes from the place where the Higgs boson has been discovered, not from some remote university in a country with no research tradition.

   This kind of hype is problematic when students ask for a master thesis (having in perspective a PhD). I am in a mathematical-physics group, inside a math department. Every year we have students from the physics department asking us for a master thesis, because they found that their courses in physics were leaving aside too many mathematical details. Some of them are hesitating between say, a master thesis on supergravity or supersymmetry in physics, or some subjects of mathematical physics we may propose. What should we say ? SUSY is dead, don't listen to hype, come to maths ? (knowing that the job situation in math-physics is very difficult).
   Am I in position to say: don't listen to what you might heard from the CERN lectures, this is pure propaganda ?

10. **Martin**
    August 2, 2020

    Peter,

    Juggling axes is dangerous. In contrast, saying that fundamental physics has become "quite dangerous" is a hyperbolic appeal to fear.

    Calling ideas "dangerous" is a common trope and is a pet-peeve of mine. Nobody who criticizes an academic position as being "dangerous" ever traces the line of causation that leads to grad students (or whomever) being maimed or killed. Not even paper cuts. Because if they tried, they would suddenly appear hopelessly speculative and foolish. Let's not degrade our arguments in this way! Call it "counter-productive," not "dangerous." Don't make appeals to fear.

    In other respects, please keep up the good work.

11. **Peter Woit**
    August 2, 2020

    Martin,
    Maybe "dangerous" is not the right word, but neither is "counter-productive". What's getting maimed or killed is not any person, but the credibility of the subject. This is going to get worse the longer the hype campaign and refusal to admit an idea doesn't work goes on.

12. **Martin**
    August 2, 2020

    Peter,
    "quite dangerous" -> "damaging to the scientific endeavor"

13. **Low Math, Meekly Interacting**
    August 2, 2020

    Well, there's different levels "giving up", I suppose. Maybe, for instance, there's giving up on the notion one should devote a lot more effort to studying ways to "unify the fundamental forces" in the absence of some more obvious empirical indication that line of inquiry is going to lead somewhere. Landscapology is in its own league of capitulation. Its practitioners have decided unification is so important that empiricism itself ought not to get in the way of achieving it.

    Can't one eschew GUTs or TOEs for the time being and still do first-rate HEP without giving up on science altogether? I'm still waiting for someone to make an exciting public pitch for determining the shape of the Higgs potential that doesn't promise far more than it might deliver. My understanding is precision measurement of the Higgs self-interaction is fascinating "new physics" in its own right (being completely unlike any other interaction in the Standard Model).

    It's giving up on the addiction to, and perhaps a "belief system" based on the notion of a "Final Theory" I was thinking of.

14. **Amitabh Lath**
    August 2, 2020

    Physics is less prone to groupthink. At some point as a student you must develop a spine and go up against your mentor. I remember winning an argument with my advisor (effin' Nobel Laureate!) something to do with polarized electrons. My students have gone to the mat about machine learning and artificial intelligence in data analysis until I cried uncle. I am sure the same happens with string theory and SUSY etc. in the theory community. Physics students may be many things but they are not sheep.

15. **DB**
    August 3, 2020

As I see it, the maximum responsibility lies within the string theorists themselves.
Not with teachers, not with students and not with “scientific” journalists.
If they (especially the “top” ones) came out publicly in their conferences, and stated that ST is not the “final theory” they were looking for, that things/ideas have taken a different route and that ST, as it is, needs some big changes (has to be clearly rethought, as some do acknowledge privately…), the situation might start getting better in the HEP world.
Also, maybe everyone should be a bit more humble, and settle for something less than a final TOE which, IMHO, might be too much for us to ask for, and might very well not even exist.
Weigand’s presentation was an absolute joke.

16. **anonymous...**
August 3, 2020

Stop the String Theory bashing ! It’s “not even funny”.

String theory is dead and we will have in a few years the first generation of high energy theoretical physicist without a single interesting article in their whole sad career (mid 80’s-mid 2020’s)

We should instead discuss about recent articles and emphazize on :
– neutrino (https://en.wikipedia.org/wiki/List_of_neutrino_experiments)
– g-2 (Fermilab E989) vs LatticeQCD
– cosmological simulations vs observational cosmology (and the cool new toys : Euclid, LSST, …)
– syntax and models of type theories, infinite categories, abstract homotopy
– periods and motives

it’s not hype-driven development… these are just (some of) the 2020’s healthy scientific communities

“la fécondité se reconnaît par la progéniture”

17. **Peter Shor**
August 3, 2020

The problem with saying “the students are smart and not impressionable; they’ll be all right” is that the people who decide which students become professors are the string theorists who have bought into the failed theory, and they’re going to promote the students who aren’t saying that string theory has reached a dead-end.

So we may have to put up with another generation of string theorists before we can get fundamental physics on a reasonable track again.

18. **A.J.**
August 3, 2020

@PeterShor

The CERN summer students are not — generally speaking — future theorists of any kind. They’re future experimentalists, and the experimentalists who’ll be hiring them are not noted for being especially friendly to string theory. (Yes, many of them liked the idea of weak-scale SUSY, but I don’t know any who were particularly heartbroken when it turned out to be wrong.) Also, how much of an impact do you think a single lecture on string theory is going to have on people who spend all the rest of their days working on the nitty gritty details of a high energy experiment?

19. **Peter Woit**
August 3, 2020

A.J.,
I think you’re right that this is mostly an audience of potential experimentalists not theorists. But then, since there’s no relevance to any experiment, why do you think the organizers thought lectures on string theory of this kind were a good idea? I’m seriously trying to understand what is going on in people’s minds. “String theory” seems to have become some bizarre totem or something, completely divorced from evaluation as conventional science, but brought out to wow certain groups of people. This is starting to seem to me understandable only as some sort of religious or tribal ritual, a parading of mysterious golden tablets that have 40 years of the tribe’s hopes for the future invested in them. Why does anyone think this is what science looks like?

20. **A.J.**
August 3, 2020

Peter,

I was there about 20 years ago, and was a bit of an oddball for having much interest in theory or mathematics. Those students were quite serious experimentalists. I’ve kept in touch with many of them over the years, and the number who’ve become successful HEP experimentalists is a bit shocking. I’m used to theory, where maybe 1/30 got past the postdoc. For the CERN summies, it was at least 10x that. Some of them are even giving summer lectures this year.

In any case, the student lectures are a mix of Basic Practical Thing You Must Know to Do Real Physics and Glimpse Into Another Nearby But Probably Less Important Field of Physics. At least when I was there, theory wasn’t presented as anything to idolize.

21. **Paul Gor**
August 4, 2020

About 8 years ago my daughter and I were at a University Open Day in Sydney to choose her studies in science. As we walked around different faculties, we came across the Physics department where we met some eager young Physics students of the University. They were trying to appeal to my daughter to do Physics. One of their main selling point was that they do research in String Theory. I remember feeling disappointed, I thought, is String Theory now really the ‘Poster Boy’ of Physics?
PS.
My daughter has now finished her Masters Degree in Biology and Environmental Sciences.

22. **Bernhard**
August 4, 2020

“Someone, not me, should be complaining to the organizers and to CERN management.”

I agree, but it is very nontrivial to find someone with nothing to lose to make such a complaint. Anyone without a permanent position is ruled out for the fear of backlash, and even if you have a permanent position there are political reasons not to do it. Experimentalist professors who are group leaders won’t feel comfortable or judge they have the right credentials to make such a complaint, theorists won't want to "have a problem" with their friends, even those who think this is pure BS. And, especially if you work at CERN (be as staff or user), which is basically a small town, you won't want this attention drawn to you.

23. **WTW**
August 5, 2020

Peter,
Purely by accident, a recent Google search included a link to one of your old posts:
Two Cultures https://www.math.columbia.edu/~woit/wordpress/?p=6208
Just out of curiosity, following links you provided there, and reading (and remembering) what people back in 2013 were saying "must be true", and "what we've known for decades", is rather scary.

I recently came across a quote attributed to Saul Perlmutter that seems appropriate here (and to much that is going on in the world today):
"People forget that when we talk about the scientific method, we don't mean a finished product. … Science is an ongoing race between our inventing ways to fool ourselves, and our inventing ways to avoid fooling ourselves."
Perhaps that's the lesson that should be communicated to those summer students at CERN: that the latter should be their goal, with Weigand's presentation a case in point of the former.

Unfortunately, the former often seems to be winning over the latter lately, in HEP and elsewhere, despite ongoing evidence. This is not "new news", but for an example of more hard data re. SUSY from CERN, here's some of the latest published results, in PRL:
Search for Heavy Higgs Bosons Decaying into Two Tau Leptons with the ATLAS Detector Using pp Collisions at √s=13 TeV
https://journals.aps.org/prl/abstract/10.1103/PhysRevLett.125.051801

24. **Juan**
August 5, 2020

I've just finished my PhD in HEP. I must say many students are, in fact, quite impressionable. I used to think I wanted to do research on ST until I started attending lectures by the big fishes of the community (including the superstring winter school at CERN)… It was a total disappointment being told about the swampland conjectures and exotic string compactifications without any reference to real physics and being surrounded by very arrogant students.

I've also got to know many students who sadly label ST and the like as "real" theoretical physics, as the path to follow, regarding (for example) solid state physics as less relevant. Many also think that phenomenology is BS and you are an idiot if you don't do research in sugra/extended susy/ads-cft. It seems that many just follow the fame and the hype of the big names in the field. Their PhD advisors get perpetuated by these young people, so I think the picture is not going to change any soon.

August 5, 2020

A new article full of (not so subtle) String Theory hype: 🙂

https://www.symmetrymagazine.org/article/taking-a-risk-on-theoretical-physics

26. **More Anonymous**
August 5, 2020

Off topic but good read https://www.nature.com/articles/d41586-020-02297-2

27. **Geoffrey Dixon**
August 5, 2020

Juan, in saying "many students are, in fact, quite impressionable", has hit the nail almost on the head. I would suggest "many" be replaced by "almost all". The notion that young HEPers are straining to break free of the strictures imposed by their presumed elder betters is charmingly naive.

28. **DSS**
August 9, 2020

Maximally economic? A theory that predicts 6, 7 or 22 extra spatial dimensions, of which there is no empirical evidence whatsoever? A theory that doubles the number of fundamental particles, without being able to predicts their masses, and for the existence of which, again, empirical evidence is sorely missing? A theory that posits a preposterously large number of possible different vacua, all of them just as likely within the context of the theory? A theory that takes the values of fundamental physical constants as deus ex machina-given? A theory that evolves in a deus ex machina-given space-time? This is a maximally economic theory? What is this guy smoking?

I, for one, really, really hope that theoretical physicists will eventually be able to do much better than that.

(Imaginary) Time Asymmetry

August 6, 2020
Categories: Quantum Mechanics

When people write down a list of axioms for quantum mechanics, they typically neglect to include a crucial one: positivity (or more generally, boundedness below) of the energy. This is equivalent to saying that something very different happens when you Fourier transform with respect to time versus with respect to space. If $\psi(t,x)$ is a wavefunction depending on time and space, and you Fourier transform with respect to both time and space
$$\widetilde{\psi}(E,p)=\frac{1}{2\pi}\int_{-\infty}^\infty \int_{-\infty}^\infty \psi(t,x)e^{iEt}e^{-ipx}dtdx$$
(the difference in sign for E and p is just a convention) a basic axiom of the theory is that, while $\widetilde{\psi}(E,p)$ can be non-zero for all values of p, it must be zero for negative values of E.

This fundamental asymmetry in the theory also becomes very apparent if you want to "Wick rotate" the theory. This involves formulating the theory for complex time and exploiting holomorphicity in the time variable. One way to do this is to inverse Fourier transform $\widetilde{\psi}(E,p)$ in E, using a complex variable $z=t+i\tau$:
$$\widehat{\psi}(z,p)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^\infty \widetilde{\psi}(E,p)e^{-iEz} dE$$
The exponential term in the integral will be
$$e^{-iE(t+i\tau)}=e^{-iEt}e^{E\tau}$$
which (since E is non-negative) will only have good behavior for $\tau <0$, i.e. in the lower-half z-plane. Thinking of Wick rotation as involving analytic continuation of wave-functions from $z=t$ to $z=t+i\tau$, this will only work for $\tau <0$: there is a fundamental asymmetry in the theory for (imaginary) time.

If you decide to define a quantum theory starting with imaginary time and Wick rotating (analytically continuing) back to real, physical time at the end of a calculation, then you need to build in τ asymmetry from the beginning. One way this shows up in any formalism for doing this is in the necessity of introducing a τ-reflection operation into the definition of physical states, with the Osterwalder-Schrader positivity condition then needed in order to ensure unitarity of the theory.

Why does one want to formulate the theory in imaginary time anyway? A standard answer to this question is that path integrals don't actually make any sense in real time, but in imaginary time often become perfectly well-defined objects that can be thought of as expectation values in a statistical mechanical system. For a somewhat different answer, note that even for the simplest free particle theory, when you start calculating things like propagators you immediately run into integrals that involve integrating a function with a pole, for instance integrating over E integrals with a term
$$\frac{1}{E-\frac{p^2}{2m}}$$
Every quantum mechanics and quantum field theory textbook has a discussion of what to do to make sense of such calculations, by defining the integral involved as a specific limit. The imaginary time formalism has the advantage of being based on integrals that are well-defined, with the ambiguities showing up only when one analytically continues to real time. Whether or not you use imaginary time methods, the real time objects getting computed are inherently not functions, but boundary values of holomorphic functions, defined of necessity as limits as one approaches the real axis.

A mathematical formalism for handling such objects is the theory of hyperfunctions. I've started writing up some notes about this, see here. As I find time, these should get significantly expanded.

One reason I've been interested in this is that I've never found a convincing explanation of how to deal with Euclidean spinor fields. Stay tuned, soon I'll write something here about some ideas that come from thinking about that problem.

Comments

1. **Pascal**
   August 6, 2020

   Isn't it possible to create some 'negative energy' with the Casimir force?

2. **Peter Woit**
   August 6, 2020

   Pascal,

   Energy is basically only defined up to a constant. You can always shift where E=0 is, so the point really is that energies are bounded below, that they can go off to infinity in only one direction. That's the asymmetry in the theory.

3. **Douglas Natelson**
   August 6, 2020

   Of course, in classical GR there is an absolute zero of energy density, corresponding to flat spacetime, right?

4. **Peter Woit**
   August 6, 2020

   Douglas Natelson,

   Yes, in classical GR. But I'm just trying to make a simple very general point about quantum theory, where very generally you have a Hamiltonian and it generates time translations. The positivity (perhaps after a shift in definition) of the energy eigenvalues is a very general fundamental aspect of a quantum theory, and if you work with Euclidean QM or QFT, this gets reflected in an asymmetry in the behavior in imaginary time. If you think about Euclidean QFT this is kind of surprising, since the theories one works with are often formulated in a Euclidean invariant manner (e.g. as a Euclidean invariant path integral or stat mech system).

5. **Sabine Hossenfelder**
   August 7, 2020

   there's a refection in your text that I believe should be a reflection

7. **Peter Woit**
   August 7, 2020

   Sabine and Aula,
   Thanks! Fixed.

8. **Moshe**
   August 7, 2020

   The relation between the Euclidean and Lorentzian theories is most transparent for specific set of quantities, which are correlators of time-ordered operators evaluated between the vacua in the asymptotic past and future (which may be different for a time-dependent Hamiltonian). This is great if you are interested in S-matrix elements, which is typically the case if you are a particle physicist.
   \
   But these are not the most general quantities you may be interested in, for example you may be interested in expectation values of Schrodinger picture operators in some excited state (as in measuring the CMB), or in some retarded correlators corresponding to physical measurements in CM physics. For these quantities, the Euclidean calculations are less useful. In fact, it is not clear to me if the Euclidean calculations alone contain all the information needed in principle to obtain the Lorentzian information (I'd be interested in opinions), but at the very least extracting that information is somewhere between difficult to impossible (for example the analytic continuations involved often do not commute with perturbative expansions).

9. **Peter Woit**
   August 7, 2020

   Moshe,
   Thanks. I very much agree that the relation between Minkowski and Euclidean calculations is non-trivial and deserves much more attention. The usual assumption, based on the kinds of S-matrix calculations you mention, seems to be that all that's involved is changing some factors of i, but there's much more to it.

10. **DKepler**
    August 9, 2020

    Moshe, Peter: There certainly is much more to Lorentzian Euclidean relation than changing factors of "i". For example, blindly applying this to an arbitrary metric gives a complex metric field that has no natural interpretation. Besides, Euclidean quantities (such as Greens functions) do not distinguish between coincidence and null limits, while null surfaces play a crucial role in Lorentzian regime. However, there does exist a covariant alternative to Wick rotation which do not have these difficulties, though much less work has been done on it.

11. **martibal**
    August 10, 2020

    DKepler: if not off topic, could you say more about this covariant alternative to Wick rotation you are taking about ?

12. **DKepler**
    August 10, 2020

    martibal,

    (Peter can decide if the question/reply are off-topic.)

    The key idea behind this (first noted, to the best of my knowledge, by Hawking & Ellis (HE)) is based on the following mathematical result: given a Lorentzian metric g_L and a nowhere vanishing timelike direction field U, one can always construct a Euclidean metric g_E. As is well known, non-compact manifolds always admit such a vector field, as well as compact manifolds with Euler number zero.

    Some references where this HE observation was discussed in the context of QFT are Candelas & Raine, PRD15, 1494 (1977) and Visser 1702.05572, while recent generalization and consequences for GR, euclidean QG, and euclidean action can be found in Kothawala, arXiv:1705.02504, arXiv:1802.07055. The latter references also discuss transition from euclidean to lorentzian, instead of just the euclidean phase.

    Hope this helps.

13. **martibal**
    August 10, 2020

    DKepler: thanks a lot, this helps a lot.

14. **Chris Oakley**
    August 10, 2020

    There is also a connection between positivity of energy and causality. If one takes a derivation of the relativistic electromagnetic vector potential from a four-current (e.g. [here](#)), and requires positivity of photon energy as a supplement to the Maxwell equations, then the retarded solution is the only possible.

15. **Andras Laszlo**
    August 11, 2020

    Dear All,

    Just recently I happened to come across a related problem. I would be interested in some comments on the below, related phenomenon. (Peter might decide if it is off-topic.)

    In QFT, in a Lorentz signature setting, one can define two kind of quantum field correlator function(al)s: simple VEV of products of the quantum field operator (let us call them Wightman correlators), and the VEV of time ordered products of the quantum field operator (let us call them Feynman correlators). The Wightman correlators are the ones which satisfy the Wightman axioms, including the Wightman positivity. (If Wick rotated, they will satisfy the Osterwalder-Schraeder axioms, including the OS positivity, or reflection positivity.) The Feynman correlators, however, are the ones which are in principle returned by a Feynman integral procedure. Also, these are the ones, which turn up when one would like to evaluate QFT predictions (S matrix, for instance). To me, it seems that the transition from Wightman correlators to Feynman correlators is basically a projection (time ordering). So, if I am not mistaken, Wightman correlators (without bringing in some external information) cannot be fully recovered from merely the Feynman correlators. The question naturally arises: to what extent the Wightman axioms (in particular, the Wightman positivity) are reflected in the properties of the Feynman correlators? (We should not assume, of course, anything to be known about the theory, except for its Feynman correlators.)

Best regards,
Andras

16. **Peter Orland**
August 12, 2020

Andras Laszlo,

In practice, it is not trivial to obtain the Wightman functions from T-ordered correlation functions (or their connected versions, which can also be defined. For example the connected T-ordered 2-point function is the retarded commutator of the two field operators). As you say, going the other way can be done straightforwardly.

In principle, however, I THINK it can be done. The T-ordered Green's functions fix the vacuum state. Then the Wightman functions are vacuum expectation values of field operators.

17. **Peter Orland**
August 12, 2020

Thinking on the matter a little more, it HAS been done where constructive field theory methods work (in for example ϕ^{4}_{d} models for $d<4$). In these models the time-ordered functions are obtained (in Euclidean space, where they are analytic continuations of those in Minkowski space), and the Wightman axioms have been proved. I'm not an expert on continuum constructive field theory, but this is an example.

18. **Andras Laszlo**
August 13, 2020

Dear Peter Orland,
Thanks, and could you give some hints where one could start looking at these claims?
(What I actually wanted to ask: what one can say _without_ knowing the field operators — i.e. without actually solving the QFT model etc. That is, how the Wightman positivity translates to a situation if only the Feynman correlators — i.e., time ordered correlators — are known about the model.)
Best, Andras

19. **Peter Orland**
August 13, 2020

Andras,

I'm not going to satisfactorily answer your questions, but I'll make some remarks, which I hope generate more light than heat.

As to your first question, the book by Glimm and Jaffe is probably where you should start. I'm no expert, so I'll tell you what little I know (I'm very familiar with these concepts on a lattice, but in the continuum, don't trust my statements as the last word). In constructive field theory, it is important to have reflection positivity, which is a statement about observables on a half space ${\mathbb R}_+\times {\mathbb R}^{d-1}$, which is in Euclidean space. This is a sufficient (but perhaps not necessary) condition for unitarity and the spectrum condition. In constructive field theory, the models are not actually solved, but bounds are place on the convergence of resummation of perturbation theory (by a Borel transform). Once the Euclidean axioms are proved, then the claim is that, after a Wick rotation, the Wightman axioms are satisfied.

Now in a cut-off theory (requiring renormalization, which is very different from the axiomatic approaches), in principle, the time-ordered correlations define the vacuum state. If you knew the vacuum, you can certainly construct these, but the inverse procedure should be possible to find the vacuum from them. For example, in a free field theory, the two-point function determines a unique Gaussian vacuum wave functional. I have not thought more deeply as to how to do this more generally. It sounds like a good project for a student, though.

Anyway, once you have the vacuum state, the un-time-ordered correlations can be found. Of course, nobody actually knows the exact vacuum state for most interacting field theories, so I am stating a matter of principle.

One more remark. Given the time-ordered functions, the connected Green's functions,
can be found. These are (as I said in my previous statement) a little different. For example, the two-point connected function is the vacuum expectation value of the retarded commutator. The advanced commutator of two fields can also have its expectation value found this way. So at least vevs of commutators can be found. This is close to the two-point Wightman function, but perhaps not good enough an answer to you question.

20. **Andras Laszlo**
August 13, 2020

Dear Peter Orland,
Thank you for the answers.
Best regards, Andras

21. **Robert**
September 11, 2020

I am not sure if the has to be bounded from below in quantum mechanics. If it is and the Hamiltonian is only defined as a quadratic form than the Friedrichs extension guarantees the existence of a self-adjoint operator but if you had a s.a. H from another source, my intuition would be that you often can avoid running into problems even if it is unbounded from below. Take for example H= sqrt(p^2+m^2) + Z/r a toy model for a relativistic hydrogen atom. If Z is big enough, this is unbounded from below. But please correct me if I am wrong.

In QFT, however, I agree that you want a spectrum condition. My preferred reason is that even in the absence of a preferred vacuum (for example in the absence of Poincare symmetry because auf background fields) it allows to define composite operators like phi^2(x) via normal ordering (subtracting the dev of that expression in your favourite vacuum) as you need it for example for an energy momentum tensor: If both your reference vacuum state and your current state obey a positive spectrum condition, you get smooth expectation values of your composite operators. This is for example (in the example of QFT on curved manifolds) described around Thms 6.3 and 6.4 in Fewster's lecture notes https://wiki.physik.uni-muenchen.de/TMP/images/9/9f/Lecturenote-3908.pdf

Quantization and Dirac Cohomology

August 7, 2020
Categories: BRST

For many years I've been fascinated by the topic of "Dirac cohomology" and its possible relations to various questions about quantization and quantum field theory. At first I was mainly trying to understand the relation to BRST, and wrote some things here on the blog about that. As time has gone on, my perspective on the subject has kept changing, and for a long time I've been wanting to write something here about these newer ideas. Last year I gave a talk at Dartmouth, explaining some of my point of view at the time. Over the last few months I've unfortunately yet again changed direction on where this is going. I'll write about this new direction here in some detail next week, but in the meantime, have decided to make available the slides from the Dartmouth talk, and a version of the document I was writing on Quantization and Dirac Cohomology.

Some warnings:

- Best to ignore the comments at the end of the slides about applications to Poincaré group representations and BRST. Both of these applications require getting the Dirac cohomology machinery to work in cases of non-reductive Lie algebras. As far as Poincaré goes, I've recently come to the conclusion that doing things with the conformal group (which is reductive) is both more interesting and works better. I'll write more about this next week. For BRST, there is a lot one can say, but I likely won't get back to writing more about that for a while.
- The Quantization and Dirac Cohomology document is kind of a mess. It's an amalgam of various pieces written from different perspectives, and some lecture notes from a course on representation theory. Some day I hope to find the time for a massive rewrite from a new perspective, but maybe some people will find interesting what's there now.

No Comments

Twistors and the Standard Model

August 11, 2020
Categories: Euclidean Twistor Unification

For the past few months I've been working on writing up some ideas I'm quite excited about, and the pandemic has helped move things along by removing distractions and forcing me to mostly stay home. There's now something written that I'd like to publicize, a draft manuscript entitled Twistor Geometry and the Standard Model in Euclidean Space, which at some point soon I'll put on the arXiv. My long experience with both hype about unification in physics as well as theorist's huge capacity for self-delusion on the topic of their own ideas makes me wary, but I'm very optimistic that these ideas are a significant step forward on the unification front. I believe they provide a remarkable possibility for how internal and space-time symmetries become integrated at short distances, without the usual problem of introducing a host of new degrees of freedom.

Twistor theory has a long history going back to the 1960s, and it is such a beautiful idea that there always has been a good argument that there is something very right about it. But it never seemed to have any obvious connection to the Standard Model and its pattern of internal symmetries. The main idea I'm writing about is that one can get such a connection, as long as one looks at what is happening not just in Minkowski space, but also in Euclidean space. One of the wonderful things about twistor theory is that it includes both Minkowski and Euclidean space as real slices of a complex, holomorphic, geometry. The points in these spaces are best understood as complex lines in another space, projective twistor space. It is on projective twistor space that the internal symmetries of the Standard Model become visible.

The draft paper contains the details, but I should make clear what some of the arguments are for taking this seriously:

- Unlike other ideas about unification out there, it's beautiful. The failure of string theory unification has caused a backlash against the idea of using beauty as a criterion for judging unification proposals. I won't repeat here my usual rant about this. As an example of what I mean about "beauty", the fundamental spinor degree of freedom appears here tautologically: a point is by definition exactly the $\mathbf C^2$ spinor degree of freedom at that point.
- Conformal invariance is built-in. The simplest and most highly symmetric possibility for what fundamental physics does at short distances is that it's conformally invariant. In twistor geometry, conformal invariance is a basic property, realized in a simple way, by the linear $SL(4,\mathbf C)$ group action on the twistor space $\mathbf C^4$. This is a complex group action with real forms $SU(2,2)$ (Minkowski) and $SL(2,\mathbf H)$ (Euclidean).
- The electroweak $SU(2)$ is inherently chiral. For many other ideas about unification, it's hard to get chiral interactions. In twistor theory one problem has always been the inherent chiral nature of the theory. Here this becomes not a problem but a solution.

At the same time I should also make clear that what I'm describing here is very incomplete. Two of the main problems are:

- The degrees of freedom naturally live not on space-time but on projective twistor space PT, with space-time points complex projective lines in PT. Standard quantum field theory with fields parametrized by space-time points doesn't apply and how to work instead on PT is unclear. There has been some work on formulating QFT on PT as a holomorphic Chern-Simons theory, and perhaps that work can be applied here.
- There is no idea for where generations come from. Instead of PT perhaps the theory should be formulated on S^7 (space of unit length twistors) and other aspects of the geometry there exploited. In some sense, the incarnations of twistors as four complex number or two quaternions are getting used, but maybe the octonions are relevant.

What I think is probably most important here is that this picture gives a new and compelling idea about how internal and space-time symmetries are related. The conventional argument has always been that the Coleman-Mandula no-go theorem says you can't combine internal and space-time symmetries in a non-trivial way. Coleman-Mandula does not seem to apply here: these symmetries live on PT, not space-time. To really show that this is all consistent, one needs a full theory formulated on PT, but I don't see a Coleman-Mandula argument that a non-trivial such thing can't exist.

What is most bizarre about this proposal is the way in which, by going to Euclidean space-time, you change what is a space-time and what is an internal symmetry. The argument (see a recent posting) is that, formulated in Euclidean space, the 4d Euclidean symmetry is broken to 3d Euclidean symmetry by the very definition of the theory's state space, and one of the 4d $SU(2)$s give an internal symmetry, not just analytic continuation of the Minkowski boost symmetry. There is still a lot about how this works I don't understand, but I don't see anything inconsistent, i.e. any obstruction to things working out this way. If the identification of the direction of the Higgs field with a choice of imaginary time direction makes sense, perhaps a full theory will give Higgs physics in some way observably different from the usual Standard Model.

One thing not discussed in this paper is gravity. Twistor geometry can also describe curved space-times and gravitational degrees of freedom, and since the beginning, there have been attempts to use it to get a quantum theory of gravity. Perhaps the new ideas described here, including especially the Euclidean point of view with its breaking of Euclidean rotational invariance, will indicate some new way forward for a twistor-based quantum gravity.

Bonus (but related) links: For the last few months the CMSA at Harvard has been hosting a Math-Science Literature Lecture Series of talks. Many worth watching, but one in particular features Simon Donaldson discussing *The ADHM construction of Yang-Mills instantons* (video here, slides here). This discusses the Euclidean version of the twistor story, in the context it was used back in the late 1970s to relate solutions of the instanton equations to holomorphic bundles.

Update: After looking through the literature, I've decided to add some more comments about gravity to the draft paper. The chiral nature of twistor geometry fits naturally with a long tradition going back to Plebanski and Ashtekar of formulating gravity theories using just the self-dual part of the spin connection. For a recent discussion of the sort of gravity theory that appears naturally here, see Kirill Krasnov's Self-Dual Gravity. For a discussion of the relation of this to twistors, see Yannick Herfray's Pure Connection Formulation, Twistors and the Chase for a Twistor Action for General Relativity.

Comments

1. **Warren Siegel**
   August 11, 2020

   How do you get around the related problems that (Penrose) twistors are inherently massless & on shell?

2. **Peter Woit**
   August 11, 2020

   Warren Siegel,

   This is meant as a proposal for short-distance physics, conformally-invariant physics. What's missing is how to do gauge theory on PT and how to give dynamics to the Higgs, providing the interactions that would give you an effective field theory at longer distances that would have masses.

3. **John C. Rodney**
   August 11, 2020

   I don't have the background to evaluate your paper. Still, I am impressed that you have put it out to allow all those whom you have criticized to take their shots at you.

Also, does your theory predict anything and how can it be experimentally verified?

4. **Peter Woit**
August 11, 2020

John C. Rodney,
At this point in my life, the last thing I want to waste my time on is dumb arguments about these ideas, string theory, testability, etc. One could for instance argue that what I'm discussing predicts four space-time dimensions, only SU(2), SU(3) and U(1) internal symmetries, spontaneous breaking of electroweak symmetry, etc. For a truly completely convincing prediction, what you want is a calculation of one of the Standard Model parameters, or, better, some prediction from a model based on these ideas that is different than what the Standard Model predicts. There's still a lot missing here, with perhaps the most important idea missing being an idea about where different generations of fermions come from.

String theorists have argued that it doesn't matter how bad a unified theory string theory provides, that it has to be compared to other ideas about unification. I don't think that there's a serious argument that string theory unification based on the multiverse, the swampland or whatever can be compared favorably to the ideas presented here.

I'm happy to engage anyone in serious discussion of these ideas, but string theory really is off-topic.

5. **vmarko**
August 12, 2020

Hi Peter,

There are many unification models out there. Even I have one (easily found on arXiv) — using category theory, it allows you to discuss fermion generations, automatically includes gravity, works only in 4D, and has potential to circumvent Coleman-Mandula. And some other stuff. So the lack of unification proposals, with various interesting properties, is not the problem.

The problem is lack of peer interest.

Namely, until someone demonstrates that one of all those models out there actually reduces the number of SM free parameters, or predicts something outside the SM, it's all nothing more than just fascinating math. The majority of researchers will not bother to pay any attention to unification models. This is quite unfortunate, and IMO a bit sad, but I don't see any other way to attract a bit of attention and gain interest from other researchers in the field.

Even if one explicitly demonstrates that some model reduces the number of free parameters, it is tough to convince people. A typical example is the noncommutative SM, developed by Chamseddine, Connes and their collaborators. That's also based on some intriguing and fascinating math, and has some provocative properties regarding unification of interactions. Does the hep-th community pay any attention to it? Not much, really.

I share your point of view that proposing unification models and studying them is a worthwhile endeavour, but it appears that any such model requires a substantial number of people to drive the research in order to flesh out a convincing prediction. But attention of other researchers can apparently be obtained only if one already has a prediction. And thus you reach Catch 22, having a nontrivial manpower-problem to move the idea off the ground.

Math is always beautiful, various algebraic structures have some captivating properties, and offer tempting ways to explain various properties of nature that we do not yet understand. But the lack of collective peer interest in any such structure is a warning to all of us pursuing this research area — physics requires *more* than math.

Best, 🙂
Marko

6. **Low Math, Meekly Interacting**
August 12, 2020

Since this is your (pre-?)preprint's debut, I'm guessing the preliminary answer is "no", but…

Have you discussed this with or gotten feedback from others with deep interest in twistors? You wrote some very nice things about Andrew Hodges a while back, and he seems to be among the outstanding proponents of Penrose's invention, and something of a guru.

Not that anyone's opinion matters ultimately, but what constructive assessments you receive will be of interest to readers of this blog (even those who can't understand ~95% of the above post).

I share others' interest in hearing more about any observational consequences of these ideas, when the time comes.

Best of luck!

LMMI

7. **Peter Woit**
August 12, 2020

vmarko,
The main problem right now is that the SM is too good. Traditionally the way the field made progress was by focusing on explaining experimental results that contradicted the best available model. At this point all there is of that kind is arguably dark matter, where you have an extremely small amount of relevant info and a huge number of people working on it. In reaction to this difficult situation, most of the field has essentially abandoned the problem, which is a rational thing to do.

The only reason to keep working on this is if you see some possible way forward. To me there have always been aspects of the SM that don't quite fit together (the issue of Wick rotation and spinors is an example), and new things to learn about mathematical ideas that somehow relate to the SM, giving possible new ways of thinking about it. I've spent 40 years doing this, learned a huge amount, enjoyed myself, but until recently never felt that I'd come upon a set of ideas that fit together in a really convincing way. I've now tried to write up what I do understand, there are lots of new obvious questions and directions to pursue that I don't understand, plenty to keep me busy. I'd like to think that others will sooner or later find something in these ideas that resonates with them, we'll see…

8. **Peter Woit**
August 13, 2020

LMMI,
I did start writing people about this a while before making this public. Not a lot of reaction, partly I think because this is far from what people are used to thinking about, partly because it's August. There have been a small number of extremely helpful responses, of the form: "I'm not understanding this particular point", making it clear

where I need to do more work to clarify what it going on and explain it. I"m working now on expanding parts of what I've written, will write more on the blog once that is done.

9. **Anonymous**
   August 13, 2020

   This feels to me like the story relating the standard model to the octonions. In both cases, there is a beautiful mathematical structure that happens to have the standard model gauge group sitting inside it, maybe even acting in a somewhat suggestive way. It feels to me like the group theory version of the Strong Law of Small Numbers, as in "there aren't enough small Lie groups to meet the many demands made of them."

10. **Peter Woit**
    August 13, 2020

    Anonymous,
    There may very well be a role for the octonions, twistor space is conventionally thought of as four complex numbers or two quaternions, perhaps the octonionic structure can be exploited.

    But note that what I'm discussing is not just an algebraic framework for internal symmetries, but is based on twistor geometry, which is normally thought of as explaining space-time symmetries. It is putting internal and space-time geometry together which I think is what makes these ideas so interesting.

11. **Dave Miller**
    August 14, 2020

    Peter,

    As you know, putting fermions on a lattice is a mess. Does your work give any clues as to how to do that? My gut feeling is that any theory that cannot be cleanly discretized is missing something.

    Have you sought out comments from John Baez? This is the sort of thing he has been publicly musing about for decades, and I would think John would either have some interesting ideas as to how to move forward or, perhaps, some ideas as to why your approach won't work (if the latter is true, better to learn earlier than later!).

    And please continue to keep us all informed: one of us may come up with some useful idea.

    Best of luck!

    Dave Miller in Sacramento

12. **Peter Woit**
    August 14, 2020

    Dave Miller,
    Actually, thinking about fermions on the lattice a very long time ago is what got me interested in this whole subject of the geometry of spinors. Euclidean lattice gauge theory is beautifully adapted to the geometry of connections and curvature, one would like something similar for spinors.

    One problem with twistor methods and the lattice is that they typically very much exploit the properties of holomorphic functions, and it seems hard to do that in a discretized theory.

    Someday maybe I'll get back to thinking about the lattice and spinors. What is natural on the lattice is not spinors but differential forms, and those give you Kogut-Susskind fermions. The Euclidean twistor picture says you need to take into account at each point in 4d the fiber above it, which you can think of as projective (half)-spinors, or orthogonal complex structures. This gives you what you need to deal with spinors. Maybe there is some way to exploit this on the lattice.

    As always, John Baez has been helpful…

13. **Robert A. Wilson**
    August 15, 2020

    I think there is a misprint at the end of section 4.1: surely you mean Spin(2,2) = SL(2,R) x SL(2,R), and not Spin(3,3)?
    There is of course a well-known translation from twistors to octonions, which may throw up new insights. If you take the real split octonion algebra, and fix a choice of complex subalgebra, then you get SU(2,2) acting by (left, say) multiplications, and SO(2,4) acting by bi-multiplications. If you intersect with the automorphism group, you get SU(1,2), whose compact part is the EW gauge group U(2).
    If I had a model like this that only covered one generation of fermions, I'd be wondering what role the choice of complex structure within the quaternions plays in all this. I take it this is what you are hinting at by suggesting extending to Spin(7) or Spin(8)? The appropriate real forms would seem to be Spin(3,4) and Spin(4,4), but I'd be worried about the group getting too big, and would wonder what could be done by restricting to Spin(3,3) instead.

14. **Klas**
    August 16, 2020

    "One problem with twistor methods and the lattice is that they typically very much exploit the properties of holomorphic functions, and it seems hard to do that in a discretized theory."

    That might depend on which properties of holomorphic functions you are interested in. In the last decade a theory of univariate holomorphic functions on planar graphs has been developed. This was motivated by questions from statistical mechanics, and does e.g. connect to conformal field theory.

    The first steps were taken by Smirnov but now many others are working on this as well.

    A survey talk by Smirnov

Guys and Their Theories of Everything

August 21, 2020
Categories: Uncategorized

I'm a big fan of Sabine Hossenfelder's music videos, the latest of which, Theories of Everything, has recently appeared. I also agree with much of the discussion of this at her latest blog posting where Steven Evans writes

> nobody wants to see Peter Woit sing.

and Terry Bollinger chimes in:

> Please, under no circumstances and in no situations, should folks like Peter Woit, Lee Smolin, Garrett Lisi, Sean Carroll, or even John Baez try to spice up their blogs or tweets by adding clips of themselves singing self-composed physics songs.
>
> Trust me, fellow males of the species: However tempted you may be by Sabine's spectacular success in this arena, it just ain't gonna work for you!

The chorus of Sabine's song goes:

> All you guys with theories of everything
> Who follow me wherever I am traveling
> Your theories are neat
> I hope they will succeed
> But please, don't send them to me

One reason for her bursting into song like this was probably her recent participation in this discussion. I'd like to think (for no good reason) that it had nothing to do with my recently sending her a copy of this.

Today brought a new discussion of theories of everything, by Brian Greene and Cumrun Vafa. When asked by Greene to give a grade to string theory, Vafa said that he would give it a grade of A+, although its grade was less than A on the experimental verification front.

While I'm enthusiastic about new ideas involving twistors and happily continuing to work on them, it's pretty clear that this is not a good time to be bringing them to market. The elite academic world of Harvard and Princeton theorists that I was trained in has been doing an excellent job of convincing everyone that even the smartest people in the world could not make any progress towards a TOE, and that all claims for such progress from the most respected experts around are not very credible. Best to ignore not just the cranks who fill up your inbox with such claims, but all of them, judging the whole concept to be doomed until the point in the far distant future when an experiment finally provides the clue to the correct way forward.

Be warned though, if people don't pay some more attention, I'm going to start writing songs and singing them here.

Update: Note, an ill-advised attempt at humor referring to identity politics was obviously a mistake and has been deleted (along with some references to it in the comments). The threat to start singing is also a joke.

Comments

1. **Edward M Measure**
   August 21, 2020

   I don't know, John Baez may have some familial talent

   […]

2. **Peter Shor**
   August 21, 2020

   If you dream up a theory of everything,
   Grab your guitar, write some lyrics, and sing!
   Don't put it in a journal; that's not gonna cut it—
   The usual suspects would simply rebut it
   And chances are that your article would just be ignored.
   Take up songwriting if you want to be heard!

3. **graboluk**
   August 22, 2020

   @Peter Shor, for completeness, should I force "ignored" to rhyme with "heard" or the other way around? Or is there an english dialect where they rhyme by default?

4. **Kerberos**
   August 22, 2020

   ""Be warned though, if people don't pay some more attention, I'm going to start writing songs and singing them here.""

   The Ur-Twistor did the same:
   https://www.youtube.com/watch?v=Bwt2jktwAqU

5. **Peter Shor**
   August 22, 2020

   graboluk: Words that nearly rhyme (slant rhymes) are fairly common in English song lyrics and poetry. Usually, people pronounce them the way they normally do.

6. **Lars**
   August 22, 2020

It just *couldn't* have been your recent comment about beautiful math that got Hossenfelder's songwriting juices flowing, could it?

"Twistor theory has a long history going back to the 1960s, and it is such a beautiful idea that there always has been a good argument that there is something very right about it."

As we all know, Hossenfelder has a soft (some might say sore) spot for argument from beauty.

7. **Michael Weiss**
   August 22, 2020

   To amplify on Peter Shor's comments, one can do no better than to turn to a Nobel Laureate:

   "Rhyming doesn't have to be exact anymore," Bob Dylan told Paul Zollo of American Songwriter magazine in a 2012 interview. "It gives you a thrill to rhyme something and you think, 'Well, that's never been rhymed before'. Nobody's going to care if you rhyme 'represent' with 'ferment', you know. Nobody's gonna care."

   Dylan once admitted to Rolling Stone magazine that he stunned himself when he wrote the first two lines of 'Like a Rolling Stone' and rhymed "kiddin' you" with "didn't you". "It just about knocked me out," he said.

8. **Peter Woit**
   August 22, 2020

   Kerberos,

   Exactly that song had occurred to me as the right music for the topic.

9. **former mathematician**
   August 22, 2020

   In his arithmetically titled "love minus zero / no limit," Dylan rhymed "fire" with "buy her."

10. **FB36**
    August 22, 2020

    "When asked by Greene to give a grade to string theory, Vafa said that he would give it a grade of A+"

    Maybe we should allow all students to decide their own grades "since they are the ones who best know/understand their own work, they are the best qualified"? 🙂

11. **Sabine Hossenfelder**
    August 23, 2020

    Hi Peter,

    Happy to like it! And no, it didn't have anything to do with your paper, which came when I was pretty much already done.

12. **graboluk**
    August 23, 2020

    "kiddin you" and "didn't you" is legit (not even slant imo). On the other hand "heard" and "ignored" sound like, so to speak, a confirmation of Gromov's opinion on english and poetry.

    In any case, as a peace offering 🙂 I've just checked an online rhyming dictionary, which suggested both "absurd" and "nerd" for rhymes to "heard", so perhaps these potentially could be used instead in the penultimate verse.

13. **ohwilleke**
    August 24, 2020

    I could swear that I have seen John Baez do this once or twice.

    My late father was a professor and also did several for his students (fortunately for us all, pre-YouTube).

14. **Jacob Zelten**
    August 25, 2020

    I read this as "We String Theorists have failed to produce a Theory of Everything and we're the smartest people in the room. So obviously, nobody else is smart enough to create one."

15. **Peter Shor**
    August 29, 2020

    To rather belatedly defend my inadequate rhymes, let me point out that in one of the most famous poems in the English language, *Ode on a Grecian Urn*, John Keats rhymes *morn* and *return*, with the same two vowels that are found in *ignored* and *heard*. So this rhyme was acceptable long, long before Bob Dylan. (Of course, in all other respects, my lyrics above are vastly inferior to Keats'.)

16. **graboluk**
    August 31, 2020

    Peter Shor, I see your point but this isn't entirely convincing to me. The Oxford Dictionary of Original Shakespearean Pronunciation claims "rɪˈtɐːɹn" as the pronunciation for return, and "retornth" appears in a 16th century poem by Thomas Wyatt. So to me, you'd need an early 19th century english pronunciation expert in order to confirm the intended pronunciation of ode on a grecian urn. A few years back newspapers in UK ran articles about Shakespeare, whose general theme was along the lines of "it's not that his rhymes suck, it's just that the pronunciation has changed".

Funding Priorities

August 26, 2020
Categories: Uncategorized

The research that gets done in any field of science is heavily influenced by the priorities set by those who fund the research. For science in the US in general, and the field of theoretical physics in particular, recent years have seen a reordering of priorities that is becoming ever more pronounced. As a prominent example, recently the NSF announced that their graduate student fellowships (a program that funds a large number of graduate students in all areas of science and mathematics) will now be governed by the following language:

> Although NSF will continue to fund outstanding Graduate Research Fellowships in all areas of science and engineering supported by NSF, in FY2021, GRFP will emphasize three high priority research areas in alignment with NSF goals. These areas are Artificial Intelligence, Quantum Information Science, and Computationally Intensive Research. Applications are encouraged in all disciplines supported by NSF that incorporate these high priority research areas.

No one seems to know exactly what this means in practice, but it clearly means that if you want the best chance of getting a good start on a career in science, you really should be going into one of

- Artificial Intelligence
- Quantum Information Science
- Computationally Intensive Research

or, even better, trying to work on some intersection of these topics.

Emphasis on these areas is not new; it has been growing significantly in recent years, but this policy change by the NSF should accelerate ongoing changes. As far as fundamental theoretical physics goes, we've already seen that the move to quantum information science has had a significant effect. For example, the IAS PiTP summer program that trains students in the latest hot topics in 2018 was devoted to From Qubits to Spacetime. The impact of this change in funding priorities is increased by the fact that the largest source of private funding for theoretical physics research, the Simons Foundation, shares much the same emphasis. The new Simons-funded Flatiron Institute here in New York has as mission statement

> The mission of the Flatiron Institute is to advance scientific research through computational methods, including data analysis, theory, modeling and simulation.

In the latest development on this front, the White House announced today \$1 billion in funding for artificial intelligence and quantum information science research institutes:

> "Thanks to the leadership of President Trump, the United States is accomplishing yet another milestone in our efforts to strengthen research in AI and quantum. We are proud to announce that over $1 billion in funding will be geared towards that research, a defining achievement as we continue to shape and prepare this great Nation for excellence in the industries of the future," said Advisor to the President Ivanka Trump.

This includes an NSF component of \$100 million dollars in new funding for five Artificial Intelligence research institutes. One of these will largely be a fundamental theoretical physics institute, to be called the NSF AI Institute for Artificial Intelligence and Fundamental Interactions (IAIFI). The theory topics the institute will concentrate on will be

- Accelerating Lattice Field Theory with AI
- Exploring the Multiverse with AI
- Classifying Knots with AI
- Astrophysical Simulations with AI
- Towards an AI Physicist
- String Theory Conjectures via AI

As far as trying to get beyond the Standard Model, the IAIFI plan is to

> work to understand physics beyond the SM in the frameworks of string and knot theory.

I'm rather mystified by how knot theory is going to give us beyond the SM physics, perhaps the plan is to revive Lord Kelvin's vortex theory.

Update: Some more here about the knots. No question that you can study knots with a computer, but I'm still mystified by their supposed connection to beyond SM physics.

Comments

1. **Sabine Hossenfelder**
   August 26, 2020

   Looks like Chris Anderson was right when he proclaimed the end of theory.

   (There's a "b" missing in the last sentence.)

2. **Peter Woit**
   August 26, 2020

   Thanks Sabine,
   Typo fixed. The Chris Anderson argument she refers to is here
   https://www.wired.com/2008/06/pb-theory/

3. **Warren Siegel**
   August 26, 2020

   How about
   • NSF run by AI

4. **Alex**
   August 26, 2020

Reply to Chris Anderson – https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2711825/

5. **Mayer Landau**
August 26, 2020

It is absolutely fascinating, from a Frankenstein monster that will not die perspective, that the multiverse and string theory live on through AI.

6. **Tim Bradshaw**
August 26, 2020

I think what this probably really means is that the latest AI bubble is about to burst (or has burst). Certainly an AI winter is coming.

7. **David Brahm**
August 26, 2020

I did not think I'd live to see the day that the direction of physics research was announced by Ivanka Trump.

8. **sdf**
August 26, 2020

This sounds like an Onion article. Let's just have everything run by AI shall we? What about AI run by AI? Then we can all just stay in bed in the morning and avoid all this bullshit.

9. **Peter Erwin**
August 27, 2020

I suspect a large part of the "White House announcement" is congressionally mandated, in spite of the boilerplate, "Leadership of President Trump" bombast, in part because that's where the money has to come from. (And way down at the bottom of the announcement is an acknowledgment that "The National Quantum Initiative Act, bipartisan legislation signed by President Trump in 2018, called for the creation of research centers nationwide to accelerate foundational QIS research and development.")

10. **Thomas Larsson**
August 27, 2020

@Warren Siegel. How do you know that NSF is not run by AI today?

Artificial intelligence is better than none.

11. **Peter Woit**
August 27, 2020

David Brahm/Peter Erwin,
While Ivanka Trump was doing the announcing, the decisions that this is the way science needs to go are getting made elsewhere, often with the participation of the physics community. What I wonder more is what sort, if any, of peer review signed off on the multiverse AI business.

All this reminded me that I've written about some of this before, see
https://www.math.columbia.edu/~woit/wordpress/?p=10680

12. **DB**
August 27, 2020

I think we are underestimating the imminent role that AI is about to play in expanding our knowledge of the Universe. I'm with those 'tech geeks' who see the future discoveries of physics not coming out of Princeton, Harvard or Cambridge but rather out of Apple, Google and their Chinese equivalents. AI will be an existential tool to expand knowledge, but Chris Anderson's view is too radical. In about twenty or twentyfive years, 200 million teens in their bedrooms are each going to have access to more computing power and tools than the top physics institutions have today.
Quantum computers and AI are ALREADY the future of cosmology/string theory/multiverse/knot theory… whatever field you prefer.
Theoretical physics, as has been done/studied up till now… is at the verge of a massive paradigm shift. I know there are a couple of radicals out there (some are string theorists pretty well known in this blog, especially one of them from Central Europe…) who still believe that men alone will find that final TOE (which they consider to be ST itself!), but… sorry for them. It's not going to happen as they expect. Not a snowball's chance in hell!!
The field is screwed without the help of that powerful technology. And contrary to what some top theoretical physicists go about saying that it's a great time to become a theoretical physics student, well… bollocks.

13. **Yash Sharma**
August 27, 2020

The current approach to AI is highly data-dependent and statistical in nature. Causal understanding has not been introduced yet. And most active Machine Learning research is not primarily geared towards that.
Given that, as physicists do you think there is even a possibility that theoretical physics topics have any chance of benefitting from AI (without it having causal understanding) in the near future? Are there any planned physics experiments to which AI would add a significant value?

(I am from computer science and engineering background.)

14. **Peter Woit**
August 27, 2020

DB,
It's not just certain string theorists who believe human beings can come up with a successful unified theory, since I happen to also believe this, and would have thought that if anyone's not a string theorist, it's me. I might be wrong though about what I am, since I just saw in Katie Mack's new book the following definition of string theory: "String theory is a blanket term for theories that try to bring together gravity and particle physics in new ways" and that definition fits what I work on.

Apple and Google might be sources for certain kinds of physics discoveries, but I'd bet these will always be in certain restricted subfields (e.g. those relevant to building quantum computers). Those companies are pretty tightly focused on making money and achieving world domination, not likely to devote much effort to other fields with little practical, exploitable, applications.

The idea that increase in computer power and new computer algorithms will revolutionize physics has been around for at least the last 50 years I've been following the subject. Actual progress of this kind has always been much more limited than expected. When I was a grad student in the early 1980s I spent a lot of time doing computer calculations (lattice gauge theory Monte-Carlo simulations). That field has had interesting results, but not revolutionized the subject at all. One of the most likely possible applications of quantum computers would be in that area, but I suspect they will always be rather specialized, not affect most people's work.

On the experimental side of physics, I'm quite willing to believe that AI will find some very useful applications, from what I hear it's already being seriously exploited in LHC data analysis, with more to come. There's no evidence though that this sort of thing will lead to breakthroughs in fundamental experimental issues, for instance helping overcome the barriers to getting information about what's happening at energies above the TeV scale.

It's not hard to believe that a large fraction of the stupid things people do can be done just as stupidly, but faster, by artificial intelligence. Given the depressing state of the world, this might mean that most of what human beings do can be done by machines. On the issue of finding a better unified theory, all evidence I've seen in that the machines will do a great job of calculating away on bad, failed ideas, none that they'll help come up with better ones.

15. **Peter Woit**
August 27, 2020

Yash Sharma,
The main problem with beyond the SM HEP theory is that there is essentially no relevant data at all (maybe, making a lot of assumptions about astrophysics, a couple numbers about "dark matter"). So, it seems no role for "Big Data"- based approaches.

Back before the LHC turned on, a bunch of people organized an "LHC Olympics" designed to get algorithms ready to sort through and figure out the correct beyond the SM model based on the large number of new (non-SM) physics signals they expected. It always seemed more likely that things would work exactly as they had always worked in the past: intensive effort devoted to finding even one new physics signal. That's where the field is now: experimentalists will use all the help they can get to find such a signal, but for theorists whether there's no signal or one signal, Big Data is not what they will ever have.

16. **Yash Sharma**
August 27, 2020

Thanks, Peter.
About the other discipline set to receive great funding, Quantum Information Science, it seems much more likely to help theoretical physics, guessing from this nice article – https://www.quantamagazine.org/john-preskill-quantum-computing-may-help-us-study-quantum-gravity-20200715/ . Thats about quantum gravity. Do you see any other ways in which quantum computing might help (apart from lattice gauge theory that you mentioned). Specifically, are there any experiment or simulations that quantum physicists cannot perform in labs because they are infeasible or too expensive, but with a scalable quantum computer they might be able to do it?

17. **Peter Woit**
August 27, 2020

Yash Sharma,
Theorists have been promoting the idea that quantum information science will give us a theory of quantum gravity for a long time now, with little solid to show for this, and I'm extremely dubious that that will ever change. The only substantive reference in that Preskill article, was to the article discussed here
https://www.math.columbia.edu/~woit/wordpress/?p=11648

While I thought that Preskill article was disappointing, the best answer I know of to your question is a much better article he wrote a while back, see
https://arxiv.org/abs/1811.10085

18. **Miquel**
August 27, 2020

As a researcher in AI I am quite surprised to see such cranky topics being given respectability.

There is a lot of serious work on bringing optimisation, search and automated theorem proving (all of them techniques employed in research in AI) to help with experimental design, finding proofs and programming quantum computers.

Seeing a topic "exploring the multiverse with AI" – that sounds like something out of a work of fiction such as Neal Stephenson's "Anathema" – breaks my heart.

19. **vmarko**
August 27, 2020

Hi Peter and others,

Regarding the AI in theoretical physics, the only potentially useful application I can imagine is the following — unlike any human, the AI could "read" and sift through all scientific papers on the arXiv, with a possible outcome of finding one or two obscure papers which contain some crucial piece of result for some open problem, written by some people not very well known by the research community.

Namely, a human simply cannot read *all* papers, and most of the researchers only pay attention to papers authored by the people they are familiar with. So some crucial insight, put on the arXiv, can go completely unnoticed for a long time, if it was authored by a researcher who has no social contact with leaders in the field. Simply, nobody bothered to read it. On the other hand, in principle if properly trained, an AI could analyze all the arXiv papers, and turn everyone's attention to that one inconspicuous little paper written by those anonymous couple of guys from that obscure University of Whereever — which actually solves something important, but nobody paid any attention to it because its authors are not recognized as relevant by the main community of researchers.

I think the above could be a useful application of AI in theoretical physics, and IMO this is the best case scenario — I am in fact very skeptical that AI could do even that (perform a semantic analysis of papers on the arXiv), since semantic analysis usually requires actual understanding of the underlying problem, paths to possible solutions, etc. — all that stuff that we do in science that AI usually *cannot* do.

Other than that, I don't see AI being helpful in theoretical physics in any way whatsoever, except maybe in some highly specific usecases, like sifting through petabytes of LHC data looking for a non-SM signal. But do note that the latter is just a more efficient way of performing a very dull, boring and non-intelligent work what humans (or even monkeys) could eventually do even without AI, given enough time. A machine just does it faster.

Also, I am baffled that some people have an impression that AI can be somehow "smarter" or "more inteligent" than humans (whatever the definitions of those words may be). On the contrary, AI is just an efficient lossy compression algorithm (think jpeg or mp3). It is a mathematical function with a huge number of tunable parameters, and once tuned to give desired output to certain known inputs (process called "training" the AI), one can use it to approximate outputs for unknown inputs, hoping that the resulting outputs would not be "too far off" from the outputs one would expect to get. That is why mp3 playback sounds rather similar to the original song, and why google seems to be able to "predict" what will be the next word you type into its search box. There is nothing "intelligent" about it, it's just pure (and very stupid) large scale data-fitting.

All this stuff (that makes up the AI) has absolutely nothing whatsoever to do with creative thinking, which is what science is all about, IMO.

Best, 🙂
Marko

20. **Yash Sharma**
August 27, 2020

Using AI to perform analysis on arxiv papers is possible now. Hopefully we will soon know if this approach works, as they have already released arXiv papers dataset for a large ML community. https://blogs.cornell.edu/arxiv/2020/08/05/leveraging-machine-learning-to-fuel-new-discoveries-with-the-arxiv-dataset/

21. **Alessandro Strumia**
August 28, 2020

Understanding intelligence will be an interesting science, important for theoretical physics because it's plausible that IQ will be scalable. For the moment, "*AI" (adding AI to whatever theorists were doing) is not going to be a breakthrough. But it's nice that some physicists become apolitical when Ivanka throws money.

22. **vmarko**
August 28, 2020

Yash Sharma,

Yes, arXiv has opened its database for ML purposes. But training the AI to do something useful with it is a completely different story, and a much harder problem to solve, IMO.

Best, 🙂
Marko

23. **Jackiw Teitelboim**
August 28, 2020

You all have already been fooled. The NSF announcement was written by an IA. (That is why "strings" and "knots" are in the same sentence!) Penrose predicted this. The Emperor has no mind.

24. **George**
August 28, 2020

"Exploring the Multiverse with AI" – helping sift all that data?

25. **André**
August 29, 2020

Peter,
there are good reasons not to model particles as knots. One is that in the weak interaction, particles can change (electrons to neutrinos, for example) and this change cannot be described with knots, which are stable structures. Another is that knots do not yield spin 1/2. (Even stronger reasons arise in string theory: in 10/11/12/26 dimensions, knots of one-dimensional objects do not exist at all: every knot is equivalent to the unknot. Maybe the AI system will rediscover this result …) As a consequence, modelling particles as knots has never been successful, despite about a dozen attempts in the literature – starting with Kelvin, as you mentioned.

26. **DB**
August 29, 2020

Peter,
thanks for your detailed reply above.
Preskill's arxiv paper and the link that you include in your update are on the same track of the idea I'm trying to convey.
No matter what string theorists or non string theorists say and proclaim all over the world, there's not a f… chance for us humans to discover that final TOE… if it exists. We will need the help of quantum computers/advanced AI, and, slowly but surely, they will be taking over that task from us.
Does that mean that we will disappear and have no role at all?
No, it just means that evolution will carry on its due course and our role will be diminishing. Of course, it won't happen overnight. We will probably have a big role to play at least during this century. After that… I'm not betting my money.

Re the world's situation… I can't agree with you more. The disaster is absolute. And it doesn't look better for the near future at least. It just sends massive shudders down my spine to think that in a decade (or less!) we could be in the hands of people like Ivanka or Jared… Not to mention the totalitarian oligarchs that already run many other parts of the world.

Finally, the reason why I don't believe we will be able to find that TOE, is because, IMO, "Ultimate Reality" is ineffable. It can't be expressed with words because it is diffused, almost imperceptible and lacks precision. It seems to me that the material Universe comes from the Immaterial. And that sounds like jumping over the physical realm into the META-physical, which I consider totally out of reach.
Oh, and I'm not referring to a god as religious people understand. I mean something so abstract that it can't be perceived/understood, a noumenon type of idea/concept.

27. **Peter Woit**
August 29, 2020

André,
I agree, and am not aware of any non-crackpot ideas to use knot theory to get a viable beyond SM model. That's why I was surprised to see that there's a new NSF-funded institute that advertises work on this.

DB,
I don't see any point in arguing from anyone's human intuitions about what fundamental physics should look like or not look like at the deepest level, including whether it should be comprehensible to us, or beyond our comprehension. Those who look at the problem and are sure that engaging with it would be like a dog trying to learn GR should do something else. Personally there seem to me several things about the SM and GR which I don't understand, for which continuing to try and learn more about them may lead to something new, and I see possible ways forward that might work.

I'm in a good position to keep working on what I want to work on, unfortunately young people at this point are going to face overwhelming obstacles if they try and pursue this kind of fundamental theory. Instead they're encouraged to go to work in an AI institute training them to develop more powerful tools to further the goals of our new overlords. Even if we are all just dogs, better to howl at the moon…

28. **André**
August 29, 2020

Peter,
the arguments against knots as particles are strong and hold water. But related topological structures, maybe made of open strings, might be possible – of course again only in 3d.

To me it is astonishing that a string theory institution includes a knot theory group. Knot theory is only possible in 3d. Knots and strings are simply incompatible. Or is there a kind of open string theory derivate in 3d?

29. **Peter Woit**
August 29, 2020

André,
This isn't a string theory institution, it's an "AI and fundamental physics" institution. The theory of knots is very intricate and complicated, and you can easily generate lots of data, so it's plausible that AI techniques might be useful. The problem is that this has no connection to fundamental physics, and I don't see one even in the Northeastern PR material specifically about this.

If I had to guess, the supposed connection would be through some sort of extremely complicated constructions of possible "string vacua", where you manage somehow to use knots as one piece of the construction. I'd guess though that such constructions are of even less interest than the usual complicated constructions, but that doesn't mean they couldn't play a role in attracting NSF funding.

30. **Jean Tate**
August 30, 2020

As an extragalactic astronomer (optical, radio) I have some experience with AI and how it might help, perhaps even leading to learning something new about dark matter. Yes, it's certainly "sexy", but I think we're still very much learning that AI GIGO is real, and that a lot of work has yet to be done before autonomous cars stop killing jaywalkers (to stretch an analogy). Before AI unleashed on SKA datasets starts telling us marvelous things about dark matter and dark energy, perhaps AI could help with identifying consistencies, inconsistencies, myths, and even reproducibility issues in astrophysics and cosmology?

31. **Joseph Healy**
August 31, 2020

Jean Tate,
Autonomous vehicles are easy. Autonomous vehicles on the same road with humans, on the other hand, is hard because humans are infinite fonts of novel behavior which simply cannot be anticipated. Because of that, we are facing a couple of decades of random slaughter and mayhem while we catalog and suppress most of the edge cases we can't foresee. That may seem a steep price to pay but, to put it in perspective, it likely pales compared to the WMD-like prospect of aging baby boomers behind the wheel en masse over the same coming decades. Personally, I'll take my chances with autonomous vehicles so we better get the AI cracking on that front…

But AI advancing theoretical physics? Autonomous vehicles will be accident-free before that comes to pass.

32. **Jonathan**
September 1, 2020

It seems to me much of this work would be useful in advancing AI research, but not advancing fundamental physics research. With particle physics, we have a large amount of data that can be explained quite efficiently with a relatively small number of abstract rules. Current AI/machine learning research is able to build predictive models from large amounts of data, but isn't able to produce human comprehensible rules.

If you can understand how to build an AI able to go from raw LHC data to the Standard Model, that would be incredibly valuable from an AI perspective. If you apply current AI models to physics data you'd get a black box model which in the best case scenario would be able to reproduce the physics data, but provide little to no additional understanding.

33. **Chris Austin**
September 4, 2020

The comment above by Joseph Healy is an outrage. People have to be killed randomly by driverless cars, until driverless car programmers have anticipated "every situation" that can arise? Why not put in a set of semi-catchall control conditions, so that for example if a driverless car is confused about the situation ahead, or it's not clearly safe to proceed, and it's not a fast busy road, then the driverless car will slow down and stop? Why not require prototype driverless cars to go through an appropriate very lengthy period of testing with dual controls, so that a human supervisor inside a prototype driverless car can take control immediately, if the car starts to behave in a dangerous manner?

34. **Peter Woit**
September 4, 2020

Chris Austin,
I don't want to host a discussion of driverless car technology or of the social significance of AI here, but will use this as an excuse to use my control of the blog to editorialize.

Most of the AI advances I hear about don't seem to me to be doing anything to make the world a better place. In my city, there's no good reason for most people to own a car. What we need is good public transportation and taxis. I don't believe AI can anytime soon reliably drive a cab or bus around New York. Even if it could, I don't see how eliminating the professions of bus driver and cab driver are likely to make New York a better place.

35. **Lee Smolin**
September 4, 2020

Dear Peter,

I don't know if this is the reason that knots are mentioned in the announcement along side of strings, but it is worth mentioning that knot theory is fundamental to loop quantum gravity. The basis result of the field, proved by Rovelli and myself, is
that the gauge and spatially diffeomorphism invariant states are in one to one correspondence with diffeo classes of knots and graphs. Thus many basic steps to construct quantum gravity are problems in knot theory. One example of this is that the Jone's polynomial (Kauffman bracket) is a specification of a physical state of the gravitational

field, with a non-zero cosmological constant.

Meanwhile, Will Cunningham at PI has been using machine learning to get unprecedented results on the causal set approach to QG. He and I are also part of a collaboration of computer scientists and physicists developing applications of machine learning to problems in fundamental physics.

Thanks,

Lee Smolin

36. **isomorphismes**
October 8, 2020

Knots: It's not a bad thing if an area of real inquiry with the possibility of definite results gets a splash from the latest mania.

IAIFI: This sounds like science fiction. I could see data processing being useful in astronomy … how is it going to help *theory*?

Thanks for a very nice rep theory book, Dr. Woit. It took me a long time to be ready to appreciate it; now I'm very thankful to you.

Quantum Reality

September 2, 2020
Categories: Book Reviews

Jim Baggott's new book, [Quantum Reality](), is now out here in US, and I highly recommend it to anyone interested in the issues surrounding the interpretation of quantum mechanics. Starting next week I'll be teaching a course on quantum mechanics for mathematicians (more about this in a few days when I have a better idea how it's going to work). I'll be lecturing about the formalism, and for the topic of how this connects to physical reality I'll be referring the students to this new book (as well as Philip Ball's [Beyond Weird]()).

When I was first studying quantum mechanics in the early-mid 1970s, the main popular sources discussing interpretational issues were uniform triumphalist accounts of how physicists had struggled with these issues and finally ended up with the "Copenhagen interpretation" (which no one was sure exactly how to state, due to diversity of opinion among theorists and Bohr's obscurity of expression). Everyone now says that the reigning ideology of the time was "shut up and calculate", but that's not exactly what I remember. The Standard Model had just appeared, offering up a huge advance and a long list of new questions with powerful methods to attack them. In this context it was was hard to justify spending time worrying about the subtleties of what Copenhagen might have gotten wrong.

In recent decades things have changed completely, with the question of what's wrong with Copenhagen and how to do better getting a lot of attention. By now a huge and baffling literature about alternatives has accumulated, forming somewhat of a tower of Babel confronting anyone trying to learn more about the subject. Some popular accounts have dealt with this complexity by turning the subject into a morality play, with alternative interpretations portrayed as the Rebel Alliance fighting righteous battles against the Copenhagen Empire. Others accounts are pretty much propaganda for a particular alternative, be it Bohmian mechanics or a many-worlds interpretation.

Instead of something like this, Baggott provides a refreshingly sane and sensible survey of the subject, trying to get at the core of what is unsatisfying about the Copenhagen account, while explaining the high points of the many different alternatives that have been pursued. He doesn't have an ax to grind, sees the subject more as a "Game of Theories" in which one must navigate carefully, avoiding Scylla, Charybdis, and various calls from the Sirens. One thing which is driving this whole subject is the advent of new technologies that allow the experimental study of quantum coherence and decoherence, with great attention being paid as possible quantum computing technology has become the hottest and best-funded topic around. Whatever you think about Copenhagen, what Bohr and others characterized as inaccessible to experiment is now anything but that.

While one of my least favorite aspects of discussions of this subject is the various ways the terms "real" and "reality" get used, I have realized that one has to get over that when trying to follow people's arguments, since the terms have become standard sign-posts. What's at issue here are fundamental questions about physical science and reality, including the question of what the words "real" and "reality" might mean. In *Quantum Reality*, Baggott provides a well-informed, reliable and enlightening tour of the increasingly complex and contentious terrain of arguments over what our best fundamental theory is telling us about what is physically "real".

Update: For a much better and more detailed review of the book, Sabine Hossenfelder's is [here]().

Comments

1. **Matt Grayson**
   September 3, 2020

   I have just started reading Quantum Reality, and I'm grateful for the sensible definitions of "reality", a term I've always hated, but one thing confuses me still.

   How can anyone contemplate Netwonian mechanics and see "smooth continuities and merciless certainties"? Imagine two balls colliding. At the moment of collision there is infinite acceleration. Not large, infinite. Make the balls spongy? Still infinite where they first touch. The only way I can see to avoid infinities is for the balls to interpenetrate – overlap – and then gradually, if very quickly, rebound.

   And yet we have no worries about the interpretation of Newtonian mechanics. We say "clockwork" as if that explains anything. It is truly a theory of "shut up and calculate".

2. **Thomas**
   September 3, 2020

   I don't know .. it seems to me that the added value of yet another popular book on the foundations of QM is approaching zero exponentially fast. Why not write a book on progress in quantum technology and engineering?

3. **Peter Woit**
   September 3, 2020

   Matt Grayson,
   It has always seemed to me that the classical picture of the world is far more incoherent, inconsistent, and hard to make sense of than the quantum one.

   Thomas,
   I disagree, since while there have been lots of such books recently, mostly they have been of either little value, or seriously negative value, with the amount of attention they get often proportional to how misleading they are. Philip Ball's is the only other recent one that I think gets things right, having another one written in a somewhat different way I think is quite valuable.

   I won't disagree that a good new book on quantum technology would be great, and advances in this technology I think will ultimately help clarify interpretational issues. Baggott has some interesting material on this, in particular about implications of quantum computer designs for the preferred basis problem in many-worlds theory.

4. **Terry Jenkins**
   September 3, 2020

   Dear Peter,

   You write, " Whatever you think about Copenhagen, what Bohr and others characterized as inaccessible to experiment is now anything but that."

   Extraordinary claims require extraordinary evidence, but as you are quite busy, perhaps we could get just an example or two, or even a reference?

   Thanks in advance.

5. **Peter Woit**

September 3, 2020

Terry Jenkins,

What I was referring to was for instance one of the main issues in developing a quantum computer: how do you keep qubits from decohering, while at the same time being able to manipulate them to do computations? This is currently under intensive experimental and theoretical study, though you'll have to find someone more expert than me for good references on the state of the art.

The fact that such study was impossible in the early days of QM I think had a lot to do with the early Copenhagen insistence that one needed to treat the classical and quantum in completely different ways.

6. **Mark**
September 3, 2020

I think this might be a good reference on one approach to quantum computing:

Robust encoding of a qubit in a molecule
Victor V. Albert,1,2 Jacob P. Covey,1 and John Preskill1,2
Institute for Quantum Information and Matter1 and Walter Burke Institute for Theoretical Physics2 California Institute of Technology, Pasadena CA 91125, USA
(Dated: November 20, 2019)

https://arxiv.org/pdf/1911.00099.pdf

7. **Peter Woit**
September 3, 2020

Mark,
That's more of an alternate proposal for a quantum system to encode qubits, doesn't really address the transition to classical question.

For something closer to what I had in mind, see the Nobel citation for Haroche/Wineland
http://www.nobelprize.org/prizes/physics/2012/press-release/
and the textbook "Exploring the Quantum" by Haroche/Raimond.
The Physics Today review of that book
https://physicstoday.scitation.org/doi/full/10.1063/1.2774103
starts out

In 1952 Erwin Schrödinger wrote in the British Journal of the Philosophy of Science , "We never experiment with just one electron or atom or (small) molecule. In thought-experiments we sometimes assume that we do; this invariably entails ridiculous consequences."

which shows the very different situation the first generation of quantum theorists faced when thinking about the measurement problem.

8. **Mark**
September 3, 2020

Peter,

Thanks, I have read the book Exploring the Quantum, and highly recommend it. Forty years ago when I read Zurek & Wheelers: Quantum Theory and Measurement, I thought to myself that this will all be resolved in the next few decades with advancing technology. But that does not seem to have been the case. Not sure if the "measurement" problem is a real physics problem or simply one of those philosophical problems that never get resolved.

9. **Michael Weiss**
September 3, 2020

Peter and Matt,
With regard to QM being more sensible than classical mechanics, you may remember the late Ed Purcell's light-hearted remark when we were undergraduates that it made as much or more sense to speak of a "quantum certainty principle" than of the standard "uncertainty principle." Ed was referring to the implausibility of classical mechanic's infinite precision; he might also have had in mind Matt's point about infinite accelerations in hard-sphere collisions. Ed's quip reflected his always-deep insight. John Preskill was Ed's TA in intro QM in 1975 ("Physics 143") and might have more insight.

10. **Mark Hillery**
September 3, 2020

For something a lot more technical, and very recent, that summarizes several different approaches to obtaining a classical world out of quantum rules, I recommend "Roads to objectivity: Quantum Darwinism, Spectrum Broadcast Structures, and Strong quantum Darwinism" by J. K. Korbicz arXiv:2007.04276.

11. **Low Math, Meekly Interacting**
September 4, 2020

I'm probably getting this partially wrong…I donated most of my old pop-sci books a long time ago. Anyway, I think it was in "Dreams of a Final Theory". Weinberg recounted a colleague's rueful explanation for a promising student's eventual failure: He tried to understand quantum mechanics. The larger point, I think, was Weinberg sympathized with this point of view. However, despite his distaste for philosophy, he saw the unavoidable need. Otherwise, one could never truly understand cosmology; and perhaps a "final theory" would remain forever out of reach until QM was, in fact, "understood".

I don't recall if Weinberg had the measurement problem in mind specifically, or something else. Anyway, that book is about 30 years old now. My sense is one could pick it up today and find an essentially contemporary summary of the outstanding issue(s), i.e. troubling and completely unresolved. Every new pop-sci article I read these days on "foundations", a new experimental result is hyped as if it sheds some incredible new light. But you read past the click-bait and it turns out the results agree as precisely as one can measure with QM as currently formulated. The results don't actually resolve any interpretational issues, despite sometimes weaselly, or even borderline dishonest language suggesting the contrary. It's wonderful that these experiments may be pushing us ever closer to a veritable and practical quantum computer, etc., but I do scratch my head at the notion foundational progress is being made. To use a variant of the deadly word: Really? I'll likely purchase this book, just because it's been a while since I've read anything book-length for fun. But I bet I'll still feel disappointed.

12. **Peter Woit**
September 4, 2020

LMMI,
Weinberg has continued to be concerned about whether interpretational problems mean we are missing something fundamental about QM, writing about this in 2017 in the New York Review of Books. He has pursued some ideas about introducing non-linearities in the theory, but I think concluded they don't work.

Unlike Weinberg, my point of view on this has always been that it's not quantum mechanics we don't understand, it's classical mechanics (i.e. how our classical reality emerges from a fundamental quantum theory). The quantum mechanical formalism is simple, of great mathematical beauty, and completely successful experimentally. What's hard to understand is not that story, but why the classical picture works as a way to describe our everyday experience of reality.

I don't think there's the slightest reason to believe that new more powerful experimental techniques will see a violation of the laws of quantum mechanics. What they can do though is help understand the really difficult and complicated problem of classical emergence. The paper Mark Hillery points to is a good example showing the kinds of questions that one can now experimentally study to learn more about this, experiments of a kind that Bohr and his generation could not seriously consider.

13. **Matt Grayson**
September 4, 2020

Peter,
"Everyday experience of reality" is, IMHO, the elephant in the room. I frequently compare our perception of Nature with a flatworm's experience at the Opera (borrowed from Vernor Vinge). There's no reason at all that Nature should be in the tiniest bit comprehensible to flatworms or to us. Nor need our experience meaningfully reflect it. This means giving up on the "thing-in-itself" problem – e.g., reality of the wave function or the aether – but it does not in any way mean that we should give up on science, nor fail to visit both metaphysical and empirical shores.

14. **WTW**
September 5, 2020

Peter,
When you said
"…the advent of new technologies that allow the experimental study of quantum coherence and decoherence, with great attention being paid as possible quantum computing technology has become the hottest and best-funded topic around. Whatever you think about Copenhagen, what Bohr and others characterized as inaccessible to experiment is now anything but that…"
I thought that you were referring to the now commonplace practice in quantum experiments to infer the values of observables without causing the "collapse of the wave function" — e.g., preserving coherence of separated systems even during "weak" measurements.

Similarly, "using single electrons [or photons] as observers" is precisely what recent experiments claim to be doing. Yet most philosophers of quantum mechanics seem to want to ignore such topics, and few theorists seem to want to deal directly with the results of those experiments.

In terms of understanding "quantum reality", Nature seems to want to continually throw up roadblocks in our path. See, for example, the issues related to "quantum pigeon hole" experiments,
https://www.pnas.org/content/116/5/1549
and see
https://www.sciencemag.org/news/2020/08/quantum-paradox-points-shaky-foundations-reality
also at
https://www.nature.com/articles/s41567-020-0990-x and
https://arxiv.org/pdf/1907.05607.pdf

Then there's "Closing the superdeterminism loophole
in Bell's theorem" at
http://philsci-archive.pitt.edu/16203/1/Bell%20free%20will%202019.pdf
all more grist for the mill/food for thought.

15. **Jim Baggott**
September 5, 2020

Matt,
If you're currently reading 'Quantum Reality' then you'll be discovering – spoiler alert – that I'm sympathetic to the Kantian position of giving up on acquiring knowledge of 'things-in-themselves' beyond the basic assumption that, whatever 'they' are, they continue to exist when we're not looking. This is why it's so fundamentally important in my view to try as much as possible to distinguish our (metaphysical) ideas about reality from our (empirical) experience of it.
But this is the nature of the Game we play: we blend our ideas and experience in a scientific theory and the extent of correspondence between theory and experience allows us to judge its relative success. After studying both anti-realist and realist interpretations of QM for 30 years or so, I've developed a very bad feeling about it.

LMMI,
In 'Dreams of Final Theory' Weinberg wrote: 'A final theory will be final in only one sense – that it will bring an end to a certain sort of science, the ancient search for those principles that cannot be explained by deeper principles'. I understand this to mean that, for Weinberg, finality implies futility. With the deepest possible principles in hand, there's little sense in seeking a deeper scientific understanding. We are then left with philosophical questions, for which good arguments can be formulated, this way and that, but for which lack of empirical evidence will mean that any kind of resolution or consensus on the answers will remain forever elusive. If indeed quantum mechanics is science's final word on the physics of quantum objects, then foundational questions can only ever be philosophical questions. Just don't expect physicists with more realist preconceptions to agree with this anytime soon.

Peter,
I barely touch on it in 'Quantum Reality', but anyone broadly comfortable with the notion that QM is no more than a convenient (but extraordinarily powerful) way of connecting our experiences of quantum physics will be interested to explore what this means for classical mechanics. The simple answer is of course that precisely the same interpretation can be given to classical mechanics. Instead of the debating the reality of the 'wavefunction' we debate the reality of classical concepts such as space, time, energy, mass, momentum. The fact that we can 'see' objects moving through space, in time shouldn't prevent us from realising that there's still a big difference between the 'objects in reality' and our scientific representations of them. There's no arguing with the utility of assuming that something like mass is a real physical property of a real physical thing, but I think it helps if we don't lose sight of the fact that this is still a (metaphysical) assumption.

16. **Kevin S Van Horn**
September 5, 2020

> "I don't think there's the slightest reason to believe that new more powerful experimental techniques will see a violation of the laws of quantum mechanics. What they can do though is help understand the really difficult and complicated problem of classical emergence."

You're sounding a lot like an Everettian there; those two sentences would be at home in David Wallace's book *The Emergent Multiverse*. It makes me wonder if there's really all that much difference between your positions. I guess it comes down to wave-function collapse: do you think that's an actual, fundamental physical phenomenon, or some sort of emergent phenomenon?

17. **Alessandro Strumia**
September 5, 2020

The unsatisfactory aspect (at least to me) of Copenhagen QM is that it's probabilistic. This is the root of all debates about wave-function ontology. Physical progress would be understanding how randomness arises. But we don't have sensible deterministic theories that reproduce quantum randomness in some limit, so we don't know where we should search. Maybe it's some fast high-energy dynamics, and low-energy experiments are irrelevant. For sure, neither the papers by Weinberg nor experiments about decoherence address this issue.

18. **More Anonymous**
September 6, 2020

Hey Peter,

"my point of view on this has always been that it's not quantum mechanics we don't understand, it's classical mechanics (i.e. how our classical reality emerges from a fundamental quantum theory)" … It's obvious to me that classical mechanics emerges in the limit of some parameter. Do we know what this parameter is though?
I was under the impression that it would be the thermodynamic limit but I don't know of any heursitic argument that suggests the same. Is there any in the literature?

19. **Peter Shor**
September 6, 2020

Kevin S Van Horn:

I don't see why you think Peter Woit's belief that these issues are not going to be settled experimentally has anything to do with belief in the Everett interpretation.

There are two possibilities here:
• There is some way of predicting which of the outcomes that quantum theory says are random will be realized, at least with better accuracy than quantum mechanics gives.
• There is no way of predicting these outcomes more accurately than quantum mechanics.

If the first case holds, it means that the myriads of quantum mechanical experiments we have done just happened to have their experimental set-up completely orthogonal to the means of predicting the outcomes, as otherwise we would have observed probabilities that are not in accordance with quantum mechanics.

And the second case holds if you believe in any of the standard interpretations of quantum mechanics — wave function collapse, pilot waves, or many-worlds.

So I would agree with Peter that the first case is extremely unlikely.
(Of course, we believe that QFT is incompatible with GR, so something may happen at very high energies. In this case, it may still be impossible to settle the situation experimentally, as we are not going to build particle accelerators the size of galaxies.)

20. **Peter Woit**
September 6, 2020

More Anonymous,
It's not at all obvious that classical mechanics emerges as a limit of a parameter. For an interesting read, see this blog posting by Jess Riedel
https://blog.jessriedel.com/2015/03/24/how-to-think-about-quantum-mechanics-part-4-quantum-indeterminism-as-an-anomaly/
One simple point he makes is that
"The most glaring problem is that the state spaces of classical and quantum mechanics are completely different, so you can't have a simple limiting procedure unless you describe how you're going to map one onto the other. "

21. **Peter Woit**
September 6, 2020

Alessandro Strumia (and Kevin van Horn),
Yes, I agree that's the most unsatisfactory aspect of QM, especially in the Copenhagen interpretation where you make Born's rule a fundamental axiom. I take Copenhagen to say that you can in principle analyze an experimental setup purely using Schrodinger's equation, with no probability (except that in practice, your description of the initial state is always as a mixed state), but as you try and push your description to the point where it would capture our notion of "I measured X and got result Y", at some point you're going to have to give up on Schrodinger, introduce a "Copenhagen cut", and use Born's rule.

The only substantial Copenhagen/Everettian difference I see is that the Everettian's try to get rid of the Copenhagen cut, finding a way of understanding "I measured X and got Y" in a context purely governed by the Schrodinger equation. I'm an Everettian to the extent I think it's reasonable to expect this is possible. But what I see happening when people go down this path is one of two things
1. Serious, very interesting and difficult research about the emergence of classicality and well-defined outcomes (see for example the paper Mark Hillery pointed to).
2. Just ignoring the problem or waving it away as essentially solved, and claiming silly things like invoking a multiverse solves the problem. This is the usual multiverse situation: theorists without a viable theory claiming that an empty idea solves their problems.

I'm sorry to see that 2. gets a lot more public attention than 1.

22. **Kevin S. Van Horn**
September 6, 2020

Peter Shor:

This is the relevant part: "the really difficult and complicated problem of classical emergence." Wallace's book is all about investigating how the classical world can emerge from QM, without assuming the problematic wave-function collapse.

23. **Thomas**
September 7, 2020

In the mean time I did read (most of) Baggott's book, and I have not really changed my mind regarding its merits. Some years ago I read Becker's book, which is indeed annoying in its emphasis on the struggle between the quantum dissidents against the evil Copenhagen empire. However, the book was interesting because it contained many historical tidbits that are not well known in the physics community. Bagott's book may be more sensible, but there is just absolutely nothing new or interesting here. And regarding him being more sensible, how about this about the Everett interpretation: "The ship of science is hurtling towards .. a dangerous whirlpool of metaphysical nonsense about the nature of reality" (this is about Everett, DeWitt and Wheeler, not Everett channeled by Tegmark).

24. **André**
September 7, 2020

@ Peter Woit: "… my point of view on this has always been that it's not quantum mechanics we don't understand, it's classical mechanics…"

I think this distinction is a bit mute. We understand both just fine, it is the connection of the two that is the problem. Would you say, for instance, that Boltzmann's contribution to understand the emergence of thermodynamics from statistical mechanics improved upon our understanding of thermodynamics or of (stochastic) classical mechanics? I would argue that it was neither.

The relevant question is, if the emergence of classicality can be understood on the basis of only quantum mechanics as it stands today (as in the case of thermodynamics from stochastic mechanics) or if there is some ingredient missing, something one would need to modify about quantum mechanics.

I understand your preference for the first possibility, although I don't think that the solution can come out of nonrelativistic (Schrödinger equation) quantum mechanics. But maybe there is a way to keep all of the nice mathematical structures (e.g. connections with group theory) and still understand the emergence of classicality, for instance, once gravity is properly included.

If, however, you opt for the second possibility, then it should be out of question that the missing ingredient, the required change must be something on the quantum theory side. I don't see a way how you can explain away the difficulties in the foundations of quantum mechanics by somehow modifying classical mechanics (in a way that would still be compatible with observations).

Hence, in this sense I would argue against your point, and would say that the problem with our understanding is with quantum physics and not with the properties of its classical limit. But my impression is, what you actually have in mind is a derivation in a similar sense as Boltzmann's work?

@ Alessandro Strumia: "But we don't have sensible deterministic theories that reproduce quantum randomness in some limit, so we don't know where we should search."

Although I am not a big fan of Bohmian mechanics for other reasons, I would argue that it does give a satisfactory explanation on this issue, with the Born rule following as a corollary and the randomness coming entirely from the initial conditions, just like in stochastic classical mechanics.

I agree with your feeling, that this is the most unsatisfactory aspect, and I hold a strong belief that the solution must be somewhere along those lines, that the stochasticity ultimately stems from the initial state of the universe, in some sense.

25. **peter hoffman**
September 7, 2020

Question for Peter Woit:
Does your phrase "Others' accounts are pretty much propaganda for … a many-worlds interpretation" apply to David Wallace's book? Or similarly does Baggott's "… a dangerous whirlpool of metaphysical nonsense about the nature of reality" ?
If not, indeed in any case, it would be interesting to hear more concrete criticisms of that book now, so we needn't wait for when your notes on this general question become available.
That book is at least far more (mathematically) detailed than anything either Baggott or Ball has ever written as far as I know. So it is open for no end of specific criticism.

26. **Peter Woit**
September 7, 2020

peter hoffman,
My reference to "propaganda" was to "popular accounts" (of which Wallace is not one), and for more about what I had in mind (and lots more discussion of "many-worlds" and Wallace) see here
https://www.math.columbia.edu/~woit/wordpress/?p=11128

I don't want to here start up again a serious discussion of Wallace and many-worlds, that's both a different topic than Baggott's book and I don't think renewing the old discussion is going to lead to anything new. If you don't want to read all the old stuff, the short version of my view of Wallace's book and its attempt to argue based not on physics but on decision theory, is that it seems to me to not deal at all with the real problem (the difficult physics of the emergence of classicality). Put more bluntly, I don't believe at all that it's possible to solve deep problems about physical reality using the methods of social science.

27. **Nick Herbert**
September 8, 2020

In 1984, a book on quantum foundations with the same name as Baggott's was published by Doubleday, sold close to 100,000 copies and is still in print. I know this because I am still receiving royalties from that book.

28. **Bob**
September 9, 2020

Similarly, there are many books out there titled "Quantum Mechanics", "Quantum Field Theory" or "General Relativity", etc.

29. **Robert A. Wilson**
September 13, 2020

On the strength of this review, I bought a copy of Jim Baggott's book. Once I started reading it, I found it almost impossible to put down. Very clear, well-organised, wide-ranging, balanced, exactly what a well-educated non-expert requires. It steers me back towards Copenhagen, balancing my tendency to take too much notice of Einstein.

30. **Will Sawin**
September 29, 2020

@Peter Woit: In the quest to understand how the classical emerges from the quantum, one could begin by setting some ground rules. Presumably some of the most fundamental questions are?

(1) Does the quantum wave function exist? (in some objectively real sense)
(2) Does anything except for the quantum wave function exist? (except by supervening on the quantum wave function)
(3) Does the quantum wave function evolve under a souped-up, generalized form of Schrödinger's equation? (and not some different evolution law.)

I think it's reasonable to answer "yes" to all these questions and proceed to understand how classical theories can emerge from that.

Subjective theories of the wave function would be the prototypical rejectors of (1) (in addition to QM denialists, I guess), Bohmian mechanics is the prototypical rejector of (2), and objective collapse theories are the prototypical rejectors of (3).

If you answer "yes" to all three, the existence of many worlds is the first, most basic, corollary. It's immediate that you can only hope to derive a theory of multiple, branching classical worlds, with a probability measure assigned to each.

I agree that it is silly to take this trivial observation and then claim that you have completely solved the difficult problem of classical emergence.

I also think it is strange to accept the premises and rush off into attacking this difficult problem using lots of math without acknowledging the elementary point that there are many worlds.

31. **Peter Woit**
September 29, 2020

Hi Will,
My problem is with 1, I think it's meaningless and does nothing but obfuscate the fundamental problem.

Personally I'm not rushing off trying to solve the problem of classical emergence,I can see why it's extremely difficult and not something I have the energy or competence to make any progress on. If someone has a promising idea, that's great and should be encouraged. As for those who think the reality of multiple worlds is some sort of insight needed to move forward, this proposal is now as ancient as I am (I was born in 1957, same year as Everett's publication), and in a long career I've seen little worthwhile coming from it. Worse, in the last two decades I've seen a huge amount of damage to the field of fundamental physical theory from bogus claims that a many worlds ontology solves one important problem or another. I've seen such claims do a good job of selling books and convincing people not to work on important problems, seen none that they further any real science.

32. **Will Sawin**
September 30, 2020

Hi Peter,

Thanks for allowing us to discuss quantum interpretations in your comments section, even though it can get silly and repetitive.

I don't think many worlds is necessarily an insight needed to move forward. It's like, the fact that rocks on the moon are grey in color is not really a big insight into lunar geology, and is not really needed to move forward in any research direction for studying the moon. But it would still be strange to study moon rocks and steadfastly refuse to ever let slip that they are grey.

I admit, though, that it's possible that saying that there exist multiple worlds has a poisonous effect on many people's minds that impedes scientific progress. You would certainly know more about this than me.

How is anyone going to derive the classical from the quantum if they don't first accept that the quantum state exists? Is the plan to describe how something that exists emerges from something that doesn't exist?

To me, the blog post you linked, and the paper that Mark linked, and the other paper you linked in a previous discussion from this, all look like they are starting from the assumption that a quantum state, possibly though not necessarily a pure quantum state, exists as a real physical object, and then describing why that object would "appear" in some sense to have classical behavior. If to you they look like an alternative to doing that, then probably that points the way to a more fundamental disagreement.

33. **Peter Woit**
October 1, 2020

Will,
My problem here is that I don't believe the statements "the quantum state exists" or "many-worlds exist" have any substantive meaning. As such, in practice such statements shed no light on anything, and, when coupled with bogus claims that such statements solve significant problems (see e.g. Sean Carroll's recent book) can be seriously counter-productive.

I'm perhaps over-sensitive to this because of the huge damage done to HEP theory by similar claims about a supposed cosmological multiverse. I wrote specifically about that in the short essay "Theorists without a Theory", but much the same argument applies to the QM case. People are claiming to have solved a deep problem with an untestable idea, and if you look into it you realize that the source of the untestability is that there is no actual theory there. Their idea provides nothing substantive that addresses the problem at hand.

34. **John Baez**
October 1, 2020

Will Sawin wrote:

From the rest of what you said, I believe you think it's reasonable to answer "no" to question (2). Or did I misunderstand?

If someone answers "yes" to question (2), my followup question is "what?"

35. **Will Sawin**
October 2, 2020

Peter,

If you're not prepared to assert the quantum state exists, what does exist? Do electrons exist? Do Higgs bosons exist? Do I exist?

You can deny that something like, say, the sun, exists, but believe that every other observable phenomenon behaves as if there were a miasma of incandescent plasma in the sky illuminating everything half the time. If so, then someone telling you that the sun exists wouldn't really shed any light on anything. But, I mean, the sun exists, and the sun is made mainly of quarks, so quarks exist, and quarks are excitations in the state of certain quantum fields, so that state exists.

To me it's simpler to take the best, most mathematically elegant theory of the universe, and accept that whatever structures it describes exist, no matter how silly they sound.

I really don’t think the analogy between many world and the multiverse is that good. One proposal has the problem that there is no good notion of measure, the other we know roughly which notion of measure to use. One has the problem that it makes no predictions, except sometimes you can get it to make predictions that contradict our observations, while the other predicts our observations beautifully, with the only drawback that the exact same predictions are also made by a different, worse, theory that was discovered earlier because of a failure of bravery and imagination (and maybe an attachment to subjectivity).

36. **Peter Woit**
October 3, 2020

Will,
I don’t disagree with your comments about the use of the word “exist”, I just think they’re irrelevant to the problem. The situation seems not that different to me than arguing that whether or not prime numbers “exist” is relevant and important to understanding the problem posed by the Riemann hypothesis.

37. **Will Sawin**
October 7, 2020

Peter,

I mean, the Riemann hypothesis is a very interesting problem, but it’s a problem of mathematics, not physics. If prime numbers existed in the physical world in some clear sense, then the Riemann hypothesis might be considered a physical problem.

If this problem of “how does the classical emerge from the quantum” is supposed to be considered a physics problem, then presumably some component of the problem has to be something that really physically exists or a reasonable approximation of something that exists. I think one can argue that if anything in the setup exists, it has to be the quantum state, and that any attempt to argue that the quantum state is an approximation to something else that doesn’t lead to “many worlds” conclusions is untenable.

So I don’t think you need to claim that quantum states exist to solve the problem. But at some point you need to justify why you are working on this problem and not, say, relaxing on the beach. I think “I am trying to understand what everything in the universe is made of” is a compelling answer to that.

AMS Open Math Notes

September 6, 2020
Categories: Uncategorized

The AMS for the last few years has had a valuable project called AMS Open Math Notes, a site to gather and make available course notes for math classes, documents of the sort that people sometimes make available on their websites. This provides a great place to go to look for worthwhile notes of this kind (many of them are of very high quality), as well as ensuring their availability for the future. They have an advisory board that evaluates whether submitted notes are suitable.

A couple months ago I submitted the course notes I wrote up this past semester for my Fourier Analysis class, and I'm pleased that they were accepted and are now available here at the AMS site (and will remain also available from my website).

Comments

1. **Swol**
   September 6, 2020

   The idea of the AMS Open Math Notes is cool, but it is unfortunately very much not "Notes" or "Open".

   It is not "Open" in the sense that their reCAPTCHA (the thing that's checking to see whether you're a robot) doesn't work. It isn't "Notes" either because, for one particular entry (and maybe for more, haven't checked) you get a message "This book is now available for purchase at the AMS Bookstore." and no access to a pdf!

2. **Peter Woit**
   September 6, 2020

   Swol,
   I haven't had any trouble with their reCAPTCHA thing, or run into an example of something they had shifted to a book they publish and sell. It is worth noting that their traditional business model for how to finance the AMS is to get a lot of their revenue from selling books and journal subscriptions, so unless they come up with a new revenue source they're not likely to give that up.

3. **ArshadM**
   September 28, 2020

   I'm not sure who the target market is for this initiative, I am guessing it's fellow lecturers that can borrow and enhance. As a self-study student, these kinds of notes are not very helpful without problem sets and solutions (I don't mind paying a little bit for the solutions and that could be a source of revenue for the AMS/Author).

Fall Quantum Mechanics Class

September 7, 2020
Categories: Quantum Mechanics

I'll be teaching a course on quantum mechanics this year here at Columbia, from a point of view aimed somewhat at mathematicians, emphasizing the role of Lie groups and their representations. For more details, the course webpage is here.

The course is being taught online using Zoom, with 37 students now enrolled. I've set things up in my office to try and teach using the blackboard there, and will be interacting with the students mostly via Zoom. As an experiment, I've also set up a Youtube channel. If all goes well you should be able to find a livestream of the class there while it's happening, which is scheduled for 4:10-5:25 Tuesdays and Thursdays, starting tomorrow, September 8. I'll also try and make sure the recorded livestreams get uploaded and saved at this playlist. Unfortunately I won't be able to interact with people watching on Youtube, should have my hands full trying to get to know the students enrolled here in the course, with only this virtual connection.

Comments

1. **David Appell**
   September 7, 2020

   Peter, making your course widely available is really good of you. Thanks.

2. **Jeff Berkowitz**
   September 7, 2020

   Hello Peter. The link from your syllabus to John Preskill's lecture notes on quantum computation (http://www.theory.caltech.edu/people/preskill/ph229) is giving me Caltech's 404 page, both with and without the #lecture anchor.

3. **Blake Stacey**
   September 7, 2020

   I taught graduate statistical physics via Zoom back in the spring. It's definitely a different experience than lecturing live, with a lot less feedback. With the students on mute, you of course don't get the laughs at little jokes, and because everyone is visible in tiny boxes if at all, body language is much harder to read. It can feel like speaking into a void. But I still got reasonable questions in the video chats and by e-mail, the performance on problem sets and the midterm was in line with my expectations, and the final presentations that the students gave went well.

   Good luck!

4. **Anish**
   September 8, 2020

   Interacting with students is quite challenging in this remote setting. I suggest having a shared Google Doc between you and your students where students can give their feedback and ask questions increasing interaction in students themselves and Zoom chat is not really that easy to navigate. Furthermore, A YouTube channel named 3blue1Brown, which just started doing some live streaming, published an article with some tips for remote lessons like live quizzing, etc that you may find useful to integrate in your system. (https://www.3blue1brown.com/blog/livestream-setup). Thanks for making the lectures public.

5. **E K Shaji**
   September 8, 2020

   That's really cool, but can you also try to make your PSets/Assignments widely available?

6. **Michael Ball**
   September 8, 2020

   You should check out Richard Borcherd's Youtube channel. At the moment it has great content for undergrads. Definitely worth keeping an eye on (sorry if I posted this comment twice!)

7. **cyd**
   September 8, 2020

   Use a visualizer. The quality is much better than with a blackboard, unless you have a seriously good camera and audio equipment. They're going for $100 on Amazon.

8. **Peter Woit**
   September 8, 2020

   Jeff Berkowitz,
   Thanks. Fixed.

   E.K. Shaji,

   The assignments will be pretty much the ones in the book, although I may be revising those and adding some more. They're listed on the course page
   https://www.math.columbia.edu/%7Ewoit/QM/fall2020.html

9. **I**
   September 8, 2020

   Peter, will you be placing solutions to problems on your web page for those watching on Youtube?

10. **Peter Woit**
    September 8, 2020

    I,

No, I won't be making solutions to the problems available. Having solutions to problems available makes people less likely to engage with the whole point of such things. What's important is not solving a problem, it's what you learn by struggling with understanding how to solve the problem.

11. **I**
September 8, 2020

Peter,
Doesn't putting the solutions up a few weeks after each problem set have the same benefits? Plus the students get feedback on whether they're right. Alternatively, you could stream lectures where you go over the problems afterwards.

12. **Robert A. Wilson**
September 9, 2020

Michael Ball,
Richard's name is Borcherds, not Borcherd.

13. **Peter Woit**
September 9, 2020

I,
I generally go over some of the problems that students have had trouble with in class, likely will also do that this year, so that would be on the videos. The "give solutions to the students after the problems are due" model only works if everyone is doing the problems with the same due date, and the solutions don't become public. I hope lots of people are reading the book, and now watching the lectures, at very different times, and best for all of them if they struggle through the problems.

Something one doesn't appreciate as a student typically is that it's quite hard to come up with good problems at the right level. The problems in the book took a lot of effort to come up with, and they are not that great, could use a lot more work to improve them and come up with more. I hope to do some of that this year, but it's a task I find difficult and not rewarding (even though it really is important for the students).

14. **Michael Ball**
September 9, 2020

Robert A. Wilson

Noted

15. **Bill93**
September 9, 2020

Thanks for making available. Zoom screen sharing could let you display PowerPoint or other visuals prepared in advance and might let the discussion flow more smoothly, avoiding delays while something gets written on the chalkboard. Also, not pushing for speed and thus avoiding false starts might result in a similar overall pace.

16. **Peter Woit**
September 9, 2020

Bill93,
Thanks for the comments/suggestions, that's helpful.

I should probably make much more explicit the relation of what I'm doing in class to the book. For most of the lectures, essentially I'll be going over one chapter of the book, but what I'm not trying to do is give a polished lecture covering everything in that chapter. Instead the idea is to try and emphasize the main ideas, go over confusing points carefully, encourage students to stop me with questions and have lots of time for them.

I could in principle screen share the page of the book corresponding to what I'm talking about. What would really be ideal is if students try reading the chapter beforehand, mark it up with their questions, then during the lecture stop me if their question is not clarified by what I say when I get to that point (sorry to those of you on Youtube who can't ask questions. If people email me questions before the lecture I may or may not be able to say something about them during the lecture).

17. **pmcs**
September 9, 2020

Hi Peter,

I look forward to the rest of this series. One slight issue: when I try to save the first video to watch later, Youtube tells me that this is forbidden since "This action is turned off for content that is made for children."

Do you happen to know how this might be overcome?

18. **Peter Woit**
September 10, 2020

pmcs,
Thanks for pointing this out. That should be fixed now. I had selected a "for kids" option, thinking that meant "all right for kids" (why shouldn't kids be learning about unitary Lie algebra representations?). Instead it meant "intended for kids", which is different.

19. **Tobin Fricke**
September 26, 2020

Students of this class might also enjoy A. Zee's book titled "Group Theory in a Nutshell for Physicists." It's an excellent tour of the Lie groups and why we care about them; kind of a much more fleshed-out and beginner-friendly version of Georgi's famous "Lie Algebras in Particle Physics."

Another nice resource is Frederic P Schuller's "Lectures on the Geometric Anatomy of Theoretical Physics" on YouTube, which is a sort of grand tour of the relevant mathematical structures starting with the definition of sets, topology, fields, groups, etc. He has a shorter "winter school" version that also includes some exercises.

Thanks for making your lectures and text available here – I've enjoyed the first several lectures and hope to continue!

Quick Links

September 10, 2020
Categories: Uncategorized

A few quick links:

- I was sorry to hear of the recent death of Vaughan Jones. A few things about his life and work have started to appear, see here, here and here.
- For a wonderful in-depth article about the life of Michael Atiyah written by Nigel Hitchin, see here.
- There are now many new places where you can find talks about math and physics to listen to. For instance, just for math and just at Harvard, there is a series of Harvard Math Literature talks and Dennis Gaitsgory's geometric Langlands office hours.
- Breakthrough Prizes were announced today. There's an argument to be made that the best policy is to ignore them. Weinberg has another 3 million dollars.
- For an interview with Avi Loeb about why physics is stuck, see here.
- For an explanation from John Preskill of why quantum computing is hard (which I'd claim has to do with why the measurement problem is hard), see here.

Update: Last night I watched The Social Dilemma on Netflix, which included some segments with my friend Cathy O'Neil (AKA Mathbabe). Highly recommended, best of the things I've read or watched that try and come to grips with the nature of the horror irresponsibly unleashed by Mark Zuckerberg and Facebook in the form of the AI driven News Feed. Comparing to a documentary about Oxycontin from a while back, the effects of the News Feed are arguably more damaging. I'm wondering why the Oxycontin-funded Sackler family donations to cultural organizations and universities have been heavily criticized, unlike the News Feed-funded Zuckerberg/Milner donations to scientists.

Update: Alain Connes has written a short appreciation of Vaughan Jones and his work here.

Update: For another article about Vaughan Jones well-worth reading, see Davide Castelvecchi at Nature.

   September 10, 2020

   Peter Woit wrote:
   "Breakthrough Prizes were announced today. There's an argument to be made that the best policy is to ignore them. "

   Well the "Breakthrough Prize in mathematics" is actually for a serious work in mathematical physics:

   https://www.imperial.ac.uk/news/203853/imperial-mathematician-scoops-3m-breakthrough-prize/

   Professor Hairer is recognised "for transformative contributions to the theory of stochastic analysis, particularly the theory of regularity structures in stochastic partial differential equations."

   When you look on the work for which the prize was given

   https://arxiv.org/abs/1303.5113

   then you see that it threats the stochastic quantization (a mathematical version of quantization that works by converting a classical system into a stochastic pde) and the renormalization of phi^4 theory.

   As the author writes:
   "One major difference between the results presented in this article and most of the literature on quantum field theory is that the approach explored here is truly non-perturbative"

   It is always important if someone invents mathematically rigorous methods for threating quantum field theories non-perturbatively, because more difficult systems like qcd and gravity display intense self interactions where such methods could be helpful.

   I therefore would say that the prize for this work is well deserved.

   The paper should be read, especially by mathematical physicists and high energy theorists.

2. **Peter Woit**
   September 10, 2020

   Hansi,
   No disrespect intended towards the winners of the math and physics Breakthrough Prizes, who are quite distinguished scientists. Note that Martin Hairer has already won many awards for his work, including a Fields Medal. He's not an unknown. To the extent that it's a good idea to pay attention to prizes, there's a good argument that the ones awarded by the math community are worth paying attention to. As for the ones trying to make a splash using large sums of Zuckerberg money, maybe you should (after deleting your Facebook account) ignore those. In other words, follow the example of Peter Scholze…

   For the physics prize, among the many good reasons to appreciate the work of Steven Weinberg, the $3 million he got today isn't among the top 1000.

3. **gentzen**
   September 11, 2020

   The lecture series from ETH like the Paul Bernays Lectures or the Wolfgang Pauli Lectures are also nice talks about math and physics to listen to.

4. **Jackiw Teitelboim**
   September 11, 2020

   I only wonder why some people are "ignored" in these prizes, like Deser for SUGRA, and Glashow for the SM now.

5. **Peter Shor**
   September 11, 2020

Jackiw asks why Weinberg was given a Breakthrough Prize for his role in the SM, while Glashow wasn't.

This is baseless speculation, but one possibility is suggested by the following two quotes from their Wikipedia pages:

> Glashow is a skeptic of superstring theory due to its lack of experimentally testable predictions.
>
> Steven Weinberg continued his work in many aspects of particle physics, quantum field theory, gravity, supersymmetry, superstrings and cosmology.

I'd like to believe this wasn't the reason, and maybe it wasn't. You could also argue that the sum total of Weinberg's research outweighs Glashow's.

6. **Douglas Natelson**
September 11, 2020

   And once again, in a relatively high profile platform like Salon, the Loeb interview uses the rather global term "physics" when they mean high energy theory.

7. **John Baez**
September 17, 2020

   To me the most exciting prize handed out by Breakthrough this year was the Maryam Mirzakhani New Frontiers Prize given to Nina Holden for her mathematically rigorous work on random surfaces and Liouville quantum gravity, one of the simplest irrational conformal field theories. I think it was given for her 7-paper series leading up to Convergence of uniform triangulations under the Cardy embedding with Xin Sun. I wrote a quick basic overview of some of the underlying ideas.

8. **SD**
September 20, 2020

   Given this is a post on various links, I thought your readers might like to know that Richard Borcherds has been putting up excellent video lectures on graduate courses in Algebraic Geometry, Representation Theory etc.

   Youtube Playlist

9. **Generic mathematician**
September 20, 2020

   Is there a good summary that describes the work of Vaughan Jones that Alain Connes briefly describes in his blog – something accessible to a mathematician without specialist background. (I'm familiar with the Jones polynomial defined via skein relations, but I know absolutely nothing about the underlying inspiration apparently arising from some classification in von Neumann algebras that somehow relates to knots – but I got intrigued by the brief description in Connes' blog.)

10. **Rob Meyer**
September 22, 2020

    Here is the citation for Steven Weinberg:

    2020 Special Breakthrough Prize in Fundamental Physics

    For continuous leadership in fundamental physics, with broad impact across particle physics, gravity and cosmology, and for communicating science to a wider audience.

11. **Pineapple**
September 23, 2020

    Thank you for pointing me at The Social Dilemma, I enjoyed it a lot and have spent some time since creating my own news aggregation using plain old RSS (your blog was first!). It's hard to find an RSS reader that doesn't ask you to create an account but once you've managed that and if you use FireFox Focus over ProtonVPN then your news and aggregation of it are finally private and not the subject of scrutiny by an overbearing AI marketing model. One thing that's a little frustrating is that so many sites have abandoned RSS in favour of Facebook and Twitter buttons!

12. **Arnold Neumaier**
September 25, 2020

    The full citation for Weinberg's price is here:
    https://breakthroughprize.org/News/61

13. **Richard**
September 27, 2020

    Pineapple,

    Which RSS reader are you using?

14. **Grigori Avramidi**
September 29, 2020

    Michael Freedman's Sept 28 talk in the Harvard Math Literature series was especially good. It gets into the meat of his 4-d Poincare proof and at the same time makes it look … not that hard. Hopefully they will have the video up soon.

15. **Davide Castelvecchi**
October 2, 2020

    Generic mathematician: I found Joan Birman's lecture about Jones' work at the ICM quite helpful and concise

2020 Physics Nobel Prize

October 6, 2020
Categories: Uncategorized

The 2020 Physics Nobel Prize was announced this morning, with half going to Roger Penrose for his work on black holes, half to two astronomers (Reinhard Genzel and Andrea Ghez) for their work mapping what is going on at the center of our galaxy. I know just about nothing about the astronomy side of this, but am somewhat familiar with Penrose's work, which very much deserves the prize.

Penrose is a rather unusual choice for a Physics Nobel Prize, in that he's very much a mathematical physicist, with a Ph.D. in mathematics (are there other physics winners with math Ph.Ds?). In addition, the award is not for a new physical theory, or for anything experimentally testable, but for the rigorous understanding of the implications of Einstein's general relativity. While I'm a great fan of the importance of this kind of work, I can't think of many examples of it getting rewarded by the Nobel prize. I had always thought that Penrose was likely to get a Breakthrough Prize rather than a Nobel Prize, still don't understand why that hasn't happened already.

Besides the early work on black holes that Penrose is being recognized for, he has worked on many other things which I think are likely to ultimately be of even greater significance. In particular, he's far and away the person most responsible for twistor theory, a subject which I believe has a great future ahead of it at the core of fundamental physical theory.

In all his work, Penrose has shown a remarkable degree of originality and creativity. He's not someone who works to make an advance on ideas pioneered by others, but sets out to do something new and different. His book "The Road to Reality" is a masterpiece, an inspiring original and deep vision of the unity of geometry and physics that outshines the mainstream ways of looking at these questions.

Congratulations to Sir Roger, and compliments to the Nobel prize committee for a wonderful choice!

Comments

1. **Shantanu**
   October 6, 2020

   Peter, a data point. About two decades ago, students requested that Roger Penrose give a physics colloquium at MIT, but they were vetoed by the faculty there, who thought his talk would be too fringe or non-mainstream

2. **David Appell**
   October 6, 2020

   I saw someone speculate on Twitter that this may be a reaction to regret among the Nobel Academy that they didn't give Hawking a Prize.

3. **Tim Bradshaw**
   October 6, 2020

   When I read the news that he had jointly won this morning I just immediately thought how right it was that he should win. I don't know the rules around the prize, but he richly deserves an award for the singularity theorems, and as you say his other work (one day I will try, again, to get my head around twistors: there must be better resources on them now than there were in the 1980s) as well.

   This is not to sneer at the other two recipients: the kind of experimental work which has gone on around GR since I stopped trying to be an academic is just heroic I think.

   But the news made my day, anyway.

4. **william e emba**
   October 6, 2020

   The Penrose-Hawking theorems were the main reason astronomers stopped deluding themselves that singularities were avoidable. No-hair theorems did not exist yet. (To be fully truthful, they don't really exist to this day.) Big Bang models at the time were along the lines of Gamow's Ylem. If you wanted to be sophisticated then, you did something like Lifshitz's linearized perturbation calculations that incorrectly ignored self-gravitation.

5. **Andrew P. Mullhaupt**
   October 6, 2020

   Lars Onsager got the Chemistry Nobel; his Ph.D. is technically in chemistry from Yale, where he was a postdoc (actually accidentally predoc) and they suggested he use one of his published papers, but he did new research instead, on periodic solutions ofthe Mathieu equation. At the time none of the chemistry or even physics faculty at Yale could decide whether to award a Ph.D. for this, so they took it to the mathematics department who said that they would award a Ph.D. for it if nobody else did.

   So Lars Onsager, got the Chemistry Nobel (but really for physics) while holding a Chemistry Ph.D., which was really a Mathematics Ph.D. (in sheep's clothing).

6. **Peter Woit**
   October 6, 2020

   Andrew P. Mullhaupt,
   Thanks, I didn't know the Onsager story. Too bad his prize wasn't for his solution to the 2d Ising model. Then the first prize in mathematical physics would have been a prize in Chemistry to a Chemistry Ph.D….

7. **Pascal**
   October 6, 2020

   From the Nobel prize press release about the massive object at the center of our galaxy: "Around four million solar masses are packed together in a region no larger than our solar system." The Schwarzchild radius of the sun is about 3km, so for 4 million solar masses we have a Schwarzchild radius of 12 million km. This is much, much smaller than our solar system (for comparison, the distance between the Earth and the sun is 150 million km).
   So how do we know that this is really a black hole?

8. **Maciej**

October 6, 2020

It is pretty clear to me why Penrose did not receive the breakthrough prize.
First couple of breakthrough prizes went to string theorists who then became members of the board that decides who gets the prize. Penrose has never been hiding his strong critique of strings (in books, interviews et.c.), so it adds up.

9. **gtr_gradstudent**
October 6, 2020

This news made me check if Roy Kerr was still alive. And indeed he is.

On the topic of the mathematical physics, I wonder if physicists know or care about Christodoulou and Klainerman's work, which to me is one of the summits of the subject in the last fifty years.

10. **Mark Weitzman**
October 6, 2020

The real question is why it takes about 55 years to give such an award? I remember first reading about Penrose (and Hawking) in MTW's Gravitation book published in 1973. I realize it helps to have observational evidence of black holes, but I think this has been around for quite a while. I am glad that he lived long enough to get his recognition from the Nobel Committee.

11. **martibal**
October 6, 2020

Besides the question of the title of the PhD, is there any other example of a Nobel prize awarded for a theorem ? As a side question: what about the Fields Medal ? Was Penrose already to hold for it, or was not it considered as a mathematically significant enough result ?

12. **Chris Oakley**
October 6, 2020

I never expected Penrose to get a Nobel Prize, but am very glad that he did. A true original thinker!

13. **Peter Woit**
October 6, 2020

martibal/Mark Weitzman,

I don't know of another example of a theorem getting a Nobel Prize. Hawking I think never got a Nobel prize because Hawking radiation is all too testable in principle, but not in practice and the theorems with Penrose were theorems and thus not something testable about the real world.

One guess as to what's going on here is that the lack of good new testable ideas about fundamental physics in recent decades has meant that if the Nobel committee wants to stick to rewarding only things that pass experimental test, then they will have to give awards to less and less impressive results. At some point the fact that they are ignoring hugely important ideas like those of Hawking and Penrose starts to become an obvious problem and perhaps this has caused them to rethink their criteria. In Penrose's case, the fact that he has a hugely impressive other body of work gives a good reason to find something to give him the prize for, even if they need to fudge their usual criteria. Hawking unfortunately didn't live long enough to take advantage of this.

14. **DS**
October 6, 2020

Dear Professor Woit,

I think the comment about the prize being awarded for a theorem in mathematics is a mischaracterization. It is not at all about making a previously known physical result rigorous!

In those days most physicists (including for example John Wheeler) believed that the singularities of the Schwarschild and Kerr solutions were unphysical and were due to either a poor choice of coordinates or because of symmetries.

Penrose showed that singularities were inevitable and physical, at least in the sense that empirically verified equations predicted them in generic situations (not only in special, symmetric solutions).

Hence, Penrose radically changed the physical picture and he did it by proving a mathematical theorem!

15. **Nicole**
October 6, 2020

Why doesn't anyone read the advanced information on the website?

https://www.nobelprize.org/uploads/2020/10/advanced-physicsprize2020.pdf

Nobel prizes are not given for theories. They are given for fundamental discoveries. Even Einstein's Nobel was for one of his ideas proven through experimentation.

Clearly it was Penrose's 1965 paper which won him this year's prize. Hawking would not have shared the prize even if he were alive. Penrose's ideas came before Hawking's. The Nobel does not award subsequent or derivative work.

16. **rhodium**
October 6, 2020

I cannot speak for physics, but it seems sometimes a chemistry prize is awarded to X for being who he is. Perhaps Penrose got the prize because he is Penrose and nobody else is.

17. **Peter Woit**
October 6, 2020

DS,

You won't find me arguing for a rigid distinction between math and physics, or that proving a mathematical theorem about a set of equations can't provide new insight into them that counts as "physics".

18. **FlyingCar**
October 6, 2020

I have mixed feelings tbh. I love Penrose's work, but, like with Hawking's theorems, rigorous experimental verification is almost impossible by the very nature of the topic. So why relax prize requirements decades after the theorems were first proposed? Perhaps it's to benefit the very theories Penrose dubs 'Fashion, Faith and Fantasy'. What's to prevent work on inflation from being awarded next year? I hate to sound conspiratorial but I actually think it's very likely to happen now.

Frankly, Penrose deserved a share of the Nobel prize for quasicrystals back in 2011. It's really strange how it all turned out.

19. **Alessandro Strumia**
October 6, 2020

The problem is that the time gap gets so large that it's more important than the science. The main work was done by Einstein, Hilbert and Schwarzschild. They died long ago. Hawking died in 2018. Why waiting 2020, if this old work deserved a prize? And why not Kerr, given that LIGO/Virgo see rotating black holes?

20. **Chris W.**
October 6, 2020

By the way, in 2017 Quanta Magazine published [this interview] with Andrea Ghez.

21. **Justin Glick**
October 7, 2020

This seems to be the anti-symmetric analog of Witten's 1990 Field's Medal. Wasn't the math community surprised to see a physicist win the medal, much the same as some in the physics community are surprised to see a mathematician win the Nobel?

22. **Ricardo Cavalcanti**
October 7, 2020

Max Born was another recipient of the Nobel Prize in Physics with a Ph.D. in Mathematics. (Source: https://en.wikipedia.org/wiki/Max_Born)

23. **Lars Johansson**
October 7, 2020

I was also delighted that Roger Penrose was awarded, although I'm not familiar with the details of his work on black holes. I've read his book The Road to Reality over and over and I'm slowly beginning to grasp more and more of it. It's totally fascinating!

According to the Nobel committee, this is the first time in history that GR is awarded (remember that Einstein was not awarded for GR but for his work on the photoelectric effect).

Besidess, I think that Penrose could as well have been awarded the 2011 Nobel prize in chemistry for his work on "Penrose tilings" which paved the way for the discovery of quasicrystals.

24. **Jackiw Teitelboim**
October 7, 2020

Eugene Paul Wigner was given the Nobel prize "for his contributions to the theory of the atomic nucleus and the elementary particles, particularly through the discovery and application of fundamental *symmetry principles*."

Formally, Wigner was a chemical engineer, whose thesis was Bildung und Zerfall von Molekülen ("Formation and Decay of Molecules"). However, Wigner education, thanks to the flourishing interaction between the mathematical and physical sciences at Göttingen around the 1920's, is not easy to define him into simple categories such as theoretical/mathematical physicist or a pure mathematician. After his thesis with PhD work with Michael Polanyi, he was interacting with people ranging from Arnold Sommerfeld to David Hilbert. So regardless what his PhD was for, it's still worth mentioning that *group theory* was the main reason for his Nobel prize.

In this sense, I consider his nomination as a recognition of representation theory in QM, even before gauge theories and the geometrical theory of p-bundles became widely recognized as the mathematical language of the fundamental interactions.

This besides Bohr calling it Gruppenpest.

PS: Pascal Jordan certainly was a founding member of QM and a high caliber mathematician, and I am sure he did not received a Nobel prize for reasons which the interested reader may find for herself by searching his biography, e.g., Bert Schroer's https://arxiv.org/abs/hep-th/0303241

25. **Jim Holt**
October 7, 2020

I agree that "The Road to Reality" is a masterpiece. In ploughing through it repeatedly over the years, I've learned more from it about a wider range of topics than any other math/physics book I can think of. (Although I hate his tensor diagrams!)

26. **DS**
October 7, 2020

For those complaining that the Nobel committe changed its criteria, in 1999 T'Hooft and Veltman got the Nobel prize for showing the renormalizability of Yang-Mills theories and as far as I know you can't experimentally verify if a theory is renormalizable. Also as far as I can tell https://webspace.science.uu.nl/~hooft101/gthpub.html they did not make any experimental predictions in the work that was awarded the prize. The quote is "for elucidating the quantum structure of the electroweak interactions in physics" and analogously Penrose elucidated the structure of general relativity, showing it generically produces singularities.

On the whole, asking for experimental verification on Penrose's work is nonsensical. If you went inside an event horizon and never met a singularity, the truthness of the theorem remains, it simply means that in the real world either the energy condition is broken or general relativity is incorrect at a certain scale. Either of these breakdowns would be revolutionary. The prize is due to: "for the discovery that **black hole formation is a robust prediction of the general theory of relativity**." It is a statement about general relativity as a theory, not about reality.

27. **Tim Bradshaw**
October 7, 2020

Pascal,

I believe the most conclusive evidence that Sag A* is a black hole is that orbital motions have been detected very close to the innermost stable orbit of the object if it is indeed a BH, and that these observations agree very closely with models of what I think are hot spots in the accretion disk. These orbits have periods of under an hour and velocities around 0.3c. ArXiv copy of the paper on this is here: https://arxiv.org/abs/1810.12641.

Apart from that, there's the question that we don't have any other candidates for anything that would pack 4 million Solar masses into something the size of the Solar system, I think.

28. **Laurence Lurio**
October 7, 2020

I am a bit surprised so many people love "The Road to Reality". For a book that is supposed to assume no prior knowledge of physics, I found it confusing and very dense. I came at it with a prior knowledge of physics and it took ideas which I previously understood and made them confusing. Possibly fun to look at things from a new perspective, but a lot of work to plow through when the end goal is twistor theory, which seems to be a Penrose pet project that no one else really uses. Possibly this book is like the Feynman Lectures, supposedly aimed at the neophyte but only really read by the experts looking for a novel approach. Is anyone aware of someone without a degree in physics who was actually able to get something out of this. Who is the intended audience? Maybe the next Penrose ?

29. **Peter**
October 7, 2020

I think it was Pauli who first used the expression "Gruppenpest".

30. **Peter Woit**
October 7, 2020

Laurence Lurio,
It's definitely not a book for beginners. It is highly original: Penrose is doing things his way, not the way that is in most standard textbooks. This is confusing at first, he's asking you to think about the subject of space-time geometry in a different way than you are used to. I'm sold on the twistor point of view, but even if you're not, his way of thinking puts front and center the conformal geometry of Minkowski space, which is rather different than the usual way of thinking about space-time geometry, and often more enlightening. The work he got the Nobel prize for grew out of this point of view, showing the power of it.

31. **Low Math, Meekly Interacting**
October 7, 2020

I consider Penrose a fine visual artist, something I appreciate all the more because he is able to express his ideas so accessibly with pictures. I encountered the famous figure representing trapped surfaces many years ago and found it stirring. Likewise the Penrose diagram of a Kerr black hole (however unphysical, I'm not aware of a more concise description of how bizarre it really is). The only explanation of Twistors I've really been able to get my head around came from him: Start by imagining the dome of the heavens, full of stars…

I always admired Penrose most for communicating a highly original perspective that is nonetheless bracingly lucid and (perhaps deceptively) comprehensible. I've had similar feelings about Feynman's popularizations. They both (I hope) helped me understand better how incredible advanced concepts in established physics can still be.

I don't know who really "deserves" a Nobel Prize, but I'm very encouraged that he got it.

32. **Stuart**
October 7, 2020

I'm curious where my countryman Roy Kerr fits in on the Nobel front. My understanding is that the Event Horizon Telescope data from last year confirmed his model of black holes, but this year's prize is about black holes but not about the EHT data?

Like Penrose, Kerr's no spring chicken. Hang in there, Roy!

33. **Matt Grayson**
October 8, 2020

I have no physics degrees. I loved "Road to Reality". I did not *understand* everything in it, but it's a large book and contained much that was interesting – more details than a popular science book, fewer than a graduate text. Feynman's QED is the only similar, though more basic, book I can think of.

34. **Peter Woit**
October 8, 2020

Matt,
It should be mentioned that your professional background is in geometry, which should have helped a lot to make the book accessible.

35. **Jules**
October 8, 2020

Peter, in 1997, out of curiosity, I went to the "Strings" Conference in Amsterdam. Hawking spoke with his computer voice. He said: "It is a pity that a black hole has not been found yet, because then I would get the Nobel prize." He was really unlucky …

36. **Peter Woit**
October 8, 2020

Jules,
I think to count as experimental vindication of Hawking's work, you'd need not just finding a black hole, but observing Hawking radiation from it. That hasn't happened yet, and I suspect is a very long time off. As Nicole above pointed out, the singularity theorem for black holes was due to Penrose, not Hawking, so the reason this award went to Penrose would not have worked to justify an award for Hawking.

37. **EDP**
October 8, 2020

Roger Penrose is certainly a brilliant mind, but why does he think that consciousness somehow arises from the quantum vibrations of microtubules? This I cannot fathom.

38. **Christopher Blanchard**
October 9, 2020

I am the neophyte Laurence Lurio can't see. My degrees are in economics and management, which are juvenile and silly attempts at intellectual disciplines. I have no great talent for mathematics, though economics did give me the basics of linear algebra – although it isn't much. For all that I found The Road to Reality, with four readings of all of it and quite a few more for several bits, completely fascinating, wonderful, illuminating, and all the rest. The sort of thing Penrose does is to offer me the clearest explanation I know anywhere for basics (like Goedels theorem – can't remember whether that is in The Road or one of his others – doesn't matter), and then those marvelous diagramatic explations of more complex material. This neophyte is happy.

39. **Lars**
October 10, 2020

The Penrose Singularity

A singular prize
For a singular role
A singular surmise
'bout a singular hole

40. **Peter Shor**
October 10, 2020

Laurence Lurio: My physics class in college, back in 1977, used *The Feynman Lectures*. As far as I can tell, the real complaint about them is that while they give a good "big picture" perspective on the material and provide what I thought was excellent intuition, they don't actually teach you how to solve the homework problems.

So possibly this is another instance of the "shut up and calculate" mindset.

41. **cedric bardot**
October 11, 2020

Thanks Peter to praise Roger Penrose's inspiring original and deep vision of the unity of geometry and physics. It's worth emphasizing it indeed more explicitly than (but also be glad with) Sean Carroll in his recent tweet:
Roger Penrose is the first "theorist" to win for work in gravitational physics since — well, ever. Even Einstein won for quantized light, not general relativity.

(https://twitter.com/seanmcarroll/status/1313489948578902018?s=20)

Do you or does any commenter know any kind of theoretical physics progress or experimental evidence could bring the conditions to convince the Nobel committee that the discovery of a 125 GeV scalar boson at the LHC has something to do with the discovery that the Standard Model Lagrangian is a robust prediction of some advanced new spacetime geometric theory?
I would be interested to read an answer from @martibal for instance.
If some theoretical particle physicists at CERN would consider this naive question, the hope the Higgs boson has something to say about spacetime geometry could become less dark & the hope for a future award to the achievements of LHC phenomenologists & experimentalists could materialize, couldn't they?

Incidentally a framework for unification of all fundamental interactions including gravity I have in mind happens to have a connexion with Penrose twistor theory (cf conclusion at p 578 of https://onlinelibrary.wiley.com/doi/epdf/10.1002/prop.201000069, also available on arxiv https://arxiv.org/abs/1004.0464).

42. **Curious Mayhem**
October 11, 2020

It's not clear Hawking could have won the Prize. His theorem is about cosmology. Penrose is an unexpected but appropriate choice, given how much evidence there now is for black holes. The pictorial breakthrough of Penrose diagrams and the interplay of timelike and spacelike regions are physics gold, for the ages.

43. **Peter Woit**
October 11, 2020

Cedric Bardot,
About the Sean Carroll comment, I think he soon realized other theorists have gotten Nobel prizes for gravitational physics. The unique thing about Penrose is that this is an the award for mathematical physics.

The rest of your comment is off-topic, but thanks for pointing to the reference by Connes-Chamseddine to twistors. I've been trying to figure out if there is any relationship between the ideas about twistor unification I've been thinking about and the non-commutative geometry unification program, so this is helpful. But it has nothing much to do with Penrose, so off-topic here. I'll surely be posting again about twistors and unification…

44. **martibal**
October 11, 2020

Since I was mentioned in a comment, I give a short answer: I do not think the way the Higgs field appears in the noncommutative geometry description of the standard model can be viewed as a "proof of the Higgs" similar to the "proof of black hole" by Penrose's singularity theorem. It would be off topic to develop my point here, but I do not think the two situations are comparable.
\\
I take this occasion to ask once more if anybody knows how much mathematicians value the singularity theorems ? Penrose was in his thirties in 65, so still in the competition for a Fields medal. Not that prizes are so important, but in our math department in Genoa we have a course specially devoted to the singularity theorems (and we did not open it because of the Nobel prize !). So far it attracts more the physics students than the maths ones. In our university, mathematical physics seems to be more appealing to physicist than mathematician, although in Italy "mathematical physics" officialy exists as a sector of math (not of physics). I was wondering if this is a general situation, and if so, what can be done to "sell" the subject better to mathematicians ? Maybe the Nobel prize may have a pervert effect, convincing mathematicians that all this stuff has definitely more to do with physics than maths 🙂

45. **Peter Woit**
October 11, 2020

martibal,

At the time Penrose did this work, interest of mathematicians in questions related to physics was at a minimum, so not surprising Penrose was not likely seriously considered for a Fields medal.

The situation now is quite different. Here at Columbia there is a great deal of interest in the mathematics of classical black hole solutions in the math department, less in the physics department. This is the specialty of one member of our department, Mu-tao Wang, and there has been an active seminar on the topic, see
https://sites.google.com/prod/view/grgas/home

A frequent visitor has been Princeton's Sergiu Klainerman who also works on this, see
https://web.math.princeton.edu/~seri/homepage/seri.htm

Another prominent mathematician who works in this area is Shing-Tung Yau. To inspire mathematicians, one thing you could point to is this relatively recent conference
http://www.fields.utoronto.ca/activities/workshops/international-conference-black-holes
at the Fields institute.

46. **william e emba**
October 11, 2020

Regardless of mathematicians' attitudes to physics in the 1960s, I don't think Penrose's singularity theorem would have merited a Fields medal as such. Certainly his other work (the Penrose triangle!) wasn't top of the world, however fascinating it was.

There was some awareness of mathematical physics at the highest levels back then. Laurent Schwartz received his 1950 Fields medal for developing and applying the theory of distributions, which made rigorous the Dirac delta-function. Not that the physicists were concerned, or even noticed.

As for Yau, his solution with Schoen of the positive mass conjecture (a significant foundational question for general relativity) was cited as part of his reason for receiving the Fields medal 1982. Their method of proof involved generalizing Penrose's 1965 arguments from 1D to 2D.

Hawking's extension of Penrose's work to cosmology and the Big Bang was certainly pivotal in forcing cosmologists to accept it. As for black holes, Hawking's area theorem has now been experimentally verified numerous times by LIGO.

October 12, 2020

For people interested in this, see the comments by David Wiltshire and also Roy Kerr himself on Peter Coles blog
https://telescoper.wordpress.com/2020/10/06/the-2020-nobel-prize-for-physics/#comments

48. **John Baez**
October 13, 2020

I'm really happy that Penrose won this prize. I wrote an explanation of the theorem he proved, that won him the prize.

49. **DrDave**
October 15, 2020

I'm curious what people here think about the effect, if any, of how the prize will affect teaching and research at the institutional level.
Specifically, will students consider Penrosian ideas (and others) more favorably as they plan their research, and will faculty appointments be weighted towards research related to the prize. Perhaps even a curriculum shift of emphasis. Or is the status quo going to continue.

50. **Peter Woit**
October 15, 2020

DrDave,
I think that kind of effect of the Nobel exists, but is fairly marginal. The prize gives Penrose's work more attention, but it was already well-known to people in the field. A good example of the effect might be that the prize announcement encouraged John Baez to write the really nice explanation that he links to above, so that gets more people aware of this.

My own agenda these days is to promote twistors, so it would have been great for me if Penrose got the award for twistors, but that's not the case. On the other hand, most people seem to believe that Witten got the Fields medal for work on string theory, so maybe some day they'll all believe that Penrose got the Nobel for twistors…

51. **Anonymous**
October 18, 2020

martibal,
The 1966 Fields Medals were for exceptionally groundbreaking mathematical work even by Fields Medal standards so Penrose not making the cut isn't necessarily the best metric: Grothendieck for reinventing algebraic geometry, Atiyah for the index theorem, Cohen for independence of the continuum hypothesis, and Smale for the Poincaré conjecture for d>4.

Do Particle Physicists Continue to Make Empty Promises?

October 23, 2020
Categories: Uncategorized

Blogging has been light here, since little worthy of note in math/physics has been happening, and I've been busy with teaching, freaking out about the election, and trying to better understand Euclidean spinors. I'll write soon about the Euclidean spinors, but couldn't resist today making some comments about two things I've seen this week.

Sabine Hossenfelder yesterday had a blog entry/Youtube video entitled [Particle Physicists Continue to Make Empty Promises](), which properly takes exception to this quote:

> A good example of a guaranteed result is dark matter. A proton collider operating at energies around 100 TeV will conclusively probe the existence of weakly interacting dark-matter particles of thermal origin. This will lead either to a sensational discovery or to an experimental exclusion that will profoundly influence both particle physics and astrophysics.

from a recent article by Fabiola Gianotti and Gian Francesco Giudice in *Nature Physics*. She correctly notes that

> They guarantee to rule out some very specific hypotheses for dark matter that we have no reason to think are correct in the first place.

A 100 TeV collider can rule out certain kinds of higher-mass WIMPs, but it's simply untrue that such an exclusion will "profoundly influence both particle physics and astrophysics." Very few people think such a thing is likely since there's no evidence for it and no well-motivated theory that predicts it.

Where I part company with Hossenfelder though is that I don't see much wrong with the rest of the Gianotti/Giudice piece and don't agree with her point of view that the big problem here is empty promises like this and plans for a new collider. Twenty years ago when I began writing N*ot Even Wrong*, I started out by writing a chapter about the inherent physical limits that colliders were starting to hit, and the significance of this for the field. It was already clear that getting to higher proton energies than the LHC, or higher lepton energies than LEP was going to be very difficult and expensive. HEP experimentalists are now facing painful and hard choices about the future, which I wrote about in detail here under the title Should the Europeans Give Up?. The worldwide experimental HEP community is addressing the problem in a serious way, with the European Strategy Update one aspect, and the US now engaged in a similar Snowmass 2021 effort.

Many find it tempting to believe that the answer is simple: just redirect funds from collider physics to non-collider experiments. The problem is that there's little evidence of promising but unfunded ideas for non-collider experiments. For the last decade there has been no new construction of high energy colliders, with as much money as ever available worldwide for HEP experiments. This should have been a golden age for those with non-collider ideas to propose. This continues to be the case: if you look at the European Strategy Update and Snowmass 2021 efforts, they have seriously focused on finding non-collider ideas to pursue. This should continue to be true, since I see no evidence anyone is going to decide to go ahead with a next generation collider and start spending money building it during the next few years. The bottom line result from the European process was not a decision to build a new collider, but a decision to keep studying the problem, then evaluate what to do in 2026. For the ongoing American process, as far as I know a new US collider is not even a possibility being discussed.

While HEP experiment is facing difficult times because of fundamental physical, engineering and economic limits, the problems of HEP theory are mostly self-inflicted. The decision nearly 40 years ago by a large fraction of the field to orient their research programs around bad ideas that don't work (SUSY extensions of the Standard Model and string theory unification), then spend decades refusing to acknowledge failure is at the core of the sad state of the subject these days.

About the canniest and most influential HEP theorist around is Nima Arkani-Hamed, and a few days ago I watched an interview of him by Janna Levin. On the question of the justification for a new collider, he's careful to state that the justification is mainly the study of the Higgs. He's well aware that the failure of the "naturalness" arguments for weak-scale SUSY needs to be acknowledged and does so. He also is well aware that any attempt to argue this failure away by saying "we just need a higher energy collider" won't pass the laugh test (and would bring Hossenfelder and others down on him like a ton of bricks…).

The most disturbing aspect of the interview is that Levin devotes a lot of time (and computer graphics) to getting Arkani-Hamed to explain his 1998 ideas about "large extra dimensions", repeatedly telling the audience that he has been given a \$3 million prize for them. This paper has by now been cited over 6300 times, and the multi-million dollar business is correct, with the prize citation explaining:

> Nima Arkani-Hamed has proposed a number of possible approaches to this paradox, from the theory of large extra dimensions, where the strength of gravity is diluted by leaking into higher dimensions, to "split supersymmetry," motivated by the possibility of an enormous diversity of long-distance solutions to string theory.

At the time it was pretty strange that a \$3 million dollar prize was being given for ideas that weren't working out. It's truly bizarre though that Levin would now want to make such failed ideas the centerpiece of a presentation to the public, misleading people about their status. The website for the interview also promotes Arkani-Hamed purely in terms of his failures, presented as successes:

> Nima Arkani-Hamed is one of the leading particle physics phenomenologists of the generation. He is concerned with the relation between theory and experiment. His research has shown how the extreme weakness of gravity, relative to other forces of nature, might be explained by the existence of extra dimensions of space, and how the structure of comparatively low-energy physics is constrained within the context of string theory. He has taken a lead in proposing new physical theories that can be tested at the Large Hadron Collider at CERN in Switzerland,

This is part of the overall weird situation of the failed ideas (SUSY/strings) of 40 years ago: they still live on in a dominant position when the subject is presented to the public.

At the same time, the topics Arkani-Hamed is working on now are ones I think are more promising than most of the rest of what is going on in HEP theory. The interview began with a discussion of Penrose's recent Nobel Prize, with Arkani-Hamed explaining Penrose's fantastic insights about twistor geometry and noting that his own current work involves a fundamental role for twistor space (personally I see some other promising directions for using twistor geometry, more to come about this here in the future).

In contrast to Hossenfelder, what I'm seeing these days in HEP physics is not a lot of empty promises (which were a dominant aspect of HEP theory for several decades). Instead, on the experimental side, there's an honest struggle with implacable difficulties. On the theory side increasingly people have just given up, deciding that it's better to let the subject die chained to a host of \$3 million prizes for dead ideas than to honestly face up to what has happened.

Update:
In case anyone needs any reminder of how bad the propaganda problem is:
https://kids.kiddle.co/String_theory
It appears this kind of thing is driven by a propaganda problem on Wikipedia.

October 23, 2020

Hi Peter,

Thanks for the reasoned response.

A few remarks. Firstly, the rest of the Giudice & Gianotti piece repeats unconvincing arguments I have debunked many times before, see eg here for a summary. Take eg the "spin offs" and "other benefits" claim. True. But the same can be said about any similarly large investment into science funding. Doesn't have to be a collider. So then we should put the money in a science experiment that also makes scientific sense.

Second, and more importantly, you state "This should have been a golden age for those with non-collider ideas to propose." Excuse me for being frank, but have you ever even considered to write a proposal for a large scale experiment? Probably not. Because if you had you would realize that you need funding to even put together a proposal. You need people. You need expertise. But all the people and the expertise are in particle physics. And of course particle physicists propose more particle physics experiments.

This whole process is so obviously incestual; it is beyond me why it's still allowed to happen. It's a chicken and egg problem: people go where money goes and money goes where people go. To make matters worse, then there are outside people, like you, who don't understand how it works and say "But look, this is where money and people go, so this must be where we should put in more money and people." *facepalm*

Third, I don't want to start this all over again because I have literally written a whole book about it, but I think we need to make more efforts to evaluate the promise of investing huge amounts of money based on looking at what strategies worked in the past. As I have explained, theory-based breakthroughs have only been successful when they were studying inconsistencies. There isn't any such inconsistency in the range in the new 100 TeV collider.

Fourth, that the last decade should have made it easy to get funding for other things is just wrong, look eg at the funding troubles of the SKA. The SKA was a good idea, once, but after it was slimmed down it failed making much sense which led more nations to pull out. We are talking here about a billion that was missing, not 20 billions. And you know what they're building next to Frankfurt what's been eating up 2 billions? A particle collider. Srsly. Not a 100 TeV machine, but a particle collider. And as you have probably heard RHIC is getting an upgrade that will eat up a few billions too. So please stop claiming there ain't no money going into this field, it's just wrong.

As to Arkani-Hamed. Fun fact. I was recently interviewed by someone who writes for a little known German science magazine (I believe it's a German version of the MIT Tech review). He told me he previously spoke with Nima. And you know what Nima told him? The good old finetuning story with the balanced pen and all that. (It's in print now, so not like I'm spilling secrets.)

It's really hard for particle physicists to give up their numerological arguments (naturalness, WIMP miracle, etc) because those are the only arguments they have. If they'd stick with the truth, nobody would give them funding, and they know this. That's why they continue to make false claims about dark matter and dark energy and new particles and fuzzy things about the baryon asymmetry, all of which fall apart to dust if you look a little closer.

2. **Johannes**
October 24, 2020

Peter and Sabine,

now I am an old theoretical physicist, reading your blogs since almost from when they started, but I still do not understand both of you. Allow me to explain the reason.

It is indeed correct that both theoretical particle physics and quantum gravity have not come up with the correct approach to go forward. And this is so since decades. You both have shown this in great detail, and for this you indeed deserve much praise. You both stress the importance of experiment, the fallacies of wrong arguments, the traps of untestable premises, etc.

After so many years, it is obvious that in the vast field of possible approaches, the correct one is like a tiny plant still waiting to be discovered among the large number of wrong ones. What today's theoretical physics needs, is a guidance from older experts to younger ones on where to go on searching.

We have a crisis in theoretical physics, not a crisis in experimental physics. But both of you also explicitly state "don't send me your TOEs". And you also act consequently. Indeed, there are so many bad ideas around. But it implies that you do not give *any* approach a chance. Not even the correct one. Ok, I can understand this attitude as well – time is valuable.

But if we cannot give answers to younger people, we should at least give them questions. However, you both have become so negative that it is not even allowed to write questions in your blogs. You do not believe it? Let me add some questions to this comment. It will lead to rejection.

(1) To Peter and Sabine: It is clear since decades that gravitation is of thermodynamic origin and that black holes have microscopic degrees of freedom. One goal of quantum gravity is to discover these microscopic degrees of freedom: What are they? How do they make up black holes and space?

(2) To Peter: How are these microscopic degrees related to twistors?

(3) To Sabine: A correct approach to particle physics must explain the fine structure constant or the mass of the electron. Yes, strings failed, and so did loop quantum gravity. Can other microscopic degrees of freedom achieve this?

We need to pass on questions such as these to younger people. We need to distinguish carefully between telling people not to take a wrong path and telling people not to take any path. As long not even asking questions is possible, we stifle progress.

3. **Alessandro Strumia**
October 24, 2020

Fact check: "a proton collider operating at energies around 100 TeV will conclusively probe the existence of weakly interacting dark-matter particles of thermal origin" is not true. Not even close. CERN is struggling for its survival, and it's not struggling in the best way.
The good way should have been: recognise that LHC will be scientifically over soon and that it's time to either invent how to build a smarter muon collider in the LHC tunnel, or to return the place to cows.
The bad way is: keep LHC running until its generation retires (current funds: ≈1 billion/year) and try exaggerations and public relations to get ≈30 billions for a bigger collider.

4. **Sabine Hossenfelder**
October 24, 2020

Hi again,

It occurred to me I should add something for context, which many of us "out here" tend to forget. I suspect the vast majority of particle physicists have no idea what we are even talking about. They live in a bubble in which there's only particle physicists. They haven't heard that naturalness arguments and the WIMP miracle died 5 years ago — and that's in the optimistic case that they know how much they relied on these arguments to begin with.

The reason I suspect this is that each time I am asked to "debate" a particle physicist they tell me 30 years old stories. They say that dark matter should be made of WIMPs and that there is supposedly something special about the TeV scale, and when I tell them the predictions made with these arguments have been falsified they are just stunned. It's like the past 5 years didn't happen.

(A small fraction of them will then argue one can't falsify numerological arguments, but, well, either way — falsified or unfalsifiable — it's arguments on the basis of which you should not invest tens of billions of dollars.)

Alessandro (above), btw, is the rare exception of a particle physicist who understands the situation (if you look at his publications, probably understood this long before I did).

5. **Doug McDonald**
   October 24, 2020

   Its a long shot, but I consider the most likely "effort" to succeed in getting theoreticians "on track" to success is "An experimental effort in astronomical observations measuring cosmological parameters with emphasis on no systematic errors" aka "pushing the cosmological constant to the other sign" plus "which side is wrong on Hubble?".

   Perhaps accurate full 4 pi measurement of the cosmic microwave background at numerous widely spaced different wavelengths, or even at continuous wavelengths, not just spot ones. That would spend a bundle. It would also pay for developing better continuously powered helium refrigerators for space use.

6. **Peter Woit**
   October 24, 2020

   Doug McDonald,
   What I'm discussing here is the situation with high energy particle (HEP) physics. Cosmology and astrophysics are a completely different story. Trying to do better CMB measurements is a very active and well-funded subject. I see zero reason to believe that any CMB measurement will ever tell us anything about the questions a next generation collider would be designed to address: the details of the behavior of the Higgs and whether the SM continues to work perfectly at scales of 1-10 TeV.

7. **Peter Woit**
   October 24, 2020

   Johannes,
   What I'm discussing is HEP physics, not quantum gravity, especially the increasingly common attitude that HEP physics is dead, with quantum gravity the only thing worth thinking about. The problems of quantum gravity are a completely different story.

   It's currently very much not true that I give no alternative approach a chance, since I now see a relatively clear path towards progress along the lines of the ideas about twistor geometry I've advertised.

8. **Peter Woit**
   October 24, 2020

   Alessandro,

   Yes, part of the story is that CERN's future is at stake, and those with jobs there have a vested interest in large projects that would keep it in business. This is worth keeping in mind when evaluating people's arguments.

   A muon collider in the LHC tunnel would be an ideal project in terms of keeping CERN going. I don't see any reason to believe that the reason for not pushing that instead of the 100 TeV idea isn't simply lack of feasibility (among other problems, such a thing might produce unhealthy levels of neutrino radiation over a large chunk of France and Switzerland).

   I wouldn't be at all surprised though if in 2026 CERN gives up on the 100 TeV pp idea as unfundably expensive and instead turns to the muon or some other lepton collider idea.

9. **Peter Woit**
   October 24, 2020

   Sabine,
   If you listen to Arkani-Hamed, he is acknowledging that the "new weak scale physics will restore naturalness" argument has been pretty much discomfirmed by the LHC. Unfortunately I think what's going on is that he hasn't abandoned the naturalness argument, he's just drawn a conclusion from it that he doesn't want to talk about.

   For many years he would give talks about how the LHC would lead to one of two possible outcomes: new physics restoring naturalness, or the anthropic multiverse. I suspect what's going on with him and many others is that they still believe these are the two possibilities, have drawn the conclusion that the LHC has vindicated the anthropic multiverse, and as a result have given up on HEP physics. They've seen the reaction of their colleagues and the public to the campaign for anthropic multiverse pseudo-science, so they're not repeating this publicly. You see this fairly clearly in some of Witten's statements of the order of "I don't like the multiverse but I now don't have an argument against it".

   About the funding issues, I have no idea whether giving up on HEP physics will free up money for other currently under-funded fields which I know little about. My point was just about HEP experiments. The argument for an energy frontier collider is that it's the only way to get better information about details of Higgs and 1-10 TeV scale physics. If anyone had a better, cheaper way to do this, it would get a lot of interest. The US already a long time ago did what the Europeans are faced with doing (giving up on energy frontier machines), and the experience here provides a pretty clear idea of what will happen if the Europeans do the same (very good for neutrino physics…).

   Any obstructions to people with good but much cheaper proposals getting funded are worth addressing, I just don't believe the main problem is collider spending crowding everything else out.

10. **OC**
    October 24, 2020

    Contra Sabine's claim that particle experimentalists only do more particle experiments, and speaking as an old timer who got his (theory) degree back in the '80s, I know 3 HE experimentalists from that era, two now quite senior. All three have since switched to other experimental areas, one working on the LSST and now on ground based CMB, another one now doing CMB stuff, and the third doing stuff with liquid xenon, first to look for neutrinoless double beta decay, now to look for other interesting things with the "backgrounds" from that setup. Oh, and a fourth friend – an ex-phenomenologist – now works on improving the cosmological constant measurement with large-scale galaxy surveys.

Physicists can change their spots. Not everyone gets permanently attached to unproductive lines of work.

Personally, I still think the ideas that have come out of string theory – particularly gauge/gravity duality and the related and more recent “it from qbit” ideas – are tremendously interesting, even if connecting them to the standard model looks very far off. That our society allocates a small fraction of the cost of one more pointless jet fighter to giving a few talented people the resources to pursue those ideas seems to me a good measure of our merit as a civilization, and it’s a shame that the meagerness of that commitment pits people who should be allies against each other.

11. **Anders**
October 24, 2020

The muon-g2 experiment at Fermilab, would that be considered HEP? It seems to be poking at a possible discrepancy of the standard model.

As for the 100 TeV collider in Switzerland, I just don’t see that happening. Building a 150 km tunnel would be ridiculously expensive, and its not like there is a new Higgs boson to look for.

12. **Peter Woit**
October 24, 2020

Anders,
The muon g-2 experiment is a good example of the sort of the thing US HEP is doing in the absence of an energy frontier collider. Unfortunately, the only information such low energy experiments can give you about what is happening at higher energy scales is quite indirect and just one number. If the g-2 result comes out in conflict with the Standard Model, that will be interesting evidence that there’s something beyond the SM, while at the same time telling you almost nothing about what it is.

13. **Amitabh Lath**
October 24, 2020

Please! Enough with this big physics vs. little physics death matches. Govt. money simply does not work that way. Case in point, the US govt. sent me (a tenured professor!) over $3k a few months ago just for…well I don’t know what for. Money rules are not the same when you own the printing press for dollars.

The only valid reason for NOT continuing down our path towards short distance physics would be if someone could guarantee there is NO new physics at these higher energies (or energies that would be reached by the next next collider). If you could prove there was no new physics until the Plank scale then fine, colliders are pointless.

14. **Shantanu**
October 25, 2020

If I was a 2nd year Ph.D student having taken particle physics courses and maybe attended a few colloquia/seminars etc, my first reaction would have been after reading that article is
“Wait a minute. We already know from neutrino experiments that there is evidence for Physics beyond standard model. So why are Giudice/Gianotti talking as if there is no evidence. what have we learned about TeV scale physics from 20+ years of neutrino mass results.? Else if neutrino experiments can tell us nothing about BSM of particle physics, besides measurements of delta m^2, sin^2 theta and delta CP, then why waste money on neutrino experiments? Conversely why aren’t top theorists (like Nima) working on these issues?”
Also I don’t see reporters asking this question to HEP theorists or Sabine/Peter stressing these points.

15. **Johannes**
October 25, 2020

Peter, Amitabh,

searching for new physics is the wrong path. We have new physics in front of us since 100 years! Here it is: What is the origin of the coupling constants? And what is the origin of the particle masses?

The trouble is that 99% of the proposed answers are by crackpots. But the truth it that this is the problem to solve. Do we need colliders to solve it? Maybe. Maybe not. But who is working on this problem? Nobody. That is the real scandal of (theoretical) particle physics.

The problem is clear, and everybody is avoiding working on the solution. Avoiding to work on a solution has indeed allowed many people to get a lot of money from funding agencies. Avoiding to work on a solution has also created a wide spectrum of fantasy theories.

Physicists and the funding agencies have a century old problem, but the search and use money in all sorts of directions – except in the correct one. Look at Snowmass 21. Look at what their theory frontier group does on this issue: NOTHING. Look at what CERN does in this direction: NOTHING. Look at what the rest of the world does: NOTHING.

String theorists gave up. Loop quantum gravity gave up. I know too little about twistors, but chances seem slim that they will solve the problem.

Fact is, asking for calculations of the parameters of the standard model is the best way to discard wrong theories.

The real scandal of particle physics is (1) that nobody is looking at understanding the parameters of the standard model. (2) That nobody encourages such research. (3) That nobody funds such research. And (4) that nobody even mentions that this is the real issue.

And to be a little direct: point (4) is true for most of the people who comment on this blog as well. As long as we keep sweeping the problem under the carpet, nothing will happen. Point (4) is the silent agreement of all particle physicists. As long as it holds, there will be no progress. As long as this silent agreement is kept, particle physics will not prosper.

We should tell young people that this is what we need to find out.

16. **Johannes**
October 25, 2020

Peter,

thank you for posting my comments. One more remark in the same direction. Some months ago, a blogger whom usually I admire a lot wrote that any TOE is tested by looking for deviations from the standard model. Even though many have agreed, many will agree or tend to agree, this is wrong. And it is misleading.

A TOE is first of all tested by checking its calculation of the coupling constants and the particle masses. (We do not know whether deviations from the standard model exist.)

This anecdote shows how deeply we all – the whole HEP community – have buried the goal to understand the parameters of the standard model below other, much less important activities and aims. Without noticing, we are misleading young people. (And I include myself here.)

We must tell the younger people what the goal is: understanding masses and couplings. The goal is NOT understanding supersymmetry, nor strings, nor loops, nor quantum gravity, nor the amplituhedron. The goal is NOT understanding baryon-antibaryon asymmetry, nor dark matter, nor dark energy. And: The goal is NOT finding deviations from the standard model.

The real goal we have before us, since over 100 years, is to understand the ratio 511 keV/Planck mass for the electron, the corresponding ratios for the other particles, the number 137.036, and the other two coupling constants, and a few more parameters (and, of course, the running with four-momentum of all of them).

Why are CERN, NSF, research agencies, sponsors, and research ministers not taking up this goal? It is the biggest problem in physics. It is orders of magnitude bigger than Fermat's last theorem. There are of course many obvious reasons (money does not help solving it in an obvious manner, accelerators probably will not help solving it, it is hard to plan, we have no clue yet how to get to a solution).

But let me be a bit provoking: If you, Peter, or I, or any of several dozen of other people had a billion dollars every year to spend on this goal, then you, or I, or any of this dozen of other people would be able to organize a world-wide project that would achieve that goal. And probably they would need less that a billion dollars a year.

In this sense – but only in this one – I agree and understand Sabine's point. And working towards this real goal would not be an empty promise. It would be a worthwhile effort.

17. **Peter Shor**
October 25, 2020

@Amitabh Lath:

> The only valid reason for NOT continuing down our path towards short distance physics would be if someone could guarantee there is NO new physics at these higher energies

Do you really believe this? Suppose you knew that the probability of discovering a new particle at the next-stage collider was one in fifty million (the chance of winning the lottery). Would it be worth it? Do you buy lottery tickets?

Assuming that the cost of the next machine is $20 billion, your expected value is positive at this probability if you put the benefit of a new particle at one quadrillion dollars. But surely, nobody would think of claiming that it would be worth it to pay a quadrillion dollars to discover a new particle. That's the GNP of the U.S. over 50 years.

So now that we've established that it's just a matter of probabilities, at what probability of seeing something would it be worth building the next collider?

Clearly, we should wait until the LHC run is finished and see whether there's any hint of new physics. But if the LHC doesn't give any hint of new physics, do you really think the probability of seeing something with the next-generation collider would be more than 10%?

18. **Peter Woit**
October 25, 2020

Johannes,
The problem is that no one has a good idea about this, and a billion dollars is not likely to change that. This is actually one of the strongest arguments for a new collider: the source of the mass problem is the Higgs sector, so the highest priority should go to a machine able to study the Higgs, and this has to be done at the energy frontier. Yes, it's possible that all an experiment will see are the SM-predicted numbers, but this is not guaranteed (and the Amit/Peter Shor comments show that this is the crux of the funding question).

The situation is somewhat analogous to that of the Riemann hypothesis. All indications are that we're missing some basic idea there, that the problem is not going to be solved by more strenuous efforts to apply ideas we already know about. A billion dollars in grant money handed out to people engaged in such strenuous efforts likely would change nothing.

A big difference of the Riemann hypothesis case is that RH hasn't been the victim of a campaign to claim that the best research has proved that it is inherently insoluble. This is what has happened to HEP physics: there has been a huge and all too successful "we couldn't solve it, so no one can" campaign to convince people that string theory research has shown that the problem of particle masses is inherently insoluble, that these numbers are just random environmentally determined artifacts of some very complicated and unknowable physics going on at the Planck scale.

One aspect of the particle mass problem is that there are obvious more basic questions we have no good ideas about, in particular that of why there are three generations. Before we can explain an entry in a matrix, likely we first need to explain the dimension of the matrix.

If you look at how the great unsolved problems of mathematics get solved, it's often not by a large well-funded group effort. The solutions of the Poincare and Fermat problems by Perelman and Wiles are instructive examples. In neither case would money have helped, probably quite the opposite, since accepting money would have likely required producing reports about their progress, something neither of them thought was a good idea. The way such problems get solved in when the best people in the field think hard about them, engage in research programs designed to turn up new fundamental ideas, and don't get convinced the problem is insoluble and stop thinking about it.

19. **Alessandro Strumia**
October 25, 2020

Peter,

to avoid excessive neutrino radiation (while keeping desired luminosity) one needs to make narrower muon beams. Achieving this seemed impossible, but now there are ideas, see e.g. https://arxiv.org/abs/1509.04454.

45 years ago Rubbia and Van den Meer could persuade the field to pursue a risky new idea. 20 years ago I saw the resistance to the LEP to LHC transition: a new collider meant a change of generation. This is not happening now that the field is dominated by mega-collaborations.

20. **George Ellis**
October 25, 2020

OC: “more recent “it from qbit” ideas” certainly did not come from string theory. They came from John Wheeler long before string theory was fashionable.

21. **Amitabh Lath**
October 25, 2020

Peter Shor: Yes it is worth it to me because the Standard Model pisses me off. It’s hodgepodge and annoyingly half-baked.

I am not going to play the “how much money is too much money” game because as we have discussed before, money spent on big science is research and infrastructure spending, it pays for itself many times over.

22. **martibal**
October 25, 2020

Peter: since I come from a region very close to CERN, your argument about unsafe neutrino radiation makes me worry. Is this a joke ? Or do we have any knowledge about how bad can heavy neutrino radiation be ?

23. **OC**
October 25, 2020

@George Ellis: (*the* George Ellis?!?) I’m well aware of the history of “it from bit”. I saw JW present the idea in person, with his self-gazing, eyeball-bearing U at the Einstein Centennial celebration at the IAS in 1979. But JW’s ideas were pretty inchoate, or at least I didn’t understand them (not surprising – I was an undergrad at the time). I don’t think anyone else understood them as a real direction for research then either, though in hindsight perhaps they’re related to the then-new Bekenstein-Hawking ideas about black holes and entropy, though I’m pretty sure Wheeler was concerned more with issues related to the measurement problem.

Anyway, the string theory connection, as best I understand it, is the effort to translate gauge/gravity duality into ideas about how entangled quantum bits give rise to geometry. The detailed formulations of these ideas that have come out in the last decade were – at best – very implicit in JW’s slogan.

24. **Peter Woit**
October 25, 2020

martibal,
Not a joke, but I wouldn’t worry right now.

The main reason a muon collider is difficult is that muons have a lifetime of only two microseconds. So, very hard to store and collide. Everything in the beam is decaying quickly, with decay products including two high energy neutrinos, which you can’t shield. Normally one thinks of neutrinos as famously harmless: huge numbers come from the sun, and then go through the earth without interacting (mean free path a light-year of lead). But the cross-section goes up with energy and is much higher for TeV scale neutrinos. Also, you need a lot of muons in the beam. So, the neutrino radiation problem is real for a muon collider. Alessandro may be right that there are ideas for keeping this to a low enough level.

In any case, if you’re worried you should figure out the coordinates of the circle where the plane of the LHC tunnel intersects the surface of the earth, and just make sure not to live there.

25. **martibal**
October 25, 2020

Damned ! I made (rightly) fun of people fearing black hole production at LHC, but I’ll have to be more careful about neutrinos then ! I had in mind the usual story you recalled (“lots of neutrino from the Sun pass across the Earth all the time etc). The surface of the Earth is far from flat around Ginevra, that may not be so easy to figure out the intersection of the circle with the surface.
Private joke for the italian readers: let’s ask Gelmini, she is an expert in neutrino 🙂

26. **Alessandro Strumia**
October 26, 2020

Dear Martibal, don’t worry about neutrinos. Neutrinos emitted by pp colliders are a problem only for Dark Matter searches. Neutrinos are one reason why a 100 TeV pp collider cannot “conclusively probe the existence of weakly interacting dark-matter particles of thermal origin”. If you want to worry about something, I would suggest perfluorocarbons

27. **Marco**
October 27, 2020

The FCC statement from the Nature article is in contradiction with the FCC CDR.

> No experiment, at colliders or otherwise, can probe the full range of dark matter (DM) masses allowed by astrophysical observation.
https://link.springer.com/article/10.1140/epjc/s10052-019-6904-3#Sec8

Both authors are on both publications.

28. **Martin S.**
October 27, 2020

+1 for muon collider
It would be something **new**.

When you look for something completely new, you’d rather use something completely new. HE-LHC can serve the current generation, with the new generation doing something new.

While no one will put huge money to the same (just bigger, but still the same) collider, muons can be sold as a new way that nobody has ever walked. And if it will provide a lot of neutrinos, you can make it a double experiment.

29. **The Spirit of Harry Lipkin**
October 27, 2020

The procrustean effect… Hossenfelder kinda believes theoretical displeasure with the WIMP miracle, but also lambasts other theoretical claims that she thinks provided a false basis for other experiments.

As a matter of fact I have written a lot of proposals and have organized big teams of researchers. Hossenfelder reminds me of Pickering and “Fabricating Quarks”.

Look, `twas ever thus. Experiment goes kinda where it can go, we only have tools to illuminate under certain lampposts. Often we’ve found incredible surprises… Harry Lipkin used to be eloquent about that…. the poor record of theory in guiding discovery in particle physics in the 20th century. But nonetheless, surprises were many.

Seems like Peter Woit, you get it. The experimental community is earnestly struggling. Doesn’t seem like Hossenfelder gets it at all, and the hardbitten hardcore gnomes who roll around in the radioactive dust pulling cables and stuff don’t yet listen much to her. But she could still be right, whatever it is she is saying. That is the shocking nature of all profound discovery… it could appear from anywhere.

30. **Peter Woit**
October 27, 2020

Martin S.
The problem with the HE-LHC idea is that the needed magnets are very expensive (3 billion) and only give a factor of two in energy above the LHC. The current plan for the next few years emphasizes working on the magnet technology, maybe that will help the situation.

Yes, a muon storage ring would make a great neutrino factory. It is definitely a project for a new generation, only question is whether it’s a generation that has yet been born…

31. **Suomynona**
October 29, 2020

@Johannes,

I don’t think the problem is so much that the old guard is not giving open questions to the younger generation, but rather they are also providing the supposed answers. For any number of open questions in high energy physics, the answer is given to be “string theory”. So the young people are primed to accept that the answers must have a given form, the form of string theory.

32. **From philosophy with physics**
November 14, 2020

Dear Peter,
thank you for trying to balance out. What I really like about your blog, is that you do not have an obvious agenda (as Hossenfelder has, or Smolin had in his book that was published parallel to yours).

Building accelerators is much less empty than a TOE or QG. It should not be underestimated that CERN is a peaceful facility that has quite an outreach+attraction to and on young people. This spin-off is worth a lot and will not be acquired by proposing to focus on quantum foundations or inconsistencies.

I happened to be in Geneva last year as they opened up CERN for the general public. It was a completly fee-free event. There would be much to tell about seeing the detectors, the special facilities (like the Anti Matter Factory) and much more, but the most important thing I really liked about it was the positive message this community conveyed.

They might oversell a lot of things (but so do all us if we want the money, Hossenfelder not excluded!), but they at least provide also a vision that science is something worth doing, that there are things beyond your imagination and everyone can be part of it. A positve perspective.

All the best

Various Links, String Theory now Untethered

November 13, 2020
Categories: Uncategorized

I've been spending most of my time recently trying to get unconfused about Euclidean spinor fields, will likely write something here about that in the not too distant future. Some other things that may be of interest:

- I did an interview a couple days ago with Fraser Cain, who runs the Universe Today website. He had some excellent and well-informed questions about the state of HEP physics. I regret a little bit that I focused on giving an even-handed explanation of the arguments over a next generation collider, didn't emphasize that personally I think building such a thing is a good idea (if the money can somehow be found), since the alternative would be giving up and abandoning this kind of fundamental science.
- On Monday, the Simons Center celebrated its 10th birthday, talks are here, giving a good overview of the kinds of math and physics that have been going on there during its first decade.
- For the latest on the formulation of the local Langlands correspondence in terms of the geometry of the Fargues-Fontaine curve, Peter Scholze is teaching a course now in Bonn, website here.
- Kirill Krasnov has a book out from Cambridge, Formulations of General Relativity. If you share my current interest in chiral formulations of GR and twistors, there's a lot about these in the book. For a more general interest survey of what's in the book, see Krasnov's lectures last year at Perimeter (links and slides are on his website).
- A couple weeks ago, a very well-done explanation of what's been going on around the black hole information paradox written by George Musser appeared at Quanta Magazine. Periodically in recent years I've tried to follow what's up with this subject, generally giving up after a while, frustrated especially at not being able to figure out what underlying theory of quantum gravity was being studied. All that ever was clear was that this was about low-dimensional toy model calculations involving some assumptions that had ingredients coming from holography and AdS/CFT.

  Musser's article makes quite a few things clearer, with one striking aspect the news that:

  > researchers cut the tether to string theory altogether.

  which I gather means that any foundation in AdS/CFT is gone, with what is being discussed now purely semi-classical. I don't understand what these new semi-classical calculations are, and whether optimistic claims that the information paradox is on its way to a solution are justified (history hasn't been kind to previous such claims). In recent years the pro-string theory research argument has often been that while there no longer were any prospects that it would tell us about particle physics, it was the best route to solving the problem of quantum gravity. It will be interesting to see what the effect will be of that cord getting cut by leading researchers.

  If you think it's a good idea to follow discussions of this kind of thing on Twitter, you might enjoy threads from Sabine Hossenfelder and Ahmed Almeiri.

Comments

1. **Patrick Bryant**
   November 13, 2020

   My understanding of the new semiclassical calculations is that by computing the gravitational path integral over an ensemble of n boundary conditions, and allowing topologies which connect the boundaries, one can reproduce the Page curve when n is analytically continued to 1.
   These new topological terms ("euclidean wormholes") can be computed 'easily' in 2d JT gravity and the page curve is reproduced there. The problem is that no one knows what exactly to make of these topologies that don't factorize and it's not obvious that effects in 4D won't spoil the magic. On page 29 of https://arxiv.org/pdf/1911.11977.pdf the authors suggest this isn't an issue, "2d gravity is convenient for drawing pictures, but the topological argument relating replica wormholes to the island extremal surface is similar in any spacetime dimension: one just replaces each point in the discussion below by a sphere."

   It seems the interpretation of the euclidean wormhole topologies in the limit n->1 is somehow related to an ensemble average of chaotic quantum systems and it is not clear that the gravitational path integral can be interpreted as a semiclassical limit of any single quantum system. I really don't understand the connection between the SYK model and JT gravity which seems central to this idea.

   I found these talks by Douglas Stanford to be illuminating:
   1) Conceptually helpful https://www.youtube.com/watch?v=-hfcApA9s8Q
   2) Technically helpful https://www.youtube.com/watch?v=Yi2hx0GH624

2. **Peter Woit**
   November 13, 2020

   Patrick Bryant,
   Thanks. My problem here is that the claims being made all are about "doing the gravitational path integral", but the whole problem of quantum gravity is that in 4d that (summing over all geometries using the classical action) is something no one has made sense of, and nothing is being said that addresses that problem.

   In 4d you can decide to give up on the full sum, just look at classical solutions and do a semi-classical calculation, but this doesn't touch the underlying quantum gravity problem. It sounds like this is what is being done here in a simpler context. Maybe it resolves the question of how to make sense of the semi-classical calculation in a black hole background, but I don't see anything addressing the problem of how to actually quantize the gravitational degrees of freedom.

3. **S=k_B log(W)**
   November 14, 2020

   There are (at least) two other lines of recent developments that relate to AdS/CFT and black hole physics. Both of them are very much tethered to string theory and are concerned with black holes in more than 3 space-time dimensions.

   1. One is the program of microstate geometries/fuzzballs. See this recent review

   https://arxiv.org/abs/1902.07176

   and this Quanta magazine article from a few years ago

   https://www.quantamagazine.org/how-fuzzballs-solve-the-black-hole-firewall-paradox-20150623/

   2. There has also been a flurry of activity showing how to use holography to successfully relate exact QFT path integral calculation to learn about the dual AdS black holes. See this review for a nice (but already outdated) summary

https://arxiv.org/abs/1902.07176

Of course, given the premise of this blog, I suspect that you may label both of these research programs as "not even wrong".

4. **Peter Woit**
   November 14, 2020

   S=k_B log(W),

   Your point seems to be that some people have not given up on hopes that they can use AdS/CFT to produce a viable quantum gravity theory describing our world (dS, four large space-time dimensions). Back in 2006 when I wasted a lot of time arguing with string theorists like Lubos Motl about this, it was a nine year old idea that was going nowhere. Now it's a 23 year old idea which has gone nowhere. As for claims that this line of work can solve the information paradox, the five year old Quanta article you refer to has

   "If Samir says he has a solution to the paradox, he is linguistically correct. He's also in good company," said Marolf. "There are lots of people with resolutions to the paradox. Whether it's the way physics actually works in our universe remains to be seen."

   On the information paradox front, the newer Quanta article tells a different story: apparently the resolution of the paradox is semi-classical, nothing to do with string theory or hopes of getting quantum gravity (4d, dS) out of AdS/CFT.

5. **John Baez**
   November 15, 2020

   Peter wrote:

   > Maybe it resolves the question of how to make sense of the semi-classical calculation in a black hole background, but I don't see anything addressing the problem of how to actually quantize the gravitational degrees of freedom.

   I think you're right. That's not *necessarily* bad. If folks could figure out how to solve the black hole entropy problem "semiclassically" – without inventing a full-fledged theory of quantum gravity – they could find a solution that applies to many candidate theories. It could be a bit like thermodynamics versus a detailed theory of the microscopic structure of matter: thermodynamics tells you less, but its results are more general, so the further you can go on solving a problem using just thermodynamics, the more robust your solution will be.

   However, the analogy to thermodynamics is weak, because in thermodynamics we know the rules of the game, whereas it would take a lot of work to isolate and clarify the principles underlying the calculation described in the *Quanta* article. As they say:

   > The work is highly mathematical and has a Rube Goldberg quality to it, stringing together one calculational trick after another in a way that is hard to interpret. Wormholes, the holographic principle, emergent space-time, quantum entanglement, quantum computers: Nearly every concept in fundamental physics these days makes an appearance, making the subject both captivating and confounding.

   I think the title of the *Quanta* article is only accurate if one reads it very generously. We are not near the end of work on the black hole information paradox.

6. **John Baez**
   November 15, 2020

   It's great to hear Kirill Krasnov has come out with a book on formulations of general relativity. We used to work together on spin foam models of quantum gravity, and we kept playing around with different formulations of general relativity, trying to find one that worked best for our purposes. I'd sort of lost touch with him in recent years until he came out with a paper on octonions and the Standard Model, which focuses on the importance of SO(9). I've been talking to him about that recently… but he didn't tell me he'd come out with a book on GR! It's a good thing I read this blog.

7. **Blake Stacey**
   November 16, 2020

   I've slipped behind in trying to understand the ways in which my fellow theorists are torturing black holes these days. Coming at the problem from the quantum information side, I never quite followed the arguments or grasped the underlying intuitions, I think. When "ER = EPR" came out, for example, I just didn't get it — it sounded like they would have had a wormhole between any two correlated systems in the Spekkens toy model, which is just silly. A lot of what I read since then seemed more likely to give a geometric description of certain types of many-body entangled states, rather than to turn entanglement into spacetime. (I know multiple people who knew John Wheeler, and we've had plenty of long chats about "it from bit" aspirations, so I *am* coming at "it from qubit" from a sympathetic place.) And for weird reasons of my own, I distrust the applicability of any conclusions from AdS, whether or not a gauge/gravity duality is invoked. The new "replica wormholes" effort seems to rely a lot on AdS still, even when it's not being stringy, doing things like gluing AdS to Minkowski in order to provide a place for radiation to escape into. I'm not sure how I feel about that!

   > … by computing the gravitational path integral over an ensemble of n boundary conditions, and allowing topologies which connect the boundaries, one can reproduce the Page curve when n is analytically continued to 1.

   This is probably a very smart tactic being employed by some very smart people, but it also gives me the feeling that somebody is going to pop out from behind the corner and declare that the total number of black holes in the Universe is now -1/12.

8. **Fen Zuo**
   November 17, 2020

   I read through Kirill Krasnov's 6d/7d model. As he mentioned in his talk, it could be related to the topological strings. Nevertheless, I believe it must be related to the so-called 6d (2,0) SCFT and its 7d dual. Some twisted version of the 6d theory is also called Theory X by some mathematicians. Here the cosmological constant naturally presents itself through the Omega parameters of Nekrasov. However, the relation to the twistor formulation is unclear, at least for me.

9. **Peter Shor**
   November 17, 2020

   One thing that worries me is whether all of this means anything. There's the quote from the article that John Baez pointed out:

   > The work is highly mathematical and has a Rube Goldberg quality to it, stringing together one calculational trick after another in a way that is hard to interpret. Wormholes, the holographic principle, emergent space-time, quantum entanglement, quantum computers: Nearly every concept in fundamental physics these days makes an appearance …

So how do we know that you can't find a way to string all these calculational techniques together in a Rube Goldberg way to come up with any result you want? In this case, the fact that they've come up with the Page curve isn't all that meaningful.

10. **John Baez**
November 17, 2020

Stringing together lots of calculational techniques makes sense when the rules of the game are clearly laid out – for example, this is how people proved that [8 and 9 are the only two powers of positive natural numbers that differ by 1](). It's a lot more risky when one is doing physics calculations that aren't based on a well-defined underlying theory. Then one is in real danger if there isn't a solid intuition grounding one's work. It's interesting that nobody in the *Quanta* article claims to understand what's really going on here – exactly how the information gets out of the black hole. I suspect people will be arguing about this for many years.

Personally I'd be quite happy with information loss.

11. **anon**
November 19, 2020

Replica wormholes do not depend on AdS and, as is now understood, arise for a good reason. They can be derived solely from the goal of approximating certain information theoretic quantities of a subsystem of a larger system in a more sophisticated way than just replacing your reduced state on the subsystem with a thermal density matrix (but while still not actually using more fine-grained information than equilibriation).
This was recently shown here: https://arxiv.org/abs/2008.01089
In this controlled approximation, certain matrix elements arise, and these matrix elements will in a gravity system be calculated exactly by these wormholes. Analogous objects would arise in other many-body systems.

12. **Somdatta**
November 20, 2020

Shouldn't quantum gravity really stem from quantum geometry, since gravity is after all the consequence of the dynamical geometry of manifolds? In the regime where gravity is strong, shouldn't one consider that the evolution of one spacetime slice to another takes place via all possible interpolating manifolds, to be summed over in a path-integral formulation? I believe that is what one is doing in JT gravity, but extending that to 4d is not trivial at all. For one thing, the theory of 4-manifolds is in a state of flux, so shouldn't one hold all theories of 4d quantum gravity in abeyance until that has settled down? And all this is over and above the problem of doing a path-integral quantization, where one is faced with the usual problem of defining the path-integral unambiguously. Not to speak of the issues of non-renormalizability plaguing such a formulation.

13. **Peter Woit**
November 20, 2020

Somdatta,
The problem with just saying quantum gravity is a "sum over geometries" is that there's a huge variety of very different ways of specifying what a "geometry" is, and once you have done that, another huge variety of ways to try and put a measure on the space. You need a much more substantive idea to say anything useful about this, I have no idea whether this recent work has one or not.
Whenever I try and read about this to understand better what is going on, I get put off by a wall of claims about "wormholes", then decide that my time is better spent thinking about other things.

14. **Somdatta**
November 20, 2020

Peter,
You're right, but what I wanted to point out was that even if you figured out how to solve those problems, most of the work on 4-manifolds concentrates on the simply connected ones, with claims in the literature saying that the non-simply connected case is intractable. So one might be thwarted for a very long time to come if not forever, from even defining the space of interpolating manifolds in the sum over geometries, let alone a measure over it. Wonder what LQG has to say on all this.

15. **Peter Shor**
November 22, 2020

After having a discussion with Sabine Hossenfelder on her blog, I am beginning to see the problem. Physicists have always treated mathematics sloppily and non-rigorously (e.g. Dirac delta functions, the replica method, Feynman path integrals, AdS-CFT applied to condensed matter). And they have gotten some amazing results this way. But they've always had experiment to tell them when their calculations gave the right answer or were completely off-base.

With the black hole information paradox and quantum gravity, they no longer have experiment to guide them. I think what they have to do is go back, look at what they think they've shown, and treat everything much more carefully (if not completely rigorously). But I suspect that most physicists find it inconceivable that this has become necessary.

If I recall the history of mathematics correctly, there are several times that mathematicians have needed to do this (one being the treatment of set theory that Cantor et al. put back on the right track).

16. **Jack Morava**
November 22, 2020

@PeterShor:

It is said that the

https://en.wikipedia.org/wiki/Italian_school_of_algebraic_geometry

started having annual conferences around the turn of the twentieth century, in order meet and vote on the theorems.

17. **Peter Shor**
November 22, 2020

@Jack Morava:

Wow! That's an amazing story, even just reading the short version in Wikipedia. I knew there were problems with making probability theory rigorous in the early 20th century, but I foolishly assumed that applied mathematicians were to blame, and that pure mathematicians had figured out how to do things better before then.

18. **John Baez**
November 22, 2020

Peter Shor wrote:

But I suspect that most physicists find it inconceivable that this has become necessary.

I disagree. I think most physicists realize that more careful thought is required to understand quantum gravity. Theoretical physicists are used to floundering around, writing papers that try different things until the truth finally becomes clear. They aren't like mathematicians or mathematical physicists, who start with clear assumptions and deduce consequences. They're doing something much harder, where the rules of the game only become clear near the end. So most of their papers are wrong, but that's okay – that's how it works.

19. **Somdatta**
November 23, 2020

Another thing worth pointing out that appeared in the Quanta article.

"When researchers set out to analyze how black holes evaporate in AdS/CFT, they first had to overcome a slight problem: In AdS/CFT, black holes do not, in fact, evaporate. Radiation fills the confined volume like steam in a pressure cooker, and whatever the hole emits it eventually reabsorbs. "The system will reach a steady state," said Jorge Varelas da Rocha, a theoretical physicist at the University Institute of Lisbon.

To deal with that, Almheiri and his colleagues adopted a suggestion of Rocha's to put the equivalent of a steam valve on the boundary to bleed off the radiation and prevent it from falling back in. "It sucks the radiation out," said Netta Engelhardt of the Massachusetts Institute of Technology, one of Almheiri's co-authors. The researchers plopped a black hole at the center of the bulk space, began bleeding off radiation, and watched what happened."

The point is, this artificial way of bleeding off the radiation doesn't take place naturally, so all analyses based on such a thing are artificial, and may not apply to nature. One might say AdS black holes themselves are unnatural, but then that becomes the point. One is applying unnatural assumptions to unnatural black holes and then making the claim that they apply to the real world. Why would such a thing be believable?

20. **jsm**
November 23, 2020

@Jack Morava Can you cite a source for your statement?

21. **Peter Woit**
November 23, 2020

John Baez,
I can't find the source, but one of my favorite John Baez quotes I recall as comparing doing theoretical physics without either mathematical rigor or connection to experiment as "playing tennis without a net".

There's a good argument for people trying whatever they can, if it ultimately leads to rules of the game getting clarified and the truth becoming clear. The problem is that sometimes that doesn't happen, and people keep doing the same thing endlessly, telling everyone what great tennis players they are (cf. string theory).

I'm very wary of saying much about this latest work because I don't understand it. But looking at many decades of similar claims about "solving the information paradox", and seeing what people claim to now have done convinces me that my time is better spent on other things. There's no way this kind of thing can connect with experiment, what would more likely make it interesting is having a well-defined solution to a well-defined problem of some kind. If a problem is hard, maybe all people can do is flail around and do wrong things, hoping to learn something that will help. Nothing wrong with that, but then there's no reason for articles in Quanta magazine or elsewhere.

22. **Jack Morava**
November 23, 2020

@jsm : It's a joke; ask your friendly neighborhood algebraic geometry grad student. I think I first heard it at Columbia in the 60s, perhaps from Spencer Bloch or George Kempf.

23. **Robert A. Wilson**
November 24, 2020

My father was one of the last members of the Italian school of algebraic geometry before its collapse, being a student of J. G. Semple, and publishing on the subject in 1947, 1950 and 1955. The abstract of the last contains the phrase "no great degree of rigour can be claimed" and refers to "experimental" justification (his inverted commas). That about says it all, I fear.

24. **Blake Stacey**
November 24, 2020

John Baez:

> Personally I'd be quite happy with information loss.

I'd be happy with that, too. (I remember watching a lecture by Bill Unruh during the heyday of the firewall back-and-forth where he suggested that information might just be "gone — *pfft!*") I've also played around with a toy model where a black hole is described by a mixed state all the way from formation through evaporation, so the intuitions based on (as Page says) "forming the black hole from a pure state of radiation in a box" simply aren't applicable.

25. **John Baez**
November 25, 2020

Peter Shor wrote:

> I can't find the source, but one of my favorite John Baez quotes I recall as comparing doing theoretical physics without either mathematical rigor or connection to experiment as "playing tennis without a net".

No fair using John Baez quotes against me! I'm compelled to agree.

Hawking's original work on black hole radiation had no connection to experiment but it could be, and was, made mathematically rigorous – in a "semiclassical" approach where the geometry of spacetime was described classically and the radiation was described using quantum field theory (a free quantum field, describing noninteracting photons).

So, the rigor was obtained by avoiding use of the nonexistent theory of quantum gravity and hoping that in some circumstances the semiclassical approach was a good enough approximation to the unknown reality to be worth thinking about.

The thermal nature of the radiation emitted led to a puzzle, mistakenly called the "black hole information paradox" because it only becomes a paradox if you put enough constraints on the solution that there's… no solution.

One way to push the puzzle toward the jaws of paradox is to adopt the AdS/CFT philosophy, which roughly says that everything about the universe can be observed from arbitrarily far away, on a "sphere at infinity", where it's described by a quantum field theory. This philosophy is not based on experiment: on the contrary, our universe is nothing like anti-de Sitter spacetime. It's also not mathematically rigorous. And the idea that everything about he universe can be observed from arbitrarily far away tends to conflict with the idea that once something falls into a black hole you can't observe it. So it should come as no surprise that with this approach the information loss puzzle became closer to a paradox, and researchers began to contemplate something very strange: that anyone falling into a black hole would be burnt to a crisp by a "firewall" lurking right beneath the horizon.

> But looking at many decades of similar claims about "solving the information paradox", and seeing what people claim to now have done convinces me that my time is better spent on other things.

Me too. All my best work came after I gave up working on quantum gravity. The "firewall" stuff happened after that, so I've never studied it carefully: I just listen to what people say, shake my head bemusedly, and shrug. I still hope that theoretical physicists can make progress on the black hole information puzzle by clear thinking, and I guess you caught me on an optimistic day. But the jury is still out on that.

> If a problem is hard, maybe all people can do is flail around and do wrong things, hoping to learn something that will help. Nothing wrong with that, but then there's no reason for articles in *Quanta* magazine or elsewhere.

If pop-sci magazines could manage to present the current flailings in fundamental physics in a way that made it really clear they were really just flailings, it would be okay. But somehow they feel the need to present each development as if were a wonderful burst of progress.

John Baez:

I've sometimes wondered whether the AdS-CFT correspondence might not be an exact correspondence, but only a good approximation. In this case, it leaves enough wiggle room that you can speculate that information could be lost.

The few times I've asked somebody who works in the area, they say "no, the AdS-CFT correspondence is exact, and physics is reversible because CFTs are reversible" without ever giving me a good justification for this statement. Of course, if they did have a good justification, I wouldn't be able to understand it. But I've suspected for some time that they don't. And when they assume that AdS-CFT exact, they often end up postulating something else, like locality in GR is violated, and locality is something that we do have a great deal of experimental evidence for.

I'd much rather assume that AdS-CFT is a very good approximate correspondence.

Yeah, I don't think it's been proved, not even in the physics sense of "proved", except in some baby cases like 2+1-dimensional gravity which have no local degrees of freedom, which makes it far less surprising that you can reconstruct solutions from data observable at infinity. (If nothing interesting is happening in any bounded region of space, it's not shocking that you can figure out what's happening by only doing measurements very far away.)

It's also probably worth reminding nonexperts (like me) that the most famous case of AdS/CFT doesn't apply to a four-dimensional universe governed by general relativity, like our own. It applies to superstring theory on a 10-dimensional spacetime that's the product of 5-dimensional anti-de Sitter space and a large 5-sphere. So there is unbroken supersymmetry, not seen in our universe, and also a spacetime quite different from ours.

There are also other cases of AdS/CFT, but if anyone makes strong claims for the relevance of AdS/CFT to our universe you can have fun pressing them for details about which case they're talking about.

Contemplating the End of Physics

November 24, 2020
Categories: Uncategorized

In a remarkable article entitled [Contemplating the End of Physics] posted today at Quanta magazine, Robbert Dijkgraaf (the director of the IAS) more or less announces the arrival of the scenario that John Horgan [predicted for physics back in 1996]. Horgan argued that physics was reaching the end of its ability to progress by finding new fundamental laws. Research trying to find new fundamental constituents of the universe and new laws governing them was destined to reach an endpoint where no more progress was possible. This is pretty much how Dijkgraaf now sees the field going forward:

> Confronted with the endless number of physical systems we could fabricate out of the currently known fundamental pieces of the universe, I begin to imagine an upside-down view of physics. Instead of studying a natural phenomenon, and subsequently discovering a law of nature, one could first design a new law and then reverse engineer a system that actually displays the phenomena described by the law. For example, physics has moved far beyond the simple phases of matter of high school courses — solid, liquid, gas. Many potential "exotic" phases, made possible by the bizarre consequences of quantum mechanics, have been cataloged in theoretical explorations, and we can now start realizing these possibilities in the lab with specially designed materials.
>
> All of this is part of a much larger shift in the very scope of science, from studying what is to what could be. In the 20th century, scientists sought out the building blocks of reality: the molecules, atoms and elementary particles out of which all matter is made; the cells, proteins and genes that make life possible; the bits, algorithms and networks that form the foundation of information and intelligence, both human and artificial. This century, instead, we will begin to explore all there is to be made with these building blocks.

In brief, as far as physics goes, elementary particle physics is over, from now on it's pretty much just going to be condensed matter physics, where there at least is an infinity of potential effective field theory models to play with.

Dijkgraaf ends with an argument indicating that human intelligence is outmoded, artificial intelligence is our future:

> Science concerns all phenomena, including the ones created in our laboratories and in our heads. Once we are fully aware of this grander scope, a different image of the research enterprise emerges. Now, finally, the ship of science is leaving the safe inland waterways carved by nature, and is heading for the open ocean, exploring a brave new world with "artificial" materials, organisms, brains and perhaps even a better version of ourselves.

Along the same lines, today also brings an article in the New York Times by Dennis Overbye, [Can a Computer Devise a Theory of Everything?] The article discusses the new [MIT Institute for Artificial Intelligence and Fundamental Interactions] and Max Tegmark's hopes that AI will "discover all kinds of new laws of physics". My guess is that this will work just fine if you give up on the 20th century understanding of what a "law of physics" is and follow Dijkgraaf's lead. The problem then may be not so much "will we understand the new laws of physics found by AI?", but rather that of them not being interesting enough to be worth understanding…

Update: To clarify the point I was trying to make about the Dijkgraaf piece arguing against the "end of physics", compare it to the [similar 1996 piece] Gross and Witten published in the Wall Street Journal (a summary is [here], an extract [here]). Gross and Witten were strongly disagreeing with Horgan, whereas it seems to me that Dijkgraaf implicitly agrees with Horgan that fundamental physics has hit a wall and theorists are moving on to do something else.

Comments

   How ironic. Not two hours ago I decided on a Miltonish title for my next blog: Paradigms Lost.

2. **David Appell**
   November 24, 2020

   Huh, I didn't realize we understood the laws followed by dark energy or dark matter. My bad.

3. **anon**
   November 24, 2020

   > Huh, I didn't realize we understood the laws followed by dark energy or dark matter. My bad.

   To add a bit more detail, Dijkgraaf starts by asking "Is physics finished?," he answers that it is not, and he gives three reasons. His third reason is the one discussed in this blog post (condensed matter is a basically endless subject). His second reason though, is that we don't understand dark energy and dark matter and physics can't be finished without understanding them.

4. **chris bolger**
   November 24, 2020

   We are not reaching the end of physics, we are reaching the end of affordable physics. 100 years ago one could physics with one person, on a table top with extra time, and a few dollars. Now it costs a discernable amount of GDP from many countries and teams of 1000's. We have found deeper layers of reality much faster than the growth of the economy by pooling money, resources and people. That can only go so far and we are reaching that limit. Progress in physics will inevitably slow down to the growth rate of the economy unless something revolutionary occurs like a miracle in AI. It is not the end of physics, it is just much slower.

5. **John Baez**

   David Appell wrote:

   > Huh, I didn't realize we understood the laws followed by dark energy or dark matter. My bad.

   These sarcastic comments seem to overlook what Dijkgraaf wrote:

> Recent advances in cosmology allow us to state, with a fair amount of certainty, that 95 percent of the universe is missing. These missing parts consist of dark matter and dark energy, both equally mysterious forms of new physics. As long as such mysteries remain — and there are others — the work of physics will not be complete.

So, I don't think he's saying fundamental physics is done. Indeed his comments seem pretty well-balanced to me. The title, "Contemplating the End of Physics", is overblown and misleading, as often for articles in pop-sci magazines.

6. **WTW**
November 25, 2020

Pardon me if I've just become too cynical, but I read Dijkgraaf's Quanta article as just another PR piece, similar to those we have come to expect from senior management at CERN. (One clue: the bizarre depiction of phonons as somehow relevant, or even an accurate description of "sound" much less elementary quantum physics.) It's another justification for why, despite diminishing returns and increasing irrelevance for much of fundamental physics' "scientific" output, places like IAS (and, in the future, CERN) should continue to exist and be funded.

But it gets worse: If you just ignore the gaping holes in our current formulation of the 5% of the universe we're supposed to now "understand", that have been unable to be closed over that last half century, and concentrate instead on just re-arranging various pieces into ever more bizarre and intricate patterns, and call that a "search for knowledge", then you essentially remove any chance of being objectively critiqued or judged as having been successful (or not). While I doubt that these attempts to put a "positive spin" on the situation [pun intended] are a pre-planned subterfuge by people like the directors of these agencies, that is the net result. While, as Peter has previously said, just combining a bunch of ingredients and essentially throwing the resulting mess against the wall to see what sticks and what doesn't could hopefully someday result in something useful, no one wants to admit that's what they/we are doing. Especially not to the general public, nor to funding agencies.

7. **Luigi Foschini**
November 25, 2020

I don't think physics is ending, but there is a serious possibility of a decline of human beings able to do it. We think about science as an endless progress, but history teaches us that there were dark ages where science was destroyed (e.g. the end of Hellenic science). Today, Big Science is the real threat for physics. I wrote some notes in a Section of my book *Scienza e Linguaggio* (Aracne, Roma, 2015; in Italian); the English translation can be found here: http://www.brera.inaf.it/utenti/foschini/Foschini_translation.pdf

November 25, 2020

We're in the late stages of the latest AI hype cycle: this one is based on a fairly old idea which has only recently become practical, which is throwing deeply astonishing amounts of training data at machine learning systems. As with previous hype cycles, impressive early results lead to wild claims about artificial general intelligence coming in a few years usually followed by some kind of exponential runaway in intelligence. As with previous cycles it is not coincidence that many (not all) of the people making these claims are seeking funding for AI work. As with previous hype cycles the impressive early results will be followed by less impressive later ones as the tricks hit a wall – once you have trained your language model on all the natural language that there is and it still doesn't produce very good natural language, where do you go? And what does it tell you about how intelligent systems learn language (hint: nothing)? And so the bubble of hype will burst, a new AI winter will follow, people will look back on the wild claims as being rather silly, until eventually they forget and the cycle repeats.

Well, perhaps it will repeat. Previous AI hype cycles have been both started and stopped by various exponential processes: available computing power increased exponentially with time, but the computing requirements of AI increased either exponentially with a shorter time constant, or worse than exponentially. But computing power certainly can not increase exponentially for ever: its increase is bounded above by some constant power of time (which is probably effectively 2). We're perhaps some way from the exponential increase hitting the physical limits, but probably not tens of years away.

The good part of all this is that, as with the previous hype cycles, good applications will be found. My favourite is weather forecasting: there is a vast torrent of data and tomorrow's initial conditions are the data against which you can train today's run.

But what isn't going to happen is some artificial general intelligence deriving new and interesting laws of physics. That's just what that the people hyping AI need us to believe so they keep getting funded.

November 25, 2020

A child discovered to be a mathematical prodigy may be directed from that point onward by establishment figures into doing research intended to advance ideas supported by the majority. In acquiescing the child will likely lose all chance of ever fulfilling his/her potential – of ever doing anything truly original.

Likewise, an AI might well be a computational prodigy, but it too will be nudged into areas supported by those feeding its algorithms data and methodologies. However, unlike the child prodigy, the AI will never have the potential to shatter paradigms, or to conceive something truly original. Indeed, it can not conceive at all.

10. **Thomas Larsson**
November 25, 2020

Yes, we know that 95% of the universe consists of dark stuff, but this is "knowing" in the sense that renaissance astronomers knew that the universe is governed by 13 epicycles. Within the framework of epicycle theory, experiments implied that there were at least 13 of them, and within the framework of GR+QFT, experiments show that 95% of the universe is dark. Both GR and QFT have of course been tested to much higher accuracy than epicycle theory ever was, but only in domains where the other can be ignored, and we know that they appear to be mutually inconsistent. In particular, the naïve quantum calculation of the CC is off by 120 orders of magnitude, which may indicate that GR+QFT might fail in situations where the CC is important.

11. **Peter Woit**
November 25, 2020

Dijkgraaf does say he has three arguments against physics being finished. Most of his article is about the third argument, which is what I discussed. For the first of his arguments, he himself gives the counterargument.

The second is the usual "we don't understand dark energy/matter, and it's most of the universe" argument. Everyone who makes this argument likes to cite the relative abundance, but I don't see how that matters for the question of how large a hole in our understanding these things are.

On dark energy, it appears there's a single number that describes it, one of 30 or so numbers in our best theory which we don't understand. The issue of understanding this particular number has been dead in the water for a long time: I know of no viable idea for calculating it. The string theory landscape people will tell you it is inherently uncalculable, it's an environmental artifact of the baby universe we happen to be in.

Dark matter is a much more complicated phenomenon, and it has received a huge amount of attention from theorists over several decades. All the relevant data is astrophysical, and I'm willing to believe astronomers in coming years will get us more. But, it seems to be very tough to move beyond "there's something out there gravitating, but we don't know what it is". Maybe it's right-handed neutrinos, or some other sort of unknown fundamental particle whose interactions are purely gravitational. But maybe it's instead something we don't understand about astrophysicsics, e.g. primordial black holes. Sure, this is an open problem, fundamental physics is not finished. I don't think Horgan's claim was that no open problems would remain, it was that progress towards solving them would stop.

12. **Scott Aaronson**
November 25, 2020

I mean, you could criticize Dijkgraaf's piece for being anodyne—yes, *of course* fundamental science has been gradually shifting its emphasis for decades from "what is" to "what could be," that's why so many of us now work on subjects like quantum information or topological matter or synthetic biology, welcome to the club! But like John Baez, I find it hard to argue that Dijkgraaf's thesis is *wrong.*

Indeed, let me propose a corollary: if (contrary to John Horgan) fundamental science does continue indefinitely, then it will be for basically the same reason why *pure math* continues indefinitely—namely, because the relevant limits turn out to be only those of possibility-space, not of physical space.

13. **Peter Woit**
November 25, 2020

Scott,
I'm not at all arguing that Dijkgraaf's thesis (or that of John Horgan from 1996) is "wrong". Sticking to the case of fundamental physics, I think Horgan was correct in pointing out that research was hitting limits, and that fruitless speculation like string theory was evidence of this. Lots of physicists were outraged by Horgan's argument, for an example of the reaction at the time, see a Wall Street Journal editorial by Gross and Witten
https://www.wsj.com/articles/SB837118256541339000
They argued that new revolutions were on the way, with string theory and supersymmetry promising ideas about to be tested at the Tevatron and LEP.

What I think is remarkable is the way Dijkgraaf now seems to be agreeing with Horgan. That much of the focus of theoretical physics at Princeton for many decades has been a huge failure is not something Dijkgraaf is going to say, but it's implicit in his not mentioning it. His job is to generate enthusiasm for theoretical physics and to get funding agencies and wealthy people to pay theoretical physicists, so he's putting the best face possible on what is happening.

My own agenda is somewhat different, so I'd rather see a clear-eyed examination of what went wrong and of what possible ways forward remain for those who don't want to give up and do something else. Maybe one day we'll see that in Quanta also.

14. **John Horgan**
November 26, 2020

Peter, thanks for kicking off this discussion of the themes my old book. I found Dijkgraaf's essay to be, as you and others suggest, mere marketing, and not very original at that. Michio Kaku and others were saying in the 90s that learning the laws of nature is like learning the laws of chess. The game is just beginning! And so on. I addressed that wan hope in 1996, as well as the hope that super intelligent AI will jumpstart a new era of physics, which Hawking proposed in the early 80s. I too, would love to see a "clear-eyed examination" of the status of physics, but that's asking a lot from people who have so much invested in positive outcomes.

15. **David Garfinkle**
November 26, 2020

The point of view of the Dijkgraaf article is not that unusual: essentially it is what the condensed matter physicists have been saying for decades. The only unusual thing is that a string theorist is saying it.

16. **tulpoeid**
November 26, 2020

There is no very mild way to put it, Dijkgraaf's view is pathetic. I'm happy to have my tax money going into basic science and avant-garde engineering, but not at all to engineering that poses as basic science.

17. **Peter Shor**
November 26, 2020

tulpoeid: So condensed matter theory is just engineering and not basic science?

There is a ridiculous amount of real science related to condensed matter theory that we don't understand, and one approach to trying to improve our understanding of it is to build specially designed materials.

Is making new chemicals just "engineering that poses as basic science" if you're doing it to better understand the laws of chemistry, and not for a specific application? (Maybe some research directions that involve making new chemicals are not worth funding, but I would hope that the funding agencies would decide not to fund them; the same should be true of new materials in condensed matter physics.)

18. **anon**
November 26, 2020

A minor comment, maybe not even worth making, is that you can do fundamental physics with condensed matter. For example, it is possible to imagine an alternate version of history where the leap from classical to quantum physics was made entirely via condensed matter experiments, basically because hbar has units of (length) * (momentum), and so you don't need to go to short distances to find it– you can see quantum effects on large scales by going to low momenta (or low temperatures). And so if there's another layer of physics out there beyond quantum mechanics, and/or another basic constant like hbar, it may well show up via condensed matter experiments. (Of course, the timescale for such a basic discovery could well be centuries, which is why this comment is a bit hollow.)

19. **Tim Maudlin**
November 26, 2020

I am just seconding things already said here, maybe with a different emphasis. The heart of the controversial "third argument" of the piece is this:

"The aim of physics is to understand in a precise, mathematical way all manifestation of matter and energy in the universe — and we have barely started to explore this infinitude of possibilities. Claiming that physics is finished is akin to arguing that mathematics ended after the introduction of natural numbers and basic arithmetic, or that chemistry was over with the advent of the periodic table. Learning the rules of chess doesn't make you a grandmaster.

The truth is, the realm of the smallest particles is not the only place you can find the fundamental laws of physics. They can also "emerge" out of the collective behavior of many constituents."

There is a name for the discipline devoted to to studying how systems can be constructed using known or given fundamental laws so that it behaves in a certain way. That name is "engineering". That can be as hard, and insightful, and interesting as any scientific discipline. Quantum information theory and quantum computation, in this sense, are obviously engineering. They ask the question: *Given* that the constituents of the system are governed by the laws of quantum mechanics, how can systems that transmit or process information be built?". That is an extremely interesting and hard question.

The only issue seems to be about terminology. No one would doubt that quantum information and computation are disciplines that can properly be called "physics". No one should doubt that they also can be properly called "engineering": the terms are not mutually exclusive even if the academic world creates different "schools" for each. If some physicists had not spent a lot of time denigrating engineering (cf. The Big Bang Theory) that observation would go down easier. The last ditch of the fight is then over the term "fundamental". In the usual sense in which that term is used, engineering and, say, condensed matter and solid state physics are not "fundamental", and the principles they employ are not "fundamental": they are both "emergent" and often just reliable generalizations that can, physically, be violated (like the "Second Law" of Thermodynamics which in a clear sense in not a physical "law" at all since it can be violated by a physical system).

There are some people (like me) who are largely interested in fundamental physics, fundamental ontology and physical law (properly speaking). That is just a sort of intellectual preference or matter of taste. Some of us think that the whole project of trying to figure out these fundamentals went bad, and the badness goes back to Bohr and Heisenberg. We wonder whether progress has slowed not merely because the issues are harder in various ways but because the whole intellectual approach has been corrupted. The flourishing of the non-fundamental disciplines really does not help us in our particular arena of interests, but it is certainly a thing to be celebrated.

20. **Peter Orland**
November 26, 2020

To add to anon's remarks above: you can measure $\hbar$ with photocells or light-emitting diodes.

21. **David**
November 26, 2020

Hi Peter,

Why is it you think potential future physics discoveries by AI could be not "interesting enough to be worth understanding"?

Is it because one can envision the AI being programmed to think based on the same ways theoretical physicists do and thus will further engage in the kinds of stagnation we've seen with things like string theory etc?

I find it plausible that the AI could eventually think very differently to the way humans do and thus circumvent our limitations.

22. **JE**
November 26, 2020

My take on Dijkgraaf's article is that no, physics is not finished, but for much better reasons he has been able to expose. He is even borrowing the success of other fields, like cosmology, to hide the lack of success of his own field (HEP and theoretical physics) in the first place.

-Not because the first two decades of this century have been pretty successful for physics, which they have not, even if the Higgs, gravitational waves and the first image of a black hole's event horizon have been discovered or taken.

-Not because 95% of the universe is missing. This is just a statistical fact or a teaser, not a reason. Maybe it is missing because we do not have the correct theory of quantum gravity. Or even the correct theory of quantum electrodynamics.

-Not because any authority claimed that natural numbers or the periodic table had put an end to maths or chemistry, or at least not as explicitly as those who claim now that progress in HEP and theoretical physics has come to an end because we cannot afford more expensive particle accelerators. They might help, but nothing else.

-Not because the behavior of phonons is similar to the behavior of photons, because it is only very vaguely similar.

-And certainly not because the fundamental laws of physics, which are quantum laws, can emerge out of the collective behavior of many constituents. We already know that the laws of the macroscopic world are quite different from the laws of the subatomic world.

The rest of the arguments are even weaker imho.

No, it is because, despite the lack of support or further experimental evidence, some researcher or group of researchers will be able to make their way through it. And because this effort is already underway.

23. **Peter Woit**
November 26, 2020

David,

All evidence I've seen is that the only ideas theorists have about using "AI" in theory are ideas for how to automate dumb things people are doing so they can be done more quickly and on a larger scale. Large scale dumb is still dumb.

I see how AI can have a role when there's a lot of relevant data that a human mind is going to have trouble making sense of. The basic problem of current fundamental theory though is that there is virtually no relevant data (i.e. data that disagrees with our best model).

As John Horgan points out, already back in the 1980s people were talking about this. Nothing ever came of it, I don't see any reason to believe that situation will change anytime soon.

On the other hand, invoking computers has historically been a good way for theorists to try and get money. That has often worked, is working now, and will work in the future.

24. **John Baez**
November 26, 2020

To me the question of whether condensed matter physics is "fundamental" or "engineering" is infinitely less interesting than… *condensed matter physics!*

You can make a supersolid where holes in a crystal – the *absence* of electrons – form a Bose-Einstein condensate and flow like ghosts through the crystal lattice. You can make “liquid light” using exciton-polaritons, which are a blend of photons and electron-hole pairs. You can make a Wigner crystal: a 2-dimensional periodic structure of repelling electrons. And it goes on and on: we’re in the golden age of new forms of matter! A physicist would need to have a really sour disposition to remain unexcited by these things.

25. **Tim Maudlin**
November 27, 2020

John Baez: There is a sense in which I agree with your comment, but it also illustrates the sense in which the fundamental is, well, *fundamental* in a way that creates an asymmetrical dependence of understanding. It certainly sounds quite amazing that the *absence* of an electron, or a *hole*, can behave like the *presence* of an electron or a *particle*. And one would like to understand that better. But what claim is even being made cannot really be grasped without first understanding what an electron *is* and what are the physical conditions that make it accurate to say there is one *present* and to ascribe to it a location. When reading your comment, one reflexively falls back on a Democritian picture of electrons as sharply located particles, maybe even point particles. And maybe that is even correct! But most physicists would flatly deny that that is the right way to understand what an electron is. So this is a nice illustration of how unclarity about the foundations inevitably flows upward to a sort of unclarity about what is built on, or constructed out of, the foundations, while there is no obvious necessity of an analogous retro-transmission of lack of understanding downward. That’s part of what draws some of us to the fundamental questions.

26. **Thomas Larsson**
November 27, 2020

” why *pure math* continues indefinitely”

Scott, I’m not sure this is really the case. A long time ago, people (Wigner and probably others) used to say that “God is a mathematician”. But of course the dual formulation of that statement is that “Physics is divine mathematics”. Not necessarily because divine math is better than mundane math, but because it is the kind of math that God the mathematician does and publishes in Nature (the bitch, not the journal).

But then again, some of us believe that divine math really is better than mundane math. So if fundamental physics runs out of steam, so does divine math.

27. **Amitabh Lath**
November 27, 2020

The conversations are good indicators of where these elder statesmen of the field feel we are going. But they are not the only voices we should listen to.
Physics will end when the brightest young people no longer want to pursue it. I have not seen this. In fact, even during the pandemic there are many undergraduate and graduate students wanting to work in particle physics. Generally speaking these are top tier students who could probably join any group in the department.

28. **Moshe**
November 28, 2020

Peter Orland and anon., historically in the way quantum mechanics was developed statistical mechanics played a huge role, say in the story of the black body radiation or in most of Einstein’s contribution to the subject. It could be an illustration of why often what is “fundamental”, to the extent that this is even an interesting question at all, can be only decided after the fact.

29. **Pierre Ramond**
November 28, 2020

Every so often, human beings like to believe that their century is special, and its impressive new tools and advances will take us to some sort of final clarity. Sounds a lot like Constantin’s world-view. It is good to remember that today’s queries which are firmly in the realm of science were viewed not so long ago as pertaining to the sacred.

The most striking aspect of universe-view today is the lack of paradoxes and contradictions with experiment! As noted by Mark Twain, history does not repeat itself, but it sure rhymes; science is not so different. I wonder how people felt after Newton’s death where the explanations of all phenomena led to his world-view. The challenge came not from the mind of great people but from the study of electricity. Will the study of dark matter provide the clues to go beyond?

We live in the post-Einstein era, a time of great synthesis that left us with the General Theory of Relativity and Quantum Mechanics, neither challenged by thought nor experiment. Yet both seem incomplete in different way. What price compatibility?

The spectacular Standard Model explains most forces in the early universe; but it still is a fragmented view of matter with many loose parts.

As Brownian motion nailed the molecular theory of bulk matter, will the Cosmological constant be a pointer to the underlying theory of space-time?

So many questions, so little time …

Read Einstein’s paper on the photoelectric effect. There is a wonderful discussion of in volume II (1963) of “The Natural Philosopher” by the late Martin J. Klein. That is what sublime physics is like!

Voltaire’s “Lettres Philosophiques” (letters 14,15,16) discuss the world views of Descartes and Newton.

Peter Shor:

If something is application of science then, yes, it is engineering.
Examples of condensed matter applications specifically with the goal of advancing “basic” knowledge would be useful, though.

In any case, I can read this passage only as trying to sell engineering as basic research:
“All of this is part of a much larger shift in the very scope of science, from studying what is to what could be. In the 20th century, scientists sought out the building blocks of reality… This century, instead, we will begin to explore all there is to be made with these building blocks.”

31. **Sundar Narayan**
December 9, 2020

What Dijkgraaf seems to be saying is that engineering will replace and supersede physics. As an engineer, this is music to my ears, which is precisely why I do not believe Dijkgraaf. If it sounds too good to be true, then it probably is. Without physics, there will be no engineering. Period.

Various and Sundry

A few recent items of interest:

- Martin Greiter has put together a written version of Sidney Coleman's mid-1990s lecture Quantum Mechanics in Your Face, based on a recording of one version of the lecture and copies of Coleman's slides.

  It's often claimed that leading physicists of Coleman's generation were educated in and stuck throughout their careers to a "shut up and calculate" approach to the interpretation of quantum mechanics. Coleman's lecture I believe gives a much better explanation of the way he and many others thought about the topic. In particular, Coleman makes the crucial point:

  > The problem is not the interpretation of quantum mechanics. That's getting things just backwards. The problem is the interpretation of classical mechanics

  He ends with the following approach to the measurement problem:

  > Now people say the reduction of the wave packet occurs because it looks like the reduction of the wave packet occurs, and that is indeed true. What I'm asking you in the second main part of this lecture is to consider seriously what it would look like if it were the other way around—if all that ever happened was causal evolution according to quantum mechanics. What I have tried to convince you is that what it looks like is ordinary everyday life.

  While some might take this and claim Coleman as an Everettian, note that there's zero mention anywhere of many-worlds. Likely he found that an empty idea that explains nothing, so not worth mentioning.

- For the past year the CMSA has been hosting a Math-Science Literature Lecture Series. The talks have typically been excellent surveys of areas of mathematics, given by leading figures in each field. To coordinate with Tsinghua, the talks have often been at 8am here in NYC, and several times the last couple months I've made sure to get up early enough to have breakfast while watching one of the talks. All of the ones I've seen were very much worth the time, they were the ones given by Edward Witten, Andrei Okounkov, Alain Connes, Arthur Jaffe and Nigel Hitchin. Jaffe's covered some of the ideas on Euclidean field theory that I've been spending a lot of time thinking about. For a more detailed version of his talk I highly recommend this article.
- Peter Scholze has posted at the Xena blog a challenge to those interested in formalizing mathematics and automated theorem proving (or checking): formalize and check the proof of a foundational result in his work with Dustin Clausen on "condensed mathematics". As part of the challenge, he provides an extensive discussion of the motivation and basic ideas of this subject, which attempts to provide a replacement (with better properties) for the conventional definition of a topological space.

  Spending a little time reading this and some of the other expositions of the subject convinced me this is a really thorny business. Scholze explains in detail his motivation for making the challenge in part 6 of the posting. My suspicion has always been that most of the value of computer theorem checking lies in forcing a human to lay out clearly and unambiguously the details of an argument, with that effort likely to make clear if there's a problem with the theorem. It will be fascinating to see what comes of this project.

  I see there's also a blog posting about this at the n-category cafe.

- On the topic of theorems that definitely don't have a clear and unambiguous proof, supposedly PRIMS will be publishing Mochizuki's IUT papers in 2021. Mochizuki and collaborators have a new paper claiming stronger versions of Mochizuki's results.

Comments

1. **Michael Weiss**
   December 6, 2020

   Peter,
   I write to provide a nuance to your inference that Sidney Coleman's question–"what it would look like if it were the other way around, if all that ever happened was causal evolution according to quantum mechanics?"– was unrelated to Everett's Many Worlds Interpretation (MWI).

   I believe that MWI was in fact the starting point for Sidney's line of thought. The evidence comes from his final lecture in Physics 143 in May, 1977 at Harvard College. (You took this class a year earlier, I think, with Ed Purcell.) Prof. Coleman ended this wrap-up lecture by asking the class exactly the above question and suggesting an answer: "It would look like ordinary everyday life." We sat in silence for a minute, trying to make sense of this insight.

   Frank DeLucia (a few years later to develop the DeLucia-Coleman Theorem) was TA that semester and (if he reads this blog) may have further insight. John Preskill was TA in 1976 with Ed, and may also remember how Sidney's thoughts evolved.

2. **Peter Woit**
   December 6, 2020

   Michael Weiss,

   Coleman explicitly does refer to Everett, and yes, he's an Everettian in the sense of seeing no reason QM without a reduction postulate can't describe the world as we know it. My point was just that he doesn't invoke a splitting into "many worlds" to replace wave-function reduction.

   I'd be curious to know if his views evolved, whether exposure to Everett changed an earlier, different point of view. The point of view he's taking (reduction of the wave-function is apparent, arising out of properly treating Sidney Coleman as a quantum system and the emergence of classical mechanics and our consciousness built around that) seems to me what I would have thought was the conventional one of the mid-1970s era when we were learning the subject. On the other hand, at that time I remember never hearing about Everett, hearing a lot about Copenhagen.

   Coleman explicitly says that arguing over a Copenhagen vs. Everett interpretation of QM is "getting things just backwards", ignoring the real problem of how we get classical out of quantum. He refers to "vernacular quantum mechanics", which is a "looser and sloppier" Copenhagen interpretation. That may be a better way than "shut up and calculate" to refer to a standard QM course's approach to "interpretation".

3. **John McAndrew**
   December 6, 2020

I'm a little disappointed that the questions he answered from the audience at the end aren't recorded in the text. He's asked if he's a follower of Everett's Many Worlds interpretation at 1:04:20:

Sidney Coleman, Quantum Mechanics in Your Face [1994]
https://youtu.be/EtyNMlXN-sw?t=3853

'Everett wrote a truly wonderful paper, then everyone got on their horse and rode off in all directions"

I'm guessing this is: Relative State' Formulation of Quantum Mechanics", Reviews of Modern Physics, 29: 454–462, cited here: https://plato.stanford.edu/entries/qm-everett/

4. **Peter Woit**
   December 6, 2020

   John McAndrew,

   Thanks for pointing that out. Does anyone know what he had in mind by the "everyone got on their horse" comment?

5. **S**
   December 6, 2020

   It's nice that Coleman doesn't bring in "many worlds," but on the other hand, it seems to me that his solution of "Where does Born come from?" is going to suffer from the same thing as any Everettian theory — some (possibly hidden) additional axiom or measure that is not clearly any better motivated or more coherent than collapse.

   (The problems with Coleman's own approach to getting Born's rule have been documented by, e.g., David Albert. I can dig up the reference if anybody is sufficiently interested; otherwise I'll spare myself the hassle.)

6. **Peter Woit**
   December 6, 2020

   S.
   Coleman was explicitly not claiming to be saying anything original.

   I'm curious to hear if others know more specifically about Coleman's views, but don't want to start a rehash of the usual arguments over interpretations.

7. **Frank Wilhoit**
   December 7, 2020

   Coleman's complete course on QFT, from the 1975-76 academic year at Harvard, is online here: https://www.physics.harvard.edu/events/videos/Phys253

8. **James Smith**
   December 7, 2020

   Your suspicion "..that most of the value of computer theorem checking lies in forcing a human to lay out clearly and unambiguously the details of an argument…" is spot on in my opinion.

9. **Michael Weiss**
   December 8, 2020

   Peter,
   Please forgive my lack of clarity: I left out that that in his last lecture in 1977 Sidney Coleman explicitly defined and discussed Everett and the MWI–but as a topic of enrichment not on the final exam. I guess he was unusual among the Harvard Physics faculty at that time in including this material even as a bonus topic.

   I believe that Prof Coleman ended Physics 143 with these conceptual issues because he simply loved playing with ideas and engaging young minds.

   Curiously, you may remember that Sidney late in his life gave an interview in which he claimed to have disliked teaching. If so, he sure fooled my classmates and me! We loved him.

10. **Peter Woit**
    December 8, 2020

    Michael,
    Thanks! I'm sorry I missed that version of Physics 143. The version I took a year earlier was taught by Norman Ramsey, using David Saxon's textbook. It's been far too long for me to really remember, but if he discussed interpretational issues, I don't recall that.

    I'll take a longer look at the Saxon book later, but from a quick look online, there's nothing like a "Copenhagen interpretation" discussion, and what is there isn't inconsistent with Coleman's Everettian viewpoint that in principle the state of the observer should also be described by QM.

    Sorry for my continual negative reaction to the "Many-Worlds" terminology. As I've written about here far too often, I think it's a really bad terminology to use to refer to the ideas Coleman was discussing, especially given recent publicity campaigns for the idea that invoking multiple worlds explains things that it doesn't. I'd be very curious to hear what Coleman thought of this, it's a shame he's no longer with us to discuss.

11. **Jon101**
    December 8, 2020

    There seems tobe some renewed interest in Mochizuki's work: he gave a colloquium at Berkeley in november https://mathoverflow.net/questions/375889/berkeley-mathematics-department-colloquium-by-s-mochizuki and there is a joint Rims-Lille seminar where several people from both inside and outside Mochizuki's circle are giving talks http://www.kurims.kyoto-u.ac.jp/~bcollas/IUT/index.html

12. **martibal**
    December 8, 2020

    Off topic but could be of interest for Peter: the last paper of Penrose, together with Marcolli, about twistors and noncommutative geometry
    https://arxiv.org/abs/2012.02823

13. **Peter Woit**
December 9, 2020

Frank Wilhoit,
Perhaps more useful than the videos, Coleman's QFT lectures are now available as a book, see
https://www.math.columbia.edu/~woit/wordpress/?p=10799

Jon101,
I've seen no evidence of increased interest in IUT recently, quite the opposite. Mochizuki and his circle have dealt with the problem pointed out by Scholze and Stix essentially by ignoring it based on a claim that Scholze and Stix are ignorant incompetents. It's striking (and actually, disturbing) that neither in Mochizuki's talk nor anywhere in the Lille/RIMS program is there any mention of the Scholze-Stix argument that the proof is flawed. Until Mochizuki or someone else comes up with a convincing rebuttal to Scholze/Stix, very few experts will pay attention to this.

14. **John Baez**
December 9, 2020

Peter Woit wrote:

> Does anyone know what he had in mind by the "everyone got on their horse" comment?

I don't know what he meant, but Everett *did* write a wonderful Ph.D. thesis on the relative state interpretation, which said very little if anything about "worlds" or "branches" — and then Bryce DeWitt and John Wheeler and others got into the act and introduced, or at least popularized, those terms. You can see the whole process of degradation in the book *The Many Worlds Interpretation of Quantum Mechanics*, edited by DeWitt and Neill Graham, which includes Everett's thesis followed by essays by DeWitt, Wheeler, Graham and others. It's sad how Everett gets blamed for other people's interpretations of his work. I don't know how much he went along with it.

15. **Jack Morava**

Re: theorems that definitely don't have a clear and unambiguous proof

Physics is very interesting. There are many, many interesting theorems. Unfortunately, there are no definitions.
David Kazhdan.

(stolen from https://www.jmilne.org/math)

16. **John Baez**
December 9, 2020

That's why category theory and physics work together so synergetically: category theory has tons of great definitions but no interesting theorems. 😜

17. **Low Math, Meekly Interacting**
December 9, 2020

I stumbled on this a while back because I was a big fan of the Eels, long before I knew Mark Oliver Everett was Hugh Everett's son.

A letter Hugh Everett wrote to Bryce DeWitt…

https://www.pbs.org/wgbh/nova/manyworlds/orig-02.html

18. **John McAndrew**
December 9, 2020

John Baez and Peter,

you might be interested in Everett's amoeba analogy from an early draft of Hugh Everett's doctoral dissertation at Princeton Universty:
https://www.pbs.org/wgbh/nova/manyworlds/orig-01.html

"The same is true of [sic] one accepts the hypothesis of the universal wave function. Each time an individual splits he is unaware of it, and any single individual is at all times unaware of his "other selves" with which he has no interaction from the time of splitting."

How does one interpret this?

It looks to me that Everett was the first to get on a horse and ride off in some bizarre, speculative direction, eventually crafting the paper that Coleman admires after Wheeler and co reigned in some of his 'not even wrong' ideas.

19. **Peter Woit**
December 10, 2020

John McAndrew,

Thanks. I should make clear that I don't think the problem with the "splitting into multiple worlds" business is that it's bizarre or speculative, it's that it's meaningless, and pretends to solve a problem that it doesn't. I'd be curious to hear what Coleman thought of this, but the fact that he doesn't mention multiple worlds and does explain that the hard problem is understanding how to interpret classical mechanics makes me guess he would have agreed that multiple worlds explain nothing.

20. **TonyK**
December 10, 2020

Peter, this is from the Wikiquote page on Stephen Leacock:

"Lord Ronald said nothing; he flung himself from the room, flung himself upon his horse and rode madly off in all directions."

"Gertrude the Governess", Nonsense Novels (1911)

Coleman realised that this quote could be interpreted literally in an Everettian world (or worlds? — syntax fails me here).

21. **Low Math, Meekly Interacting**
December 10, 2020

I am myself struck by the similarity between the quote from Coleman's lecture and Everett's expressed point of view, in regards to human experience. In fact, in essence their positions appear to be identical almost down to the wording. The only possible distinction seems a purely philosophical one, i.e. whether or not the notion of a single "reality" is justifiable if one agrees there is nothing but "causal evolution according to quantum mechanics".

22. **Peter Woit**
December 10, 2020

LMMI,
Unlike Everett, I don't see Coleman anywhere mentioning "splitting". The only place the term "reality" occurs is once in the combination "Quantum Reality", part of a proposed title for the talk. He seems to have no interest in the usual arguments over "reality".

My quantum education was very conventional for the early-mid-seventies, no exposure to Everett, directly or indirectly through Coleman. I distinctly recall being well aware that the obvious and simplest way to interpret QM (without wave-function reduction) was as a theory that applied to everything, including the observer and the observer's consciousness, that there was nothing about our experience of the world in conflict with this.

23. **Low Math, Meekly Interacting**
December 10, 2020

Hi, Peter,

I probably should have expressed myself better: They appear to be in 100% in agreement about the scientific content. All that's left to disagree about appears to be the "reality" of other possible experiences, including whether or not that's even something worth pondering.

24. **S**
December 10, 2020

I guess, Peter, that I'm confused about how one could take a unitary-only / Everettian / Colemannian approach to QM and *not* talk about many "worlds" or at least, if the "worlds" seem confusing, about many parallel non-interacting observers who all think that they are the same person. You end up with a wave function on configuration space that is extremely sharply peaked over various "classical" configurations, each of which corresponds to a different observer + environment, and if one takes each of those observers seriously, then there are a bunch of different Peters, who will have made (say) different moderation decisions about the value of this comment.

Call it worlds or don't — and I can see where talk of "branching" is maybe not helpful (although it's a reasonable description of decoherence in the Everett model, no?) — but this feature seems unavoidable at that point.

And so do problems with getting the Born rule out of the picture.

One thing I've wished is that I understood better what your — Peter's — alternative to this view is when you talk about unitary-only without many-worlds.

25. **Peter Woit**
December 10, 2020

S,
I just don't think saying "my initial more or less classical state branched into multiple other more or less classical states and I'm in one of them, other mes are in the others" explains anything about anything, or answers any kind of meaningful question. You can think about the world that way if you want, but you haven't solved any problem by doing so.

There are endless problems with making any sense out of "branching", in practice that's nothing but a meaningless word standing in for not understanding the measurement problem. What you're doing is trying to recover a classical description of reality, by ignoring the quantum nature of reality except at these mysterious places where classical reality "branches". I take Coleman as saying it's a mistake to try to describe reality classically, there is only quantum reality. Put differently, classical behavior is a complex, hard to understand emergent phenomenon. If you take that as the fundamental nature of reality and try and express everything in terms of it, you're going to end up with a confusing and paradoxical conceptual framework.

26. **Peter Shor**
December 11, 2020

Some questions that I think show that many-worlds doesn't actually solve the "measurement problem".

How do two photons in an Aspect-type experiment that are well separated in space know whether they're supposed to be in the same "world" or not? Do the "splits" between worlds happen everywhere in the universe at once (and does this violate the theory of relativity?) or do they start at a single point and radiate out like waves the speed of light (and in this case how do two world-splitting waves approaching each other know which worlds in one of these waves should be merged with which worlds in the other?)?

27. **Jim Akerlund**
December 11, 2020

Peter,
Of all your comments on the Coleman lecture, I at least expected a comment about this statement from the lecture.

"There's no point in trying to wow him with the anomalous
magnetic moment of the electron or the behavior of
artificial atoms that we just heard about or anything like
that, because he is so deeply opposed to quantum mechanics
and so old and stubborn that as soon as you
start putting a particular quantum mechanical equation
on the board his brain turns off, rather like my brain in
a seminar on string theory."

28. **Homodyne**
December 11, 2020

Coleman's derivation has an analogue in terms of classical probability.

If we imagine a system, say a coin, that is probability p to be heads and 1-p to be tails we could write it as:
p[H] + (1-p)[T]

Then imagine a detector which enters the state D or E depending on whether it sees heads or tails.
Well then after measurement we have:
p[H,D] + (1-p)[T,E]

Nobody would read this as "two separate worlds". As Peter Woit says it doesn't really solve anything. It's just tortuous semantics for a basic probability assignment.

What Coleman then goes on to describe is say we do this again with more and more coins then the probabilities essentially go to 1 for histories where the ratio of heads events to the total number of event is p and converges to 0 for other histories. In essence it's the law of large numbers.

The only mystery/issue is that in the case of a quantum system and recording device we would have:
c|H,D> + d|T,E>
where c and d square to p and 1-p.

The issue/thing to be explained is that we only recover the same probabilistic reading provided we can only measure the device in the |D>,|E> basis and that other "interference" bases are non-physical such as {|D>+|E>,|D>-|E>}.

This indeed seems to be the case from empirical evidence, but we need a detailed explanation as to why. Roland Omnes's famous 1994 book has a good sketch in Chapter 8 (although one would need Chapters 6 and 7 to fully understand it) and I'd also recommend Allahverdyan et al's paper here:
https://arxiv.org/abs/1303.7257
It's a summary of a much longer paper by them from 2011.

29. **Moshe**
December 13, 2020

One of the issues I have with MWI is that (like many other interpretational issues) it is not specific to quantum mechanics. In fact there is already an old approach to probability called modal realism which is essentially the same as the MWI. The fascinating thing about quantum mechanics is that it is not equivalent to a classical probabilistic system. Focussing on issues that already exist for classical stochastic systems misses all the real mysteries. Another common example is attributing some mystery (like conflict with relativity) to quantum entanglement that already exists for plain statistical correlations.

30. **Homodyne**
December 13, 2020

Moshe,

Thanks for that. It's what I was clumsily getting at above. If you treat the classical probability distribution as "real" then one essentially has many worlds for classical probability. I wasn't aware that it had a formal name, i.e. "modal realism".

Of course Spekkens toy model shows that many of the features people commonly say are quantum can be reproduced in a classical theory. For example super dense coding, teleportation, entanglement, no cloning, interference.

Thus allowing one to focus on what classical probability cannot replicate: Kochen-Specker contextuality and CHSH violating correlations.

31. **John Baez**
December 14, 2020

"Focussing on issues that already exist for classical stochastic systems misses all the real mysteries."

Not all of them. Classical probability theory is *already* deeply mysterious – witness the Bayesian/frequentist arguments about what probabilities actually mean. Any mystery one doesn't get straightened out in classical probability theory is likely to come back with redoubled force when you start thinking about probabilities in quantum mechanics.

But yes, quantum theory holds new mysteries.

32. **J Frager**
December 14, 2020

In the paper mentioned above (http://www.kurims.kyoto-u.ac.jp/~motizuki/Explicit%20estimates%20in%20IUTeich.pdf), Mochizuki et al. seem to propose an entirely new proof of Fermat's last theorem for prime exponents large enough. Has this been checked/confirmed/peer-reviewed? I haven't seen much discussion on that, although such a claim would seem to warrant it. Have the people involved in the original proof of FLT (Wiles, Taylor, Conrad etc.) expressed an opinion?

33. **Peter Woit**
December 14, 2020

J. Frager,
It has long been known that a proof of abc can be used to prove Fermat in this way. The problem is that this new paper depends crucially on the part of Mochizuki's IUT-based arguments which Scholze/Stix have convincingly argued can't work. As far as I can tell, essentially no one outside of RIMS and Nottingham thinks there is a proof, either in the original work, or in this new one.

The new work does imply much stronger claims than the earlier IUT papers. Perhaps the most interesting aspect of these is whether any of them can be shown to not be true, providing a direct disproof of Mochizuki's original work.

34. **Peter Woit**
December 14, 2020

For an example of what the problem is with the multiverse publicity campaign for MWI, check out the latest New Scientist
https://www.newscientist.com/article/mg24833122-100-if-the-multiverse-exists-are-there-infinite-copies-of-me/
where you'll learn that the way to think about quantum mechanics is this:
"The startling upshot of this view is that there are potentially squillions of versions of you going about their (your?) business in parallel universes.

Well, sort of. Those other versions of you aren't really copies, says Sean Carroll, a physicist at the California Institute of Technology: they are individuals who used to be you, but at some point split off and became separate. "You are not spread out over worlds," says Carroll. "You are here in this world, and there are a lot of other people in other worlds who are closely related to you."

As to how many other-worldly relations you have, it is impossible to say. "The number could be infinite or there could be a continuum of worlds rather than a discrete set," says Carroll. "But the number might also be finite. We're not sure.""

35. **Moshe**
December 14, 2020

John Baez, I think you know what I mean. But as an aside, it is an interesting sociological phenomena how philosophical discussions of scientific subjects can be completely decoupled from the scientific ones. My impression that people that use probability for a living, for an example as reflected in graduate texts in statistical learning theory, are uniformly Bayesian for well articulated reasons. Similar phenomena can be observed in discussions of quantum mechanics, general relativity, etc. etc.

36. **John Baez**
December 15, 2020

Yes, one great thing about working at the Centre for Quantum Technologies part-time is that when I'm there, I never hear the usual tiresome arguments about interpretations of quantum mechanics.

37. **Godfrey**
December 17, 2020

Anent Mochizuki, Scholze and Stix's paper seems to have gone?

http://www.kurims.kyoto-u.ac.jp/~motizuki/SS2018-08.pdf

38. **Peter Woit**
December 17, 2020

Godfrey,
The links may have changed. Mochizuki's page discussing this is here
http://www.kurims.kyoto-u.ac.jp/~motizuki/IUTch-discussions-2018-03.html
and it links to the Scholze-Stix paper as
http://www.kurims.kyoto-u.ac.jp/~motizuki/protectedpdf-2018-08/SS2018-08.pdf

39. **random reader**
December 26, 2020

That Mochizuki's claimed results imply effective ABC was known and published on the arxiv in 2016, by Vesselin Dimitrov. This goes back to Dimitrov's MathOverflow postings in 2012 on the implications of (incorrect, overly strong) claims in earlier versions of Mochizuki's papers, https://mathoverflow.net/questions/106560/philosophy-behind-mochizukis-work-on-the-abc-conjecture . Back then, Mochizuki acknowledged correspondence with Dimitrov and (independently) Venkatesh about those problems in 2012, and apparently revised his papers in response.

Now in the new article by Mochizuki et al, they elliptically refer to someone who must be Dimitrov as a mysterious "one mathematician" who had some related results (which they disparage) using Belyi maps (which are indeed used in the 2016 arxiv paper) but whose work they say they cannot find written down anywhere. As though Mochizuki and company could not get back in touch with Dimitrov or do a web search for any papers he might have written about this.

Not naming the person gives some not very plausible deniability, but it sure looks like Team Kyoto has graduated from denial of problems to outright erasure of work outside their clique.

40. **David Yager**
December 26, 2020

Fermilab's Muon g-2 pages have been updated recently – they had been left unchanged since 2015! Is the announcement near to hand? Probably not this year …
https://muon-g-2.fnal.gov/

Still no leaks to here or to Resonaances – it's just a shame how information no longer wants to be free.

41. **Anot Heran Dom**
December 26, 2020

@random reader,

I was thinking it might have been Taylor Dupuy, but you're right, Dimitrov seems more likely. I think it extremely bad form to not even name the person, let alone the disparaging remarks, verging on academic dishonesty. Imagine if people went around merely alluding to others' prior results but not naming them or giving a citation.

42. **F. Zaldívar**
December 27, 2020

Vesselin Dimitrov's 2016 preprint: https://arxiv.org/abs/1601.03572

43. **random reader**
January 3, 2021

Footnote on Mochizuki from last week's arxiv.

Jakob Stix, who together with Peter Scholze went through the Mochizuki ABC papers and diagnosed the mistake, has found an error that went unnoticed since 1997 in a famous paper by Caporaso-Harris-Mazur. Stix also contributed a lemma to the article by C-H-M announcing and fixing the mistake.

https://arxiv.org/pdf/2012.14461.pdf

Interesting data point on Stix' ability to find errors.

20 Years Later

December 29, 2020
Categories: Uncategorized

Almost exactly twenty years ago I started writing a short article about the problems with string theory. I had been thinking about doing this for quite a while, and the timing of entering the twenty-first century seemed appropriate for evaluating something that had long been advertised as "a piece of 21st-century physics that had fallen by accident into the 20th". The piece was done in a week or two, after which I sent it around to a group of physicists to ask for comments. The reaction was mostly positive, although at least one well-known theorist told me that publicly challenging string theorists in this way would be counter-productive.

One person who wrote back was Phil Anderson, I've quoted some of what he wrote to me in [this posting](). He suggested I send it to Gloria Lubkin at Physics Today, and evidently talked to her about it. I did do this, and after not hearing anything back for a week or two, decided to go ahead and post the article to the arXiv, where it appeared as [String Theory: An Evaluation]().

Rereading that article today, there's little I would change. Its argument is even more valid now than then. The problems of the theory and how it was pursued evolved over the next twenty years in ways far worse than what I could have imagined back then. In particular, the "multiverse" argument explaining away why string theory predicts nothing is something I could not have conceived of in 2001. The tribalistic sociology that has led to a large group of people calling themselves "string theorists" when what they do has nothing to do with string theory is also something I would have thought impossible.

In many ways, twenty years of further failure have had less than no effect. Lubos Motl is [still arguing]() that string theory is the language in which God wrote the universe, and Michio Kaku has a new book about to appear, in which it looks like string field theory is described by [the God Equation](). Ignoring these extreme examples, string theory remains remarkably well-entrenched in mainstream physics: for example, my university regularly offers a course training undergraduates in string theory, and prestigious \$3 million prizes are routinely given for work on the subject. The usual mechanisms according to which a failed scientific idea is supposed to fall by the wayside for some reason have not had an effect.

While string theory's failures have gotten a lot of popular press, the situation is rather different within the physics community. One reason I was interested in publishing the article in Physics Today was that discussion of this issue belongs there, in a place it could get serious attention from within the field. To this day, that has not happened. The story of my article was that I finally did hear back from Lubkin on 2/21/2001. She told me that she would talk to the Physics Today editor Stephen Benka about it. I heard from Benka on 5/6/2001, who told me they wouldn't publish an article like that, but that I should rework it for publication as a shorter letter to the editor. I did this and sent a short letter version back to them, never heard anything back (a few months later I wrote to ask what had happened to my letter, was told they had decided not to publish it, but didn't bother to let me know). In 2002 an editor from American Scientist contacted me about the article, and it ended up getting published there.

Looking back at how Physics Today has covered string theory and related speculation over the past 25 years, I did a search and here's what I found:

- [Reflections on the Fate of Spacetime]() (Witten) (April 1996)
- [String Theory Is Testable, Even Supertestable]() (Kane) (Feb. 1997)
- [Duality, Spacetime and Quantum Mechanics]() (Witten) (May 1997)
- [Large Extra Dimensions: A New Arena for Particle Physics]() (Arkani-Hamed, Dimopoulos, Dvali) (Feb. 2002)
- [Is string theory phenomenologically viable?]()(Gates) (June 2006)
- [The case for extra dimensions]()(Randall) (July 2007)
- [String theory in the era of the Large Hadron Collider]() (Dine) (Dec. 2007)
- [String theory and the real world]() (Kane) (Nov. 2010)
- [What every physicist should know about string theory]() (Witten) (Nov. 2015)

The only thing I could find anywhere during those 25 years indicating to Physics Today readers that none of this speculation had worked out was a short opinion column by Burt Richter

- [Theory in particle physics: Theological speculation versus practical knowledge]() (Richter) (October 2006)

It seems to me that those now in charge of Physics Today should be thinking about this history, their role in it, and what they might be able to do to make up for this heavily one-sided coverage of a controversial issue.

   December 29, 2020

   In 2020 we have webinars. It would be interesting to have a debate between you and Lubos.

2. **André**
   December 29, 2020

   Peter,

   About your last sentence: some people get elected because they lie more and bark louder than others, and some opinions get coverage in the press because the people behind them lie more and bark louder than others. The sad consequence is that in both politics and theoretical particle physics, the US hast lost its claim for leadership. Hopefully, the change on politics will be followed by a similar change in the physics press.

3. **Peter Woit**
   December 29, 2020

   André,
   While there are some analogies between the way tribalism and reality-denying fake news sources have wrecked US democracy and the problems of theoretical physics, I don't think debating that is useful (and I'll suppress further comments trying to do so…).

   Physics Today plays a fairly unique role as the "physics press" in the US. There's not much else in the way of media here aimed at covering physics news for professional physicists. The role it has played in the string theory controversy is rather peculiar. Some of the articles linked to above explicitly say their goal is to answer criticisms of string theory, but they don't explain these criticisms or provide a link to them, and such criticisms have not been allowed to appear in the pages of Physics Today. There appears to have been an editorial decision to only host one side of the argument.

4. **Udi**
December 29, 2020

You complain that people are calling themselves "string theorists", when in practice their work has nothing to do with string theory. But isn't this a good thing? Doesn't it demonstrate that "string theory" is actually not a mono-culture?

5. **Shantanu**
December 29, 2020

Peter : Did you try contacting Physics World (Brit equivalent of Physics today)?
what kind of articles have appeared there?

6. **Peter Woit**
December 29, 2020

Udi,
I don't think training students in string theory and refusing to admit that it's a failed research program, while at the same time moving on to something completely different is a healthy situation.

Shantanu,
The Physics World coverage of string theory has always been more even-handed, and in particular they've covered my criticisms of the theory, see for instance
https://physicsworld.com/a/still-not-even-wrong/

7. **Sabine Hossenfelder**
December 30, 2020

Physics Today last year (2019) published a piece by Gordon Kane in which he argues for a larger particle collider by once again shifting the predicted masses of supersymmetric particles up. Frankly I think it's embarrassing that a scientific magazine would run pseudoscientific "predictions" like this on their pages. I wrote about this here

http://backreaction.blogspot.com/2019/03/particle-physicists-continue-to-spread.html

I also contacted PT about it and said that it would be appropriate if they let someone argue the opposite side. Needless to say, I did not suggest myself, but said if they can't find anyone else I'd be available. They wrote back to say they might do a collider pro-con, then I didn't hear again from them. I asked a few months later what happened to this and got no reply.

The bottom line is that they ran all the false assertions by Kane and never corrected them.

I have since stopped reading Physics Today and have been happier with Physics World.

8. **lol**
December 30, 2020

I've been reading this blog fora while, and never commented. But I guess 20 years is indeed a good time to take stock of what has been accomplished. So lets briefly discuss what has happened in "string theory" (i.e. high energy theory, i.e. whatever theoretical physicists at top places work on) in the last 20 years.

1. A wide range of conformal field theories have been solved numerically using the conformal bootstrap. This has resolved decades old questions about phase transitions in statistical physics and condensed matter, including many ongoing experiments.

2. The AdS/CFT correspondence conjecture, which is the only known non-perturbative definition of quantum gravity, has been rigorously proven in several specific examples (i.e. a certain 2d example, as well as for vector model like CFTs). Also tons of extremely nontrivial evidence has been amassed in pretty much every other well defined example, such as precise derivations of black hole entropy.

3. Dualities between quantum field theories, again many with immediate experimental relevance (such as electrodynamics in 2+1 dimensions and O(N) models) have been proposed and nontrivially tested. These non-supersymmetric, completely physical, dualities were inspired by earlier dualities that involved supersymmetry, and were inspired directly from string theory. This is one particularly beautiful example where idea from string theory and condensed matter have worked together to produce a profound result of great interest to people in both fields.

4. Numerous extremely general theorems about QFT have been proven. One particularly famous example are C theorems (i.e. quantities that are monotonic under RG flow, which is basically the most fundamental aspect of QFT), originally shown in 2d by Zamolodchikov decades ago, which have now been proven rigorously in 3d and 4d.

Note that in these examples, I have avoided any speculative topics (i.e. black hole information, the origins of dark matter, string pheno, etc), since those are more open to debate, and less universally accepted.

I would say by any reasonable standard, this is a very impressive list of accomplishments, certainly more impressive than anything alternatives to string theory have offered (tho in fairness, almost no one works on such alternatives, which might come as a surprise to laymen who only read blogs), and certainly worth the extremely trivial amount of funding that theoretical physics gets (which altogether in the last 20 years probably amounts to less than a standard mid scale experiment).

In sum, I would encourage readers of this blog to retain an open mind. Sure, the standard model has not been derived from string theory, and no one has observed a string, but string theory has continued to profoundly influence numerous fields ranging from pure math to experimental condensed matter physics. This is why everyone is still working on it… not bc of a sinister cabal of the Elders of Physics. Also, no string theorists read Lubos blog anymore, he went over the deep end years ago (and Gordy Kane is like 80 years old? give the guy a break… hes earned the right to say crazy things in his retirement). Unfortunately there are no blogs written by active competent string theorists these days (perhaps bc they are too busy producing results!).

9. **Peter Woit**
December 30, 2020

Sabine,
I wrote about that spectacularly bad Kane piece here
https://www.math.columbia.edu/~woit/wordpress/?p=10881

It's hard to argue with Physics Today's decisions to publish what Witten has to say, but their decision to repeatedly publish articles by Kane containing claims that are outright wrong or that no one except him believes is pretty bizarre.

10. **Alessandro Strumia**
December 30, 2020

Dear LOL, what is very impressive in your list is that you consider it a "very impressive list". The field needs smart young theorists, not those who can be attracted through hype. Why not telling that all predictions about new physics at LHC were wrong, that best hopes for discoveries are now gone, that theorists moved to reconsider a variety of old QFT problems and made some technical progress while waiting that something really very impressive will appear on the horizon?

11. **Peter Woit**
December 30, 2020

lol,
You demonstrate very well exactly the problem: instead of admitting that string theory has failed, you've redefined QFT, or more generally "high energy theory, i.e. whatever theoretical physicists at top places work on" as "string theory". Your justification for this is a list of developments in QFT that have either zero to do with string theory or only a tenuous "inspired by" connection.

Nati Seiberg predicted this back in 2005

https://www.theguardian.com/science/2005/jan/20/science.research

""Most string theorists are very arrogant," says Seiberg with a smile. "If there is something [beyond string theory], we will call it string theory.""

He didn't predict though that what string theorists would discover "beyond string theory" was just QFT.

One problem with this redefinition of string theory as QFT is that it's not done consistently. For instance, the Columbia undergrad course on string theory I believe follows Zwiebach and aims at the light-cone quantization of the string. If "string theory" now means "QFT", why isn't this course instead explaining how to quantize a field (for instance the free EM field, so students could understand what photons really are)? Not everyone has gotten the memo that "string theory" no longer means string theory, and that it now means QFT (or maybe something else, whatever is most convenient for those who don't want to admit that what they used to call "string theory" has been a failure).

12. **Sabine Hossenfelder**
December 30, 2020

lol,

There are so many things wrong with your comment, I don't even know to begin. Let me just highlight two of your most glaring mistakes. First, you seem to believe that AdS/CFT is the only "non-perturbative definition of quantum gravity". Gross. You should stop commenting on things you clearly know nothing about. Also, have you heard that we don't live in Anti de-Sitter space? Second, black hole entropy. Do you realize that no one actually knows what the entropy of a black hole is? So what the heck do you think this calculation shows? As Doyne Farmer put it so nicely, it's "math piled on top of math". Physics is not math. Physics is about describing nature.

But, yeah, thanks for being here to document the problem everybody else is talking about. You have evidently never thought about what you believe. Time to start using your brain.

13. **Apostolos Syropoulos**
December 30, 2020

Someone who works at Columbia University posted on Twitter someting about an interview with Susskind the inventor of the super duper theory of string. I dared to reply that string theory is a failure and he blocked me and send me a direct message asking me if this was a joke or if I am as stupid as I look. I can only imagine what people have told you all these years…

If you think this comment is interesting but do not wan to mention the university just say an American university. If you like I can send you a screen shot of his post

14. **AcademicLurker**
December 30, 2020

My impression, from this blog and elsewhere, is that the formalism of string theory requires a considerable investment of time and effort to understand. Do string theory-ish techniques have applications outside of string theory itself? If not, it seems like having students spend significant time learning it is like having them spend time learning to write calligraphy in elvish. Perhaps the time could be more profitably spent on other subjects.

15. **CFT gal**
December 30, 2020

Dear Sabine,

Can you explain what you think is wrong with lol's statement "AdS/CFT is the only "non-perturbative definition of quantum gravity"? To be honest, lol's comment demonstrates way more expertise in the subject than you do.

16. **Peter Woit**
December 30, 2020

lol/Sabine Hossenfelder/CFT gal,

I'm going to put a stop to this kind of argument about AdS/CFT, since I'm getting flashbacks to years of the String Wars, where endless arguments of this kind shed more heat than light. I will add my own final point, agreeing with Sabine that we don't live in 5d AdS space-time: there is no such thing as a well-defined AdS/CFT-based theory that describes quantum gravity in a universe like ours.

Another aspect of the flashback problem is that I'm reminded of something I really detested about the behavior of string theory partisans during the String Wars: posting anonymously from major physics research institutions, hiding behind anonymity to attack the competence of others and make really dubious arguments. Please don't misuse anonymity to engage in unprofessional conduct.

17. **Peter Woit**
December 30, 2020

Apostolos Syropoulos,
I'd suggest engaging in discussions about string theory on Twitter is even more of a waste of time than most discussions on Twitter, which is a pretty extreme situation.

I noticed that this posting made it to Hacker News, so if you want an unmoderated computer nerd discussion, see
https://news.ycombinator.com/item?id=25573989

18. **lol**
December 30, 2020

Alessandro Strumia,

You raise a good point, that indeed theoretical particle physics is struggling due to the lack of new interesting experimental data, the failed predictions, etc. The questions being considered today clearly are not as groundbreaking as the golden age of the standard model. But there are other interesting questions that can be answered, and I hope my list provided some of them. For instance, the numerical solution to the 3d Ising model phase transition from the conformal bootstrap is no trivial thing, some of the giants of physics (e.g. Onsager) most famous work was on this theory, and its taught us countless deep things about nature (to quote ICP: "****ing magnets, how do they work?"). It is in many ways, the simplest and most fundamental QFT, of interest far beyond its numerous realizations in nature. I would say preferring 4d SU(3)xSU(2)xU(1) gauge theories is a matter of taste, similar to the classic debate between micro and macro (Phil Anderson has a fun essay where he prefers the meso).

Also, considering how incredibly difficult it is to write a consistent theory of quantum gravity, I'm happy with any version at this point (tho of course like everybody it would be great to find a version in 4d flat space without supersymmetry!). There has been lots of interesting work in the last few years about trying to get flat space holography from AdS… but the jury is still out there (its a hard problem!)

Peter,

You also raise a good point, that indeed many of the things called "string theory" today have nothing to do with string theory, and its more sociological that its called that (which is less arrogance of string theory than the fact that people are lazy with labels). But it's worth noting that many of the big accomplishments I mentioned directly come from either the methods developed to understand string theory, or the theory itself. E.g. most intro string theory classes like the you mention spend half the semester teaching just 2d CFT methods. These are the exact same methods that are used to study some of the most cutting edge theories in condensed matter (like the work of Nicholas Read, who ironically works at a place that is no fan of string theory in general), but most of them were developed by people mostly motivated by string theory (e.g. sasha polyakov, one of the most underappreciated [by the public] and profound physicists of the latter 20th century). Also, the stuff about the 3d dualities, thats very trendy in condensed matter these days, was directly inspired by analogous supersymmteric 3d dualities derived from string theory (and found by a former string theorist now full-time condensed matter theorist Dam Son). Some people even claim you can derive the new condensed matter ones from the supersymmetric one.

Sabine,
[*Juvenile 3 letter response deleted*]

19. **Peter Woit**
December 30, 2020

Academic Lurker,
Yes, string theory is a highly technical subject for students to learn, much of this technology not very generally useful. I'd argue the most useful is the 2d conformal field theory part of a course on string theory, but this is quite a demanding subject, best learned on its own, without the extra baggage it comes with when used in string theory.

The undergrad-level courses I'm aware of use Zwiebach and I believe don't discuss conformal field theory, just try and quantize the string in light-cone gauge. This technology is pretty much useless for anything else.

20. **Peter Woit**
December 30, 2020

lol,
About flat space AdS/CFT: very smart people have been trying to do this not just in "the past few years", but from 1997 on. After 23 years, I think the jury is in on that one.
The 3d Ising problem is a great problem in mathematical physics, with theorists trying to solve it using strings back before my student's parents were born. All in all, if high energy theorists want to give up on high energy theory and instead go work in condensed matter physics, good for them. Will be interesting to see how they do competing for grants, jobs, etc. in that field. And what the tolerance level among condensed matter experts for hype is…

21. **Naive Postdoc**
December 30, 2020

Dear Peter,

I unfortunately think that the hype is already present (though to a lower degree) in theoretical condensed matter physics, particularly in the field of symmetry protected topological phases of matter (SPT) and I don't think they have a problem with grant money.

There's a reason why so many string theorists and string mathematicians such as Witten, Kapustin, Gaiotto, Freed, Hopkins, Johnson-Freyd among many others are working on this topic and have, in my naive opinion, brought a similar attitude to the one they have in HEP as a community. Let me not expound my accusations too much and only say that they use emergence as a wild card and the worrisome thing is that there are almost no SPT experiments, though much more likely to be in the near future than in HEP, but in the meantime speculation reigns.

22. **Alessandro Strumia**
December 31, 2020

Dear LOL, I agree that this work might indirectly lead to useful tools to understand physics of fundamental relevance. Still, computing the brachistochrone is just the optimal way of spending theorists time, while the main line of development stagnates. The difference between 4d SU(3) x SU(2) x U(1) and QFTs for magnets* is discussed in a footnote of Weinberg QFT book:

«* This section lies somewhat out of the main line of development and may be omitted in a first reading».

23. **BootsTrap**
December 31, 2020

Lol, it is strange to see numerical bootstrap on the list and even at the top. These CFT's were understood long ago and various perturbative schemes to compute are available, e.g. the famous 4-epsilon expansion. The recent attempts were about putting some old equations on a computer and present nothing new, just another numerical gadget to add few digits to the already known exponents. That it became somewhat popular is due to a low entrance fee – even a student could put these things on a computer and get some plots for a paper. The 3d non-SUSY dualities are exciting, as well as the a-theorem, and sphere free energy but have nothing to do with strings and are not even related to them.

24. **tomate**
December 31, 2020

I was then a bachelor student, but already interested in getting a picture of what contemporary physics was all about. I remember finding this paper in the stack of unclaimed papers on the side of the printer in the computer room. I read it with curiosity, happy that I would have some arguments I could hardly understand to give myself a posture in my chats with my senior pals. It contents stuck with me for quite some time, until I had to take decisions on my future, and this paper was a big part of my choices, in a physics department were if you were a HEP theorist there was no choice apart from strings and branes.

25. **Peter Shor**
December 31, 2020

@Naive Postdoc: Symmetry protected topological phases of matter is not an area which physicists have worked on for 40 years with very little to show for it.

Theoretical physics tends to have fads, with lots of people working in the popular areas, and new areas tend to get overhyped. The worrying thing is that string theory is *still* overhyped after people have spent 40 years on it with very little return, and many of the researchers have given up on doing active research in it and are working in other fields.

26. **Naive Postdoc**
December 31, 2020

Dear Peter (Shor),

I totally agree with you that the case in string theory is much worse. I was addressing a particular issue raised by Peter (Woit) that we would see how much of their hype was tolerated by condensed matter physicists and how much money they would get … My point was that perhaps condensed matter physicists are more tolerant than he thinks, SPT and the string theorist's move towards it being the case and point. On the whole, the influence of string theory may have permeated other branches and their subcultures deeper than we're aware.

27. **lol**
December 31, 2020

BootsTrap,

I'm not sure what you mean by "These CFT's were understood long ago". Most interesting CFTs are strongly coupled, which means that just writing down some Lagrangian isn't very helpful (and of course many interesting CFTs don't even have Lagrangians, especially in higher dimensions, such as the 6d (2,0) theory), bc Feynman diagrams teach you nothing about them. Things like epsilon expansions give some intuition, but they are totally nonrigorous and don't always work (for the obvious reason that epsilon=1 is not a good expansion parameter). The big question in formal QFT for the last 30 years or so is how to find non-perturbative ways of understanding QFTs (eg CFTs), and most experts in both condensed matter and particle physics acknowledge the numerical bootstrap to be one of the biggest breakthroughs in that regard. The point is that the progress is not just computing a few more digits of accuracy, its conceptually having a way to define and compute things in theories for which no non-perturbative method was known before (except Monte Carlo methods in some of the simplest cases, but those don't give very much physical intuition, and are limited to the most simple quantities in the theory). For instance, you can read this writeup in a condensed matter journal here (https://www.condmatjclub.org/uploads/2020/01/JCCM_January_2020_02.pdf), which discusses recent experiments (involving a spaceship!) that bootstrap results have influenced.

Also, the reason i mentioned 3d non-SUSY dualities and the a-theorem, is precisely bc they were derived using cutting edge CFT and QFT techniques that were developed by string theorists. In particular, the dilaton effective action (which is how the a-theorem was proved) and mirror symmetry (which is how the supersymmetric version of the 3d dualities were proven, which strongly influenced the non-susy dualities. mirror symmetry of course has had a profound influence on pure mathematics as well).

Finally, on a sociological note, it's always hard to judge an extremely technical fields as an outsider (even a very smart one, say a prominent scientist in an adjacent field). I think a good rule of thumb is to see if the people working in that field have produced results that have influenced many other fields, in addition to things just of interest to their field. For instance, the giants of string theory (like Witten, Moore, Polyakov, Maldacena, Gross etc), even if they had done absolutely nothing for string theory, would still be famous due to their numerous profound contributions to cosmology, condensed matter, pure math, etc, many of which have had direct experimental repercussions (I can give you a long list for each of these people if you want, but you could prob just go on Inspire and see for yourself). This is why people take them seriously, not just bc quantum gravity is trendy, or silly hype. Conversely, if you come up with your own theory of quantum gravity, but haven't already done anything profound in other less speculative fields, and if you're new methods aren't useful for anything outside what you're doing, then you shouldn't be insulted if people don't take you that seriously (even if you write lots of popular books to convince laymen that theres a conspiracy against you). A good analogy might be CERN: you might know nothing about what particles are, but you'll certainly appreciate the world wide web that was invented as a byproduct. The point is that good lines of research inevitably produce useful byproducts (since all correct things are eventually connected in theoretical physics), whereas bad lines of research don't. After all, they are Not Even Wrong 😉

28. **yaron**
December 31, 2020

@Peter Shor: Indeed, physicists have not worked on topological phases for 40 years with little return, *yet*. But how long should one wait?

From yours and Native postdoc's comments it seems we share some discomfort from the situation in string theory, but the question is what lesson do we apply to other research programs. Since people made nice careers in strings (40 years is probably around average from graduate school to pension) it seems there is less risk in following the hype than trying something new, even after one sees the hype is false.

29. **Avals Tsetrot**
December 31, 2020

I can offer a reason why most high energy theorists comment on this blog anonymously. It's because not many people are willing to admit that they, looking for a distraction and in a moment of weakness , come to this blog to waste some time reading this incompetent dirt. Here we go, let's see if the blog's owner will have the balls to let this comment through, I bet he won't.

[*Attacks on others deleted*]

30. **Avals Tsetrot**
December 31, 2020

Since the owner deleted a part of my comment which he qualified as an attack on the others, let me try to waste a bit more of my time and rewrite it in a less polemic form.

First of all I do not believe it's a job of string theorists to predict new physics at the LHC, rather it is the job of hep-ph community, some of whose most illustrious representatives have deigned to comment in the above thread. Hep-ph people, not string theorists, apply for and win Advanced ERC grants to predict signals of new physics at the LHC.

Second, there is no shortage of funding for alternative theories of quantum gravity, as long as they have a sliver of hope to be successful. One example is the Horava theory of Lorentz violating gravity http://arxiv.org/abs/0901.3775 (BTW Horava is a string theorist), whose ramifications have been investigated vigorously. This activity was supported e.g. by the CERN theory department (which at some point hired two junior staff members working on it http://arxiv.org/abs/1410.2408). Higher-derivative gravity is also under active investigation in spite that it is not perturbatively unitary, and one has to jump through all sorts of hoops to pretend that perhaps in some pickwickian sense it is. This activity has been supported by at least one Advanced ERC grant http://arxiv.org/abs/1705.03896.

31. **Peter Woit**
December 31, 2020

lol,
I'm actually very sympathetic to the program of exploiting conformal symmetry in 3d QFT, but have a different perspective on it, and see motivating it by string theory as seriously misguided.

You write:
"The big question in formal QFT for the last 30 years or so is how to find non-perturbative ways of understanding QFTs (eg CFTs)"
What you're missing is that this began not 30 years ago, but 47 years ago, with the 1973 discovery of asymptotic freedom and realization that the correct theory of the strong interactions was QCD, strongly coupled in the infrared. By the time I got to grad school in 1979, for quite a few years everyone at Princeton had been focused on non-perturbative QFT, aiming at understanding QCD. A lot of effort was going into studying other QFTs as toy models and everyone was spending their time studying what the condensed matter people knew about such QFTs. My thesis work was Monte-Carlo computer simulations aimed at QCD, but I began with testing out methods on some stat-mech models such as the 2d XY model (the simplest model with interesting topological features).

The current interest in strongly-coupled stat-mech models among ex-string theorists looks to me like not a development inspired by string theory, but a return to what everyone was working on in the early 1980s, before they abandoned it in 1984 for 10d superstrings and complex 3d algebraic geometry (because Witten and others convinced them that all one needed to unify physics was to find the right Calabi-Yau).

Of course there has been a lot learned since 1984 about non-perturbative QFT. I share your fascination with the question of how to exploit conformal symmetry in QFTs above dimension 2. In particular, I've been spending a lot of time looking at what Rychkov and others have done by studying the very non-trivial relations between the Euclidean and Lorentzian signature situations in 3d. I differ though I suspect in believing that string theory is worse than useless here. While some theorists may have gotten to this problem by starting at string theory and AdS/CFT, trying to understand 3d QFT by compactifying 10d superstrings is likely to at best tell you something highly obscure about uninteresting models.

Where my point of view is completely different is that I'm not ultimately interested in condensed matter, but in fundamental physical laws, so care about 4d, not 3d. One of the main motivations of the twistor ideas I'm excited about is that twistors provide a compelling way to get 4d conformal symmetry. What I see as new has to do with the relations between the Euclidean and Minkowski conformally invariant theories, but in 4d, not 3d.

So, I'd be happy to see a campaign to promote the study of conformal symmetry in QFT as the guiding principle (or even fad) in the subject. But to get students and others interested in this, starting by teaching them about 10d superstrings and AdS/CFT is a mistake, even if this is convenient for those who don't want to admit failure of their research programs.

32. **Peter Woit**
December 31, 2020

Avals Tsetrot,

"I do not believe it's a job of string theorists to predict new physics at the LHC"
The problem is that string theorists have given up not only on predicting new physics at the LHC, but on predicting new physics anywhere at any energy, as well as giving up at explaining anything about fundamental physics.

The current problem is not that research on string theory is still dominant after 40 years, it's that leading string theorists have given up on fundamental physics, trashing the subject on the way out with crap like the landscape, and continuing to try and convince people that their failure was not actually a failure.

33. **BootsTrap**
December 31, 2020

Lol, imagine that on a cold morning in 1984 Belavin-Polyakov-Zamolodchkov publish a paper where they put the 2d bootstrap equations on an average computer available back then and observe a kink close to the expected position of the 2d Ising model. This does not sound very exciting as compared to what they actually wrote. This could have generated couple of hundreds papers more… One thing it would not had led to it is understanding of the beauty behind 2d CFT's. Well, the same is with the 3d numerical bootstrap. It cannot even prove that these CFT's exist as the technique gives you 'exclusion plots' and adding one more operator can kill the solution. It does not lead to any understanding that would be comparable to BPZ. Just another technique to get more digits. Yes, it was popular some time ago, just because it was very easy to write a paper and we all need papers. The SUSY dualities have not helped to prove the non-SUSY 3d dualities. 3d and 4d generalizations of the c-theorem do not require any knowledge of string theory, as is clear from the proofs.

34. **Slava Rychkov**
December 31, 2020

Hi BootsTrap,

let me tell you a bit about the history of conformal bootstrap. When I gave the first talk at the IAS about the conformal bootstrap revival back in 2008, I was challenged by noone else but my PhD advisor Sasha Polyakov who did not believe at the time the equations I was using were applicable to higher dimensional CFTs. So much for the fact that conformal bootstrappers are using well-known equations, if one of the CFT classics did not outright agree with those equations 🙂

Also I challenge you to write a few more papers like e.g. the recent bootstrap work http://arxiv.org/abs/2011.14647 if you believe that any grad student can nowadays write a valuable bootstrap paper. You have to be a pretty damn smart grad student to master all the theory which goes into the conformal bootstrap AND develop an efficient numerical algorithm to put all that theory to good use. Good luck.

Finally, if you don't like numerical work, I do encourage you to look for analytical understanding of the numerical bootstrap bounds (which are rigorous bounds, mind you, even if computed numerically). Then you will become an equal of BPZ. It should be easier to understand analytically something which you know exists, shouldn't it? So here is a nice challenge for you and everyone else, a challenge which did not exist before the numerical bootstrap work. You may wish to familiarize yourself with the work of Dalimil Mazac who did find analytical proofs of some numerical bootstrap bounds.

The point being, before the numerical bootstrap, most people were skeptical that 3d critical phenomena would one day be accessible to the CFT techniques, and now nobody can doubt that.

35. **Dalimil**
December 31, 2020

BootsTrap,
what BPZ understood in 1984 are extremely special and simple examples of CFTs, namely the unitary ones in d=2 with central charge between 0 and 1. This leaves out a vast landscape of CFTs, namely irrational 2d CFTs (with central charge above 1), and all CFTs in d>2. There is currently no explicit solution of any interacting example of either kind but it is clear that if there is, it would be orders of magnitude more complicated and interesting than what BPZ accomplished. What the modern bootstrap has shown is that the CFT axioms are powerful enough to plausibly single out such theories, giving us some hope that one day somebody smart will find a solution of either an irrational 2d CFT, or an interacting CFT in d>2. Furthermore, from this point of view, the current understanding of 2d CFTs is almost as rudimentary as that of d>2 CFTs.

36. **TS**
December 31, 2020

It is not a new thing that "phenomenology" is thought of as being outside of "theory" but to see this as blatantly as in lol's comment and the following discussion is rare. All the amazing progress in precision calculations that accompanied the LHC era? Didn't happen, or isn't "theoretical physics"!

Maybe people should consider whether they actually believe that physics is about the real world when they can't even be bothered to acknowledge the progress that is being made in predicting experimental results in the world's largest lab.

37. **Alessandro Strumia**
January 1, 2021

Dear "Avals",

you don't believe that "it's a job of string theorists to predict new physics at the LHC", but in past decades lot of activity in string theory had been done assuming that there is one vacuum and two scales: the Planck/string scale, and the SUSY/weak -breaking scale (while the vacuum energy vanishes for reasons to be clarified in the future). Then one constructs string models with N=1 SUSY to be discovered at LHC, focusing on Calabi-Yau compactifications, etc, etc.

Unfortunately, whoever wrote laws of nature had not good taste or was not as smart as string theorists. The vacuum energy was found to be positive, and no SUSY was found at LHC. In the string context, this might mean that there is a huge number of vacua with SUSY broken at the string scale.

If now you Aesopically like to think that you never cared about LHC, you miss what made physics more interesting than abstract theory: the pleasure of being slapped by experimentalists, hoping that a kick in the back will point to a better theoretical direction than keeping dragging the aether or retracting to pure math.

PS: Peter, don't worry about attacks. To keep physics serious we need people like the P-dual of "avals", who bluntly say what they think, rather than what is polite and convenient.

38. **André**
January 1, 2021

Peter, Avals,

it might seem that the job on any theorist working on high energy physics is to explain why there are three particle generations, where the gauge groups come from, where the particle mass hierarchy comes from, and where the coupling constants come from.

It might also seem that most proposed theories, including string theory, where not really that successful in this endeavor, despite the help of a lot of brainpower.

Avals, are you working on these questions? If not: Are you honestly and really saying that string theory will solve these questions?

39. **BootsTrap**
January 1, 2021

Dear Lol, Slava and Dalimil, I hope that most people agree that an analytical understanding is much better than a (yet another) numerical approach (even if it is the most computationally efficient one at present). There can be two versions of BPZ: economy class: with the help of a computer BPZ draw a plot with a kink in the neighborhood of 2d Ising model. First class: what they actually done. It does not solve all 2d theories, but solves the important ones, and it advances greatly our understanding. I guess we know what is the 3d economy class version of that. Instead of yet another paper that improves the numerics I would recommend to read some of the recent analytic bootstrap papers (for example, Alday and pals who might give us the first class version of the 2d story in the future). Perhaps, one should create hep-th-numerics for people who gave up. No offense, the better numerics for 3d Ising are useful, but I would not put it on the list at all, which is where this debate has started. Dalimil, I disagree that the numerical bootstrap has shown anything apart from adding more digits and it is nice that you moved to analytical methods: the CFT existed before, the kinks that finally turned into the islands are due to 3d Ising-type theories having actions, equations of motions etc, which singles them out of the continuum of 'theories' – they are disconnected from the continuum and we knew that.

40. **Slava Rychkov**
January 1, 2021

Hi BootsTrap,

what a biased perspective on the conformal bootstrap past and present history! So many fertile exchanges exist in the conformal bootstrap community between the numerical and analytical methods! The numerical bootstrap people did not give up, on the contrary, by 2008, it's the analytical people who long gave up the hope to access strongly coupled non-supersymmetric CFTs via the conformal bootstrap equations. Paraphrasing you, they could not afford a first class ticket and so they refused to fly instead of trying out the economy. The economy salon was pretty cushy, and totally empty, when we tried it. 🙂

Thanks to the numerical bootstrap, this hope is now back and, to my joy, it stimulates a huge amount of analytical thinking which would not otherwise exist. The numerical work showed a window of opportunity, and afterwards analytically-minded, intellectually curious, and very smart, people decided to take a look at what is going on, not the other way around.

As to the fact that numerical bootstrap "just adds more digits", I do like to stress that it does so with rigorous error bars, unlike resummed perturbation theory and Monte Carlo simulations, where error estimation is often an art rather than science. This is pretty unique: in fact there is hardly any other method in quantum field theory which has this property. It gives bootstrap results the status of a final verdict in cases when one has to decide the fate of borderline cases, and more conventional techniques disagree. By now we have several experimentally relevant applications of this unique role of the bootstrap.

But OK, it's not like we need everyone's approval. In fact your opinion is not uncommon, my ENS colleague Volodya Kazakov likes to bug me with very similar remarks, while I bug him back saying that it's his job as an expert in integrable models, not mine, to figure out if the 3d Ising CFT is integrable and solve it. 🙂

There are many real physicists out there struggling to understand concrete condensed matter systems. They know the value of a practical method when they see it, and it's them who I consider the primary bootstrap audience.

Good buy!

41. **Dalimil**
January 1, 2021

Bootstrap,

Your comparison of the modern bootstrap with BPZ is substance-free because solving CFTs in d>2 (or irrational 2d CFTs) is a very different (and apparently much more difficult) mathematical problem than solving rational 2d CFTs. So your dismissal of the recent advances is a bit like if a mathematician were dismissing the importance of partial results on the location of zeros of the Riemann zeta function by arguing that we know the location of roots of quadratic polynomials since many years ago.

Of course, an exact analytical solution of a d>2 CFT would be optimal, but in its absence, if I were to decide whether it's better to have an analytic answer to 5 orders in perturbation theory (with unknown errors) or a numerical answer with rigorous error bars of size 10^{-5}, I'd probably choose the latter.

Perhaps the most important point though is that the modern bootstrap advances have made interacting conformal field theory in general dimension into totally rigorous fields of mathematics. It's true that axiomatic approaches to QFT exist since the 1950s, but it was understood only from 2008 onwards that the CFT axioms are powerful enough to determine dynamical data. In principle, you can now explain these axioms to a mathematician who can then start proving rigorous theorems about interacting CFTs and thus also nonperturbative quantum gravity in AdS — quite remarkable if you ask me.

42. **Peter Woit**
January 1, 2021

Alessandro Strumia,
I agree that we need more professional theorists who say what they think, even if it's unpleasant. What I object to and don't want to tolerate here is abuse of anonymity.

Trying to think about what Physics Today should be doing (as opposed to what it has done), what's needed is not so much articles by people like me or Sabine Hossenfelder answering the kind of articles they have been publishing. Instead, what's needed is a different kind of article, with an honest discussion of what the problems are and what experts think about them. Instead we get these highly political one-sided arguments (which don't even acknowledge explicitly the other side). A good start might be for Physics Today to go to the authors of the articles I linked to, along with others who over the years have argued for heavily promoted speculative ideas that have now been disconfirmed, and ask them to honestly address the current situation.

43. **Peter Woit**
January 1, 2021

André,
In general I don't think that theorists need to be addressing directly experimental results or fundamental open issues in the theory, since most of the time they won't have anything useful to contribute if they try and do that. Better to work on possibly more obscure and technical things that are not understood, where progress is possible and might someday inspire a new idea that can help with fundamental issues. But fundamental open issues are not going to ever get solved if people misleadingly tell themselves and others that they have alread been solved (or have been shown to be insoluble).

44. **Lee Smolin**
January 1, 2021

Dear LOL,

I agree that your four points are an impressive list of accomplishments, of whom the many who contributed should be rightly proud. But in the generations who entered physics in the 1940s to 1970s there are a number of individuals who each had a lasting impact on science greater than your whole list, while addressing both theoretical and experimental issues: Polyakov, Wilson, Feynman, Gell-Mann, Weinburg. Anderson, 't Hooft, Dyson, And then think that they knew Einstein, Bohr, Born, Heisenberg, Schrodinger, Dirac…

May I gently suggest that those of us who aspire to argue about the future of physics might, after 20 years, include humbleness on our list of New Years resolutions?

Best wishes for the new year,

Lee

45. **Alessandro Strumia**
January 2, 2021

Physics so far kept attracting best people, so it's possible that LOL & co are as smart as Polyakov & co, and that the real difference is that old generations did the easier important jobs, leaving the harder less important jobs to current generations. This might have now contributed to avoiding open discussions about difficulties and to hyping partial achievements. But the real end of physics will come if it will stop attracting smart "un-humble" persons.

46. **lun**
January 2, 2021

Alessandro, your comment is pretty telling on many levels.
The "top talent" drift from theoretical physics to various incarnations of data science and computer science has been going on for decades. The fudamental problems theoretical physicsts are struggling with now, far from being "less important", are are precisely the ones the likes of Einstein, Maxwell and their ilk struggled with: unification of all forces, quantization of gravity, microscopic understanding of entropy and so on. Its just that the current "elite" has been making a lot less progress in their resolution while feeling much more self-important about it.
Then again, one big problem with "meritocracy" is that self-selected elites who believe they are the best and only people like them are the best is that intellectual incest and group-think, to the point of blatant blindness, follow naturally. We see this all over theoretical physics today, it is part of the problem with it.

47. **Fabien BESNARD**
January 2, 2021

lun, I'd like to concur with you using the words of Roger Penrose : I once heard him say that there are two types of mathematicians, smart ones and dumb ones, and that he fell in the second category. I think the problem of today's theoretical physics is that there are too many smart physicists.

48. **Peter Woit**
January 2, 2021

Some thoughts on comments above:

I continue to see very smart young people wanting to go into fundamental theoretical physics. The best go to get Ph.Ds at the same sort of elite programs where I was educated. What I don't see is papers with impressive new ideas from young theorists. This is not their fault: their elders are not coming up with anything either, and the way in the past you often got breakthroughs was young people working not in a vacuum, but set in a promising direction by their advisors or others around them.

The combination of few new ideas, tribalism and a celebrity culture has led to more examples of huge rewards and attention for not so great (or even wrong) work, with people labeled as "geniuses" and collecting $3 million on very dubious grounds. A screwed-up rewards structure carries serious implications for the ability of a field to make real progress.

As for "humility", that's definitely needed and missing in terms of people not admitting that an idea has failed, or has produced only very modest results. On the other hand, a fair amount of arrogance is needed to believe that one can make a breakthrough and be willing to bet one's time and energy on it. So, we need more of both humility and arrogance…

49. **lol**
January 2, 2021

Dear Lee, Peter, etc,

Happy new year!

I think we actually agree on a lot more than than the stereotypes would assume. None of us think string theory has solved the deepest fundamental issues, none of us like overhyped results (especially when the scientists are to blame, not just the science journalists), we all seem to appreciate some nice results from the last 20 years (even if they aren't as groundbreaking as those from the golden age of physics), and that progress in technical nonsexy things (like computing Ising model critical exponents to a few more digits) is still a worthwhile and honorable thing for scientists to do, even if it wont explain the hierarchy problem or solve global warming.

One last thing I would try to emphasize tho, is that while a few famous string theorists at well funded institutions might well give off the impression of great arrogance in their accomplishments, for most of us, we're working for very low pay, for many many years, and certainly not basking in the glow of media attention. Speaking personally, I have chosen anonymity on this forum not bc I'm secretly Ed Witten in disguise (he seems too busy tweeting about Israel these days lol), but bc i'm just a lowly postdoc at a non-American institution with very poor job prospects, making probably the equivalent of minimum wage in the US, and I don't want any inadvertently foolish thing that I say online to hurt my already dismal prospects. For people like me (who are the vast majority of string theorists, high energy theorists, formal theorists, whatever), we do what we do out of love for science, fully aware of the huge experimental and theoretical problems with our field, out of a perhaps quixotic dream that perhaps we will stumble upon a solution, or at the very least make substantial, if not groundbreaking, progress on worthy technical and sometimes conceptual issues.

The main reason I spoke out was simply to convince laymen (or non-string theory scientists) reading this blog that despite what they may have been told, we are making steady progress in some directions (maybe not the sexiest ones), and that we would appreciate to continue receiving our paltry salaries, which seem to decrease by the year. My main concern is that excessive negative press will defund not just those doing extremely speculative work (which I do think also deserves some funding, tho Im not the right one to defend them), but also the 90% of us doing humble meaningful work, and contributing to the results I listed.

Perhaps going into the new year, in addition to decrying excessive hype, we could vow to also promote humble progress?

50. **Alessandro Strumia**
January 2, 2021

Dear lun,

bibliometric data show that fundamental theory was concentrated in a few main centers up to ≈30 years ago. Next, internet made research diffused. Access to internet become enough to find articles and books and tools, and follow courses and webinars. A very strong young physicist can now get a safe position somewhere even outside main centers. Actually, IAS seems to me the last concentration of excellence. Recently we also got a diffusion in the topics that are being explored. This should be enough to bypass sociological problems.

I fear that stagnation on big issues mostly happened because these are difficult problems.

51. **AcademicLurker**
January 2, 2021

On another blog, people were answering a "What should I keep in mind when applying to graduate school?" question from a physics student who seemed interested primarily in theory.

One respondent, who identified themselves as being at a "top" department said that perfect test scores, perfect grades and undergraduate research experience weren't enough to winnow the field of candidates, so the big deciding factor was the number of papers published as an undergrad. I don't know if this person was exaggerating or not.

No doubt the requirements described select for people who are very good at what they do, but they likely also select for a very specific type, when maybe some variety is what's needed (Lee Smolin addresses something like this point in his book).

52. **Peter Woit**
January 2, 2021

lol,
Thanks for your comments. I appreciate that especially non-tenured theorists have a very good reason to comment anonymously. When I started the blog I was thinking that anonymity was necessary for younger people critical of string theory to be able to speak without fear of retribution, soon realized that young string theory enthusiasts also had reason to be fearful (a lot of the physics community has never been sympathetic to string theory). The tribalistic aspects of this controversy are disturbing.

A lot of what people worry about does have to do with funding and with the always precarious job situation (by the way, the job situation was just as bad if not worse before string theory became popular). Many people seem to react to the yearly multi-million dollars in prize money from Milner/Zuckerberg by arguing that it's money going to theorists, so good. I'd love to see pressure put on the Breakthrough Prize people to change what they're doing to fund modestly paid permanent positions for theorists, rather than give huge amounts to people who already have a permanent position.

53. **Peter Woit**
January 2, 2021

AcademicLurker,

I think one thing that is true is that there has been significant grade inflation over the years, so having a transcript with a string of As isn't worth what it once was. This is not good for the unusually talented, who now need to find other ways to distinguish themselves.

One problematic aspect of string theory for a long time has been that ambitious young people are told that it's "the best hope for a unified theory" or some such, so naturally try to study the subject. But, it's a very technical business and working your way through Polchinski requires a huge investment of time and energy, arguably a really bad way for the best young theorists to be getting trained. A modest proposal would be that physics departments should serious considering getting rid of any courses teaching supersymmetric field theory and string theory. What students are learning in these courses is not very useful, and giving them a warped perspective as they try and enter the field and become researchers in their own right.

54. **Richard**
January 2, 2021

Peter,

What about https://physics.aps.org/ ?

How do they compare to PT and PW with regards to the presentation of string theory and other speculations?

55. **Peter Woit**
January 2, 2021

Richard,
That's kind of a different sort of publication, essentially news articles based on new papers. There's not a lot about string theory there, because not a lot of new developments. Physics Today also does news stories (as opposed to the kind of promotional feature articles I was counting and linking to), and relatively few of those have been about string theory. Actually, an editor at Physics Today wrote a blog entry

https://physicstoday.scitation.org/do/10.1063/PT.5.010017/full/

responding to someone asking why there were so few news stories about string theory (he didn't address the sort of problems I'm raising).

56. **Douglas Natelson**
January 3, 2021

AcademicLurker, I think that's a major overstatement. It is true that undergraduate (co)authorship is something that gets noticed in admissions, but smart people know that some of that is a matter of access (e.g., students who can't do REU programs over the summer and may come from smaller schools just might not ever have a credible opportunity to be on a paper as an undergrad. That doesn't imply something about their ability to succeed at the doctoral level.).

57. **martibal**
January 3, 2021

Regarding the lack of humbleness, the problem may not be so much in the attitude of postdocs or young researchers than in the mind of whom is in position to hire other people. And sadly this is not limited to string theory.

Some 20 years ago, when a renowned center for theoretical physics was founded, it seemed easier to be hired there as a postdoc by claiming great ideas about foundations of quantum mechanics or quantum gravity, than by presenting humble calculations on, say, the metric interpretation of the Higgs field in noncommutative geometry.
I remember some (non-stringy) conferences on quantum gravity with highly non-humble plenary talks about some models – a little bit more evolved that Ising-1D – that were presented as bright new paths towards quantum gravity just because a potential in 1/r popped out. When someone asked "how do you go from this to full gravity", the answer was "well yes, the technical details are still to be worked out".

Humbleness is not a value appreciated by hiring committees. In a french maths department, I was once asked what I was hoping for the future of mathematical physics. I answered "more humbleness". I thought this was a smart answer. I learnt later on that the committee did not appreciate it at all.

As a last example, some years ago, french CNRS edited some guideline to apply to ERC grant (the main european funding agency). One of the main advice was to use key-words like "breakthrough", "multidisciplinary", "high-risk, high-gain" and – my favorite one – "to be at the cutting edge of knowledge". Quite far from humbleness…

58. **CWJ**
January 4, 2021

martibal,

The irony is, in my experience in the US at least, is that reviewers of proposals (and papers) are generally extremely conservative and tend to strongly prefer well-trodden paths. This is independent of what the funding agencies call for. For example, NSF proposals explicitly must include some component that addresses a broader social good (this isn't the exact wording), but typically reviewers hate anything more than 'train the next generation.' Anything the slightest bit of out-of-the-ordinary outreach will get slammed as a waste of time. That goes for the scientific part of the proposal as well–even though the funding agencies ask for 'innovative' scientific visions, in practice most reviewers are harsh towards anything save incrementalism. Maybe other people's experience is different…

59. **Ash Jogalekar**
January 4, 2021

As a chemist who has always enjoyed your blog tremendously, I have the following question. What do you think about the argument that string theory, even if it may not lead to productive ends in itself, provides excellent training in physics and mathematics that would set up students for careers in other fields?

The reason I ask is because it reminds me of the field of "total synthesis" of organic molecules in chemistry where graduate students spend five or six years undertaking very arduous, risky syntheses of complex organic molecules, many of which don't have an obvious use. The argument has often been made that while the field itself provides little benefits, it's an excellent training ground for students because it exposes them to multiple techniques, ideas and arguments in organic chemistry that are hard to find in other subfields.

60. **Peter Woit**

January 5, 2021

Ash Joglekar,
The problem is that how to calculate in string theory is an extremely specialized subject, which doesn't have a lot of overlap with more useful fields. The really weird thing that is going on is that there's also little overlap between what theory students are getting trained in (for example, the content of Polchinski's two-volume textbook) and mainstream current theoretical research by "string theorists". I'm not sure what function studying Polchinski now fulfills, other than as a tribal rite of passage.

DAU. String Theory

January 4, 2021
Categories: Uncategorized

I first wrote here in 2015 about DAU, the unusual film project based to some extent on the life of Landau. Parts of the film first were shown in Paris early in 2019, and this past year started appearing on the DAU website. I'd been looking forward to seeing Gross, Yau, Rovelli and others in the film, so paid to watch one of the first parts, DAU. Degeneration, when it became available last year. It's over six hours long, for a review, see here. I ended up doing a certain amount of fast-forwarding, was disappointed to only see Nikita Nekrasov and Dmitri Kaledin, none of the other math/physics world figures I had heard had participated.

DAU largely was funded by Russian oligarch Sergei Adoniev. For an excellent article discussing the project and its context in current Russian culture, see Sophie Pinkham's article Nihilism for Oligarchs.

There wasn't much physics in DAU. Degneration, but evidently it plays a significant role in other parts of the film. According to the DAU website,

> Real-life scientists, who were able to continue with their research in the Institute, included: physicist Andrei Losev; mathematicians Dmitri Kaledin and Shing-Tung Yau; string theorist Nikita Nekrasov; Nobel-Prize winning physicist David Gross; neuroscientist James Fallon; and biochemist Luc Bigé. "One group was researching string theory and another researching quantum gravity. These groups hated each other. One stated there were 12 dimensions, the other claimed there were 24. The string theory group believed there couldn't be 24 dimensions. The quantum gravity group believed that the other scientists were narrow-minded," explained Khrzhanovskiy.

Now available is a part which seems to more centrally involve physics, DAU. String Theory, which is described as follows:

> Nikita Nekrasov is a scientist, a theoretical physicist who studies our world and other possible worlds. He refuses to make a choice between mathematics and physics, between one woman and another, as he ponders the existence of the multi-universe. At scientific conferences, attended by eminent foreign scientists and a rising younger generation of physicists alike, Nekrasov gets carried away debating the beauty of string theory. He attempts to explain to all of his women – Katya, the librarian, Zoya, the scientific secretary, Svetalana, the head of department – about the theory of his own polygamy, and the possibility of having enough feelings to satisfy everyone.

Multiple universes have always been advertised with "in some other universe you're dating Scarlett Johansson", relating the idea to multiple partners in this universe is an innovation.

I haven't yet watched DAU. String Theory, will likely find time for that soon. I'm worried that I'll still not get to see Gross, Yau, Rovelli and others though, and lack the time and energy to look through all the other parts of the film. I'd like to crowd-source a solution to this problem: if anyone watching these things can let the rest of us know in which parts (at what times) well-known math/physics personalities appear, that would be greatly appreciated.

Comments

1. **Alessandro Strumia**
   January 4, 2021

   In case you watch the film, please let me know if somebody impersonated the academic mob that in 1937 attacked in this way their colleagues in the Landau UPTI institute who got accidentally involved in Stalinist purges:

   "Vile agents of fascism, Trotskyist-Bukharinist spies and saboteurs … Enemies penetrated among physicists, carrying out espionage and sabotage assignments in our research institutes … Soviet physicists more closely unite around the Communist party and Soviet government, around our great leader Comrade Stalin". (Source: https://arxiv.org/abs/1508.03578, page 22)

2. **Julie**
   January 5, 2021

   Peter,
   Gross and Verlinde appear at ~56 min.

   You can watch free at
   https://filmix.co/drama/143039-dau-teoriya-strun-2020.html

   Although its in Russian, the relevant parts are in English.

   The protagonist mostly speaks to his women. I can't even start to explain all the things that are wrong with it. Haven't expected anything else from a production by a Russian oligarch though.

3. **Peter Woit**
   January 5, 2021

   Julie,
   Thanks! For me though the site you link to gives an error
   "Video blocked at the request of the copyright holder"
   At some point I'll invest the \$3 to pay to watch this.

4. **Low Math, Meekly Interacting**
   January 5, 2021

   I'm a little leary, in spite the modest investment. The Degeneration review makes the project sound like a mashup of David Cronenberg and Seymore Butts on PCP. That said, I'm not altogether unsympathetic to the notion of slogging through to see what such luminaries could possibly be doing as characters in such a production. Julie, is it anything interesting, at least?

5. **Nikolas Claussen**
   January 5, 2021

I went to visit the DAU exhibition when it was on show in Paris almost two years ago; it is my impression that the whole thing is basically a fraud, or at least, behind all the hype, pretty hollow. When I arrived at the exhibition, a friend and I were refused entry on account of an invalid reservation number although we had bought the tickets from an authorized seller – never saw my money again. Two other friends who had bought tickets elsewhere did manage to see the exhibition which was rather underwhelming, resembling a collection of pop-up bars (you could get drunk, at least) with a few shock elements (e.g. pornographic films). In different rooms, various, mostly unrelated film snippets were shown and there were a few actors wandering through the corridors. Although booked out according to the website, most rooms where conspicuously empty. No comparison to the kind of immersive, concept-art exhibitions you can see at the Palais de Tokyo, for example.

6. **Peter Woit**
   January 5, 2021

   LMMI,
   DAU. String Theory sounds a bit more promising than DAU. Degeneration, the one I saw and that most of the reviews are about. For one thing, DAU. String Theory is less than half as long, for another, Julie reports that string theory celebrities are in it, unlike DAU. Degeneration, where all you get is Nekrasov.

   The reviews of DAU. Degeneration are also somewhat misleading in promising pornography, violence and other outrageous conduct. From what I remember it was mostly long sequences of murkily lit scenes of people talking and not much happening. Long scenes of people drinking and behaving badly. If you're hoping for David Cronenberg you'll be disappointed. On the other hand, if you're a fan of Dogme film-making, you might be interested. A lot of the scandal revolves around reports that the non-professional actors were coerced into participating in some of the sexual behavior and drunken violence that one sees on-screen. As a spectator though one can't tell what the truth of that might be.

7. **Julie**
   January 6, 2021

   To be honest, I didn't had the patience to watch it all. The twitching of a male ego.

   There are pictures of physicists in dark suits before black boards, wearing hats, walking the streets, Gross smoking a cigar, sitting together in their trousers with braces, drinking alkohol – Yau and Rovelli sit at the table, where young women serve food and drinks. Later some slow dancing.
   Nekrassov calles himself a polygamist – multiple disciplines (physics and math), multiple countries, cities, and – of course – multiple wives. The main message: why should I choose anything (anyone), if I can have it (them) all. Which is a rather typical stringy message which has brought much damage to the perception of this community (see e.g. B. Greene, the main prophet).

   Low Math, Meekly Interacting, no, not really. But that depends of course on your general degree of enthusiasm for a nerdy guy who is uncovering the very hard and important secrets of the universe and his twitching ego. And since it's ought to be a piece of art, the interest is to be found in the eye of the beholder, right?

8. **Alex**
   January 10, 2021

   DAU is a bad project. It was funded by money stolen from russian people.
   Its screenplay is made to denigrade human dignity.
   And "DAU. Degeneration" specially features russian neo-nazi Maxim Martsinkevich (https://en.wikipedia.org/wiki/Maxim_Martsinkevich).

9. **D. K.**
   January 11, 2021

   it's a macho project that unwillingly uncovers the backwarded macho mentality within math and physics and it is not even in any sense irony. Painful.

Martin Veltman 1931-2021

January 6, 2021
Categories: Obituaries

I heard today of the recent death of Martin Veltman, a theorist largely responsible (with his student Gerard 't Hooft) for showing the renormalizability of non-abelian gauge theories, a breakthrough crucial to the Standard Model that won both of the them the 1999 Nobel Prize. For the story of this work, the best source is likely Veltman's Nobel lecture.

My one memory of meeting Veltman in person was when he visited Stony Brook at the time that I was a postdoc there (mid 1980s). There was a party at someone's house, and I spent part of the evening talking to him then. What most struck me was his great passion for whatever it was we were talking about. One topic I remember was the computer algebra program Schoonschip (which Wolfram acknowledges as an inspiration for Mathematica). I vaguely recall that at that time Veltman had recently ported the program to a microprocessor and he was selling copies in some form. It also seems to me that one remarkable aspect of the program was that it was written in assembly language, not compiled from a higher level language. At the time I was doing computer calculations, but of a very different kind (lattice gauge theory Monte-Carlos). Since my own interests were focused on non-perturbative calculations, I wasn't paying much attention to Veltman's work, although I do remember finding his Diagrammar document (written with 't Hooft) quite fascinating.

A comment that evening that really struck me was about students, in particular that "you give your students your life-blood!". This seemed likely to have some reference to Veltman's relations with his ex-student 't Hooft, but I'm pretty sure I didn't quiz him on that topic.

Many years later, when I was trying to get *Not Even Wrong* published, I contacted Veltman and he was quite helpful. At the time he had recently published his own popular book about particle physics, Facts and Mysteries in Elementary Particles, which contained his own version of the Not Even Wrong critique:

> The reader may ask why in this book string theory and supersymmetry have not been discussed. . . The fact is that this book is about physics and this implies that theoretical ideas must be supported by experimental facts. Neither supersymmetry nor string theory satisfy this criterion. They are figments of the theoretical mind. To quote Pauli, they are not even wrong. They have no place here.

That book is quite good, I strongly recommend it. May its author rest in peace.

   January 7, 2021

   A giant of theoretical physics and a true loss to the community and to me personally. I spent several hours chatting with Tini and his wife when they visited Heidelberg in 2004 which was a wonderfully natural and insightful experience. Squeezing himself out of our small 3-door car, he smilingly told me that next time the car needs to be bigger. Undoubtedly sharing my warm sentiments for him with many physicists of our time, I do stand in awe of his intellect, unadulturated convictions, and accomplishments in establishing the gauge principle for the description of fundamental particle interactions.
   You'll be missed greatly, Tini!

2. **shantanu**
   January 7, 2021

   He also never believed in dark matter. I don't know much about his relationship with T'hooft. Can you elucidate on that?

3. **David Brown**
   January 7, 2021

   In 2010, Roger Highfield, science editor of "The Telegraph", published several comments from theoretical physicists concerning the LHC start-up.
   "Martin Veltman, Nobel Laureate University of Utrecht, Netherlands: 'It would not surprise me if the experimenters don't find the Higgs particle. I don't trust the theory behind it. But if it does appear to show up, it will be crucial to check that it behaves as the theory predicts. I would be surprised if supersymmetry were found. I supported the idea when it was first suggested, but I've gradually lost confidence in it, though I might well be wrong. To be sure, if the LHC finds nothing to support supersymmetry, its advocates will just make excuses and keep using it. As for string theory, it's all mumbo jumbo, with no connection with experiment.' "

4. **Peter Woit**
   January 7, 2021

   Shantanu,
   For a very old blog posting about Veltman and some of his views, see
   https://www.math.columbia.edu/~woit/wordpress/?p=106

   About Veltman/'t Hooft, I've heard little second hand, and first hand all I know is what I quoted from Veltman in the posting, and comments by 't Hooft at the Coleman memorial conference, see
   https://www.math.columbia.edu/~woit/wordpress/?p=171

5. **Arnold Neumaier**
   January 7, 2021

   Peter,

   "his own popular book about particle physics, Facts and Mysteries of Elementary Particles […] That book is quite good, I strongly recommend it."

   In contrast to you, I strongly unrecommend it. It is very misleading in giving virtual particles an appearance of reality that is not even slightly backed by theory or experiment. See https://www.physicsforums.com/insights/vacuum-fluctuation-myth/ and https://www.physicsforums.com/insights/misconceptions-virtual-particles/

   In contrast, his book "Diagrammatica: the path to Feynman diagrams"
   https://www.cambridge.org/nu/academic/subjects/physics/theoretical-physics-and-mathematical-physics/diagrammatica-path-feynman-diagrams is a textbook on quantum field theory covering the standard ground up to QED in an essentially standard manner. This technically precise (though not mathematically rigorous) book contains not a single mention of the word 'virtual'. Instead, Veldman explains here in an exemplary way what Feynman diagrams are and how they are interpreted and used. From the

introduction:

”Perturbation theory means Feynman diagrams. It appears therefore that anyone working in elementary particle physics, experimentalist or theorist, needs to know about these objects. […] This then is the aim: to make it clear which principles are behind the rules, and to define clearly the calculational details. This requires some kind of derivation. The method used is basically the canonical formalism, but anything that is not strictly necessary has been cut out. No one should have an excuse not understanding this book. Knowing about ordinary non-relativistic quantum mechanics and classical relativity one should be able to understand the reasoning.”

6. **David**
January 7, 2021

There is a statement on Lubos' blog by 't Hooft:

https://motls.blogspot.com/2005/03/sidneyfest.html,

"Oeps, in my comparison of Sidney's fast and brilliant mind with that of my advisor Veltman, I must have left a false impression of my admiration of Veltman. I was making jokes about him (much as how he would do that himself), but please be assured that he is brilliant in his own way, as his richly deserved Nobel Prize testifies."

7. **Peter Woit**
January 7, 2021

David,
Thanks. You can also read there Lubos's description of the 't Hooft talk, which starts with "Before the talk, I had roughly 20 seconds to chat with Peter Woit."…

January 8, 2021

All,
Sorry, but I don't want to host a debate here about "virtual particles".

11. **Peter Orland**
January 9, 2021

I remember Veltman giving a talk on problems with the Higgs mechanism in Brighton at a big meeting 1983. I had a job in London, and went down there with some students and other postdocs.

The beginning of the talk was interesting, but after 15 minutes I was fast asleep. Veltman's voice was very gravelly and hypnotic; the perfect background noise to facilitate a nap. When I heard the applause at the end, I was very embarrassed by my faux pas. As people asked questions, I looked around and noticed that a few other physicists were still slumped in their chairs.

I had to find out what the talk was about from the proceedings.

12. **Deepak Aryal**
January 11, 2021

Veltman gave a very entertaining talk titled "The future of particle physics" at 2019 Lindau Physics Meeting (Especially the Q&A part). Here is the video: https://www.mediatheque.lindau-nobel.org/videos/38224/2019-meeting-martinus-veltman

14. **Francesco Vissani**
January 18, 2021

Thank Peter for remembering the 2003 book and his brilliant statement.

I had the great fortune to meet him at the end of my PhD (1993) in Zakopane and had the opportunity to discuss with him and learn many things. (As well as drinking a beer and discussing late into the night with him and other young people). One of those persons who gives you the desire to do better than you are capable of doing.

If I remember correctly, a few years later (1996) his contract was terminated. I got the impression that the reason was not particularly noble or profound, he was 65, but simply that in the place he was in, criticism of supersymmetry was not well tolerated. In 1999 fortunately there was the recognition we all know.

An important issue for him was the status of the cosmological constant; he also talked about it in the Nobel lecture. I have tried to raise this issue with others by talking about supersymmetry, but I have always seen very little interest. The typical response was: you don't understand, this is not relevant. Surely I do not understand a lot of things, but I hold that Veltman understood a lot. Thank you Tini.

15. **David Roberts**
January 22, 2021

I met Veltman briefly in 2001 at a public lecture I went to, that he gave at the University of Adelaide (I was a first-year physics student. It was the 26th of April, I find, looking back). I vaguely recall my mum asked a question at the end and he came over to hear it more clearly and give us an answer. I was starstruck meeting a Nobel laureate, and I thought he was really old then! The night also stuck out to me because I learned (from the late Rod Crewther) how to pronounce Lagrangian correctly, as I had only ever seen it written in books.

I still have a very nicely written and illustrated booklet from the night ("Very elementary particle physics") explaining the basics of the subject, which Veltman wrote.

Our semester at Columbia started earlier than usual this year, with first classes this week, my first class yesterday. This semester I'm teaching the second half of a year-long course on the mathematics of quantum mechanics. There's a Youtube channel with the lectures for the first half of the course, and now also for the second half. The course is largely following the textbook I wrote based on teaching this is earlier years. The first lecture yesterday was a summary of a point of view on canonical quantization explained in the first semester and in the book. This point of view is essentially that Hamiltonian mechanics is based on a Lie algebra (functions on phase space with Poisson bracket the Lie bracket), and canonical quantization is all about the essentially unique unitary representation of (a subalgebra of) that Lie algebra. On Thursday I'll start on the fermionic version of canonical quantization, which has a very much parallel structure, giving a super-Lie algebra and spinors.

A few other items:

- John Baez's This Week's Finds in Mathematical Physics was an unprecedented project conducted over 17 years, providing a wealth of fantastic expository material on topics in math and physics. It started in 1993, and on its twentieth anniversary I wrote an appreciation (in an appropriate font) here. John has now announced that this material has been typeset (2610 pages!) and he is editing it, to be released in batches. The first part is now available, on the arXiv as This Week's Finds in Mathematical Physics (1-50). As I find time, I'm looking forward to reading through these, encourage everyone interested in math and physics to do the same.
- Frank Wilczek has a new book out, and there's an interview with him at Quanta. You can see a conversation between him and Brian Greene here on Friday.
- Another physicist with a new book is Jesper Grimstrup, whose Shell Beach: The search for the final theory I've just finished reading and enjoyed greatly. The book is quite personal and non-technical, with topic Grimstrup's life as a theorist pursuing a unified theory. His career story is quite interesting, giving insight into the ways academic theoretical physics is challenging for young theorists trying to pursue non-mainstream research programs. Several books have appeared in recent years aimed at putting this kind of physics research in a human and philosophical context, telling you what it has to do with the meaning of life. There's some of that in this book too, of a much more compelling sort than what you see elsewhere. Grimstrup has a website here, and in recent years has ended up leaving academia and trying to fund his research with donations. I can think of a lot worse things you could do with your money than send him some.

  I'm quite sympathetic to the underlying theme that he describes pursuing (together with Johannes Aastrup) in the book, that of bringing together the insights of loop quantum gravity and non-commutative geometry. More recently they've been working on some new ideas for formulating QFT non-perturbatively that seem worth investigating. There's a survey blog post here.

Update: Another bit of private math/physics funding news. The IAS has announced establishment of the Carl P. Feinberg Cross-Disciplinary Program in Innovation

> Scientific research at the Institute is traditionally driven by the collaboration and independent projects of a full-time Faculty and a revolving class of more than 200 researchers at various stages in their careers. The Carl P. Feinberg Cross-Disciplinary Program in Innovation will build on this successful model with the recruitment of mid-career scholars who have pioneered foundational developments in new areas. Bringing together scholars with such unique insights—which may not be obviously connected to the existing themes of the past 20 or 30 or 40 years—ensures that IAS will remain agile and responsive to new intellectual developments that do not yet fit the mold of what graduate students and postdocs generally know. In order to close this knowledge gap, the program will feature intense, focused workshops and "master classes."
>
> "Since its founding, the Institute has served as a world center for investigations into the fundamental laws of nature. We are currently in the middle of a grand symbiosis of ideas, from the equations of general relativity to the quantum information of black holes," stated Robbert Dijkgraaf, IAS Director and Leon Levy Professor. "This revolutionary program will provide a dedicated space and the necessary flexibility to accelerate these exciting developments, and will surely forge new connections across fields."

Comments

1. **Peter Morgan**
   January 13, 2021

   And another interview with Wilczek, doubtless another of many, with Brian Keating, here, https://www.youtube.com/watch?v=prJjVUuDhvg

2. **Jeff**
   January 15, 2021

   Congrats to John Baez! Might there be any way to get a "top ten finds" for each year, or even just overall? Thank you!

3. **Ilyas Khan**
   January 15, 2021

   Peter thank you for highlighting Jesper's book. I remember the first call for assistance and how pleased I was to help. The book is a lovely "dividend"

4. **Felipe Pait**
   January 23, 2021

   Thanks to your suggestion, I'm reading "Shell Beach." Can you suggest a good book on non-commutative geometry? I'm an engineer who knows some differential and Riemannian geometry, would prefer a reference that brings out the intuition but is not too much geared towards specific problems in physics.

5. **Peter Woit**
   January 23, 2021

   Felipe Pait,
   Alain Connes has written various inspirational survey articles and given lectures that give a good introduction to the subject. Many are at his website alainconnes.org
   Have a look at
   http://alainconnes.org/en/downloads.php
   especially the section on survey papers.

   Among his talks, there was a very recent survey one at a Harvard seminar, see
   the first one listed under
   http://alainconnes.org/en/videos.php
   but you might find many of the others valuable.

Is the Standard Model Just an Effective Field Theory?

January 13, 2021
Categories: Uncategorized

An article by Steven Weinberg entitled On the Development of Effective Field Theory appeared on the arXiv last night. It's based on a talk he gave in September, surveys the history of effective field theories and argues for what I'd call the "SM is just a low energy approximation" point of view on fundamental physics. I've always found this point of view quite problematic, and think that it's at the root of the sad state of particle theory these days. That Weinberg gives a clear and detailed version of the argument makes this a good opportunity to look at it carefully.

A lot of Weinberg's article is devoted to history, especially the history of the late 60s-early 70s current algebra and phenomenological Lagrangian theory of pions. We now understand this subject as a low energy effective theory for the true theory (QCD), in which the basic fields are quarks and gluons, not the pion fields of the effective theory. The effective theory is largely determined by the approximate SU(2) x SU(2) chiral flavor symmetry of QCD. It's a non-linear sigma model, so non-renormalizable. The non-renormalizability does not make the theory useless, it just means that as you go to higher and higher energies, more possible terms in the effective Lagrangian need to be taken into account, introducing more and more undetermined parameters into the theory. Weinberg interprets this as indicating that the right way to understand the non-renormalizability problem of quantum gravity is that the GR Lagrangian is just an effective theory.

So far I'm with him, but where I part ways is his extrapolation to the idea that all QFTs, in particular the SM, are just effective field theories:

> The Standard Model, we now see – we being, let me say, me and a lot of other people – as a low-energy approximation to a fundamental theory about which we know very little. And low energy means energies much less than some extremely high energy scale 10^{15}–10^{18} GeV.

Weinberg goes on to give an interesting discussion of his general view of QFT, which evolved during the pre-SM period of the 1960s, when the conventional wisdom was that QFTs could not be fundamental theories (since they did not seem capable of describing strong interactions).

I was a student in one of Weinberg's graduate classes at Harvard on gauge theory (roughly, volume II of his three-volume textbook). For me though, the most formative experience of my student years was working on lattice gauge theory calculations. On the lattice one fixes the theory at the lattice cut-off scale, and what is difficult is extrapolating to large distance behavior. The large distance behavior is completely insensitive to putting in more terms in the cut-off scale Lagrangian. This is the exact opposite of the non-renormalizable theory problem: as you go to short distances you don't get more terms and more parameters, instead all but one term gets killed off. Because of this, pure QCD actually has no free parameters: there's only one, and its choice depends on your choice of distance units (Sidney Coleman liked to call this dimensional transvestitism).

The deep lesson I came out of graduate school with is that the asymptotically free part of the SM (yes, the Higgs sector and the U(1) are a different issue) is exactly what you want a fundamental theory to look like at short distances. I've thus never been able to understand the argument that Weinberg makes that at short distances a fundamental theory should be something very different. An additional big problem with Weinberg's argument is its practical implications: with no experiments at these short distances, if you throw away the class of theories that you know work at those distances you have nothing to go on. Now fundamental physics is all just a big unresolvable mystery. The "SM is just a low-energy approximation" point of view fit very well with string theory unification, but we're now living with how that turned out: a pseudo-scientific ideology that short distance physics is unknowable, random and anthropically determined.

In Weinberg's article he does give arguments for why the "SM just a low-energy approximation" point of view makes predictions and can be checked. They are:

- There should be baryon number violating terms of order $(E/M)^2$. The problem with this of course is that no one has ever observed baryon number violation.
- There should be lepton number violating terms of order E/M, "and they apparently have been discovered, in the form of neutrino masses." The problem with this is that it's not really true. One can easily get neutrino masses by extending the SM to include right-handed neutrinos and Dirac masses, no lepton number violation. You only get non-renormalizable terms and lepton number violation when you try to get masses using just left-handed neutrinos.

He does acknowledge that there's a problem with the "SM just a low-energy approximation to a theory with energy scale M=10^{15}–10^{18} GeV" point of view: it implies the well-known "naturalness" or "fine-tuning" problems. The cosmological constant and Higgs mass scale should be up at the energy scale M, not the values we observe. This is why people are upset at the failure of "naturalness": it indicates the failure not just of specific models, but of the point of view that Weinberg is advocating, which has now dominated the subject for decades.

As a parenthetical remark, I've today seen news stories here and here about the failure to find supersymmetry at the LHC. At least one influential theorist still thinks SUSY is our best hope:

> Arkani-Hamed views split supersymmetry as the most promising theory given current data.

Most theorists though think split supersymmetry is unpromising since it doesn't solve the problem created by the point of view Weinberg advocates. For instance:

> "My number-one priority is to solve the Higgs problem, and I don't see that split supersymmetry solves that problem," Peskin says.

On the issue of quantum gravity, my formative years left me with a different interpretation of the story Weinberg tells about the non-renormalizable effective low-energy theory of pions. This got solved not by giving up on QFT, but by finding a QFT valid at arbitrarily short distances, based on different fundamental variables and different short distance dynamics. By analogy, one needs a standard QFT to quantize gravity, just with different fundamental variables and different short distance dynamics. Yes, I know that no one has yet figured out a convincing way to do this, but that doesn't imply it can't be done.

Update: I just noticed that Cliff Burgess's new book Introduction to Effective Field Theory is available online at Cambridge University Press. Chapter 9 gives a more detailed version of the same kind of arguments that Weinberg is making, as well as explaining how the the Higgs and CC are in conflict with the effective field theory view. His overall evaluation of the case
"Much about the model carries the whiff of a low energy limit" isn't very compelling when you start comparing this smell to that of the proposals (SUSY/string theory) for what the SM is supposed to be a low energy limit of.

Comments

1. **Sabine Hossenfelder**
   January 14, 2021

   I am just here to give my usual speech: The "naturalness" problems in the standard model are not scientific problems. They are aesthetic problems. They come about because physicists claim an unobservable number that temporarily appears in the math is "unlikely".

There are two problems with this. First, the debate about the supposed singularity at black hole horizons should have taught physicists that fretting about non-observable issues in mathematical calculations is a waste of time. Second, one can't speak about probabilities without probability distributions, and we will never be able to obtain an empirically supported probability distribution over unobservable parameters*.

Add to this that "naturalness" arguments haven't worked with the axion (the original one), haven't worked with the cosmological constant, haven't worked with supersymmetry.

(The charm quark prediction btw wasn't a naturalness argument, it was a good old-fashioned argument from Occam's razor. It's just that people at the time used the word "natural" in their argument.)

The bottom line is, naturalness should go out of the window.

For what the SM is concerned, well, it doesn't contain gravity, so of course the short-distance physics isn't fundamentally the right one.

—
* Same problem with multiverse arguments.

2. **Mitchell Porter**
January 14, 2021

I'm trying to understand what the central thesis of this post is.

On the one hand, we seem to have the suggestion that the fundamental theory really could be just a QFT which consists of the standard model coupled to a new form of gravity. Well, it's a striking idea, and one always has the 2009 prediction of the Higgs boson mass by Shaposhnikov and Wetterich, that was premised on exactly such an assumption.

On the other hand, there is the criticism of naturalness, on the grounds that naturalness predicts new weak-scale particles and they haven't turned up.

I guess I don't understand whether this constitutes grounds for criticizing the very idea of treating the SM as an effective field theory. Yes, if it's SM all the way to the Planck scale, then the SM is not just an EFT. But that's an extremely bold hypothesis that may or may not be true.

Meanwhile, for now, it's surely legitimate to still be interested in the possibility of new particles or forces. Is it claimed that EFT is a wrong way to model this or a wrong way to be systematic about it?

If naturalness is a bad guide, to me that implies, not that the use of EFT is overall misguided, but that you need to be ready for the coefficients to be larger or smaller than expected.

3. **Warren Siegel**
January 14, 2021

Lattice QCD is the exact opposite of what you describe: It's exactly because of the ambiguity in the action that you have "non-universality". This shows up when trying to take the continuum, or small-coupling, limit. This is a result of the running of the coupling (asymptotic freedom), & shows up in arguments for analyticity in the complex coupling-constant plane (e.g., see 't Hooft). It's also related to the inability of constructive quantum field theorists to prove the existence of theories that aren't @ least superrenormalizable (besides the instanton problem, also a difficulty on the lattice). These problems also show up in (resummation of) perturbation theory, as renormalons, which require (an infinite number of) new couplings as energies rise (like nonrenormalizable theories), appearing as vacuum values of (color-singlet) composite operators. (Thus, contrary to the belief of loop quantum gravity people, lattices don't eliminate problems seen in perturbation theory.)

The only known solution is (perturbatively) finite theories, which require something you hate — supersymmetry.

4. **Peter Orland**
January 14, 2021

Hi Warren,

If I understand you (and perhaps I don't) lattice QCD doesn't suffer from any of the problems you describe (at least according to conventional wisdom. Not theorems). The ambiguities you mention concern semiclassical methods (perturbative, with resummation, summing over saddles points).

It is expected (but not proved) that the only real couplings where physical quantities are not analytic are 1. zero (at $\theta=0$) and 2. some nonzero value (at $\theta=\pi$).

QCD is (presumably) a completely finite theory, with very few parameters (one if there are no quarks and $\theta=0$).

5. **Peter Orland**
January 14, 2021

Just to be technically precise, there can be other nonanalyticities, but these are not universal and depend on irrelevant terms in the lattice action.

6. **lun**
January 14, 2021

Sabine, actually this post explains clearly why naturalness is not an esthetic argument but a mathematical one.
QFT is formulated in terms of functional integrals, which are in general divergent and irresolvable. However,
(i) they can be expanded, in various ways: perturbing around the coupling constant (perturbation theory), around scale separations (EFTs), saddle points and so on.
(ii) The divergence can also be regulated in such a way that it does not affect physical quantities, which are generally correlators measured at a certain scale, provided we use some experimental data as input, the bare minimum (which as Peter explains is sufficient for QCD) is the scale.

The most used expansion that includes (i) and (ii) will have a few normalizeable and super-renormalizeable terms (where there are no factors dependent on scale separation) and infinitely many non-renormalizeable and trivial ones that go away if the scale separation is large enough (this last point is where people most often use natuarlness arguments).

Saying axions, ccs, Higgs mass etc are not natural is a shorthand for saying
that if you take this theory and try to do the functional integral with (i) and (ii) in mind
(i) and (ii) do not quite work for these observables. That is a rigorous mathematical statement about a physical theory, which might indicate problem with the theory, or problems with the approximation (see the discussion after your comment). But it is not just aesthetic. If would be aesthetic if we realized Feynmans dream

——————————————————
https://arxiv.org/abs/2006.08594 "This makes me dream,
or speculate, that maybe there is some way, and we are
just missing it, of evaluating the path integral directly"
———————————————————-
and STILL had to use naturalness. But we did not as yet, so its a legitimate maths question.

7. **Peter Woit**
January 14, 2021

Cliff Burgess here
https://twitter.com/CburgesCliff/status/1349579929462198273
characterizes this by
"Very early 70s take on things in that blog post, it seems"

Not quite right, since until 1973 and asymptotic freedom the consensus was that QFT was no good at short distances, or for describing strong interactions. From about 1974 -1984, it's true that the point of view of this posting may have been the dominant one. Post 1984 things went back to "QFT no good at short distances (need string theory)" and that's been the prejudice the past 30 years. I think the failure of the field to make any progress during this period argues for going back to before the wrong turn.

One aspect of the history of the subject is that it was only for a short ten year period (1974-1984) that grad students entering the field were being told that maybe QFT works at all distance scales. At every other point during the nearly 100 year history of QFT they've been told it fails at high energy.

8. **Peter Woit**
January 14, 2021

Michell Porter,
Nothing wrong with EFT. Lots of QFTs are EFTs. All QFTs used in condensed matter are EFTs. I don't think though that the idea that the SM is not just an EFT is an "extremely bold hypothesis". All expected failures of the theory based on the idea that it's just an EFT have not worked out. It agrees with all experimental results and (modulo Higgs +U(1) problems) seems to make perfectly good sense at all distance scales. It should be the baseline conjecture that it can describe all distance scales, until someone comes up with something better. No one has.

9. **Peter Woit**
January 14, 2021

Warren Siegel,
I won't try and argue that issues of the perturbation and semi-classical approximations to a putative rigorous non-perturbative lattice-regularized QCD are well-understood. But all evidence I'm aware of is that (keeping things simple) lattice pure gauge theory is a well-defined non-perturbative theory, with expected infrared and ultraviolet behavior if you take the continuum limit appropriately. And when you do this, the limit is insensitive to the definition at the cutoff scale as I stated.

In any case, even if you can find a problem with this, the larger point is that this is as close as there is to a well-defined 4d theory that makes sense at short distance scales and gives behavior we observe in nature. For no well-defined X is there any evidence that "we should be doing X instead of QFT at short distances".

10. **Warren Siegel**
January 15, 2021

@ Peter & Peter:

't Hooft's arguments are based entirely on the running of the coupling, & are not tied to perturbation theory. But the same problems are seen in perturbation theory, & in constructive quantum field theory, which is rigorous & entirely nonperturbative.

Lattice QCD is an alternative approach to perturbation theory that provides results for different observables. But it does not avoid any of the fundamental problems of the theory. The conclusion is that QCD is a low-energy effective theory. Of course, the problem is worse with the Standard Model because of the U(1) gauge group, which is seen to be a problem even @ finite coupling on the lattice. (Problems with asymptotically free couplings show up only near vanishing coupling, as proven by Tomboulis, but in agreement with 't Hooft's argument.)

11. **Peter Orland**
January 15, 2021

Hi Warren,

But 'tHooft's arguments are based on renormalons/instantons. Although these don't emerge from perturbation theory per se, they are not pure running-coupling constant arguments.

He also had a program for constructing large-N theories in four dimensions, but I don't know what came of this (maybe this is what you mean by constructive FT).

By the way, there is a long paper by Magnon, Rivasseu and Seneor, written almost 30 years ago, claiming a construction of SU(2) Yang-Mills in 4 Euclidean dimensions, in finite volume (not the infinite volume limit). If correct, this work goes a long way towards overcoming the problems you raise; in a finite volume, all the same features are present.

12. **Peter Orland**
January 15, 2021

… and Peter Woit will tell us soon to shut up and conduct this technical discussion elsewhere.

13. **Peter Woit**
January 15, 2021

Peter Orland,
No, technical discussions that are relevant to the topic are encouraged! The question of whether QCD is just an effective theory or not is highly relevant.

Warren Siegel,
My understanding is that there is good evidence (much of it numerical) for the conjecture of the existence (at all distance scales) of a well-defined non-perturbative version of QCD, as specified precisely in the Millenium prize document

https://www.claymath.org/sites/default/files/yangmills.pdf
If Tomboulis or anyone else has a solid argument for non-existence (can you give a reference?), they should be putting in their claim for the \$ 1 million. My suspicion is that what you're discussing is a different problem involving the subtleties of the perturbation expansion or semi-classical approximation for QCD, for which I'm willing to believe there are all sorts of issues.

14. **Thomas**
January 15, 2021

I think the misunderstanding in Warren Siegel's comment is this:
"Lattice QCD is an alternative approach to perturbation theory that provides results for different observables."

The lattice can of course be used as a regulator in perturbation theory, and this theory has the sames issues as weak coupling perturbation theory using other regulators. (The lattice has a convergent strong coupling expansion, albeit with a finite radius of convergence). However, the main point is that the lattice provides a fully non-perturbative definition of the theory. There is indeed no proof, but we have strong physical arguments, and plenty of numerical evidence, that the continuum and infinite volume limits exist, and that they define the theory we observe in nature.

This means that QCD is a perfect theory, one that can be extended to arbitrarily short distances. But in practice this does not help, because QCD is embedded into electroweak theory, and we have an equally strong expectation (and, again, numerical evidence) that the \$U(1)\$ and scalar sectors cannot be extended to arbitrarily short distances. This means that the SM, even without gravity, must be viewed as an EFT.

What is maybe somewhat unusual is that the only estimate of the breakdown scale that we have right now is from RG running of the scalar sector. It would be nice to directly observe a higher dimension operator. It is possible that neutrino mass comes from a higher dimension operator, but until we observe a Majorana mass we don't know (which is why double beta decay experiments are so important).

15. **Peter Woit**
January 15, 2021

Thomas,

To be clear, since the SU(3) and SU(2) gauge theories are asymptotically free, the remaining problem is the U(1) and Higgs. The U(1) "Landau pole" problem is at scales way above the Planck scale. The Higgs problem is intriguing, indicating borderline instability up near the Planck scale.

I agree that the SM cannot just stand on its own, ultimately one wants to unify it with a quantum theory of gravity. To me, the simplest scenario would be a unification with a gravity QFT, that would resolve the issues of the high energy limit of the U(1) and the Higgs. Then, yes, the SM decoupled from gravity would not be fully consistent, but on the other hand characterizing it as just a low energy effective approximation would be misleading (since to a large degree the theory would work at all distance scales).

16. **Peter Orland**
January 15, 2021

Lun,

Although it is true that renormalizable "unnatural" theories are not fully consistent at high energies, those energies are EXTREMELY high.

For example, QED is unnatural, but its cut-off cannot be predicted from the theory itself. If we didn't know about SU(2)\$\times\$U(1), we would not know where (below \$10^19\;eV\$) QED breaks down.

In this sense, Sabine is completely correct. There is no ability to predict where the theory breaks down, and naturalness is an attempt to do the impossible (to predict what cannot be predicted). We only know that such theories must break down, below some very large momentum.

17. **Arnold Neumaier**
January 15, 2021

That a QFT has a Landau pole is a problem only for approaches that regulate the theory with a noncovariant cutoff. This includes lattice approximation.

However, a Landau pole is not a problem for covariant regularizations.

In particular, in causal perturbation theory, the renormalization is done covariantly at an arbitrarily chosen renormalization energy parameter. The theory is well-defined for any choice far away from the Landau pole and, by the Peterman-Stückelberg renormalization group, is independent of this choice — only the quality of approximation depends on the choice.
The Landau pole only says that one cannot choose the renormalization energy parameter close to the pole without getting meaninglessly inaccurate results.
(This is unlike renormalization through cutoffs, where the covariant theory is only obtained in a limit, a process that suffers from a UV induced Landau pole.)

Relevant in this context is also the not widely known fact that QCD has like QED a Landau pole. But while for QED the UV induced Landau pole is at physically inaccessible energies (far larger than the Planck energy), the IR induced QCD Landau pole is at physically realized energies! Nevertheless the pole does not invalidate predictions at these energies. Thus arguing for inconsistency based on Landau poles is a relic from ancient times where QFT was not yet well enough understood.

For further details see my article on Causal perturbation theory at https://www.physicsforums.com/insights/causal-perturbation-theory/
and the discussion at https://www.physicsoverflow.org/32752/ and
https://www.physicsoverflow.org/21328/

18. **Peter Orland**
January 15, 2021

The Landau pole is an artifact of the one-loop (or finite loop) approximation. The pole is present in a region of momentum space where this approximation can't be used.

I don't think it is helpful to think of triviality/unnaturalness in connection with Landau poles. In Wilson's discussion (see Sections 12 and 13 of Wilson and Kogut's Physics Reports article on the renormalization group) concerning (non)triviality, the Landau pole is not mentioned at all. Corrections to Landau's mean field theory (an entirely different development) and Ginzburg's criterion are, however, relevant.

19. **lun**
January 15, 2021

Peter Orland, for sure "naturalness" is not a very useful tool to understand what exactly is wrong (the last decades of theoretical physics have conclusively shown this).

Rather, lack of naturalness is a symptom of a problem, and its wrong to say the problem is aesthetic, it is mathematical consistency rather then aesthetics.

20. **JE**
January 15, 2021

I cannot add much to the technicalities some of you have quite accurately exposed regarding the shortcomings of QFTs in general, the SM in particular, and most notably QG. To me, wondering whether or not the SM is just an EFT pertains more to psychological aspects of the scientific process than to the purely physical or mathematical ones. The SM very successfully predicts almost all (if not all) results we can currently measure. We know that there are some mathematical inconsistencies and the U(1) and scalar sectors fail at very short distances, but we can still safely use the SM, Higgs sector included, because it matches our experimental results, so these shortcomings should not be an everyday worry except because we still lack a valid theory of QG.

I have raised the psychosocial factor because Weinberg himself is appealing to herd mentality by saying that, "The Standard Model, we now see – we being, let me say, me and a lot of other people – as a low-energy approximation to a fundamental theory about which we know very little. And low energy means energies much less than some extremely high energy scale 1015–1018 GeV."

Saying "Me and a lot of other people" (true or not) seems to me like a clear attempt at concocting herd mentality based on his recognized authority.

Let's be frank. The SM cannot be the final theory, because it lacks something. But it's probably much closer to the final theory than e.g. string theory, because it has much more pros than cons (unlike ST). So the farther you depart from it, the less likely you will find a final theory. And ST really goes very far away from it. Herd mentality has been a problem for HEP for decades. Had we devoted 1% of the effort we have invested in trying to square the circle of considering the SM a correct, but only effective, field theory, and searching for an entirely new theory that can replace it, instead of trying to fix its shortcomings, we would probably be there by now.

21. **Geoffrey Dixon**
January 15, 2021

Just curious: I'm assuming the discussions going on here could easily have occurred 5 years ago. How about 10? Or 20? How far into the past could one go and these debates would have still been by-and-large possible? Not that there's anything wrong with that … just curious.

22. **Peter Woit**
January 16, 2021

Geoffrey Dixon,
The point of view Weinberg is arguing for was worked out in detail by him and others over 40 years ago (some of the basic papers about this are his from 1979-80). The discussion here is much the same as one could have had back then. The only difference is that lots of evidence against this point of view has accumulated over the last 40 years: no violations of the SM (+Dirac neutrino mass terms), existence of the Higgs with its hierarchy problem, CC with its hierarchy problem, failure of all attempts to come up with a plausible theory of different physics at the GUT/Planck scale.

Back in 1980, the EFT point of view was not dominant, with lots of people (for example see Hawking on N=8 supergravity) taking the point of view that physics at high energy was likely to be some QFT extending the SM (so the SM is a piece of the final theory, not an approximation to a different kind of theory). The EFT point of view on the SM has now been dominant for decades, with no sign of influential physicists like Weinberg re-evaluating things based on what has been learned in the last 40 years. There seemed to be some hope post LHC results, but people mostly seem intent on trying to not draw conclusions based on those.

23. **Warren Siegel**
January 17, 2021

@ Peter & Peter,

QCD has a running coupling because it has a divergence. If Yang-Mills theory were finite, it would be conformal; its coupling wouldn't run. So 't Hooft's argument holds outside of perturbation theory.

Tomboulis only showed the problem could only occur near vanishing coupling, not that it did occur.

Constructive quantum field theory, which is a nonperturbative approach, also has problems with instantons & renormalons.

To my knowledge, lattices have never solved any problem of principle that had been discovered in perturbation theory.

Perturbative finiteness is the only known solution to renormalons. & the only such theories known are supersymmetric.

24. **André**
January 17, 2021

Peter,

can you explain how your point of view and that of Weinberg differ in practice?
Weinberg says that the standard model is valid (maybe) up to 10^18 GeV. Up to which energy do you think that the standard model is valid? 10^19 GeV? More?

25. **Peter Orland**
January 17, 2021

Hi Warren,

Finiteness of QCD means that the renormalized theory exists and is finite. It is not conformal invariant.

The massless limit of the regularized theory, after removing the regulator, is Weyl and conformal invariant. That's not what Peter and I are writing about.

Again, instantons and renormalons appear in trying to ressum perturbation theory (in the case of instantons summing over saddle points). There was a lot of optimism that some sort of resummation of perturbation theory over saddle points would yield an analytic solution of QCD, and people are still working on this. It doesn't mean the theory does not exist apart from these methods.

26. **Peter Orland**
January 17, 2021

Just to make it clear what is meant by finiteness:

The lattice theory is ultraviolet regulated and well defined. Calculate physical quantities (cross sections, string tension, maybe some Green's functions multiplied by anomalous powers of the lattice spacing). Now, fixing one of these quantities, take the lattice spacing to zero. This is what Peter W. and I are arguing exists (there is no theorem to this effect. It is a conjecture).

At no point are there any divergences. Nor does Weyl or conformal invariance appear (there are scaling violations).

27. **Peter Orland**
January 17, 2021

"To my knowledge, lattices have never solved any problem of principle that had been discovered in perturbation theory."

There are examples where such problems of principle are solved on the lattice, but they are asymptotically-free models in lower dimensions. These models can also be solved by other methods and the solutions agree.

28. **Arnold Neumaier**
January 17, 2021

Warren Siegel said: "Perturbative finiteness is the only known solution to renormalons."

This was only true long ago. Another solution to renormalons, known since 2015, are resurgent transseries. For recent results, see, e.g., https://arxiv.org/pdf/2007.01270.pdf

29. **More Anonymous**
January 17, 2021

Peter

I was pondering about something which lead to hopefully a relevant line of thought. I am under the impression the continuum limit of QFT is equivalent to micro causality. The Lieb-Robinson bound in lattice QFT does become the usual (micro-)causality property in the continuum limit see (arxiv.org/abs/2006.10062). That paper stops short of establishing my this, because they don't take a strict continuum limit. They show that the exponentially-small tails are small enough to be unimportant on scales much larger than the lattice spacing, with some technical definition of "unimportant," but they leave the strict continuum limit as an exercise for the reader.

Thus, from this point of view micro causality is a derived property of the lattice spacing. Now in a theory of gravity one would expect the light cone (of micro causality) to be deformed. But since the the propagation of information is dependent on the lattice spacing. The Large scale behaviour does affect the small scale and visa-versa.

P.S: I am far from an expert.

30. **Peter Woit**
January 17, 2021

Warren Siegel,
It still seems to me you're just pointing to problems with the perturbation series and the semi-classical approximation, not the non-perturbative theory, defined as Peter Orland states.

In particular, as far as problems with instantons go, how this works in lattice QCD is something I spent a lot of time working on long ago. Instantons are classical solutions, and their role in the full theory is an issue about the semi-classical expansion. They're irrelevant to the question of whether the lattice sums have the expected continuum limit. I haven't followed recent developments, but when I was involved, the problem was to identify not instantons on the lattice, but a sensible notion of net topological charge of a lattice configuration. One wants something that agrees with the continuum formula for configurations near classical solutions, and such that ambiguities due to the lattice regularization become unimportant in the continuum limit. Problems doing this might in principle cause trouble for non-zero theta parameter, but for QCD at theta=0, issues about assigning topological charges to lattice configurations shouldn't be relevant.

31. **Peter Woit**
January 17, 2021

All,
I don't want to try and have a discussion here of general issues about proposals for making sense of QFTs at short distances, so only issues directly about the SM are on topic.

André,
Neither I nor Weinberg have any idea where the SM breaks down or how. I am arguing that some sectors of the SM show no signs of breakdown at any scale, but that doesn't mean I know what happens at inaccessibly high energy scales. Much of what I object to here is making pure speculation about what's happening at scales we know nothing about sound like it has some solid evidence.

Weinberg and others pushing this point of view don't claim to know what the higher scales are, they are just setting up a framework in which there can be higher energy scales with different physics, with the SM a low energy approximation. For instance, in some models of neutrino mass of this kind, one explains the low values of neutrino masses by the existence of some high scale, still below the GUT or Planck scales. But, that's just one kind of model. Once can avoid the higher scales by just assuming neutrino masses are Dirac, with Yukawas small for some reason we don't understand (we don't in any case actually understand anything about why Yukawas take the values they do).

32. **(a different) André**
January 18, 2021

I have a different perspective, but perhaps the same conclusion as Weinberg (and many others) on the SM being an EFT of whatever is a more complete theory. My background, just to provide some perspective for my comments, is that I utilize lattice QCD and EFT to determine various properties of nucleons and their interactions which are required with various levels of precision, in order to interpret current bounds, and hopeful signals, of beyond the SM signatures in low energy experiments (such as an EDM in a nucleus or the observation of neutrinoless double beta decay or signatures of non V-A decays of neutrons etc.). Interpreting the current limits as bounds on new physics requires some quantitative understanding of BSM matrix elements in nucleons and nuclei, some of which need to be propagated to more complex systems with EFTs of nuclear physics.

Now – about the SM being and EFT of some more complete theory. My perspective could be summarized by the question, what right do we have to expect that the SM is correct to arbitrarily short-distance/high-energy? It seems far more probable that we are ignorant of some very short-distance physics than the SM being The theory that can take us to the Plank scale. Assuming there is something we are missing, and assuming that this new physics is short distance, describing the SM as an EFT of more complete theory is the most general framework to have this discussion with our current understanding of how to describe physics (using QFT). It also provides a framework to combine constraints from low-energy precision tests of the SM and signatures in colliders like the LHC, and thus helps the community significantly reduce the parameter space of possibilities.

If the presumed BSM physics is light (dark photons etc.), then this EFT description is less useful too useless, depending upon the details of the new physics. The community of people using this EFT language to make these constraints is also generally quite aware of this limitation as well.

33. **Peter Woit**
January 18, 2021

(a different) André,
There's nothing wrong with conjecturing that there's new physics at a high energy scale and using EFT as the appropriate framework for deriving the implications of such a conjecture. But you need to then acknowledge that
1. Despite decades of intensive effort, we haven't seen any of the expected implications of such new physics.
2. What we have seen of the Higgs and CC is in strong contradiction with the conjecture of such new physics.

Given these facts, "SM all the way up to Planck" is also a perfectly valid conjecture.

The problem with "It seems far more probable that we are ignorant of some very short-distance physics than the SM being the theory that can take us to the Plank scale." is that it's really just a historical prejudice (in the past we kept finding new things at higher energy scales). We don't at all know one way or the other what the truth of the matter is, so one should look at all possibilities. The "SM just a low energy approximation" possibility has gotten a huge amount of attention, become a bit of a fixed ideology, and led to finding nothing. I'm just arguing that the alternate possibility is every bit as worthy of being taken seriously and its implications explored.

34. **(a different) André**
January 18, 2021

Hi Peter,

Sure, it should be considered. But, in order to be viable, there are a few significant challenges that such a proposal would have to address. For example, as we understand things now, the CP violation in the SM is orders of magnitude too small to generate the observed abundance of matter over anti-matter in the universe. So one would have to come up with some new explanation how the SM only could circumvent this otherwise failure to explain the observation. Or, we would have to decide this is not a question worth trying to answer. Assuming we want to find some explanation, and without clear ideas how to generate the excess with just the SM, I stand by my statement that it "It seems far more probable that we are ignorant of some very short-distance physics than the SM being the theory that can take us to the Plank scale."

35. **Peter Woit**
January 18, 2021

(a different) André,
Sure, although the matter/anti-matter problem brings in the question of one's model of the early universe, which adds another source of complexity to the issue.

36. **WTW**
January 19, 2021

Peter,
No one has mentioned the Muon g-2 experiment investigating the apparent anomaly in the anomalous magnetic moment of the muon, and the very detailed theoretical work going on in parallel that includes extending calculations down to extremely fine precision by the Muon g-2 Theory Initiative. (See, for example, https://news.fnal.gov/2020/06/physicists-publish-worldwide-consensus-of-muon-magnetic-moment-calculation/, and https://arxiv.org/abs/2006.04822) That precision is required in order to differentiate between SM prediction and experiment, and it includes non-perturbative lattice QCD calculations as well as dispersive.

As some of those folks have said, this is a very highly technical and specialized field, and I have no insight into what hoops they are having to jump through to get low enough error bounds. Perhaps someone can comment on how relevant such work is to this discussion. (But it does illustrate that state-of-the-art investigations into the validity/applicability of the SM at extremely short distance scales does not necessarily require Planck-scale experimental energies, and that such work is active and on-going — even if relatively rare.)

37. **Peter Woit**
January 19, 2021

WFW,
The Fermilab muon g-2 experiment is supposed to be reporting results soon, which will be interesting. The problem though with this is that if they do find a deviation from the SM, it will be a frustrating situation. This just gives you one number, and all sorts of new possible non-SM degrees of freedom could contribute to that number, as part of some complicated higher loop calculation. So, that number, if non-zero, will tell us there's something going on we don't understand, but give very little to go on about what this might be.

38. **WTW**
January 19, 2021

Peter,
"So, that number, if non-zero, will tell us there's something going on we don't understand, but give very little to go on about what this might be."

Yes, but — to your point, above — it could give us an indication of a limit (if there is one) on just how "effective" an EFT the SM actually is. Something we don't now have.
And the lattice QCD and other techniques being developed there could potentially/hopefully be useful in other contexts as well, in helping to identify anomalies in other experimental data that could give further clues.

39. **Warren Siegel**
January 20, 2021

@ Peter & Peter,

Lattice QCD is exactly as finite as renormalized perturbation theory.

I'm not claiming QCD doesn't exist, only that it's nonperturbatively nonrenormalizable, due to renormalons, a consequence of only the running of the coupling, which can be seen from its divergences, which appear even in lattice quantization if one tries to take the continuum limit w/o renormalization of the bare couplings by giving them singular dependence on the lattice spacing.

Instantons are a separate problem from renormalons. Various solutions have been proposed, such as the 1/N expansion.

Perhaps the lower-dimensional theories with other solutions to which you refer are the superrenormalizable ones treated by constructive QFT. Those people never had success in 4 dimensions.

@ Arnold,

I'm not familiar with your solution of "long ago" 2015, but thanks for the reference. My experience with claimed UV fixed points away from the origin is that their position & even their existence is strongly prescription dependent. Also, it would be nice to see an example of a gauge theory, since theories that are not asymptotically free are known to have difficulties even in lattice field theory. Furthermore, such treatments of improved resummation in the literature tend to focus on instantons rather than renormalons, & may even fail to distinguish the two.

40. **Peter Orland**
January 20, 2021

Hi Warren,

Yes, renormalons appear as a class of diagrams which are clearly not Borel summable, even if the regulator used is a lattice. Maybe resurgence, or another scheme can cure this, or maybe not.

If you could solve this problem via rigorous methods, this might give a proof that the lattice theory is well-defined. Or maybe a proof would have nothing to do with summing graphs (including saddle points).

So renormalons may mean zip, zero, nada for the existence of the theory.

As an illustration, renormalons exist in field theoretic models in lower dimensions. I am thinking of the principal chiral model (which I have some experience with). Resummation methods are not fully successful for this model, but there is no doubt it exists. There are even exact results for the S-matrix and (at large N) correlation functions.

41. **Peter Orland**
January 20, 2021

PS I mentioned above the constructive field theory paper about SU(2) Yang-Mills in a finite volume, by Magnon, Rivasseu and Seneor. They claim that the continuum theory exists, for a finite volume. They can't take the thermodynamic limit, but (assuming their paper is correct. I guess I'll have to slog through it), this means NO fundamental ultraviolet problems with renormalons.

42. **Warren Siegel**
January 23, 2021

@ Orland,

As I said, constructive QFT can prove existence if they are SUPERrenormalizable, not just renormalizable, hence <4 dimensions.

Also as I said, the examples I've seen for defining resummation for (very) low dimensions have been for "instantons", not renormalons, i.e., corresponding to finite-action solutions to the classical field equations.

43. **Peter Orland**
January 23, 2021

Hi Warren,

"As I said, constructive QFT can prove existence if they are SUPERrenormalizable, not just renormalizable, hence <4 dimensions."

Yes, but that is NOT proving the renormalizable asymptotically-free theory does not exist. You are only saying that constructive field theory methods have not been successful (unless Magnon, et. als. is correct) for non-superrenormalizable theories. There is no no-go theorem.

Please read my other remarks above. I think I addressed your assertions quite adequately.

44. **Erickson**
February 1, 2021

Hi Peter,

If gravity QFT is one of the simplest options, wouldn't asymptotically safe gravity be the most promising track to go with? There's even attempts to make just the non-gravitational forces asymptotically safe (removing Landau poles). I believe this is along the lines of works by Eichhorn et. al., and Donoghue seems to have a fair number of things to say along this direction.

February 2, 2021

Dear Warren, Peter & Peter,

recently we found a very simple model with renormalons where perturbation theory can be explicitly re-summed using a particular contour prescription in the Borel plane. The model is simple enough that is non-perturbatively defined and can also be solved non-perturbatively and exactly. The S-matrix obtained that way matches perfectly to the one obtained by resummed and renormalized perturbation theory. The model has no supersymmetry.

Now, this might sound too beautiful to be true and you are already wondering "where is the catch"? The catch is that this model is not a relativistic QFT but rather a simple one-particle quantum mechanics model. The advantage this offers is that we have a well defined Hilbert space with self-adjoint Hamiltonian and everything is under perfect mathematical control. Although it is a very poor version of QCD it has a logarithmically running coupling that induces exactly the same renormalon ambiguities (at least the UV ones) as its QFT cousins.

The actual details can be found in our paper arXiv:1906.07198 .

Wilczek on the Problems of Fundamental Physics

January 18, 2021
Categories: Uncategorized

Sean Carroll has a new interview up with Frank Wilczek in which they discuss, among other things, the problematic current state of fundamental physics. On the topic of string theory, here's the discussion:

> 0:58:34.8 SC: Well, some of this worry has come out of string theory, many of our colleagues for the last several decades have pointed to string theory as the most promising way forward. As far as I know, you have not done a lot of work directly on conventional string theory. What is your feeling about that approach to moving beyond quantum field theory?
>
> 0:58:54.8 FW: Well, I think it has produced a lot of attractive work that's intellectually rich and has spun off into fertile mathematics, but I don't see that it's been converging towards informative assertions about the physical world…
>
> 0:59:18.7 SC: That's very elegantly stated, actually, yes.
>
> 0:59:21.0 FW: That you can check. And for me personally, I've kind of voted with my feet, I think there are more promising things to think about, that's partially a sociological statement, but I think it's, string theory is getting plenty of attention, it doesn't need me. I'm happier doing things that other people aren't doing, but that's a personal statement, and so far, I haven't regretted my choice, but I watch what people… I watch the subject and I watch what people are doing and I wish them good luck, and if and when things that I think are promising insights into the physical world emerge, I will pay a lot of attention.
>
> 1:00:12.3 SC: Sure Do you think that the rest of the field has voted with their feet in a slightly too uniform way, do you think that too much of our intellectual effort is going in that particular direction?
>
> 1:00:21.8 FW: I do, but I might be wrong, so I don't want to discourage. Plenty of people are doing other things, so it's not as if the rest of the world is feeling the lack of input from people who are working on string theory, it's fine, people can work on string theory and it doesn't hurt anything. I feel… Well, it's going to sound, I don't want to be patronizing, the people who do it are mostly adults and they know what they're doing, but students and people who are thinking about what they're going to do should go into it with open eyes. They should realize that the prospect of making an impact in our understanding of empirical science or technology are not… The prospect that you'll make impact like that is probably not optimized by going into string theory.
>
> 1:01:20.8 SC: Yeah, no, actually, I think that we're in exact alignment here. I feel a need to defend the string theory against unfair criticisms, but I do worry a little bit about the fact that it seems hard these days to connect it directly to empirical reality.
>
> 1:01:36.2 FW: Yeah, well, some nice ideas are coming off, as coming out as spin-offs, very, very clever people do string theory and they do clever things. So as I said, there's been a lot of fruitful mathematics, there have been new techniques that have proved somewhat useful in condensed matter, although certainly not proportional to the amount of effort that's going into it, and the future may look different, they may be real breakthroughs that come out of string theory that wouldn't have come otherwise. But so far, the amount, I would say, other people may disagree, and I might be very unpopular among some of my colleagues for saying this, but I think the output compared to the input has been pretty disappointing on the empirical side.

I find it kind of remarkable that Carroll, known for defending string theory and string theorists, here reacts to Wilczek's pretty negative characterization of string theory with "I think that we're in exact alignment here."

About current hot topic work on the black hole information paradox:

> 1:02:33.5 SC: Right. You have been involved in productive ways on the black hole information problem, which a lot of string theorists care about… What is your current feeling on the state of that problem? Do you think we're making real progress?
>
> 1:02:50.8 FW: I think progress is being made in the sense that more intellectually coherent pictures are being drawn and some surprising connections to error correction and really interesting new chapters of quantum theory are emerging. On the other hand, it is a very esoteric problem, nobody's going to produce… I don't see a way, but who knows, but nobody has produced an experimental system to which these ideas apply in any reasonably direct way. So what does it mean to solve a problem like that? I'm not even sure what it means, where you can't check. Many hypotheses go into it, the distance between the models and actual black holes that were phenomena you can observe are vast and many things could go wrong along the way in making these models.
>
> 1:04:04.7 FW: So I guess, yeah, it's wonderful that people are making progress at the field, they're making progress and have a literature that they enjoy, and it really is interesting from any point of view, it's good, and maybe I should leave it at that, but how should I say? I don't think it's… I don't think it's the pinnacle of physics, let me put it… Let me put it that way.

On SUSY, Wilczek acknowledges

> I'm a supersymmetry diehard.

which he certainly is.

If you look back at his many talks about prospects for the future, you'll see that pre-LHC he was arguing

> By ascending a tower of speculation, involving now both extended gauge symmetry and extended space-time symmetry, we seem to break though the clouds, into clarity and breathtaking vision. Is it an illusion, or reality? This question creates a most exciting situation for the Large Hadron Collider(LHC), due to begin operating at CERN in 2007, for this great accelerator will achieve the energies necessary to access the new world of of heavy particles,if it exists.

In the current interview and elsewhere, Wilczek makes clear the reason he believes in SUSY is his 1981 calculation with Dimopoulos/Raby showing that in SUSY versions of GUTs you could get the coupling constant evolution to overlap at the same energy. He's still quite devoted to this argument, for him it's of greater significance than the usual hierarchy problem arguments.

He has by now lost multiple bets that the LHC would see SUSY particles, including ones with Garrett Lisi in 2009 and Tord Ekelöf in 2012. At this point, even diehards like Wilczek acknowledge that chances that the LHC will see SUSY are slim. Another problem is that increasingly sensitive proton decay experiments have also ruled out a large part of the proton lifetimes predicted by the SUSY models Wilczek favors. He puts his faith in further proton decay experiments and a new, expensive collider. This is pretty much exactly the sort of thing that causes Sabine Hossenfelder to go ballistic over arguments for a new collider.

For a flavor of the SUSY discussion, here's one piece of it, with Carroll starting off with a quite peculiar argument for SUSY:

> 0:29:28.8 SC: Yeah, maybe you can opine on this, but the way that I like to say it is, we could, in the space of all possible worlds that we live in, only one of them,

we could have found supersymmetry already at the LHC very easily, but the fact that we haven't doesn't mean it's not there. Maybe it's less likely that it's there, but it's easy also to imagine theories where supersymmetry is real, and we just haven't seen it yet.

0:29:53.1 FW: Right. So supersymmetry, as I said, there have to be… For supersymmetry to be valid, there have to be these superpartner particles that are the particles that the particles we know about turn into when they move into the quantum dimensions, but we don't know what their masses are. We know some of their properties, but not their masses, and they could be very heavy. If they're very, very heavy, we lose the benefit of improving… The benefit that supersymmetry would otherwise give in improving how the couplings unify, but okay, maybe that was a cruel joke on the part of nature. I want to think not, but the alternative is that they're just a little bit too heavy to have been produced easily and identified easily at the LHC, and we just have to work a little bit harder and spend a little more money on…

   "Il est dangereux d'avoir raison dans des choses où des hommes accrédités ont tort." Voltaire

4. **Sabine Hossenfelder**
   January 19, 2021

   Scientists with secure positions tend to overestimate how much of a choice the vast majority of researchers in the field really have. Voting with our feet means, for most of us, leaving academia because we can't pay rent from doing the research we think is promising. I have seen dozens of friends drop out that way, not because they wouldn't have been able to get funding, but because they felt that the research they could have gotten funding/a job for would have been a waste of their time. The result is though, that some research just doesn't get done, and academia remains a universe of research bubbles in which popular areas continue to float forever, carried by social reinforcement.

   I think it would be good if instead of listening to the top 0.1% of lucky scientists and their rosy experiences with academia over and over again, the media and podcast hosts and so on would spend some more time talking to the other 99.9% and ask them just why they work on what they work on. Better still, talk to some of those who left and ask them why. That should be eye-opening.

5. **Alessandro Strumia**
   January 19, 2021

   Last time I heard a seminar by Wilczek was when LEP closed and CERN organised talks to discuss what was the lesson. At that time some data suggested supersymmetry at LHC, while other data pointed in the opposite direction. But the talk was stubbornly one-sided.

6. **David Brown**
   January 19, 2021

   According to Wilczek, string theory has "… produced a lot of attractive work that's intellectually rich and has spun off into fertile mathematics …" Has supersymmetry generated any new mathematics that mathematicians find impressive?

7. **Peter Woit**
   January 19, 2021

   David Brown,
   Supersymmetry has led to a lot of new mathematics. For instance, Witten's "Supersymmetry and Morse Theory" paper is the founding document of the whole field of topological quantum field theory, and the Seiberg-Witten work on N=2 supersymmetric Yang-Mills revolutionized the field of four-dimensional topology with the Seiberg-Witten equations. One could argue that these developments are even more significant than what has come out of string theory.

   The problem with this, as with the mathematical advances coming from string theory research, are that they are pretty much in a direction orthogonal to the direction of the the string or susy unification program. As an idea about fundamental physics, what is relevant is N=1 4d SUSY and issues of its spontaneous breaking, and this is the part of SUSY that seems to have relatively little deep mathematical signficance.

8. **Peter Woit**
   January 19, 2021

   Alessandro Strumia,
   I'm completely mystified by Wilczek's diehard attitude about SUSY. On other topics he's a model of cautious, careful reasoning. Besides his very early paper with Dimopoulos/Raby, SUSY is not something he devoted much of his career to, so he's not someone like Ellis or Kane who have much of their career invested in the idea. In addition, making many public statements that the LHC would decide the SUSY issue, together with losing mutiple public bets, you would think would argue for a stance of "looks like I was probably wrong on that bit of speculation", not the diehard "there's still a chance I was right, let's build a new collider to find out".

9. **Low Math, Meekly Interacting**
   January 19, 2021

   Isn't it simply due to a hardened bias in favor of observable unification, which SUSY purportedly provides in an especially neat and (to some beholders) beautiful way?

   Perhaps this is overly provocative, but an alternative, which your last post may hint at, is that it's pretty much the SM all the way up to the Planck scale, right? Maybe dark matter is taken care of by a (directly unobservable) sterile neutrino, gravity is "asymptotically safe" or something, and…that's it. Nothing really new or interesting happens until you reach unimaginably high energies, things are the way they are for reasons humans can never conceive of , much less probe, and there's essentially nothing left for HEP theorists to do.

Maybe that's the mother-of-all-nightmare-scenarios, and accepting SUSY is wrong makes it that much more plausible. It's unacceptable because it kills an entire field of investigation that once occupied the very pinnacle of human achievement, perhaps never to be duplicated again.

My deeply pessimistic psychosocial take.

10. **Marco**
January 20, 2021

> Better still, talk to some of those who left and ask them why. That should be eye-opening.

Sadly, academia thinks of people that are critical of academia and have left as disgruntled scientists that were not good enough to succeed and are thus bitter, and shrug off any criticism (valid or not) from such persons.

What is a Spinor?

January 21, 2021
Categories: Uncategorized

Recently Jean-Pierre Bourguignon recently gave the Inaugural Atiyah Lecture, with the title *What is a Spinor?* The title was a reference to a 2013 talk by Atiyah at the IHES with the same title. Bourguignon's lecture is not yet online, but I realized there are lectures explaining what a spinor is that I can highly recommend: my own, in this semester's course on the mathemematics of quantum mechanics. I'm closely following the textbook I wrote.

Teaching this course this past academic year has made me all too aware of things that are less than ideal about the book, and I unfortunately haven't had time to get to work on making any significant improvements. Going through the material on spinors though, I'm pretty happy with how that part of the book turned out, think it provides a clear explanation of a beautiful and important story, one that is not readily available elsewhere.

One aspect of this that I emphasize is the remarkable parallel between

- The usual story of canonical quantization, which is based on an antisymmetric bilinear form on phase space, giving an algebra of operators generated by Q_j,P_j acting on the usual quantum state space.
- Replacing antisymmetric by symmetric, you get the Clifford algebra, generated by γ-matrices, acting on the spinors.

For a table summarizing precisely this parallelism, see chapter 32 of the book.

For more video from my office, I recently had a long conversation with Reza Katebi, who has a Youtube channel of interviews called The Edge of Science.

   January 21, 2021

   Does anyone know Micheal Atiyah's reason for distaste of supersymmetry (mentioned around minute 36 of the video)? He seems to evade the question :/

2. **Geoffrey Dixon**
   January 22, 2021

   Bass ackwards, starting from something inherently bosonic to get to something fermionic. As pointed out by John Conway, each of the normed division algebras is a spinor space. Starting from there you get – among other things – Dirac neutrinos and a matter dominated universe.

   I know this is too self serving to pass muster, but sometimes these conversations using ideas that are fundamentally flawed are a tad irksome. Start with spinors.

3. **Peter Woit**
   January 22, 2021

   Geoffrey Dixon,
   The discussion of spinors I give in the book and lectures isn't bosonic, it's inherently fermionic. What I find remarkable and wanted to emphasize is the tight parallelism between the initially very different looking bosonic and fermionic versions of canonical quantization.

   What this is most useful for is getting a uniform way of dealing with spinors in any dimension, including infinite dimensions. Fundamental matter particles are described by a quantum field theory based on fermionic canonical quantization of the solutions of a Dirac equation. The solution space is infinite dimensional, fermionic quantization gives a state space that can be thought of as the spinors for this infinite dimensional space.

   The question of how to best think about the physical spin 1/2 degree of freedom and spinors in real 3 space or 4 space-time dimensions is at the other end of the problem from a uniform treatment of spinors valid in complex vector spaces of arbitrarily high dimensions. For real vector spaces you get a much more intricate algebraic story, bringing in the quaternions at least. The mysteries of division algebras are relevant there, as is my currently favorite idea about fundamental space-time geometry (twistors, where points in space-time are precisely spinors).

4. **Geoffrey Dixon**
   January 22, 2021

   Several years ago I encountered Atiyah in London. This was not long after he'd given a talk at Princeton extolling the algebra C ⊗ H ⊗ O as a basis for a unified HEP theory, with the octonion algebra, O, accounting for gravity. Those attending the talk were nonplussed, for they'd expected something else. Anyway, back in London, surrounded by a fawning throng, I told him his division algebra idea was wrong in its essentials. He was chagrined.

   Still, that algebra, like twistors, has the hope of forming a bottom up theoretical HEP foundation, one that might lead inexorably to unique and unavoidable explanations of many of the things that perplex us. As I am not an expert in QFT, this comment may be out of line, but it has always seemed to me that reliance on QFT to show the way is top down, relying on inconsistencies, infinities, and anomalies to exclude paths that are not viable – trial and error.

   As to twistors, in one of Penrose's tomes he referenced me, along with a cluster of others who exploited division algebras beyond C. But it was not a positive reference. His twistors are intimately connected to C, and he felt that going beyond C would be like pouring molasses on caviar – unnecessary, and unwanted. Your willingness to consider pouring higher dimensional division algebras onto twistors I find intriguing. I have hopes it'll be more like pouring maple syrup on pancakes.

5. **Peter Woit**
   January 22, 2021

   Geoffrey Dixon,
   Unfortunately, as far as I can tell, Atiyah's enthusiasms in the last few years of his life were not based on anything very substantive, and I think that includes whatever he was thinking about octonions and gravity.

   Most of what has been achieved with twistors crucially uses holomorphicity which is based on complex numbers, so I can see why Penrose thinks those are crucial. Twistors naturally give you not space-time but complexified space-time, and if you want to work with fields on this, you need holomorphicity in order to get usual fields on usual space-time.

One place where it is clear that quaternions play a role in twistor theory is in the Euclidean signature version, where the conformal group is $SL(2,\mathbf H)$. Penrose must know about this, but to get back to Minkowski signature you need holomorphicity, so complex not quaternionic analysis. The fact that twistor space can be taken to variously be $\mathbf C^4$ and $\mathbf H^2$ makes one suspicious that there's an octonionic story buried there somewhere. But when I try and understand what people have tried to do along these lines, I remain baffled so far, unclear to me what's going on.

6. **Chris Oakley**
January 23, 2021

Backtracking a little bit, physicists quite reasonably objected to relativity on the grounds that measurements of distance and time could not possibly depend on the observer's motion and to quantum theory on the grounds something could not possibly be a particle and a wave at the same time. Electron spin, although it explained doublets in spectral lines nicely, was another idea that took a while to be accepted. I am guessing that one objection was that all objects in nature surely had to be invariant under a 360° rotation. So if spinors are real, spacetime is not as simple as we imagined. I would not know what to do with Penrose's notion of spacetime being formed from composite spinors, but it does at least "explain" this one thing.

7. **Bertie**
January 23, 2021

The interview with Reza Katebi was wide-ranging and insightful.
At 2 hrs long, I never expected to watch it through to the end, but am happy I did
🙂

8. **Rollo Burgess**
January 23, 2021

Thanks v much for your video interview which is is very interesting.

I am also thrilled finally to find a topic on this blog in which I possess some cognitive authority: per the comment in the video, in cricket a googly is a delivery which has an off spin but is delivered with a leg spin action, thus tricking the batsman into thinking the ball will break in the opposite direction on the bounce from what it in fact does. 🙂

9. **I**
January 25, 2021

Well, your book is quite good for an auto-didact. Trouble is, it is lacking in exercises. What other flaws do you think there are?

10. **Peter Woit**
January 25, 2021

I,
Yes, there are some exercises, but too few. There are a bunch of places in the book where I'd now do things somewhat differently, or in a different order. One major flaw I think now is chapters 24-26, which spend too much time developing certain things that will get used later, but probably should have been relegated to an appendix, to be consulted as needed.

In recently years I've spent a lot of time thinking about the Euclidean version of QM, and someday would like to incorporate some of that into the book.

11. **Art**
January 26, 2021

Look likes the Bourguignon video is now up.

This Week’s Hype

January 25, 2021
Categories: This Week's Hype

I had just been thinking the other day about how little one hears recently about the multiverse, with those previously involved in heavy promotion of the idea perhaps having thought better of it. Today however, Quanta has [Physicists Study How Universes Might Bubble Up and Collide](). This describes work of a sort that has become popular in recent years: study of various condensed matter systems, with a huge dollop of hype on top about quantum gravity based on some aspect of the condensed matter theory calculation having some vague relation to some calculation in some toy quantum gravity model or other.

I’ve written extensively here and elsewhere about the real problem with all claims by theorists to be studying the multiverse: they’re [Theorists Without a Theory](), lacking any sort of viable theory which could make the usual sort of scientific predictions. The main problem with the Quanta article is at the beginning:

> What lies beyond all we can see? The question may seem unanswerable. Nevertheless, some cosmologists have a response: Our universe is a swelling bubble. Outside it, more bubble universes exist, all immersed in an eternally expanding and energized sea — the multiverse.
>
> The idea is polarizing. Some physicists embrace the multiverse to explain why our bubble looks so special (only certain bubbles can host life), while others reject the theory for making no testable predictions (since it predicts all conceivable universes). But some researchers expect that they just haven’t been clever enough to work out the precise consequences of the theory yet.
>
> Now, various teams are developing new ways to infer exactly how the multiverse bubbles and what happens when those bubble universes collide.

The big problem is with:

> they just haven’t been clever enough to work out the precise consequences of the theory yet.

The reference to “precise consequences” is a common misleading rhetorical move, implying that there is no problem getting “imprecise consequences”, that the problem is just getting those extra digits of numerical precision. What’s really going on is that we know of no theoretical consequences of the multiverse, precise or imprecise, because there is no viable theory. The logic here is pretty much pure wishful thinking: if you look at colliding Bose-Einstein condensates and see a particular pattern, then if you saw a pattern like that in the CMB, you could try and infer something about your unknown multiverse theory. It’s not unusual for theorists to work on speculative ideas involving some degree of wishful thinking, but this is a case of taking that to an extreme.

Update: One of the very few theorists who has pushed back on the multiverse ideology is Paul Steinhardt. Howard Burton [has posted here]() something from [his interviews with Steinhardt](), which includes this from Steinhardt:

> “I’ve had this discussion where I’ll say, ‘Well, what do you think about the multiverse problem?’ and they reply, ‘I don’t think about it.’
>
> “So I’ll say, ‘Well, how can you not think about it? You’re doing all these calculations and you’re saying there’s some prediction of an inflationary model, but your model produces a multiverse — so it doesn’t, in fact, produce the prediction you said: it actually produces that one, together with an infinite number of other possibilities, and you can’t tell me which one’s more probable.’
>
> “And they’ll just reply, ‘Well, I don’t like to think about the multiverse. I don’t believe it’s true.’
>
> “So I’ll say, ‘Well, what do you mean, exactly? Which part of it don’t you believe is true? Because the inputs, the calculations you’re using — those of general relativity, quantum mechanics and quantum field theory — are the very same things you’re using to get the part of the story you wanted, so you’re going to have to explain to me how, suddenly, other implications of that very same physics can be excluded. Are you changing general relativity? No. Are you changing quantum mechanics? No. Are you changing quantum field theory? No. So why do you have a right to say that you’d just exclude thinking about it?’
>
> “But that’s what happens, unfortunately. There’s a real sense of denial going on.”

Update: Ethan Siegel has an [excellent piece on the basic problem with string theory]() (to the extent it’s well-defined, it has too large a (super)symmetry group and too many dimensions, no explanation for how to recover 4 space-time dimensions and observed symmetry groups).

> Here’s why the hope of String Theory, when you get right down to it, is nothing more than a broken box of dreams.

Update: If you’re looking for a detailed discussion of multiverse theories, of neither the usual promotional sort, nor the highly critical sort I specialize in, I can recommend Simon Friedrich’s new book [Multiverse Theories: A Philosophical Perspective](). Friedrich has a blog entry about the book [here]().

Comments

1. **John Baez**
   January 26, 2021

   Why do writers at *Quanta* and other science magazines bother with this crud when there’s plenty of much more interesting *actual new physics* to write about? – you know, physics where people use theories to make predictions, test these predictions in the laboratory, and then refine their theories. Are condensed matter physicists just too busy making actual discoveries to chat to the journalists?

2. **Peter Woit**
   January 26, 2021

   John Baez,

   Quanta is more focused on the kind of actual new physics you suggest than just about any other publication, but I guess the multiverse is still irresistible for use as a hook to get attention.

   The main problem is with the physics community itself, which has over the years produced far too little pushback on multiverse pseudo-science. A rare exception is Paul Steinhardt. I just ran into Howard Burton’s interviews with him, will add a link to the posting. He quotes Steinhardt explaining that the physics community basically tries to sweep the multiverse problem under the rug instead of confronting it.

3. **Syksy Räsänen**

January 26, 2021

Steinhardt's comments on the multiverse are misleading.

Some inflationary potentials give eternal inflation. Usually this occurs when they are extrapolated into a regime far from where the observed inhomogeneities are produced, and in a region where the calculations cannot be trusted any more.

Some inflationary potentials do not give eternal inflation.

The conflation of inflation, eternal inflation and multiverse (all distinct things) by Steinhardt et al is part of the multiverse hype problem, not a welcome respite.

4. **Peter Woit**
   January 26, 2021

   Syksy Räsänen,
   I don't want to start up the usual arguments over inflation, or get involved in arguments over different behavior of different inflationary potentials.

   Steinhardt is one of the founding fathers of inflation, now argues against it. His main argument about this is that inflation doesn't do one of the things it was supposed to do: explain why you get a smooth, flat universe without having to tune that into the initial conditions. As far as I can tell, he's on solid ground when making that argument.

5. **Blake Stacey**
   January 26, 2021

   "What lies beyond all we can see?"

   Fluffy nougat.

   This answer is just as scientific as multiversology while having the added benefit of being much more delicious.

6. **jackjohnson**
   January 26, 2021

   I should keep my mouth shut because of my ignorance, but it seems to me that mathematical work of Uhlenbeck and others on compactification of moduli spaces by adding `bubbles' is important and interesting: and that if someone has something serious to say about `the multiverse', they should be aware of that literature. As far as I can tell, the set of such persons is well-approximated by the empty set.

7. **Michael Weiss**
   January 26, 2021

   Not to change the subject, but as a chemist I think that Paul Steinhardt should have shared the 2011 Nobel Prize in Chemistry for quasicrystals. His contributions were deep and wide-ranging.

8. **John C. Rodney**
   January 26, 2021

   Check out particleclara on TikTok for songs and info about CERN and the LHC. Maybe not directly relevant to this post but it just went up today and it is certainly relevant to this general blog.

9. **vmarko**
   January 27, 2021

   Is it possible that the writers of Quanta are simply not aware that there are other topics to write about in fundamental physics? Alternatives to string theory, multiverse and inflation, but still quite interesting, thought-provoking and equally captivating for the non-expert audience? Maybe they simply don't know that such topics exist?

   🙂
   Marko

10. **Low Math, Meekly Interacting**
    January 28, 2021

    I saw a couple hopeful signs, with effort. Yeah, it's "crud". But unlike the majority of related content I've read, there was at least an attempt at moderation. Some work is characterized as "the [most] baby version of this problem that you can think of,". If the reader doesn't recognize how pointless it all is, they may still come away with a sense that the odds aren't good: "you've taken a lot of things that are just very hard for physicists to deal with and mushed them all together and said, 'Go ahead and figure out what's going on,'". There's even a hint of an admission: "It's a long shot".

    Not great, but not nothing. Multiverse Mania has set a low pop-sci bar, but I felt this article rose a smidgen above the norm.

11. **Syksy Räsänen**
    January 28, 2021

    Peter:

    I don't think Steinhardt's argument that inflation -> eternal inflation -> multiverse is on solid ground. Let me elaborate… (I won't even go into the eternal inflation -> multiverse part.)

    1) The eternal inflation regime only exists for potentials of certain shape. You can easily write a potential such that there is no eternal inflation.

    2) Even for the potentials that have an eternal inflation regime, it is typically far separated from the observable regime.

    For example, for the archetypical quadratic potential, observable modes are generated around 60 e-folds before the end of inflation, and eternal inflation regime is about 10^6 e-folds earlier. In terms of field value, this is a factor of 10^3. There is no reason to suppose that we can just extrapolate the potential there.

    3) Even if the potential shape for large field values supports eternal inflation, there is no reason that the initial conditions have to be such that the field starts there. In fact, Steinhardt has criticised inflation with the argument that we don't know the initial conditions – but his argument about eternal inflation requires specific initial conditions.

4) Eternal inflation (in slow-roll inflation) means that the power spectrum is of order unity, so perturbations are of the same order as the background and perturbation theory breaks down. So we cannot trust the calculation anymore.

This of course does not mean that eternal inflation is ruled out – simply that we do not know it to be an inevitable feature of inflation.

I find popular articles about this a bit depressing to follow, as they often focus on two sides who both think inflation->multiverse, divided only by whether they think this is good or not… Not really representative of the cosmology community.

The situation at Leicester again (somehow related to a previous post on the AI fad)
https://www.reddit.com/r/math/comments/l7yyir/not_joking_university_of_leicester_to_make/

13. **Geoffrey Dixon**
January 31, 2021

By the way, re the Quanta article, I've commented elsewhere how annoying I find it when such articles, often relating to some very outré, and lurid, notion, claim that the notion in question is being investigated by "physicists", the very unspecific plural leaving the uninitiated with the impression that physicists as a class – en masse – are focused …

Anyway, "A physicist thinks there is a black hole in Newark, NJ", in being singular, is less likely to grab eyeballs – and that, after all, is their business. Although I'd sure read that one.

14. **Frank Wilhoit**
February 1, 2021

Why was Ethan Siegel's piece published in *Forbes*, of all places? Who is the audience?

It is well written and accurate, but the nut graf is the third from last, topic sentence: "If String Theory is correct, then somehow — and nobody knows how — this ultra-symmetric state broke, and it broke incredibly badly."

That word "incredibly" is doing (as they say) a lot of heavy lifting there. Siegel's use of language is otherwise careful. Is he really making an argument from intersubjective plausibility? And if he is, isn't that just another manifestation of the same lgical fallacy as the arguments from "naturalness"? To whom, exactly, and why, exactly, is this symmetry breaking "incredible"? There is such a thing as scientific imagination; whose imagination fails here, and whose does not?

15. **Peter Woit**
February 1, 2021

Frank Wilhoit,
Siegel has a regular column on the Forbes site, often dealing with fundamental physics, similar to this one. He does a good job of trying to explain serious physics to a general audience.

The point he is making I think is the main one that needs to be made, and that rarely gets explained. It's been the problem with string theory (and GUTs and supersymmetry) since the beginning. They posit huge new symmetry groups (in the case of string theory, 10d super-Poincare as well as things like two copies of E8) which imply physics that looks nothing at all like what we observe. You then have to come up with symmetry-breaking mechanisms which explain why and how the symmetry is broken to the much smaller (4d Poincare + SU(3)xSU(2)xU(1)) we observe.

Calling this symmetry breaking "incredible" is perfectly reasonable. That this happens is an extraordinary claim that should require extraordinary evidence. Instead there's none at all. The original hope that an exotic compactification scheme using Calabi-Yaus would solve the problem was always highly speculative and hard to believe (it could properly be described as "incredible"). That doesn't mean people shouldn't have looked into it, but for a long time it has now been clear this doesn't work.

16. **jack morava**
February 1, 2021

I think Ethan Siegel's account of the dream of string theory: "… that we can take this theory, like some enormous unbroken box, and stick the right key in it and watch it crumble away, leaving only a tiny piece left that perfectly describes our Universe…" is cogent and realistic; but then IICC, the Planck mass is something like twenty orders of magnitude greater than the Higgs mass, which sounds like plenty of room for new physics. It reminds me of people like Lyell who came to understand that the age of the world was much greater than they had imagined. An old academic cartoon shows two bearded guys at a blackboard, one says to the other, `It's not that they want you to promise results; it's that they want you to promise results IN THEIR LIFETIME!' Apparently Archimedes, based on work of Aristarchus, estimated the size of the universe as roughly two light-years; today we might say he was off by ten orders of magnitude. It is not so clear to me that string theory should be abandoned just because it has a lot of unexplored room in it.

17. **jack morava**
February 1, 2021

PS the previous comment escaped before I had the chance to say that all this hype nevertheless creeps me out.

18. **Frank Wilhoit**
February 1, 2021

Peter,
If he had used the word "improbably" rather than "incredibly", I would have had no point to make. Perhaps I had none, even so.

Thanks,
FW
.

19. **Bernhard**
February 2, 2021

Simon Friedrich's blog post is well-written and diplomatic. Though I think none of the hard critics of the multiverse claim that might not live in a multiverse.

20. **Lars**

February 3, 2021

” these large groups are enormous, like a block of uncut marble, and we want to get just a tiny, perfect statuette (our Standard Model, and nothing else) out of it.”

“String Theory truly is: a large, unbroken box that must somehow crumble in this particular, intricate fashion, to recover the Universe we observe”

He is mixing his metaphors — and very badly.

21. **Low Math, Meekly Interacting**
February 3, 2021

I concur with Bernard, and I’m in disagreement with Friedrich on other matters. I don’t understand how a concept that may be as malleable as “God”, and may require god-like powers to probe, can be described as “far from unscientific”. It’s far from helpful, at best. Of course there are mysteries grounded in good science that may be beyond humans to explain or test, but that’s hardly a new or especially deep idea. That the obvious happens to take a on a most abstruse manifestation in the speculative realm of untestable hypotheses doesn’t strike me as terribly “serious”. There’s a mountain of negative data to stack up against the notion of new symmetries where they should have been found in the most “natural” places, tons of non-evidence of collisions with bubble universes and so forth. It’s not as if these idea haven’t been quite thoroughly vetted, and we’re butting up against real physical limits to testing them any further, quite aside from the fact that they’re no longer promising. Where’s practical “science” in any of these multiverse scenarios to hide any longer? Aren’t such concepts already so seriously constrained by evidence as to stretch credibility to the breaking point? I don’t think there’s much room for diplomacy, anymore, however congenial one wishes to be. Hasn’t “the multiverse” already conclusively failed?

22. **Robert A. Wilson**
February 3, 2021

As a group theorist, I can confirm that these large groups really are enormous. However, they bear no resemblance to a block of uncut marble. Nor do they bear any resemblance to the universe we observe.

Geometric Langlands News

February 11, 2021
Categories: Langlands

There's various news to report on the geometric Langlands front, spanning number theory to quantum field theory:

Minhyong Kim has been running an Online Mini-Conference on the Geometric Langlands Correspondence for the past month, and Dennis Gaitsgory has been doing something similar since last spring at his Geometric Langlands Office Hours.

Very recently Edward Frenkel has given talks in both places (see talks here, here and here, slides here and here). He's been talking about joint work with Etingof and Kazhdan on a function-theoretic (as opposed to sheaf-theoretic) version of geometric Langlands. They have a paper out here, are working on two more.

This work to some extent has its origins in attempts by Langlands to come up with his own version of such a function-theoretic approach. Frenkel was asked to discuss this topic by the organizers of the Abel Conference in honor of Langlands. I wrote about what happened here. Frenkel came to the conclusion that what Langlands was suggesting could not work (Langlands vehemently disagreed…), but this led him to the current research he is pursuing with Etingof and Kazhdan. For a written version of Frenkel's talk explaining all this, see here.

On the quantum field theory front, Witten and Gaiotto have been working on relating older ideas of Gukov-Witten about using branes as a general method of quantization, applying this to geometric Langlands, in the new context that Frenkel's talks discuss. Witten talked about this last week in the Kim seminar (video here, slides here). Gaiotto last week also spoke about this at a Kansas State seminar, video here, slides here.

The original 2008 Gukov-Witten paper on branes and quantization is here, Gukov's 2010 Takagi lectures on this are written up here. The problem of how to quantize a general symplectic manifold is a fascinating one, and at the time I was very interested to see this proposal. It does however invoke a very sophisticated set of ideas about quantum field theories in order to deal with what one would think are much simpler examples of the quantization problem. Perhaps this program would come into its own in this new case, where the quantization problem involves similarly sophisticated mathematical constructions.

From another side of the geometric Langlands world, Peter Scholze is continuing his lectures on his ongoing work with Laurent Fargues that reformulates the local Langlands correspondence in terms of geometric Langlands on the Fargues-Fontaine curve. There are associated discussion sections, with a web-page here.

Announcement: I'd been reading about how the hot new idea for authors on the internet is Substack, where all sorts of interesting material can now be found. After thinking about this "back to the email newsletter" model for a minute, I realized that I should try and see if I could get email subscriptions to this blog working. There's now a place over on the right where you can ask for an email subscription. No experience with this yet, so I can't guarantee either that it works or that problems won't turn up that will cause me to have to turn that feature off.

Update: For another talk by Witten about this from today (Feb. 11) see here.

   February 11, 2021

   Peter,

   For the email notifications, will the notification say who is doing the post, or will it just say "new post in topic "X"?

   Jim Akerlund

2. **Peter Woit**
   February 11, 2021

   Jim Akerlund,

   When I post a new blog entry, you'd get an email from "Not Even Wrong", with a subject line like
   [New post] Geometric Langlands News
   and then the full text of the blog entry as an email. So you can read the blog entry in your email, and get it write when it's posted.

   It's actually very similar to the Substack model, where subscribers get content in their email exactly this way. Only difference is that subscriptions are free!

   This is being done by a WordPress feature called JetPack, and everything is being managed at wordpress.com. My only concern about this is that it's something I don't have full control over, since it is managed by wordpress.com. On the other hand, it does seem convenient for people, and I don't want to manage subscriptions + sending out bulk emails myself.

3. **4gravitons**
   February 12, 2021

   As reassurance, I've had people subscribing by email via JetPack to my blog for several years. There is one issue that's come up a few times, and that is that if someone replies to the email, that reply is automatically submitted as a comment on the blog. I had a few family members reply thinking it was just going to me, only for it to end up in moderation as a comment instead. But as long as your readers don't confuse the blog emails with your personal email you shouldn't have any problems.

   Sad news from MIT: Isadore Singer died yesterday.

5. **Will Sawin**
   February 12, 2021

   Further recent progress in geometric Langlands theory is the work of Arinkin, Gaitsgory, Khazdan, Raskin, Rozenblyum, and Varshavsky (https://arxiv.org/abs/2010.01906), which like the work of Etingof, Frenkel, and Khazdan, is devoted to finding concrete, function-theoretic consequences of geometric

Langlands, but in a different direction: they give a new statement of the geometric Langlands correspondence which formally implies, and doesn't just suggest, the (everywhere unramified) Langlands correspondence for function fields over finite fields.

6. **Peter Woit**
   February 13, 2021

   Thanks Will!
   Looking forward to the day when it will again be possible for you to help explain this sort of thing to me over lunch…

Isadore Singer 1924-2021

February 12, 2021
Categories: Obituaries

I was sorry to hear this morning of the death yesterday at the age of 96 of Is Singer, a mathematician who led much of the interaction between mathematics and physics during the 1970s and 1980s. In the early stages of my career, among mathematicians investigating the amazing relations between mathematics and the quantum field theories describing fundamental physics there were three towering figures: Atiyah, Bott and Singer. That the last of them has now left us marks the end of an era.

Each of the three had a huge influence on me, both intellectually and personally. Reading their papers and listening to their lectures were great intellectual experiences, shaping early on my understanding of what is central to mathematics and how it fits together with physics. Especially inspirational was the way that they brought together very different fields of mathematics, with Atiyah having his roots in algebraic geometry, Bott in topology and Singer in analysis. Their work together makes a strong case for the unity of mathematics and the relation to physics makes an equally strong case for the unity of mathematics and physics.

On a personal level, at a time when I was tentatively moving from a career in physics to one in mathematics, getting to meet and talk to each of them had a big impact. Much as I respected the great theoretical physicists I had met, rarely had I found them to be particularly friendly or encouraging, and their attitudes influenced the general atmosphere of the field. Atiyah, Bott and Singer struck me each in their own way as wonderfully warm and enthusiastic personalities, and I believe this influenced the atmosphere among mathematicians working in their fields. They were among the most respected figures in the math community, so their enthusiasm for ideas coming out of physics generated a lot of interest in these ideas among a wide variety of mathematicians.

Singer had always had an interest in physics, majoring in physics as an undergraduate at the University of Michigan, then after the war going to graduate school in mathematics at the University of Chicago. I highly recommend reading or watching this long interview with him from 2010, where you can learn the story of his career.

A mathematical high point of this career was his work during the early 1960s with Atiyah that led to the Atiyah-Singer index theorem. A crucial part of this story was Atiyah in 1962 asking Singer why the A-roof genus was integral. Singer realized that this was because it counts the number of solutions of an equation, and that the equation was the Dirac equation. This example in some sense generates a huge amount of mathematics which is described by the index theorem, and which links together very different mathematical fields. On this and other topics, well-worth reading is the 2004 interview with Atiyah and Singer after they were awarded one of the first Abel Prizes.

One can trace much of the history of the modern interaction of mathematics and quantum field theory to an origin back in the summer of 1976, when Singer visited Stony Brook and talked to physicists there about gauge theories, geometry and the BPST instanton (Simons and Yang a year earlier had started to realize how gauge theory, geometry and topology were linked). The next year he was in Oxford working with Atiyah and Hitchin on instantons, which really set off an explosive development of new ideas, inspiring and fascinating both mathematicians and physicists.

Singer spent the years from 1977 to 1983 at Berkeley, which he turned into a major center for this new mathematical physics. During this time he was also one of the founders of MSRI, which to this day plays a major role in worldwide mathematical research. After 1983 he returned to MIT, from which he retired in 2010. I believe the last time I saw him was at his 85th birthday conference, which I wrote about here.

Update: The New York Times has an obituary here.

Update: Dan Freed (who was a graduate student of Singer's) has a piece about Singer at Quanta magazine here.

Comments

1. **Jeff Berkowitz**
   February 12, 2021

   I am sorry for your loss, and the world's.

   Now we (those of us in our age group, each in our respective disciplines) are the elders.

   We can only hope to play the role so well.

2. **Davide Castelvecchi**
   February 13, 2021

   Is there a good, reader-friendly source for understanding what the index theorem means and what its implications are? My student self — who desperately tried to read Lawson and Michelson back in graduate school but found it inscrutable — would love to know!

3. **Peter Woit**
   February 13, 2021

   Davide,
   When I was learning this stuff I found Atiyah's own expository articles clear and inspiring. See for instance

   1966 ICM lecture
   1967 Algebraic topology and elliptic operators
   1973 The index of elliptic operators (colloquium lectures)
   Classical Groups and Classical Differential Operators on Manifolds

   For the heat equation method and later developments, one place to look is Dan Freed's unfinished notes on Dirac operators (he was Singer's student)
   https://web.ma.utexas.edu/users/dafr/DiracNotes.pdf

   For relation to quantum mechanics:
   Orlando Alvarez, Lectures on Quantum Mechanics and the Index Theorem

4. **D R Lunsford**
   February 13, 2021

   Thanks for that – I met Feigenbaum once, and had the same experience that mathematicians at the high level were more engaging than physicists. Was just thinking about Irving Segal and his conformal c0smology and then find out here he was Singer's advisor. Small universe.

-drl

5. **Peter Woit**
February 13, 2021

drl,

Feigenbaum was a rather unusual character, and many would consider him a physicist, not a mathematician.

I was interested to see a nice tweet by Erik Verlinde about Singer:
https://twitter.com/erikverlinde/status/1360328234743836676
where he also notes that Singer was much friendlier than the people he was used to dealing with
"[Singer was] one of the friendliest people I have met."
Verlinde though also shows the difference between theoretical physics and math culture when he writes:
"In my view, he was the only mathematician with a deep understanding of theoretical physics."
Among mathematicians I know, even the few who might think there is only one physicist with a deep understanding of mathematics would never say that out loud…

6. **rhofmann**
February 15, 2021

Well written, authentic obituary. Many thanks, Peter. I am looking forward to read the 2010 interview with Prof. Singer tonight. Isadore Singer has contributed a lot to the renewed fertile interaction between physics and mathematics initiated by physicists' discoveries of selfdual field configurations in gauge theories in the 1970ies, and it makes me feel sad that another grand master of the field is no longer among us. The index theorem and how it counts the zero modes of the Dirac operator on an instanton is wonderful stand-alone math stuff which, moreover, has deep physical implications in pointing to the essentials of dynamical chiral symmetry breaking and quantum anomalies in Yang-Mills. In addition, its significance for the physics of gauge theory is expressed by the fact that Nahm's duality transformation between instantons on T4, which vastly generalises the important ADHM construction, significantly relies on the index theorem. Nahm's transformation, in turn, is the venue to calorons of non-trivial holonomy which mediate the emergence of mass and charge from pure energy in Yang-Mills.

7. **John Baez**
February 15, 2021

Davide wrote:

> Is there a good, reader-friendly source for understanding what the index theorem means and what its implications are?

I don't know the perfect one for you. John Rognes wrote a popular account for the Abel prize which might be good for people who know less math than you. You might find it unsatisfyingly vague.

Briefly put, the Atiyah-Singer index theorem gives a topological formula for the dimension of the space of solutions of a differential equation on a manifold. As such, it's a great way to use topology to learn something about the solutions of differential equations without actually solving them. And conversely, it's a great way to use differential equations to learn things about the topology of manifolds!

It was extremely important sociologically. It built a bridge between two fields — partial differential equations and topology — which had not existed before. And because the differential equations it applies to are important in physics, it connected physics more firmly to both these fields.

More precisely, the Atiyah-Singer index theorem is a formula for the "index" of a differential equation, where the index is the dimension of the space of solutions (the "kernel") minus something else (the dimension of the "cokernel"). So, you have to be clever to use it to get precise information about the dimension of the space of solutions. But it easily gives a lower bound.

Furthermore, it only works when the manifold is compact and the differential equation is "elliptic" (like the Laplace equation, not like the wave equation or heat equation).

On the bright side, it works for differential equations where the solutions are not just functions, but sections of vector bundles — like the elliptic version of the Dirac equation, which turns out to be the key to the general case. Another interesting thing is that because Dirac equation involves spinors and Clifford algebras, the Atiyah-Singer index theorem highlights the role of spinors and Clifford algebras in topology.

I spent a lot of time in college reading *Seminar on the Atiyah-Singer Theorem*, by Richard Palais. It had great explanations of the analysis prerequisites, like pseudodifferential operators on vector bundles, Sobolev spaces, and chain complexes of Hilbert spaces. Somehow all that seems second nature to me by now. But I still don't feel I have a great intuitive feel for the topology: that is, why the formula for the index in terms of characteristic classes is what it is.

When I went to grad school at MIT, Singer was one of the stars there: he ran a seminar on mathematics connected to quantum field theory, and a huge crowd attended, including Raoul Bott and many other bigshots. When visitors like Witten or Atiyah came to town, we'd all go to their talks.

At that time — say, 1982-1986 — it seemed that everyone wanted to learn the Atiyah-Singer index theorem and generalize the heck out of it. I attended Dan Quillen's seminar where he was trying to find a really simple proof of the Atiyah-Singer theorem. It was very exciting, because he was working in real time. Each class he would start flawlessly, and then continue until he got stuck on something. In the end he was scooped by Ezra Getzler, who however used some fancy analysis that Quillen would have wanted to avoid.

8. **Alex**
February 16, 2021

Just want to add, for those interested in the topic, that learning about the index theorem is the best way to prepare if you want to study noncommutative geometry in the sense of Connes, which pretty much involves (among other things) trying to generalize the index theorem to the noncommutative setting. So, that's one modern spinoff of the Atiyah-Singer index theorem.

9. **JC**
February 16, 2021

@Davide

I also attempted to go through Lawson & Michelsohn "Spin Geometry", and also found it heavy going back in the day.

Years later, I found Rosenberg's "Laplacian on a Riemannian Manifold" slightly less heavy going.

Yet More Geometric Langlands News

February 27, 2021
Categories: Langlands

It has only been a couple weeks since my last posting on this topic, but there's quite a bit of new news on the geometric Langlands front.

One of the great goals of the subject has always been to bring together the arithmetic Langlands conjectures of number theory with the geometric Langlands conjectures, which involved curves over function fields or over the complex numbers. Fargues and Scholze for quite a few years now have been working on a project that realizes this vision, relating the arithmetic local Langlands conjecture to geometric Langlands on the Fargues-Fontaine curve. Their joint paper on the subject has just appeared . It weighs in at 348 pages and absorbing its ideas should keep many mathematicians busy for quite a while. There's an extensive introduction outlining the ideas used in the paper, including a long historical section (chapter I.11) explaining the story of how these ideas came about and how the authors overcame various difficulties in trying to realize them as rigorous mathematics.

In other geometric Langlands news, this weekend there's an ongoing conference in Korea, videos here and here. The main topic of the conference is ongoing work by Ben-Zvi, Sakellaridis and Venkatesh, which brings together automorphic forms, Hamiltonian spaces (i.e classical phase spaces with a G-action), relative Langlands duality, QFT versions of geometric Langlands, and much more. One can find many talks by the three of them about this over the last year or so, but no paper yet (will it be more or less than 348 pages?). There is a fairly detailed write up by Sakellaridis here, from a talk he gave recently at MIT.

In Austin, Ben-Zvi is giving a course which provides background for this work, bringing number theory and quantum theory together, conceptualizing automorphic forms as quantum mechanics on arithmetic locally symmetric spaces. Luckily for all of the rest of us, he and the students seem to have survived nearly freezing to death and are now back at work, with notes from the course via Arun Debray.

For something much easier to follow, there's a wonderful essay on non-fundamental physics at Nautilus, The Joy of Condensed Matter. No obvious relation to geometric Langlands, but who knows?

Update: Arun Debray reports that there is a second set of notes for the Ben-Zvi course being produced, by Jackson Van Dyke, see here.

Update: David Ben-Zvi in the comments points out that a better place for many to learn about his recent work with Sakellaridis and Venkatesh is his MSRI lectures from last year: see here and here, notes from Jackson Van Dyke here.

Update: Very nice talk by David Ben-Zvi today (3/22/21) about this, see slides here, video here.

   February 27, 2021

   Geometric Langlands is reflected in integer/fractional quantum Hall effect and the so-called Hofstadter's butterfly, according to recent work of Kazuki Ikeda.

2. **Jim Eadon**
   February 28, 2021

   Can anyone provide a (hand-wavy) summary for the educated layman (Physics post-grad) of what a Fargues-Fontaine curve is, and what's special about, e.g. in the context of the Langlands programme?

3. **Arun Debray**
   February 28, 2021

   Re: DBZ's course, I am not the only student taking notes. Jackson Van Dyke is also posting his notes online: https://web.ma.utexas.edu/users/vandyke/notes/langlands_sp21/langlands.pdf (Github link: https://github.com/jacksontvd/langlands_sp21). Jackson's notes go into quite a bit more detail, and he's gone back and added more references and figures than I have. In the end we'll hopefully combine our notes into one document. If anyone has any questions, comments, or corrections about either set of notes they're welcome to get in touch with me or Jackson.

4. **Peter Woit**
   February 28, 2021

   Arun,
   Thanks a lot, both for producing the notes, and for letting us know about the other ones.

5. **David Ben-Zvi**
   February 28, 2021

   Peter – thanks for the references!
   Maybe let me note the series of talks in Korea (by Sakellaridis, Venkatesh and me) are aimed at a more arithmetic audience, some previous talks (eg at MSRI last March) might be more accessible to the audience here.

   Also I might add that the perspective on automorphic forms as quantum mechanics is very old and widely used. A newer perspective I'm trying to advertise in the course and talks is to think of automorphic forms (and the Langlands program) as being really about 4d QFT — an arithmetic elaboration of the Kapustin-Witten picture for geometric Langlands. This accounts for many of the special features of quantum mechanics on arithmetic locally symmetric spaces – e.g., dependence on a number field is the analog of considering states on different 3-manifolds, Hecke operators — a form of quantum integrability– come from 't Hooft line operators, the choice of level (congruence subgroup) corresponds to consideration of surface defects, and most importantly the relation with Galois representations (the Langlands program) can be viewed as electric-magnetic duality.

   The new feature of the work with Sakellaridis and Venkatesh (the first paper should appear relatively soon..) is that the theories of periods of automorphic forms and L-functions of Galois representations can fruitfully be understood as considering boundary conditions in the two dual TQFT, and that the electric-magnetic duality of boundary conditions (as studied by Gaiotto-Witten) can be used to explain the relation between the two (the theory of integral representations of L-functions).

6. **Peter Scholze**
   March 1, 2021

Jim Eadon,

let me try to answer. This paper is about the (local) Langlands correspondence over the p-adic numbers $\mathbb Q_p$. Recall that p-adic numbers can be thought of as power series $a_{-n}p^{-n} + \ldots + a_0 + a_1 p + a_2p^2 + \ldots$ in the "variable" p — they arise by completing the rational numbers $\mathbb Q$ with respect to a distance where p is small. They are often thought of as analogous to the ring of meromorphic functions on a punctured disc $\mathbb D^*$ over the complex numbers, which admit Laurent series expansions $a_{-n} t^{-n} + \ldots + a_0 + a_1 t + a_2t^2 + \ldots$. More precisely, there is this "Rosetta stone" going back to Weil between meromorphic functions over $\mathbb C$, their version $\mathbb F_p((t))$ over a finite field $\mathbb F_p$, and $\mathbb Q_p$.

However, there is an important difference: t is an actual variable, while p is just a completely fixed number — how should $p=2$ ever vary? In geometric Langlands over $\mathbb C$, it is critical to take several points in the punctured disc $\mathbb D^\ast$ and let them move, and collide, etc. What should the analogue be over $\mathbb Q_p$, where there seems to be no variable that can vary?

In one word, what the Fargues–Fontaine curve is about is to build an actual curve in which p is the variable, so "turn $\mathbb Q_p$ into the functions on an actual curve". It then even becomes possible to take two independent points on the curve, and let them move, and collide. With this, it becomes possible to adapt all (well, at least a whole lot of) the techniques of geometric Langlands to this setup.

This idea of "turning p into a variable and allowing several independent points" is something that number theorists have long been aiming for, and is basically the idea behind the hypothetical "field with one element". I would however argue that our paper is the first paper to really make profitable use of this idea.

March 1, 2021

David,
Thanks! I've added some links to your MSRI talks, which do look like a better place for people to start.

I've always been fascinated by analogies between number theory and QM/QFT, the new angle on this you're pointing out is really remarkable, looks like a significant deep link between the subjects.

Could you (or Peter Scholze!) comment on any relation of this to the other topic of the posting (local arithmetic Langlands as geometric Langlands on the Fargues-Fontaine curve)?

8. **Jim Eadon**
March 1, 2021

Professor Scholze,
You give a sense of how exciting it is, to, literally? connect the dots between different fields. I'm glad I studied pure mathematics as a hobby enough to get the gist of your explanation. I will re-read your reply a few times, as it's deep, and connects several fascinating objects and techniques.
I really appreciate you taking the time to engage, it means a lot. And thanks too, to Professor Woit, for bringing such mathematics to my (and others) attention, I enjoy the blog.

9. **David Ben-Zvi**
March 1, 2021

Peter – the way I see it (somewhat metaphorically) is as follows. In extended 4d topological field theory we seek to attach vector spaces to 3-manifolds, categories to 2-manifolds etc. The Langlands program fits beautifully into this if you accept the "arithmetic topology" analogy: besides ordinary 3-manifolds we consider (Spec of ring of integers of) global fields (number fields and function fields over finite fields) as "3-manifolds". Besides surfaces we also admit local fields (such as p-adics or Laurent series over finite fields) and curves over the algebraic closure of finite fields as "2-manifolds" (this is the theme I'd like to get to in my course, though still a way to go).

If you accept this ansatz, there's no "geometric Langlands" and "arithmetic Langlands", we're just considering different kinds of "manifolds" as inputs. For example geometric Langlands on surfaces and local (arithmetic) Langlands both concern equivalences of categories (in the latter case, one seeks descriptions of categories of reps of reductive groups over local fields are described in terms of spaces of Galois representations).

The Fargues-Scholze work is (among many other things!) a spectacular realization of this kind of idea. They show that the local Langlands program can be (and arguably is best) considered as geometric Langlands on an actual curve attached to the local field (the Fargues-Fontaine curve). Moreover the most crucial structure here, the Hecke operators, are miraculously described in a geometric way (factorization — the colliding points in Peter's response) that descends directly (via Beilinson-Drinfeld) from the structure of operator products in 2d QFT.

The wonderful recent work of Arinkin, Gaitsgory, Kazhdan, Raskin, Rozenblyum and Varshavsky that Will Sawin mention in a recent comment also fits into this general paradigm, in that they show that [unramified] arithmetic and geometric Langlands in the function field setting are precisely related by "dimensional reduction" – you pass from "2-manifolds" (curves over alg closure of finite fields) to "3-manifolds" (curves over the finite fields — which you should think of as mapping tori of the Frobenius map, so 3-manifolds fibering over the circle) by taking trace of Frobenius, just as TFT would tell you.

10. **Laurent Fargues**
March 5, 2021

I'm late but I'm going to say a few words to complement Peter's comments. Since this is a Physics blog I'm going to give a few key words that may speak to physicists. A lot of things work by analogies in this work, trying to put together some ideas from arithmetic and geometry together, make some mental jumps and trying to fill the gaps.

When Peter is saying "turning into a variable and allowing several independent points" this is analog to the fusion rules in conformal fields theory. There is the possibility in the world of diamonds to take different copies of the prime number p and fuse them into one copy. Here there reference, if I dig in my mind the first time I heard about this, is the work of Beilinson Drinfeld on factorization sheaves in terms of D-modules. You will find this fusion process in the Verlinde formula too in a coherent sheaves setting for compact Riemann surfaces in the work of Beauville "Conformal blocks, fusion rules and the Verlinde formula" for example where you fuse different points on a Riemann surface. I typically remember a talk by Kapranov about 'The formalism of factorizability' and did not get why the Russian peoples, who are known to have a huge background in physics, were such obsessed with this. No doubt this is linked to vertex algebras, where there are fusion rules, too and plenty of things of interest for physicists. For arithmeticians the declic, I remember saying to myself "at least I understand why peoples are obsessed with those factorization stuff", came from Vincent Lafforgue who remarked that if you work in an étale setting instead of a D-module setting, the moduli spaces of Shtukas (a vast generalization of modular curves for functions fields over a finite field) admits a factorization structure and this factorization structure gives you the Langlands parameter for global Langlands over a function field over a finite field.

For the curve here is what I can say. If you take an hyperbolic Riemann surface it is uniformized by the half plane on which you have a complex coordinate z. You can imagine the same type of things for the curve where the variable is the prime number p.

By the way there is an object in the article that may speak to physicists : Bun_G, the moduli of principal G-bundles on the curve. The analog for physicists would be the moduli of principal G-bundles on a compact Riemann surface, where now G is a compact Lie group, that shows up in the work of Atiyah and Bott. Still by the way, one of the origin of my geometrization conjecture is trying to understand the reduction theory "à la Atiyah Bott" for principal G-bundles on the curve (the analog for any G of the work on the indian school (Narasimhan-Seshadri) + Harder for GL_n i.e. usual vector bundles).

There are other objects that may speak, by analogies, to physicists in this paper. Typically the so called local Shtuka moduli spaces "with one paw" (i.e. only one copy of the prime number p). The archimedian analogs are hermitian symmetric spaces. Realizing local Langlands in the cohomology of those local Shtuka moduli spaces has an archimedian analog : Schmid realization of Harisch-Chandra discrete series in the L^2 cohomology of symmetric spaces. Schmid uses the Atiyah-Singer index formula to obtain his result, a tool well know to Physicists. Hermitian symmetric spaces are moduli of Hodge structures and this has been a great thing to realize that p-adic Hodge structures à la Fontaine are the same as "geometric Hodge structures" linked to the curve.

I could speak about this during hours and do some name-dropping that speaks to physicists but one thing is sure: there is no link with the multiverse, this I'm sure. Anyway, I have no idea how the curve looks like in other universes of the multiverse.

11. **Peter Woit**
March 5, 2021

Thanks Laurent!

The Atiyah-Bott story (involving gauge fields + the Yang-Mills equations) and the Atiyah-Schmid story (involving, for SL(2,R), the Dirac operator on a 2d space) are two of my favorite topics. They're essentially the two main components of the Standard model (the Dirac equation for matter fields, the Yang-Mills equation for gauge fields). Only difference is that they're in 2d rather than 4d….

I hope you're still planning to come to Columbia for fall 2022, look forward to seeing you then!

12. **Laurent Fargues**
March 6, 2021

My Eillenberg lectures are reported to 2023 sadly, because of the virus. I'll try not to enter into the technical details and give some general picture of the objects showing up in this work.

By the way, the cancelled program "The Arithmetic of the Langlands program" jointly organized with Calegari, Caraiani and Scholze is officially reported to 2023, same period of the year as before.

13. **Thomas**
March 7, 2021

A very nice popular sketch of the idea of "the curve" by Matthew Morrow:

@Thomas thanks for the link.

ABC is Still a Conjecture

March 4, 2021
Categories: abc Conjecture

Just a reminder that the abc conjecture is still a conjecture, there is no known valid proof (don't believe what you might read in an EMS journal). For more about why one attempted proof doesn't work, see here and here. For extensive background on this, you could start at this blog posting and work backwards, to the first announcement of a claimed proof back in 2012. By 2018 Scholze and Stix had shown that the claimed argument was flawed, and since then the math community has lost interest and moved on. Devotion to the idea that the proof is valid seems now restricted to a small circle of die-hards based in Kyoto and Nottingham who are doing what they can to try and pretend the hole pointed out in the proof does not exist. There will be an IUT Summit in Kyoto in September, but the organizers don't seem to have found anyone from outside Kyoto or Nottingham willing to participate.

Update: Mochizuki today on his website has put out a 65 page manuscript dealing with criticisms of his proof, it's entitled:
ON THE ESSENTIAL LOGICAL STRUCTURE OF INTER-UNIVERSAL TEICHMULLER THEORY IN TERMS OF LOGICAL AND "∧"/LOGICAL OR "∨" RELATIONS: REPORT ON THE OCCASION OF THE PUBLICATION OF THE FOUR MAIN PAPERS ON INTER-UNIVERSAL TEICHMULLER THEORY

I've taken a quick look at this document, and I don't think it will convince anyone Scholze is wrong about the flaw in Mochizuki's proof. There's a long third and final technical section, but the first two sections do a great deal of damage to Mochizuki's credibility. Nowhere in the document do the names Scholze or Stix appear (they are referred to as "RCS: the redundant copies school"), but it starts off with statements such as

> the response of all of the mathematicians with whom I have had technically meaningful discussions concerning the assertions of the RCS was *completely uniform* and *unanimous*, i.e., to the effect that these assertions of the RCS were **obviously completely mathematically inaccurate/absurd**, and that they had no idea why adherents of the RCS continued to make such manifestly absurd assertions.

and

> the assertions of the RCS are nothing more than **meaningless, superficial misunderstandings** of inter-universal Teichmuller theory on the part of people who are clearly *not operating on the basis of a solid, technically accurate understanding of the mathematical content and essential logical structure* of inter-universal Teichmuller theory.

Before going on to the more technical third part, the second part is an extensive discussion of elementary mathematical errors, as some sort of "explanation" of what's wrong with Scholze and Stix.

Essentially the claim Mochizuki is making in these first two sections is that the most accomplished and talented young mathematician in his field is an ignorant incompetent, and that everyone Mochizuki has consulted about this agrees with him. It's hard to imagine a more effective way to destroy one's own credibility and to convince people not to bother to try and make sense of the third section.

There's no direct reference to the Scholze-Stix document, just a reference to Mochizuki's own web-page about March 2018. Mochizuki has even gone to some trouble to stop anyone from accessing the Scholze-Stix document without first reading his own web-page.

As for the long discussion by Scholze and others of the problems with the proof that was hosted here and gathered here, the only apparent reference to this is

> More recently, one mathematician with whom I have been in contact has made a quite intensive study of the mathematical content of recent blog posts by adherents of the RCS.

followed by

> Despite all of these efforts, the **only justification** for th **logical cornerstone RCS-identification** of (RC-Θ) that we could find either in oral explanations during the discussions of March 2018 or in subsequent written records produced by adherents of the RCS were statements of the form
>
> "I don't see why not".

Update: To take a look at the preface, see here.

Comments

1. **lroberth**
   March 5, 2021

   Funny, I was just thinking about the conjecture and visited your page for the first time in months to see if you'd weighed in… sure enough! If I understand in layman terms, Mochizuki wants to imbue his objects with a history and this was flawed; regardless, many of us marvel how the most advanced mathematicians simply cannot agree on what should be the rules of logical argument itself. Is math fuzzy or just too hard to understand beyond this level except for just a few?

2. **Peter Woit**
   March 5, 2021

   lroberth,
   I think you're misunderstanding the situation. The experts in this field are in close to unanimous agreement there is no proof. The math is not fuzzy and the rules of logical argument are clear. What experts in the field are finding hard to understand is why anyone is still claiming there's a proof and why any journal would publish such a claim.

3. **lroberth**
   March 5, 2021

   @Peter, no I get it, I just don't get it why Mochizuki doesn't! He is an accomplished and brilliant mathematician after all, so why doesn't a widely-agreed logical disproof work with him and his supporters? This is the fascinating meta to a lot of us.

4. **Peter Woit**
   March 5, 2021

lroberth,
Mathematicians are human beings, not calculating machines. Over the years, I've become all too familiar with how hard it is to get someone who has invested their soul in an idea to realize that it doesn't work. The abc story is nothing compared to some others I could think of…

5. **Simon L.**
March 5, 2021

Oh, I wasn't aware that this is going to be published by the EMS! Why on earth did they do this? They should have been aware of the context. Ugh.

I cannot read the preface due to paywall. Is there any context provided at least?

6. **anon**
March 5, 2021

This might be nitpicking, but I wouldn't say that PRIMS is an EMS journal. It's published by the EMS Publishing House, but I don't think that makes it an EMS journal (unlike, for example, JEMS).

7. **Peter Woit**
March 5, 2021

Simon L./anon,

The EMS name dominates the web-page for this publication. I understand that contractually they may not be able to affect what PRIMS publishes, but I don't understand why they haven't issued a statement explaining the situation, but instead recently put out this
https://ems.press/updates/2020-11-16-prims-special-issues-2021

I still haven't accessed the journal through the paywall, but somewhere I can't now find did see the first page of the preface. It appears to be the only introductory material and is just a statement that Mochizuki did not participate in review of the papers, and I believe states that there were five referees. Nothing about Scholze-Stix or any indication that there's any controversy over the proof.

8. **Robert A. Wilson**
March 5, 2021

This journal is one of those old-fashioned ones that there used to be lots of, run by an academic institution and published by a commercial publisher who didn't interfere. We have become too used to the modern situation in which the commercial publisher interferes far too much in the running of a journal. To add to the confusion, this commercial publisher is linked to a mathematical society, which gives the false impression that the EMS endorses what is published in this journal. Nevertheless, I would consider it to be inappropriate for either the EMS or the EMS Press (which are separate organisations) to make any comment of the kind you suggest: it would amount to exactly the kind of interference from a publisher that you would normally suggest should be strongly condemned.

9. **Florian Stümpfl**
March 5, 2021

Just skimmed through the first pages of the Mochizuki manuscript mentioned in the update. Nothing of substance really, all he does is slander Scholze and Stix. So nothing new.

10. **JE**
March 5, 2021

Just a brief quote on the EMS reaction to the announcement of the upcoming publication of Mochizuki's papers on ABC, taken from an article published in Nature on April 3, 2020: "If the editors of the journal "waved away these criticisms" and published the paper without major revisions, it would reflect badly on them and on Mochizuki himself, says Volker Mehrmann, the president of the European Mathematical Society (EMS), which publishes the journal on behalf of the RIMS. (The EMS has no editorial control over the journal's content, Mehrmann says, and he was unaware that an announcement was imminent until contacted by Nature.)"

What strikes me as mystifying in this whole Mochizuki affair is not the fact that a highly reputed mathematician who has invested his soul in an idea, as Peter rightly put it, is finding big trouble to realize that it doesn't work, even to the point of engaging in ad hominem attacks on two equally reputed mathematicians in a seemingly desperate attempt to whisk away criticism on his work, but rather that he has been able to convince a small but important group of die-hard mathematicians in Kyoto and Nottingham to ignore the criticism and side unequivocally with him, and have two other highly reputed mathematicians, like Kashiwara and Tamagawa, making the announcement.

11. **Peter Woit**
March 5, 2021

Robert A. Wilson,
The EMS Press is owned by the EMS, and its president is the president of the EMS (this is Volker Mehrmann, mentioned by JE).

Yes, editorial independence is an important principle, but no matter what the context, publishers have some basic level of responsibility for what they publish. I'm not surprised that the EMS Press felt it could not intervene in a Kyoto editorial decision, was surprised that they thought it a good idea to advertise this issue and put it in a positive light.

12. **xyz**
March 5, 2021

The EMS publishes Portugaliae Mathematica and Rendiconti del Seminario Matematico della Università di Padova too. Some people have focused rather on the fact that the editor-in-chief of PRIMS is Mochizuki himself.

13. **Peter Woit**
March 5, 2021

xyz,
If you read Mochizuki's new document, you'll find his explanation of why his journal and his colleagues at RIMS were the only people "technically qualified" to referee his papers.

14. **David Roberts**
March 5, 2021

….and even tell people how they can buy their own special copy of the papers:

> Individuals interested in purchasing a print copy of the PRIMS special issue on Inter-universal Teichmüller Theory may contact us at preorders@ems.press.

as if it's a souvenir!

15. **random reader**
March 6, 2021

The next step seems obvious: set up an open online bulletin board, independent of the involved parties, for discussing and disputing the papers.

If Mochizuki is confident that he is right, he can not only vindicate his credit for solving ABC, but publicly "own" (pwn!) the entire mathematics community simply by answering questions in a public, archived forum. It would be the biggest flex in mathematical history, maybe all of modern academic history.

But if he were not entirely confident of his position, he would need to find a justification for not taking any further questions, and somehow de-legitimize any further scrutiny lest things get out of hand. The anonymity and obscurity of the refereeing process creates a circular, perpetual excuse —- if the referees approved the paper, then it must have been sufficiently well explained, and thus Mochizuki does not have to explain it to anyone else if he doesn't want to.

If referee comments (not identities) were published this illusion would be harder to pull off, even as a pretense.

16. **Peter Woit**
March 6, 2021

random reader,
Mochizuki and the PRIMS editors have here taken unjustifiable advantage of the traditional confidentiality of the refereeing process. In their statement publishing the papers, they do not acknowledge the existence of the Scholze-Stix objection or the consensus of experts in the field that the proof is flawed. They explain that a committee was formed to evaluate the proof and imply that it considered the objections, but have refused to make public anything from this committee justifying its decision. All we have to go on is Mochizuki's new document, and I don't think that's going to convince anyone.

As for an "open online bulletin board" debate, that's essentially already happened, hosted here April 6-19 of last year. I'm sure Mochizuki and those around him in Kyoto were aware it was going on, and they would have been welcome to participate, either anonymously or identifying themselves, but they chose not to. One could argue that the moderator (me) had a particular point of view, but I stand by the decisions I made about moderating comments, which emphasized allowing anyone who actually understood the mathematics involved to have their say. At this point, anyone who wants to evaluate this for themselves can read the earlier Scholze-Stix document and Mochizuki's response, + the discussion here, and now Mochizuki's new contribution. I think if one does this, it's clear there is currently no proof of abc, and that Scholze and others have much better ways to spend their time than engage with Mochizuki's claims that they are ignorant and just don't understand.

17. **W**
March 6, 2021

Another response to Mochizuki's earlier work that I was disappointed he didn't engage with was David Roberts' notes discussed here https://thehighergeometer.wordpress.com/2018/09/28/on-mochiukis-report-on-discussions/ which elegantly explains how the confusions/contradictions/difficulties he describes in various simplified examples in his response to Scholze and Stix can be easily resolved using the standard mathematical language of categories and functors.

The new document contains many other simple examples trying to get the underlying point across, and if there really is an underlying point being communicated, the first order of business would be to explain why the usual mathematical language is insufficient.

One part of the document I found interesting is when he says

" In fact, however, the RCS-identifications of (RC-log), (RC-Θ) do not resolve
such issues [i.e., of relating corresponding objects in (Θ±ellNF-)Hodge theaters at
distinct coordinates "(n, m)" of the log-theta-lattice] at all [cf. the discussion of
symmetries in Example 2.3.1, (iii)!], but rather merely have the effect of
translating/reformulating such issues of relating corresponding objects in
(Θ±ellNF-)Hodge theaters at distinct coordinates "(n, m)" of the log-theta lattice into issues of tracking the effect on objects in (Θ±ellNF-)Hodge theaters as one moves along the paths constituted by various composites
of Θ- and log-links."

This is striking to me, because to my understanding "tracking the effect on objects as one moves along the paths" is precisely what Scholze, Stix, etc. propose to do! This seems like conceding that their approach could be made to work, if one tracks these effects appropriately. (Which, of course, makes me think I am reading it wrong.)

The fundamental issue here is not that working with a single concrete object and tracking how it transforms along paths (i.e. compositions of various automorphisms) is better in some abstract, logical, philosophical sense, but rather that it is much less likely to conceal hidden errors, than Mochizuki's approach of defining an infinite number of distinct objects and identifying some of them by definition, even ones written by quite different notation, meaning that objects with quite similar notation mean quite different things.

Another quote I found striking was

"it should be emphasized that it is entirely unrealistic
to attempt to obtain the inequality of the final numerical estimate as the result of
concatenating some chain of intermediate inequalities since this is simply not the
way in which the logical structure of inter-universal Teichmuller theory is organized.
That is to say, in a word, the logical structure of inter-universal Teichmuller theory
does not proceed by concatenating some sort of chain of intermediate inequalities.
Rather, […] the logical structure of inter-universal Teichmuller theory proceeds by
observing a chain of AND relations "∧""

Similarly, the key point here is that (1) any argument involving combining a bunch of relations between points of different torsors for the real number can be logically translated into an argument involve combining a bunch of equalities and inequalities of real numbers by fixing an identification of each torsor with R, (2) any symmetries of the situation that existed prior to doing this are preserved, at the cost of introducing terms in the formulas describing those symmetries to account for isomorphisms between torsors that are incompatible with the identifications, (3) an argument written this way is less likely to conceal errors.

18. **Charlie G**
March 6, 2021

Not a mathematician here. All of this is far over my level, but while ABC is still a conjecture, I wonder if Mochizuki's attempted proof has revealed any techniques that are of more general value for other purposes – in the way Wiles' proof has – I gather – opened up useful avenues for other research.

19. **anon**
March 6, 2021

To be fair to Mochizuki, his manuscript has a section two for non-specialists like myself which shows he's sincere in trying to get people to understand his ideas.

Initially it didn't make sense to me and I was tempted to arrogantly dismiss it as gibberish; but after reading it a few more times its main points are becoming profoundly clearer: how apparent contradictions disappear in mathematics once the overall structure is restructured in some part, despite the total information content remaining the same.

20. **Peter Woit**
March 6, 2021

anon,
Mochizuki likely is sincere in his belief that those who think his proof is flawed are making elementary mistakes in their reasoning. The problem is that this is not even slightly credible. If you know anything about how the best mathematicians work, his trying to explain why Scholze disagrees with him by listing elementary mistakes a student might make comes off as just bizarre.

One thing that strikes me about this document is that Mochizuki sadly now appears to lack colleagues willing or able to tell him not to do things that destroy his own credibility.

21. **André**
March 7, 2021

Peter, Charlie G,

the question whether Mochizuki has produced valuable insights or tools is the central one. The question will decide whether, in the future, people will treat him like Wiles or like a crackpot. Is there any information on this? As an outsider, I have a second question: the term "inter-universal" makes no sense at all. Why is it called that way?

22. **Pedro**
March 7, 2021

From the 65-page document:

"There is a fundamental difference between criticism of a mathematical theory that is based on a solid, technically accurate understanding of the content and logical structure of the theory and criticism of a mathematical theory that is based on a fundamental ignorance of the content and logical structure of the theory."

That is totally right. But pretending that the time employed by Stix-Scholze (who have more things to do) just led them to "fundamental ignorance" says a lot about his thinking process. And about the clarity of his writing.

Also all the praise of PRISM and its history and the editors in the preface to the publication, and dismissing other journals (Annals, Inventiones…) as unsuitable for publication only point the reader to doubting the refereeing process.

23. **The Vlad**
March 7, 2021

What's the deal with the odd stylistic structure of the Mochizuki document (i.e. littered with bold text, italics, randomly dispersed quotation marks, no numbering of equations)? I've never seen anything like it in the math literature. Is this just some quirk of his or is it standard in some math fields, or something else? I found it very distracting.

24. **Jon1**
March 7, 2021

Apparently there are also some people interested by Mochizuki's work in Lille, he will answer questions in a seminar in a few weeks and other folks will talk there later on, see this page https://math.univ-lille1.fr/d7/sarit

25. **UF**
March 7, 2021

Let me draw attention to p.58/ step 3 of the descent process in Mochizukis manuscript, which is (very superficially) perhaps the most counterintuitive of the descent process described by Mochizuki: Here one passes from (0,\circ)^\perp to (0,0)^\perp. How can this be "passing to weaker information", if we go from unspecific vertical \circ position to the specific vertical position 0?

As far as I understand, the point is the following: we can in the reconstruction algorithm reconstruct all data \pi_1, monoids and the action on monoids etc. up to some indeterminacies. However, keeping in mind the algorithm these data were reconstructed from, these reconstructed data (are claimed to) contain more information than the information contained just in the output data (forgetting about the algorithm constructing this output). One may thus decide to forget some of this information, and replace some (not all) of the reconstructed objects by abstract, unrelated ones. In this step 3 one replaces reconstructed monoids by abstract monoids and builds with the algorithm some "shells" in these abstract monoids (instead of in the reconstructed monoids). The claim is that the reconstruction algorithm still works (up to further indeterminacies Ind2) even if the monoids are unrelated, and not reconstructed like other data showing up in the algorithm.

If one accepts this, one can take advantage of this by taking as the unrelated monoid the specific one which is shared via the theta-link from the 1-column. Whereas before (in step 2) the input data into the algorithm was vertically invariant, it is no more so with this specific choice of abstract monoid. On the other hand the (via step 3) reconstructed data has now some relation to the q-pilot in the 1-column: the monoid in which the shells are constructed comes from the q-pilot via the theta-link. (Breaking this vertical invariance of the input data is essential to prove anything meaningful related to the q-pilot, which is located at a specific vertical position).

This may also indicate a reason to pass from X to \pi_1(X): In IUT, one decides to share across the theta-link a "part" of $\pi_1(X)$ (or X), which is "easily" describeable in terms of \pi_1(X) (but not so much in terms of X), namely for instance the monoid on which \pi_1(X) acts (this monoid can be viewed as "part" of \pi_1(X), since a copy of it can be reconstructed by $\pi_1(X)$).

26. **Peter Woit**
March 7, 2021

The Vlad,
It's a quirk of Mochizuki's. Again, I think an increasingly large part of his problem is that he has no one around him willing or able to advise him to not do things that don't help with his credibility.

Jon1,
This is part of a program organized by Collas out of Kyoto, see
http://www.kurims.kyoto-u.ac.jp/~bcollas/IUT/IUT-schedule.html
In all the materials linked to there, again, no mention even of the existence of Scholze-Stix, much less any discussion of the problem with the proof they have pointed out. The Kyoto standpoint is pretty uniformly to try and pretend that Scholze and Stix don't exist.

Charlie G/Andre,

One big problem with publishing the IUT papers without acknowledging that the consensus of the field is that they contain serious error is that people will now have trouble using anything in those papers to build on and do something else with. If you use results from those papers in a proof, you're going to need to show that they're independent of the problematic parts of the papers if you want to publish your results outside of Kyoto. Essentially this may create a fork in the math literature.

27. **xyz**
March 7, 2021

Charlie G/Andre,

You're raising a very good question, the answer to which (so far) strengthens the sceptics' case: Months after Wiles' first announcement, many original, universally accepted results were produced on the basis of his methods. (That was already before the full proof of the part of modularity conjecture required for Fermat's Last Theorem). In the claimed proof of the ABC-conj. nothing remotely like this has happened during all those years after its announcement. This may indicate something about the applicability/generality/strength of the tools and insights employed for the claimed proof.

28. **A. Rukhin**
March 7, 2021

" Both Professors Kashiwara and Tamagawa have an outstandingly high international reputation, built up over distinguished careers that span several decades."

The mention of these two stands out as somewhat interesting: what have these two said publicly about the latest developments? Apparently, they supported the decision to publish…

29. **Peter Woit**
March 7, 2021

A. Rukhin,
Kashiwara and Tamagawa chaired the committee that decided to publish the papers, and appeared at the press conference last year announcing this. Mochizuki's main argument at this point is to pit their reputations against Scholze's, and politically this may work well in Kyoto, less well elsewhere.

Kashiwara is not an arithmetic geometer, but Tamagawa is, and he should be in a good position to evaluate Scholze's argument that the proof is flawed. That he made the decision to publish implies that he understands why Scholze is wrong and how the proof overcomes Scholze's objections. Tamagawa is at RIMS, has collaborated with Mochizuki, and should be very interested in Mochizuki's IUT ideas and how they prove abc. As far as I know though, he has not spoken at any of the various IUT workshops, or written anything about this.

The one thing that has been missing here has been an explanation of how the proof overcomes Scholze's objections from one of the people other than Mochizuki who supposedly understands the proof. This is something that Tamagawa should be able to provide, and it would be very helpful if he were to do so.

30. **Timothy Chow**
March 8, 2021

lroberth: You used the term "logical disproof," but the Scholze-Stix argument falls just short of that. As I understand it, they are not explicitly claiming that the notorious Corollary 3.12 is provably false. What they are saying is that Mochizuki's argument fails to establish Corollary 3.12. That is, the objection is that there is a glaring *gap* in the argument. In theory, the question of whether there is a gap in a mathematical argument that B follows from A is an objective one, because someone who says there is no gap should be able to fill in all the intermediate steps in the chain of reasoning from A to B on demand, to the point where even a machine could check that each step is correct. The catch is that this process might require, say, one million intermediate microsteps, so in practice, mathematicians don't actually produce all the intermediate steps explicitly. An expert might be able to see how to get from A to B without any further explanation; a less expert mathematician might require ten intermediate macrosteps spelled out; a graduate student might require a hundred intermediate mesosteps, and so forth.

What happens if mathematician X claims that B follows from A but mathematician Y does not see it? If X and Y have a healthy relationship then X will spell out some intermediate steps for Y's benefit, and will keep increasing the amount of detail until either Y is able to see how to supply the remaining details, or X realizes that there is a problem with the argument. But if X and Y do not have a healthy relationship, then X might lose patience at some point and stop cooperating. That is basically what has happened here, except that a lot more than two mathematicians have gotten involved, and a sizable sub-community has become alienated from the rest of the community.

These kinds of rifts are rare, and it is not just laypeople who are perplexed. Most mathematicians are watching the IUTT fiasco from the sidelines with amazement. But perhaps what we should really be surprised at, and grateful for, is that such rifts don't happen more frequently. Human nature being what it is, sociological rifts are to be expected, and it is a wonder that the mathematical community functions as well as it does.

31. **David Roberts**
March 8, 2021

@W

Luckily Peter Scholze confirmed in the previous extended discussion that he and Stix had internalised and compensated for Mochizuki's hangups that I describe around "copies". My observation is only a very tiny contribution trying to unravel what's going on.

There's stuff in the new document that utterly mystifies me (I've not read or even looked at the whole thing). Section 2.3 for instance is … Not Even Wrong.

32. **André**
March 8, 2021

The 65 page document has a clear message: to understand what IUT is, you need to think about it for 6 months or 3 years (section 1.6), come to Japan (sections 1.6 and 1.9), talk to "M" for a long time, and think about it, discussing with "M", until you understand it. As a result, the worldwide number of people who understand it is of the "order of 10" (section 1.6), centered around Kyoto.

The math examples that "M" gives are so simple that nobody will ever believe that Scholze and Stix stumbled over such issues.

"M" clearly states, page over page, that Scholze and Stix are stupid. In fact, the document states that all his critics are stupid. Above all, the document shows that "M" is abusive towards people of different opinion.

The whole paper is clearly written by an aspiring leader of a sect. There is no need to come to Japan to understand this. I have lived in Japan, and this type of sect leaders is common there. It is sad to see that such people exist in mathematics, and especially sad to see that they exist at Kyoto University, one of the best in Japan.

33. **Peter Woit**
March 8, 2021

André,

I'm not sure that "sect" is the right name for the weird phenomenon going on here, but if it is, this "sect" has not been very successful at gaining adherents. Back in 2018, according to Fesenko, 12-18 people had studied the proof sufficiently to understand it and believe it correct, see
https://www.quantamagazine.org/titans-of-mathematics-clash-over-epic-proof-of-abc-conjecture-20180920/
Two and a half years later, Mochizuki now describes the number of people who understand IUT as "roughly 10".

A weird aspect of this story is that almost no one admits to actually understanding the proof themselves. Back in 2014, Mochizuki described the main people working on checking the proof as Yamashita, Hoshi and Saidi. Many years later, the only documents not from Mochizuki that I'm aware of explaining the proof and addressing the Scholze-Stix argument are from Yamashita. Hoshi has also written something pre-Scholze-Stix in Japanese, and participated in discussions with them. But as far as I can see, there's no evidence that anyone besides Yamashita and Hoshi can publicly vouch for the proof and answer questions about it. PRIMS had some undisclosed number ("several") of referees (quite possibly including Hoshi and Yamashita), but it's unclear how many of them could vouch for the whole proof (as opposed to just checking some piece of the IUT papers).

If this is a "sect", it's a small one, arguably getting smaller.

34. **Peter Woit**
March 8, 2021

Timothy Chow,
I don't think your portrayal of the current situation as due simply to a lack of detail is accurate.

Scholze-Stix not only say that there is a gap, but give an argument for why the gap cannot be closed using Mochizuki's methods. The debate hosted here last year mostly revolved around whether that argument was bullet-proof or whether there might still be some way to get Mochizuki's methods to work. What did not show up here (or anywhere else) was anyone claiming they knew how to do this and could provide details.

It's not the case that Mochizuki has lost patience and stopped engaging with the Scholze-Stix argument. He just put out 65 pages supposedly doing this. The problem is that what he is doing is classic behavior of someone who has lost an argument but won't admit it and wants to fight on. I think those 65 pages will do a lot to convince mathematicians that he does not have a proof. Scholze and Stix are the ones who now seem to have stopped responding, for the good reason that Mochizuki has no serious counter-arguments, just insults.

By the way, I just noticed this from Scholze, in case anyone thinks that the publication might have changed his mind:
https://t.co/0zbGxpgAfy?amp=1

There has also been a long discussion of this at Reddit, see
https://www.reddit.com/r/math/comments/lz4ccm/mochizuki_strikes_again/
I recommend the comments by "whisperfiends"
https://www.reddit.com/user/whisperfiends/
who makes an attempt to follow Mochizuki's claims that Scholze-Stix are confused about something basic, is suspicious that it is Mochizuki who is confused about this.

35. **W**
March 8, 2021

@Charlie G and André:

There exist other works which apply Mochizuki's language to other questions of anabelian geometry. However, my understanding is that this language is not essential, and the works would be shorter and clearer without it.

@The Vlad:

If you look at his old papers like "The local pro-p anabelian geometry of curves", when he was doing work that everyone agrees is correct (and brilliant), you can see some strange formatting, but much less (mostly a lot of italics – also the equations aren't numbered, but that isn't too strange in the more algebraic fields of mathematics).

@Peter Woit

I don't think there will be so much of a problem with people trying to cite the papers but avoid the problematic parts, simply because there doesn't seem to be much worth citing in the unproblematic parts. But there certainly could be a fork in the mathematics community regardless.

@David Roberts

My interpretation of what Peter Scholze says there is a bit different. I just bring your observations up because they are very helpful to me!

Isn't 2.3 also the exact kind of thing you discussed – gluing topological spaces is a colimit of a diagram, and if you define diagrams correctly you can't get into trouble based on whether you identify things or not?

36. **JE**
March 8, 2021

As of now, the English-speaking media have turned their backs on the publication of Mochizuki's papers. In fact, one can hardly find any mention of it other than on this blog or reddit. The situation vastly differs from last year's, when many articles quickly announced their publication. Be it the result of poor communication strategies on the part of the EMS or exhaustion, Mochizuki's attempted proof of the ABC conjecture seems to be a dead issue in Western media's terms. Coupled with his 65-page manuscript, containing plenty of arguments from authority, implicit ad-hominem attacks and appeals to herd behavior, the damage he is inflicting on his reputation by either refusing to accept that the proof is flawed or being able to provide valid counter-arguments is enormous, as Peter said.

And this is really unfortunate, because he has proved to be an extremely talented mathematician. The fact that no senior mathematician or anabelian geometer in Kyoto has been willing or able to convince him otherwise may be hard to grasp by Western standards. Mochizuki is a highly respected mathematician in Japan, who was appointed as editor-in-chief of PRIMS few months before his papers on IUTT were released (and from being excluded from the editorial committee, paradoxical as it may seem), and one of the most prominent figures at an institution with a strong background of success, including Fields medalists Hironaka and Mori, among many other respected figures.

At this point, I seriously doubt that this affair may even create a fork in the math literature. Any figures, other than Mochizuki, who have implicit or explicitly sided with him may slowly backtrack and even take advantage of the media impact of this affair to propel their careers in Japan or elsewhere. The number of mathematicians who have published explanatory reports on his proof, like Yamashita and Hoshi, has even decreased in the last few years. And the highly-respected figures who have been involved in the process (as co-editors-in-chief) have solid mathematical careers and are not facing a reputational risk in any way comparable to Mochizuki's.

37. **David Roberts**
March 8, 2021

@W

The idea that having an equivalent subcategory of Top where there is only a single terminal object means that the somehow [0,1] (called \mathbb{I}) becomes the same as S^1 (called \mathbb{L}) is laughable. The same argument would imply that **every single topological space** collapses to a single point, since every one-element subspace is the "same", according to Mochizuki (as in: why are the endpoints of [0,1]—in more proliferation of useless notation, called \alpha and \beta—singled out? you could replace them by any pair of points of [0,1], or any space). The argument confuses taking a colimit with taking a skeleton, as far as I can tell around the verbiage (why do we need to be reminded of the standard topology on [0,1], and that it is a topological manifold with boundary?)

38. **Timothy Chow**
March 8, 2021

Peter, I pretty much agree with what you say. All I was trying to do was explain to lroberth that "logical disproof" isn't quite the right term. We have seen how Taylor Dupuy has argued that the Scholze-Stix argument isn't, as you put it, bullet-proof. I have privately asked other experts for their opinion, and a common response I get is a shrug and a comment that Mochizuki hasn't provided a clear argument. I think that this behavior (as well as the behavior of Mochizuki's quiet supporters) is more puzzling if there really is a "logical disproof," but it's easier to understand if there is a gigantic gap.

As for "lose patience," perhaps I should have said "lose his cool." Also I didn't say "stop engaging"; I said "stop cooperating."

39. **S**
March 8, 2021

I've noticed an (understandable) resistance to taking Scholze/Stix's word for it, among interested onlookers (mostly non-mathematicians, I think). If I can't engage with Mochizuki's material or Scholze/Stix's objection to it, I should remain neutral, goes the thinking. To these people, I would emphasize the fact that it's been 8 years, and if IUT were actually right, it's overwhelmingly likely that someone would have written it down in an understandable and uncontroversial form by now. The specific objection of Scholze and Stix brings this point into greater focus, because we know exactly which aspect of the theory must be zoomed in on, in order to clarify matters. There is just no plausible explanation for why this hasn't happened yet, except that it can't be done.

Things could change in the future if Mochizuki or someone else provides new mathematical content. But that wouldn't retroactively change the fact that there's no valid proof now.

40. **Jim Eadon**
March 9, 2021

Peter,
The publishing house must surely be aware of the explicity identified error(s) in the proof, identified due to Scholze and Stix.
If they do publish the paper, and they fail to acknowledge the identified error(s), then are they not fraudulent, in some way, for selling fraudulent documents with false advertising?
Could they be accused of (even illegally) misleading consumers? There are legal consumer-rights acts in many countries, where you're not allowed to mislead consumers.

41. **Timothy Chow**
March 9, 2021

I just noticed that on March 18, Mochizuki is conducting an "Interactive Q&A Session on the Essential Logical Structure of Inter-universal Teichmüller Theory." It seems that this session is not open to the public, since the List of Participants page says, "In order to ensure a cohesive and focused working group, note that participation is restricted to a limited number of participants, and that registration is done by invitation only." I wonder if the session will be recorded and made available to the public later. Over 30 people are listed as participating; I wonder if any of them will dare to ask a difficult mathematical question? Failing that, will anyone request that the "mathematicians with whom I [Mochizuki] have had technically meaningful discussions concerning the assertions of the RCS" (saying that Scholze and Stix's objections are "obviously completely mathematically inaccurate/absurd") identify themselves?

42. **Peter Woit**
March 9, 2021

Jim Eadon,
I know for a fact that the EMS Press is aware of the issue, am somewhat mystified by the fact that they promoted this issue of PRIMS and have so far not apparently done anything to address the problem. Likely they have contractual arrangements such that they can't interfere in editorial decisions of PRIMS, but I find it hard to believe there is nothing they can do here.

43. **The Vlad**
March 9, 2021

@W

I took a look at the M paper you mentioned, and even there I find his style and the paper structure highly unusual (e.g. no abstract, acknowledgements section in the introduction, the unnecessary quotation marks and italics everywhere). He also makes some sweeping meta-mathematical statements, such as:

"Moreover, it is the feeling of the author that,more than the technical details of the state-ment of TheoremA, it is this fact – i.e., that the Grothendieck Conjecture for hyperboliccurves is best understood not as a global, number-theoretic result, but rather as a result inp-adic Hodge theory – that is the central discovery of this paper."

Putting all this together, it paints a picture of M abandoning or disregarding standard math communication conventions in favor of his own idiosyncratic style (this also fits with his refusal to travel overseas to convince others of his work). As PW points out, this seems to indicate an inability of mentors, colleagues and.or reviewers to dissuade M from behaving in a way that may harm his reputation.

44. **Peter Woit**
March 9, 2021

The Vlad,

Mochizuki's typographical idiosyncracies are easily ignored, and his not liking to travel isn't unusual. I actually like the "sweeping meta-mathematical statements" that tell you what the author thinks the "big picture" is, often find them helpful to understand what the author is doing. When the papers first came out, they were long and technical, beyond my abilities or patience to try to read. Later Mochizuki came out with
http://www.kurims.kyoto-u.ac.jp/~motizuki/Panoramic%20Overview%20of%20Inter-universal%20Teichmuller%20Theory.pdf
which did give a readable overview of what he was trying to do.

After talking to some experts it became clear that they could understand what he was trying to do, they just couldn't understand whether what he was trying to do really worked, because crucial parts of the argument were unclear and not well explained. Scholze changed everything by pointing to specific place where the argument could not work for general reasons, and most experts are now convinced by that.

So, the real problem here is not Mochizuki's idiosyncracies, it's his behavior when faced with someone pointing out a flaw in his argument.

45. **David Roberts**
March 9, 2021

For what it's worth, I think my previous comment was not quite right. I thought through what was going on in this weird example a bit more in a blog post here. Now I think it's just a straw man argument, at best.

46. **mahmoud**
March 9, 2021

Timothy Chow,
as Scholze repeatedly said himself in prior comments to this blog Mochizuki could easily clear up the issue regarding the Scholze-Stix objection by pointing out where in their argument a non-commutating diagram shows up that in fact will commutate provided one replaces it with one of his "mutually alien copies" diagrams. Instead, however, he keeps putting out new documents with increasingly bizarre analogies (the latest where he substitutes a real number for the integral sign is a new record).

Talking about a "gap" in the proof or the S&S objection as a "logical disproof" muddles what is a quite simple situation: there just is no proof that has been communicated in an intelligible fashion. Thus I also take issue with Woit saying Mochizuki's idiosyncracies can be ignored; in fact his highly idiosyncratic style (of communication and – apparently – thinking about perfectly conventional mathematical topics) has prevented any progress on understanding his purported proof from the very beginning.

47. **DrB**
March 15, 2021

Has someone taken a look at this recent (Nov 2020) "RMS preprint" by Mochizuki et. al.: http://www.kurims.kyoto-u.ac.jp/~motizuki/Explicit%20estimates%20in%20IUTeich.pdf

It is stated that it contains a proof of Szpiro's conjecture and an alternative proof of Fermat's last theorem.

48. **Peter Woit**
March 16, 2021

DrB,
This depends on the flawed proof in the IUT papers, so is also not a proof. It will be interesting to see if any journal other than PRIMS is willing to publish it.

49. **John**
March 17, 2021

I understand where Timothy Chow is coming from. Someone not familiar with academic mathematics might wonder why a complex paper can take so long to verify. The reason is that most papers will have a dozen gaps in them, with the understanding that an expert can easily fill them. So when a mathematician encounters corollary 3.12 his first instinct is not 'this argument is non-sensical' but rather 'I don't have the background required to fill in the gaps'. So, how do errors ever get found? The clearest but most difficult way is to prove that one of the statements in the paper is wrong, this is not something Scholze and Stix did, and it can't find out wrong proofs of true statements either. Another way is to take an example of the things in the statement, one where you understand how to fill in the gaps better, and show that some of the logical implications does not follow in this example, this is less decisive but often does point to a genuine gap. The way Scholze and Stix did if I understand correctly is to introduce modifications to the theory, so they are talking about different objects, but these objects have enough properties in common with the original theory that the arguments seem to follow, but the conclusions are false. There are two ways this can happen, either the argument is wrong in some way it can't be filled easily somewhere in one of those gaps, or the modified theory is different in some important ways (contained in those gaps in understanding). My understanding is that Mochizuki claims the second of course, but he hasn't pointed any 'important' difference, important is a bit of a value judgement, so instead you could say he hasn't pointed to one that helps understand the gaps better. So most people at this point believe the argument to be either wrong or at least not convincing.

What I find surprising about this is that several serious mathematicians seem to be convinced of Mochizuki's proof in ways that they have a lot of trouble communicating, I don't recall anything like that happening before.

50. **Peter Woit**
March 17, 2021

John,
About
"several serious mathematicians seem to be convinced of Mochizuki's proof in ways that they have a lot of trouble communicating"
I'd put it a bit differently. There is literally nothing written down by a mathematician other than Mochizuki engaging with the Scholze-Stix argument and showing that it is wrong, and Mochizuki's engagement with the argument has no credibility.

As far as I know, Yamashita and Hoshi are the only two people besides Mochizuki supposedly understanding the proof and able to provide a counter-argument to Scholze-Stix, and Hoshi has not written such a counter-argument down. Yamashita has written a long survey of the proof, but it makes no explicit reference to Scholze or Stix or

their argument.
Mochizuki's own attempts to engage with Scholze-Stix involve a large amount of absurd ad hominem attacks on their competence, coupled with a refusal to directly reference and deal with the core of their argument. This is the sort of thing you expect from someone who has no real counter-argument. As a non-expert trying to read the more technical parts of Mochizuki's supposed counter-argument, I can't follow the details, but I also can't find anywhere where he engages with the arguments Scholze has made here. He goes to a lot of trouble to not use Scholze's name and not refer directly to anything he has written. Checking with people who are experts to ask if they see something I'm missing I'm told it's not there.

51. **DrB**
March 17, 2021

Perhaps part of the difficulty is that the unwritten rules for acceptance of a proof within mathematics seem to be adhered by. These rules state that the elders need to accept the proof as correct. The elders usually means experts in the field. Unfortunately, as is often the case, the field of Anabelian Geometry is very small in terms of the number of experts. Scholze works in Arithmetic Geometry. Fields medal or not, he is not an expert in Anabelian Geometry. It seems to me people like Fesenko, Yamashita and the anonymous referees that accepted the paper count as the experts. Their verdict counts by the unwritten rules. Who can really say that it is necessary for the experts within a field to address any kind of criticism raised, except to state that the criticism is unfounded based on an insufficient understanding of the theory? If they were in fact obligated to do this it would change the entire paradigm of peer review. Experts would be obliged to address endless amounts of misunderstandings by mathematicians that do not work in the field in question. Publication could be protracted indefinitely as a result. It is pretty clear by now that the system is completely broken. We need objective or objectifiable methods to validate results in mathematics.

Btw that preprint of Mochizuki et. al. that I have mentioned is already being cited in published work:
https://www.sciencedirect.com/science/article/abs/pii/S0022314X2100055X?dgcid=rss_sd_all

52. **Peter Woit**
March 17, 2021

DrB,
Anabelian geometry is a subfield of arithmetic geometry. The "Scholze is just too ignorant to judge work in anabelian geometry, and too incompetent to realize he's out of his depth" argument isn't plausible, and if you do believe that, he was joined in this by Stix, who is an expert in that subfield.

The paper you mention evidently is based on old, pre-IUT work, just mentions the new IUT-based claims, but does not use them. It will be interesting to see if any reputable journal will publish a paper claiming to prove something assuming the flawed IUT-based stuff.

53. **Jens Franke**
March 19, 2021

Dr. B,

while it is obviously reasonable to cover the identity of referees who decide against a paper (eg, to protect them against retaliation), it is less obvious why the same thing should be done for the referees who give their OK to a paper. So maybe this is what at least some journals should do?

For me, someone who OKs a paper should be able to explain it at least to experts of neighboring fields. Also, it makes sense to mention the referees of a published paper to credit them for the work they had to invest. In some cases this is known (eg, Herbert Federer being the referee for the hard case of the Nash embedding theorem). In the case of the series of IUT papers by Mochizuki, the amount of work required to go through it must be huge, even for experts in anabelian geometry. Why not credit them for this effort?

Outside the field of mathematics/theoretical physics, I know of at least one example (Organic Syntheses) who seem to do just that. They did so when they started in the days of world war I and seem to have stuck to this habit ever since.

54. **Peter Woit**
March 19, 2021

Jens Franke,
In this case, having your name made public as a referee who approved the IUT paper might be problematic.

On the other hand, the names of the committee at PRIMS that approved the paper were published with the paper. Those mathematicians agreed to publicly put their reputation behind an approval of the proof. It seems to me that they're the ones who need to provide an explanation. They have decided based on some argument that Scholze-Stix are wrong and the consensus of the arithmetic geometry community is wrong. What is that argument? Is it Mochizuki's argument that Scholze-Stix are incompetent? Is it something else? If it's based on a report from a referee, they should be able to provide the substantive part of that report, stripped of the identity of the referee.

55. **Jens Franke**
March 19, 2021

Peter Woit,

yes they give the names of the committee members but they just say "Several mathematicians kindly accepted an invitation to referee the papers; …". So it does not list anyone who claims to have made his way through the proof. This, of course, is the usual way of doing things. For me, it does not make that much sense, but the only journal I know of which does not have this approach is Org. Synth.

I do not see why it would be problematic to be named as the person who gave his OK to the IUT series of papers, provided that you are able to defend your opinion. After all, it would be a big honour and for most mathematicians it would be the most important thing they have done in their lives.

56. **Peter Woit**
March 19, 2021

Jens Franke,
I think it's extremely implausible that there is an anonymous referee who has a convincing counter-argument to Scholze-Stix, but that everyone involved in this is keeping it secret.

On the other hand, it's unfortunately plausible that the referees agreeing to approve the proof were people who might have reason to fear significant career implications if they took a stand that the proof was incorrect. The proof should have been refereed by an independent journal and independent editors, not by Mochizuki's colleagues at RIMS.

57. **HM**

March 19, 2021

What could be the long-term consequences of such a fork in the mathematics literature? Does it become a political statement whether one assumes ABC?

58. **Jens Franke**
March 19, 2021

Peter Woit,

They speak of “several mathematicians”, so there are several persons possibly involving Fesenko as well. But if PRIMS had the policy of publishing the names of referees giving their OK to a paper, they would not be able to make an exception for the IUT papers and we would know rather than merely suspect.

I now think your “having your name made public … might be problematic” applies to the hypothetical case of a journal J run by persons close a powerful person X publishing an article by X choosing a poor devil D working under X as the referee, with D being practically forced to OK the paper. Obviously, it would be embarrassing for D to be named as a referee. But then, it would be even worse for the editors of J as it would force them to openly admit they picked someone close to X. Would they still dare to do so?

59. **Peter Woit**
March 19, 2021

HM,
Since there are so few mathematicians who accept that Mochizuki has a proof, the impact of this is very limited, essentially a small number of people cutting themselves and their work off from the rest of the math community. It seems likely this is how things will stay. A larger scale split in principle is possible, hard to imagine how that would evolve, I don’t think we’ve seen anything like in modern mathematics.

60. **Peter Shor**
March 19, 2021

Jens Franke:

Occasionally, papers get published despite one terrible referee report. In this case, you really shouldn’t make the names of the person responsible for the negative report public. But I suppose it would possible to make the names of referees who gave positive reports public.

61. **Jens Franke**
March 19, 2021

Peter Shor,

Yes, its the positive ones which should be made public.

62. **Peter Woit**
March 19, 2021

All,
I’d like to discourage this turning into a general discussion of refereeing practices. This is an extremely unusual case, with general issues of referee anonymity I don’t think particularly relevant. In particular, if the referee’s names were known I doubt that would change anyone’s mind about the viability of the proof. What would change minds would be a serious mathematical counter-argument to Scholze-Stix, from any source.

63. **Mizan R Khan**
March 19, 2021

A result published in a good journal does not necessarily mean that it is accepted by the general mathematical community. A good example of this phenomena is the work of Heegner on the the class number 1 problem. He published his proof in 1952, but it was only in the late 60’s that the number theory community acknowledged that the proof was essentially correct. This was through the efforts of Birch and Stark. Without their intervention, it is conceivable that Heegner’s work would still be viewed as a failed attempt at proving the class number 1 problem.

64. **David J. Littleboy**
March 21, 2021

FWIW, a quick Google revealed a short article in the Asahi Newspaper* March 5, 2021 digital edition on the Mochizuki question. A quick and dirty translation:

“A paper by Prof. Mochizuki of Kyoto University that is said to prove the abc conjecture has been published on March 5th after a consecutive period of 8 and a half years since its submission. The publisher, the EMS publisher, has responded to Asahi Newspaper inquiries. It will be published first in electronic form and then in printed form a month later by PRIMS, an international mathematical journal that publishes mathematical research”

“The paper is titled (title here) and since it comes to a total of 720 pages of English text, PRIMS will dedicate a single issue, which normally would consists of five or more papers, to this paper. Since the paper is extremely difficult and there are mathematicians who doubt the correctness of the proof, EMS is taking this opportunity to make this work more widely known.”

I find that last sentence rather interesting. (The Japanese does not use quote marks, and uses a Japanese abbreviation for EMS (without explaining it), but it sure looks to me that EMS told the Japanese newspaper that there were doubts about the proof.)

*: https://www.asahi.com/articles/ASP355S0CP35ULBJ00Q.html

65. **AZ**
March 22, 2021

About the Asahi article, the part about mathematicians doubting the proof, it says that RIMS (数理研; not EMS) is taking the opportunity to make this work more widely known. The part about a response from EMS Press in the first paragraph only concerns the fact that it will be published electronically one month before the printed version.

The article is actually longer. In one part it says that the papers are so novel/eccentric and hard to understand that even mathematicians say “they don’t understand where they don’t understand” them, as if the papers “came from the future”. A well-known mathematician has also said “there is an uncorrectable gap in the way the proof proceeds”, therefore the verification took the unusually long time of seven and a half years to complete.

This is only the public part; the rest of the article is behind a paywall and I haven't tried to access it.

66. **Dan Winslow**
March 22, 2021

From my read they are definitely still saying that it's considered 'proved', it just took longer because of that pesky mathematician.

67. **TonyG**
March 22, 2021

Actually, the May 3, 2020 issue of the same newspaper had a story quite a bit more critical of the claim than the recent one: https://tinyl.io/3lQo

68. **Per Östborn**
March 22, 2021

Found a Japanese article which says (in Google's translation):

'Some overseas mathematicians are skeptical about the content, but Professor Akio Tamagawa of the institute, who was involved in the editing, said, "The counterarguments have been exhausted and may remain parallel in the future." I hope that young researchers will read the treatise seriously and that subsequent research such as improvement, generalization, and application will appear.'

https://this.kiji.is/740458703363735552

As a layman unable to make a judgement of my own, I wonder why nobody seems to discuss the technical third part of Mochizuki's document. If the treatment there is correct, then the simplifications made by Scholze and Stix are invalid, and their objections irrelevant to the validity of Mochizuki's claimed proof (if I understand the structure of the arguments correctly).

Is this because the content of the third part is 1) wrong, 2) meaningless/irrelevant, 3) incomprehensible, or 4) nobody thinks it's worth the effort trying to understand it?

69. **Peter Woit**
March 23, 2021

Per Östborn,
I don't want to speak for others and I'm not an expert, but when I look at Mochizuki's third part all I see is what seems to be a repetition of the argument of his papers, with no attempt to engage at all with Scholze-Stix. He doesn't refer anywhere in that section to them, to anything they've written or said to him explaining the problem. In particular Scholze has repeatedly asked for something very specific that Mochizuki should be able to produce if their argument is wrong (a diagram with certain properties). No one else has been able to produce this, and Mochizuki just ignores the question (along with all the rest of the substance of what Scholze is saying).

70. **Greg Price**
March 31, 2021

In that Asahi article from last year, it's also interesting that they give it quite an explicitly geographical framing. The headline is:

ABC conjecture: "Is the proof real?"
In the West, objections one after another

And that accurately captures the framing in the first paragraph, which says that on the subject of the paper, "mainly in Western countries, the discussion has become 'has it really been proved?'".

(Or one might read "Europe and America" what I've translated as "the West" or "Western countries" — the original says 欧米, which literally means the former but commonly means the latter.)

71. **Taro Nakano**
April 2, 2021

In the April 3 issue of the Japanese business magazine Weekly Diamond, Professor Fumiharu Kato of the Tokyo Institute of Technology wrote about the reasons for the "misunderstanding" surrounding IUT. He is a researcher who has regularly held seminars with Mochizuki to discuss IUT and is known as an evangelist of IUT in Japan.

This article is a column for the general public and has no technical content, but I have translated it into English for your reference.

https://tar0log.tumblr.com/post/647331299812638720/column-by-prof-fumiharu-kato-on-the

The researchers around the Kyoto University group who support the Mochizuki paper do not often mention that the paper has been questioned overseas. I think this column is a rare example of a supporter of the Mochizuki paper speaking out about the controversy.

72. **Peter Woit**
April 2, 2021

Taro Nakano,
Thanks. Kato is just following Mochizuki in his claim that Scholze and Stix are just incompetents making elementary mistakes. This is not plausible or a serious response to their argument.

73. **Taro Nakano**
April 2, 2021

FYI, I translated into English two articles published by the Asahi Shimbun at the stage when the Mochizuki paper was accepted in 2020 and published in 2021. I have translated the entire articles including the paid part.

– May 3, 2020, Asahi Shimbun article, "ABC Conjecture: 'Is the Proof True?'"
https://tar0log.tumblr.com/post/647382973188112384/may-3-2020-asahi-shimbun-article-abc

– March 5, 2021, Asahi Shimbun Article, "Proof of the ABC Conjecture Finally Published"

74. **Winnie Pooh**
April 13, 2021

@Peter Woit:

You've complained several times already about Mochizuki failing to refer to Scholze & Stix by name in his paper. I think there's a misunderstanding here about Western vs. Asian culture that needs to be cleared up. Source: I'm Asian.

In Asian culture, it is considered impolite to point your finger at somebody, or even gesture in their general direction. Similarly, when you want to point out that somebody else is wrong (as Mochizuki does with Scholze & Stix), it is considered more polite to do so in an oblique, indirect way.

Ultimately, this is all about "saving face", an important concept in Asian culture. What Mochizuki basically does with his "no names" criticism is (1) point out that Scholze & Stix are wrong (or so he believes), while still (2) minimizing the number of people who know who exactly he's criticizing, and thereby minimizing the damage to the "social standing" of Scholze & Stix. At least that's the theory and rationale behind "saving face" and "no names". Whether it works in this particular case is of course another matter.

An example that might be easier for Western people to wrap their heads around is when you criticize somebody in public (which will damage their public reputation) vs. when you criticize somebody in private or at least in a small group (= minimal damage to their public reputation).

To summarize, Mochizuki's "no names" criticism is probably a form of Asian politeness, not an attempt to deprive Scholze & Stix of deserved recognition.

75. **Peter Woit**
April 13, 2021

Winnie Pooh,
Many people seem to want to attribute the problems with Mochizuki's response to criticism of the abc proof to cultural differences, but I don't see that at all (although maybe you could argue that culturally-determined unwillingness to embarrass a colleague explains why people at RIMS went along with publication of the defective proof). Looking at everything Mochizuki has to say about this, the problem is that he refuses to actually engage with the mathematical arguments Scholze and Stix are making, to the extent of claiming that everyone he has talked to agrees with him that they have no substantive argument. I don't want to psychoanalyze him, but it looks to me like this refusal to engage with their argument (because he has no counter-argument) has a lot more to do with why he refuses to write their names or link to the document with their argument than any cultural explanation.

I sometimes see people suggest that the problem here may be Mochizuki's unfamiliarity with the English language or Western culture. For those unaware of his background, note that from age 5-25 he lived in the US, and was educated at Philips Exeter and Princeton (and was a postdoc at Harvard).

76. **Winnie Pooh**
April 15, 2021

@Peter Woit

Fair enough, and thanks for your answer. I only commented to provide an alternative angle, not to start a pointless psychoanalytical debate. In the end, who knows what the man is thinking.

Another angle that occurred to me after I wrote my first post is that maaaaybe Mochizuki feels deeply offended by how Scholze & Stix handled the situation, and now does what the stereotypical Japanese person seems to like doing when offended, which is to clam up and passive-aggressively refuse to acknowledge the other person's existence. I think this is more in line with how you view his behavior.

As to how Scholze & Stix could have managed to offend Mochizuki, maybe he felt he wasn't given enough time to explain himself before Scholze left Japan? Of course that would be Mochizuki's side of the story. Whether he has any right to feel offended is another matter.

Anyway, both feeling offended and the ensuing passive-aggressiveness strike me as fairly "stereotypically Japanese" (and also somewhat typically Asian, for that matter), so I still feel there's a cultural component to all this.

77. **Winnie Pooh**
April 16, 2021

@Peter Woit

After giving your reply some more thought, I now realize that we seem to fundamentally disagree on one important point:

If I understand your position correctly, what you are suggesting is that deep down Mochizuki knows he's screwed or at least in a very weak position, and now he and his buddies are trying to cover it up / pretend it didn't happen. That would make this a case of deliberate deception, and would make Mochizuki the Donald Trump of mathematics (if you squint hard enough).

But honestly, I don't see this at all. After rereading the Mochizuki passages you quoted, I get the impression that, even if his attempted proof turns out to be a dud in the end, and even if he has no substantive counter-argument for Scholze & Stix, right now he still seems genuinely convinced that he's right, or at least "essentially" right. So under this interpretation the worst one could accuse him of is being a delusional cult leader, but not one who's actively lying.

78. **Peter Woit**
April 16, 2021

Winnie Pooh,
I don't think this is deliberate deception on Mochizuki's part. In my (extensive) experience with very smart people unwilling to admit that an idea they've worked on for decades is flawed, all evidence I've seen is that the human capacity for self-delusion under such circumstances is an essentially infinite quantity.

New Spaces in Mathematics and Physics

March 22, 2021
Categories: Book Reviews

Available online today (if your institution is paying…) from Cambridge University Press are two volumes well-worth spending some time with: New Spaces in Mathematics and New Spaces in Physics. These contain write-ups based on a workshop organized back in 2015 by Mathieu Anel and Gabriel Catren, the videos of which are available here.

It would be hard to write in any detail about the wealth of material in these volumes, so I'll mainly just link to the essays that seemed especially interesting to me:

- Microlocal analysis and beyond by Pierre Schapira.
- Spaces as infinity groupoids by Timothy Porter.
- Sheaves and functors of points by Michel Vaquié.
- Stacks by Nicole Mestano and Carlos Simpson.
- The geometry of ambiguity: an introduction to the ideas of derived geometry by Mathieu Anel.
- Geometry in dg-categories by Maxim Kontsevich.
- Noncommutative geometry, the spectral standpoint by Alain Connes.
- Supergeometry in mathematics and physics by Mikhail Kapranov.
- Derived stacks in symplectic geometry by Damien Calaque.
- Twistor theory: a geometric perspective for describing the physical world by Roger Penrose.

For several decades now one often hears from prominent theoretical physicists that "Space-time is doomed", to be imminently replaced by something new coming out of the latest ideas about fundamental physics. For a long time the claims of this sort getting the most attention were from string theorists, and in these volumes Marcos Mariño explains these in his Stringy geometry and emergent space. More recently, Nima Arkani-Hamed has been making well-publicized claims along these lines, with space-time to be replaced with volumes of objects in Grassmanians such as the amplitudehedron.

A large fraction of the theory community is now working on things like "it from qubit", which propose to somehow get space-time emergent out of things like qubits or quantum information theory. For most of this kind of thing, I've found it hard to figure out exactly what the proposal is for the more fundamental objects from which space-time is supposed to emerge. One recent extreme proposal, by Sean Carroll, has the virtue of specifying what the object is (a self-adjoint matrix acting on a complex vector space), but I don't think there's a plausible route from that to our observed physics.

As many of the articles linked to above should make clear, mathematicians have over the past centuries developed a range of deep and surprising ideas about new sorts of ways to think about space and geometry. This activity continues: Peter Scholze's perfectoid spaces and condensed mathematics are examples of new directions of this kind, too new to make it into these volumes.

Of all of these ideas, the ones that at the moment I find most compelling are the twistor geometry ideas of Roger Penrose, and I'll have much more to say about those in another blog post soon.

Comments

1. **Paolo Bertozzini**
   March 22, 2021

   Dear Peter,

   great news 🙂 I have been really waiting to read these two volumes. I personally think that there is a great need to look into such mathematical structures (mostly from (higher) category theory and (algebraic) non-commutative geometry) in order to define an appropriate notion of "geometry", "localization" and "holonomy" adapted to quantum physics. I feel that currently there is really a big and unjustified hype about *emergence* of space-time (a "fashion" even stronger than certain propaganda on strings and related ideas, since it is shared by essentially all of the competing lines of research on quantum gravity): everything geometrical is considered to be a macroscopic feature *emergent* from non-geometrical or pre-geometrical phases. There is something that I find quite weird and wrong about such ideology of emergence: four-dimensional Lorentzian manifolds might well turn out to be some "large-scale limit", but this does not mean that a geometrical description at the quantum level is impossible and uninteresting (and these developments in mathematics seem exactly to suggest the contrary).
   Best Regards.

The Future of Fundamental Physics

March 24, 2021
Categories: Uncategorized

IAS director Robbert Dijkgraaf will be giving the CERN colloquium tomorrow, with the title The Future of Fundamental Physics. Here's the abstract:

> The reports of the death of physics are greatly exaggerated. Instead, I would argue, we are living in a golden era and the best is yet to come. Not only did the past decades see some amazing breakthrough discoveries and show us the many unknowns in our current understanding, but more importantly, science in general is moving from studying `what is' to `what could be.' There will be many more fundamental laws of nature hidden within the endless number of physical systems we could fabricate out of the currently known building blocks. This demands an open mind about the concepts of unity and progress in physics.

I don't know of any "reports of the death of physics", but there are a lot of reports of the death of string theory (Dijkgraaf's specialty) and of the larger subject of attempts to go beyond the Standard Model, experimentally or theoretically. CERN yesterday announced new results from LHCb testing lepton universality (a prediction of the Standard Model). LHCb sees a ratio of decays to muons vs. electrons in a certain process that is off from the Standard Model prediction by 3.1 sigma.

If this result is confirmed with better data and careful examination of the theory calculation, that will be a dramatic development, indicating a significant previously unknown flaw in the Standard Model. BSM theory and experiment would be very much undeniably alive (no known relevance of this though to the troubles of string theory). Unfortunately, the experience of the past few decades is that 3 sigma size violations of Standard Model always go away after more careful investigation (see for instance the 750 GeV diphoton excess). It's exactly this pattern that has people worried about the health of the field of high energy physics.

Dijkgraaf's claim that "we are living in a golden era" is an odd one to be making at CERN, which has seen some true golden eras and is now facing very real challenges. Even odder is arguing at CERN that the bright future of science is due to it "moving from studying `what is' to `what could be.'" CERN is at its core a place devoted to investigating "what is" at the most fundamental level. I'm curious to hear what those at CERN make of his talk.

Dijkgraaf's abstract to me summarizes the attitude that the best way to deal with the current problems of HEP theory is to change the definition of the goals of the field, thereby defining failure away. The failure of heavily promoted ideas about string theory and supersymmetric extensions of the Standard Model is rebranded a success, a discovery that there's no longer any point to pursue the traditional goals of the subject. Instead, the way forward to a brighter future is to give up on unification and trying to do better than the Standard Model. One is then free to redefine "fundamental physics" as whatever theorists manage to come up with of some relevance to still healthy fields like condensed matter and hot new topics like machine learning and quantum computing. I can see why Dijkgraaf feels this is the way forward for the IAS, but whether and how it provides a way forward for CERN is another question.

Update: I just finished watching the Dijkgraaf talk, together with the question session afterwards. Dijkgraaf basically just completely ignored HEP physics and the issues it is facing. He advertised the future of science as leaving the river of "what is" and entering a new ocean of "what can be", with the promising "what can be" fields biotech, designer materials and AI/machine learning. He hopes that theorists can contribute to these new fields by trying to find new laws governing emergence from complexity, perhaps via new ideas using quantum field theory tools.

With nothing at all to point to as a reason to be optimistic about HEP, a couple questioners asked whether his river of "what is" might be now hitting not an ocean but a desert, and he didn't have much of an answer. All in all, I'm afraid that the vision of the future he was trying to sell is not one in which high energy physics has any real place. It fits well with the depressing increasingly popular view of the field, as one which had a great run during the twentieth-century, but now has reached an end.

Update: For more discussion of the reliability of the LHCb result, see comments here and here, as well as Tommaso Dorigo's blog post.

Update: Tommaso puts his money where his mouth is.

Comments

1. **Marcus C Thomas**
   March 24, 2021

   Dijkgraaf seems to jump around a bit beginning with "fundamental physics" leaping into "science in general" and then ends with what seems to be a philosophical reference to "unity in physics." Buried within these wild leaps is what appears to be the primary aim of his comments, "science…is moving from studying `what is' to `what could be.'" His point seems to be to justify the trend of highly speculative model-building ("what could be") rather than methodologies that are testable and rely on evidence ("what is").

2. **Anon**
   March 24, 2021

   Hi Peter,

   There's not really a theory calculation to be examined for R_K, the Standard Model just gives unity. Of course theory goes into the simulations used to perform parts of the analysis, but this is generally reliable for these use cases.

   What you say about 3 sigma excesses is of course true but what's interesting here is that in almost doubling the data sample from 5 to 9 fb^-1 the significance increased. If it were a fluctuation one might expect it to gradually reduce as more data is added.

   https://lhcbproject.web.cern.ch/Publications/p/Directory_LHCb-PAPER-2021-004/FigS5.pdf

3. **Peter Woit**
   March 24, 2021

   Marcus C Thomas,

   I think the "what is" versus "what could be" distinction Dijkgraaf is making is not one of testable vs. speculative. His next sentence "There will be many more fundamental laws of nature hidden within the endless number of physical systems we could fabricate out of the currently known building blocks" indicates that he has is mind more
   "what is": the elementary particles and interactions (e.g. the SM).
   "what could be": complicated systems with new emergent behavior that we can make out of elementary particles.

   Dijkgraaf and the theorists at the IAS are basically quantum field theorists, take QFT as "fundamental" and are interested in finding new ideas about QFT and new things to do with it. To me he's basically saying the time for trying to find something new about elementary particles using QFT is over, the future is in new QFT ideas that could describe emergent behavior in complex systems, with practical implications.

4. **Peter Woit**
   March 24, 2021

   Anon,
   Thanks!

   Is there another experiment able to compete on this measurement (Belle II)?
   Two competitors seeing the same thing tends to be more convincing than one experiment's error bars.

   As a theorist, other evidence would be a compelling model that explains this as well as other anomalies. I gather the ambulance chasing has already started, will wait and see what that leads to.

5. **Anon**
   March 24, 2021

   Hi Peter,

   For this particular measurement yes it's Belle II. There are other similar ratios which also have tensions with the Standard Model and can likely be measured by the other LHC experiments. For example:

   https://hflav-eos.web.cern.ch/hflav-eos/semi/spring19/r_dtaunu/rdrds_rds_spring2019.pdf

   Plenty of ambulances have been chased already (see the references in the paper). Compelling is subjective, but they're reasonably conventional BSM theories like leptoquarks or Z'.

6. **Low Math, Meekly Interacting**
   March 24, 2021

   I was also under the impression that the LHCb excess has a more encouraging pedigree than the diphoton excess, which reportedly seemed from the outset about as random as it turned out to be.

   But, as with other BSM ideas and their myriad possibilities, there are diverse ways to conjure up leptoquarks. Maybe too many. A sense of plausibility, or what about the SM is crying out for that particular addition is lacking almost entirely from the popularized accounts that I've been able to find. Are mass differences between the generations enough of a reason to expect anything like it? And so on. Seems unwise to get too excited, or to crank up the siren on the ambulance just yet.

7. **Thomas Larsson**
   March 24, 2021

   Dijkgraaf and myself belong to the same generation and were, I believe, shaped by the same event: the success of CFT in 2D statistical physics (he is of course also shaped by the first superstring generation, something I never was because I didn't understand it). Although Dijkgraaf made real contributions and comes from the Netherlands, the Mekka of statphys, whereas the train had already left the station when I figured out what was going on.

   In the context of 2D statphys it does make sense to talk about what can be and what can not. Here, we know that some things are (the Ising and somewhat more complicated models), but we also know what can be (the discrete unitary series) and what cannot be (values of c inbetween). This is a fundamental success which I think is underappreciated, even if 2D statphys has admittedly a limited domain of applicability.

   Alas, applying a similar attitude to SUSY, which does not have the underpinning of a theory which is mathematically deep and empirically successful, makes no sense to me.

8. **Peter Woit**
   March 24, 2021

   Thomas Larsson,
   I think you're right that Dijkgraaf's point of view has been shaped by starting out in 2d CFT/string theory back in the mid 1980s. He started on his Ph.D. around the time of the first superstring revolution of 1984. At the time the excitement about string theory was driven by hopes to get a unified theory out of it, something that never worked out. From the beginning Dijkgraaf worked not on this failed project of string theory unification, but on doing other things (e.g CFT, TQFT) often motivated by string theory, that had applications elsewhere (2d stat mech, topology). So, to the extent that his current point of view is that one should give up on unification and find QFT applications elsewhere, it's consistent with his work from the beginning.

9. **John Baez**
   March 24, 2021

   Dijkgraaf says:

   > "There will be many more fundamental laws of nature hidden within the endless number of physical systems we could fabricate out of the currently known building blocks."

   This sentence seems to be talking about condensed matter physics. I'd be really happy if Dijkgraaf openly admitted high-energy physics has been stagnant for decades, while condensed matter physics is full of exciting discoveries. I'm trying to convince young theoretical physicists of this myself. But he seems reluctant to come out and say this openly.

   I'm also not sure what his definition of "fundamental laws" is here, or "fundamental physics". If he wants to redefine them to include the approximately true but mathematically deep laws governing some condensed matter systems… well, there's a case to be made for that. But I think to do it he should come out and say the words: "condensed matter". Otherwise it's all rather mysterious.

10. **Sabine**
    March 25, 2021

    Since I am presently reading Chiara Marletto's new book about counterfactuals, maybe that's what he is referring to with the "could be"? The argument is in a nutshell that what you can do with a system is an important property of the system in and by itself. Not sure what Dijkgraaf has to do with that though, so maybe it's not what he meant.

As to the 3.1 sigma. They need some semi-discovery that the present collider just about can't confirm to argue we need a bigger collider. Might be this or another one.

Oh, and just in case any young people are reading this, let me add I agree with John about condensed matter physics. It's interesting and cool and it's somewhat unfortunate that it has a reputation of being somewhat dull. There's much to be done there and almost certainly a better research direction at the moment than high energy physics.

11. **Wandering mudhen**
March 25, 2021

On the 3.1 sigma excess in B+ > K+ e+e-… the detector is not e/mu symmetric at all… very, very different acceptance/efficiencies. And electrons emit bremmstrahlung. So the observed number of K+e+e- events is a factor of 2 to 3 smaller than K+mu+mu-, and K+e+e- has a broader signal shape, and extends over more backgound.

Then simulation is used to correct back for that… and LHCb claims (systematically) 1% error in that correction.

In, say, 1970, this claim would not be accepted. But simulation tools are far more powerful today.

K+e+e- ends up being quite a bit nearer to the floor of background due to lower acceptance*efficiency and bremm smearing.

The kaon system has an awful lot of higher resonances that were part of the particle explosion of the 1960's, prior to acceptance of quarks… the phenomenology of those resonances is hardly airtight. Predicting the coupling of those resonances to the bag of partons the appears after the quark decay of b to s l+ l- seems to me to be a big challenge.

Then if some of the decay products of the higher resonances are missed by LHCb, they'd appear as background under the bremm tail of the K+e+e-. Getting that background wrong by a few percent would put them down to 2 sigma, and 10-20% would explain the entire effect.

So, either lepton non-universality, or, difficult to model regge-pole type resonances from the 1960's… which would Carl Sagan say needs the more extraordinary evidence? But good that LHCb is getting out near the envelope of what we understand.

12. **Peter Woit**
March 25, 2021

Wandering mudhen,
Thanks for the cautionary comments. I think it's correct to summarize the situation as "this is an extraordinary claim, with not now extraordinary evidence".

13. **André**
March 25, 2021

Peter,

you write "It fits well with the depressing increasingly popular view of the field, as one which had a great run during the twentieth-century, but now has reached an end." Sorry, HEP will reach an end only if there is no physics beyond the standard model (which indeed seems more and more likely) AND once the origins of the parameters of the standard model are understood.

The origins of the parameters are still in the dark, completely. In your blog I have never read about any attempt to explain their origin – neither in your posts nor in the comments. This needs to change. There is still fun ahead, even if there is a desert and nothing beyond the standard model.

14. **Peter Woit**
March 25, 2021

André,
I don't disagree. What Dijkgraaf is doing is refusing to admit that string theory has failed, trying to act like it was a success, providing us with a "new way of doing science". This unfortunately discourages anyone from continuing to try and solve these problems for real.

15. **Alessandro Strumia**
March 26, 2021

"We are living in a golden era and the best is yet to come": all Standard Model particles have been seen, LHC discovered no new physics, no next collider is underway because costs got so high and no smarter muon collider has been planned. These multiple issues suggest that maybe we are living in the historical era where hep-ex reached its end.
I wonder if this possibility can be openly discussed, given that members of the last center that explores high energy "shall conduct themselves with due regard to the interest and proper functioning of the Organization", and "refrain from any act of activity … which would be morally or materially prejudicial to the Organization" and "to express their personal opinions on matters connected with the functioning of the Organization or its activities shall first obtain the written authorisation of the Director General".

16. **Constantin**
March 26, 2021

I think there is little to no possibility of having a truly open community discussion onn the future of HEP as it must involve both thinking and voicing "the unthinkable" (which means different things to different people).

17. **Jose Alvarez**
March 26, 2021

CERN would be well advised to invite younger physicists who did not grow up believing that the LHC would be the answer to the future of the field. For example, there are a number of active efforts initiated by theorists that have lead to new experimental initiatives to probe a variety of dark matter candidates. Almost all of these initiatives are driven by folks under the age of 45.

At the end of the day, none of the grand challenges of particle physics have actually gone away. It is abundantly clear that specific directions that have been religiously pursued such as string theory and low energy supersymmetry have gone nowhere. The junior folks, especially in phenomenology, pretty clearly understand this. If CERN wants to hear about the future of the field, they would be better off inviting these folks to give such seminars rather than people who have been cheerleaders for failed efforts.

18. **Patrick**
March 26, 2021

Wandering mudhen, you describe the challenges of the measurement well. That's why it takes so much time to update this measurement. Once we understand the simulation, we test the measurement at the J/psi resonance and get 1, as expected from electromagnetism. As we have 100 times more data there we can plot that ratio against any variable of interest. See Figs 3,9,10 of https://lhcbproject.web.cern.ch/lhcbproject/Publications/LHCbProjectPublic/LHCb-PAPER-2021-004.html : it's flat. In particular the opening angle of the leptons is crucial. The bottom line is that the B is so much boosted at the LHC that differences in the B frame between the J/psi mass range and the signal 1-6 GeV range are washed out. Once the J/psi is understood, we test the Psi(2S) and get 1 again. Only then did we look at the dilepton mass range of interest.

For the K resonances, they affect the signal region and the Psi regions similarly, so we can test our understanding on the control samples. But indeed we improved our modelling of these backgrounds compared to the previous analysis. The net effect on RK is negligible.

19. **Tommaso Dorigo**
March 27, 2021

Hi,
an Anon above seems impressed that the significance of the R excess grew over time. This is a very common circumstance for null results when experimentalists underestimate their systematic uncertainties. The latter may come from a number of sources, from underestimates of intervals of confidence of internal parameters used in the inference-extraction procedures, to subtle detector effects. We have seen so many of these over the past 40 years that it is just bad propaganda to claim that the growth of a significance is additional evidence for the effect being genuine.
Cheers,
T.

20. **Krzysztof**
March 27, 2021

On slide 13, R. Dijkgraaf claims that the graviton was proposed in 1915 and discovered in 2015.

Well… all this presentation looks like some slick corporation show-case.

21. **Peter Woit**
March 27, 2021

Krzysztof,
I noticed that during the talk, thought it was quite strange for that mistake to be there.

22. **Tommaso Dorigo**
March 27, 2021

Hi again Peter,

so the comment by Anon stimulated me to write about systematic uncertainties and other things, and how one should still be very careful with anomalies that "grow with the data" – https://www.science20.com/tommaso_dorigo/another_3_sigma_fluke_from_lhcb-253707

Cheers,
T.

23. **Tommaso Dorigo**
March 27, 2021

And thanks for linking it from the post!
Cheers,
T.

24. **Lorenzo Di Pietro**
March 29, 2021

Before the talk: you are disappointed because you predict he is going to oversell the future of HEP. After the talk: your prediction turned out to be wrong, but somehow you are still disappointed.

25. **Peter Woit**
March 29, 2021

Lorenzo Di Pietro,
I wasn't predicting Dijkgraaf would oversell the future of HEP, was wondering how HEP fit into his argument that science is moving away from "what is" questions. On the LHCb announcement, there is some danger that's oversold, but that's a separate question, and I also had no idea if Dijkgraaf would mention that.

I was surprised that Dijkgraaf's talk to the CERN audience dealt with the future of HEP by not mentioning it at all, essentially implying that it has no future worth talking about.

26. **Doug McDonald**
March 29, 2021

Speaking of bets and leptons, are there any bets, to be decided very soon, on what Fermilab is about to say about muon g-2? Bets on the number itself, or its standard deviation? Or even guesses?

27. **Peter Woit**
March 29, 2021

Doug McDonald,
I've seen no bets. I'm a little surprised expectations are so high about this. Maybe I'm wrong, but my impression was that this upcoming announcement is going to be about their Run 1 data, which was of similar size to the earlier Brookhaven experiment. So, no expectation of significantly better precision or more conclusive (5 sigma level) ruling out of the SM prediction. We'll see soon…

28. **Sundar**
March 31, 2021

Dear Dr. Woit: https://en.wikipedia.org/wiki/Lepton#lepton_universality_anchor says that the Babar and Belle experiments too found similar deviations from lepton universality just like LHCb did, but the statistical significance did not meet the 5 sigma threshold. When 2 other experiments possibly found deviations from the Standard Model prediction, does the latest LHCb announcement sound so improbable?

29. **Peter Woit**
April 1, 2021

Sundar,
The problem is that there are a large number of possible decays you can measure and check for lepton universality, and if you measure a lot of them, statistically you expect to see deviations in some of them, even if lepton universality is correct. You need something more than a random-looking pattern of some decays satisfying lepton universality, some not, at levels not big enough to be convincingly significant.

30. **ML**
April 6, 2021

Hi,

the talk is a typical Dijkgraaf for the public ears – saying a lot without saying much. I like the more honest ones when Robbert is a cheerleader for stringy maths. And don't get me wrong, I like him very much. He's always been for experiment and testable consequences to a theory next to other more stringy things.
However, I am not sure what the point was with the ocean of what could be. I imagined first RD would talk about the (endless) possibilities coming out of strings and the likes – and perhaps discovering exactly the five centimeters next to the map. But then he explained how our knowledge leads to the engineering of what there could be. Which plays well with stringy engineering, but needs the very important addition that it's purely theoretical knowledge. RD but was talking about "unexplored physical phenomena" without any qualification on their kind. And so, the HEP community would hear that they may continue on their track of smashing what there is to discover what there could be. And the theoreticians would hear that they might continue with playing around on and with their models deriving what they could lead to. That is but a description of the current (and much criticized) state of this particular areas of physics today.

It was announced as a talk about the "future" but it was rather a motivational speech to those whose hope is fading into the shadows of other exciting topics in science that are not about fundamental physics.
I remember seeing a Strings'XX talk by Strominger about the "fun" and adventures on the sea, string theorists were sailing like Magellan into unknown shores. And certainly the discoveries will be similarly significant. And perhaps they already are, but not in the way of the actual 'golden era' of HEP. They have not discovered the promised new continents so far but saw many Magical things and discovered new Monsters.
The golden era ships were sailing along the river, the shores always in sight. Out into the ocean, let's not forget, many sailors got lost and eaten by the monsters.

It might be helpful to step from the sailing ship for a moment on to the ground. To look for the five centimeters or something else.

And btw – does anyone know who's the inquirer at 1:18:18 ? 🙂

Cheers, M

Twistor Unification

April 1, 2021
Categories: Euclidean Twistor Unification

I've finally finished writing up a new version of some ideas that I first wrote about here last summer. The latest draft is here, I may set up a web page with more info here.

Several people had very helpful comments on what I wrote last summer, especially in pointing out that I wasn't providing sufficient justification for the most radical claim I was making, that the problems with analytic continuation of spinor fields indicated that one could interpret one of the Euclidean space rotation group SU(2)s as an internal symmetry. I then spent a lot of time mastering aspects of Euclidean QFT I had never properly understood. Section two of the current paper is the result. It's in some sense quite elementary, people may find it of independent interest, even if you're not interested in the ideas involving twistors. Section three, an exposition of relevant aspects of twistors, is pretty much unchanged. Section 4 is an outline of the ideas about how to get a unified theory out of twistors, much there is still sketchy. I understand a lot better than last year how what I'm proposing fits into some standard ideas about "chiral" formulations of gravity, also have learned a bit more about previous attempts to formulate chiral gravity and gauge theory on twistor space. Some highly speculative remarks that this might all be somewhat related to N=4 super Yang-Mills have been added.

Here's a little bit more here about the hardest to believe claim being made (about analytically continuing spinors). The standard assumption (this is what I always thought) has been based on the analytic continuation behavior of correlation functions: Schwinger and Wightman functions are analytic continuations of each other, and one might think there's nothing more to analytic continuation between Euclidean and Minkowski space theories. After learning more about the Euclidean QFT literature, I was struck by how different this is from the physical Minkowski space formalism: states and fields don't just analytically continue, they're quite different sorts of objects in the Euclidean case. Anyway, this is all explained in detail in the paper…

Update: No, this is not an April Fool's joke. I've now created a twistor unification page where I'll try and maintain updated information about this unification proposal

Comments

1. **Art**
   April 1, 2021

   um, the date?

2. **Elias**
   April 1, 2021

   Can someone say what makes this April 1, aka what is the fake part?

   I don't know anything about twistors and QFT or relativity, but, from a cursory glance it gave a legit feeling. Perhaps it's the LaTeX formatting?

3. **Lowell Brown**
   April 1, 2021

   One should understand that Schwinger's comment about the doubling of spin 1/2 fields in order to transform to Euclidian space involved starting with HERMITIAN four-component spin 1/2 fields in space time.

4. **Peter Woit**
   April 2, 2021

   All,
   No, not an April Fool's joke, perfectly serious.

5. **Peter Woit**
   April 2, 2021

   Lowell Brown,
   From Schwinger's Euclidean Quantum Electrodynamics paper

   "Thus the requirement of a Euclidean formulation excludes the simplest field in space-time, the four-component Hermitian spin-1/2 field (Majorana). In this context a a trivial observation may be worth repeating – a four-component Hermitian field is fully equivalent to a two-component non-Hermitian field."

   The issue of hermiticity of fields here is confusing, but my focus is on something else, the relation between the Spin(4)=SU(2)xSU(2) symmetry in Euclidean space and the Spin(3,1)=SL(2,C) symmetry in Minkowski space for a Weyl spinor theory. Looking just at the Wightman and Schwinger functions that are analytic continuations of each other, the analytic continuation relates the symmetries. But if you try and define states and operators, something different happens (the Euclidean theory state space is a different sort of thing than the Minkowski state space).

6. **Low Math, Meekly Interacting**
   April 2, 2021

   I was about to request an exegesis myself, as this either had either to be an inside joke of diabolical sophistication or, well, not a joke.

7. **Peter Woit**
   April 2, 2021

   LMMI,
   At some point it became clear I'd have the draft done around April 1 and I thought best to avoid that date. Later decided might as well post on April 1, maybe people would carefully read the thing looking (unsuccessfully) for the joke. As far as I can tell, that didn't work out…

8. **Robert A. Wilson**
   April 2, 2021

   In this subject these days it is sometimes difficult to distinguish between an April Fool's joke and an idea that is meant to be taken seriously. Perhaps that is not such a bad thing – there is many a true word spoken in jest.

9. **Justin**
   April 3, 2021

   Do you plan on publishing a 2nd edition of Quantum Theory, Groups and Representations: An Introduction, with added material on twistors?

10. **Jamie**
    April 3, 2021

    Hi Peter. I was wondering if you could comment on Eric Weinstein's article on Geometric Unity.

11. **Peter Woit**
    April 4, 2021

    Justin,
    I would at some point like to write a revised and expanded version of that textbook, now have a long list of notes to myself about ways it could be improved based on teaching the class again this year. Unclear when I'll have the time and energy for this project, and whether I'd be able to explain about twistors in a useful way that wouldn't take writing hundreds of pages. So, not any time soon, but maybe some day.

    Jamie.

    No, especially certainly not here, where I think there's a much more interesting set of ideas about unification to discuss…

The God Equation

April 4, 2021
Categories: Book Reviews, This Week's Hype

When I was out for a bike ride yesterday I stopped by a large book store and looked to see if they had a copy of Michio Kaku's new book The God Equation. They didn't, but did have plenty of copies for sale of his various previous efforts to promote string theory, such as 1987's *Beyond Einstein*, 1994's *Hyperspace* and 2005's *Parallel Worlds*. If someone interested in fundamental physics walks into a bookstore, and looks in the Science section for something to read written by a well-known physics professor, these books are what they're likely to end up taking home and reading.

When I got back from the bike ride, several people had forwarded me a link to this story from the Guardian which gives a good idea of what's likely in the book, claims like:

> Well, string theory has also created a tremendous amount of interest, as well as a backlash. People say, well, where is the proof? Quite frankly we don't have the proof, in the same way that Newton did not have the proof of his inverse square law back in 1666. Sometimes, the mathematics and the ideas are ahead of the concrete experimental data. That's where the Large Hadron Collider comes into play…
>
> The Standard Model is the theory of almost everything. It works spectacularly well but it's one of the ugliest theories proposed so far. There's this avalanche of experimental numbers you have to put in by hand. But in string theory the Standard Model just pops right out. With just a few assumptions you get the entire Standard Model. So the point here is that we need experimental proof and the LHC may give us hints of a deviation in the Standard Model and that's where this post-LHC physics comes into play.

This is just complete and unadulterated bullshit, of exactly the same sort Kaku and a host of others well-credentialed physicists have been heavily and successfully promoting for the last 35 years. I started writing about this 20 years ago, and there have been some changes since then (for one thing, we have Sabine Hossenfelder). I'm still waiting though for any of the leading figures in the physics community responsible for the string-theory hype campaign to do anything at all to try and stop Kaku and the rest of the Fake Physics onslaught that they unleashed.

Usually with books like this, once I get a copy of the book I try and write here a careful review quoting the writer accurately and explaining the problems with what they've written, but this time I think I'll pass on the grounds that this would be a waste of time.

The funny thing though is that I probably agree with Kaku far more than most people about the possibility of unification, although I wouldn't use the terminology "God equation" to describe a unified theory. Unfortunately Kaku has done far more than most physicists to discredit the search for a better unified theory, through the endless nonsense he has put out about the subject in books like this. I do think we'll find a better, more unified theory, and I even think I know a couple of the crucial equations, which, leaving God out of it, are:
$${D\mkern-11mu/}_A\psi=0$$
and
$$F_A^+=0$$

Update: You can read the book's introduction here. It seems that Kaku has conceptualized the book as a response to criticism of string theory. Near the end of the introduction, he assures us:

> This book will hopefully give you a balanced, objective analysis of string theory's breakthroughs and limitations.

This morning he's on Morning Joe.

Comments

1. **Dylan Mahoney**
   April 4, 2021

   What do those crucial equations represent, and where do they come from?

2. **Peter**
   April 4, 2021

   That Guardian quote makes me want to twist my own head off.

3. **David**
   April 4, 2021

   "Newton did not have the proof of his inverse square law back in 1666."

   Newton computed the force required for an apple to fall as it did, for the moon to "fall" in its orbit around Earth, and for Haley's comet to orbit as it did, and found the forces varied as the inverse square of the distance to Earth.

4. **Topologist Guy**
   April 4, 2021

   "The standard model pops right out." Isn't this simply false?

   The truth coming closest to this, I think, is that perturbative superstring theory on a flat 10D background reduces to a 10D supersymmetric quantum field theory at low energies (whose fields come from the low-energy excitations of the string). The project to get the specific 4D QFT that is the standard model, with its specific fields and numerical parameters, from a compactification of superstring theory has been a dream for decades and is farther than ever from being realized, with the enormous moduli space of possible string vacua. Of course we all already know this.

   So I think Michio Kaku is saying that superstring theory (on a flat background) reduces to *a* (10D) quantum field theory at low energies. It's very disingenuous to precede this with a remark on how "ugly" the standard model is, precisely because of the apparently arbitrary assortment of fields and parameters (not because QFT itself is an ugly framework), which suggests that string theory reproduces these specific fields and parameters as a low-energy limit, which is simply untrue. Kaku's statement really reduces to "you can recover a QFT as a low-energy limit of strings," which is far less impressive.

5. **Peter Woit**

April 4, 2021

Dylan Mahoney,
The first equation is the Dirac equation, and governs the behavior of matter fields. The second is the (anti)self-duality equation, which (especially from the twistor Penrose-Ward correspondence point of view) governs the behavior of gauge (force) fields.

6. **Peter Woit**
April 4, 2021

David/Topologist Guy,

The serious question here is why Kaku makes obviously absurd claims and arguments (that the SM pops out of string theory, that the status of Newton's law of gravitation when he came up with it was like the status of string theory). He's clearly not operating according to any usual scientific principles. Ash Joglekar, see here
https://twitter.com/curiouswavefn/status/1378833441702039554
says he understands Kaku not as a scientist, but as a fantasist and storyteller.

7. **Peter Orland**
April 4, 2021

David,

Newton did not have to calculate anything new to get his law of gravitation. He just needed Kepler's summary of Tycho's observations.

Kepler's first law (a planetary orbit is an ellipse, with the sun at one focus) and Kepler's second (equal areas) law, together imply an inverse square relationship of acceleration towards the sun. Then Kepler's third law enforces that $GM_{\odot}$ is the same for each planet. I don't know if Newton discovered the gravitational force law this way, but that would be my guess (a historian would know better).

8. **Douglas Natelson**
April 4, 2021

Kaku drives me up a wall. Time and again, he deliberately erases or obscures the line between science and complete bs speculation, presents all of this on TV or in print without qualification, and acts like that's fine because it gets people interested in science.

9. **Michael Weiss**
April 5, 2021

Newton's theory coherently and quantitatively retrodicted key observations (Kepler's laws, Tycho rich database of astronomical observations) and in turn predicted a vast body of further observations. (Indeed, the precision of the classical predictions enabled future rigorous testing of GR. The Lamb shift was also quantitative and precise, enabling the development and testing of QED.)

Given experimental constraints, it is not credible to equate the Newtonian paradigm with the status or sociology of String Theory, however brilliant the mathematics and however elegant its continuing impact in condensed-matter physics.

10. **Amitabh Lath**
April 5, 2021

Strings are one of those concepts that have become accepted by repetition. I have had to correct generation-Z/alpha members of my extended family from proclaiming to their grade-school science class that their "…uncle works at the LHC which is a powerful microscope that can make out strings inside quarks inside protons inside atoms…"

11. **Sabine**
April 5, 2021

Thanks for the link.

As Douglas mentions above, lots of people trying to excuse this by claiming it's okay because it "gets people interested in science". What they forget to mention though is that the people who actually get interested in science by things like this figure out very quickly that they've been sold vacuous quackery and end up being cynical nay-sayers and general science skeptics.

It's an interesting question why the Guardian would run factually incorrect scientific statements like this. Suppose the topic hadn't been string theory but climate change. Would they have printed utter nonsense just because it might "get people interested in science"? Certainly not. Why not? Because it's irresponsible.

I suppose when it comes to string theory they believe it doesn't really matter whether what you say about it is right or wrong. I think that's incredibly short-sighted though. Because research in the foundations of physics is a long-term investment into new technologies. I wish the Guardian editors would think a little more about what they run on their pages, or at least add an explanation for the reader for how to gauge the scientific credibility of Kaku's statements.

12. **Julien**
April 5, 2021

I think you can write to the guardian and they may publish your letter. See the links at https://www.theguardian.com/help/contact-us#nav2

Also, Katharine Viner is editor-in-chief and the page above tells you how to build her email address from her name.

13. **Low Math, Meekly Interacting**
April 5, 2021

"…in the same way that Newton did not have the proof of his inverse square law back in 1666."

Seriously, WTF is this about? I'm not being facetious. I have to believe there's some point being made here that is obscured by an outrageous level of omission. Like maybe he's thinking of the fact that Newton had no mechanism to explain the inverse square law, like maybe instantaneous action at a distance, which made Newton himself uncomfortable, begged for further insight. Or something. My ever-dwindling faith in humanity increasingly depends on such generous rationalizations.

14. **Peter Woit**
April 5, 2021

Julien,
I don't think a letter would be worth the effort. If they did publish such a letter no one would see it.

It would be great if somebody would contact the Guardian and ask them to issue a correction, to appear on the same page as the bogus claims by Kaku. Also good to get them to be aware they need to do some basic fact-checking before publishing claims like Kaku's. In particular his claim that Isaac Newton's discoveries were at the time untestable speculation should have set off red flags for any author or editor who had taken even a high school class in physics.

In general, this phenomenon of the huge amount of public misunderstanding of string theory should be addressed. I've done my part, string theorists themselves should take some responsibility for the mess that their proponents have created and do something about it.

15. **Ash Jogalekar**
April 5, 2021

"Unfortunately Kaku has done far more than most physicists to discredit the search for a better unified theory."

Although I agree that Kaku often says nonsense that's highly misleading, I think professional physicists pushing string theory have done far more harm to "discredit the search for a better unified theory" than Kaku ever did.

16. **Douglas Natelson**
April 5, 2021

I could be wrong, but a quick look at Google scholar suggests that Kaku hasn't published anything academic in many years, and there is nothing on the arxiv after 1999. I have no issue with people shifting gears into popularization, but to have pretensions of being an active scientist when not publishing for over two decades is too much.

17. **maciej**
April 6, 2021

While many Kaku's statements are clearly exaggerated, I think it is only for the PR of his books or PR of himself. Unfortunately this is how the "sales" work. Kaku has not been publishing scientific papers for years. He has became a sales man of his books, so I would not care much for his claims and I don't think scientists do.

Also, look at his textbooks on QFT or String Theoy/M-theory. Do you see those out-of-touch claims there? Not at all. Actually these books are rather well written. This shows that his exaggerated claims are only for the public. You may still not like it, but I don't think it is creating any more harm for the scientific community i.e. there would be still hype about ST even if Kaku was not known to the public.

In my opinion, the real damage comes from known and active researches in ST who still make similar unsupported claims.

18. **Jim Eadon**
April 6, 2021

True story. Yesterday (before reading this post) I asked a famous String Theorist for how String Theory connected with testable physics. He answered that the testable predictions of String Theory are "Super Symmetry" and the "Hagedorn tower of particles".
Perhaps dissatisfied with his own reply, he then simply deleted his (Twitter) tweet, and blocked me.
That exchange with a String Theorist (I'll not mention his name, but he's high-profile) told me more convincingly even than critics that the String Theory HEP programme has not gone well…
Interestingly, he also said that you did not need to test String Theory to see whether it is correct, because "it *is* the laws of physics"

19. **Peter Woit**
April 6, 2021

Maciej/Jim Eadon,
Kaku is an extreme case, but the problem of misleading/exaggerated claims for string theory is a widespread one.

20. **Robinson**
April 6, 2021

I am not a physicist, just an interested reader. It's funny you mention his books being very visible. I have a copy of Hyperspace, purchased in just such a manner as you describe. Kaku is charismatic (like Brian Greene) and has been in many TV shows like Horizon (BBC), which give him name recognition with us hoi polloi.

I cannot really comment on the content.

21. **Ted Rogers**
April 6, 2021

He was also interviewed about the book by Michael Shermer:

https://youtu.be/cDiN1JSdirs

It is very long, but still seems like something of a missed opportunity for a skeptic.

22. **Peter Woit**
April 6, 2021

Ted Rogers,

I took a quick look at the transcript. Shermer is supposedly a professional skeptic, but when he asks Kaku for experimental evidence of string theory, he seems all right with a response about strings vibrating in 11 dimensions and the mind of god. Inviting Kaku on and then seemingly taking the attitude that "this guy is a reputable scientist, so whatever he says must make sense", he's not exactly an advertisement for his brand of skepticism.

23. **Ted Rogers**
April 6, 2021

Peter,

Yes, that was my reaction. Very frustrating.

24. **Bernhard**
April 6, 2021

Kaku should stick to writing about the future (he's a fantasist, as someone said), since his books on this are quite entertaining (whether one believes his predictions is not the point), and I think he's rather careful interviewing people outside his own area of expertise.

In all his books, it is always when he talks about string theory that I have to roll my eyes. He has excellent technical knowledge (which is the reason he continues to get a "pass"), there is no excuse to write some much BS about the Standard Model popping out of string theory no matter what amount of simplification he wants to get behind in order to have the excuse. This is technically so wrong that no amount of simplification justifies writing it.

25. **Peter Woit**
April 6, 2021

Took a closer look at the transcript of the Shermer interview. When pressed about testability he lists three ways to test string theory:

1. String theory predicts dark matter, will see this at next generation post-LHC collider.
2. LISA will see gravitational waves from the big bang predicted by string theory
3. Measurements of the gravitational force inverse square law "in your living room" will see deviations predicted by string theory.

Utter horseshit.

Shermer's reaction: "You always blow my mind with these things."

26. **Peter Woit**
April 6, 2021

One fun thing about the Shermer interview:
Around 19:47 he refers to a book called "Not Even Wrong" that came out a decade or so ago and criticizes string theory as untestable, he thinks authored by a guy named "Witten".

27. **David Roberts**
April 6, 2021

>he thinks authored by a guy named "Witten".

who thinks? I presume you mean Shermer, since surely Kaku wouldn't make that mistake.

28. **Peter Woit**
April 6, 2021

Yes, it's Shermer who thinks this.

29. **Amitabh Lath**
April 7, 2021

If you got kicked off the fnal muon g-2 webinar, it is on youtube.
http://www.youtube.com/watch?v=81PfYnpuOPA

30. **Bernhard**
April 7, 2021

"he thinks authored by a guy named "Witten"."

I can't stop laughing about this…

31. **Patrick Dennis, MD**
April 8, 2021

David, Peter O. — The story goes that Robert Hooke and Edmund Halley were trying to work out the nature of gravity. The best guess was that it varied inversely as the square of the distance, but they were frustrated that they could not show that such a force would lead to elliptical orbits. So one (Halley, I think) asked Newton what kind of orbit would result from an inverse-square gravity, and Newton immediately answered, "an ellipse." He said he had already proved it, but did not have the proof immediately at hand. When he eventually showed it to his colleagues in the form of a brief manuscript, they realized that he was on to something very big indeed, and it was at their urging that the off-the-cuff calculation emerged years later as Principia.

32. **David**
April 8, 2021

Why had he worked out the equation of the orbit? Because he had already thought about the force law of gravitation.

" After dinner, the weather being warm, we went into the garden and drank thea, under the shade of some apple trees…he told me, he was just in the same situation, as when formerly, the notion of gravitation came into his mind. It was occasion'd by the fall of an apple, as he sat in contemplative mood. Why should that apple always descend perpendicularly to the ground, thought he to himself…" from Memoirs of Sir Isaac Newton's Life by William Stukeley, 1752

Stukely got the story straight from Sir Isaac. Newton worked out that the force on the moon was the same as the force on the apple, diminished by the square of the ratio of the distances. That, combined with his fluxions, was enough for him to work out the orbit as a conic section.

Muon g-2 Result

April 7, 2021
Categories: Experimental HEP News

The long awaited FNAL muon g-2 result was announced today, you can watch a video of the seminar here, look at the paper and a discussion of it at Physical Review Letters, or read stories from Natalie Wolchover at Quanta and Dennis Overbye at the New York Times. Tommaso Dorigo has an extensive discussion at his blog. In terms of the actual new result, it's not very surprising: quite similar to the previous Brookhaven result (see here), with similar size uncertainties. It's in some sense a confirmation of the Brookhaven result. If you combine the two you get a new, somewhat smaller uncertainty and ($a_\mu=\frac{1}{2}(g-2)$)
$$a_\mu(Exp)=116592061(41)\times10^{-11}$$

The measurement uncertainties are largely statistical, and this is just using data from Run 1 of the experiment. They have accumulated a lot more data since Run 1, and once that is analyzed the FNAL experiment should be able to provide an experimental value with much lower uncertainty.

The big excitement over the g-2 experimental number has to do with it being in conflict (by 4.2 sigma now) with the Standard Model theoretical calculation, described here, which gives
$$a_\mu(Theory)=116591810(43)\times10^{-11}$$
An actual discrepancy between the SM theory and experimental value would be quite exciting, indicating that something was missing from our understanding of fundamental particle physics.

The problem is that while the situation with the experimental value is pretty clear (and uncertainties should drop further in coming years as new data is analyzed), the theoretical calculation is a different story. It involves hard to calculate strong-interaction contributions, and the muon g-2 Theory Initiative number quoted above is not the full story. The issues involved are quite technical and I certainly lack the expertise to evaluate the competing claims. To find out more, I'd suggest watching the first talk from the FNAL seminar today, by Aida El-Khadra, who lays out the justification for the muon g-2 Theory Initiative number, but then looking at a new paper out today in Nature from the BMW collaboration. They have a competing calculation, which gives a number quite consistent with the experimental result:
$$a_\mu(BMW)=116591954(55)\times10^{-11}$$

So, the situation today is that unfortunately we still don't have a completely clear conflict between the SM and experiment. In future years the experimental result will get better, but the crucial question will be whether the theoretical situation can be clarified, resolving the current issue of two quite different competing theory values.

Update: Also recommended, as always: Jester's take.

Comments

1. **Mark Weitzman**
   April 7, 2021

   I wish the New York Times would have better science reporting – typical error:

   "That leads the factor g for the muon to be less than 2, hence the name of the experiment: Muon g-2."

   Of course (g_mu-2)/2 from PDG website is about (10^-10) * 11659208.9± 5.4±3.3 and |g_mu|>2.

2. **Anonyrat**
   April 7, 2021

   The BMW pre-print: https://arxiv.org/abs/2002.12347

3. **Roger**
   April 7, 2021

   So BMW showed up to crash the party with the news that their paper is now published in Nature. Its not often we get that degree of excitement in particle physics.

   A lot of people worked on that result. They didn't deserve their result day being hijacked the way it was.

   That said, I'd be interested in knowing the back story of what went on and why the BMW paper wasn't included in the calculation that led to 4.2 sigma. Was there a prescribed procedure for deciding whether or not a calculation would be included or was this decided on the fly in response to the BMW work ?

   To be clear, I certainly don't think that it was the intention of the g-2 collaboration and the Theory Initiative to put across a misleading estimate of the size of the data-theory discrepancy (and they not have done this at all, even inadvertently). However, given the events of today, there is an unfortunate impression of a stitch-up.

   For an outsider like me (I'm a collider physicist), today's events were interesting from both a scientific and sociological perspective.

4. **Alessandro Strumia**
   April 7, 2021

   4.2σ anomaly with respect to one theoretical prediction, omitting the other theoretical prediction close to the measured g-2.

5. **Amitabh Lath**
   April 7, 2021

   Muons are having a moment.

   So what physics could be causing this 4.2 sigma (assuming it remains)? After the LHCb results there was a lot of chatter about leptoquarks, but I don't see much here?

6. **Henry McFly**
   April 7, 2021

   Assuming that the muon g-2 Theory Initiative's calculation is correct, what kind of BSM explanations are there to explain the discrepancy between the SM prediction and the experimental measurement?

7. **e**
April 7, 2021

Roger,

The value for the leading-order HVP recommended by the g-2 Theory Initiative is that of the data-driven approach. The white paper notes that

"For HVP, the current uncertainties in lattice calculations are too large to perform a similar average and the future confrontation of phenomenology and lattice QCD crucially depends on the outcome of forthcoming lattice studies. For this reason, we adopt [the data-driven evaluations of HVP] as our final estimate [..]"
[Section 8, above (8.12)]

From v1 of 2002.12347 to the paper published today, the quoted result for the LO HVP in units of 10^{-10} has shifted from 712.4(4.5) [v1, Feb '20] to 708.7(5.3) [v2, Aug '20 — after the white paper] to 707.5(5.5) [published], so the assessment that all lattice results need to be further scrutinized seems to have been warranted.

8. **Rollo Burgess**
April 8, 2021

The media are saying that these results can be taken in conjunction with the LHCb data also recently discussed to give an indication of something going on beyond the SM.

I was a bit unsure about this.

Is it correct that these 2 anomalies could be related and the the probability of BSM physics being present is higher than just the sum of either being real? Or is this not right?

9. **Mark**
April 8, 2021

I'm an experimentalist, but am very curious about the BMW 20 result. The theory seminar speaker implied, I recall, one should not take it seriously because it was not "data-driven", unlike the 3 calculations that show the 4.2 sigma discrepancy. Is this a conclusion that is widely shared in the theory community?

When I read the abstract of the BMW20 paper last night they imply their calculation is independent because it does not rely on the e+e- experimental results that the others use and position their calculation as a new independent result which resolves the discrepancy in that it agrees with the experimental measurement, but not the other theory estimates quoted. Reading the full paper today on the archive I don't get the same impression that they claim that though and instead they talk about further calculations being needed to confirm or refute their result, thus implying its unresolved as to which calculations are the most correct.

10. **Roger**
April 8, 2021

"e"

The argument for not including the lattice number is plausible but that's not really the point.

When it comes to stats, as an experimentalist, I'm taught to decide on the analysis strategy and to stick to it (unless this becomes impossible in practice) so that any conclusion I draw from the data will have a certain statistical integrity.

The key question is whether the lattice number would have been omitted if it had agreed with the dispersion-based estimates. If it would have been omitted then fair enough. If it wouldn't have been omitted then this further weakens any attempt to claim a 4.2 sigma discrepancy.

11. **Peter Woit**
April 8, 2021

Something that strikes me about the BMW vs. Theory Initiative story. At least one of the two is wrong, having made a significant mistake in their calculation/analysis. One would hope that both groups will look very carefully at wherever they are getting inconsistent numbers and focus on finding the error(s), whether their own or errors of the other group.

12. **André W-L**
April 8, 2021

Some comments on the theory discrepancy and lattice QCD (from a lattice QCD practitioner who does not work on g-2):

1 – Even if the theoretical determination of the hadronic vacuum polarization (HVP) moves the theory prediction to match the experimentally measured muon g-2, this just shuffles the tension to other parts of the electroweak constraints (with similarly sized tension)
https://arxiv.org/abs/2003.04886

The only way to eliminate this global tension without invoking new physics, presently, is if the experimental value moves towards the current standard model theory prediction that is in 4.2-sigma tension with the experimental result.

2 – The Theory White Paper (WP – arXiv:2006.04822) considered both lattice QCD determinations of the HVP as well as data-drive (dispersive) ones. Besides the BMW result, no other lattice QCD results have a precision comparable to the dispersive approaches. Therefore, they decided to not use a lattice QCD determination in the final estimate, until the lattice results have an uncertainty small enough to compete with the data-driven determination (as noted above).

3 – Regarding BMW (arXiv:2002.12347) not being included in the the WP average, there was a well known deadline of 15th Oct. 2019 for papers to be included, if and only if they were published (not just arXiv'd). This deadline was relaxed to 31 March 2020, but is still too soon for the BMW paper to be included in the averaging procedure. See 3rd bullet on the 10th page of the arXiv version.

4 – Regarding lattice QCD results as theory predictions, as Aida El-Khadra nicely summarized in her presentation, we do not base our lattice theory predictions on any single lattice QCD result, as they all contain systematic uncertainties which must be controlled and eliminated. For example, different choices of discretizing QCD lead to finite differences that are not universal and so the continuum limit must be obtained through an extrapolation (for many quantities, all discretization effects arise from higher dimensional "irrelevant" operators). But, there is no proof this works, it is just a very well-motivated expectation based on asymptotic freedom. Therefore, we rely upon multiple independent calculations to be performed as a cross check that these systematic effects are under control. This is very synonymous to the situation that we do not accept new physics results until multiple experiments can confirm the finding (as best we can).

5 – Regarding the precision of the BMW result, as Aida also nicely summarized, the BMW result is so stochastically precise, the final result is dominated by the

systematic uncertainties, which for HVP calculations, involve more complex systematics than in more typical calculations. This increases the importance of having multiple groups independently perform the computations since systematic uncertainties do not automatically improve with more statistics and computing power. It is not statistically very significant, but as a measure of the challenge with these systematics, the BMW value shifted 1-sigma over time (from first arXiv release to publication): 712(4) [v1] to 709(5) [v2] 708(5), based upon community "criticism" of how they handled some of the systematic uncertainties, not through additional computations etc. (as noted above).

It is therefore premature to rely upon lattice QCD results to constrain the hadronic vacuum polarization contribution to g-2 with sufficient precision to make a statement about new physics or not. It is anticipated that by the time the higher-precision experimental results are available, the lattice results will be sufficiently precise and cross-checked to provide a constraining determination of the HVP and hadronic-light-by-light contributions.

13. **clayton**
April 8, 2021

André W-L — thanks for chiming in here, I for one consider your perspective to be informative 🙂

You say in closing that "the lattice results will be sufficiently precise and cross-checked" by the time the experiment becomes more precise, which is in the next year or two as a rough timescale. That indicates that other lattice groups are already working on this ab initio calculation. Do you know which groups are working on this?

14. **WTW**
April 9, 2021

In re. "criticisms" causing updates of their original paper, the BMW group has actively solicited such evaluations and critiques from other experts, including from the g-2 Theory Initiative team. While there may inevitably be some level of competitiveness between groups, in general they seem to have tried to use any available resources to improve the results. Hopefully such collaboration will continue, to help reach a consensus from lattice QCD calculations.

As to many people noting the LHCb report of possible EW lepton flavour violation in B-hadron decays as somehow further validation of these g-2 results, Tommaso Dorigo's comments seem extremely timely.

It should also be noted that a recent ATLAS report "sets a new constraint on lepton-flavour-violating effects in weak interactions, searching for Z-boson decays… " — https://arxiv.org/abs/2010.02566 And as to some new ultra-light particle being the culprit affecting the anomaly in the muon's anomalous magnetic moment, there is a recent paper showing no detection of any Axion-like particle having any EM interaction within a network of synchronized ultra-precision optical clocks, down to a level of ~ 8 x 10^-18 second. (https://www.nature.com/articles/s41586-021-03253-4.epdf) Likewise, CERN's Baryon/Anti-Baryon Symmetry Experiment (BASE) has recently published new limits on (non) detection of coupling of Axion-like Particles and photons, using a cryogenic Penning trap: https://journals.aps.org/prl/abstract/10.1103/PhysRevLett.126.041301#fulltext

Throw in the ANAIS experiment failing to replicate DAMA's problematic detection of dark matter particles after 3 years of data, and it seems that the tactic of just adding some more particles to the mix might be getting more constrained of late.

15. **André W-L**
April 9, 2021

It was pointed out to me that in their latest version, BMW addresses the electroweak tension pointed out by Crivellin et al – page 82 of the BMW arXiv is section 26, addressing this point. They present a detailed argument that the global electroweak tension (if g-2 theory moves to be consistent with experiment) is more like 2.4 sigma (than ~3-4).

16. **Roger**
April 9, 2021

André W-L
Thanks a lot for your comments. I'm pleased that a rule wasn't made up to exclude BMW.

Beyond this, while I accept and respect your experience with lattice QCD, I found your last remark a bit baffling "It is therefore premature to rely upon lattice QCD results to constrain the hadronic vacuum polarization contribution to g-2 with sufficient precision to make a statement about new physics or not."

Nobody is suggesting that lattice QCD be used to make a statement about new physics. There is simply no statement to be made with the current precision of the data and theory calculations. Instead we are in a situation in which a calculation has been made which has been peer-reviewed and has now appeared in Nature and this should surely now merit being shown next to the data even if the experiments would also feel the need for a caveat. Perhaps two plots could have been prepared. I saw the CERN seminar of the g-2 results (theory talk + experiment talk) and felt the experiment was making a mistake by not showing the new calculation in its standard publicity plot since it gave the impression of being in bed with its own theorists , which is very unfortunate. Perhaps that was ok – doing the right thing isn't always easy, if it was the right thing. However, whether the experiment and Theory Initative like it or not, people are making their own plots. It will be difficult for the experiment to keep up its standard publicity plot with its "approved" prediction given that Nature has just published a plot that is "unapproved" for comparison. Politically they need to think carefully about how to proceed.

Regarding the tension moving elsewhere, this is certainly interesting but should have nothing to do with a decision on whether to show a theory prediction for a specific observable in comparison to a measurement of that observable. Indeed,the whole business of much of particle physics these days is looking for tensions and trying to interpret them.

17. **Martin H.**
April 9, 2021

Dear Andre,

thanks for your comments! If I may add to your point about the electroweak fit: in our paper we presented several scenarios how big the tension would be depending on the energy range in which the changes in the e+e- cross section occur. In response, BMW provided arguments that these changes will be concentrated at low energies, in which case the tension in the electroweak fit only increases moderately.

However, this then implies that the low-energy cross sections would have to be changed by a lot, see
https://arxiv.org/abs/2006.12666
https://arxiv.org/abs/2010.07943
so unless the Fermilab number changed, the tensions would be moved somewhere else.

18. **Joseph Conlon**
April 9, 2021

Whether it's in Nature (the journal) is neither here nor there. Glossy covers and fancy editorials do not correct science make.

19. **André W-L**
April 9, 2021

Martin H. – thank you for the update! (those who don't know, unless Martin H has conspicuously the same initials – he is one of the leading experts on the data-driven dispersive methods for g-2 and also an expert on the electroweak fits).

clayton – if you look at Table 8 (page 80) of the theory white paper (https://arxiv.org/abs/2006.04822), the top 3 panels are results from various groups working on the problem. It is one of the most intensely studied problems with lattice QCD these days, so there are a large number of groups working on it. Figure 44, on the next page, gives you a visual representation of the same results.

WTW – I did not mean to imply BMW were not looking for feedback. My point is that the systematic uncertainties are sufficiently challenging that even one of the worlds leading lattice QCD groups did not "get it right" the first time.

Roger – BMW, in their paper, claim there is no need for new physics, the "or not" part of my statement about it being premature to rely upon lattice QCD results.

If I were one of the co-authors, I would make a similar claim as I'm certain they put a tremendous amount of effort in trying to ensure everything was controlled, and are therefore confident that within the uncertainties they quote, they have the correct Standard Model prediction. As someone without "skin in the game", I see the value in "community consensus", meaning more LQCD results need to be performed with uncertainties similar to BMW before we (the lattice and broader community) can have higher confidence.

Take it another way – if the LQCD results do not agree with the data-driven dispersive results for the HVP, at a similar level of tension that is currently quoted for g-2, that would be evidence for new physics (or a larger than expected systematic uncertainty) since LQCD is pure Standard Model and the data-driven analysis is nature.

I also agree that it is unfortunate, and a mistake not to show the BMW results on the same, or at least a companion plot. Their result is among the highest quality lattice QCD results available, if not the highest quality.

20. **SG**
April 9, 2021

@Martin H.: If all the changes are indeed below 1 GeV what is the significance of the discrepancy between the e+e- cross-section measurements and BMW ? From the lower panel of Fig 30 of https://arxiv.org/pdf/2002.12347.pdf (BMW) it seems that the first bin has a discrepancy that is more than 3 sigma. Am I reading this correctly?

21. **Martin H.**
April 9, 2021

SG: not quite. This plot shows bins in the space-like region, which you cannot directly compare to (time-like) e+e- cross sections. But the emerging picture, see Fig. 8 in
https://arxiv.org/abs/2010.07943
is similar: the e+e- data would have to be wrong way outside their quoted uncertainties. As for the significance, the global tension between e+e- and BMW (v3) is now 2.1sigma, but since the changes need to be concentrated at low energies, the local tension is bigger than that. The exact significance depends on energy range and data compilation, but to give you some idea: for a partial ("window") result the BMW paper quotes a tension of 3.7sigma, see caption of Fig. 4 in
https://www.nature.com/articles/s41586-021-03418-1
Such detailed comparisons, especially with forthcoming new data and results from other lattice collaborations, should allow for some clarification in the near future.

22. **SG**
April 9, 2021

@Martin H– Thanks a lot for your answer. So is it correct to say that BMW either has a 3 sigma(-ish) tension with electroweak precision tests or if the changes to e+e- cross section are concentrated at low energies, it has a 3 sigma (-ish) tension with e+e- data ? So whichever way we see it there is a significant tension between theory and experiment.

23. **cssm**
April 10, 2021

In the theoretical prediction, I noticed, components from individual gauge sector are mentioned. I was just wondering what happened to the cross terms from gauge mixing. Also if there is some new physics, shouldn't that be already present in the lepton-hadron cross-section data? In that case iterative approach and convergence test should also be incorporated.

24. **Anonyrat**
April 11, 2021

Experimentalists, please explain how this is disentangled: Bhabha scattering is used to measure the integrated luminosity in electron-positron colliders, which is a key to measurement of the hadron vacuum polarization. But hadron vacuum polarization is apparently necessary to calculate Bhabha scattering to the required precision.

Recently (2020), a newly computed Bhabha scattering cross-section, reducing it by 0.048% resolved a 2-decade-old 2-sigma discrepancy of LEP data with the Standard Model.
https://www.sciencedirect.com/science/article/pii/S0370269320301234

If BMW is correct, there is a correction needed to the Bhabha scattering cross-section, and to the measured e+e- data. How big is it, and will its direction go toward resolving the tension mentioned in the comments above?

25. **Ahcci**
April 11, 2021

The BMW collaboration has a new, semi-technical article up at "The Conversation." The URL is https://theconversation.com/proof-of-new-physics-from-the-muons-magnetic-moment-maybe-not-according-to-a-new-theoretical-calculation-157829

26. **someone**
April 12, 2021

@SG: No, BMW is in 3sigma tension with with chiPT predictions from e+-e-. The direct lattice prediction effort of e+-e- is just starting.

27. **SG**

April 13, 2021

@someone: I did not mean comparison with lattice but experimental data on e+e-. Fig. 8 in https://arxiv.org/abs/2010.07943 , pointed out by Martin H., is a comparison between real data and the shift in e+e- cross-section implied by BMW. This is, of course, just a restatement of the tension between the BMW and data-driven value for the HVP contribution but now focussing on the <1 GeV region for the e+e- data.

28. **Luca**
April 13, 2021

Honestly I find the work on the non-perturbative behavior of the standard model even more exciting than potential new particles. From this situation is clear that we do not understand the model well enough to make some predictions, or at least that a substantial amount of work needs to be done here. New physics is where physicists work and it is perhaps time to give more glamour to the hard work of connecting our best theory to the reality we have instead of always looking for jet another reality. High energy physics is alive and well.

29. **Will Sawin**
April 13, 2021

Exciting!

Are there other interesting situations where the discrepancies between different attempts to calculate the standard model prediction differ by multiple sigma, so that we aren't necessarily able to tell whether an experiment is evidence for a failure of the standard model?

I am tempted to ask "Could we have already observed, in some experiment, the effects of beyond-the-standard-model physics, but not have noticed it because our calculation of the standard model prediction is different from the correct standard model prediction but not from the experimental data?" but I realize this is probably not a very helpful question, in part do the the fact that "the correct standard model prediction" might not be a mathematically well-defined concept outside of the existing calculational techniques.

30. **Peter Woit**
April 13, 2021

Will Sawin,
The calculational problems with the Standard Model are pretty much just with the strong interactions (there are problems of principle with perturbation expansions for weak and electromagnetic interactions being only asymptotic expansions, but these issues only show up at too high orders of the expansion to matter).

The problems with strong interaction calculations are very serious: typically the best you can do is a lattice gauge theory calculation (Monte-Carlo simulation of a path integral), and there you're lucky to get a calculation to 1%. The only reason the g-2 calculation is so accurate is that the strongly interacting contributions to the calculation are a very small part.

So, for most things involving strongly interacting particles, the theoretical calculation has much larger errors than the experimental measurement (e.g. the masses of such particles). In general the much more precise measurements are consistent with the low precision calculations. An example where there's a possible problem involves spin and the proton, see eg. "Proton spin crisis" on Wikipedia or someplace better. But there, the theoretical understanding of how to calculate things is so bad that it's likely that the problems are just with the calculations, not problems with the underlying theory.

31. **Luca**
April 13, 2021

Hi Peter,

"But there, the theoretical understanding of how to calculate things is so bad that it's likely that the problems are just with the calculations, not problems with the underlying theory."

Can we actually say to have a theory then? We have an asymptotic perturbative theory for sure, but does this fully constraints the non-perturbative behavior, especially concerning bound states? To my naïve eye, it is more a rough set of ideas than a full theory.
I have the impression that the "beyond the standard model" things we should look for are protons, atoms and tables and chairs, not superstrings. It puzzles me why we have a fundamental theory that is utterly incapable of predicting the behavior of something as elementary as a hydrogen atom and jet we think that all that physics is boring and already understood. Where does all this confidence comes from? Who decided that the perturbative regime of a theory is its only fundamental aspect? Am I missing something? I mean I know that the people who actually work in these fields takes these problems very seriously, but jet the general consensus seems to be that there isn't new physics to be understood here. Why? Because all the physics is implicitly in the Lagrangian? But as far as I know we do not even a proper way to make sense of the Lagrangian theory in the non-perturbative regime. Do we have strong evidence to suggest that the perturbative behavior can be continued in a unique way to the non-perturbative regime without introducing anything new?

32. **Peter Woit**
April 13, 2021

Luca,
What we have for QCD is not a "rough set of ideas", but a well-defined cut-off theory, the lattice theory, so precisely defined that you can write code and do computer calculations. What we don't have is rigorous or calculational control of the continuum limit, there all we have is conjectures that there's a well-defined limit with certain properties, together with all the computational evidence being consistent with those conjectures. To convince yourself this is more than a "rough set of ideas", look for instance at
https://arxiv.org/abs/1203.1204
in particular the hadron spectrum in figure 2.

The one place where there might be an actual hole in our ability to write down a precise non-perturbative theory is not for the strong interactions, but for the weak interactions, where the gauge interactions are chiral. That's a complicated story, and there since the interactions are weak, perturbation theory gives all we need to compare to experiment.

33. **Luca**
April 14, 2021

Peter,

Thank you for the clarification. I am aware that lattice QCD is a well defined theory. However, it's value is as a proxy for an underlying continuous limit which is truly the theory we would like to have. I understand that the conjecture of a unique and well defined limit is supported by evidence, but is as far as I understand this is limit to specific settings. Your discussion about the proton spin suggests that in many, perhaps most, situations we do not have idea how to approach this limit. Is it just a problem of limited computational resources? Are you confident that a correct MC estimate of the proton spin composition could be obtained if we just had bigger computers? Or it will require novel ideas? If the latter is true then we cannot say to have a complete theory.

34. **Mark Weitzman**
April 14, 2021

Hi Peter:

Have all the fundamental difficulties of lattice gauge theory, such as fermion doubling problem been resolved, or is it simply the case that workarounds have been found for the current calculations. I have always felt that a physical theory is not really well defined unless it can be simulated on a computer in principle.

35. **Peter Woit**
April 14, 2021

Luca/Mark Weitzman,
I'm not that well-informed about the latest state of the technology of QCD calculations with fermions, but not aware of any problems of principle, i.e. that can't be solved with more computational power. This is different for the chiral weak interactions, where there may very well be remaining problems of principle.

These issues are actually related to the work I've been doing with twistors, going way back. Early in my career I worked on pure lattice gauge theory calculations, trying to take into account the role of topology, so needed to understand well the geometry of what was going on. I was very interested in the fact that the geometry was straightforward for pure gauge theory, but that when you introduced spinor fields, some sort of new geometry was coming into play and it was unclear both what it might be and whether lattice difficulties were due to not taking spinor geometry into account.

One way of thinking about what's going on is that there's a natural lattice version of fermions if they're differential form fields, with 0-forms given by fields on the sites, 1-forms on the links, 2-forms on the plaquettes, etc. These are "Kahler-Dirac" fermions. The problem is that they're not spinor-valued fields, but anti-symmetric tensor valued fields. Spinors are in some sense "square-roots" of the anti-symmetric tensors, but to construct such a square root, you need to choose a complex structure on R^4. Then spinors are (up to a phase factor) either the holomorphic or anti-holomorphic differential forms.

There is an S^2 of appropriate choices for the complex structure on the tangent space at each point in R^4, and a point in the projective twistor space is just a point in R^4 together with a choice of the complex structure (a point in the fiber S^2). So, on projective twistor space, the spinor fields have a straightforward geometrical interpretation (although in terms of holomorphic geometry).

I haven't thought seriously about this in a long time, but back when I was thinking about it, I didn't see any obvious way to use this to solve any of the problems of lattice fermion fields. Some of the things I've started thinking about now (how to relate chiral Yang-Mills theory on R^4 to holomorphic theories on projective twistor space) might though give some new ideas on the lattice stuff, we'll see…

36. **Andre W-L**
April 15, 2021

Luca, Mark, Peter, Will,

A few more comments related to your comments and questions.

1. The fermion doubling problem is practically solved in several ways now, and each method has been used to make post-dictions of well known quantities that agree with the experimental numbers and each other (after the continuum limit extrapolation and physical quark mass extrapolation/interpolation).

2. It is now common for quantities of mesons (pions, kaons, charmed and bottom mesons) that lattice QCD results are obtained at the sub-percent level of precision with a fully quantified uncertainty budget. This level of precision requires the inclusion of QED and Weak interactions to reduce the uncertainty from the ~1% level down to the 0.2% level (the target precision for many quantities). This is starting to become the case for simple properties of nucleons, which have now started to reach the 1% level of precision.

3. The "Proton spin crisis" is a red herring. In units of h-bar, we know the spin is exactly 1/2. What is complicated is to determine how the various constituents of the nucleon contribute to the spin. Now, there are several complete calculations including the quark contribution and gluon contribution that obtains the total spin. For example, this result obtains the total spin with a 15% uncertainty:
https://arxiv.org/abs/2003.08486

The "spin crisis" came because, based upon the quark model (which is an extremely naive and in many cases surprisingly successful description of protons, neutrons etc), there was an expectation that the spin of the proton would come almost entirely from the "valence" quarks of the proton (which has up, up, down valence quarks). It was found experimentally that the total contribution from these valence quarks fell far short of adding up to 1/2. But, we know these valence quarks are confined (very strongly) by gluons, and so it is not surprising at all that there is substantial contributions to the spin from the gluons and the orbital angular momentum contributions from the proton's constituents.

4. There are several interesting puzzles related to strong interactions. There is the more famous "proton radius" puzzle in which the size of the proton when measured from electrons or muons disagreed by as much as 7-sigma. This puzzle is now expected by most in the community to have come from systematic uncertainties in the experimental determinations which are now beginning to be resolved.

There is the "neutron lifetime puzzle" in which the lifetime of the neutron when measured in a "beam" and "bottle" experiment disagree at the 4-sigma level. The beam experiment only measures Standard Model decay modes and the bottle measurement simply counts the number of neutrons vs time and so measures all effects. This generated a lot of interest that there might be new, relatively light, new physics decay modes. Many expect this discrepancy is driven by a systematic uncertainty.

In both cases, lattice QCD can be used in principle to help resolve these puzzles, but the challenge of obtaining a sufficient precision to be useful has prevented the calculations from contributing so far. Calculations of nucleons generically require exponentially more stochastic samples to obtain the same relative precision as for mesonic quantities (this is a well understood Monte-Carlo sampling problem related to sign-problems and stochastic sampling of fermions).

5. There are other exciting examples in "nuclear physics" where lattice QCD can be used to compute quantities with a 20% uncertainty which will be useful. For example, the search for neutrinoless double beta decay of large nuclei requires an understanding of short distance contributions to how two-neutrons can simultaneously beta-decay to two protons, assuming the neutrino is Majorana in nature (it is at least in part is its own anti-particle – the only fermion we know of for which this is possible, as it does not cary any Standard Model "charge"). While we can never use lattice QCD to calculate the decay of a large nucleus, we can compute the basic neutron-neutron to proton-proton amplitude for various models of Majorana neutrino exchange between two nucleons. Knowing the QCD contribution to this amplitude with a 20% uncertainty is more than sufficient to help the field. Unlike many other processes, there is no experiment that can measure this neutron-neutron to proton-proton process because if it occurs, it is only in a big nucleus, so isolating the underlying amplitude is not possible.

Lattice QCD can also be used to constrain the interactions of strange-matter (hyperons) with neutrons in principle much better than experiment. This is because the hyperons rapidly decays through Weak interactions and so the data set is very limited (there are now several international experiments that will significantly improve the data set). In lattice QCD, we are free to "turn off" the Weak interactions so the hyperons are stable. What is interesting is that an improved understanding of hyperon-neutron forces, and triple-neutron forces, may improve our ability to predict the nuclear equation of state which is relevant for understanding neutron stars and how they might merge in binary systems, and if supernovae will result in a neutron star or black hole.

We (the community) are optimistic that as the exa-scale supercomputers come online (starting next year), we may get enough computing power to reliably compute these processes. I could go on, but I've already written a "bit" more than I intended.

37. **Gianni**
April 15, 2021

Andre W-L,
I am very grateful for the extensive and stimulating, though short, list of issues that the lattice community is able to investigate either with great precision, good precision, or an acceptable one.
I would like to ask your opinion on the challenge presented by lattice calculations of the parton distribution functions, which are so relevant in the analysis of HEP experiments. I know that there efforts along this directions.

38. **André W-L**
April 16, 2021

Gianni,

That is a very exciting topic these days also. Until a few years ago, the lattice community had come to the conclusion that lattice QCD could be used to only compute moments of the parton distribution functions. A few years ago now, the field was re-vitalized by a proposal of Xiangdong Ji, that, instead of computing these structure functions directly, one could approach the problem by computing a related quantity (quasi-parton distribution functions) that in the limit of large nucleon momentum, become the parton distribution functions. It took a few years for the community to sort out the most essential details and now great progress is being made (the critical difficulty was understanding how to renormalize these objects). There are now at least three variants of the idea being used in the community, each with their own advantages and disadvantages, which is also great as it provides multiple ways to get at the same quantities (perhaps in different kinematic regimes). There are at least as many lattice groups working on this problem as those who are working on g-2 calculations. The community is now pushing the idea to compute the transverse momentum dependent distribution functions with some promising ideas being pursued.

One of the biggest challenges in these computations is related to the same signal-to-noise problem mentioned above. As you look at a boosted nucleon, the noise issue becomes more severe because, the boosted nucleon has more energy, and so the correlation functions decays more rapidly in Euclidean time, while the noise of the correlation function has an energy scale that does not increase as the momentum is increased, and thus the mass gap which dictates the degredation of the signal-to-noise becomes larger, causing a more rapid loss of the signal. People are actively working on clever ideas to circumvent this problem (in addition to using bigger/faster computers). These calculations are well on track to help with HEP and NP problems (the planned electron-ion-collider).

There are already collaborations between lattice groups and those who work on the structure functions to begin figuring out how to use lattice QCD results as inputs to help determine and constrain them, so I anticipate the next several years will be very fruitful for this type of research.

39. **Gianni**
April 16, 2021

André W-L ,
thank you very much for the very nice overview. Let us hope to see soon reliable calculations also on parton distribution distributions and TMDs! I heard that the issue of the renormalization within the Ji framework is highly non trivial, but as you pointed out the sinergy between different approaches should lead us to the goal.

Hawking Hawking

April 8, 2021
Categories: Book Reviews

There's a very good new book about Stephen Hawking that just came out, Charles Seife's Hawking Hawking. Some detailed reviews can be found at Prospect Magazine (Philip Ball) and the New York Review of Books (James Gleick). Seife has chosen to write the story of Hawking's life starting at the end and ending at the beginning, which takes some getting used to, but provides a different perspective.

Hawking was a huge world-wide celebrity, widely considered by the public and the press to be the modern-day analog of Einstein, dominating the field of theoretical physics. His personal story, involving a long life battling a disease that left him quadraplegic and severely disabled, added greatly to the phenomenon he became. His life has been the subject of various books, films and TV shows, but only now, three years after his death, has something appeared that gives an account of this life corresponding not to myth but to reality.

The reality of this story is that Hawking was a very good theorist, with a high point of his career his work on Hawking radiation in 1974. I remember attending lectures by him at Princeton in the early 1980s, when he was actively working on Euclidean quantum gravity. His speech was hard to follow, so one of his graduate students or postdocs would translate for the audience. Unfortunately, the disease continued to take its toll, and after he nearly died from it in 1985, losing the ability to speak to a tracheostomy, all evidence I've seen is that he was no longer able to continue to do research at the highest level. From then on he lived a remarkable and full life for another 33 years, including some collaborative work with other theorists, but he was no longer the driving force behind any new research programs. Seife quotes extensively many physicists who worked with Hawking during this time, including Andy Strominger and Hawking's student Marika Taylor, who give a fairly good idea of what it was like to work with him.

During the early 80s Hawking was quite fond of the idea that N=8 supergravity would be a successful unified theory, famously giving a talk about it entitled Is the end in sight for theoretical physics?. The advent of string theory coincided with the serious deterioration in his health and ability to communicate. From then on he was reliant on others to explain to him what was going on in string/M-theory:

> Taylor didn't yet know how difficult the task ahead of her was. Her thesis was going to be on M-theory, but Hawking was not an expert on the subject. Taylor would largely have to guide herself straight to the frontier of an incredibly difficult branch of theoretical physics, digest all the important work of the past few years, and then teach Hawking what she had learned before even being able to come up with a thesis idea. On top of that, Hawking wasn't particularly enthusiastic about the string-theoretic parts of the theory: he just cared about supergravity. "As I was starting to go into those areas, I wouldn't say that he was skeptical," Taylor says. "He was just not interested… Actually I think the real truth is that he didn't want to engage with people on territory he was unfamiliar with."

Soon after I started this blog in 2004, I wrote here and here about Hawking's heavily publicized talk in Dublin announcing that he had figured out how to resolve the black hole information paradox. I was baffled by reports of his talk and his paper, and not the only one. Seife tells the story of this in some detail, and I think the consensus is that there was no there there.

A large part of Hawking's celebrity and income derived from his work as a popular author. His 1988 popular book, *A Brief History of Time*, was a huge success. Seife tells the story of how that book came about, partly motivated by the need for a new source of income. An initial manuscript due to Hawking was edited and improved a great deal before the published version was done. Many other books followed, and if you go to any bookstore with a science section, you're likely to find quite a few of them for sale. The problem is that, on the whole, they're not any good, and they're not written by Hawking. Seife documents this sorry tale in some detail.

I first noticed this when I ran across a copy of God Created the Integers, a thick anthology of writing on mathematics, supposedly edited by and with commentary by Hawking. At least he's listed as the sole author. Given the topic and the volume of material, it seemed highly implausible to me that Hawking was actually the author. For a review of the book, see here. Seife explains in detail that much of it is essentially plagiarized from other sources, and that to this day, it seems to be unknown who wrote the material (just that it clearly wasn't Hawking).

At least this sort of thing got little attention, which unfortunately was not true of his 2010 *The Grand Design*, co-written with Leonard Mlodinow. I wrote about this book in some detail here. Put bluntly, it was an atrocious rehash of the worst nonsense about M-theory and the string theory landscape, with an argument for atheism thrown in to get more public attention. This is the sort of thing that has done a huge amount of damage to both the public understanding of fundamental physics, and even to the field itself. James Gleick's otherwise excellent review of the Seife book ends with

> Hawking promoted the theory of everything with a vengeance. He made it part of his brand. It was the title of the 2014 biopic in which Eddie Redmayne played Hawking. The much-quoted ending of A Brief History of Time raised the prospect of a complete theory—a final theory: "It would be the ultimate triumph of human reason—for then we would know the mind of God." At the 1998 White House event, Hawking told the assembled dignitaries:
>
> > We shall have to rely on mathematical beauty and consistency to find the ultimate Theory of Everything. Nevertheless I am confident we will discover it by the end of the 21st century and probably much sooner. I would take a bet at 50-50 odds that it will be within twenty years starting now.
>
> He would have lost that one, too. It was hubris—but it sold, and it is part of his legacy. He showed younger colleagues how to chase grand theories and best-selling books. Hawking is not the only physicist guilty of hawking.
>
> The theory of everything is a false idol. Why should the universe, which grows more gloriously complex the more we see, be reducible to one set of equations and formulae? The point of science is not the holy grail but the quest—the searching and the asking. Let us hope there will never be a final theory.

We now live in an environment where the idea that there may be a deeper, more unified theory has become completely discredited, through the efforts of many, with Hawking playing an unfortunate part.

If you have any interest at all in Hawking's story, you owe it to yourself to read this book. It's a rich and thoughtful examination of his life and work, pushing aside the myth and bringing out the much more interesting reality behind it.

Update: There's now a review of the book by Frank Wilczek in the New York Times.

   I suppose it was a difficult branch, not bran?

   I'm just here to say I've read the book too and also recommend it.

2. **Martin Visser**
April 9, 2021

I can't quite make out what this phrase was meant to say – "and I think the consensus is that there was no there there."

3. **Davide Castelvecchi**
April 9, 2021

I have a much more positive view of The Grand Design. For one thing, it's well written and extremely readable, contrary to A Brief History of Time. And the central thesis of the book is precisely that there may not be one ultimate theory, only a number of partial theories, each explaining a limited range of phenomena. I found that surprising and refreshing because it suggested that Hawking (to the extent that he had anything to do with the contents of the book) had decided to move on from his "reading the mind of God" propaganda.

4. **Genghis Khan**
April 9, 2021

Whenever anyone mentions Leonard Mlodinow, I cannot help but think of Langlands's incredible review of his book "Euclid's Window".

5. **Philip Gibbs**
April 9, 2021

It's not unusual for physicists to do their most original work before the age of 40. Hawking gave us singularity theorems, Hawking radiation, quantum cosmology and much more. He brought new mathematical insight and tools to work on general relativity and opened up the field of quantum gravity when most physicists had no idea how to make any progress. He may not have solved the black hole information paradox, but he was the one who highlighted the significance of the problem in the first place and that is at least as important.

It's futile to compare the achievements of physicists who worked on different topics many years apart, but Hawking was a great physicist by any standard. In the UK his work was the subject of television documentaries from the mid 1970s, long before he started writing books, and it was very clear that being in a wheelchair was not the main reason for his fame. Nobody gets to be the Lucasian Professor of Mathematics at Cambridge because of media popularity.

If he went on to popularise his work when it became difficult for him to keep up with later developments due to his condition, then that is to be celebrated. It was probably beyond human reach for him to take in the new mathematics of string theory enough to contribute to research given his disabilities, but he had worked on supergravity and could certainly see that it was a worthy natural progression. There is a wide range of opinions on the current state of subjects like M-theory, supersymmetry and multiverses among physicists and not everyone agrees with your conclusions. The status of the subjects may well be overhyped but the endgame has yet to be played out.

If Hawking needed more and more help with writing his later books then that is understandable. It's safe to assume that he was able to set directions, read drafts and suggest changes. Being able to keep up any kind of active life required finances and he may not have had his name attached to some of these later works otherwise, but I am sure he kept his integrity intact. Both his scientific work and his popular books will continue to be highly influential for a long time, and rightly so.

"There is no there there" is how Gertrude Stein famously described the state of broadband access in Oakland, the city of her 1874 birth. For more on this:

https://www.wsj.com/articles/why-gertrude-steins-no-there-there-is-everywhere-1517589198

7. **Bill**
April 10, 2021

Who says the idea of a unified theory is discredited??

It's true that one or two first pass ideas didn't work so far, but come on, even the over-the-top hype machine (hawking included) and a couple of possibly-failed attempts does not mean the universe doesn't admit a simpler description than the standard model. It may be that unification is somehow truly, ultimately impossible, but the idea has barely just come into existence compared to the timescale over which we've been continuously simplifying our scientific theories of nature. I think people are generally smart enough to know not to take 20-30 years of limited work by a very finite set of people to mean that the whole idea of a unified theory is somehow "discredited" at this point.

8. **DSNYC**
April 10, 2021

It is worth pointing out here that had he lived not too much longer, there is every likelihood that Hawking would have shared the Nobel Prize with Roger Penrose.

9. **Peter Woit**
April 10, 2021

Bill,
I should clarify what I see as Hawking's role in this, it's complicated. For evidence that the idea of a unified theory has been discredited, see the Gleick quote above, also Davide Castelvecchi's comment (both of them are excellent science journalists). There are many examples of this from leading physicists that I've documented here on the blog, the latest was a couple weeks ago from Robbert Dikjgraaf, the IAS director, see here
https://www.math.columbia.edu/~woit/wordpress/?p=12245

What's driving this are various forces. The main one is the failure of the string theory unification program, together with the decision by many string theorists to refuse to acknowledge this, but to instead try to make the case that the conventional idea of a unified theory should be abandoned. Dijkgraaf is one example.

Another force driving this is people like Kaku and his recent book. He's loudly making the case for unification, but a case based on ridiculous claims about string theory and its testability that can't be taken seriously. This does just as much damage to the case for unification as Dijkgraaf.

Hawking is a more complicated story. Back in 1980, when he was still quite active and very aware of what was going on in the field (and pre-string theory), he made a strong case for unification via N=8 supergravity. That theory doesn't quite work as a unified theory, although it comes remarkably close. His 2010 "The Grand Design" book was completely different. For a detailed discussion of it, see my review at the time, which I titled "Hawking Gives Up"
https://www.math.columbia.edu/~woit/wordpress/?p=3141

That book really is a rehash of string theory multiverse pseudo-science, explicitly abandoning his 1980 point of view. Does it really reflect a thoughtful evaluation by Hawking of all the evidence or is it Leonard Mlodinow's uninformed retelling of what people like Susskind were pushing at the time? I'd argue it's likely more the latter than the former.

10. **Alan**
April 10, 2021

The book sounds interesting. My perspective may be biased because I did my PhD with Stephen in the late 1970's so I was there when he became Lucasian Professor and I heard his talk about the possible end of theoretical physics. At that time his reputation among physicists was incredibly high due to over ten years of highly successful research. This included his analysis of general relativity, building on tools that Penrose had developed, and his work on quantum field theory on curved spacetime which culminated in his theory of Hawking radiation. At that time he seemed, at least to a lowly graduate student like myself, to be completely on top of the technical material. He had a great sense of humour so I wouldn't be surprised if he joked about how he became Lucasian Professor just as he joked that deciding to study quantum gravity was the first sign that you are going mad. I had much less contact with him after my PhD because I decided that I didn't have a clue about how to quantize gravity (and suspected that nobody else did either) so I left physics for the new and obscure subject of AI. When his book came out I was surprised that half way through it switched from material that was well established (e.g., by experiments or by strong circumstantial evidence) to ideas that were much more speculative, but without this being signaled to the reader. I found this, and the popularity of the book puzzling and always assumed that the success of the book was largely due to the photo on the front cover. The lack of distinction, in popular accounts of physics, between theories which are speculative and those which are experimentally verified has grown enormously over time and is the main reason why I keep coming back to this blog for a dose of heathy skepticism. It is now more than forty years since Stephen gave his lecture about whether the end was in sight for theoretical physics. My personal view is that in science, like in many things, it is important to be in the right place at the right time with the right skills. Quantizing gravity, or unifying physics, may be almost impossible to do by pure thought and might need to wait until there are experiments to guide us (perhaps finally there is a crack in the standard model). When I started my PhD I asked Stephen if there were any experiments to guide a theory of quantum gravity and he answered no with a big grin.

11. **Bill**
April 10, 2021

Hi Peter,

Ok, fair that some people have somehow declared either failure or a moved the goal posts with respect to unification. However, just a comment from a "boots on the ground" theorist, I would say pretty much everyone actively working (e.g. not including Dijkgraaf) on hep/qg is still quite open to the idea of unification.

OTOH, true enough that few people are very actively working on it, since at the moment there's now a lack of promising immediate directions. In my biased/anecdote-based opinion, I think most people (especially younger people) would view this as likely a temporary situation rather than some fundamental roadblock. An undercurrent of current work is to poke around looking for news ways to approach unification, rather than to throw our hands up and declare it's impossible.

I suspect we would probably agree that the set of very public voices (e.g. Kaku and company) is an unfortunately very unfaithful representation of the field as a whole.

12. **Peter Woit**
April 10, 2021

Bill,
It's not that most theorists think unification is impossible, more that the general attitude now is that progress on unification is not on the agenda, but must await finding M-theory, or replacing space-time with amplituhedra or error-correcting codes, or finding a new particle at the LHC, or some new young Einstein telling us all the answer, etc. But that situation is a complicated topic, with people having many different attitudes.

Staying with the topic of Hawking, I think the situation now is dramatically different than that of the 1980 when Hawking gave his talk and I was a grad student. At the time we'd just been through a period of huge progress on unification and there seemed every reason to believe that more was possible, so this was very much worth thinking about. Now we're in very different times, with Hawking's 1981 talk often treated the way Gleick treats it: a hubristic worship of a false idol.

I see this history very differently: Hawking was not wrong to argue that N=8 supergravity was remarkably close to a unified theory and such a thing might be within humanity's grasp. But within a few years after 1980, Hawking got too sick to keep working at the highest level, and most theorists working on unification turned to something different which really was a false idol. Leonard Mlodinow's 2010 book was an example of where this led, perhaps a healthier Stephen Hawking would had a very different point of view.

13. **Mark Hillery**
April 11, 2021

The Grand Design should really not be referred to as Leonard Mlodinow's book. An account of the writing of that book can be found in Leonard's recent memoir about working with Hawking. Hawking was very much involved in its writing. To my knowledge, and the memoir reinforces this, the views expressed in the The Grand Design are mainly those of Hawking.

14. **Peter Woit**
April 11, 2021

Mark Hillery,
I haven't seen Mlodinow's recent book about working with Hawking, remember though reading something many years ago from him about this experience. From that and from the accounts of others working with Hawking in Seife's book, my impression is that Hawking's communication difficulties in later life meant that he was getting all his information second-hand, filtered through others. One thing I don't know about is the extent to which he could, for instance, read a book or article on his own.

My point about attributing the book to Mlodinow is somewhat of an exaggeration (likely the book reflected Hawking's views accurately on many topics), but I think not when it comes to many scientific rather than philosophical issues. As an example, in my posting about the book, I quoted this:
"various calculations that physicists have performed indicate that the [super]partner particles corresponding to the particles we observe ought to be a thousand times as massive as a proton, if not even heavier. That is too heavy for such particles to have been seen in any experiments to date…"
This is misleading nonsense. Maybe it's Hawking's own nonsense, but I strongly suspect it's nonsense that Mlodinow got not from Hawking but from somewhere else.

15. **Doug McDonald**
April 11, 2021

Peter: what does "finding M theory" in " more that the general attitude now is that progress on unification is not on the agenda, but must await finding M-theory" mean?

16. **Peter Woit**
April 11, 2021

Doug McDonald,

I think a common attitude among “string theorists” these days is that any hope of unification must await first finding out what M-theory=non-perturbative string theory is, i.e. actually have a full definition of what string theory is. The problem with this is that it’s a problem that has been around for 25 years, with no one having any viable ideas, so hardly anyone working on it.

17. **Lee Smolin**
April 17, 2021

Dear Peter,

While we are talking about relativists, one of the very greatest, Ezra Ted Newman, died on March 24. He made many lasting contributions to our understanding of general relativity (Kerr-Newman black holes, Newman Penrose spinors, heaven theory, (related to twistor theory and many others) and was much loved by many friends and colleagues.

Thanks,

Lee

18. **Peter Woit**
April 17, 2021

Thanks for letting us know Lee. I noticed there’s an obituary here
https://www.utimes.pitt.edu/passings/physics-ted-newman
Also, an older article about Newman here
https://www.chronicle.com/article/a-humble-heavyweight-in-physics-finally-gets-his-due/
compares him to Hawking:
“the physicist Stephen W. Hawking, who is about as good at attracting attention as Mr. Newman is at deflecting it.”

19. **Luysii**
April 17, 2021

Hawking did much more than physics. I ran a muscular dystrophy clinic for 15 years. I made sure my ALS patients knew of him (they didn’t in the 70s). Hawking gave them all hope, something no physician could do.

Finished Some Things

April 13, 2021
Categories: Uncategorized

I've now finished with two things that I've been working on over the last year or so:

- The paper explaining my proposal for "Twistor Unification" is now done and uploaded to the arXiv, see here.
- I've finished lecturing for the course on quantum mechanics for mathematicians that I've been teaching this academic year. Because of the Covid-required online format for the lectures, they could easily be put on Youtube, where they're available here. I'm hoping to never ever have to teach this way again, so don't expect to ever again be producing Youtube lectures. The lectures pretty closely follow my book, and I had been hoping to work on improving and expanding the text. Unfortunately, partly due to laziness and partly due to the twistor stuff, while I found a lot in the book that needs improvement, I didn't find the time to do the necessary rewriting and writing. I do however have a notebook full of notes on what needs to be done.

For the future, I'm hoping to go on some sort of vacation in a couple weeks, and soon get back to work on some of the major issues raised by the unification proposal (much of which is very sketchy, a lot to be done). I hope to do quite a bit of traveling the rest of this year, likely won't be teaching in the fall, but probably will be teaching the quantum course again next year during the spring semester. At that point perhaps I'll get finally get around to the project of rewriting and expanding the quantum book.

   Another eclipse?

2. **Peter Woit**
   April 13, 2021

   LMMI,
   Unfortunately the only total solar eclipse in the next couple years is December 4 in Antarctica, which is not so easy to get to (could be done, but the cost is somewhat prohibitive). I'm hoping to make it to Europe late summer or fall, Covid permitting…

3. **Jim Lai**
   April 13, 2021

   Thank you Prof. Woit for the book and the online course.

   I am a self learner. I am still in Chapter 6. I am taking my time (doing it carefully and making notes in LaTeX) and enjoying the study. This may be the only good thing that has come out of COVID.

4. **Martin van Staveren**
   April 14, 2021

   In the intro of the book it is stated

   "Some of the main differences with standard physics presentations include:
   • The role of Lie groups, Lie algebras, and their unitary representations is
   systematically emphasized, including not just the standard use of these to
   derive consequences for the theory of a "symmetry" generated by operators
   commuting with the Hamiltonian."

   If the group is not that generated by an operator commuting with the Hamiltonian, then what does the group refer to? This is the conceptual problem of gauge field theory: we just posit a local non-abelian symmetry and plop there is the gauge field. But why demand this local non-Abelian symmetry?

5. **Martin**
   April 14, 2021

   From p. 34:
   > An argument from beauty can be made …
   You might get some backreaction from a comment like that

6. **Peter Woit**
   April 14, 2021

   Martin van Staveren,

   The reason for local symmetry (Abelian or non-Abelian) is that, while the theory of a free field is not invariant, the theory of a field coupled to a gauge field is, so this gives you an interacting theory. In the usual way of thinking about this, there's not much representation theory going on in the case of gauge symmetry: you're looking for states that are trivial representations of the gauge symmetry.

   For the sort of thing I had in mind in what you quote, two examples are:

   1. Lorentz boosts: there are a unitary symmetry of the state space in a relativistic theory, they don't commute with the Hamiltonian.

   2. For a system of oscillators, some quadratic operators in the P,Qs or in the a,a^dagger s that don't commute with the Hamiltonian (e.g. different number of annihilation and creation operators) can be understood as the Lie algebra representation operators for a larger (symplectic) group than the usual unitary group of dimension n acting on n oscillators. This action of the larger symplectic group has physical significance, you can use it for instance to understand squeezed states in quantum optics (this is explained in detail in the book).

7. **Peter Woit**

April 14, 2021

Martin,

I'm hoping so, that was meant to provocatively challenge a common point of view (one with a very eloquent expositor…).

8. **Martin van Staveren**
April 14, 2021

"The reason for local symmetry … is that, while the theory of a free field is not invariant, the theory of a field coupled to a gauge field is, so this gives you an interacting theory".

Yes, that what I meant, The need for a local symmetry follows from the need for an interacting theory. Usually the logic runs in the opposite direction.

9. **anon**
April 14, 2021

Peter, I found your book outstandingly clear, benefiting from you teaching the subject and getting feedback from your students no doubt. But I feel the exercises should be more carefully integrated into the relevant sections rather than left at the back.

10. **Peter Woit**
April 14, 2021

anon,
I agree completely. Probably the weakest aspect of the book pedagogically is that it needs more exercises, ideally I'd think at least twice as many, integrated with the chapters. This is among the things I'd hope to work on this past year while teaching the course, but never got to. Maybe next year….

11. **Low Math, Meekly Interacting**
April 15, 2021

I'm guessing this ranks pretty low on your list of priorities, but worth a try: Any chance of an expository piece, either here or elsewhere, meant to convey the main concepts of "Twistor Unification" to non-experts?

For instance, it appears you are identifying what I might have understood to be a "mathematical trick", i.e. analytic continuation (a.k.a. Wick rotation in this instance, I think), with an actual physical process, i.e. electroweak symmetry breaking. I wonder to my naive self if this implies something about the nature of spacetime before and during the corresponding cosmological epoch. What does it imply in general to take Euclidean spacetime "as fundamental"? That Minkowski spacetime is not? And so forth. I probably can't even formulate the right questions, which makes this attempt to understand all the more embarrassing. But I am interested, nonetheless, it what it all "means".

12. **Peter Woit**
April 15, 2021

LMMI,
I had been thinking that there are aspects of this that I should try and write about in a way that would be as widely accessible as possible, maybe as a blog post. An example would be the the basic picture of twistor theory and how it relates Euclidean and Minkowski space. It took me a while to get the right picture in mind, and what I wrote in the paper doesn't easily convey that. So, may be will try that sometime soon.

On the analytic continuation business, there I did try and write things out in an expository manner in the paper. There's a lot to say about this, but one simple fact is that if you say you are only going to think about Minkowski space-time and functions on Minkowski space-time, avoiding analytic continuation, that's not actually an option. As you find in every textbook and as I work out in the paper, if you try and write down the simplest theory of free particles you end up with ill-defined formulas (this is true even for the propagator of the non-relativistic free particle). You have to do something to make sense of these formulas, the textbook tells you what to do as an "i\epsilon prescription". When you do that, you're defining your propagator as the boundary value (as \epsilon goes to zero from the positive direction) of an analytic continuation.

If you look at almost all the non-perturbative work on QFT, it is actually done in Euclidean space-time, with the idea that at the end of the calculation you analytically continue to Minkowski. The hard to believe claim I am making is that the way space-time symmetries behave under analytic continuation is much trickier than you might think (the behavior is straightforward for correlation functions, but for states you need to take into account the fact that you must break Euclidean invariance to define states and to know how to analytically continue to Minkowski).

I've been trying to think more about what this point of view implies for quantum gravity, and what strikes me is that how to even formulate the problem there is quite unclear. Beyond a recent paper of Kontsevich and Segal where they try and analytically continue in a space of metrics, I know of very little that seems to have been done about this (would love to hear from those who know more).

13. **Arnold Neumaier**
April 16, 2021

Peter,

"what this point of view implies for quantum gravity, and what strikes me is that how to even formulate the problem there is quite unclear."

Canonical quantum field theory is formulated in curved spacetime (where analytic continuation makes sense only in special cases) by defining the propagators using the theory of linear hyperbolic PDEs rather than by an $i\epsilon$ prescription. See, e.g.,

Hollands, Stefan, and Robert M. Wald. "Quantum fields in curved spacetime." Physics Reports 574 (2015): 1-35.

This works very well perturbatively. It also covers canonical gravity if one accepts that for higher and higher accuracy you need to use more and more coupling constants.

14. **Peter Woit**
April 16, 2021

Arnold Neumaier,

Except, see page 68 of that paper
https://arxiv.org/abs/1401.2026
I don't think that using microlocal analysis really gets you away from having to consider analytic continuation.

In general, I just don't understand the point of view that one should avoid having analytic continuation a part of your fundamental theory. One gains nothing and loses a lot.

15. **Arnold Neumaier**
April 19, 2021

Peter,

Microlocal analysis allows and heavily uses analytic continuation on tangent and cotangent spaces (which are flat vector spaces), but not on the manifold!

'page 68 of that paper' is a distribution in flat space, hence has no bearing on curved space modeling.

'I just don't understand the point of view that one should avoid having analytic continuation a part of your fundamental theory. One gains nothing and loses a lot.'

Analytic continuation of curved space-time without symmetries is simply ill-defined. p.7/8 of the above paper by Hollands and Wald states:

"However, a general curved spacetime will not be a real section of a complex manifold that also contains a real section on which the metric is Riemannian. Thus, although it should be possible to define "Euclidean quantum field theory" on curved Riemannian spaces [65], there is no obvious way to connect such a theory with quantum field theory on Lorentzian spacetimes. Thus, if one's goal is to define quantum field theory on general Lorentzian spacetimes, it does not appear fruitful to attempt to formulate the theory via a Euclidean approach."

They don't give a reference for their no-go statement, but I think this is a theorem of differential geometry. Thus one loses nothing but gains logical correctness.

16. **Igor Khavkine**
April 19, 2021

Peter Woit: "In general, I just don't understand the point of view that one should avoid having analytic continuation a part of your fundamental theory. One gains nothing and loses a lot."

It's just a sad fact of life that analytic continuation is a luxury that not everyone can afford (borrowing a social justice metaphor). For a non-flat Lorentzian manifold, the existence of a Wick rotation via analytic continuation is a highly restrictive condition (one of course has to first make a reasonable definition for what Wick rotation might even mean in general). Questions about it occasionally come up on MathOverflow. Here's an example where there was a somewhat detailed discussion of the differential geometric obstructions.

Presumably, a satisfactory theory that would include both standard model and gravitational physics, would eventually have no problem describing particle creation/scattering in the vicinity of two merging black holes emitting gravitational waves into an expanding cosmological background. Such a theory does not yet exist, but if one were to also require the ability to Wick rotate as a fundamental property of such a theory, it immediately becomes highly suspect whether these two requirements are actually compatible.

17. **shantanu**
April 19, 2021

Peter: are you submitting this manuscript for publication?

18. **Peter Woit**
April 19, 2021

shantanu,
Will likely do so, need to look more into what an appropriate journal would be (e.g. non-problematic business model and copyright policy, able to referee an unusual manuscript).

19. **Peter Woit**
April 19, 2021

Arnold Neumaier,
I haven't followed through all the details in Hollands-Wald, but it looks to me like they still need to define distributions as boundary values of something holomorphic, so are assuming some analyticity of the manifold (so locally analytically continuing it) and the complex analytic story is not just on the tangent space.

Arnold Neumaier/Igor Khavkine,
I'm well aware of the usual problems with
1. Analytically continuing an arbitrary classical Lorentzian solution to a Euclidean one.
2. Making sense of Euclidean space-time gravitational path integrals.

The relation of Euclidean and Lorentz in quantized gravity theory has always seemed highly unclear to me (if anyone knows a good discussion, would like to hear about it). Perhaps the twistor picture gives a different perspective, as might the proposal here for unification with electroweak degrees of freedom.

—
I am pasting a response which might be relevant for this, from the comment section of an earlier blogpost of yours: **(Imaginary) Time Asymmetry** (Aug 6, 2020)
———————————————————————————————————-
The key idea behind this (first noted, to the best of my knowledge, by Hawking & Ellis (HE)) is based on the following mathematical result: given a Lorentzian metric g_L and a nowhere vanishing timelike direction field U, one can always construct a Euclidean metric g_E. As is well known, non-compact manifolds always admit such a vector field, as well as compact manifolds with Euler number zero.

Some references where this HE observation was discussed in the context of QFT are Candelas & Raine, PRD15, 1494 (1977) and Visser 1702.05572, while recent generalization and consequences for GR, euclidean QG, and euclidean action can be found in Kothawala, arXiv:1705.02504, arXiv:1802.07055. The latter references also discuss transition from euclidean to lorentzian, instead of just the euclidean phase.

Hope this helps.

Peter Woit wrote: “I haven’t followed through all the details in Hollands-Wald, but it looks to me like they still need to define distributions as boundary values of something holomorphic, so are assuming some analyticity of the manifold (so locally analytically continuing it) and the complex analytic story is not just on the tangent space.”

Just to clear out some potential miscommunications, here’s a bit of an explanation. The ideas about “wave front sets” and microlocal analysis referred to in the paper by Hollands & Wald do not require any kind of analyticlity of the spacetime. The basic idea of microlocal analysis is to look at the singularities of a distribution $D(x)$ by taking coordinate Fourier transforms $\hat{D}_\chi(p)$ of products $\chi(x)D(x)$, where $\chi(x)$ is a bump function with support small enough to fit into a single coordinate chart. As the Fourier transform of a compactly supported distribution, $\hat{D}_\chi(p)$ is of course analytic in the momentum variable p, but that is beside the point, as none of its p-local properties are invariant under changing the bump function $\chi(x)$ or changing the x-coordinate chart. What is invariant is the asymptotic behavior of $\hat{D}_\chi(p)$ for large p (“high frequencies”). This information is collected geometrically into a subset of the cotangent bundle of the spacetime, the “wave front set”. The key “Hadamard property” identifying physically reasonable n-point functions in QFT on curved spacetimes, as referred to by Hollands & Wald, is formulated purely in terms of this wave front set. The Hadamard property and its relatives are considered to be appropriate generalizations of all the $\pm i\epsilon$ prescriptions floating around in flat space QFT.

When the spacetime is analytic, one can indeed analytically continue the spacetime coordinates into complex directions and define distributions as boundary values of holomorphic functions. In that case, there absolutely is a relationship between holomorphicity properties (the size of the domain of the holomorphic function whose limit is being taken) and the wave front set (of the distributional boundary value). This relationship is captured by the “analytic wave front set”.

A quite detailed exposition of the above ideas can be found in the lecture notes arXiv:1901.10175 (or a bit shorter and down-to-earth one in arXiv:1412.5945, risking a bit of self-promotion 😅).

DKepler/Igor Khavkine,

Many thanks for the clarifications and the references, those are very helpful.

Some History

April 29, 2021
Categories: Uncategorized

I'm heading out soon for a 10 day vacation in the Rocky Mountains, blogging likely to change from sparse to non-existent for the next couple weeks. I've come across the following things that people with an interest in the recent history of mathematics may find worthwhile:

- S. T. Yau over the past year has organized a series of talks on the recent history of mathematics, featuring prominent people in the subject giving expository talks on a topic, sometimes writing something up. The talks are available here, the write-ups here. I can especially recommend Nigel Hitchin's detailed explanation of the work of Michael Atiyah relevant to physics, much of which he was personally involved in.
- Lieven Le Bruyn at neverendingbooks points to some wonderful French math YouTube videos. Don't miss Alain Connes interviewing Serre, with Serre explaining that he doesn't know (or care) what a topos is.
- For a good account of the fascinating life of Alexander Grothendieck, there's Luca Signorelli's The Man of the Circular Ruins. I hadn't realized that some of the weirder writings from Grothendieck's later life are now readily available, for instance La Clef des Songes.
- For a long recent account by Langlands both of his recent ideas about geometric Langlands and his fascination with languages (including White Russian language instructors), see this letter to Yvan Saint-Aubin.

Comments

1. **Richard Townsend**
   April 29, 2021

   The Grothendieck article is truly fascinating – what a story!

2. **Michael Gogins**
   May 1, 2021

   I have been interested in Grothendieck for many reasons for many years. I think this article is absolutely the best introduction that I have read. Thanks!

3. **Luca Signorelli**
   May 2, 2021

   Hi Peter, thanks for the link! Grothendieck's story, personality and achievements are indeed fascinating. It's one of those historical figures that once approached "expand" in your field of view instead of fatally shrinking. No matter how complicated and often difficult to judge they may be.

4. **jsm**
   May 3, 2021

   The point of Langlands's letter is to explain that to create a geometric Langlands theory in the style of Hecke, that is to say with eigenvalues and eigenfunctions, we will need a theory other than that of the Russians.

   > To be more precise, the theory I described in my Russian article for the group GL(2) and elliptic curves begins with an article by Atiyah, an article that is in my opinion one of his best, and it remains, I believe, to do the same for any curve and any reductive group… It will be necessary to start by pursuing the ideas of Atiyah, but generalizing his article. But this will not, in my opinion, be easy. I haven't tried it myself, especially I don't know how to guess the structure of Bun(G) in general… The structure of Bun(G) being known, it will require an understanding of all the eigenfunctions attached to a given curve and a given reductive group. In general, this last question will be much more difficult than for elliptic curves, the case dealt with by Atiyah.

5. **Will Sawin**
   May 4, 2021

   @jsm,

   In connection with your summary it is probably worth mentioning that Pavel Etingof, Edward Frenkel, and David Khazdan recently (but earlier than the date appearing on the letter) formulated a version of geometric Langlands theory with eigenvalues and eigenfunctions, using the "Russian" theory, and without any kind of Atiyah-style explicit description of the points of Bun_G, in (https://arxiv.org/abs/1908.09677).

   They also handle the ramified case, at least for sufficiently mild (unipotent) ramification, which was something else that Langlands suggested as being interesting in this letter.

The Evolution of the Physicist's Picture of Nature

May 24, 2021
Categories: Uncategorized

Reading this Nautilus article about Julian Barbour led me recently to something I don't think I've ever read before, Dirac's 1963 Scientific American article The Evolution of the Physicist's Picture of Nature. There is a very famous quote from this article that I've often seen:

> It is more important to have beauty in one's equations than to have them fit experiment

but I was unaware of the context of that quote, in which the famous part is prefaced by "I think there is a moral to this story, namely that…" The story that Dirac had in mind was that of the discovery of the Schrödinger equation. Famously, Schrödinger first wrote down a relativistic wave equation (now known as the Klein-Gordon equation). This equation is what one quickly gets if one follows de Broglie's idea that matter is described by waves, and uses the relativistic energy-momentum relation. Here's the full story, as told by Dirac, giving his famous quote in context:

> I might tell you the story I heard from Schrödinger of how, when he first got the idea for this equation, he immediately applied it to the behavior of the electron in the hydrogen atom, and then he got results that did not agree with experiment. The disagreement arose because at that time it was not known that the electron has a spin. That, of course, was a great disappointment to Schrödinger, and it caused him to abandon the work for some months. Then he noticed that if he applied the theory in a more approximate way, not taking into ac count the refinements required by relativity, to this rough approximation his work was in agreement with observation. He published his first paper with only this rough approximation, and in that way Schrödinger's wave equation was presented to the world. Afterward, of course, when people found out how to take into account correctly the spin of the electron, the discrepancy between the results of applying Schrodinger's relativistic equation and the experiments was completely cleared up.
>
> I think there is a moral to this story, namely that it is more important to have beauty in one's equations than to have them fit experiment. If Schrodinger had been more confident of his work, he could have published it some months earlier, and he could have published a more accurate equation. That equation is now known as the Klein-Gordon equation, although it was really discovered by Schrödinger, and in fact was discovered by Schrödinger before he discovered his nonrelativistic treatment of the hydrogen atom. It seems that if one is working from the point of view of getting beauty in one's equations, and if one has really a sound insight, one is on a sure line of progress. If there is not complete agreement between the results of one's work and experiment, one should not allow oneself to be too discouraged, because the discrepancy may well be due to minor features that are not properly taken into account and that will get cleared up with further developments of the theory.

There's another remarkable aspect of this Scientific American article, something about it that would be completely inconceivable today: they write down three equations, including both the famous non-relativistic Schrödinger equation for the Coulomb potential, as well as the relativistic Klein-Gordon version.

Dirac notes that Schrödinger found his formulation of quantum mechanics in a very different way than Heisenberg found his:

> Heisenberg worked keeping close to the experimental evidence about spectra that was being amassed at that time, and he found out how the experimental information could be fitted into a scheme that is now known as matrix mechanics. All the experimental data of spectroscopy fitted beautifully into the scheme of matrix mechanics, and this led to quite a different picture of the atomic world.

whereas

> Schrödinger worked from a more mathematical point of view, trying to find a beautiful theory for describing atomic events, and was helped by De Broglie's ideas of waves associated with particles. He was able to extend De Broglie's ideas and to get a very beautiful equation, known as Schrödinger's wave equation, for describing atomic processes. Schrodinger got this equation by pure thought, looking for some beautiful generalization of De Broglie's ideas, and not by keeping close to the experimental development of the subject in the way Heisenberg did.

At the end of the article, Dirac makes the case that progress in fundamental physics may not come from a theorist like Heisenberg finding a scheme to match experimental results, but from a theorist like Schrödinger pursuing mathematical beauty:

> It seems to be one of the fundamental features of nature that fundamental physical laws are described in terms of a mathematical theory of great beauty and power, needing quite a high standard of mathematics for one to understand it. You may wonder: Why is nature constructed along these lines? One can only answer that our present knowledge seems to show that nature is so constructed. We simply have to accept it. One could perhaps describe the situation by saying that God is a mathematician of a very high order, and He used very advanced mathematics in constructing the universe. Our feeble attempts at mathematics enable us to understand a bit of the universe, and as we proceed to develop higher and higher mathematics we can hope to understand the universe better.
>
> This view provides us with another way in which we can hope to make advances in our theories. Just by studying mathematics we can hope to make a guess at the kind of mathematics that will come into the physics of the future. A good many people are working on the mathematical basis of quantum theory, trying to understand the theory better and to make it more powerful and more beautiful. If someone can hit on the right lines along which to make this development, it may lead to a future advance in which people will first discover the equations and then, after examining them, gradually learn how to apply them. To some extent that corresponds with the line of development that occurred with Schrodinger's discovery of his wave equation. Schrödinger discovered the equation simply by .looking for an equation with mathematical beauty. When the equation was first discovered, people saw that it fitted in certain ways, but the general principles according to which one should apply it were worked out only some two or three years later. It may well be that the next advance in physics will come about along these lines: people first discovering the equations and then needing a few years of development in order to find the physical ideas behind the equations. My own belief is that this is a more likely line of progress than trying to guess at physical pictures.

The context for his famous quote is thus an argument for pursuing fundamental physics by looking for mathematical beauty, not giving up on a beautiful equation just because it doesn't seem to fit experiment. As in Schrödinger's case, more effort may be needed to understand the actual relationship of the equation to reality.

Besides this argument, which I've always been well aware of and sympathetic to (despite not knowing the context in which Dirac was making it), there's something else I found very striking about the 1963 article. Dirac begins by explaining that the four-dimensional Lorentz symmetry of relativity is in a sense broken by the choice of a way of describing the state of the world:

> What appears to our consciousness is really a three-dimensional section of the four-dimensional picture. We must take a three-dimensional section to give us what appears to our consciousness at one time; at a later time we shall have a different three-dimensional section. The task of the physicist consists largely of relating events in one of these sections to events in another section referring to a later time. Thus the picture with four dimensional symmetry does not give us the whole situation. This becomes particularly important when one takes into account the developments that have been brought about by quantum theory. Quantum theory has taught us that we have to take the process of observation into account, and observations usually require us to bring in the three-dimensional sections of the four-dimensional picture of the universe.
>
> The special theory of relativity, which Einstein introduced, requires us to put all the laws of physics into a form that displays four-dimensional symmetry. But when

> we use these laws to get results about observations, we have to bring in something additional to the four-dimensional symmetry, namely the three-dimensional sections that describe our consciousness of the universe at a certain time.

Dirac also refers to work on canonical formulations of general relativity, aimed at quantizing gravity:

> … if one insists on preserving four-dimensional symmetry in the equations, one cannot adapt the theory of gravitation to a discussion of measurements in the way quantum theory requires without being forced to a more complicated description than is needed bv the physical situation. This result has led me to doubt how fundamental the four-dimensional requirement in physics is. A few decades ago it seemed quite certain that one had to express the whole of physics in four-dimensional form. But now it seems that four-dimensional symmetry is not of such overriding importance, since the description of nature sometimes gets simplified when one departs from it.

Thinking about twistor unification has led me to some similar thoughts: a Euclidean formulation of quantum theory requires picking a choice of imaginary time direction and breaking SO(4) symmetry in order to define states. Dirac thinks of our consciousness as giving us access to the state of the universe defined on a 3d slice, but the twistor point of view is even more directly related to our conscious experience. A point in space time is defined by the sphere of light rays through the point, and it is this sphere that our vision gives us direct access to, with 3d space something we make up out of these spheres.

A common argument against Dirac's point of view is that it's engaging in mysticism. For another recent article that touches in a different way on the mystical nature of a discovery about fundamental physics, see this interview with Frank Wilczek, where he tells this story:

> The mystical moment came while I was visiting Brookhaven National Laboratory, on Long Island. Somehow—I don't remember how, exactly—I wound up alone, standing on a jerry-rigged observation platform above a haphazard mess of magnets, cables, and panels. This was a staging area for assembling detectors and renovating pieces of the main accelerator there, the Alternating Gradient Synchotron (AGS). I must have gotten separated from my host for a few minutes. In any case, there I was, alone inside an aircraft-hangar-sized metallic box, staring down at the kind of equipment that people use to explore the fundamentals of Nature experimentally.
>
> And then it happened. It came to me, viscerally, that the intricate calculations I'd done using pen and paper (and wastebasket) might somehow describe this entirely different realm of existence—namely, a physical world of particles, tracks, and electronic signals, created by the kind of machinery I was looking at. There was no need to choose, as philosophers often struggled to do, between mind or matter. It was mind and matter. How could that be? Why should it be? Yet I somehow, I suddenly knew that it could be so, and should be so.
>
> That was my mystical experience. I warned you that it was ineffable.

1. **Arnold Neumaier**
   May 24, 2021

   "It may well be that the next advance in physics will come about along these lines: people first discovering the equations and then needing a few years of development in order to find the physical ideas behind the equations."

   Didn't string theorists try to do just this – except that many years of development didn't produce the hoped-for reward?

2. **CWJ**
   May 24, 2021

   The problem with the argument by beauty is, who gets to decide something is beautiful? I can assure you, the crackpots who come to my office and, more frequently now, send me e-mails (maybe they post on Tik-Tok as well, but I don't follow that), believe their ideas are beautiful…. and they get quite angry when I don't agree.

3. **Nitin Nitsure**
   May 25, 2021

   Dirac says "What appears to our consciousness is really a three-dimensional section of the four-dimensional picture." What section is this? What reaches us at any instance is some information from the past null cone and its interior, which is a 4-dimensional region of the spacetime. Even if the spacetime is flat Minkowskian, all the other points on the hyperplane t=0 of our instantaneous rest frame are separated from us by spacelike intervals, so this hyperpalne cannot be a part of our consciousness. In the presence of gravity, it is interesting to note that without simplifying — and quite unrealistic — cosmological assumptions, the past null cones of points in the spacetime are horribly tangled, and global foliations by spacelike smooth hypersurfaces do not exist in general. The latest blog entry of David Mumford titled "Ruminations on cosmology and time", dated March 1, 2021, makes this point quite forcefully.

4. **Peter Woit**
   May 25, 2021

   Arnold Neumaier/CWJ,
   I've often argued that string theory unification is not a beautiful idea (the string theory landscape is the antithesis of beautiful).
   Dirac's argument I think is not so much that you should use beauty to evaluate the success of a theory, but you should use it as a criterion for choosing a promising idea to pursue. That different people will disagree about what is beautiful then just implies that different people will pursue different research programs, which is fine.

   Nitin Nitsure.
   I don't know why Dirac was bringing our consciousness into it. It seemed he was just saying that the usual way to get a state space in a relativistic theory is to choose a spacelike hypersurface.

5. **Mark Paris**
   May 25, 2021

   Dirac's Sci Am article is cited in Ch. 1 of Weinberg's QTF. To the unintiated: both the original article (Dirac) and the volume (Weinberg) are 'must read.'

6. **Art**
   May 25, 2021

   In a humorous example of your observation, I searched in vain for equations in the 2010 reprint (that you linked to) of the original 1963 Dirac SA article.

7. **Klavs Hansen**
   May 26, 2021

A bit paradoxical, isn't it, that Dirac's preference for selecting beautiful theories over those based on empiri is based on the empirical evidence of how well the former work.

8. **Peter Woit**
   May 26, 2021

   Art,
   Good point. SciAm I guess no longer has the technology to reproduce an equation. For the original, with equations, one source is
   https://www.jstor.org/stable/24936146

9. **Low Math, Meekly Interacting**
   May 26, 2021

   I am and always will be highly skeptical of reliance on esthetics, though of course scientists are human beings, and need to follow their instincts and intuitions to a certain extent to be able to function at all. Naive falsificationism is also, of course, inadequate and theorists shouldn't be held in thrall to every new bit of data that experimentalists generate. This is clearly especially true in a new field.

   But Dirac himself seemed to have followed his own esthetic sensibilities and doubts about empirical data right off a cliff with his "large numbers hypothesis", and for every example of beauty shining a guiding light, I bet there are at least a thousand for which it was the road straight to perdition. I simply can't put much faith in "beauty", except as an occasional source of inspiration or motivation to try harder, which we all need at times in one form or another. The full account of human history simply precludes ascribing it any greater significance. It always seems to be true only with a very selective form of hindsight.

10. **Frank Wilhoit**
    May 26, 2021

    "Beauty" in equations is (A) in the eye of the beholder and (B) very largely a matter of the level of abstraction of the notation. The purpose of abstract notation is to manage complexity; that is not a matter of beauty, but of legibility, and it is a double-edged sword.

    Dirac's point, if he had one, was that ugly equations (cf. A and B above) carry, or ought to carry, some degree of presumption against their correctness (he was more explicit about this elsewhere). But the reason why we appreciate beauty in reality is not because it is universal, or even typical; it is because it is exceptional.

11. **David Roberts**
    May 27, 2021

    Even worse, the text refers to at the equation(s) that is/are no longer there, so clearly the editorial capacity is somewhat lacking too.

12. **Eli Rabett**
    May 27, 2021

    Perhaps a better description than beauty of what is sought by physicists is that the description be terse

13. **Nitin Nitsure**
    May 28, 2021

    Peter Woit

    Thank you for your explanation of Dirac's quote. However, you did not address the point about a possible lack of spacelike foliations. I am curious about the following points, and request you to shed light:

    (1) Arguably, some of the most `beautiful' spaces are homogeneous spaces G/H. A lot of physics is indeed done on such, with flat Minkowski space being an example. Representation theoretic methods go furthest for these spaces. However, the actual cosmological spacetime is said to be quite inhomogeneous, riddled with blackholes which are far from symmetric, and has a complicated global topology. (This will have to be called `ugly' if beauty is understood via symmetry.) This has two consequences: On the one hand there is no nontrivial global symmetry, and so the role of representation theory will remain confined to what comes via gauge theory (via representations of the structure groups of some principal bundles on the spacetime). On the other hand, there is no reason to believe that the cosmological spacetime admits a good enough global foliation by spacelike hypersurfaces to enable the posing of physics problems in the familiar evolution (on a state space) format that you alluded to in your answer to my comment.

    (2) It is interesting to see from your extensive quotation that Dirac recommends an approach to physics via advanced mathematics. I remember reading somewhere that Dirac never recognized in his writings the difference between a hermitian operator and a self-adjoint operator, an important distinction when the operators are unbounded. Dirac's braket notation has no room for the domain of the operators, which is of importance here. As is well known from 1930's, the definition of the braket of two unbounded self-adjoint operators will need us to apply the spectral theorem for unbounded self-adjoint operators, as the intersection of their domains can be too small. How does this square with Dirac's recommendation not to shy away from using whatever mathematics that is needed for the physics that we want to understand? Einstein managed to learn the differential geometry that he needed, so what kept Dirac away from functional analysis?

    (Note: I am not a professional physicist, and I will understand if you regard the above as unsuitable for your blog for whatever reason. In that case, I will appreciate a private answer. Thank you.)

14. **Nitin Nitsure**
    May 28, 2021

    A small correction: I should have said that (as is well known) the difficulty in defining the braket [A,B] in a straight forward way as the difference AB -BA is that the inverse image by one operator of the domain of the other operator may be too small, that is, it can fail to be dense in the Hilbert space. This is where one needs some more functional analysis, namely, the spectral theorem for unbounded self-adjoint operators and Stone's theorem.

15. **Martin S.**
    May 28, 2021

    It looks like some survivor bias with having amounts of subjectively pretty theories, but only mentioning the very existence of the correct one. I understand though that Dirac would fall for it after the distrust he had to withstand before positrons got confirmed. But hey, if a theory is already successful on some stuff, one can cautiously trust it elsewhere too.

16. **Peter Woit**
    May 28, 2021

Nitin Nitsure,
1. I don't know what Dirac would have said about that sort of problem with the usual formalism. I think he was just referring to the way the formalism deals with the simplest situation.
2. Dirac was arguing for the significance of mathematical beauty, not for advanced mathematical technology, especially not for the importance of analysis involving precise definitions and rigorous proofs.

17. **S**
May 30, 2021

It seems to me to be something of a category mistake to attempt to refute Dirac's argument for beauty with a cry for falsifiability or something. It seems manifest that experimental testing/falsification is how a theory must ultimately be evaluated, but beauty can be a very good guide as to what to work on in the first place; or at least, if one wants to take it to be so, who can complain?

(Of course, nothing about the need for experiment truly seems "manifest" after string theory, and admittedly, people other than Peter or Dirac have tried to put the latter's argument into service for ditching falsifiability altogether, so the category mistake may be a natural one at this point in history….)

18. **Curious Mayhem**
May 31, 2021

Shocking: the years when Scientific American was a serious magazine. The article is a must read, indeed.

String theory was never an example of mathematical beauty, unlike, say, the Dirac equation. The notion that string theory is beautiful is yet another part of the hype that's surrounded the subject for almost 40 years.

19. **Peter**
May 31, 2021

Was beauty really the guiding principle when Dirac discovered his equation? I always thought his most important motivation was that he was looking for an equation with only a first-order derivative in time.

It was discovered (relatively rapidly, if I remember correctly) that his equation was covariant (as it should be) and that half of the solution, if I may say so, reproduced the Pauli matrices for electron spin. What Dirac suggested for the other half, his hole theory, can hardly be described as beautiful.

So if you look at the genesis of the Dirac equation, the prime motivation seems to have been not beauty but physical intuition (that first order derivative in time). Acceptance that the equation was interesting came because it was related to experimental results (electron spin). The hole theory was rather ugly, but of course, later, positrons were discovered.

I'm not denying the Dirac equation is beautiful and immensely powerful, but I'm not certain that he pursued it because of its aesthetical qualities.

Non-empirical Physics

June 2, 2021
Categories: Uncategorized

I haven't been paying much attention in recent years to the philosophers of science studying "Non-empirical" or "Post-empirical" physics or theory confirmation. At various times I did write fairly extensively about this, see for instance here, here and here. By 2015 there was a conference in Munich on the topic, which led in 2019 to a volume of papers entitled Why Trust a Theory?

There's a new paper out along similar lines, String theory, Einstein, and the identity of physics: Theory assessment in absence of the empirical, evidently to appear in a journal special issue from a 2019 conference on Non-Empirical Physics from a Historical Perspective.

The reaction of most physicists to this sort of thing is exemplified by Will Kinney's tweet about the paper:

> WTAF

In the past few years I've been writing less and less here and elsewhere about the issue of evaluating string theory as physics, for several reasons:

- String theory has effectively gone completely post-empirical, decoupling from any possible relation to experiment. This Week's Hype used to be a regular feature here, devoted to debunking the numerous bogus claims regularly being made for how to "test string theory". One rarely sees these anymore, with the string theory community now having given up on this and somehow comfortably moved into a completely post-empirical mode.
- I'm actually much more sympathetic than most people to the idea that there is a serious and very interesting question about how to evaluate ideas about theoretical fundamental physics in the absence of viable experimental tests. But I haven't had much luck finding others who share my views. The reaction to blogposts like this recent one tends to be pretty uniformly scornful, that I'm just Lost in Math. The post-empirical philosophers of science deal with me differently, pretty much doing their best to ignore me (I don't make it into the extensive bibliography of the new paper on the arXiv).
- There are two other projects that seem to be a much better way to spend my time (the twistor unification stuff, and improving the textbook on QM and representation theory).

By the way, I notice that there is an arXiv trackback already for another blog entry about this paper, wondering if trackbacks here are still censored.

Well, that's all about this for now, best to take my own advice and go think about something else.

Update: I just ran across this AIP interview with John Schwarz from last year. Schwarz seems to feel that string theory unification is a huge success, despite the testability problem. On the failure to find the superpartners he and other string theorists expected, that's a problem for experimental physics, not for string theory:

> As I said, if supersymmetry is not discovered, there's a danger that experimental particle physics will die. If that happens, it would be tragic, but it wouldn't be the end of string theory. String theory will continue, regardless, and will continue to advance.

On the topic of answering those who argued that superpartners would not be found back in the 2000s, and who have put forward detailed criticisms of string theory unification, here's what he has to say:

> There were a couple popular books that attacked string theory about a decade or so ago. The authors clearly had chips on their shoulders. For people without a physics background it's not possible to assess whether what they're reading makes sense or not. But anyone with at least an undergraduate education in physics I think can recognize that they should not be taken seriously.

Comments

1. **Sabine**
   June 2, 2021

   There's also a new book called "On The Fringe" by Michael Gordin about the demarcation problem. It has a paragraph or two about string theory, but only to say "look, sometimes even scientists can't tell if it's science or pseudoscience" (not an actual quote, I paraphrase). The book is mostly about astrology, alchemy, bigfoot, and so on.

2. **Peter Woit**
   June 2, 2021

   Sabine,
   I don't think arguing over whether "string theory" is "science" or "pseudo-science" is worthwhile. Even before you get to the demarcation problem, your problem is that these days "string theory" has no specific meaning.

   What's accurate to say is that, even if you agree to put string theory unification on the science side of your science/pseudo-science demarcation, it's a failed idea about science. My problem with what most of the "post-empirical physics" philosophers of science are doing is that they're just producing excuses for failure. They are starting from the assumption that this can't be failed science, since its proponents are leaders of the field, rewarded with multi-million dollar prizes. So, it must be a new way of doing science.

3. **André**
   June 2, 2021

   The last sentence of the conclusion of the paper arxiv:2105.14342 reads: "let's … keep funding it as generously as before." The author thus states clearly that he is making money out of his paper. This is appalling. Were it politics, not science, this would not be called a conflict of interest, but simply corruption.

4. **Alessandro Strumia**
   June 2, 2021

   Entire published papers are not appearing on arXiv. Is it wise to leave such a resource, important for the whole international field, in the hands of a few individuals and private donors?

5. **Peter Woit**
   June 2, 2021

André,
I think the “keep funding it as generously as before” plea makes explicit that what’s going on here is what I described in my response to Sabine: an attempt to evade the unpleasant implications of failure (with losing funding just the crudest of such things).

6. **Peter Erwin**
June 2, 2021

André,

The author of the paper is a philosopher/historian of science, not a physicist working on string theory, so encouraging people to continue funding things like string theory isn’t going to give *him* any money. (Arguably there is a slight conflict of interest in that he finds the topic interesting, so he’d presumably be disappointed if it was shut down; but since he’s written a number of papers on Einstein, I suspect he’d do fine academically even if string theory was shut down.)

7. **Peter Woit**
June 2, 2021

Alessandro Strumia,

I don’t want to try and host here a discussion of the general topic of arXiv moderation (from dealing with comments, I know moderation is difficult…). To the extent the problem is with them censoring politically incorrect views (whether about string theory or anything else…), it’s a problem larger than a few individuals, would likely be there whatever their institutional structure is.

To describe my experience in dealing with the arXiv over the trackback matter, it was essentially impossible to communicate with anyone there, or even find out what decisions they were making and on what basis. After a huge effort involving a lot of time and asking for help from a lot of people, all I ever got was a message from a Cornell administrator saying a decision had been made by unknown parties based upon unknown criteria. To this day I have no idea who decided what about trackbacks, based on what information and what policy, or what their current policy is.

8. **Sabine**
June 3, 2021

Peter,

“My problem with what most of the “post-empirical physics” philosophers of science are doing is that they’re just producing excuses for failure”

Well, yes, kind of. Some of them, anyway. The problem is that most philosophers don’t actually understand the topic (string theory or quantum gravity or naturalness) in any depth, are afraid to put forward an original analysis of it, and then end up doing sociology more than philosophy. Unfortunately, they then don’t factor in what we actually know about the sociology of science.

Having said that, it actually is difficult to sort out the wheat from the chaff if you can’t do it by way of experiment because that’d take centuries. So we have to change our methods, and philosophers have a role to play in that.

Merritt did a pretty good job for MOND. I mean, as I write in my review, I have some objections to his conclusions, but this isn’t the point. The point is that this kind of analysis is very important. But Merritt is an astrophysicist who only recently switched to philosophy. I think we’d need someone like this in string theory. Or, preferably, several people.

Having said that, the book by Gordin I mentioned above makes a good point, which is that it often takes time for scientists to sort out the demarcation and also, the judgement changes over time. There are quite a few ideas that we currently regard as pseudoscience but that were once considered adequate.

All of which means, basically, you are making scientific history 😉

9. **Sabine**
June 3, 2021

And while I am at it, let me echo Alessandro’s concerns about the arXiv moderation. I have personally never had an issue with them, but then I am a soundly boring person. However, I wrote a blogpost some years ago about the arXiv moderation issue (brought to my attention by others) and ever since people have contacted me asking for help. Every once in a while I try to actually do that, but it never leads anywhere. I have found it impossible to figure out who is even making a decision on what, and in the end they’ll fall back on saying “if it gets published in a journal, we’ll accept it on the arXiv” which amounts to refusing to take responsibility. Most people are afraid of saying anything about it because their good standing with the arXiv moderation decides on their career. This is not a good situation. I really think the community should do something about it.

10. **Alessandro Strumia**
June 3, 2021

It seems to me that we now have two big problems at the same time:
High-energy physics wants to keep its historically large level of funding despite lack of new physics, while institutions are affected by an ideology that denies objectivity and views science as a system of power.
Will the field survive to a short-sighted compromise?

11. **Peter Shor**
June 3, 2021

The arXiv certainly needs moderation, otherwise it would fill up with papers that are written by crackpots and become completely useless.

I haven’t had any problem with it myself, but I think making the system more transparent (it being completely opaque now) would be a considerable improvement.

12. **maciej**
June 3, 2021

If you criticize string theory on arxiv your work is likely to be rejected. They can even disable your submission rights if you don’t stop submitting your criticism. The situation is very concerning, reminds me a kind of censorship of totalitarian systems. What arxiv needs is transparency but that comes with objectively chosen committee which for decades has not been objective at all
(The only hep-th related members of arxiv committee are pro-string-theory Jacques Distler and Paul Ginsparg https://arxiv.org/help/physics/#AdvisoryCommittee).

13. **Peter Woit**
June 3, 2021

maciej,
About my problems with the arXiv, all I can do is guess what they might be. A good guess seems to be the attitude towards this blog taken by a certain arXiv moderator right at the beginning. Those interested in history might want to take a look at the discussion in the comments right at the beginning of the blog, here

https://www.math.columbia.edu/~woit/wordpress/?p=3

14. **Claudio Paganini**
June 4, 2021

"I'm actually much more sympathetic than most people to the idea that there is a serious and very interesting question about how to evaluate ideas about theoretical fundamental physics in the absence of viable experimental tests."
Could you expand on this a little more. I have spend quite some time over the last 4 years thinking about how to judge the potential of a theory by its mathematical ingredients but so far I haven't really come to a conclusion that goes beyond gut feeling and a set of pitches that catch the attention of physicists. (given we have to decide which approaches to unification should be funded, I think it is crucial that we do have a better framework to gauge the potential of new ideas).

15. **Peter Woit**
June 4, 2021

Claudio Paganini,

I think this is a difficult and complex question, with no easy answer. A couple aspects of it are:

1. Initially, speculative ideas are hard to evaluate, since there is a lot about their implications that still has to be worked out. Most speculative ideas don't work out, and it's not that one could tell this at the beginning, but as you work things out and understand them better, typically the more you learn, the more you find problems with the idea. Only in rare occasions do you find that the more you learn the better and more solid the idea looks. In some sense, the fundamental problem with the string theory unification idea is just exactly this: you could argue about how promising it was in 1984, but everything learned about it since then makes clearer and clearer the deadly problems with the idea. In slogan terms: the absolute value of the significance function of an idea may be very hard to evaluate, the derivative in time a lot easier.

2. Absent experimental confirmation, you need to actually understand ideas and their evolution to evaluate them, there's no easy way around this. If a highly complex and obscure set of ideas accurately computes the details of something you can observe, you know there is something right about it, even if you don't understand the set of ideas. If you decouple from experiment, you have no external evaluation of the ideas, have to really understand and engage with them to evaluate them.

3. Psychologically, once people have a certain amount of their time/energy/reputation invested in working on a set of ideas, it is very difficult for them to honestly evaluate whether the ideas are working.

The combination of 2 (a lot of effort needed to understand something well enough to evaluate) and 3 (if you put a lot of effort into an idea, you have a lot invested in it) creates a huge problem, and I think explains a lot about some of the pathology we've seen in fundamental theoretical physics

16. **Aristotle Pagaltzis**
June 6, 2021

> The combination of 2 (a lot of effort needed to understand something well enough to evaluate) and 3 (if you put a lot of effort into an idea, you have a lot invested in it) creates a huge problem

Not to be bleak, but does this leave room for a way out other than what one might postulate as the inverted Planck's principle? ("A failed scientific venture does not wane by disappointing its proponents and making them see the light, but rather because its proponents eventually die and a new generation grows up that is familiar with its ineffectiveness.")

17. **Peter Woit**
June 6, 2021

Aristotle Pagaltzis,
Actually, the situation is even bleaker than that. Once a complex failed research project gets institutionalized, absent a new successful one coming along and displacing it among the younger generation, the younger generation just gets trained in the complex failed project, reproducing the problem. To this day, lots of the best young students in theoretical physics are being trained by being told to spend years reading the canonical multi-volume superstring theory treatises.

18. **Jackiw–Teitelboim**
June 6, 2021

Dear Peter,
Suppose you are talking to a person belonging to the set of "best young students in theoretical physics" from some reputable university according to all standard metrics, and have been told to "spend years reading the canonical multi-volume superstring theory treatises".

What would *you* tell such student to spend their time on then?

An advice I have being often told, which I rejected based upon personal experience, is that of doing a math PhD instead of a physics one. Nevertheless, the kind of interests and standards of "rigor of proof" in a typical top math PhD program will possibly consume much more energy as reading a 2-volume Polchinski's textbooks, however with the additional risk of also losing physical intuition.

19. **Peter Woit**
June 6, 2021

Jackiw-Teitelboim,
There really isn't a good answer to give students in this position right now. HEP theory/quantum gravity is not a healthy research area and hasn't been for years. The first obvious piece of advice is to consider instead working in a healthier research area. There are a lot of them in mathematics, many with significant overlap with fundamental physics. But, sure, if what interests you is just physics and not math, getting a math phd. is problematic.

Students are inescapably highly dependent on faculty and their advisor, this can't be solved by them getting advice from the internet or figuring out themselves the problems with their advisor's research direction. I do think though that good advice at the moment is that if you're a student being told to spend a lot of time mastering the quantization of the 10d superstring, you should be asking questions and looking around for other options.

20. **Peter Shor**
June 6, 2021

Jackiw-Teitelboim: if the actual theory of quantum gravity requires math that physicists currently don't know, then if you don't learn more math you will never find that theory.

On the other hand, it's clearly much safer to read through all Polchinski's textbooks, because it's very possible that if you get a math PhD, the math you learn is not going to be the math you need for quantum gravity. And if you're not interested in proving theorems rigorously, but in using advanced math to study physics, you may not get a good academic job. [This is something that maybe could be fixed.]

However, if no physicists ever learn any more math, then it's quite possible we'll never find the theory of quantum gravity.

Looking back in history, finding the theory of general relativity needed knowledge of differential geometry. But Einstein was smart enough that he realized he needed to learn this, and he had a friend, Marcel Grossmann, who helped teach it to him. And after the theory of GR, differential geometry was added to the physics curriculum (at least for relativists).

21. **Robert A. Wilson**
June 7, 2021

Peter Shor,
An alternative approach is for mathematicians to learn more physics, so that a mathematician who actually does know the mathematics that posterity will discover is needed, can bring that mathematics to the attention of physicists. Of course, the mathematician will need to do a lot of work explaining a lot of physics in terms of a new mathematical model, before any physicists will listen. But if physicists don't know what mathematics they need, perhaps mathematicians can help?

22. **lun**
June 7, 2021

Peter Shor, at least from a historical point of view things are a bit more subtle.
Heisenberg did not know matrices, and Einstein did not know differential geometry.
Learning the required maths can be accomplished while developing the theory, after having "found it". "finding it" was about physical insight, not knowing the right maths.
Perhaps post-empiricism will change that.

23. **Ricardo**
June 7, 2021

Somebody please comment on advising a young student to choose condensed matter physics as a field of study. TIA.

24. **JE**
June 7, 2021

If you ask me, I would say that the guiding principle for advancement in theoretical physics should not be beauty, but physical intuition. The quest for beauty can easily lead you astray in physics, because beauty is quite a debatable question. Boldly put, beauty is fine for fine art, but physical intuition will more likely keep you linked to physical reality. The quest for beauty can rapidly entice you to supersede the SM with a larger theory of which it merely is a subset, while physical intuition can tell you that such a successful theory may have become a victim of its own success by obfuscating the fact that it may not even be "right".

25. **Peter Woit**
June 8, 2021

lun/JE,
The problem with the argument that "physical intuition" or "physical insight" is the answer to figuring out a new layer of fundamental physics is that there's no good reason to believe our physical intuitions based on earlier theories are relevant. Quantum mechanics famously violated all previous physical intuitions and took a lot of getting used to (with a lot of help from mathematics). Curved space-time also violates all previous physical intuitions, and Einstein could only pursue that idea and work with it by learning a lot of very sophisticated new mathematics.

26. **Low Math, Meekly Interacting**
June 10, 2021

It's been ages since I've been around bachelor's anything, but my sense is that an undergraduate physicist is going to have to go out of their way to learn much more than the basics of GR and QFT. Most won't take dedicated courses on either, even if they're on the curriculum. I know Schwarz isn't trying to be fair, but is his dismissal as absurd as it looks to me?

27. **Peter Woit**
June 10, 2021

LMMI,
Yes, it's absurd. Also kind of sad that Schwarz feels it necessary to make over the top ad hominem (chip on my shoulder?) attacks on an argument he has no good answer to. Back in 2006 the point of view of my book and Smolin's on string theory already had a lot of support in the theoretical physics community. By now, with the collapse of hopes for a SUSY extension of the SM and the multiverse debacle, the idea that string theory has not worked out is I think a majority one among physicists. Schwarz and some others may comfort themselves with the idea that criticism from their colleagues is based purely on ignorance, incompetence and resentment, but I don't think this helps his case.

Various Math Items

June 6, 2021
Categories: Uncategorized

Some math-research items:

- Mura Yakerson has been doing a really wonderful series of interviews with mathematicians, available at her math-life balance web-page or Youtube channel. I've just started listening to some of them, including ones with Peter Scholze and Dustin Clausen (Clausen is John Tate's grandson, the latest AMS Notices has a memorial article).
- There's a remarkable report out from Peter Scholze about the progress of the Liquid Tensor experiment. Back when I first heard about this, I figured it was a clever plot by Scholze to get other people to help with a very complicated part of a proof, by getting them to work out the details, with the excuse being that they would be doing a computer check of the proof. Seemed to me very unlikely you could check such a proof with a computer, but that by forcing humans to try to disambiguate things carefully enough in preparation for a computer proof, he'd get a human-checked proof. Looks like I was wrong.
- For yet more Scholze news, the Fields Medal symposium this year will be devoted to his work.
- Trying to find something of interest in math, that wasn't Scholze-related, I noticed this site devoted to the case of Azat Miftakhov, where there will be an online Azat Miftakhov Day program. Foiled though on the Scholze front, since he's a speaker there, talking about Condensed Mathematics.
- The list of those giving plenary lectures at next years ICM is here.

Update: Kevin Hartnett at Quanta has a good new article up about quantum field theory and mathematics (an inexhaustible topic…)

Update: Also from the Simons Foundation, there's a wonderful profile of my Columbia colleague Andrei Okounkov, who has been very active in bringing together mathematics and ideas from quantum field theory.

Update: Nature has a story about the Liquid Tensor Experiment.

Comments

1. **Bertie**
   June 6, 2021

   I like Scholze's riff on the metal band Liquid Tension Experiment, which was formed back in 1997

2. **Peter Shor**
   June 7, 2021

   Let me note that the big news in the list of sections for the ICM is that there are two new Applied Math sections for invited lectures:

   17. Statistics and Data Analysis, with 8–11 talks (split from Probability and Statistics, and with a lot more talks than statistics used to get)

   and

   18. Stochastic and Differential Modelling, with 4–6 talks (a completely new section).

   A lot of the other sections had their targets reduced by one talk to make room, although I think they're also expanding the number of invited lectures a little. I knew something like this might be coming (but didn't think to check it until I saw your blog post).

3. **Mark Hillery**
   June 12, 2021

   Here is a question from someone whose knowledge of quantum field theory is rudimentary. Does anyone know how the new work on making quantum field theory rigorous discussed in the Quanta article fits in with previous work in this area, such as axiomatic field theory a la Wightman, algebraic quantum field theory a la Haag (this is mentioned briefly), or constructive field theory?

4. **S**
   June 13, 2021

   I second Mark Hillery's question.

   Also — do Dijkgraaf's comments in the Quanta article seem somewhat in tension with his recent talk and earlier article? If successfully mathematizing QFT will lead us to new fundamental physics, that seems like quite another project than just using the physics we have to analyze more and more complicated things, I should think.

6. **Peter Woit**
   June 13, 2021

   Mark Hillery,

   Much of the new work discussed is based on perturbation theory, in principle providing a new mathematical framework for renormalized perturbation theory in QFT, one more adapted to things like working on arbitrary manifolds, not just flat space-time. From the point of view of mathematicians, what has always been a goal is to have a mathematically well-defined framework for describing the QFTs physicists have used to get new results in topology, i.e. topological quantum field theories. This new work to some extent gives that, but so far just for perturbative theories, while the most dramatic TQFT results use non-perturbative information.

   The kinds of approaches you mention are motivated by a desire to have a rigorous non-perturbative quantum field theory. The Wightman axioms crucially use Poincare symmetry and Minkowski signature, while the Costello stuff is set up to work on arbitrary manifolds with no Poincare symmetry, and with Euclidean signature. So, here

there’s not a lot of overlap. For the relation to AQFT, see
https://arxiv.org/abs/1711.06674
The results there are pretty limited, this paper is just about free field theory.

For constructive QFT, again the whole point is to try and construct something outside of perturbation theory. The state of the art there has always been lattice regularized QFT, with the problem that of how to take the continuum limit. Unfortunately I don’t know of a lot of work or progress on this recently.

7. **Peter Woit**
June 13, 2021

S,
To a large extent, theorists studying QFT have given up on trying to understand more about the QFT that describes fundamental physics (because the problem is too hard), and instead work on QFTs for which new ideas may give some results, but the physical relevance of these QFTs is typically in condensed matter physics.

For quantum gravity, this takes the form of people mainly studying low dimensional toy models. Whether these will tell us about 4d quantum gravity is quite speculative, but often they have direct relevance to very different subjects, e.g quantum information theory, or condensed matter problems (where the low dimension is the relevant one).

This may provide some context for reconciling Dijkgraaf’s different-sounding comments.

10. **Timothy Chow**
June 20, 2021

I made a MathOverflow post back in April 2020, where among other things I said (regarding Mochizuki’s abc proof), “I do think that it is reasonable for skeptics of the proof to request that those who claim to understand the proof, and who want to cultivate a whole new generation of younger mathematicians to pursue IUT, to formalize the proof in a proof assistant.”

I tried to post a similar comment here on Not Even Wrong, but it didn’t get published, perhaps because Peter thought the comment was silly. In light of how the Liquid Tensor Experiment has played out (which doesn’t surprise me at all except that I expected it would take about a year, rather than six months, to get to this point), perhaps the suggestion doesn’t sound as silly any more.

11. **David Roberts**
June 20, 2021

@Timothy Chow

at the very least, such a move would necessitate trimming all the cruft from the definitions and reducing to the actual key lemma of interest, which is some statement about monoid actions (as opposed to a much more complicated statement about Frobenioids). And I don’t mean Corollary 3.12, but the key sticking point inside that the claimed proof of it.
This is what Scholze did for the LTE, isolating the key technical proposition that doesn’t really involve condensed abelian groups at all, and how far the formalisation has actually gotten.

The only problem is that one needs a community of people large and invested enough (and experienced in formalisation) to divide up the labour and do it. And a person who understands all the proof being willing to give precise technical advice on the question, as Scholze supplied to the formalisation team. The forthcoming clarifications for IUT have so far not been, to my eyes, of that nature, but more like mathematical koans.

12. **Timothy Chow**
June 21, 2021

@DavidRoberts

I agree with what you say. I should perhaps amend the word “skeptics” to “funding agencies” (if you click through to MathOverflow, I explain this point in more detail). From the standpoint of a funding agency who believes that Mochizuki is acting in good faith, Mochizuki should be able to play the role that Scholze did. And the funding agency can help with assembling the formalization team, which I imagine would comprise grad students and postdocs who are on good terms with Mochizuki.

13. **Peter Woit**
June 21, 2021

Timothy Chow,
I don’t remember, but likely didn’t post your comment about abc because the issue of formalizing Mochizuki’s proof did seem irrelevant for two reasons:

1. It seemed to me highly unlikely that this was within the realm of possibility, even if one thought of the situation as involving a conventional but very complex proof, with the author of the proof behaving conventionally.

2. Going on about proof assistants just obscures the actual problem: Mochizuki refuses to engage with Stix and Scholze in the standard way a mathematician is supposed to respond to those challenging a claimed proof. Instead of providing more details for and clarifying challenged arguments, he refused to significantly add anything to his original manuscript, issuing instead documents which convincingly destroy his own credibility. In addition, it looks like no one around him is able to provide such details and clarifications.

Given the Liquid Tensor Experiment success, I agree my judgment about 1. was flawed. But I still think 2. is the relevant point, and discussing proof assistants in the context of the problem with Mochizuki’s proof is a red herring. The problem here isn’t the kind of thing Scholze was struggling with: an argument so complex that the best human mathematicians might miss a subtle problem. Yes, there a proof assistant might be the answer. But the problem here is a human one of a very different kind.

14. **Timothy Chow**
June 21, 2021

Peter, I absolutely agree that 2 is the relevant point; I absolutely agree with your characterization of the sociological situation; and I absolutely agree that the problem is a human one of a very different kind from the Liquid Tensor Experiment. But I disagree that "going on about proof assistants obscures the actual problem." Quite the opposite! The point I am making about proof assistants is that, under the assumption that they are sufficiently easy to use (point 1), they are *ideally suited* for addressing the actual (human, sociological) problem.

Abstractly, we have a small Community A that insists on the correctness of a certain proof, and a much larger Community B that is unconvinced. For sociological reasons, the usual mechanisms for resolving mathematical disagreements have broken down. Community A insists that it has provided full details and that Community B is behaving in a disrespectful manner and refusing to acknowledge the plain truth. Community B, of course, says the same about Community A. The point is that the existence of proof assistants means that Community B can fairly say to Community A, "You need to explain your proof to a proof assistant before we'll give you more money." If Community A's claims are true, then there should be no reason why Community A can't formalize the proof. The key point is that a proof assistant, being a dumb machine, cannot be accused of being disrespectful or failing to conform to some human standards of decorum.

If Community A is right, and produces a formalization, then the formalized proof should convince Community B. (I'm assuming here that the two communities can at least agree on a proof assistant that they both trust, and that they can agree on a statement that is simple enough for there to be no debate about whether the formalized statement correctly captures the disputed claim. These assumptions are reasonable in this case, I think.) On the other hand, if Community A fails to produce a formalized proof given a reasonable amount of time and money, then it's going to become increasingly difficult for them to explain what the holdup is.

The proof assistant allows a funding agency to withhold funding without having to engage in a potentially unpleasant confrontation with Community A. If it so desires, the agency can insist that it is totally on the side of Community A, and that Community B is a bunch of evil morons; its pen is poised to sign the check as soon as Community A satisfies this small bureaucratic requirement of producing a formalization. Crucially, the funding agency requires very little technical expertise to play its role in this drama.

15. **Peter Woit**
June 22, 2021

Timothy Chow,
I guess I'm just inherently skeptical about claims that the solution to human problems is "computers". A colleague of mine likes to claim that mathematics is the only academic subject where, when two people disagree about something, they go into a room to discuss it, and emerge with one of them saying "I was wrong". This is an exaggeration, but it's an important ideal to try and maintain. The problem here is a violation of community norms designed to uphold that ideal, and I don't think computers can replace that ideal.

It does look like proof assistants can be very helpful when an argument is so complicated that no one is sure whether it is right or not. This latest is a success of this kind, another example would be the Flyspeck project in the case of the Kepler conjecture. Cases where experts disagree about whether an argument is right should be resolved by more discussion, until one side gets the other to see where they went wrong. If people can't do this, they're not in any position to start on the much harder project of getting a computer to resolve their differences.

16. **Timothy Chow**
June 22, 2021

There's nothing magical about the proof assistant being a computer; any competent neutral third party would do. I claim that from time immemorial, many human disputes of all kinds have been settled by the intervention of an impartial mediator that both sides trust. Surely you're not inherently skeptical of that claim? The only special thing here is that the neutral third party happens to be a machine, and is therefore *indisputably* impartial.

I have discussed this dispute resolution procedure with a variety of people with different amounts of technical training, and just about everyone immediately understands it and is puzzled why the mathematical community doesn't follow it (I have to explain that proof assistants are much more cumbersome to use than they might think). The few people who have balked have been mathematicians. It initially puzzled me why the principle that a neutral mediator can aid in dispute resolution—a principle which is obvious to almost everyone on the planet—would be so difficult for mathematicians to grasp, but I think I understand why. It relates to the point you just made, that mathematicians have been spoiled by the scarcity of serious disputes in our field (when it comes to mathematical correctness, at least). In every other field, disputes are a dime a dozen, and so everyone intuitively understands what methods are available to address them. Mathematicians, on the other hand, know of only one method: talk it out. Since that almost always works, we never bother to think about a Plan B for cases where it *doesn't* work. If talking it out doesn't work, we have no idea what to do.

Another contributing factor, I think, is that mathematicians tend to be surprisingly slow to catch on to what computers can do for them. When the Appel–Haken–Koch proof of the four-color theorem came out, did mathematicians react by saying, "This is awesome! What other computer-assisted proofs can we come up with?" Some may have, but by and large, the initial reaction of most mathematicians was to either ignore the result or complain about the role of the computer. A similar dynamic is happening with proof assistants. For example, in Scholze's blog post, he wrote, "Initially, I imagined that the first step would be that a group of people study the whole proof in detail and write up a heavily digested version, broken up into many many small lemmas, and only afterwards start the formalization of each individual lemma." Experts in formalization have long known that proof assistants have progressed far beyond that stage, but the news has been slow to seep into the general consciousness, and I think it's partly because most mathematicians have incorrect preconceived notions about proof assistants that cause them to resist them rather than milk them for everything they're worth.

You say that invoking a proof assistant to help resolve differences is a "much harder project" than resolving them by discussion. That is true under normal circumstances, but going on about this fact obscures the actual problem, which is that the conventional method of human discussion has broken down in this case. I'm totally with you that calm discussion is the way disagreements *should* be resolved, but what if that method fails? Then the inequality flips. Human discussion becomes infinitely hard, and appealing to a proof assistant becomes potentially easier.

Note that I'm just as skeptical as you are about Mochizuki's proof. I don't expect a formalized proof of abc to emerge, for the simple reason that I doubt that "Community A" really has a proof. But that doesn't matter. What matters is the *conditional* statement that *if there is a proof then it should be formalizable in a proof assistant*. Now you might counter that *if there is a proof then it should be explainable to Community B*, and that is true under normal circumstances, but what Community A will say is that Community B is being stubborn and disrespectful. Again, the value of a proof assistant is that it cannot be accused of being disrespectful.

One final point. I don't claim that a proof assistant will completely solve the sociological breakdown by getting Community A and Community B onto the same page. If Community A does not really have a proof, then unifying the two communities probably won't happen. But what the proof assistant can do in that case is to make it clear to the whole world that Community B is right and Community A is being unreasonable. At the moment, it's unclear to many outsiders which community is right. You and I know the absurdity of Mochizuki's claim that Scholze is an idiot, but it's harder for the rest of the world (read: Japanese funding agencies) to be sure. That could change with a dispute resolution procedure that lay people could readily understand.

17. **jrrm**
July 6, 2021

Mark Hillery,

Kasia Rejzner's book (cited in the Quanta article) belongs to the Haag-Kastler school of algebraic field theory and is part of the work of Klaus Fredenhagen and coworkers on QFT in curved space times. It seems to me, that is now possible to prove rigorously much of the folklore "Theorems" of perturbative QFT in this semiclassical scheme rigorously.

Strings 2021

June 21, 2021
Categories: Strings 2XXX

Strings 2021 started today, program is available here. Since it's online only, talks are much more accessible than usual (and since it's free, over 2000 people have registered to in principle participate via Zoom). Talks are available for watching every day via Youtube, links are on the main page.

As has been the case for many years, it doesn't look like there will be anything significantly new on the age-old problems of getting fundamental physics out of a string theory. But, as has also been the case for many years, the conference features many talks that have nothing to do with string theory and may be quite interesting. I notice that Roger Penrose, a well-know string theory skeptic, will be giving a talk on the last day of the conference next week.

Another series of talks that I took a look at and that I can recommend is Nima Arkani-Hamed's lectures on Physics at Future Colliders at the ICTP summer school on particle physics. He never actually gets anywhere near discussing the topic of the title for the talks, but does give a very nice leisurely introduction to computing amplitudes for zero-mass particles. What he's doing is emphasizing ideas that are often not taught in conventional QFT courses (although they should be). His second talk explains how to think of things in terms of classifying representations of the Poincare group, an old topic that unfortunately is often no longer taught (see chapter 42 of my QM textbook). His third talk emphasizes thinking of space-time vectors as two by two matrices (see section 40.4 of my QM book). This is a truly fundamental idea about space time geometry that gets too little attention in most physics courses.

Update: At String 2021, yesterday Nima Arkani-Hamed gave a talk on "Connecting String Theory to the Real World We See Outside Our Windows", where he sometimes sounds like me, contrasting the pre-LHC claims of string theorists:

1. LHC will discover SUSY
2. String Theory Loves SUSY + Unification

to what they are saying now that the LHC has found no SUSY

> CICADAS . (Anyway, String Theory is mainly about Quantum Gravity).

He goes on to explain the "landscape philosophy", which he sees string theorists (and himself) as now adopting. According to this philosophy, "connection to particle physics appear hopeless/"parochial"/unimportant". As a result, he sees the current situation as

- String theorists are for the most part no longer actively pursuing connecting to particle physics of the real world.
- Understandable as a short-term strategy
- But in my view a real mistake in the long run…

One reason for this being a real mistake is that, divorced from input from the real world, theory becomes sterile:

> Questions Posed by Nature are Vastly Deeper and more fruitful than ones we humans tend to pose for ourselves.

Unfortunately I don't think Arkani-Hamed has any compelling argument against "string theory implies landscape implies nothing to say about particle physics". He discusses the "swampland philosophy", but gives as a challenge to theorists just making more precise the sort of empty question that this philosophy deals in (he asks whether D=9 SU(2021) to the power 2021 is in the swampland).

Update: In the final discussion section, Witten emphasizes that "What is string theory?" still has no answer, that we have "little idea what it really is". He lists two main things we know about the supposed theory:

1. General string perturbation theory using 2d conformal field theory. He mentions that one basic problem with this is that there is no understanding of what happens in time-dependent backgrounds, so, in particular, this is useless for addressing the big bang, which is the one place people now point to as a possible connection to real world data.

2. AdS/CFT

He notes that to get at non-perturbative string theory we seem to need some more general understanding of quantum theories, going beyond the usual quantization starting with an action, and ends by saying maybe quantum information theory can help. In the discussion section, Vafa challenges him on this, saying he sees no indication that quantum information theory gives any insight into dualities he sees as the central aspect of the non-perturbative theory. Witten's answer is that this was just a vague hope, that the duality ideas are now 25 years old, we haven't progressed beyond them, need something new.

Comments

   (videos of the talks at the bottom)

2. **Suomynona**
   June 22, 2021

   How is the idea that particles are irreducible representations of the Poincaré group work in the context of quasiparticles in condensed matter physics, where the underlying system background is generally not symmetric under Poincaré transformations (e.g. rotations and translations are typically discretized due to the presence of a lattice)?

3. **Peter Woit**
   June 22, 2021

   Suomynona,
   In other physical contexts you have different symmetries than Poincare, often approximate symmetries. The general principle is that whenever you have a group acting on a physical quantum system, the state space will be a unitary representation of that group, and unitary representations break up into irreducible representations. It will often be a good idea to analyze states in terms of these irreducible representations. How useful this will be will depend on the symmetries you have available. What's remarkable is how powerful Poincare space-time symmetry is as a determinant of how elementary particles behave. Condensed matter physics is a quite different story.

Much as I love this general topic, it's getting far from the topic of the posting, so I'll just advise: read my book…

4. **ay**
   June 23, 2021

   I am currently reading Weinberg's book to fill some holes in my knowledge. It's very good but he often leaves the reader a lot to figure out. I watched the entire video on the Poincare group and, although the path was the same as Weinberg, there was a lot of new information – I thought it was excellent. It also gives one a feeling for how Arkani-Hamed works through problems. The video answered some questions that I still had (e.g. how sensitive is the procedure to choice of k_mu – he did the case where k_mu included a boost).

5. **lun**
   June 27, 2021

   Starting from 1h14m of this "meet the public" vide
   https://www.youtube.com/watch?v=WwmxaXTnGMI
   you see Ed Witten, and then Shiraz Minwalla, basically agreeing with you.

6. **Peter Woit**
   June 28, 2021

   lun,
   I just took a look at that session and thought one remarkable point was where people were asked "what would cause you to give up on string theory?" The only answers forthcoming were from Igor Klebanov, who said he had been working on it his whole life, so couldn't see himself giving up on it, and Ashoke Sen, who said he would only give up on it if it were shown to be mathematically inconsistent. Of course, a few minutes earlier Witten had explained that no one knows what the theory actually is, which means there is no way to show that it is mathematically inconsistent.

   The whole tone of the discussion was pretty depressing. In response to the obvious question about relation to experiment and testability, people have clearly completely given up on this, with nothing to say (other than a bogus claim that string theory makes some prediction about B-mode polarization), going on about how it took thousands of years for the atomic hypothesis to be vindicated. There's a lot of repetition of tired old arguments from decades ago, zero acknowledgement that things have not worked out as hoped. It seems that no one in the string theory community dares to publicly breathe a word of skepticism. Skeptical challenging of arguments is supposed to be what science is all about, but the speakers in this panel made it seem that this is absolutely not something that is part of their field or what they do.

7. **Jackiw–Teitelboim**
   June 28, 2021

   This goes without saying all technically challenging fundamentally important problems required for superstring theory unification be at least *mathematically* self-consistent have been left unanswered. (With exception of a group of very few dedicated researches, to whom I sincerely keep my deep respects.) While the community just spread out to other problems.

   Paraphrasing Fermat, "I have discovered the ugly truth of this, which this margin is too narrow to contain." Nevertheless, it may be worthy registering on this blog some of those problems which aren't enough emphasized. Nothing will be said about "multiverses" or "swampland" on what follows.

   (i) No one convincingly proved the mathematical equivalence between the RNS superstrings and GS formalism.

   (ii) Every-time I receive a grant report asking for resources, penned by a senior string theorist, I'm already able to guess the 1st lines: "ST is the only mathematically consistent candidate for understanding quantum gravity while providing a framework potentially unifying all know fundamental interactions."
   I'm sorry if I cannot comment on other approaches to quantum gravity or non-stringy grand unification programs. But regarding superstrings, from such a strong statement one would expect at least proof (not rigorously by mathematical standards of course!) that perturbation series following from superstring S-matrix, already known to diverge as one sums over all moduli parameters (which isn't really the issue, since this happens even in QED, see *Dyson, F.J., 1952. Divergence of perturbation theory in quantum electrodynamics. Physical Review, 85(4), p.631.*), one would at least expect that a well-behaved asymptotically perturbation series follows as one takes into account contributions from all the moduli parameters of Teichmüller spaces of Riemann surfaces with higher genus and market points.
   At the time I drop those lines, more than 50 years from dual resonance models?, I haven't found any convincingly argument.

   (iii) Most superstring calculations are performed under euclidean worldsheet for many practical reasons, as we all know and love from Wick's rotation in standard q.f.t.'s. Nevertheless, from a theory claiming to be the only mathematically self-consistent unification program, something regarded as just a mere technicality now requires an answer. The spin-bundle required to defined fermion content from SUSY multiplet depends on the metric signature. I would be eager to read a real formal discussion if first-quantised RNS superstring in euclidean signature is quantum mechanically equivalent (unitary Boguliubov transformation) to original version starting from Minkowski signature.

   I could go on the whole night, but I believe, as most other string theorists do, there are more "urgent" or at least doable problems to solve now. In my case, I will give a run, certainly much more healthy, no?

8. **PeterH**
   June 28, 2021

   Just viewed the last question and answer session.
   The only message I hear repeatedly is that 'String theory is the only game in town'.
   Well, that would be the case if people follow the hype for last 20-30 years or more.
   For a so called well defined mathematical theory, cannot be tweaked etc, the number of unsolved issues with it and the claim not understanding what string theory is – is inconsistent.

9. **Peter Woit**
   June 28, 2021

   Jackiw-Teitelboim/PeterH,
   There's no reason to get into the technical argument over whether the perturbative expansion of various versions of the superstring in 10d is mathematically well-defined. That looks nothing like the real world, and as Minwalla points out, no one at the Strings conference is even talking about that sort of "string theory" anymore. There's a long list of things they are talking about under the name "string theory", with the generic problem that the ones that are reasonably well-defined have nothing to do with the real world (e.g., wrong dimension).

   Sen is saying he'll give up on string theory if people prove that "string theory" is inconsistent, but Minwalla and Witten are saying there is no definition of the term "string theory".

What’s really bizarre about the current situation is that “string theory” has completely decoupled from any well-defined proposal for an actual 3+1 d unified theory of gravity and the SM, while at the same time its proponents claim it is the “only game in town”. The “only game in town” in fundamental physics now is to give up on a theory of the real world.

10. **Jackiw–Teitelboim**
June 28, 2021

Hi Peter,

Thanks for allowing my last comment. As you probably guess from my former comments under the present pseudonym, I’m one of those students whom, maybe for lacking courage or ,who knows? , self-confidence, went through a Faustian-like monologue, if you allow me a little of prose:

I’ve studied, Schwarz, alas, Polchinski,
Green and Witten, recto and verso
And how I regret it, D-branes also
Oh, God, how hard I’ve slaved away,
With what result? Poor fool that I am,
I’m no whit wiser than when I began

You are possibly right it’s now pointless to debate those issues. But I went through the hard road, being told just to accept all fundamental questions I raised above as unanswered and move on to the “cutting-edge” problems whatever and whonever decides what these are. So I wrote that list as both an act of rebellion nevertheless also of relive: I don’t think one needs to wait for Planck’s law to clean up our field through funerals in this century anymore & here’s the right point for me to close: It’s time for new ideas and we are going to find them.

11. **DKepler**
June 29, 2021

I just had a look at that session, and more than anything, felt sorry seeing such eminent physicists giving such vacuous reasons just for the sake of defending a theory they have worked on for a long time. Even beginning PhD students will no longer believe that ST is the only framework that reproduces BH entropy. Even without LQG, there are many ideas on/in QG which are physically well founded. This community is indeed becoming like a religious cult, something one of the speakers explicitly denied. Ironically, the very fact that he had to refer to it at all should alarm them.

12. **David Roberts**
June 29, 2021

@DKepler

> Even beginning PhD students will no longer believe that ST is the only framework that reproduces BH entropy.

That’s interesting, can you give pointers?

13. **DKepler**
June 30, 2021

@David Roberts: There are many references that discuss this from different perspectives. The following articles by Carlip provide a nice overall perspective, drawing attention to the “universality” of BH entropy derived in different approaches to QG – what he refers to as an “embarrassment of riches”.

1. Symmetries, Horizons, and Black Hole Entropy [https://arxiv.org/abs/0705.3024]
2. Black Hole Entropy and the Problem of Universality [https://arxiv.org/abs/gr-qc/0702094]

Hope you will find them as a useful starting point.

14. **Cobi**
June 30, 2021

@DKepler
The derivations listed in 0705.3024 seem to fall into three classes:

– String Theory (D-brane/String state counting, AdS/CFT, Fuzzballs)
– The LQG “derivation”, involving an ad-hoc choice for the Immirzi parameter
– Non-QG QFT derivations that are not attempting to identify the microstates

In particular, i can not find a derivation of any black hole entropy from first principles in quantum gravity outside of string theory.
The LQG example hardly qualifies if you do not have any way to fix the Immirzi parameter and just tune it to get the desired result.
Of course there are many ways to obtain the BH formula that do not try to identify the microscopic degrees of freedom in a theory of QG, the original calculation from the 70s being an obvious example.

15. **Tom**
June 30, 2021

Off topic, but the European congress of Mathematics has finished up. The EMS prizes are always a good indication of future Field’s medalists
https://8ecm.si/prizes

16. **Log**
June 30, 2021

@DKepler

Ashoke Sen has computed the logarithmic corrections to the Bekenstein-Hawking entropy of various standard black hole solutions in this paper

https://arxiv.org/abs/1205.0971

It seems that non-stringy approaches to quantum gravity are not very successful at reproducing these universal results.

17. **Peter Woit**
June 30, 2021

All,
Please, no more about the “only string theory can compute the Black Hole entropy” arguments. These have been going on for over 25 years, with nothing new in a very long time. To summarize the situation, now as it has ever been:

1. Hawking tells you what the semiclassical limit is.
2. Any consistent theory of quantum gravity should reproduce this semiclassical limit.
3. String theory calculations that can be done in unphysical situations (wrong dimension, lots of SUSY, extremal black holes) claim to reproduce the semiclassical limit.
4. LQG calculations claim to reproduce the semi-classical limit.
5. People interested in string theory/LQG religious warfare argue about the calculations in 3. and 4.

I’ve personally never understood why showing that (unphysical limits of) your quantum theory gives the expected semi-classical result is anything other than a rather weak consistency check on your theory. Others clearly feel differently and think this is of huge significance.

If people think carrying on this argument is a good use of their time, they are encouraged to do so elsewhere.

July 2, 2021

Dear Peter, I believe you are ‘cherry-picking’ parts of comments. An exchange that was otherwise quite lively and interesting, you paint in the worst possible way. I am not a fan of string theory. I just work on Theoretical Physics topics. I saw the discussions you refer to. You are either blinded or so convinced by the idea that string theory has nothing to say about Physics, that you pick any phrase that adds to your view of things. Please, watch the discussions (there were many) and appreciate that these were honest discussion. People are attempting to understand things, with the tools at hand.

Is String Theory a Theory of Nature? Probably not if you ask me. But it is clear that these colleagues are attempting to understand topics in QFT and Gravity, with the tools they have at hand.

Please, do appreciate that negative comments like yours distort the ideas the general public (or even physicists in other areas) have about String Theory, or Theoretical Physics in general.
Of course, I do not justify equally wrong comments from certain string theorists
with the exact opposite agenda.

But this procedure you adopted in this post, is not the best way of understanding science, or communicating it.

thanks
Adrian

19. **Peter Woit**
July 2, 2021

Adrian,
I did watch fully the discussions I wrote about here, also took a look at many of the others. The quotes I gave are accurate, and links are provided so that anyone who wants to can see the full context.

You’re right that I was cherry-picking, but in the sense of ignoring the huge amount of hype about what great progress was being made, and sticking to writing about certain places where people like Arkani-Hamed or Witten chose to address the real problems (which most of the time are studiously ignored).

If you’re so concerned about the public or physics community getting misled, surely you’ve contacted the organizers of and participants in the conference’s “Outreach activities”.

20. **adrianmigueldiego**
July 2, 2021

Dear Peter,
You wrote
”If you’re so concerned about the public or physics community getting misled, surely you’ve contacted the organizers of and participants in the conference’s “Outreach activities” ”

To this I was referring with my phrase
” Of course, I do not justify equally wrong comments from certain string theorists
with the exact opposite agenda.”

I do not know if outreach sessions like the ones we witnessed in this Strings-conference are the best idea. I think a better service to the public would be made by discussing things that are well established, rather that the permanent focus on ”what is coming/the future” etc. In my view, this anxiety to communicate to the public the latest developments is a sign of certain immaturity. But this is just an opinion. There are other views, it is a matter of taste.

What I wanted with my post was to point out that (in my view, again), you were selecting particular phrases that sounded negative, in what other wise were quite interesting exchanges among physicists.

The way I see the string people (not necessarily those who appear in the media, but those who publish in the arXiv) is as a small set of honest and hard working physicists, technically sophisticated, researching mostly on QFT and Gravity, with various approaches.

I believe I am not misguided. Can they make mistakes? Over-claim? Of course, these are people. But the time, the community (and the arXiv) takes care of these mistakes.

I believe that your permanent opposing the ‘string hypes’ is good and welcomed. It is healthy. But I believe that in today’s update of this post you were not intellectually honest. This is damaging.
Once again, this is just an opinion.

Thanks for reading
Adrian

21. **martibal**

July 2, 2021

@adrianmigueldiego: as a mathematical-physics, I have been earring for 20 years that string theory is the only game in town, I have seen the “raise” of LQG as an opponent to string, and I witnessed the tentative of string theory to kidnap noncommutative geometry claiming that this was “nothing but the geometry of string theory”.

So please stop it with this idea that criticising string theory, as Peter does, is not good nor an honest way to communicating about science.
The string community has been dishonest for at least 20 years, and has absolutely no right to give any lessons about ethics in science. As Peter keeps on repeating, the denial of the string community to acknowledge the failure of string theory as a unification theory (which is nothing to be ashamed off: physics is full of beautiful theory that are not correct) is a shame for the physics community.

22. **Peter Woit**
July 2, 2021

Adrian,
I strongly disagree with you about the issue of the intellectual honesty of my account of what Witten and Arkani-Hamed had to say. Yes, I was ignoring some other things they had to say, for example, Arkani-Hamed’s
“String Theory remains the most magical structure we have encountered in theoretical physics – and the magic seems directly connected to the particle physics of the real world”
I think I was doing him a favor by not quoting that kind of thing, which he really should be embarrassed about.

Note also that I was making no comment about the work people were presenting at the conference, was sticking to discussing particular important points about the current state of the subject being made by the two most talented and hard-w0rking leaders of the field. I don’t think I was misrepresenting those at all.

The problem with the string theory hype is not that it’s new, exciting, cutting-edge speculation, rather than well-established. String theory is now older than not just my students, but also many of their parents and unfortunately it’s very well-established, sometimes even taught to high school students. The problem is not that it’s too new to be evaluated properly, but that it’s been a failure.

23. **Essenza**
July 3, 2021

In the ending remark, Ooguri makes the observation that the percentage of speakers older than him is roughly a linear function (64-2x)% where x is the number of years after his PhD. While Ooguri has his own interpretation about this observation (incoming flux of young people in the field is as healthy as ever), I wonder what others think about it.

24. **Alessandro Strumia**
July 3, 2021

Following Nima’s final recommendation, an experimentalist and a string theorist hang out together.
Experimentalist: “I have to compute QCD, Wikipedia says I need to add unphysical ghosts on a local section and their fiberwise duals and project out the quotient Fock space isomorphic to the supergraded BRST cohomology pullback of the field configuration along a vertical diffeomorphism of the principal Batalin–Vilkovisky anafestic G-bundle, as if it were antani. This jargon sounds a bit confusing”.
String theorist: “indeed, what’s QCD?”

25. **M is for Missed**
July 3, 2021

I’m posting this since I thought it could be useful for those very busy hep-ph physicists who may wish to go directly to (what I & surely many others) considers as the key moment from “perspective” lectures.

If one knows how to read between the lines, then at this lecture you finally can hear what, in different words, could well be re-phrased as: the search for M-theory using dualities *failed*.

https://youtu.be/sMvbtgE-idQ?t=1227

Of course even his brightest former student couldn’t accept that:

https://youtu.be/sMvbtgE-idQ?t=1972

26. **Ellis_AND_Wooster**
July 4, 2021

The experimental community pretty much politely ignores the string theory community, and has, well, since 1974 or so when the analytic S-matrix failed to predict the charmed quark.

Blasting is well underway in South Dakota for the $2 billion + LBNF/DUNE facility.

The real stuff happens in physics without a press release, book, or blog.

27. **André**
July 4, 2021

Ellis_AND_Wooster,

it is true that experiments are real physics. But what DUNE will find has been predicted years ago: normal neutrino mass order, no additional neutrinos, no proton decay, and no physics beyond the standard model whatsoever.

These boring predictions, if confirmed by DUNE, will show that also in experimental physics no “real stuff” is happening…

28. **Robert A. Wilson**
July 5, 2021

Witten says something about a (possible) theory that is “intrinsically” quantum mechanical, which seems to mean a theory that does not start with a continuous field and quantise it, and which (therefore) presumably cannot be described in that way. Are there any actual attempts in the literature to build such an “intrinsically” quantum theory, or is this just pie in the sky?

29. **Tony**
July 5, 2021

Penrose's talk is interesting (https://www.youtube.com/watch?v=hk_6EtWUatM), as is the discussion between him and string folks afterwards.

30. **Peter Woit**
July 6, 2021

All,
Sorry, but deleted various attempts to carry on the experimentalist vs. theorist mudfight of Ellis_AND_Wooster/André. I suppose I shouldn't have even let that get started…

Robert A. Wilson,
As I've pointed out here before (can't find a link), there's nothing unusual about a quantum system that isn't just a conventional quantisation of a classical system. The simplest example is the qubit.

31. **Robert A. Wilson**
July 7, 2021

Yes, but I can't imagine that Witten was thinking of anything as well known and well understood as a qubit.

32. **Peter Woit**
July 7, 2021

Robert A. Wilson,
Likely Witten was thinking of things like the 6d (2,0) superconformal theory which has not classical limit and its construction is somewhat mysterious. The point though is that there are plenty of much simpler examples, which often can be understood purely in terms of representation theory.

33. **Jackiw–Teitelboim**
July 7, 2021

Hello, Robert A. Wilson
If you are interested in what field theories Witten's probably interested in, then I certainly recommend you to follow the on going ICTS's Quantum Field Theory, Geometry and Representation Theory, with Witten's mini-course starting tomorrow:

https://www.icts.res.in/program/qftgrt2021/talks

In order to get a feel what is at stake here, start with:
https://arxiv.org/pdf/0809.0305.pdf

Already at p.1 one reads, "The Problem: According to textbooks, the passage from classical mechanics to quantum mechanics is made by replacing Poisson brackets with commutators. However, this is an unrealistically simple description of the situation, even for a basic example such as the classical phase space."

Go on and you certainly will be assured that's not going to be about qubits, Dear Robert.

34. **Peter Woit**
July 7, 2021

Jackiw-Teitelboim,

That's about the general problem of quantizing a symplectic manifold, but my impression was that Witten was thinking of the even more general problem of a quantum theory with no known symplectic manifold of which it is the quantization.

The qubit example is a bit unfair since in some sense it's the quantization of the sphere, although this sphere is not a classical limit of the quantum theory (and sphere isn't a cotangent bundle of some configuration space).

Even More Langlands

July 6, 2021
Categories: Langlands

Various news at least tangentially related to the Langlands program:

- Cambridge University Press this month is publishing a volume edited by Julia Mueller, entitled The Genesis of the Langlands Program. The chapters by various authors concentrate on Langlands himself and the early history of the program. For the table of contents, try Google Books.
- For more recent developments, see this survey article by Ana Caraiani.
- Today's arXiv preprints include Gaiotto and Witten's Gauge Theory and the Analytic Form of the Geometric Langlands Program.
- An online conference on Quantum Fields, Geometry and Representation Theory sponsored by the ICTS in Bangalore started yesterday. This conference features several mini-courses relevant to geometric Langlands. In particular, Witten will be giving a mini-course on Quantization, Gauge Theory and the Analytic Approach to Geometric Langlands that should provide a good survey of the subject as well as an introduction to his new work with Gaiotto mentioned above. Videos are available here.
- Getting a bit more tangential, the Simons Foundation recently announced the formation of a Collaboration on Global Categorical Symmetries, directed by Constantin Teleman.

  Even more tangential, Laurent Fargues is now on Twitter, starting off with a thread on condensed sets.

Deterioration of the World’s Thinking About the Deepest Stringy Ideas

July 12, 2021
Categories: Strings 2XXX

For quite a few years now, I’ve been mystified about what is going on in string theory, as the subject has become dominated by AdS/CFT inspired work which has nothing to do with either strings or any visible idea about a possible route to a unified fundamental theory. This work is very much dependent on choosing a special background, in tension with the idea that, whatever string theory is, it’s supposed to be a unique theory that relates all possible backgrounds. This issue came up in a discussion session at Strings 2021, and it turns out that others are wondering about this too. There’s this today from Lubos Motl:

> Aside from more amazing things, the AdS/CFT correspondence became just a recipe for people to do rather uninspiring copies of the same work, in some AdS_5/CFT_4 map, and what they were actually thinking was always a quantum field theory, typically in D=4 (and it was likely to be lower, not higher, if it were a different dimension!) whose final answers admit some interpretation organized as a calculation in AdS_5. But as Vafa correctly emphasized, this is just a tiny portion of the miracle of string/M-theory – and even the whole AdS/CFT correspondence is a tiny fraction of the string dualities.
>
> This superficial approach – in which people reduced their understanding of string theory and its amazing properties to some mundane, constantly repetitive ideas about AdS/CFT, especially those that are just small superconstructions added on top of 4D quantum field theories – got even worse in the recent decade when the “quantum information” began to be treated as a part of “our field”. Quantum information is a legitimate set of ideas and laws but I think that in general, this field adds nothing to the fundamental physics so far which would go beyond the basic postulates of quantum mechanics…
>
> When Cumrun correctly mentioned that the real depth of string theory is really being abandoned, Harlow responded by saying that there were some links of quantum information to AdS/CFT, the latter was a duality, and that was important. But that is a completely idiotic way of thinking, as Vafa politely pointed out, because string theory (and even string duality) is so much more than the AdS/CFT. In fact, even AdS/CFT is much more than the repetitive rituals that most people are doing 99% of their time when they are combining the methods and buzzwords of “AdS/CFT” and “quantum information”. Many people are really not getting deeper under the surface; they are remaining on the surface and I would say that they are getting more superficial every day.

According to Lubos, he’s not the only one who feels this way, with an “anonymous Princeton big shot” agreeing with him (hard to think of anyone else this could be other than Nima Arkani-Hamed):

> There is a sociological problem – coming from the terrifying ideological developments in the whole society – that is responsible for this evolution. I have been saying this for a decade or two as well – and now some key folks at Princeton and elsewhere told me that they agreed. The new generation that entered the field remains on the surface because it really lacks the desire to arrive with new, deep, stunning, revolutionary ideas that will show that everyone else was blind. Instead, the Millennials are a generation that prefers to hide in a herd of stupid sheep and remain at the surface that is increasingly superficial…
>
> So most of the stuff that is done in “quantum information within quantum gravity” is just the work of mediocre people who want to keep their entitlements but who don’t really have any more profound ambitions. As the aforementioned anonymous Princeton big shot told me, their standards have simply dropped significantly. The toy models in the “quantum information” only display a very superficial resemblance to the theories describing Nature. That big shot correctly told me that in the early 1980s, Witten was ready to abandon string theory because it had some technical problems with getting chiral fermions and their interactions correctly.
>
> Harlow says that many of the people – who may be speakers at the annual Strings conference and who may call themselves “string theorists” when they are asked – don’t really know even the basics of string theory. And they can get away with it. Just like there is the “grade inflation” and the “inflation of degrees”, there is “inflation in the usage of the term string theorist”. Tons of people are using it who just shouldn’t because they are not experts in the field at all. Harlow said that many of those don’t understand supersymmetry, string theory etc. but it’s worse. I think that many of them don’t really understand things like chiral fermions, either. It’s implicitly clear from the direction of the “quantum information in quantum gravity” papers and their progress, or the absence of this progress to be more precise. They just don’t think it’s important to get their models to a level that would be competitive with the previous candidates for a theory of everything – like the perturbative heterotic string theory, M-theory on G_2 manifolds, braneworlds, and a few more. They are OK with writing a toy model having “something that superficially resembles a spacetime” and they want to be satisfied with that forever.

I don’t want to start here an ad hominem discussion of Lubos and his often extreme and eccentric views. On the topic though of the devolution of string theory as a TOE to playing with toy models of AdS/CFT using quantum information, it seems quite plausible that not only the “anonymous Princeton big shot” but quite a few other theoretical physicists see the current situation as problematic.

Comments

1. **Low Math, Meekly Interacting**
   July 12, 2021

   Has not thinking about AdS/CFT also deteriorated, or at least diminished in applicability? It wasn’t that long ago there seemed to be loads of ambitious talk about AdS/QCD and stringy condensed matter physics. Now I assume it’s about relating the duality perhaps to real-world applications in quantum computing. A solution ever in search of a physically realized problem, seemingly.

2. **Gavin**
   July 13, 2021

   To me it reads like someone past his prime, blaming the lack of success in the field on anyone he can, instead of reevaluating whether the ideas themselves lead anywhere fruitful.

3. **Peter Woit**
   July 13, 2021

   Gavin,
   I agree that much of Lubos’s problem is that the dream of his youth (a unique M-theory, based on a matrix model or whatnot) has died and can’t be revived. People don’t work on what he wants them to work on because the ideas have failed. There is something to his description though of the current sorry state of the field, and what’s really interesting here is his plausible claim that Arkani-Hamed and others share it (although, unlike him, are not willing to say so in public…).

4. **Gavin**
   July 13, 2021

   @Peter Yes, I agree. The problem is that no one in the field has any idea how to make progress with the truly interesting questions. One approach is to work on topics that produce papers, even if they aren't truly interesting (this isn't really a criticism; there are always papers written making incremental progress even in healthy fields). Another approach, apparently, is to blame the lack of progress on the younger generation. I wish there was more discussion about re-evaluating the direction of the field to establish where progress realistically can be made, rather than pointing fingers or holding onto old dreams that are unattainable in the foreseeable future.

5. **Matthew Foster**
   August 10, 2021

   In condensed matter, the SYK model has generated a lot of excitement as a toy solvable model of strongly correlated matter. This is of perennial interest, because we still want to understand things like high-Tc superconductivity in the cuprates, but lack good analytical tools for tackling even the simplest models for these materials.

   SYK rather remarkably links "toy" Liouville gravity (Liouville quantum mechanics) and conformal invariance at short times, and random matrix theory at large time scales. It has a holographic description in terms of JT gravity, although I'm far from an expert on that part.

   2D Liouville field theory (as in the original Polyakov path integral, important for non-critical strings) can be formally used to describe properties of certain critical 2D wave functions in topological quantum materials. (The connection is via so-called log-correlated random energy models in statistical physics). These are related to real experiments, notably the quantum Hall plateau transition. The underlying structures seem to be logarithmic conformal field theories akin to percolation, but still very poorly understood. These are now resurfacing in yet another context: measurement-induced transitions in random quantum circuits. These toy models are not dissimilar to actual quantum hardware at Google.

   So there are indeed rich and fruitful developments that may yet profit from holography, Liouville field theory, and other stringy byproducts. I can't speak for what use any of this is to elementary or "real" quantum gravity physics, but some of us on the condensed matter side are indeed excited.

6. **Peter Woit**
   August 10, 2021

   Matthew Foster,
   There's lot of interesting work of the sort you mention, but it's about quantum mechanical models or maybe 2d QFTs, which have little connection to string theory (other than that people who worked on string theory turned to these topics as "toy models" to play with when their work on string theory failed). There's zero connection of any of this to the claimed motivation for string theory research as giving "our best hope" for a unified theory.

7. **Matthew Foster**
   August 11, 2021

   Peter, I think the part of Lubos' comments that do resonate a bit with me, although probably not in the way he intended, is that the string community seems to have moved far from its origins.

   As a condensed matter person, SUSY is the first part I'm happy to ignore (although there is a simpler version of SUSY that actually plays a useful technical role in many of the applications I described above, for quantum systems with randomness).

   But one can ask the very basic question of what goes wrong with the bosonic string?
   We know that in principle it can be defined in 4 dimensions (coupled to Liouville CFT), and it seems like a perfectly sensible starting point for an _effective_ theory of a gluon stretched between two quarks. I know real QCD is much more complicated than that, but nevertheless it is a well-defined problem.

   I find it very surprising that none of the "modern" string textbooks mention the work of discrete matrix methods that demonstrated the instability of summing over membranes to branching polymers. It's a quite basic and old result now, but it points out how hard it is to generalize path integrals to higher-dimensional membranes, owing simply to the entropic favorability of contracting the (closed, say) string to arbitrarily small radius and branching infinitely. Maybe this picture applies only in imaginary time, but it seems like the kind of result that should be more widely known and appreciated.

   On that note, if one forgets about SUSY, what about a purely fermionic string, i.e. with fermion bilinears playing the role of spacetime coordinates, instead of the free boson? It's likely strongly coupled, but has anyone tried this? One might hope that Pauli exclusion would help prevent the branching polymer collapse of the bosonic analog.

8. **Peter Woit**
   August 11, 2021

   Matthew Foster,
   Understanding string theory in four dimensions is a very old problem that has received (and continues to receive) a lot of attention from theorists. The main hope has always been that this will give you a calculational method for strongly coupled gauge theories like QCD (as opposed to a unified theory with gravity). The problem is simply that no one has managed to have more than very partial success with this.

   This kind of work goes back more than forty years, to around 1980, when it was being pursued intensively by Polyakov, Migdal and others. During my graduate student years (1979-1984), trying to solve QCD was the center of attention, and I spent a lot of time trying to understand these string theory based ideas. Post-1984, what got most attention was the 10d critical superstring and unification, but for many people working on string theory, the 4d string was always a focus of their work.

   So, sure, this remains an idea worth pursuing, but one should be aware that it's an idea the best in the field have spent over forty years banging their heads against unsuccessfully, not something that hasn't gotten attention for no good reason.

9. **Matthew Foster**
   August 11, 2021

   Hi Peter,

   "So, sure, this remains an idea worth pursuing, but one should be aware that it's an idea the best in the field have spent over forty years banging their heads against unsuccessfully, not something that hasn't gotten attention for no good reason."

   Of course. I just meant that it is surprising to me that the intrinsic difficulty of solving the 4D bosonic string is glossed over. Ivan Kostov told me that in his opinion, the bosonic string _is solved_: it has the branching polymer instability seen in the discrete approach to 2D quantum gravity (Cates, Froehlich, Ambjoern, and others), and that's it. Seems like a major omission that this wasn't included early in, e.g., Polchinski's volume 1. (And that's not a dig at Polchinksi, since I did my Ph.D. at UCSB. He was the friendliest, most approachable string practitioner there, at least as far as the students were concerned).

   Given this, without SUSY the case for strings seems doomed indeed. Another comment is that strongly fluctuating, say multifractal behavior, might make perfect sense in the context of quantum gravity. This is something we do know how to handle in certain contexts on the condensed matter side. The branching polymer picture, and what emerges generally from studies of 2D quantum gravity (dominated by extremal statistics of rare curvature fluctuations) is very different from the cartoon of smoothly joining strings in textbooks.

Would still like to know about the pure fermionic version, though…too busy with course preparation now to dig.

The Problem of Quantization

July 12, 2021
Categories: Quantum Mechanics, Quantum Theory: The Book, Uncategorized

I've been watching Witten's ongoing talks about geometric Langlands mentioned here, and wanted to recommend to everyone, mathematician or physicist, the first of them, on The Problem of Quantization (pdf here, video here, the question session is very worthwhile). For those very sensibly not interested in the intricacies of geometric Langlands, this talk is about the fundamental issue of "quantization".

Hamiltonian mechanics gives a beautiful geometrical formulation of classical mechanics in terms of the Poisson bracket on functions, while quantum mechanics involves operators with non-trivial commutators. It was Dirac's great insight that "quantization" takes functions to operators, taking the Poisson bracket to the commutator. In mathematician's language, it's supposed to be a unitary representation of the Lie algebra of the infinite dimensional group of canonical transformations of a symplectic manifold, so a homomorphism from functions with Poisson bracket to the Lie algebra of skew-adjoint operators on a complex vector space.

The problem with this is that you'd like to have an irreducible representation, but the only way to get this is to pick some extra structure on the symplectic manifold. The standard example is the phase space $\mathbf R^{2n}$, where you have to pick a decomposition into position and momentum coordinates. The state space will then be functions of just position, or just momentum. A different choice is to complexify, and look at functions of either holomorphic or anti-holomorphic coordinates. This choice is called a "polarization". One aspect of the "problem" of quantization is that, given a phase space (symplectic manifold), there may not be an appropriate polarization. Or, there may be many different ones, with no obvious reason why they should give the same quantum theory.

Witten doesn't mention one aspect of this that I find most fascinating. For relativistic quantum field theories the phase space is a space of solutions of a relativistic wave-equation. To get physically sensible results one must choose a polarization that distinguishes between positive and negative energy (or between functions which extend holomorphically in the positive or negative imaginary time direction).

In these lectures, Witten advertises a rather exotic quantization contruction, using (even for a finite dimensional symplectic manifold) conformally invariant boundary conditions in a two-dimensional QFT. I'm not convinced that this is really a good way to deal with the case where what you're doing is looking for representations of a finite-dimensional Lie algebra, but it's plausible this is the right way to think about the geometric Langlands situation, where you're trying to quantize a moduli space of Higgs bundles.

In the question section, someone asked about my favorite approach to this problem, essentially using fermionic variables and cohomology. This can be thought of in general as using spinors and the Dirac operator, with the Dolbeault operator a special case when the symplectic manifold is Kähler. Witten responded that he had only really looked at this in the Kähler special case.

Comments

1. **Jackiw–Teitelboim**
   July 12, 2021

   Hello,

   Yes, not difficult to guess from my former comments on your website that I'm the person who asked the question regarding yours, and mine, "favorite approach." I think Witten's reply was somewhat disappointing since I see no reason to constrain oneself to Kähler's structure.

2. **Peter Orland**
   July 13, 2021

   I always felt that the inverse problem was at least as important; what is the corresponding {\em classical} model corresponding to some quantum system?

   Quantization is not unique, of course, but the classical limit of a quantum system is unique (although it may have different descriptions).

   My impression is that mathematicians and people doing physical mathematics don't spend much effort on the inverse problem. It has a lot of relevance to real physics, though. For example, there are interesting condensed-matter systems which should correspond to field theories with Lagrangians (hence the classical limit), but where the connection is not proven.

3. **Arnold Neumaier**
   July 13, 2021

   Peter Orland,

   unfortunately, the classical limit of a quantum system is not unique either; it depends on the choice of a family of (generalized) coherent states in the Hilbert space of the quantum system, which is not unique. For the classical limit in terms of coherent states, see, e.g.,

   Yaffe, L. G. (1982). Large N limits as classical mechanics. Reviews of Modern Physics, 54(2), 407.

4. **Peter Orland**
   July 13, 2021

   Arnold Neumaier,

   That is not really the issue. It depends upon what you mean by classical, i.e., which parameter you take to zero. If that parameter is $\hbar$, there is no ambiguity. If you decide that the parameter is 1/N, as in the example you give, what you obtain can be entirely different.

   On the other hand, the problem I raised includes many large-N models, which have not been successfully been written as classical systems. The result should be unique, but we don't usually know what it is.

   What I was referring to above, was that the classical limit of some systems can't yet be directly produced, only conjectured. An example is the XXX spin chain, at large spin s. This is supposed to be the O(3) sigma model (Haldane's Nobel Prize was at least partly due to this identification), possibly with a $\theta=\pi$ term (for half-integer s). There is a lot of evidence for this conjecture, but it is not proved. There are other such conjectures around.

5. **Alex**
   July 13, 2021

Personally, I think the case for the finite dimensional case is pretty close to solved in many aspects, and now fully streamlined in the work of Landsman:

-Lie Groupoids and Lie algebroids in physics and noncommutative geometry (https://arxiv.org/abs/math-ph/0506024)

-Between classical and quantum (https://arxiv.org/abs/quant-ph/0506082)

-Quantization commutes with singular reduction: cotangent bundles of compact Lie groups (https://arxiv.org/abs/1508.06763)

Field theories, of course, are a different beast.

"To get physically sensible results one must choose a polarization that distinguishes between positive and negative energy".

That's true, although I would say the problem is not so much in the quantization step (an abstract Weyl C*-algebra can be defined without that choice), but in obtaining a concrete representation of that algebra, where you indeed need to make that choice (which amounts to select a particular quasi-free/Gaussian algebraic state on which to base the GNS representation of the algebra; if there's a timelike Killing vector field on the spacetime, you can make the interpretation of that step in terms of "positive/negative energy Fourier modes") And, still, all of this is in the case of free/non-interacting field theories!

6. **Arnold Neumaier**
July 13, 2021

Peter Orland,

in quantum theories not derived from an action principle there may not even an $\hbar$ in the theory!

Of course if you have a Hamiltonian where you know (or assume) the precise $\hbar$ dependence and know (or assume) which quantities should survive the limit $\hbar\to 0$ then there is no ambiguity about the classical limit, though finding it may still be nontrivial.

Can you provide references for "There is a lot of evidence for this conjecture"?

7. **Peter Orland**
July 13, 2021

I did not mean specifically theories with known S matrices, e.g. satisfying Yang-Baxter equations.

The literature on the Haldane conjecture is substantial, and the best place to find more discussion is in Haldane's paper and those citing it.

The same problem occurs for pretty much any spin chain or vertex model which is argued to be Bosonic QFT. Some degrees of freedom are relevant, hence should be kept, but others should be thrown away.

Higher-dimensional examples include quantum link models of non-Abelian gauge theories. The Yang-Mills Lagrangian has not been derived from these. Long ago, Daniel Rohrlich and I argued that some of these are YM, but some are not even relativistic.

8. **Peter Woit**
July 13, 2021

Alex,
One of the main points Witten was making is that quantization is not just producing an abstract algebra, but also a state space for them to act on. This is where you really need to introduce extra structure.

He doesn't describe this in general, but he's referring to the fundamental problem of Lie algebra representation theory: given a Lie algebra you have an abstract associative algebra (the universal enveloping algebra), which is a quantization of a symmetric algebra, but producing irreducible representations is very tricky. The orbit methods says they should be quantizations of co-adjoint orbits, but how to do this in general runs into interesting problems (which he hopes brane quantization might resolve).

9. **ARoxdale**
July 14, 2021

> What textbooks don't usually emphasize is that this doesn't work,or better, it only works approximately, to first order in h, or for a preferred class of functions on the classical phase space.
>
> Accordingly, there actually is no completely natural operation of quantizing a classical phase space – none that is known, and I believe, none that exists. Quantization always requires some additional structure.As Ludwig Faddeev used to say, quantization is "an art not a science.

Is there some qualifier for this remark? Or is quantization really only something that can be trusted to 1st order?

10. **Peter Woit**
July 14, 2021

ARoxdale,
It's not a question of being trusted, the problem is more one of ambiguity: there are lots of possible quantizations of a given phase space, all of which differ by terms which vanish in the classical limit hbar goes to zero. This is mentioned in some textbooks as the "operator ordering problem".

If you impose various conditions you want your quantization to satisfy, you can sometimes get a unique quantization, but only for some special class of functions on phase space.

My QM textbook
https://www.math.columbia.edu/~woit/QMbook/qmbook-latest.pdf
does emphasize this problem, explains in great what happens for phase space $\mathbf{R}^{2n}$
Witten is interested in more general symplectic manifolds, where the situation is much more complicated, with geometric quantization a partially successful way to deal with it (while requiring the specification of a polarization, as Witten discusses).

11. **Lowell Brown**
July 19, 2021

I have no idea why Witten is concerned with this problem.

Quantum mechanics is the fundamental theory.
So one could, perhaps, be concerned with the classical limit of quantum mechanics, not the other way round.
Physics is concerned with computing experimental results. So you do this computation and see if this class of experiments has a macroscopic limit.

Steven Weinberg 1933-2021

July 24, 2021
Categories: Obituaries

I heard this morning the news that Steven Weinberg passed away yesterday at the age of 88. He was arguably the dominant figure in theoretical particle physics during its period of great success from the late sixties to the early eighties. In particular, his 1967 work on unification of the weak and electromagnetic interactions was a huge breakthrough, and remains to this day at the center of the Standard Model, our best understanding of fundamental physics.

During the years 1975-79 when I was a student at Harvard, I believe the hallway where Weinberg, Glashow and Coleman had offices close together was the greatest concentration of the world's major figures driving the field of particle theory, with Weinberg seen as the most prominent of the three. From what I recall, in a meeting one of the graduate students (Eddie Farhi?) referred to "Shelly, Sidney and Weinberg", indicating the way Weinberg was a special case even in that group. I had the great fortune to attend not only Coleman's QFT course, but also a course by Weinberg on the quantization of gauge theory.

Weinberg was the author of an influential text on general relativity, as well as a masterful three-volume set of textbooks on QFT. The second volume roughly corresponds to the course I took from him, and the third is about supersymmetry. While most QFT books cover the basics in much the same way, Weinberg's first volume is a quite different, original and highly influential take on the subject. It's not easy going, but the details are all there and his point of view is an important one. When you hear Nima Arkani-Hamed preaching about the right way to understand how QFT comes out uniquely as the only sensible way to combine special relativity and quantum mechanics, he's often referring specifically to what you'll find in that first volume.

Besides his technical work, Weinberg also did a huge amount of writing of the highest quality about physics and science in general for wider audiences. An early example is his 1977 The Search for Unity: Notes for a History of Quantum Field Theory (a copy is here). His 1992 Dreams of a Final Theory is perhaps the best statement anywhere of the goal of fundamental physical theory during the 20th century. His large collection of pieces written for the *The New York Review of Books* covers a wide variety of topics and all are well worth reading.

At the time of the 1984 "First Superstring Revolution", Weinberg joined in and worked on string theory for a while, but after a few years turned to cosmology. In early 2002 he was one of several people I wrote to about the current state of string theory, and here's what I heard back from him:

> I share your disappointment about the lack of contact so far of string theory with nature, but I can't see that anyone else (including those studying topological nontrivialities in gauge theories) is doing much better. I thinks that some theorists should go on pushing as hard as they can on string theory, and others should do something else, but it is not easy to see what. I have myself voted with my feet (if that is the appropriate organ here) and switched entirely to work in cosmology, which is as exciting now as particle physics was in the 1960s and 1970s. I wouldn't criticize anyone for their choices: it's a tough time for fundamental physics.

A couple years after that time, Weinberg's 1987 "prediction" of the cosmological constant became the main argument for the string theory multiverse. This "prediction" was essentially the observation that if you have a theory in which all values of the cosmological constant are equally likely, and put this together with the "anthropic" constraint that only for some range will galaxy formation give what seem to be the conditions for life, then you expect a non-zero CC of very roughly the size later found. I've argued ad nauseam here that this can't be used as a significant argument for string theory in its landscape incarnation. One way to see the problem is to notice that my own theory of the CC (which is that I have no idea what determines it, so any value is as likely as any other) is exactly equivalent to the string landscape theory of the CC (in which you don't know either the measure on the space of possible vacua, or even what this space is, so you assume all CC equally likely). One place where Weinberg wrote about this issue is his essay Living in the Multiverse, which I wrote about here (the sad story of misinterpretation of a comment of mine there is told here).

Weinberg's death yesterday, taking away from us the dominant figure of the period of particle theory's greatest success is both a significant loss and marks the end of an era. His 2002 remark that "it's a tough time" is even more true today.

Update: Scott Aaronson writes about Weinberg here, especially about getting to know him during the last part of his life.

Update: For Arkani-Hamed on Weinberg, see here.

Update: Glashow writes about Weinberg here.

Comments

1. **Alessandro Strumia**
   July 24, 2021

   Weinberg was the last of the physics giants who produced fundamental theories validated by experiments. After half a century his Standard Model still holds, so maybe now is the fist time in physics history without scientific giants.

2. **Shantanu**
   July 24, 2021

   A tribute to him from one Astrophysics colleague who had recently joined UT Austin
   https://twitter.com/MBKplus/status/1418972769509855236

3. **Ricardo**
   July 24, 2021

   His last book "Foundations of Modern Physics came out a few months ago. From the preface:
   "This book treats such a broad range of topics that it is impossible to go very far into any of them. Certainly its treatment of quantum mechanics, statistical mechanics, transport theory, nuclear physics, and quantum field theory is no substitute for graduate-level courses on these topics, any one of which would occupy at least a whole year. This book presents what I think, in an ideal world, the ambitious physics student would already know when he or she enters graduate school. At least, it is what I wish that I had known when I entered graduate school."
   Does anybody have an opinion about how well he succeeded?

4. **Wei Liu**
   July 24, 2021

   It is sad news that Weinberg is not with us anymore but I cannot agree with Alessandro Strumia that "Weinberg was the last of the physics giants who produced fundamental theories validated by experiments…so maybe now is the fi(r)st time in physics history without scientific giants." Please be reminded that C. N. Yang and T. D. Lee still are healthily living.

5. **Mark Weitzman**
July 24, 2021

@Ricardo: I wrote the following review on one of my piazza sites a few weeks ago. I am currently half way through the book, and I am enjoying the book, although I am familiar with most of the content already. As I indicated below it is more of a review book, than a teaching book.

Steven Weinberg had come out with a new book: Foundations of Modern Physics. I have read the first 2 chapters, and scanned the rest of the book – the book is a short 300 pages and the hardcover is about $40. The level of the book is intermediate to advanced undergraduate.

I often encounter online students who have taken several of the MIT physics MOOC's but often feel that they either lack some background, or don't see what they have learned (especially in the QM sequence) and how it will be applied. To many of these students my advice is usually to read the Feynman Lectures on physics, to get the big picture and for more background in QM prerequisite physics, and/or find a good textbook on modern physics.

When I was in college almost half a century ago, I remember using Leighton's classic book Principles of Modern Physics 1959 (about 700 pages in length), and suggest students try and find a more recent book covering roughly the same material – I haven't seen one, so let me know if you have. There seem to be many freshman/sophomore level books covering modern physics, but I don't think these are sufficient.

Weinberg's book is less of a textbook (while there are 25 problems at the end of the book, there are no exercises at the end of chapters, and no worked out examples). It is written in Weinberg style, few pictures or diagrams, unusual symbols (m_1 for the atomic mass unit, usual notation is u), nice but sometimes terse arguments, and excellent content with interesting historical asides. The math level is low at the beginning (algebra – elementary calculus), and rises a little with the level of the material, but not nearly as difficult as his graduate level books.

There are seven chapters in the book:

Early Atomic Theory
Thermodynamics and Kinetic Theory
Early Quantum Theory
Relativity
Quantum Mechanics
Nuclear Physics
Quantum Field Theory
So the coverage is exactly what a student should be looking for in a modern physics book (perhaps astrophysics and cosmology are left out, because Weinberg just published a set of lectures on astrophysics, and has a whole book on Cosmology). The book seems more of a review or plug holes in background, and less of a teaching masterpiece.

I recommend that students looking for a book on this type of material take a look at the book and see if it is for them. I think students who are taking or have finished the MITx 8.04-8.06 sequence might find the book worthwhile as a review and also as filling out some material, and get a preview of quantum field theory as well.

6. **Ralf Hofmann**
July 25, 2021

Steven Weinberg – a great, highly creative physicist and wonderfully involved teacher of fundamental physics who shaped my own education in quantum field theory and cosmology during essential steps. I'll miss him and his sober views very much.

7. **Alessandro Strumia**
July 25, 2021

Dear Wei, thank you, let me try to explain better. Historians like to choose a somehow arbitrary moment to symbolise a gradual change. If the change I mentioned will really happen, I expect they will choose this moment.

8. **Thomas Larsson**
July 25, 2021

Alessandro, Glashow is still around, isn't he? So not quite the last. As a sophomore, I attended a talk by GSW when they were here in Stockholm to collect their Nobel prize, and I understood absolutely nothing.

Btw. I learned from Lubos that Miguel Virasoro has passed away as well.

9. **Sebastian Thaler**
July 25, 2021

I was working at Cambridge University Press in 1995 when the first volume of his "Quantum Theory of Fields" was released. I recall speaking briefly with him on the phone about something trivial like distributing review copies, and picking up a copy of the book that had been delivered to our office. I read the first page and then put it back down—it was just a *bit* over my head…

10. **Amitabh Lath**
July 25, 2021

My PhD thesis was a measurement of the Weinberg angle (sin^2\theta_W) using polarized electrons at the SLAC linear collider. Some people insisted the W stood for Weak but I always held it is W for Weinberg. I read and reread his paper A Model of Leptons many times until I could reproduce it at my defense. I wish all theory papers were as clear and understandable.

11. **Severin Pappadeux**
July 25, 2021

Miguel Virasoro died the same day

12. **Shantanu**
July 25, 2021

Amitabha: From what I understand the "Weinberg" angle was first introduced by Glashow.

13. **Amitabh Lath**
July 26, 2021

Shantanu, that is funny because I was told to call it Weak Mixing Angle (and not Weinberg angle) after I gave this talk at Harvard. Glashow was in the room but he was not the one who made that comment. I made the correction with a marker on my transparencies right there. This was a while ago, but I also vaguely remember some chatter about "well if this is right it means the higgs is light". We were, and it was.

14. **Shantanu**
July 26, 2021

Amitabha: This is also mentioned on Peter's blog https://www.math.columbia.edu/~woit/wordpress/?p=17
I have also heard this mentioned in many HEP seminars I attended as a grad student.

15. **Robinson**
July 27, 2021

Dreams of a Final Theory is available on Audible. It's read by Weinberg himself. It's written for a general audience, so even untutored but interested readers like me can understand it.

16. **D R Lunsford**
July 27, 2021

That is sad news, but it was a long life well-lived. He was an authentic giant. His book on GR is still my favorite (tied with that of Fock) and I was lucky to learn the subject in detail mostly from that. Agree also about QTF II. I wish we had made more progress in his last years for him to enjoy and contribute to. RIP.

-drl

More of the Same (Physics, Math and Unification)

July 29, 2021
Categories: Euclidean Twistor Unification, Langlands

I was going to just provide the following links with a some comments, but decided it would be a good idea to put them into what seems to me the larger context of where we are in fundamental physics and its relationship to mathematics.

For the latest on the conventional physics approach to unification (GUTS, SUSY, strings, M-theory), there's:

- The Lex Fridman podcast has an interview with Cumrun Vafa. Going to the section (1:19:48) – Skepticism regarding string theory) where Vafa answers the skeptics, he has just one argument for string theory as a predictive theory: it predicts that the number of spacetime dimensions is between 1 and 11.
- A second edition of Gordon Kane's String Theory and the Real World has just appeared. One learns there (page 1-19) that

> There is good reason, based on theory, to think discovery of the superpartners of Standard Model particles should occur at the CERN LHC in the next few years.

For the latest in mathematics and the interface of math and physics, there's

- Quanta magazine has a good article about the dramatic Fargues-Scholze result linking geometry and number theory.
- A long paper by Gaiotto and Witten on their new ideas about quantization, giving a lot of background and details, in particular exploring the link to the currently best-developed set of ideas relating geometry and quantization (so-called "geometric quantization").

About the first two links, I'm at a loss for words.

The second two are extremely interesting topics indicating a deep unity of number theory, geometry and physics. They're also not topics easy to say much about in a blog posting. In the Fargues-Scholze case that's partly because the new ideas they have come up with relating arithmetic and geometry are ones I don't understand very well at all (although I hope to learn more about them in the future). The connections they have found between representation theory, arithmetic geometry, and geometric Langlands are very new and it will likely be quite a few years before they are well understood and their implications well-developed.

In the Gaiotto-Witten case, some of what they discuss is very familiar to me: geometric quantization has been a topic of fascination since my student days, and one major goal of my QM book was to work out in detail (for the case of $\mathbf R^{2d}$) some of the subtleties about quantization that they discuss. For co-adjoint orbits in Lie algebras, geometric quantization has a long history, and "brane quantization" may or may not have anything new to say about this. For moduli spaces of vector bundles on Riemann surfaces, and Hitchin moduli spaces of Higgs bundles on Riemann surfaces, "brane quantization" might come into its own.

There is a fairly short path now potentially connecting fundamental unifying ideas in number theory and geometry to our best fundamental theories in physics (and seminars on arithmetic geometry and QFT are now a thing). The Fargues-Scholze work relates arithmetic and the central objects in geometric Langlands involving categories of bundles over curves. These categories in turn are related (in work of Witten and collaborators) to 4d TQFTs based on twistings of N=4 super Yang-Mills. This sort of 4d QFT involves much the same ingredients as 4d QFTs describing the Standard Model and gravity. For some better indication of the relation of number theory to this sort of QFT, a good source is David Ben-Zvi's lectures this past semester (see here and here). I'm hopeful that the ideas about twistors and QFT in Euclidean signature discussed here will provide a close connection of such 4d QFTs to the Standard Model and gravity (more to come on this topic in the near future).

Some Math Items

July 30, 2021
Categories: abc Conjecture, Uncategorized

Some math items that may be of interest:

- Zentralblatt Math has a review of Mochizuki's IUT papers, by Peter Scholze. Scholze explains the problem with the proof claimed in these papers. For more details, see his manuscript with Stix, or this discussion hosted last year on this blog.
- The Bulletin of the AMS will be running a special issue on the work of Michael Atiyah. Available already are two wonderful articles: Michael Atiyah's work in algebraic topology, by Graeme Segal, and The Atiyah-Singer index theorem, by Dan Freed.
- For a talk by Helmut Hofer about Andreas Floer and his work, together with contributions from others who knew Floer, see The Floer Jungle: 35 years of Floer theory.
- The latest AMS Notices has a memorial tribute to Steve Zucker, with a detailed discussion of his career and mathematical work. His collaborator David Cox explains that the origin of their collaboration was exactly what everyone has always suspected.

Update: The Scholze review has been removed (temporarily?). A cached version is here.

Update: The review was temporarily removed just because what was posted wasn't a finalized version, this is explained here. They should repost once Scholze has a chance to make any final edits.

Update: The review is back up.

Update: Michael Harris has a new substack site, where he'll be writing about the mechanization of mathematics. I'm glad to see someone doing this from his point of view.

Comments

1. **Essenza**
   July 31, 2021

   Seems like Peter's comments are removed/editted (?). Here's the original (I think; found online):
   https://web.archive.org/web/20210730194853/https://zbmath.org/pdf/07317908.pdf

2. **TS**
   July 31, 2021

   Zentralblatt took down Scholze's review and replaced it with the paper's abstract. Here is a cached version of the review https://webcache.googleusercontent.com/search?q=cache:Lm7YcNafEeoJ:https://zbmath.org/pdf/07317908.pdf

3. **David Roberts**
   July 31, 2021

   That "review" of IUT 1 is a cut-and-paste of the abstract, as can be seen by comparing with the published version here: https://doi.org/10.4171/PRIMS/57-1-1

   I haven't compared with the published abstracts, but the other "reviews" of parts 2–4 look to be the same. If there was a review by Scholze, it's been removed; I'd love to see it…

4. **David Roberts**
   July 31, 2021

   I see via Nalini Joshi on Twitter that the review was captured before it evaporated: https://web.archive.org/web/20210730194853/https://zbmath.org/pdf/07317908.pdf (and she alludes to the discussion on Reddit here: https://www.reddit.com/r/math/comments/ousg3s/scholzes_review_of_mochizukis_paper_for/)

   If some kind of political pressure has been applied to remove this, then that is not a good look for anyone involved.

5. **SD**
   August 2, 2021

   At the end of the Hofer's nice history talk, Gromov – as is usual of him – makes some interesting general comments concerning Scholze's condensed mathematics.

6. **nad**
   August 9, 2021

   It seems to me that Helmut Hofers talk was at least partially meant to keep up discussing mathematical (work) culture and it's possible effects.

   That is – it is problematic to publicly discuss possible reasons for Andreas Floer's -as the german Wikipedia writes *unexpected*– suicide, on the other hand it is not too far fetched to assume that his mathematical life took quite a role in his decisions. I therefore found it considerably well-balanced that Helmut Hofer mentioned in his talk in a matter-of-fact way some of the possible strains that may have impaired Andreas Floer.

   So for example he mentioned that Andreas Floer may have had probably felt quite under pressure, when there was some kind of "hype" about his work and that people expected him to write up his results. He mentioned that Mathematics was not Andreas Floer sole passion, but that he played viola da gamba and thus that it was probably not easy to conciliate his other passions with his mathematical passions and (new) duties. Briefly after his death I had heard someone mentioning that Andreas Floer was quite probably suffering from something that could be somewhat called "stagefright" – another strain, which may come with job duties or at least with the roles a successful mathematician is often expected to fill in.

   I had met him only very briefly before his death when he was a few days in Berlin. It may not be sensible to state the impressions I got from the very few interactions, as they are maybe simply too attached to particular moments – but in one instance he appeared to me quite deeply troubled. In the last interaction though he was sort of looking forward to his planned longer stay in Berlin and completed his farewell to me with something like a smiling "Bis dann" (see you soon). So I agree that his suicide didn't appear to have been planned, but that it was -at least to me- rather -as Wikipedia writes- unexpected.

7. **kitchin**

August 17, 2021

Nad, I wonder though if the “jungle” approach is just something made up by Hofer. Rare mathematicians do gain a wide knowledge of the waterfront early on. Yet may they still spend three months banging against a crack in the wall? I refer here to the story in the link of Floer taking three month to accomplish one of his goals after discussing it with a colleague. I admit some prejudice because Hofer seems so affable and interested in history, and he is looking for an answer to what happened.

(It does make me wonder though if I should have tried a more jungle approach when younger! I do remember reading somewhat widely, but without much effect.)

There’s also the issue of math anxiety, which can hit at any stage. Or, more likely in Floer’s case, locking up on a perfectionist writer’s block. I gather he enjoyed explaining his ideas in person.

8. **nad**
August 19, 2021

@kitchen
I had problems to understand your comment.
—————————————————————————————————————

❓ By

> “I wonder though if the “jungle” approach is just something made up by Hofer.”

do you mean “made up” versus “observed” or “made up” because it is an analogy or something else?

—————————————————————————————————————

❓ I rewatched the talk but I couldn’t find the story you are referring to:

> “I refer here to the story in the link of Floer taking three month to accomplish one of his goals after discussing it with a colleague.”

Could you please say around which minute the story was told ?

—————————————————————————————————————

❓ A prejudice -in my understanding- is often something like an idea about “how objects happen/act in some time instance in past, present or future”. What do you mean by prejudice here:

> ” I admit some prejudice because Hofer seems so affable and interested in history, and he is looking for an answer to what happened.”

Do you mean that you know what happened?

Conversations on Quantum Gravity

August 26, 2021
Categories: Book Reviews

Things for many years now have been going badly for string theory on the public relations front. Today the Economist has [Physics seeks the future: Bye, bye, little Susy](), where one finds out that:

> But, no Susy, no string theory. And, 13 years after the LHC opened, no sparticles have shown up. Even two as-yet-unexplained results announced earlier this year (one from the LHC and one from a smaller machine) offer no evidence directly supporting Susy. Many physicists thus worry they have been on a wild-goose chase…
> Without Susy, string theory thus looks pretty-much dead as a theory of everything. Which, if true, clears the field for non-string theories of everything.

Unfortunately for the public understanding of science, this is followed by

> But at the moment the bookies' favourite for unifying relativity and the Standard Model is something called "entropic gravity"… in the past five years, Brian Swingle of Harvard University and Sean Carroll of the California Institute of Technology have begun building models of what Dr Verlinde's ideas might mean in practice, using ideas from quantum information theory.

For something much more anecdotal, on Saturday night I was having dinner outside in a hut during a rainstorm on the Upper East Side (having fled an aborted Central Park concert), and started talking to a couple seated nearby. When informed I taught math and did physics, one of them recommended Carlo Rovelli's new book to me, and said he hoped I wasn't doing string theory. Luckily I could reassure him about that.

This morning I found out about [Conversations on Quantum Gravity](), a fascinating book published by Cambridge that appeared online today, [hard copies for sale in November](). It consists of interviews about quantum gravity put together by Dutch string theorist Jay Armas, starting in 2011. The scale of this project is immense: there are 37 interviews, most of them rather long and detailed, making up a book of 716 pages. What I'm writing here is based on a day's worth skimming of the book. I'll likely go back again and look more carefully at parts of it.

Roughly half the interviewees are string theorists, with the author making a concerted effort to also include non-string theory approaches to quantum gravity. I made the mistake of starting off by reading some of the string theorist interviews, which was rather depressing. By the end of the day, after making my way through about 20 long interviews with string theorists, with few exceptions the story they were telling was one I'm all too familiar with. It's roughly

> We don't actually know what string theory is, just that it's a "framework" that encompasses QFT and much more. We can't predict anything with it now and don't see any plausible way of predicting anything in the future, but the theory is a successful theory of quantum gravity, unlike our competition. There is no good reason for people to be working on anything else.

For example, here's Cumrun Vafa:

> **If a young student asks you what approach to quantum gravity they should work on, what would your answer be?**
>
> There is no question that string theory is the right framework to understand quantum gravity. By this I mean that it is closer to the truth than any other existent theory.
>
> **Is it worth exploring other approaches?**
>
> Well . . . certainly being close-minded is not good. We should be open to other developments. But the fact that there exist other subjects does not justify exploring them if they are not on equal footing with string theory.

and here's Edward Witten:

> **Due to the lack of experimental data, there exist a plethora of different approaches to quantising gravity. Which of these approaches, in your opinion, is closer to a true description of nature and why?**
>
> I would say your premise is a little misleading. String theory is the only idea about quantum gravity with any substance. One sign is that where critics have had interesting ideas (non-commutative geometry, black hole entropy, twistor theory) they have tended to be absorbed as part of string theory.

and David Gross:

> **So you don't think that other approaches like loop quantum gravity have . . .**
>
> Loop quantum gravity is total BS. I mean, it's really not worth discussing it. Don't put that in the book. But, it really isn't.

Luckily Armas doesn't take up Gross on the suggestion that loop quantum gravity is not worth discussing, interviewing quite a few people who are working on research programs that have grown out of it. I got much more out of these interviews, which were very different in tone and content than the ones with string theorists. Many of them gave a very clear account of the technical problems these approaches have encountered, referring to very specific well-defined models and calculations. Instead of the triumphalist claims and vague speculation of the string theorists there was a careful explanation of exactly what they were trying to do and the problems they were trying to overcome.

There's a huge amount worth reading in these interviews, perhaps I'll later add some more pointers. A couple specific examples that occur to me right now are Steve Carlip's careful discussion of the quantization of the toy model of 2+1 dimensional gravity, and Lee Smolin's very personal account of his frustration at the reception of his book "The Trouble With Physics".

If your institution is paying Cambridge for access, you should take advantage of this now and take a look. Congratulations to Jay Armas for bringing us this material.

Update: There's a new preprint out by historian of science Sophie Ritson, [Constraints and Divergent Assessments of Fertility in Non-empirical Physics in the History of the String Theory Controversy](), which examines in detail the arguments of the string wars and later over how to evaluate string theory. While I don't think there's a single reference in the 716 page Armas book to anything I've written, my views do make an appearance in this article.

Update: There's a linked editorial in the Economist [Fundamental physics is humanity's most extraordinary achievement](), which (rather optimistically) sees the current state of affairs as:

> Supersymmetry is a stalking horse for a yet-deeper idea, string theory, which posits that everything is ultimately made of infinitesimally small objects that are most

easily conceptualised by those without the maths to understand them properly as taut, vibrating strings.

So sure were most physicists that these ideas would turn out to be true that they were prepared to move hubristically forward with their theorising without experimental backup—because, for the first decades of Supersymmetry's existence, no machine powerful enough to test its predictions existed. But now, in the form of the Large Hadron Collider, near Geneva, one does. And hubris is turning rapidly to nemesis, for of the particles predicted by Supersymmetry there is no sign.

Suddenly, the subject looks wide open again. The Supersymmetricians have their tails between their legs as new theories of everything to fill the vacuum left by string theory's implosion are coming in left, right and centre.

Comments

1. **Jackiw–Teitelboim**
   August 26, 2021

   One might not be so unwise in conceiving the possibility that *realistic* progress in fundamental physics in near future, in the reductionist sense well articulated by Weinberg in his many writings (which ironically, many "string theorists" nowadays working on subjects such as "celestial" holography, "it from qubit," whatever, clearly gave up on superstring unification), might not be the problem of *quantum gravity* at all.

   As I student to whom reading older Proceedings and Reviews, around the time when the current SM was established, is an enjoyable weekend hobby, it seems to me that at some time, researches decided that the search for a better understanding of the fundamental interaction should necessarily include quantum gravity.

   Now it might be the time to revisit this issue of what happened when "grand unification," of SM interactions, should necessarily be a "theory of everything."

2. **Laurence Lurio**
   August 27, 2021

   How stringent a test of string theory is the non-detection of supersymmetry at the LHC? I thought that string theory would still be consistent if supersymmetry were found at higher energies, its just that this wouldn't solve the hierarchy problem.

3. **Peter Woit**
   August 27, 2021

   Laurence Lurio,
   The accurate statement is that string theory predicts nothing about anything, including nothing about whether the LHC would see superpartners. Unfortunately for string theorists, pre-LHC this is not what they were saying publicly. For some more details about this, see for instance this blog posting
   https://www.math.columbia.edu/~woit/wordpress/?p=3864
   written in 2011 when the LHC results had started to come in and string theorists had started back-pedaling.

   For another example, from a 2006 highly negative review of my book in the LA Times:

   "As for Woit's claim that string theory has "absolutely zero connection with experiment," experiments already planned for a new European particle accelerator will look for the existence of extra dimensions and extra families of particles — both predicted by string theory."

   So, pre-LHC, string theorists were happy to mislead the public with "string theory predicts superpartners at the LHC" when confronted with the lack of predictivity of the theory, and this has led to stories like the Economist's. What's really remarkable, and recurs throughout the interviews, is that they are now perfectly fine with the idea that the theory they work on can't predict anything, while at the same time claiming that a theory in this situation is much better than any other theoretical approach.

4. **DrDave**
   August 27, 2021

   " When informed I taught math and did physics, one of them recommended Carlo Rovelli's new book to me, and said he hoped I wasn't doing string theory. Luckily I could reassure him about that."
   First smile of a long day.

5. **Topologist Guy**
   August 27, 2021

   Peter,

   I've always found the claim that "string theory predicts that the LHC will find extra dimensions" to be highly misleading, more so than the claim that superpartners will be discovered at the LHC. The "prediction" that extra dimensions will be accessible at ~ 10 TeV energy scales came not from "string theory" per se, but rather from some very specific model building that used ingredients from string/M-theory (for example, the Randall-Sundrum model https://arxiv.org/pdf/hep-ph/9905221.pdf). There is no sense in which a fundamental string theory calculation "predicted" the Randall-Sundrum braneworld scenario.

   Jackiw-Teitelboim,

   I agree that there are avenues in fundamental physics research other than quantum gravity. As a mathematician, I have noticed a deep difference in the attitudes towards quantum field theory by mathematicians and high-energy theorists. Most high-energy theorists view the four-dimensional QFTs of the standard model as entirely settled science. As a mathematician, however, I feel like great progress could be made in making the quantization of four-dimensional field theories rigorous. While theorists dismiss the question of mathematical rigour, it seems clear to me that a rigorous understanding of 4D interacting field quantization would illuminate the complex mathematical structure of these QFTs. The problem of "Yang-Mills and mass gap" appeals to me, and I think there are great opportunities available in more deeply understanding the mathematical structure of the standard model QFTs, with a distant goal possibly being the quantization of Yang-Mills by cohomological pushforward or an appropriate generalization thereof.

6. **Peter Woit**
   August 27, 2021

   Topologist Guy,

   When people tried to use "the LHC might see extra dimensions or produce black holes" as a "prediction of string theory" I always thought this was so ridiculous I didn't even know how to argue with it. Just about no one ever really took that seriously.

For mathematicians it’s important to point out that most of the QFT they’ve been looking at is TQFT. Amazingly that leads to dramatic topological results in 4d, but the underlying QFTs (supersymmetric Yang-Mills with twisted differentials) used to build TQFTs like the one that gives Donaldson invariants have all sorts of different and interesting mathematical structure. The fundamental confinement/mass gap problem is just part of it. The standard model QFT is a chiral gauge theory, and these have additional poorly understood problems that go much beyond the problems of phi^4 or pure Yang-Mills. I’ve spent most of my career frustrated by the extent to which theorists have lost any interest in those problems in favor of moving into extremely complicated and ill-defined speculation about string/brane theories in high dimensions.

In what I’ve been working on recently I’ve been struck by how little is really understood about the relation between 4d Minkowski and Euclidean signature theories. For quantum gravity as far as I can tell this remains a complete mystery.

7. **Gavin**
August 28, 2021

It seems to me that loop quantum gravity (or any other approach to quantum gravity) is really no better than string theory in terms of producing useful predictions that can be tested. While LQG predicts violations of Lorentz invariance, given there isn’t a clear scale at which this would happen, this kind of prediction seems on part with saying “supersymmetry at some scale that may or may not be in reach of experiments” is a prediction of string theory. Furthermore, as I understand, it is currently not known whether GR and quantum field theory emerge from loop quantum gravity in an appropriate semiclassical limit.

I would have thought this blog would advocate for theoretical physicists spending more time understanding the mathematics behind established theories, than expressing a preference for one speculative approach over another.

8. **Peter Woit**
August 28, 2021

Gavin,
If you actually read my posting I think you’ll see nothing promoting dubious claims about predictivity of one speculative approach over another. What I am pointing to is that the unprofessional “We rule, the other side is hopeless BS” behavior is mainly coming from one side, at least in the interviews in this book.

9. **Peter Shor**
August 28, 2021

Gavin,

Does loop quantum gravity really predict violations of Lorentz invariance, or is this the same kind of non-rigorous hand-waving that theoretical physicists are prone to? I don’t see any reason why a theory that’s constructed from non-Lorentz invariant elements couldn’t give entirely Lorentz-invariant predictions.

10. **Peter Woit**
August 28, 2021

Peter Shor,
There have been various claims about this made in the past, and from what I remember, they’re discussed in some of the interviews in the book. I don’t think there’s any point in reviving arguments over those. From reading the many interviews in this book, the current situation about “predictions” is actually much more reasonable on all sides than it was in the past: neither LQG nor string theory people are any more claiming such things.

11. **Shantanu**
August 30, 2021

Peter : doesn’t string theory and also certain BSM models such as Kostelecky’s SME extension also allow for violation of Lorentz invariance?

12. **Peter Woit**
August 30, 2021

Shantanu,
The situation with string theory is always the same. Since you don’t really know what the theory is, it is consistent with just about everything, and predicts nothing. That string theory doesn’t predict anything used to be a claim that would generate some argument, but reading through the interviews in this book, it now seems to be the consensus even among string theorists.

13. **Robert A. Wilson**
August 30, 2021

Peter,
I agree with you that the relation between Euclidean and Minkowski signature is of fundamental importance for quantum gravity, and, like you, I cannot understand why people do not pay more attention to this issue. Actually understanding what the signatures mean, rather than complexifying them out of existence, is surely one of the most important issues here.

14. **Alex**
August 30, 2021

“… One sign is that where critics have had interesting ideas (non-commutative geometry, black hole entropy, twistor theory) they have tended to be absorbed as part of string theory…”

I wonder what Connes and Penrose think about that (actually, I know: they think it’s a BS claim).

“…Loop quantum gravity is total BS. I mean, it’s really not worth discussing it. Don’t put that in the book. But, it really isn’t…”

Just wow. Is this the proposed level of the debate for this Nobel prize winner? And it seems he even doesn’t have the guts to say it in public, I think it’s good that they did put it in the book. Now we know who is who.

Evidently, confrontation didn’t work with these people. So, I think it’s time to just ignore and alienate them. They did good work, they enjoyed the deserved praise, but it’s time to move on, they are doing damage to the field.

Now, if you ask me what to do in relation to research in QG, it’s really an interesting moment. A lot has been investigated, many theories have been developed, we did learn some things. But, also, all of this didn’t live to its many promises. I think it’s time to step back, make a deep breath, open the window. But not for more new ideas and theories. This method of proposing theories because of mere aesthetics, or because they make some supposedly falsifiable predictions is not good.

I think that, rather than new theories, it would be better to do research about the deep conceptual problems posed by the very notion of quantizing gravity, or to investigate phenomenological models based on the basic qualities that a QG theory must supposedly have (say, superposition of geometries, discretization of geometry, etc) in order to see if we can get some input from actual experiments. And, if we must do theory, to do it closely to the methods, principles and notions from the actual theories that we know they work (GR and QFT), and not start throwing everything in the kitchen sink (as in string theory, ending in that pathological quote from Witten). And I know that even these basic proposals are debatable, but at least they try to mark some criterion before launching to speculate.

15. **Peter Woit**
August 30, 2021

Alex,
I just realized that there's a pattern here: Vafa is Witten's student and Witten is Gross's student. Vafa is 61, Witten 70, and Gross 80. I suspect it would not be hard to find 50 year old students of Vafa, their 40 year old students, and so on, all of whom would, at least in private, argue that string theory rules/LQG sux. To a large degree, the whole subject of quantum gravity has sunk into a depressing anti-scientific tribalism, with the string theory tribe now rallying around ill-defined ideas that somehow entanglement/quantum information theory/machine learning etc. are the way forward. You can try and ignore this tribe and its behavior, but it remains the dominant one, at least in US academia.

My current weird relationship to quantum gravity is that, after a long career of mostly ignoring it since I thought the way forward was likely to be to find a unification with the parts of fundamental theory we do understand (the Standard Model) and I didn't have a good idea about that. Recently though I've become more and more convinced that the ideas about twistors and unification I've been thinking about do say something about quantum gravity, and I'm trying to write up a revised version of my paper that emphasizes that. Hope to have that done soon, doubt that it will attract any interest from the string theory tribe, but perhaps another tribe will see things differently.

16. **DKepler**
August 31, 2021

I agree with Alex.

A Nobel laureate using such a language in response to a request for a scientific opinion is simply disgusting, and indicates the insecurity String theorists are facing. Talking of unscientific biases, when entropic gravity was trending, I recall someone asking a string theorist, a Nobel laureate, about his opinion on related emergent gravity works (Jacobson, Padmanabhan, and others), and his response was he is more in favor of what Verlinde does because <>. Guess who this laureate was?

17. **Dimitris Papadimitriou**
August 31, 2021

Nothing in theoretical physics can goes on for long (and remain healthy) without, at least, some hints of experimental evidence.
In the case of QG, there is almost nothing known with confidence (with the exception of some strongly negative results about potential Lorentz- Invariance violations from astrophysical observations). A minimum of observational evidence is necessary for people to have some solid background for their QGT candidates, otherwise we'll have again and again the usual (mainly among string theorists, but not exclusively) situation:
Guesses and Conjectures built upon other Conjectures without an end, as is the case with Holography and the attempted "solutions" of the black hole information problem, where String people tried to cure an inconsistency with rather far fetched hypotheses (based on the pompously dubbed "Central Dogma"), that quickly led to even more serious inconsistencies.
They, eventually, throw out of the window almost all established physics (QFT, locality/Causality, the Equivalence Principle- is there anything left?), and these are not mild or subtle violations…
Ok, I don't mean that everything we know must remain intact, but as the situation is now, anyone can hypothesize anything without any consequences.

18. **Peter Woit**
August 31, 2021

DKepler,
I just tried re-reading the Verlinde interview in the book, it's quite remarkable. It seems that he believes there is some more fundamental theory underlying string theory
"I really think that you can try to explain string theory as an emergent framework from something else underlying it."
"In general, I think that string theory is a cleverer idea and better motivated than any of these other ideas, which I think are just guesses. When I wrote my paper [26] people sent me emails saying that they knew what the microscopic model for what I was advocating was. I didn't believe it and I didn't even have to look at it because the possibility that we just know what it is like is really small. The probability is just one in a googolplex, so I don't think we have any chance of finding it. I think we can find general principles but not the microscopic model. Also, I think that LQG is too contrived and it doesn't explain anything."
So, he has given up not only on previous hopes for some connection to experiment, but also on any hope of actually having a well-defined fundamental theory. Elsewhere he argues string theory is too beautiful, truth is something unknown and uglier.
Honestly, none of this makes any sense to me, and the Economist take that this is now our leading theory is disturbing.

On top of this, there's
"I think that people who follow other approaches should learn more about string theory as there is no other competing formulation. There's no comparison between string theory and other formulations."
Having no well-defined theory coupled with this kind of critical attitude towards others who are trying to work with well-defined theories is kind of breathtaking.

19. **Nogo**
August 31, 2021

I really don't understand the "human story" behind all this.
Why talented, respected people with real accomplishments act in such a way as to attract disrespect and even ridicule? Gordon Kane with his predictions (and now postdictions?) of SuSy discovery, string theorists just redefining "arrogance", Mochizuki with his treatment of critics… I don't get it.

20. **Peter Woit**
September 1, 2021

Nogo,
I think the "human story" is that often very smart people are not good at realizing they were wrong about something and admitting it. Perhaps being smart even makes things worse: you lack experience at being wrong.

21. **Dimitris Papadimitriou**
September 1, 2021

Peter Woit, Nogo,
Maybe it's something like a "Majority Syndrome": If someone is a leading personality of a research field that is popular and risk-free (in the sense that it's not gonna be falsified any time soon), and also has a "natural" confidence that is quite common among smart and relatively famous people, maybe he/she isn't immune to this

exaggerated kind of arrogance.

There are many other smart theorists, not only in various QG research programs, but also mathematical physisists, GR experts, and others that work in equally important areas that don't have (not even closely) such type of behaviour.
They're just doing their hard work without much publicity and far out claims.
Needless to say: If the situation was reversed, and these other research areas were more popular (and overhyped), maybe they would exhibit the same kind of unrestrained arrogance.

In my opinion, only a few string theorists have such a behaviour, though.
There are many young people that doing their thing, and avoid exaggerated claims, even if they, sometimes, adopt some pompous phrases (like the "Central Dogma" and the like) that others have invent, to make things sound more important that they really are.

22. **Peter Woit**
September 1, 2021

Dimitris Papadimitriou,
While most string theorists don't behave like this, in reading the 20 or so string theorist interviews it was disturbing how many of them do, and the overall attitude of not acknowledging failures.
String theory is a very unusual subject though, since it has gone from having a very positive public perception to a much more skeptical and negative one. Some of the bad behavior surely has to do with a feeling that string theory is under unfair attack, so the thing to do is fight back, fairness be damned.

23. **DKepler**
September 2, 2021

Thanks Peter for those excerpts from Verlinde's interview. There is a great irony here which perhaps also applies on a broader level to the entire String community. The key ideas on which Verlinde based his work came from Jacobson (and later work by Padmanabhan), and Ted's earlier research was in topics closer to canonical gravity, LQG etc. which are being called "BS" by Gross. There seems to be some kind of a zealot like attitude towards absorbing anything not coming from string theory as part of string theory and then continue abusing other ideas. LQG may be useless as a physical theory, just like string theory. How can we say that the mathematical tools it has introduced can not be useful, while using the same argument to favor string theory?

24. **Andrew Thomas**
September 2, 2021

I'm no fan of string theory, but regarding the David Gross quote, if you give an interview to a journalist "off the record" then the rules of confidentiality apply and should be respected by the journalist. That then gives the interviewee freedom to speak openly and say things he or she would not normally say, which might include highly-inflammatory opinions. If that off-the-record protocol is not respected by a journalist then that freedom is lost.

25. **Peter Woit**
September 2, 2021

Andrew Thomas,
This clearly was an on the record interview. One can argue that after saying something on the record, Gross changed his mind and asked that it be off the record. All of the interviews were edited afterwards with the collaboration of the interviewee. Armas explains
"The interviewees had the opportunity to review and modify the edited transcripts as they pleased which, in many cases, contained additional questions that I added a posteriori over the years and to which the interviewees provided answers. Some of the interviewees spent a considerable amount of time reviewing and editing their transcripts, while some performed only minimal edits or none. Given the long time span between the date of some of the interviews and the publishing date of this book, some interviewees decided to update part of their answers to better reflect their current understanding of the topics discussed, while others decided to keep their original answers."
From this I think it's pretty clear that Gross approved leaving the "BS" statement in.

26. **Anonymous**
September 2, 2021

I know this topic is getting a little old but Gross, Witten, and a number of other string theorists were asked again about LQG at the recent strings conference in this 3 min video: https://www.youtube.com/watch?v=Wh9jqAUavNo

Anyway, I don't think it's fair for people to get too upset about the "BS" comment. Scientists are still people and most work on things where there are competing explanations and ideas. There will be deriding comments occurring occasionally in group meeting and in private seminars everywhere.

27. **Peter Woit**
September 2, 2021

Anonymous,
Sure, in private scientists will often refer to competing research programs as "BS". It's not though a usual thing to do for publication or in an outreach program for the public (that's where that video came from). The public perception of string theory has become very negative (for good reason), and I think this has led string theorists to feel embattled and justified in lashing out at others in this unusual way.

The substantive critique in those video comments is that LQG is basically an attempt to quantize gravity emulating the success with the Standard Model as a quantization of connections (using for gravity the chiral spin connection and vierbein Ashtekar variables). All those commenting in the video make much the same claim, that they believe the reason you run into technical problems with this is that it is "not radical enough". The problem though is that since no one knows what "string theory" is right now, they don't have a well-defined proposal for what fundamental objects should replace connections/vierbeins. For a while this was supersymmetric versions of loops in 10 dimensions, now it's maybe a quantum error correcting code, hard to tell.

It may very well be that connections/vierbeins are the right variables, we just haven't found the right way of quantizing the theory. Gross and Veneziano make the analogy as the Fermi theory vs. Glashow-Weinberg-Salam. Maybe it's more accurate that the LQG starting point is like trying to describe the weak interactions using massive gauge fields. This has renormalizability problems, but is almost right, you just need to add the Higgs mechanism.

28. **Justin Glick**
September 3, 2021

Peter,

Regarding your last comment, are you suggesting that your latest thinking about twistors may be incorporated into LQG, perhaps providing key insights leading to a consistent theory?

29. **Shantanu**
September 3, 2021

Peter, there are other faculty at UCSB who have worked on LQG (and non-string approaches). Wonder what Gross thinks about this ? Does anyone have any data on funding in string theory vs LQG?
Some univs like Penn State and LSU have invested heavily in LQG. Someone should have asked this question how/why they did this.

30. **Nogo**
September 3, 2021

I guess "not radical enough" is in the eye of the beholder – I remember Lee Smolin arguing in his book that String theory was not radical enough, because it was not background-independent…

31. **Peter Woit**
September 3, 2021

Justin Glick,
More details to come soon in a revised version of the paper, but one idea in the older version is that gravity is a gauge theory of one of the SU(2) factors of Spin(4), which is much the same as saying you should do GR in terms of Ashtekar variables. This is the historical starting point of the LQG program. The context I'm giving for this has new features (the other SU(2) is an internal symmetry, imaginary time direction is the Higgs), perhaps these will lead to some different possibilities to pursue, we'll see.

32. **Peter Woit**
September 3, 2021

Shantanu,
The conflict over resources between LQG and string theory has been going on for over 30 years and is a long, complicated and evolving story. The unusually aggressive attacks on LQG you sometimes see from string theorists I think have something to do with that conflict.

33. **Peter Woit**
September 3, 2021

Nogo,
The funny thing is that the conventional wisdom in "string theory" these days is that Smolin was right, that string theory (a theory of strings) is not radical enough. Of course what people have done to avoid acknowledging this is to redefine the words "string theory" (nowadays, pretty much all string theorists agree that they don't know what it is, but it's not a theory of strings).

34. **off topic**
September 8, 2021

Lawrence Krauss had a long interview with Gross in July that mostly covered Gross' life in physics. At the end, Gross used the recent black hole information paradox work as an example of string theory's utility. Krauss was skeptical and said that he was not optimistic but Gross pushed back pretty strongly saying that the burden of proof was now on those that think there is a paradox. Nothing much else was said about string theory.

One funny fact that is only slightly relevant because Witten and Gross have been mentioned here was that Gross wrote a one line recommendation letter for Witten's application to the Harvard Society of Fellows: "he's smarter than me and probably smarter than you so accept him".

35. **anon**
September 10, 2021

Matt von Hippel has a blog post on the Economist article:

https://4gravitons.com/2021/09/10/stop-listing-the-amplituhedron-as-a-competitor-of-string-theory/

36. **DV**
September 13, 2021

It is indeed quite breathtaking to realise the level of contempt the string theory stalwarts have for loop quantum gravity. Especially when one considers the fact that not one of them has actually they tried to sit down and understand what LQG actually is. If they did, they would realise that it is in fact the most conservative possible approach towards quantising gravity, which does not require any extra dimensions or symmetries, and which actually succeeds (for the most part) in its original goal.

Further, re Gavin, Lorentz invariance is perfectly obeyed by LQG, unlike the situation in string theory where whether or not Lorentz invariance is broken is something that is almost dependent on the choices the theorist makes. Moreover general relativity does emerge as the long wavelength, "low energy" limit of LQG. The question of QFT is still somewhat more open but rapid progress is being made towards answering it.

It is exhausting advocating for LQG for more than 10 years now in the face of what seems like an iron curtain of willful ignorance which string theorists have put up. I take some consolation in Planck's words:

"A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

37. **Peter Woit**
September 13, 2021

DV,
I think there are string theorists who have some understanding of LQG, and the fact that it's a conservative approach to quantizing gravity is exactly what they don't like about it (if you watch the youtube video someone linked to, they are very explicit about this).

What's happened with string theory over the years is that it has evolved into ever more radical, speculative and ill-defined formulations. Starting with the quantized string, then branes, then an unknown 11 dimensional "Master/Mother/Membrane" theory, nowadays it's "It from Qubit", with no one having any idea how the qubits are going to be put together to get "It" (or even what "It" is). The people who have been doing this for nearly forty years (as well as the younger ones they have trained, no the field is reproducing, can't die off) find it inconceivable that this might all be a mistake.

38. **anon2**
September 14, 2021

The field is reproducing, to some extent, but it seems to me that the number of students interested in string theory or high-energy physics in general has dropped significantly during the last 10-15 years.

39. **Suomynona**
September 14, 2021

DV:
Last I checked it *wasn't* possible to recover GR as a low energy limit of LQG. The existence of something which can be identified with a massless spin-2 excitation is, I thought, still an open question. Do you have a reference?

It's also not obvious why SU(2) should be the gauge group of quantum gravity.

40. **Peter Woit**
September 14, 2021

All,
This really isn't the place for this kind of technical argument over LQG, which, honestly, gets tedious real fast when most people involved are trying to score points, not clarify things. The interviews in this book with people who have worked on LQG, are working on LQG, or various ideas that have grown out of it contain a lot of detailed arguments of this kind, with references. If you want to understand things, those are great sources.

About SU(2) and quantum gravity, the answer is independent of LQG, going back to the story of Ashtekar variables, explained a bit in the latest version of my paper on unification using twistors and Euclidean QFT. It's simplest in Euclidean signature, where the space-time rotation group is Spin(4)=SU(2)xSU(2). The remarkable fact is that in 4d you can write down the condition for the curvature of a connection to solve Einstein's equations just using one Lie (SU(2)) component of the spin connection, so you have an SU(2) gauge theory (you also have vierbeins though, which are a different story).

Minkowski space-time makes this more problematic, since there Spin(3,1)=SL(2,C).

41. **Juan Cristobal Latorre**
September 22, 2021

Hello Dr. Woit,
Could you please elaborate on your comment:
"Unfortunately for the public understanding of science, this is followed by […]"
What is the part of the following verbatim paragraph from The Economist article in your blog that you believe is unfortunate for the public?
This is not a facetious or cynical question. I've read your book "Not Even Wrong" (big fan, by the way), as well as similar perspectives such as Sabine Hossenfelder's material (also big fan). I'd like to understand therefore, what you think was perhaps misleading in The Economist's article.

Thank you!

42. **Peter Woit**
September 22, 2021

Juan Cristobal Latorre,

To elaborate, it's not an improvement if the physics community's idea of what the best way forward is moves from a failed non-trivial idea (string theory) to something content-free. The words "Entropic gravity" don't seem to correspond to any actual theory of anything. Sean Carroll at least explains what his ideas are, which makes it easy to see there's nothing non-trivial there.

This Week's Hype

September 8, 2021
Categories: This Week's Hype

Today Quanta has One Lab's Quest to Build Space-Time Out of Quantum Particles. No, this kind of experiment is not going to "Build Space-Time", now or ever. This kind of obfuscation about quantum gravity advances neither fundamental physics nor the public understanding of it, quite the opposite. The article does make clear what the motivation is: deal with the problem that

> String theory, still the leading candidate to replace the Standard Model, has often been accused of being untestable.

by claiming that it somehow can be tested in a lab.

Comments

1. **anonymous commentator**
   September 8, 2021

   To me, these types of articles about testing quantum gravity give off the impression that modern theoretical research into quantum gravity, AdS/CFT, and whatever else is coming out of the string theory community has more to do with to engineering toy constructions in the lab and pushing the limits of condensed matter and atomic physics than anything fundamental about the universe and high energy physics.

2. **Sabine**
   September 9, 2021

   We'll see lots more of this because there's so much money now being thrown at quantum simulations in the quantum technology packet. Doesn't matter if it makes any sense. This entire funding process is so broken.

3. **Peter Shor**
   September 9, 2021

   About the motivation for this paper …

   The people building quantum computers today are very much doing cutting-edge research. But right now, quantum computers are too small to solve any real problems, so people are looking around for neat demonstrations they can do.

   This "simulation" of quantum gravity is almost certainly worthless in terms of what it actually tells us about quantum gravity, but if you just have 18 qubits, you can't do any other calculations that would be worthwhile, either. And this "simulation" certainly seems to have been useful in terms of publicity value.

   We'll see whether quantum computer experimentalists keep on doing these "simulations" once they have a few thousand qubits and can do useful calculations.

4. **Peter Woit**
   September 9, 2021

   anonymous commentator,
   Given that David Gross and other leading string theorists think that it's "BS" to attempt to quantize gravity by trying to find a consistent quantum theory of the connection degrees of freedom that characterize geometry, one wonders what they think about claims that the way to quantize gravity is to study systems of trapped atoms in an atomic physics lab.

   I normally avoid attributing to scientists motives based on money rather than honest belief about the best way forward, but it certainly seems that the replacement of conventional HEP physics funding with large amounts of funding for "Quantum Information Science" is having an effect.

5. **Peter Shor**
   September 9, 2021

   I don't believe that funding is the reason that string theorists are now approaching their research from a quantum information viewpoint — at least, it's not the only reason. This may also be due to the AMPS (Almheiri, Marolf, Polchinski, and Sully) paper, where quantum information theory showed that Susskind's theory of black hole complementarity was probably incorrect. This was the first real result in years in the black hole information field, and researchers there started looking for more ways to apply quantum information to their research.

   And indeed, they are finding more and more ways to apply quantum information to this field, although I suspect that not all of these ways are justified.

6. **Matthew Foster**
   September 9, 2021

   I'll defend the intersection of "quantum gravity" research and stat mech/cond mat, but mainly insofar as it aids the latter solve important, intractable problems.

   One of my favorites (quite old now) is the Knizhnik, Polyakov, and Zamolodchikov (KPZ) formula for computing scaling dimensions of operators in 2D classical stat mech models at criticality (CFTs), defined on random manifolds. The "annealed sum" over all possible geometries shifts scaling dimensions in a simple way. Why is it useful? Well it turns out to be easier to calculate certain critical exponents of _logarithmic_ CFTs that describe geometric critical phenomena, e.g. 2D classical percolation, in the random case–using matrix methods. Then you can use KPZ _backwards_ to get exponents on the flat plane. This was pioneered by Duplantier et al. Annoyingly, log-CFTs (which are for the most part, still poorly understood) are the most important for applications to many interesting quantum phenomena in condensed matter, such as the plateau transition of the quantum Hall effect.

   From a condensed matter POV, though, summing over ALL geometries is rarely directly useful like this. There are, however, some important problems where a sum over _weakly_ random geometries can be important. This seems to be the case for 2D massless Dirac carriers in 2D quantum materials (cuprates, graphene, surface states of topological phases), where at least in some contexts it is natural for disorder to modulate the "speed of light" for the carriers. We are hoping there might be a way forward using some recent developments in 2D quantum gravity. In fact, this is one motivation for an Aspen workshop we are going to hold on "Random geometry" in Fall 2022, covid willing…

7. **Peter Woit**
September 9, 2021

Matthew Foster,
There's no question that issues like the ones you mention involve very non-trivial theory with a long history, and in that theory, connections to quantum gravity (especially in lower dimensions) are important.
The Quanta article though is about something completely different, experimental atomic physics results with zero connection to quantum gravity. There's now a very long history of attempts to confuse everyone about this, very sad to see that Quanta is doing this, something that deserved mention here.

I've wasted too much time in the past explaining the obvious points that the people doing this are trying to obscure (to these extent these experiments test anything, it's whether some approximation scheme works in certain calculations in standard atomic QM, nothing to do with quantizing gravity).

8. **Blake Stacey**
September 9, 2021

It has always seemed to me that the "It from Qubit" program was more likely to lead to a geometric description of some kinds of correlated multipartite states than to a theory of quantum gravity. In other words, the hype gets the arrow pointing in the wrong direction.

9. **Matthew Foster**
September 9, 2021

Peter,

I'll only say that SYK has a very similar flavor, in that
(1) on one hand, it's a very simple zero-dimensional "quantum mechanics" problem of randomly interacting Majorana fermions, or equivalently, an SO(n) bilinear "magnet" with random, fully broken SO(n) symmetry.
On the other hand, it
(2) exhibits emergent conformal invariance in 1+0-D, which maps to Schwarzian/Liouville quantum mechanics. The physics of the model is encoded in the sum over diffeomorphisms of the circle. While there is no true geometry here, it is a toy version of Liouville CFT. Moreover, at long times for a finite number of N Majoranas, there is a random matrix description that has a holographic dual in terms of JT gravity.

So realizing SYK in the lab would in principle allow one to experimentally test all of these connections. It's not "true" quantum gravity, but it's a first step. The problems I mentioned in my post are likely much harder, because they do involve 2D Liouville or other geometric (logarithmic) CFTs, and these are still poorly understood. But there has been some more recent cross-fertilization with cond mat and stat mech that might shed some further light, for example the interpretation of 2D Liouville as a log-correlated random energy model. This is a relatively simple toy model for glassy physics, which exhibits a "freezing transition" below a critical temperature. The freezing transition is related to violations of the so-called Seiberg bound in Liouville, and might have something to do with "macroscopic" operators that punch holes into the "worldsheet" of the theory.

Most of the text of the Quanta article appears pretty honest about what is being attempted, and what has been accomplished. I take it your main objection is to the headline, and the string theory preamble?

10. **Robert C Arnold**
September 10, 2021

It must be the season… Here is yet another claim re string theory's supposed testability: https://phys.org/news/2021-09-s-matrix-bootstrap-theory-quantum-gravity.html?utm_source=nwletter&utm_medium=email&utm_campaign=daily-nwletter

11. **Shantanu**
September 10, 2021

Peter : one technical problem is that after such articles they don't provide the email address of author or a place for readers to comment or provide feedback.
I wish they did so.

12. **Peter Woit**
September 10, 2021

Shantanu,
Quanta does have a comment section on the article, but their comment sections are unmoderated and thus useless (overrun by cranks, people who have no idea what they are talking about). Phys.org mostly just republishes press releases. Possibly this story has its origins in a press release somewhere. Physical Review Letters encourages people to issue press releases when a paper is published, it looks like this is an example.

By the way, looking at the PRL article, this is about the superstring in 10d, no mention of the main problem of string theory (how do you get 4d?). From the results of the authors I don't see anything like an argument that "string theory is the unique theory of quantum gravity", even in 10d. Again, lots of hype for a result that doesn't do much of what is advertised. This has been the story of string theory in the media forever.

13. **Peter Woit**
September 10, 2021

Matthew Foster,
The headline and string theory framing are completely outrageous. The rest of the article is fine if you strip out all mention of quantum gravity. It's this that's just completely misleading.

As for SYK, again you're bringing in a complicated and interesting theoretical topic, but one that has nothing to do with this article.

14. **Ian McCormack**
September 10, 2021

This reminds me of this paragraph from Sophie Rilson's paper that Peter Woit linked in his previous blog post:

'Quantum field theorist Matt Strassler and Woit had an, at times, furious debate about the relationship between string theory as a tool and as a theory of quantum gravity (see comments on (Strassler, 2013a)). Woit accused Strassler of misleading the public by claiming that progress coming from the use of string theory as a tool is indicative of progress in string theory as a theory of quantum gravity (which Woit calls string unification). For Woit, the applications of string theory are tests of an "approximation scheme" as opposed to tests of a theory (Woit, comment on Strassler, 2013a).'

15. **Peter Woit**
September 10, 2021

Ian McCormack,
That was a bit different. There the argument was over something relatively well-defined: AdS/CFT relating 4d and 5d and whether it's a good approximation to QCD. At the time there was a lot of hype about "tests of string theory" that really were tests of this approximation.

In this case, instead of a specific 4d/5d AdS/CFT duality conjecture as a tool, people are talking about all sorts of very different things in toy models in low dimensions, with basically zero relation to string theory or gravity in 4d (note that "gravity" in 1d, 2d, 3d is something of a different nature, since there are no physical gravitational degrees of freedom in those dimensions).

16. **Matthew Foster**
September 12, 2021

Hi Peter,

No vacuum gravitational waves in 2+1-D, yes. But dynamics are nontrivial with source matter fields. That doesn't qualify as physical DOF? Einstein tensor is nonzero there.

17. **Peter Woit**
September 13, 2021

Matthew Foster,
I don't think source matter fields change the basic situation: the real problems of quantum gravity aren't there. In 3+1 d the physical state space is infinite dimensional, with an infinity of gravitational degrees of freedom interacting non-linearly with renormalizability problems. In lower dimensions the degrees of freedom are pure gauge (except for maybe a finite number), which is very different.

Euclidean Twistor Unification, version 2.0

September 10, 2021
Categories: Euclidean Twistor Unification

I've completely re-organized and largely rewritten my paper from earlier this year on [Euclidean Spinors and Twistor Unification](). Soon I'll upload this as a revision to the arXiv, for now it's available [here](). This new version starts from a very basic point of view about 4d geometry, leaving the technicalities about Euclidean QFT for spinors and the expository material about twistors to appendices.

Most ideas I've worked on over the years that seemed initially promising ultimately became more and more problematic the more I looked at them. This set of ideas keeps looking more and more solid. There are several (to me at least…) attractive aspects:

- Spinors are tautological objects (a point in space-time is a space of Weyl spinors), rather than complicated objects that must be separately introduced in the usual geometrical formalism.
- Analytic continuation between Minkowski and Euclidean space-time can be naturally performed, since twistor geometry provides their joint complexification.
- Exactly the internal symmetries of the Standard Model occur.
- The intricate transformation properties of a generation of Standard Model fermions correspond to a simple construction.
- One gets a new chiral formulation of gravity, unified with the Standard Model.
- Conformal symmetry is built into the picture in a fundamental way.

There's more in this version about how quantum gravity fits into this, when formulated in terms of chiral variables (i.e. Ashtekar variables). This gives a new context for old questions about quantizing in these variables (this is in Eucldean signature, the other chirality is not space-time geometry but internal Yang-Mills geometry, and the imaginary time component of the vierbein is distinguished and given the dynamics of a Higgs field). I haven't spent much time on this yet, but suspect this new context may help overcome problems that people trying to pursue quantum gravity in this chiral connection framework have run into in the past.

One common reaction I've gotten to these ideas is the one I myself had in the past: analytic continuation relates expectation values of field operators in Euclidean and Minkowski signature, so my left-handed SU(2) after analytic continuation gives part of Lorentz symmetry, not an internal symmetry. What took me a long time to realize is just how different Euclidean and Minkowski signature QFT is. Yes, Schwinger functions and Wightman functions can be related by analytic continuation (in a rather subtle way, the Wightman functions aren't functions, but boundary values of holomorphic functions). But at the level of states and operators things are very different. It's just not true that there is some holomorphic formulation of QFT states and operators, with Euclidean and Minkowski space restrictions related by analytic continuation. There's a lot of explanation about this in the paper.

One objection I've run into is that by distinguishing a direction in Euclidean space I'm breaking Lorentz symmetry. What's true is quite the opposite: having such a distinguished direction is needed to get Lorentz symmetry after analytic continuation. If you want to start in Euclidean space and get Lorentz symmetry, you have to do something like distinguish a direction and get an Osterwalder-Schrader reflection in that direction, which you need to get from SO(4) to SL(2,C). From the other direction, if you start in Minkowski space-time and analytically continue, you have a choice of lots of possible Euclidean slices to analytically continue to. You need to pick one, and that will distinguish an imaginary time direction. This is most easily seen in the twistor formalism, where the Minkowski space-time geometry is determined by a quadratic form that picks out a 5-dimensional hypersurface in PT. This will project down to an imaginary time = 0 subspace of Euclidean space-time, which picks out the imaginary time direction.

Comments

1. **Thomas**
   September 10, 2021

   This looks like real progress, Here's hoping your theory is well-received. 2 questions:
   Does point 3 imply that you get the 3 generations of particles of the SM ?
   Does Euclidean Twistor Unification make any specific prediction at this stage ?

2. **Peter Woit**
   September 10, 2021

   Thomas,
   No, this doesn't explain why multiple generations, in particular why 3 generations.

   What I find compelling about this is that it provides a remarkable geometric framework that has exactly the local symmetries of GR and the standard model. But it involves formulating the theory on twistor space rather than spacetime, which I don't understand quite how to do correctly. Perhaps if that can be done, one would have a well-defined theory more constrained than the standard model, so able to make new predictions.

3. **Bertie**
   September 11, 2021

   Good readability, one typo, last sentence before Section 6, 'recently' =recent

   Would love to know if Penrose is aware of this!

4. **D R Lunsford**
   September 11, 2021

   Excellent! Thanks! This is very good!

   -drl

5. **SteveB**
   September 11, 2021

   Towards the bottom of p4 the expression for the determinant should be:
   x_0^2 – x_1^2 + x_2^2 – x_3^2

6. **lun**
   September 11, 2021

Very interesting. From my very incomplete understanding, what you are saying is that if you set up the integration measure for some partition function not on 4d real space (Euclidean with a Minkowski analytical continuation) but in complex space, reparametrized using twistors, GR general covariance and gauge invariance under SU(3)XSU(2)XU(1) could follow from some version of invariance of the functional integral under field redefinitions.
Is this it or is this a misunderstanding?

7. **Peter Woit**
September 11, 2021

Bertie/SteveB,

Thanks, will fix the typos.

Haven't heard from Penrose, but he's been rather busy, I hear being a Nobelist takes a lot of time.

lun,
That's not really it.
One role for twistors is that they tautologically describe spinors on complexified space time. So they give an arena where you can do analytic continuation of spinor fields between Euclidean and Minkowski 4d real slices.

Unlike most attempts to use twistor theory in physics, I'm looking not at the Minkowski slice but at the Euclidean slice. There you have usual 4d Euclidean space time, and usual Euclidean QFT as a sort of stat mech, but also
1. A distinguished imaginary time direction (this determines how you are going to recover Lorentz symmetry and the Minkowski theory).
2. Euclidean twistor space, i.e. twistor theory, restricted to the Euclidean slice. This is a bundle over Euclidean space time, fiber a sphere, which you can interpret in various ways (projective spinors at the point, orthogonal complex structures at the point).

The claim is that these elements determine local SU(3)xU(1)xSU(2)xSU(2) gauge symmetry on twistor space. The first three factors can be thought of as internal symmetries, with the SU(2) spontaneously broken by the distinguished imaginary time direction. Gauge theory with the last SU(2) gives a chiral spin connection that is used in one formulation of GR (general covariant if you use the usual Palatini action in a chiral form). It may be that this setup gives some different possibilities for the action than just the usual term.

8. **Arnold Neumaier**
September 12, 2021

Peter,
"if you start in Minkowski space-time and analytically continue, you have a choice of lots of possible Euclidean slices to analytically continue to. You need to pick one, and that will distinguish an imaginary time direction. "

This means that there are many conjugate Euclidean formulations of the same Minkowski theory, breaking explicit Poincare covariance in each Euclidean formulation and restoring it only after the Osterwalder-Schrader reconstruction.

You also didn't mention that analytic continuation is not possible in most curved spacetimes – only in the quite restrictive class of spacetimes compatible with a complex structure.

In my view, both observations send the same message: The Euclidean formulation is only a tool, rather than a basis for QFT.

9. **Peter Woit**
September 12, 2021

Arnold Neumaier,
I agree that explicit SO(4) invariance is broken by having a Euclidean QFT + analytic continuation to Minkowski space-time. Note that it is not Poincare that is broken, it is just Euclidean rotations. My argument is that this is not a bug but a feature: it corresponds to the spontaneous symmetry breaking of the electroweak theory.

For one common objection about a non-existence problem of the analytic continuation, see the 2002 survey by Gibbons, where section 20.3.1 is titled "A non-problem", and starts with
"Let us comment on an often repeated objection. This is the mathematically correct but physically totally irrelevant statement that 'not ever Lorentzian spacetime M_L admits an analytic continuation M_C containing a Riemannian section M_R.' This is also true for example of Yang-Mills connections on Minkowski spacetime, they don't always analytically continue to give real connections on Euclidean space. The answer is the same in both cases. All that is needed is the behavior of quantities like Z(\Sigma,h) as a function of boundary values. Physically the individual interior spacetimes, Riemannian or Lorentzian, that go into the functional sum have no particular significance except in the classical limit, when one is preferred, or, more interestingly in the special case when both Lorentzian and Riemannian real sections exist simultaneously in the same complex spacetime M_C."

The special case of S^4 I discuss in the paper is an example of the last phenomenon Gibbons mentions.

10. **martibal**
September 12, 2021

Hi Peter, could you give the title of Gibbons survey ? He seems to have a lot of preprints in 2002, and it is not clear to me which one is relevant here.
Thanks !

11. **Peter Woit**
September 12, 2021

martibal,
The full reference is reference 18 in the latest version of the paper.

12. **Arnold Neumaier**
September 13, 2021

Peter,

"My argument is that this is not a bug but a feature: it corresponds to the spontaneous symmetry breaking of the electroweak theory."

But the latter has physical consequences whereas the former is a nonphysical artifact of the Euclidean view. No experimental result hints at a broken Poincare symmetry!

13. **Peter Woit**
September 13, 2021

Arnold Neumaier,

You keep talking about broken SL(2,C) invariance, but what I'm pointing out is that SO(4) invariance is not a symmetry of the states or operators of the theory. To get SL(2,C) invariance on states you have to have something like an Osterwalder-Schrader reflection, which breaks SO(4). This breaking of SO(4) does not break SL(2,C), it's required to get SL(2,C).

Electroweak symmetry breaking is a breaking of gauge degrees of freedom, so the SO(4) breaking will be of that nature.

14. **Arnold Neumaier**
September 13, 2021

To get SL(2,C) invariance on states you have to have something like an Osterwalder-Schrader reflection – yes, but my point is that what you get is a representation of the Poincare group with a distinguished time coordinate, which is unphysical!

15. **Peter Woit**
September 13, 2021

Starting with Euclidean theory you just can't get a Poincare group representation at all, unless you have a distinguished imaginary time direction in Euclidean space (to do OS reflection). For a general context see for example

https://www.jstor.org/stable/2006979

This particular construction is in coordinates and has a distinguished real-time coordinate, but since it's a Lorentz group representation, it's unitarily equivalent to any choice of real-time coordinate.

16. **Peter Orland**
September 13, 2021

Whether you can map fields on Lorentzian-signature manifolds and Euclidean-signature manifolds is irrelevant (there is such a bijective mapping, as far as I know, between Lorentzian manifolds and Euclidean manifolds with a vector field everywhere. But it does not matter).

The real issue is whether {\em amplitudes}, not fields on manifolds, can be continued. That's what OS positivity is for.

17. **Peter Orland**
September 13, 2021

Sorry, what I wrote needs an edit:

Whether you can map fields BETWEEN Lorentzian-signature manifolds and Euclidean-signature manifolds is irrelevant (there is such a bijective mapping, as far as I know, between Lorentzian manifolds and Euclidean manifolds with a FIDUCIAL vector field everywhere. But it does not matter).

The real issue is whether {\em amplitudes}, not fields on manifolds, can be continued. That's what OS positivity is for.

18. **Peter Woit**
September 14, 2021

My previous comment about "predictions" didn't satisfy some, lots of comments demanding "predictions" deleted. If one wanted to play the game played by string theorists over the years, one could claim for this set of ideas "predictions" of four dimensions, chiral spinor fields, U(1) x SU(2) x SU(3) gauge symmetries and matter fields with the right quantum numbers, as well as gravitation.

But that's a waste of time, the problem with string theory (or any speculative theory) has always been much more complex than "does it make "predictions"?", and I'll continue to delete comments that want to go on about this. The interesting question is whether there are new ideas here that will be fruitful and explain things about the Standard Model + GR we've previously had no explanation for. I think so, but if you don't, do something else. There's a lot I still don't understand about the implications of these ideas, maybe further effort will show they can't work, or maybe they'll lead to progress. Time will tell.

In any case, we're still a long ways from any danger of decades of fundamental research in theoretical physics going nowhere because of being dominated by these ideas…

19. **DKepler**
September 14, 2021

Peter, Peter, and Arnold: Concerning the issue of distinguished time coordinate emerging when going from Euclidean to Lorentzian, this (inevitable fact) is most clearly evident when working with the covariant formalism for Wick rotation (using a timelike direction field) which I believe is what Peter Orland was referring to; I have left references about this earlier on this blog. The key point is that the partition function (for gravity+matter) should now presumably also include the path integral over this timelike field. (Gibbons, on the other hand, does *not* talk about this additional path integral.) I do not see any reason why Lorentz invariance will necessarily be broken in all this. In fact, at the quantum level, having such a direction field might be a bonus since we know that description of quantum vacuum is observer dependent.

20. **Shantanu**
September 16, 2021

Peter: you should give an ILQG seminar at PSU or the quantum gravity seminar series at Perimeter or other places which run a seminar series.

21. **Peter Orland**
September 16, 2021

DK, Yes, I mentioned that vector field in my first version of my post, but edited it away, after deciding I was veering off topic.

22. **Peter Woit**
September 16, 2021

Shantanu,

I’m speaking at Brown next week. If other people are interested in hearing about this, I’ll be happy to talk elsewhere.

23. **Lowell Brown**
    September 16, 2021

    This level of math is way beyond me. But I am curious were the justification for the statement

    “since we know that description of quantum vacuum is observer dependent.”

    comes from.

24. **Kingsuk Maitra**
    September 22, 2021

    Dr. Woit,
    Would you be able to share the slides from your Brown talk in this blog?

25. **Peter Woit**
    September 22, 2021

    Kingsuk Maitra,
    Just finishing the slides this evening, will post here after the talk.

26. **Anonymous s**
    September 23, 2021

    does Euclidean Twistor Unification combine space-time and internal symmetries and does Coleman–Mandula theorem apply ?

27. **Peter Woit**
    September 24, 2021

    Anonymous,
    No, I’m not embedding both space-time and internal symmetries in a larger symmetry group and having that act on the states. That’s what Coleman-Mandula says you can’t do (because you’ll end up with a trivial theory).

    For me a lot of the appeal of this picture is exactly that it gives a sort of unification that does not involve embedding everything in a bigger grand unification group, that you then have to break somehow to get back to the SM and usual space-time symmetries.

Visit to Brown

September 24, 2021
Categories: Book Reviews, Euclidean Twistor Unification

I spent yesterday up in Providence, visiting the Theoretical Physics Center at Brown, and giving a talk there (slides are available here, newer version of a paper here), At some point a recording of the talk should appear online. In the talk I tried to emphasize some basic things which it took me a very long time to appreciate:

- The ways in which Euclidean QFT is very different than Minkowski space-time QFT, in particular the necessity of having a distinguished imaginary time vector, breaking SO(4) invariance, in order to recover Lorentz (SL(2,C)) invariance.
- The way in which Minkowski space-time shows up when you do twistor theory in Euclidean space-time (see the pictures in the slides). This again makes clear the way SO(4) invariance is broken.

While I'm making a proposal for how to get gravity out of chiral 4d geometry, I've never been that expert in GR, and GR is the focus of much of the theory community these days, in particular the theorists at Brown. So, they had lots of questions about what the implications of this are for GR that I couldn't answer. I'll keep thinking more about this and may some day start to have answers (or maybe GR experts will find this proposal interesting enough to figure out the answers themselves).

I was invited to give the talk by Stephon Alexander, and got to spend some time talking with him while in Providence. He has worked in the past (see here) on ideas that bring together the gravitational and weak interactions in a similar way. More recently he has been working on ideas for how one might observe an unexpected chiral component to the gravitational interactions, and now has a grant from the Simons Foundation that will fund work in this area. Next week he'll be here at Columbia giving an astronomy colloquium on the topic.

He also has a new book (his first was *The Jazz of Physics*) out, Fear of a Black Universe: an Outsider's Guide to the Future of Physics. It's quite interesting, with much of the earlier parts describing some of his experiences making a career for himself as a theorist, together with explanations of the physics background. The last part (in collaboration with Jaron Lanier) heads off in somewhat of a sci-fi direction, an excerpt is here.

A major theme of the book (with which I'm very sympathetic) is that the community doing this sort of theoretical physics desperately needs to get out of its current rut and open itself to new ideas, which often will come from "outsiders". One aspect of being an "outsider" that Alexander has experienced is difference in racial background, but he's concerned with a more general context of hostility to ideas that aren't those currently favored by "insiders". While he started out his career doing string theory, he has moved in different directions over the years. He explains that as a postdoc at SLAC he invited Lee Smolin to come and lecture on loop quantum gravity, something which was not at all well received by the local string theorists. While I'm quite interested for my own reasons to understand better what he has been doing with the physics of possible chiral effects in gravity, it was great to see his enthusiasm for and encouragement of ideas that don't fit exactly into the narrow conception of the subject that now dominates all too much of the community doing fundamental theoretical physics.

Update: There's video of the talk available here.

   September 25, 2021

   What about Yukawa couplings? Attempts to find simplicity behind the Higgs usually sink when dealing with the fact that the SM Higgs has Yukawa couplings with messy values.

2. **Peter Woit**
   September 25, 2021

   Alessandro Strumia,

   No idea how to compute Yukawa couplings. Part of that problem is not understanding where three generations come from.

3. **Douglas Natelson**
   September 25, 2021

   Whenever I see phrasing about a chiral component to gravity, I get flashbacks to noted physics Internet personality Uncle Al, and his claims that "someone should look" to see if left-handed chiral crystals and right-handed chiral crystals obey the equivalence principle.

4. **Jackiw–Teitelboim**
   September 28, 2021

   Have you contemplated the possibility that, from the viewpoint of a QFT formulated in the standard spacetime language, the action functional corresponding to the gravitational theory following from your proposal of symmetry breaking leading from Euclidean to Lorentzian signature, would include terms that might involve metric-affine geometry (Cartan connection), e.g., torsion, instead of the standard Levi-Civita connection? Or more generically a Ehresmann connection?

   Might be worth looking for a debate between Weinberg and Hehl on the merits of such geometries, if this turns out to be relevant to what you are up to.

5. **Peter Woit**
   September 29, 2021

   Jackiw-Teitelboim,

   There are various ways to extend GR formulated with a spin connections and the Palatini action:
   1. Allow torsion
   2. What I'd call Cartan geometry, interpreting the vierbeins as a Cartan connection. One version of this is Macdowell-Mansouri.
   3. Add R^2 terms, get a conformally invariant theory, I noticed there was a paper about this on the arxiv yesterday:
   https://arxiv.org/abs/2109.12743

   All of these have a long history, perhaps reformulating in the twistor Euclidean framework with the imaginary time direction vierbein getting the dynamics of the Higgs gives something new.

6. **Sri**
   October 5, 2021

   Hi Peter,

   Long time lurker here. This twistor gravi-weak unification is really awesome and the way in which the Higgs emerges due to Osterwalder – Schrader reflection is very very deep.

   Couple of basic questions (I dont know if you have addressed these already):

   1) Where do three generations come from?

   2) How does QCD fit into this framework?

   3) Do you have any comment on what objects of algebraic quantum field theory like the modular operator look like in this framework?

   Thanks,
   Sri

7. **Peter Woit**
   October 5, 2021

   Sri,
   Thanks for your comments about the unification and Higgs ideas. The more I think about these ideas the more convinced I become that something like this can work. Also, the more I look at the literature, the more convinced I become that these ideas are actually new.

   1. I don't understand the origin of three generations, understanding that is crucial. There are various possible ideas to look at that I haven't yet had time to pursue.

   2. The definition of projective twistor space naturally provides an internal SU(3) symmetry, one can try and gauge this, use the usual Yang-Mills action, get standard QCD. There is however something different going on: the SU(3) principal bundle on projective twistor space is not the pull-back of an SU(3) principal bundle on the base space-time. The SU(3) group varies as you move around the CP1 fiber. I need to better understand the significance of this, how and if it changes the usual QCD dynamics.

   3. I know precious little about algebraic qft.

Various Math and Physics News

October 4, 2021
Categories: Uncategorized

First some items on the mathematics side:

- The latest AMS Notices has some memorial pieces about [Vaughan Jones] and [Robert Hermann]. I contributed a piece to the Hermann memorial, for more about him, see [here].
- If you read French you might enjoy Yves André's *Dix regards sur la mathématique contemporaine*, freely available [here].
- There's a wonderful overview of various conjectures in number theory last year from Barry Mazur, [About Main Conjectures].
- The Harvard Math department seems to not have had a lot of luck with its funders. Last spring they had to [close] their [Program in Evolutionary Dynamics], which was funded by Jeffrey Epstein. The very active [Center of Mathematical Sciences and Applications] has been funded by the Evergrande Group, a real estate investment company that has now run into serious financial problems. I haven't heard what the implications will be for the CMSA in the future.

On the physics side:

- The 2021 Physics Nobel Prize will be announced tomorrow morning. I gave up predicting these things after [this prediction back in 2004].
- Gian Giudice has put on the arXiv a written version of his [Theory closing talk at LCHP2021]. He ends with

  > These are interesting times for particle physics: times of great uncertainty, in which our physics perspective is changing, and in which we are laying the foundations for the future of our field. As a community, we must rise to the challenge.

  What worries me is that the much of the rest of the article contains a lot of

  1. Arguing for multiverse pseudo-science:

     > The multiverse describes a physical reality that challenges the presumption that there must be a single unified theory in the deep UV. In a sense, it is the ultimate Copernican revolution since not even the patch of the universe we live in is special. It implies a revision of the cosmological principle because the universe is approximately homogeneous and isotropic only within our horizon, but may be globally highly non-homogeneous. The multiverse is not an abstract idea, but it is a generic consequence of a large class of inflationary theories, where unavoidable quantum fluctuations of the inflaton spark a chain process with eternal creation of regions that expand faster than the surrounding space.
     >
     > The multiverse is actually a familiar instrument of our everyday physics toolkit.

  2. Arguing against the fundamental significance of symmetry principles:

     > There are also theoretical indications for questioning the concept of symmetry. It is nowbelieved (and to a certain extent proven) that any global symmetry is violated at the level of quantum gravity. This means that any global symmetry that we observe in nature is only an accidental effect of looking at a system without sufficient short-distance resolution. The case of gauge symmetries is more subtle. Gauge symmetries are not real physical symmetries, in the sense
     > that they don't correspond to an invariance under a physical transformation, but only to a redundancy of the coordinate parametrisation. We often confuse our students on this point by showing them the Mexican-hat potential and leading them to believe that there is a degeneracy of vacua, when in reality there is only one single vacuum state that breaks EW symmetry, as it is clear from the fact that the physical spectrum doesn't contain any Goldstone boson corresponding to zero-energy excitations. Gauge symmetries may not be as fundamental as we thought, but only an emergent phenomenon. They could be a mirage of a different reality that takes place at a more fundamental level.

  It's looking depressingly possible that leaders of the field will push through as new "foundations for the future of our field" the argument that "the multiverse did it and symmetry is a mirage." Instead of moving forward, the field will take a huge step backwards.

   October 4, 2021

   Hi, the article on closing the "program for evolutionary dynamics" (it does not mention genetics) only notices past inappropriate contacts. I have not seen anything about financial issues there. Why is a scientific program closed then? I guess that I do not understand it because I am not in USA.

2. **Peter Woit**
   October 4, 2021

   Martin S.
   My mistake about the name of the program, fixed. I believe the program was shut down because the main faculty member involved in it was Martin Nowak, and the main funding had come from Epstein. Nowak was sanctioned by the university after a report was issued which detailed the university's involvement with Epstein and Nowak's role in this. The report is at
   https://ogc.harvard.edu/files/ogc/files/report_concerning_jeffrey_e._epsteins_connections_to_harvard_university.pdf

3. **mqt**
   October 4, 2021

   Here is a link to André's book that lets you download the PDF:
   https://spartacus-idh.com/pdfs/078/

4. **anon**
   October 5, 2021

   Surely Harvard could have easily kept funding PED if it was only a question of money. But the centre was very much Nowak's/Epstein's creation, so keeping it going would have looked very bad.

   CMSA doesn't have the same PR issues, so maybe Harvard is more willing to increase its own contribution. Or maybe S-T Yau (I think CMSA is his pet project) can find another sponsor.

5. **Sabine**
October 5, 2021

Well I agree that the community of particle physicists must "rise to the challenge". This means they should get rid of theorists who make a living by putting forward useless speculations, like inventing particles that no one will ever see (or extra-dimensions, or unparticles, etc). If your methods of theory-development allow you to retrodict any possible fluctuation in the data, then those methods are obviously unscientific and must be discontinued.

And, needless to say, they should also make sure that the group-think which made such practices acceptable in the first place doesn't happen again. Even psychologists have managed to clean up their act and have taken steps to throw out unscientific methods. I find it depressing that particle physicists still don't even acknowledge their problem.

7. **martibal**
October 5, 2021

As many Italian colleagues think: they gave back to Parisi what they had stolen to Cabibbo!

8. **AcademicLurker**
October 5, 2021

Once again, my prediction of Aspect Clauser and Zeilinger is off.

I've been wondering for years whether Parisi would get it. His work has certainly been far reaching and influential enough. I confess I've never heard of the other two.

9. **AcademicLurker**
October 5, 2021

Re: Parisi and the Nobel prize, I must say I don't envy the poor science journalists who are now stuck with the task of trying to explain spin glass theory and replica symmetry breaking to a general audience. If they thought that the topology stuff in 2016 was difficult to popularize…

10. **CM**
October 5, 2021

Gauge symmetry as an emergent phenomenon has indeed been explicitly demonstrated in condensed matter systems. A notable example is the emergent QED in quantum spin ice. So the "different reality that takes place at a more fundamental level" could be that the fundamental theory of our world is some complex bosonic spin model, as envisioned by people like Xiao-Gang Wen or Laughlin.

11. **Peter Woit**
October 5, 2021

CM,
Sure, you can make a model of emergent QED, but emergent from what.? QED itself is hugely successful, tested to absurd accuracy, why replace it with a bosonic spin model or any such thing. This explains nothing at all, replaces a highly constrained beautiful theory based on deep geometry with something much less interesting? Why do this if there's not the slightest bid of evidence for such a supposedly more fundamental structure?

12. **OB**
October 6, 2021

@Peter
I don't think anyone's really advocating to replace QED with a spin model or any such thing. The point is to realize that just because symmetry principles, including gauge symmetries, are very useful doesn't necessarily imply that they are fundamental truths about the universe, valid at all length scales. What the Condensed Matter examples demonstrate is that one can end up with beautiful looking gauge theories as the effective theory, even if the underlying reality is quite unsymmetric and ugly (from a high energy theorist's POV)*. Indeed, there's no present experimental motivation to replace the standard model with some short distance Condensed Matter like model from which it could emerge, but philosophically its worth knowing that the success of the SM doesn't imply that its symmetries are necessarily fundamental.

*I'm a CM theorist, so I don't find lattice models ugly or boring, but each to their own.

13. **CM**
October 6, 2021

Peter Woit:

To answer your question, the QED could be viewed as emergent from some qubits defined on a lattice of extremely small length scale. I mean, if people can entertain the idea that the fundamental constituents are tiny strings, perhaps it is not too absurd to speculate that the world is build on a super-tiny lattice model.

Yes, QED is hugely successful and elegant. But until we figure out the consistent fundamental theory (super-string or not), one cannot rule out the possibility that the standard model QED is emergent from some bosonic model defined on a lattice. And the fact that such a beautiful gauge structure can emerge from a local bosonic theory is not "something much less interesting". This construction could be deeper than the "deep geometry" you mentioned.

14. **Arnold Neumaier**
October 6, 2021

CM,

the quantum spin ice does not give standard QED since it has magnetic monopoles and a fine structure constant which is far too large (besides being dependent on microscopic details of the model):

Pace, S. D., Morampudi, S. C., Moessner, R., & Laumann, C. R..

Emergent Fine Structure Constant of Quantum Spin Ice is Large.
Physical Review Letters 127 (2021), 117205.

15. **Peter Woit**
October 6, 2021

OB/CM,
I don't disagree that it's possible that the SM and its gauge symmetries are emergent from a more fundamental complicated/ugly/unsymmetric collection of qubits or whatever. But at this point, there's not a shred of evidence for this, it's completely unmotivated speculation. The string theorists at least started out with a model (10d superstring compactified on a Calabi-Yau) that in principle could explain things and that you could argue about. Replacing string theory conventional wisdom about a flawed theory by a new conventional wisdom that there's an ugly complicated fundamental theory we know nothing about isn't progress, it's just a way of convincing everyone to give up.

16. **Lowell Brown**
October 11, 2021

" Gauge symmetries are not real physical symmetries, in the sense …"
The reason people such as this guy can dispense expert knowledge is that they have no knowledge of what they are talking about.
Let's examine a nonabelian gauge theory. The group requires a specific form for the field strength F^a_{mu nu}.
F^a_{mu nu} = A^a_mu , nu – A^a_nu , mu
won't do.

String Theory and the Real World

October 6, 2021
Categories: Uncategorized

I just noticed that Gordon Kane has recently published a second edition of his 2017 String Theory and the Real World. Columbia doesn't seem to yet have full online access to the second edition, but one can already compare the two editions in a few places. For instance, on page 1-5 of the 2017 edition one reads

> The LHC is now working in a region of energy and intensity where well-motivated theories imply superpartners could be seen by late 2018.

and

> There is good reason, based on theory, to think discovery of the superpartners of Standard Model particles should occur at the CERN LHC in the next few years.

The corresponding first chapter of the latest edition has:

> The LHC has so far just entered the region of superpartner masses predicted by compactified theories, which ranges from about 1.5 to ~5 GeV (we'll discuss that range later). Those values are the only physics predictions, rather than just speculations. The LHC will run with higher luminosity after an upgrade, beginning in late 2021 if pandemic work stoppages do not delay it. That increases the possibility of discovery, though not very much. A higher energy collider is needed. From what we know now, a collider with twice the LHC energy range would probably suffice, and cover the region of gluino masses to about 5 GeV.

The concluding chapter of the 2017 edition tell us:

> The compactified M-theory implies that three superpartners (and only three) will be observed at the LHC in the current three-year run (assuming the full integrated luminosity is achieved). These are the gluino and the charged and neutral winos.

Presumably he's talking about the LHC Run II (2015-18) which did meet its luminosity goals, without any hint of the three superpartners. I don't yet have access to the later parts of the 2021 edition to see what they say about this.

This isn't the first time Kane has published multiple editions of ever changing "predictions" about supersymmetry. At one point I compared the 2000 and 2013 editions of "Supersymmetry and Beyond", you can see the results here.

Comments

1. **Sabine**
   October 7, 2021

   I am writing this comment for the interested reader, not for Peter who I know understands the situation perfectly well.

   Those particles are not scientific predictions. They are calculations based on theories that have been fabricated for the very purpose of having some "new" physics in the energy range of question. I have worked in this field myself and this is literally how it's done: You make up a theory and fiddle with the details until it shows a deviation from the established theories in a range that may become experimentally accessible soon. Then you claim this is a "prediction".

   As I have said now for more than a decade, this methodology is obviously unscientific and must be discontinued. It has become accepted practice because it's easy and convenient and allows people to crank out a lot of papers quickly. But it's a waste of time and money, and certainly not a reason to build a bigger collider.

   Many people are afraid of criticizing high energy particle physics because they don't understand the math. But you don't need to understand the math to see that these so-called predictions have as a matter of fact not worked since the 1980s. You can look at Kane's own publications to see that his predictions have been falsified over and over again and he keeps on changing them. (Which Peter has documented on this blog.)

   This is not a problem of "it's just hard to measure" (as it was, eg, with the neutrinos or gravitational waves). This is a problem of people who eternally amend their so-called theories. They live under the mistaken impression that just because a hypothesis makes predictions it is scientific. This is a trivial misunderstanding of the most rudimentary philosophy of science. Guesses aren't scientific predictions. And piling lots of math on top of guesses doesn't change the fact that they were guesses.

   I am not saying this because I am against particle physics (or other research on the foundations of physics). To the very contrary, I am saying this because I care about progress in the field. This methodology has not lead to progress. Researchers in the field urgently need to clean up their act.

2. **Peter Woit**
   October 7, 2021

   Sabine,
   I think it's important to note that what Kane is doing now is different than what most "string theorists" are doing. A lot of his book and recent writings are actually aimed at criticizing the string theory community for admitting that there is no way they can predict anything about LHC-scale physics. He's arguing for models and calculations that most of the rest of the string community has essentially disowned. They're content to take the position that if SUSY is found that proves string theory, if it's not, that's no problem for string theory.

   What I find remarkable about the Kane story, in his Physics Today articles, his earlier popular books, and now these two editions is the repeated blatant, on its face violation of conventional norms of scientific ethics. Most other people making models of the kind you describe are careful to stick to "my model shows there's a possibility the LHC will see something", and not say "if my model is right, the LHC will see something". This is because they realize that if they say the latter, when the LHC sees nothing they will be ethically bound to admit "my model is wrong", with negative implications for their career, funding, etc.

   Kane instead deals with the ethical problem by just ignoring it, never admitting anything and doing the same thing time and time again. This is not usual behavior. What's remarkable is that those responsible for maintaining ethical standards do nothing about it: the editors at Physics Today let him publish more articles doing the same thing, the publishers of his popular books and now the IOP let him publish revised editions. This really is not supposed to happen.

   I notice that while the old popular books carried endorsements from others in the field, the IOP ones don't seem to. My impression is that privately most string theorists find Kane an embarrassment, but will never say so publicly because they have for a long time circled the wagons and will not criticize behavior of members of their own tribe, no matter how egregious.

3. **anon.**

October 7, 2021

"What's remarkable is that those responsible for maintaining ethical standards do nothing about it: the editors at Physics Today let him publish more articles doing the same thing, the publishers of his popular books and now the IOP let him publish revised editions. This really is not supposed to happen. … most string theorists find Kane an embarrassment, but will never say so publicly because they have for a long time circled the wagons and will not criticize behavior of members of their own tribe, no matter how egregious."

You appear to be calling for censorship to solve the string theory hype dilemma, which is a bit like the tactics used in totalitarian regimes (by Stalin against Trotsky, for instance). This puzzles me. Surely censorship is always wrong in a libertarian world? Surely, truth will conquer all and the publishers of BS will go bankrupt when the correct model emerges? Forgive me for asking, but isn't the way to defeat evil, to fight weak arguments with reality instead of trying to ban weak arguments from being published?

4. **vmarko**
October 7, 2021

Peter,

"My impression is that privately most string theorists find Kane an embarrassment, but will never say so publicly because they have for a long time circled the wagons and will not criticize behavior of members of their own tribe, no matter how egregious."

I believe this is true to a large extent, but there are exceptions. During the "Why trust a theory" conference in Munich 2015, David Gross called out Kane for the "prediction" of the Higgs mass, and there was very vigorous discussion by Kane, Gross, Dieter Lust, and a couple of other people in the audience. I attended it, and later commented the event on your blog, here:

https://www.math.columbia.edu/~woit/wordpress/?p=8132&cpage=1#comment-220854

Afterwards, the recording of Kane's lecture became available, here:

https://videoonline.edu.lmu.de/en/node/7485

The "fun" part happens between slides 31 and 32 of Kane's talk. 🙂

Best, 🙂
Marko

5. **Peter Woit**
October 7, 2021

anon.
First of all, I'm not a libertarian and don't want to live in a libertarian world.
A healthy science literature needs editors and referees, and here I don't think they were doing their jobs.

Marko,

I do remember that, but that case was a bit different, since Kane was claiming for himself personally a huge (bogus) scientific achievement.

6. **Sabine**
October 9, 2021

Peter,

Sure I agree that Kane is an extreme case and of course there are pretty much no string theorists supporting him, but his methods exemplify those used by an entire community. The idea is that you fabricate some fancy explanation for why your particular guess is a good one, and then you do a series of impressive looking calculations which you call "predictions". That lives up to the scientific standard of today and you'll easily get it published in good journals because they can't think of a reason to reject it. The reason they should reject such guesses is, of course, that just because a hypothesis is testable doesn't mean it's scientific.

What's happened with Kane, I believe, is that since he's waded into science communication he was forced to express himself clearly which resulted in big claims that now come back to haunt him. Most people in the field will make sure their predictions have loopholes so that they can be amended should need come. This isn't hard to do since those predictions were guesses to begin with. Since Kane is only a particularly egregious example of a much more general problem, I find it actually somewhat unfair to pick on him particular.

The real issue is the entire community which, as you note, doesn't move a finger to improve the situation. That's because (to use a German idiom, if you excuse) they'd saw off the branch on which they sit. Producing these useless predictions is the only thing they know what to do. They can't discontinue it because what else would they make money with? This is of course also why they constantly complain that I'm supposedly just complaining and not making constructive suggestions. Totally wrong of course, if you read my book (or listen to my lectures) I have explained very clearly that they should focus on resolving mathematically well-defined inconsistencies rather than pulling guesses out of thin air. That, however, is difficult and would make their lives harder, so they won't do it. It's rather simple economics.

As I have mentioned before, this is the same problem they had in psychology with their sloppy ways of assessing statistical significance. (a) The problem was known for a long time. (b) It stalled scientific progress but they kept on doing it anyway (c) They justified it to themselves and others by claiming that it's a generally accepted standard.

The difference is that psychologists have taken steps to solve their problem. Particle physicists haven't.

7. **mjk**
October 9, 2021

Sabine,
I don't think it is possible to actually prove that someone is "pulling guesses out of thin air". That is just as much speculation as what you are alleging. The only evidence we can go on is what they say and write. And the only standards we can apply are how well motivated are their arguments. Are their ideas based on well established observations? Or are they based on well accepted assumptions of science? After that, it's only a matter of whether the math is correct. Perhaps these are the criteria that should be used by publishers. It seems obvious, for example, that string theory would not pass, since it is not based on observational data and the assumption that particles are strings or the like is not well motivated, IMO.

8. **Edward M Measure**
October 9, 2021

I predict that String Theory will continue to, er, thrive until some new discovery or idea appears in the current great experimental and theoretical desert. Theorists got to theorize somehow, even if it is only about how many string angels can dance on the head of a pin.

9. **Palinuro**
October 14, 2021

May be there are too many models in the market, with few new ideas and with some regions of parameters being excluded by experiments, but the problem started with the master, who after writing the SU(2)xU(1) model proposed next the SU(3)xU(1) model …

On the other hand, Sabine and Peter, is it fair to judge the whole particle physics community by the "sins" of one of its subgroups? Take for instance the work done on QCD corrections to Higgs production, with amplitudes, twistors and more into the game, it seems to me a solid pice of research, don't you think so?

10. **Peter Woit**
October 14, 2021

Palinuro,

I've never criticized "particle physics" in general, and Sabine's critique is clearly aimed at a certain mode of research, quite different than the sort of thing you mention.

The Kane case is an extreme one. Other people working on this kind of speculative model are careful to not make the kind of repeatedly falsified claims he does. The institutional problem his behavior raises is not so much about the field of research but about those institutions publishing his claims (Physics Today, his book publishers), They should be well aware that these claims have been repeatedly falsified in the past and that he does not acknowledge or address this.

11. **Rando M.**
October 27, 2021

I know this blog is a big fan of Lubos Motl. I feel like handing out some damning evidence of the futility of string theory from his own thesis advisor, Tom Banks.

https://www.physics.rutgers.edu/people/hpgs/BanksT.html

Here is his home page at Rutgers. As you can see in the second-to-last paragraph, he says:

" I've consequently decided to abandon this area of research and shift my focus to condensed matter physics. The study of quantum gravity, inflation, black hole information, and "string theory", suffers from the absence of well defined mathematical models, which define the theory in asymptotically flat or de Sitter space in a non-perturbative manner. It also suffers from a lack of contact with experiment, which is not expected to be ameliorated in the near future. Until further data becomes available on supersymmetric particles, dark matter, or finer details of the primordial fluctuation spectrum, these fields will be in the realm of uncontrolled conjecture. 15 years is enough time to spend on them."

What's astounding about this (I'm not exactly sure when he switched focus) is that in the late 90s he was co-author of the BFSS matrix model which was supposed to be the much-sought definition of M-Theory. Lubos created his own matrix model for non-perturbative string theory as an undergraduate, Banks was thoroughly impressed, Lubos became his doctoral student, and the rest is history.

So some time ago, Banks realized that all that impressive work on matrix models and other such speculation was just that, speculation, and he moved on to more concrete areas of physics that are connected to experiment. (I'm not sure if anyone else in the past has brought up Banks' change of heart on this blog, so apologies if this is redundant.)

This Week’s Hype

October 8, 2021
Categories: This Week's Hype

The latest from the BBC:

String theory – a simple way to understand the universe

Not worth more comment than it’s another reminder that this nonsense continues to be heavily promoted in our most prominent and respected mass media. I’m beginning to doubt we’re going to be rid of it in my (or anyone’s) lifetime.

News and Travels

October 15, 2021
Categories: Uncategorized

First some personally relevant items:

- I finally have a finished version 2.0 of my euclidean twistor unification paper (discussed here), it's uploaded to the arXiv, should appear there Monday.
- I'll be giving a talk October 30th at the Foundations 2021 conference in Paris, something about the unity of math and physics, and will take the opportunity to spend about two weeks in Europe, mostly in Paris.
- In other travels, I'll be in the Bay area for a week or so mid-November.
- For entertainment I tried out a WordPress plugin that dumps all my blog content into a single pdf. If you want 8,518 pages to read at your leisure when you're not connected to the internet, this would be one way to spend your time.

In math and physics news, there's:

- David Mumford has a had a remarkable career, first as an algebraic geometer (he won a Fields Medal for his work in this area) and later in the field of computer vision. He's also known as a talented expositor, with his books and papers the standard references for several different topics. He's moved into physics this month, with a wonderful article about cosmology in the Notices. His blog is well-worth following, it had the cosmology piece a few months back.
- Also in the Notices is a set of memorial articles about Lucien Szpiro, who passed away last year. I wrote a little bit about him here, am very pleased to see these articles which give a detailed picture of both the person and his mathematics.
- The Simons Collaboration on Global Categorical Symmetries had its kick-off meeting this week in Stony Brook, videos available here. There are many interesting talks to watch. I got very excited for a minute (around :05:00 in this video) when Greg Moore started talking about some of my favorite questions (e.g. what is the representation theory of gauge groups in dimension greater than one?). But then I realized he had labeled these "Traditional Questions", in Fraktur font to emphasize how old and out of date they were. He described these as "old-fashioned questions", that people were not seriously working on anymore. As he explained, you're no longer supposed to be thinking about a fixed topology, but looking for something more general that treats all topologies. My problem with this is that one tends to get interesting results about topology this way, but the physics applications seem to be in condensed matter physics, with little relevance to questions about local fundamental physics that have always been my main interest.
- I really don't understand the thinking in physics theses days at all. Nima Arkani-Hamed is a remarkable theorist who came up with a lot of highly speculative ideas about particle physics that have never worked out, then moved on to brilliant work leading efforts that have transformed the study of scattering amplitudes. The APS just announced that he's getting the 2022 J. J. Sakurai Prize for Theoretical Particle Physics, for "the development of transformative new frameworks". These "transformative new frameworks" are listed as "work on large extra dimensions, the Little Higgs, and more generally for new ideas connected to the origin of the electroweak scale", none of which has had any success, while the amplitudes work is ignored.

Comments

October 16, 2021

   Congratulations to Nima. He did so many things that we can joke that a good motivation would have been: "for amplitudes… despite extra dimensions, little Higgs…". A look at recent editions (https://en.wikipedia.org/wiki/Sakurai_Prize) shows that, given the lack of new discoveries, it become a prize for US physicists who proposed new theories not confirmed or disfavoured by experimental tests. But then, why not extending the prize to theories that cannot be tested? Or suspending this kind of prizes until something is discovered?

2. **Jackiw–Teitelboim**
October 16, 2021

   Some random comments:

   – Read Graham Farmelo's "The Universe Speaks in Numbers" to see that a fair prize to Amplitudes surely should go to Freddy Cachazo first! (I nowadays believe one should rethink what a recognition of high-quality contributions should be instead of… well, money and medals. People getting it are already wealthy as scholarships to new pos-docs around the world only diminishing particularly to the kind of physics most of us reading this blog regularly are interested.)

   – Now, more interestingly, I find amusing Mumford's take on cosmology and an excellent example of physicists vs. mathematicians approaches. The latter are clearly far more open minded even while superficially looking otherwise, sometimes maybe for the rigorous style of mathematical writing mystifying untrained minds. But of course, this "open" mindedness could be a characteristic more of David Mumford himself, but my personal experience (Peter surely have far longer than I of course!) most mathematicians are generally open minded in private but rarely are willing to publish any physics-intuition that inspired their works under their names. Another exception I liked was Connes' interview in "Conversation on Quantum Gravity," possibly one of the few interesting chapters, given string theorists self-denial depressing. (Witten's interview is a indeed just a single page or my edition allowed by my university access is limited?). Particularly Connes' answer to mathematician's rôle in society, that was witty.

   – I looked at the Foundations conference website and their program. It will be fun to see your highly mathematical motivated talk alongside philosophers of science. Good luck to you!

3. **Joseph Conlon**
October 16, 2021

   "Nima Arkani-Hamed is a remarkable theorist who came up with a lot of highly speculative ideas about particle physics that have never worked out, then moved on to brilliant work [sic] leading efforts that have transformed the study of scattering amplitudes."

   Or, this week's hype.

   QCD is not my field, and I have never contributed to it at a technical level, but over the 15 or so years I have been in particle theory, it is clear that

   (a) the ability to compute QCD amplitudes with increasing numbers of loops and legs, of direct relevance to the LHC, has developed enormously over this period

   (b) Nima Arkani-Hamed is, by quite some way, not the leading contributor to (a)

   Instead this rather illustrates one of the systemic problems with the subject, which is the idea that problems are only interesting (and progress is only made) when someone from Princeton (or Harvard, or MIT, …..) works on them.

4. **Peter Woit**
October 16, 2021

Joseph Conlon,
My point was more that assuming you're going to give him a prize, why do it for the part of his work that was a failure?

I can't evaluate the relative technical contributions of the many people working in the amplitudes area. But, besides having a position at Princeton, Arkani-Hamed is quite a phenomenon: the two-hour long inspirational talks about how advances in the study of amplitudes are going to revolutionize physics, replace space, time and maybe quantum mechanics have sometimes even almost convinced me. Whatever else he is, he's certainly the driving force responsible for turning "Amplitudes" into a major and vibrant part of theoretical physics.

5. **JJT**
October 16, 2021

They already gave the prize for amplitudes in 2014 to Bern, Dixon and Kosower who well deserved the prize.

6. **Alessandro Strumia**
October 18, 2021

I don't expect that amplitudes will revolutionise physics. Because amplitudes satisfy non-trivial properties already at tree level, i.e. classical physics. How can you expect that simple classical physics hides flat-space holography, or something better than the usual local Lagrangians in space-time? It seems more likely that amplitudes satisfy non-trivial mathematical relations with no deep fundamental meaning, and that we care about amplitudes because that's how colliders happen to practically measure small distances. Relations among amplitudes that allow to quickly compute scatterings among many gluons are useful, but maybe only to those who want to compute these higher-order processes.

7. **Peter Shor**
October 18, 2021

Alessandro Strumia:

You say:

> It seems more likely that amplitudes satisfy non-trivial mathematical relations with no deep fundamental meaning,

One comment: I don't see how you can dismiss any mathematical relations like these as having no deep fundamental meaning. These mathematical relations certainly didn't happen just by chance, and I don't believe we understand the reason for them yet.

Now, whether the fundamental meaning underlying amplitudes is interesting for physicists, or just for mathematicians, is a different question. But either way, it's worth investigating.

8. **Alessandro Strumia**
October 18, 2021

Dear Peter (Shor): because these are perturbative relations, that satisfy interesting mathematical properties that appear *already at classical level*. I don't expect that a classical field theory has a hidden formulation where big surprising things happen, such as emergence of space-time and locality. So, while I agree that it's interesting and worth investigating, I am skeptical about highest expectations that amplitudes are the magic door that will open a new level of quantum reality. I would be happy to be wrong.

9. **Joseph Conlon**
October 19, 2021

Nima is certainly charismatic – no arguing that. But, NLO and NNLO QCD – surely the beating heart of amplitudes as they relate to the real world – happened without him. I think it does a disservice to the subject when people who did the real work get written out of the subject in favour of charismatic personalities. Give people who do the work the credit they deserve.

A similar thing was true of the film Particle Fever, which left out the theorists responsible for actually working out how to see the Higgs, in favour of Nima talking about the multiverse.

Although if we are talking about emergence of spacetime – it is perhaps more remarkable that 2-dimensional supersymmetric conformal field theories can be reinterpreted as describing the dynamics of 10 spacetime dimensions……

10. **COliveros**
October 21, 2021

Could you direct me to an explanation for laymen of what your twistor unification theory does?

11. **Peter Woit**
October 24, 2021

COliveros,
Unfortunately such a thing does not now exist. At the moment I'm trying to figure out how to get experts interested in these ideas, with the project of getting laymen interested something for the future.

12. **Kingsuk Maitra**
November 9, 2021

Dr Woit,
Are you planning to give a talk on your twister unification work during your visit to
the Bay Area mid November? If so, could you please post
the time and venue?
Thanks
Kingsuk Maitra

I haven't been posting here for a while, partly due to a lot of traveling, partly due to some personal time-consuming commitments, and largely due to a lack of much in the way of news that seemed worth much attention. For some examples of such news that might be of interest:

- Due to discovery of a buckled RF finger, the LHC start-up (at 6.8 TeV/beam) has been delayed from end of next February to end of March or beginning of April. For details, see here.
- As usual in the US for many years, no one knows what the Federal HEP physics budget for the current fiscal year is, although we're a couple months into it. The formal US budgeting process involves a long process including an executive branch budget proposal and congressional committee hearings and debate. This however does not lead to actual budget numbers, which only emerge at the last minute, made in some way understandable to no one I've ever asked about this. From the latest news, the US might have a budget any day now, and then a bit later we'll find out what the HEP budget will be.

  This year the process has involved a highly peculiar situation with the budget for US LHC contributions (prospects for large cuts, assumed to get fixed mysteriously in the last minute process). For the details of what is going on, there's a news story here, and discussion at an HEPAP meeting here. For the first time I'm aware of, the HEPAP meeting videos are on Youtube (see links here), so one can follow the actual discussion between physicists and government officials there.

- In non-news about the abc conjecture, the Japanese media appears to be reporting uncritically about IUT-based claims of proofs that are not accepted by the vast majority of experts in the subject. There have been a couple of workshops devoted to IUT (see here and here) recently, with those speaking about IUT almost all based at RIMS. Recently Mochizuki has posted a strange Invitation to view IUT workshop videos. To view the videos you have to apply, and promise not to use them for "non-mathematical purposes". My guess is that one of the "non-mathematical purposes" at issue would be bloggers pointing out that nowhere in the talks does anyone discuss the fact that convincing arguments have been given by Peter Scholze and Jacob Stix that the IUT-based proof of abc is flawed and cannot possibly work. This problem is addressed with:

  > Unfortunately, it has come to my attention that certain misunderstandings concerning IUT continue to persist in certain parts of the world. Perhaps the most famous misunderstanding concerns an asserted identification of "redundant copies". This misunderstanding involves well-known, essentially elementary mathematics at the beginning graduate level concerning the general nonsense surrounding "gluings". For instance, if one "applies" this misunderstanding to the well-known gluing construction of the projective line, then one concludes that the two copies of the affine line that appear in this gluing are "redundant", hence may be identified. This identification leads immediately to a contradiction, i.e., to a "proof" that the projective line cannot exist! More details may be found in the Introduction to and the references given there.

  In case anyone thinks it's plausible that Peter Scholze is making errors in elementary mathematics at the beginning graduate level, David Roberts has an explanation of what's going on here.

On the string theory front, it's become impossible to figure out how to have any sort of scientific debate about most of the public defenses of "string theory". For two recent examples:

- In an article about What We Will Never Know, David Gross rather explicitly acknowledges that prospects for testing ideas about string theory are now an issue of "faith", with no hope of turning into science any time soon:

  > There's faith that one way or another we should be able to test these ideas… It might be very indirect—but that's not something that's a pressing issue.

- For Nabil Iqbal, string theory is now to be understood at the pre-scientific level of parable. In his parable, human beings trying to understand the equations of string theory are like fish trying to understand the equations governing the behavior of water. I'm trying to think of a sensible comment about this, but I've got nothing.

Comments

1. **S**
   November 26, 2021

   So presumably it would be like humans trying to understand the equations that govern air? If so, that seems like good news. The Navier-Stokes equations are challenging no doubt, but there's enough optimism surrounding them that it seemed reasonable to attach a $1M prize to one of the biggest outstanding problems relating to them. String theory being in a similarly coherent state would be unambiguously good news — right?

2. **Peter Woit**
   November 26, 2021

   S,
   In the parable, humans are trying to understand the vacuum, not air, and our current understanding of the vacuum based on QFT is like a smart fish understanding water using fluid mechanics. A string theorist telling us that the vacuum needs to be understood in terms of strings is like a really super-duper smart fish telling other fish about atomic physics.

   Again, trying to think of something intelligent to say about this parable, but failing utterly.

3. **David Roberts**
   November 26, 2021

   I sent the note I wrote to Mochizuki, and he responded to explain more of what he meant, in terms I could understand this time. He says that his approach to diagrams ('labels', etc), is the same as the standard approach that I give, which is true—up to isomorphism and idiosyncratic notation and terminology. But his contention is that Scholze and Stix are not just replacing merely isomorphic objects by equal objects, but also collapsing the diagram indexing them so that the indexing nodes become equal.

   For those not used to category theory, one can have a nontrivial diagram—take a directed graph, for simplicity,—with many nodes, where different nodes can be labelled by the same object. Mochizuki's style is to additionally decorate objects at different nodes with distinct labels (wholly unnecessary, from a technical point of view). Ordinary category theory just remembers the shape of the diagram to distinguish the nodes. Mochizuki contents that his critics are collapsing the diagram so that if two nodes are decorated by the same object, the nodes are collapsed, forming a quotient of the diagram. I cannot imagine a situation where someone well-versed in category-theoretic vernacular would make this mistake.

Our discussion is ongoing; at this point I'm simply trying to diagnose the thought process that leads to his claim at a technical level (not the sociological, mind!). We are only discussing a simple example, far, *far* from IUT, but it's an example that Mochizuki himself claims is a very good illustration of the actual construction, and the error he claims is being made in the critique.

4. **anon**
   November 27, 2021

   It would be interesting to hear from someone who has followed the Japanese media if the situation there really is as bad as it looks from the outside (to someone who has to rely on Google Translate etc. to read Japanese). Is there any even slightly critical commentary about the IUT in popular media?

5. **Martin Rosinberg**
   November 27, 2021

   Anon,
   As far as I know, there has been no critical commentary of Mochizuki's claim in the japanese media.
   (PS: I presently live in Kyoto).

6. **Jim Eadon**
   November 28, 2021

   The Fish analogy reminds me of a different fish analogy I read many years ago.
   The author claimed that Linde explained that our universe is like an ocean, and scientists are like fish trying to explain why water is the temperature it is from first principles. However, the universe actually contains many oceans, and the temperature of our ocean is just down to random chance. The conclusion? Apparently, our universe must be one universe of a vast multiverse of possible universes, each with differing physics. This was "explaining" why String Theory is unable to, well, explain our universe. Nothing changes…

7. **Peter Woit**
   November 28, 2021

   Jim Eadon,
   It's the same analogy, with the same "explanation" of why we can't explain anything (viscosity replacing temperature).

8. **Blake Stacey**
   November 30, 2021

   David Roberts wrote:

   > Mochizuki contents that his critics are collapsing the diagram so that if two nodes are decorated by the same object, the nodes are collapsed, forming a quotient of the diagram.

   It would definitely change the character of the Four Color Theorem if a map that could be colored with four colors must only contain four countries.

9. **Peter Woit**
   November 30, 2021

   All,
   There's no point to following Mochizuki in debating things which have nothing to do with Scholze's actual argument. If anyone wants to engage with that, there's a detailed discussion at
   https://www.math.columbia.edu/~woit/szpirostillaconjecture.pdf

   There at the beginning Scholze asks

   "If this further identification causes problems, just tell us which diagram it is whose commutativity is rescued by not explicitly identifying $\pi_1(X)$'s."

   No one in the discussion there was able to answer this, and Scholze reports that Mochizuki could not do so in their private discussions. Publicly, Mochizuki has never answered the question, preferring to argue that Scholze is an incompetent who needs to spend more time studying the IUT papers to find the answer to his question.

   Given this situation, what's going on here is clear, and there's no point to wasting more time on it.

    Some real mathematics news: it seems that the 2026 ICM will take place in Philadelphia. The official decision will of course only be made at the IMU General Assembly in July, but there are no other applications this time.

Unifying Foundations for Physics and Mathematics

November 28, 2021
Categories: Uncategorized

During recent travels I attended two conferences (in Paris and Berkeley) and met up with quite a few people. At the Paris conference I gave an intentionally provocative talk to the philosophers of physics there, slides are here. The argument I was trying to make is essentially that more attention should be paid to evidence for a deep unity in much of modern mathematics, which at the same time is connected to our best unified theory of physics (the Standard Model and GR). Edward Frenkel has made some similar points, referring to the Langlands program and its connections to physics as a "Grand Unified Theory of Mathematics". The specific structures underlying this unification seem to me to deserve attention as providing an important way of thinking about what's at the "foundations" of both math and physics.

Another motivation for this talk was to make an argument against what I see as having become a widespread and standard ideology about the search for a unified theory in physics. Talking to many physicists and mathematicians interested in physics, I noticed that the conventional wisdom, shared by the establishment and contrarians alike, is that the SM and GR are likely low energy emergent theories, that some completely different sort of theory is needed to describe very short distances such as the Planck scale. Physics establishment figures tend to believe that following the path started with string theory, then AdS/CFT, lately quantum error correction or whatever, will someday lead to a dramatically different sort of theory, replacing space, time and maybe quantum mechanics. Contrarians often have their own favorite idea for a radically different starting point. For an example of this, take a look at Figures 2 and 3 of Mike Freedman's The Universe from a Single Particle (he spoke about this in Berkeley). Figure 2 is the "establishment" picture, with AdS/CFT the fundamental theory, well-decoupled from the emergent SM + GR (since no one has any idea how to relate them). His Figure 3 shows his own proposal, even better decoupled from any connection to the SM + GR.

Given the extreme level of experimental success of the SM + GR, the obvious conjecture is that these are close to a unified theory valid at all distances. That the mathematical framework they are built on is closely connected to unifying structures in mathematics provides yet more evidence that what one is looking for is not something completely different. The odd thing about the present moment is that arguing that our well-established successful theories can provide a solid basis for further unification makes one a contrarian, with the "establishment" position that a revolution sweeping such theories aside is needed.

I hope to find time in the next few weeks to write up what's outlined in the slides as a more detailed article of some sort. More immediately, I plan to write a blog entry and perhaps some more detailed notes about the "twistor P^1" mentioned at the end of the talk, explaining how it shows up in Euclidean twistor theory as well as in recent work on the Langlands program.

Comments

1. **AP**
   November 28, 2021

   The Langlands program is important, but it is hardly a "Grand Unified Theory of Mathematics". It does not even interact with the majority of areas of mathematics, and outside of number theory it is a pretty niche subject (e.g. it does make contact with algebraic geometry and representation theory, but most workers in those fields do not care about it). It's even stranger to think of it as "foundational", at least in the way that mathematicians usually use the word.

2. **Peter Woit**
   November 29, 2021

   AP,

   The use of a different meaning than usual for "foundations" was meant to be provocative, drawing attention to a too-little recognized and poorly understood deep structure unifying different areas of mathematics. That what most mathematicians work on and care about has little to do with this is true, but also true of "foundations" in the usual sense (and also true in physics where most research has nothing to do with a possible unifying theory).

3. **DL**
   November 29, 2021

   "Given the extreme level of experimental success of the SM + GR, the obvious conjecture is that these are close to a unified theory valid at all distances. " Does not the Dark Matter vs Mond problem indicate that something is seriously wrong?

4. **Peter Woit**
   November 29, 2021

   DL,
   I don't want to start a serious discussion of dark matter here (especially not of MOND vs. dark matter). It's a huge and very complicated subject that is the main focus of attention for attempts to get beyond the SM, precisely because it's the only significant source of a possible discrepancy between the SM and observations.

   Just note that there's no discrepancy between the SM and observations in any earth (or solar system..)-bound experiment. The dark-matter problem shows up in very large scale astrophysical observations, as a conflict between these and best astrophysical modeling. While the evidence seems to be against this, in principle the problem could be in the astrophysical modeling, not the underlying theory (e.g. primordial black holes).

   Even if dark matter is a new non-SM particle, such a thing can be accommodated with a small change to the SM, adding one or more new fields with no SM, only gravitational interactions. You might even be able to do this just with right-handed neutrino fields, which fit very nicely into the SM, in some sense are expected.

5. **Low Math, Meekly Interacting**
   November 30, 2021

   I could be conflating issues relevant to this post with irrelevant ones, but hopefully not. Whether connecting unifying developments in mathematics and physics seems too mystical strikes me as a very superficial objection. What I wonder about is how such conjecture helps with the problem everyone typically cites, namely incurable infinities. One could reasonably say GM and QFT were unified back in the 50s or thereabouts, but such theories were "diseased", as Feynman put it. The current approaches aspire to cure the disease with discretized space-time, extended objects, "asymptotic safety". They give mathematically sensible answers that, so far, don't agree with reality very well.

   So what does something akin to connecting number theory and algebraic geometry credibly do to make quantum gravity yield finite answers that resemble our world without introducing something very new at the microscopic level?

6. **Peter Woit**

November 30, 2021

LMMI,
The way things work is not that some particular piece of known mathematics directly solves deep problems in theoretical physics.

My argument here is that the answer to the problems of quantum gravity are not going to be found by throwing out the ideas about geometry, gauge symmetry, spinors, the Dirac operator that our best theory is built on, that have been wildly successful and that are mathematically very deep. What's needed is an extension of these ideas, not abandoning them for something completely different, arguing that somehow you'll recover them later as emergent phenomena.

I don't want to host now a discussion of everyone's favorite ideas about quantum gravity. Since it's my blog, I will just mention that the work I've been doing points in the direction of fundamental space-time degrees of freedom being closely related to the SM ones, using spinors, twistors, and the chiral spin-connection. I don't claim to have solved the problem, but do see new things to think about that may go somewhere: use of just one chirality of spin connection and a fundamentally conformally invariant formalism, working in Euclidean space time as primary, having a degree of freedom that distinguishes the imaginary time direction. For more details, see
https://arxiv.org/abs/2104.05099

7. **WTW**
November 30, 2021

Peter,
Following is a transcription excerpted from an IAS Video Lecture by Leonard Susskind on 29 March 2021. https://www.ias.edu/video/some-half-baked-thoughts-about-de-sitter-space
(The transcription is my own, not from Google; the only AI used was that which is between my ears. Any errors are mine.)

"…
Let's begin with a nice thought… In fact let's imagine a group of very smart theorists. They know all about quantum mechanics and relativity, but have never heard about modern astronomy or particle physics.

If they were anything like us, they would eventually discover black holes, quantum field theory, string theory, supersymmetry, the holographic principle, large-N matrix theory, AdS/CFT. In other words, from a pure theory point of view, they would be about where we are now.
What would they take away from all of this?

Here's what I think they would say: I think they would say, first of all, if you want to put gravity and quantum mechanics together, you better have a frozen time-like boundary to anchor the theory, and to define observables. AdS is great in this respect. And maybe flat space is OK. To make the string scale much smaller than the cosmic radius, since in this case the cosmic radius would be the AdS scale, the boundary theory better be super-strongly coupled — but knowing as much as we do, they might believe that the only theories that can be pushed to super-strong coupling are supersymmetric. That would also fit with what they know about matrix theory, where without supersymmetry you can't even seperate two particles. Asymptotic boundaries, super-strong coupling, supersymmetry — these would be their touch stones.

What would happen, then, if some crazy man showed up and told them that he had seen the data, and could assure them that space has no boundary, that spacetime is more like deSitter space than Anti-deSitter space, that there's no supersymmetry, and — despite that — locality works down to ultra-microscopic scales?

I tell you what I think they would say. I think they would say, "Baloney! Your model is in the swampland."
They'd say this not because of some made-up input bound on the inflaton, but because the model violates the entire foundation of their mathematical understanding!

OK, what should we take away from this parable?
The answer is, I don't really know. …"

I've heard similar "parables", with varying descriptions of what is or isn't discrepant, from people like Arkami-Hamed and Ed Witten among others. I believe the general summary is "We're missing something, and we don't know what it is." And we tend to think (or at least pretend) — since people in this field are so damn smart — that we know more than we actually do.

The critique I would give of your presentation is that you are underestimating the fundamental inconsistencies between and among these theories, that have tried to be papered over with mathematical slight of hand. Rather than providing some deep underlying fundamental truth, it tends to be used as fairy dust. Separating the wheat from the chaff while navigating our desire for universality of mathematical form is one of the key issues that must be addressed if we are to make real progress.

8. **Paolo Bertozzini**
November 30, 2021

Dear Peter,

thanks for pointing this out clearly. There is indeed an unusual and quite widespread consensus between most of the current approaches to quantum gravity: not only that geometry of space-time (and the standard model) is an emergent macroscopic feature, but that it is even impossible to talk about "geometry" at the fundamental quantum level (for example one can see the recent brief talks at the "1st Workshop of the International Society for Quantum Gravity" [https://isqg.org/first-isqg-meeting/] that are available on the ISQG YouTube channel). Surprisingly this "emergentism" seems relatively common even in areas, like non-commutative geometry, that in principle are already capable of "saying something" on space-time (and standard model) at the quantum level.

One should probably make here a distinction between "macroscopic emergence" exclusively via phase-transitions (that is the position I was referring to in the previous paragraph) and an "operational/spectral" point of view (where space-time, commutative or not, is determined by other degrees of freedom, but is otherwise perfectly well defined also at the fundamental level).

In the current trends in AdS/CFT, some geometric properties (related to the modular structure of the local operator algebras in CFT with respect to the vacuum or its perturbations) are being investigated; such results will likely survive even without the background propaganda of "emergence" and will continue to make sense also in situations that are different from the original AdS/CFT string-theoretic motivation (since they are just based on Reeh-Schlieder theorem in QFT and Tomita-Takesaki modular theory). The recovery of "space-time geometry" from states on local algebras of operators has actually a much older tradition, going back to works in Algebraic QFT by Haag, Bannier, Keyl, Buchholz, Summers (just to cite a few).

Best Regards.

9. **Peter Woit**
November 30, 2021

WTW,
Susskind's
"If they were anything like us, they would eventually discover black holes, quantum field theory, string theory, supersymmetry, the holographic principle, large-N matrix

theory, AdS/CFT. In other words, from a pure theory point of view, they would be about where we are now."
This indicates the fundamental psychological problem of the field. He can't even imagine the possibility that string theory, SUSY, etc were wrong turns, that he and others have gone down a blind alley for decades.

A huge problem with the current relation of math and physics is that those with a deep belief in the unity of math and physics who can't believe they're in a blind alley are left searching for unity in an unpromising place (e.g. AdS/CFT), limiting what they can find. It's really important for people to distinguish what is solid fundamental theory (SM +QG), concentrate on looking for deep mathematics there, being very wary about starting with unsuccessful speculative physics as a starting point.

In some sense all mathematics is connected, and if you start at an unpromising place you may sooner or later make your way somewhere interesting (for instance, if you start by believing 6d Calabi-Yaus are fundamental). But it's much, much harder to make progress that way and you're likely to end up convincing others that you're "Lost in Math", that looking for unity through math is a fool's errand.

10. **Peter Shor**
December 1, 2021

Peter, you say

> Physics establishment figures tend to believe that following the path started with string theory, then AdS/CFT, lately quantum error correction or whatever, will someday lead to a dramatically different sort of theory.

It seems to me that trying to base a fundamental theory of quantum physics on quantum information and quantum error correction is an error on the order of trying to base a fundamental theory of classical physics on thermodynamics.

Thermodynamics will tell you a lot about classical physics (and maybe you can even derive the ideal gas laws from it), but ultimately it will leave a lot of physics unspecified; thermodynamics will never give you the properties of electrons.

11. **d_b**
December 1, 2021

@Peter Shor
Isn't that precisely the idea, though? The claim (or speculation, rather — I'm not sure that I would elevate it to a "claim" just yet) is that classical gravity is part of the emergent, low energy behavior of complex quantum systems (or perhaps ensembles of quantum systems). The fundamental theory would just be quantum mechanics, and the quantum error correction is supposed to explain how a quantum mechanical system can robustly encode classical spacetime.

12. **Peter Shor**
December 2, 2021

d_b

My point is that I think it's much more likely that some theory of quantum gravity is fundamental, and all the quantum information type stuff these researchers are looking at is emergent. And if this is true, there's a limit to how far they can go unless they realize this.

13. **SRP**
December 6, 2021

Given the accessible experimental anomalies that have to do with the proton, notably the Krisch transverse-polarized collision data (repeatedly confirmed as showing spin effects not dying out as they are supposed to at higher energies), statements about how the SM is just too gosh-darn perfect to give theorists any clues strike the layman as avoidance.

14. **Peter Woit**
December 6, 2021

SRP,
I'd be very interested (because of the euclidean twistor unification picture I've been working on) to see a discussion of spin-dependent effects in proton collisions that indicates experimental anomalies that cannot be plausibly attributed to our lack of a reliable non-perturbative calculational methods for those effects.

15. **SRP**
December 9, 2021

Here is Krisch in 2010, after telling the story of how from the beginning QCD theorists firmly predicted the wrong result based on general principles (I've found a few presentations by others since then saying yep, still an anomaly, along with some other problems):

"To summarize, for the past 30 years QCD-based calculations have continued to disagree with the ZGS 2-spin and AGS 1-spin elastic data, and the ZGS, AGS, Fermilab and now RHIC [28] inclusive data. To be specific:
* These large spin effects do not go to zero at high-energy or high-Pt, as was predicted.
* No QCD-based model can yet explain simultaneously all these large spin effects. There is a BASIC PRINCIPLE OF SCIENCE:
* If a theory disagrees with reproducible experimental data, then it must be modified. Precise spin experiments could provide experimental guidance for the required modifica- tion of the theory of Strong Interactions. New experiments at higher energy and higher Pt on the proton-proton elastic cross-section's: dσ/dt, Ann and An could provide further guidance for these modifications, just as the RHIC inclusive An experiment [28] confirmed the earlier Fermilab experiments [27]. Elastic scattering is especially important because:
* It is the only exclusive process large enough to be measured at TeV energy. This is probably because proton-proton elastic scattering is dominated by the diffrac- tion due to the millions of inelastic channels that compete for the total cross-section of only about 100 milibarns at TeV energies. Many people may have forgotten this simple but essential geometrical approach [1], which I learned from Prof. Serber's optical model in 1963 [3]; perhaps it should now be learned or relearned by others."

Lex Fridman Podcast

December 3, 2021
Categories: Uncategorized

A couple months ago I recorded a podcast with Lex Fridman, it's now available [here](#).

A lot of Fridman's other interviews are well worth watching or listening to, and I thought we had an interesting conversation. I can't stand listening to or watching myself, so not sure how it turned out. But happy to answer here any questions about what we were discussing.

Comments

1. **Bryan**
   December 4, 2021

   Very cool! I love this blog and Lex's podcast so what a great treat!

2. **Lino D'Ischia**
   December 4, 2021

   "I can't stand listening to or watching myself . . . "

   I know the feeling!

3. **Jason S.**
   December 4, 2021

   Was there a mutual softball agreement when it came to the topic of Eric Weinstein? Surely you or Lex must be aware of the technical criticisms of his Geometric Unity theory that's been out for awhile now (the only one in existence by Nguyen and Polya).

4. **Peter Woit**
   December 4, 2021

   Jason S.,
   If I'm going to spend time specifically criticizing people's ideas, it's because I think there's a problematic situation with the ideas, that they're getting significant attention and funding within the research community, crowding out better ideas. I don't see any point to spending time discussing technical criticisms of Weinstein's work (or Garett Lisi's, or any number of other similar if less well-known research programs).

   What I thought was worth talking about (and from what I remember, did talk about with Fridman) is the underlying fundamental problem that Lisi/Weinstein's ideas share with mainstream ones that are now in the textbooks (GUTs/SUSY). If you try to get unification by embedding the SM symmetry groups in a larger group, you have to then introduce new physics to break the symmetry group down to the observed SM one. Generically, this removes most if not all of the explanatory power of your idea about unification.

   Anyway, happy to discuss that point more, I think it's very much underappreciated. I'll leave debating pro/con the work of Lisi, Weinstein, Wolfram and others to those who feel it's a good use of their time, don't want to host that here.

5. **Jason S.**
   December 4, 2021

   Peter:
   While your answer makes sense and explains why you would not criticize such theories on your platform, it would seem that the right metric for answering a question on a podcast is whether ideas are getting podcast attention (vs scientific community attention). So it looks to me like a missed (deliberate?) opportunity to give a non-generic comment when one seemed possible. If there wasn't a point to evaluate Weinstein's (or anybody else's) work, the question would not have been asked.

6. **jjohn**
   December 4, 2021

   I wasn't aware of Lex Fridman or his blog before this. He seemed to understand almost nothing that you said, judging by his inane follow-up questions, silly reformulations of your points, etc.. Was he having a bad day or is this representative of his work? You say his blog his interesting, so I suppose it was a bad day…

7. **DF**
   December 4, 2021

   At ~7:00 you mention that recent developments in Number Theory "fit into a context where the theory is kind of four-dimensional." Could you elaborate what in particular you were referring to?

8. **Peter Woit**
   December 4, 2021

   Jason S.,
   For me, what's worth giving attention to, on a podcast or elsewhere, is exactly those topics that are interesting and not getting attention.

   jjohn,
   Fridman's own expertise is far removed from math/theoretical physics. I think you underestimate how hard it is for someone who hasn't spent a lot of time following controversies in physics to understand what is going on and carry on a thoughtful conversation about them. I've often run into people trying to do discuss or write about such issues who are well-meaning but completely clueless. Given the challenges I think he did quite a good job. It was clear that his own interests are mostly in different directions than mine, but he found common ground .

   Also worth noting is that he interviews a large number of people, with very different interests. The sheer number of interviews he has done is remarkable, and from what I've seen the quality is pretty high.

9. **Peter Woit**
December 4, 2021

DF,
What I had in mind specifically was Witten's reformulation of geometric Langlands in terms of a four-dimensional QFT. It's true this is geometric, not number theory Langlands, so more of an analogy. I also had in mind the dictionary relating knots and 3 manifolds with number theory, in which a number field is three-dimensional. See here
https://web.ma.utexas.edu/users/vandyke/notes/langlands_sp21/langlands.pdf
for notes from a recent course by David Ben-Zvi in which he relates this knot/3 manifold point of view on number theory with the 4d QFT.

10. **Steve E**
December 5, 2021

Haven't visited this page in years, but the Lex Fridman podcast brought me back! Great to be here. Your conversation with Lex was great.

11. **JohnB**
December 5, 2021

That was a very good interview, be interesting to hear more approachable discussions like this, that touch on the potential of spinors/twistors for physics! (though having it broken up with other varied/interesting topics, like in this interview, helps :))

12. **George H.**
December 5, 2021

I very much enjoyed your podcast with Lex. Thank you.

13. **Jono**
December 5, 2021

Hi Peter,

I think there may of been some string theory hype back in September that you may of missed, since I don't see that you made any blog post about it. Apparently there's a paper that was published in Physics Review D that claims to of found gravitational wave spectra of merging "fuzzballs" by numerical computer modelling that are different from different from those predicted by ordinary GR for merging black holes. The authors appear to claim that these could be potentially detected by current or future gravitational wave detectors. It was reported here:

https://physics.aps.org/articles/v14/s110

and the pre-print is here:

https://arxiv.org/pdf/2103.10960.pdf

I've already taken a look at the paper. Do you have any comment on this?

14. **Jay H.**
December 5, 2021

That actually was an interesting conversation. Now I couldn't help but noticing that, when string theory became a topic of discussion, you never mentioned the fact that LHC has not found any supersymmetric partners. My understanding is that, given the energy regions that LHC has explored, this already discards most supersymmetric schemes – leaving only those that are highly contrived and therefore far less compelling.

Is this right? If not, do you think LHC is likely to find these partners some time in this decade?

15. **Low Math, Meekly Interacting**
December 5, 2021

I'm also admirer of Lex Fridman's interviews. The list of interviewees and breadth of subjects covered are indeed impressive, and I have yet to listen to one for which I would use the word "inane" to describe any part of the exchange.

Enjoyed this one, too.

16. **Peter Woit**
December 5, 2021

Jay H.,

No I don't think there's any reason to believe in the usual SUSY extensions of the SM. There's zero evidence for them, and they have exactly the problem I mentioned earlier: you introduce a new symmetry and immediately create a huge problem: how do you break it to explain why we don't see it? For SUSY this problem is pretty deadly: SUSY-breaking schemes are ugly and introduce lots of new undetermined parameters. A good idea should reduce the number of parameters you can't calculate, not increase that number. That the LHC did not see SUSY was not unexpected at all for most theorists.

The problem with string theory is different. You don't really have an understood full theory, all you understand well is a perturbative expansion in 10d space-time of a supersymmetric theory. The problem with trying to use this is that you have to get rid of 6 of the dimensions and there are too many ways to do that, so your theory can't predict anything. Some string theorists found it convenient for many years to answer people saying their theory predicted nothing and couldn't be tested by claiming "our theory predicts SUSY, can be tested at the LHC" (which wasn't really true). This blew up in their face with the null LHC results. That's a complicated story, best to keep it simple: the theory predicts nothing and can't be tested, mainly because the only version you understand has six dimensions you can't get rid of without destroying the predictivity of the theory.

17. **bryan**
December 7, 2021

I just listened to the first half and what a great interview!

Peter, you mentioned a fundamental idea about mapping the integers to a geometric space with the function mod p. What is this called and where can I read more about it?

18. **Peter Woit**
December 7, 2021

bryan,
The general story is that to a commutative ring R one can associate a "space" Spec(R), with R then in some sense functions on this space. This is at the foundation of modern algebraic geometry, which gets rather sophisticated.

What I was referring to was the case of R=Z, the ring of integers. In that case what happens is that Spec (Z) is basically the set of prime numbers p. Given any integer n in Z, you can think of it as a function on the set of prime numbers, with f(p)=n mod p (so your functions are taking values in integers mod p at the point p).

19. **bryan**
December 7, 2021

Peter, thanks! This is going to keep me busy for a while!

20. **Patrick Malloy**
December 8, 2021

Another long-time, non-technical, blog reader. Very much enjoyed the podcast. I think your gentle push back on the relationship between the sceince you and Fridman were talking about and a meaning of life nicely illustrates one of the qualities that I find valuable in your presentations.

One thing I do not think you addressed, and that might have come near the surface of the conversation is a point you have made several times on the blog. If I remember correctly, you have noted that mathematics practice could serve as a useful model for theoretical physics in absence of new experimental data. (Please forgive if I am mischacterizing.)

I was always intrigued by this idea and wondered what sorts of practices these might be? You may have alluded them in a couple places, for example when you touched on Lisi and Weinstein.

You have already dealt with this issue at length elsewhere, and, as you rightly note, life is short and there are many things yet to do.

Thank you and very best.

21. **Peter Woit**
December 8, 2021

Patrick Malloy,

There are two different ways I think mathematics practice can help with the current state of physics:
1. Mathematicians are very careful about stating things precisely and making it clear exactly where the line is between what we understand and what we don't. Physicists traditionally haven't needed this, they could rely on experiment for guidance, mathematicians have never had this to rely. I'm convinced physicists could benefit from adopting more of these concerns. At the moment, in many physics theory papers it's hard to impossible to figure out what the exact statement is, and there's a huge lack of clarity over whether ideas work or don't.

2. Much more speculatively, I believe there's a deep unity between fundamental physics and deep unifying ideas in mathematics. Taking this principle seriously gives one at least some very vague guidance as to what is a promising way forward and what isn't.

22. **gentzen**
December 9, 2021

I really enjoyed your podcast with Lex. It taught me some things I liked to know. It made me wonder whether your old book was also at the level of Penrose's books when it comes to explain physical and mathematical concepts. Read some of its reviews, but decided that I would rather read your newer stuff, when I find time to read more of your writtings.

Some Math and Physics Items

December 7, 2021
Categories: Uncategorized

First some math news:

- An anonymous commenter claims here that the 2026 ICM will take place in Philadelphia. I had heard that a US group was submitting a proposal, so this rumor is plausible.
- Many mathematicians and physicists have signed an Open Letter on K-12 Mathematics pointing to problems with attempts to reform mathematics education such as the California Mathematics Framework. For more about this, see the blog entry posted here and on Scott Aaronson's blog, and more detail here.

  While I've always had some sympathy for the general idea that there's much that could be changed and improved about the US K-12 math curriculum, there's a huge problem with all proposed changes based on the "algebra/pre-calculus/calculus sequence is too hard and not relevant to everyday life" argument. Students leaving high school without algebra and some pre-calculus are put in a position such that they're unequipped to study calculus, and calculus is fundamental to learning physics. Without being able to learn physics, a huge range of possible fields of study and careers will be closed to them, from much of engineering through even going to medical school. Whatever change one makes to K-12 math education, it shouldn't leave students entering college with a severely limited choice of fields they are prepared to study.

- Davide Castelvecchi at Nature has a story about machine learning being useful in knot theory and representation theory. Given my personal prejudice that hearing endlessly about how AI and machine learning will take over everything is just depressing, I'm trying to ignore this kind of thing. But, together with stories like the success of proof assistants in solving a problem posed by Scholze, it's harder and harder to believe what I would like to believe (that this is all a bunch of hype that should be ignored).

For some physics items:

- Jim Baggott has an excellent article at Aeon about the "Shut up and calculate" meme, featuring a retraction by its originator, David Mermin

  > In a quick follow-up discussion with me in July 2021, Mermin confessed that he now regrets his choice of words. Already by 2004 he had 'come to hold a milder and more nuanced opinion of the Copenhagen view'. He had accepted that 'Shut up and calculate' was 'not very clever. It's snide and mindlessly dismissive.' But he also felt that he had nothing to be ashamed of 'other than having characterized the Copenhagen interpretation in such foolish terms'.

- For some wisdom on the thorny issue of how to relate Euclidean and Minkowski signature metrics in gravity, see the recent IAS lecture by Graeme Segal on Wick Rotation and the Positivity of Energy in Quantum Field Theory.
- In fundamental theoretical physics these days, it's quantum information theory all the time, with conferences around now here, here, here, and here. I can't figure out what the relevance of any of this is supposed to be to actual models describing reality. Best guess would be that this is supposed to "solve the black hole information loss paradox", although in that case Sabine Hossenfelder has some apt comments here.
- For something more inspirational, see Natalie Wolchover's long piece at Quanta on the JWST.

Update: For more from Geordie Williamson about the math/AI story, see here. For more about the problems with the California Mathematics Framework and its co-author see here.

Comments

1. **Jim Akerlund**
   December 7, 2021

   Not sure if you will want to change it, but your first sentence begins "First some math news: …". Then later you say "For some math items: …". But they seem to be about physics. My guess is that the second one you will replace the word "math" with the word "physics".

   Jim Akerlund

2. **Topologist Guy**
   December 7, 2021

   Machine Learning:

   Is this the problem posed by Scholze that you mentioned, Peter?

   https://xenaproject.wordpress.com/2020/12/05/liquid-tensor-experiment/

   So it seems to me that the problem was to formalize/verify Scholze's proof of a theorem in condensed math—not to prove a conjecture. I don't think the computer contributed any original or creative insight here. In principle, the formalization could have been done with a pen and (a lot of) paper, so the computer here served as more of a digital bookeeping mechanism than an artificial intelligence! But I am woefully unknowledgable about this whole project, so if the computer supplied some crucial step in Scholze's proof, I would be glad to hear it!

   Like you, I find the prospect of machine learning surpassing human beings in our mathematical pursuits quite depressing. I am confident however that us humans will continue to supply creative insights and perspectives on hard problems that machines are incapable of providing. Could computers have originated schemes and etale cohomology? I find that very hard to imagine.

   Education:

   I don't support the California reforms whatsoever. In particular I am appalled by the notion of doing away entirely with programs for gifted students, not least because of my memories of being a child prodigy and forced to endure fourth-grade mathematics. At the same time, I question whether calculus should be the goal of a high-school math education. As a mathematician, it seems like a rather arbitrary goal. If I were to reform math education in America—indeed, to rebuild it from scratch—I would spend a lot more time inculcating a sense of logic and the skill to read and write proofs in abstract mathematics. I see no reason why you can't teach set theory, ZFC, infinite cardinals/ordinals, topology, groups/rings/fields or even differentiable manifolds and some of the basic elements of Lie groups and representation theory to high-school students, if they were taught appropriately. It would be a much better use of time than explaining how to compute the integrals of different rational functions by hand, and it's certainly more interesting, beautiful and foundational material.

3. **Rando M.**

December 7, 2021

Regarding the quantum information theory point, did you see that at Strings 2021 this year, Witten said that quantum information theory could lead the way to an explanation of what string theory "really is"? And then he got into an argument with Cumrun about it? I feel like that for me was the final demonstration of what an all-around waste of time string theory has been and now they're trying to shoehorn every popular fad and meme into it to maintain relevance. It's sad really.

P.S. not sure if you already mentioned this earlier, I'm only a casual reader, sorry if this is a redundant point

4. **cgh**
December 7, 2021

On the education item: I don't support the California reforms and lent my name to the petition. I think the issues are more subtle and widespread, though. I left academia about two decades ago but have steadily hired a large number of PhD/MSc level people from the "hard sciences" in that time. There's a consistent trend I've seen within the interview process that often separates people with US-based educations prior to university versus the others. It's stranger today as everything is "data science", "machine learning", or "artificial intelligence". I can't imagine a CV in previous times simply stating "kalman filter" or "support vector machine" or "particle filtering" so independent of a goal or outcome. I recently spoke to someone with a bunch of machine learning language wrapping a post-doc in numerical GR. I asked and was told "If I don't talk about machine learning I don't get grant money."

As a father of two children I've seen large changes in education that roughly fall into two camps: first is the wide spread adoption of "common core", similar to California, and second is the influence of all this new-fangled training that upsets the progressive (graded) aspect of education and really creates these strange ways topics are introduced. This seems to hit math and reading the most obviously. The former is the reason why I put my children in private school. My 8th grader is in algebra I. I expect that he will have calculus and linear algebra by graduation. I am less concerned with him having calculus proper and more interested in mathematical reasoning beyond the rote memorization of rules that are used in fluency during earlier years or primary and early secondary school. I can tell what they are doing, pedagogically, is trying to introduce more abstract thinking in earlier years, but it seems very inconsistent and contrived (as opposed to abstract). It is a hodgepodge of ideas that seems to be a dangerous experiment with something that was already presenting a challenge (in the US). More broadly than California I have seen efforts to level the playing field not by creating more opportunity but by removing material deemed challenging. Often this is accompanied by some kind of DEI statement which limits the debate. Open to change and evolving the curriculums but it all seems a bit to politicized and arbitrary. I've also witness new-fangled material displace material with little debate (more broad than maths, eg reading lists) And if jobs are the litmus test the reality remains that I produce many jobs for PhD level quantitative researchers and I am not hiring many people educated at US primary and secondary schools.

The comments in this blog aren't the right place for a discussion on this topic so I will stop here, but certainly wanted to voice my support and solidarity with colleagues and others mentioned above.

5. **cgh**
December 7, 2021

BTW, I recall doing some work on applying knot theory to protein folding many years back. The difficulty was in the computing power. Several years later I started building proprietary systems that were more and more powerful. There's a ton of marketing behind Google (just as there was with IBM). Not to diminish their work but when the details of AlphaGo emerged it was remarkably similar, if not identical, to a proprietary system I have been running on massively parallel GPU cluster for years. My point being that while there's been progress, largely due to speed and the availability of data, very little has changed otherwise. Sometimes we joke that it's still all OLS despite the hype. It's fun to write down Ax=b on a quantum computer. After a little while it becomes clear that it's a perfectly good classical problem whether or not we have error correction and massive qubits.

6. **Peter Woit**
December 7, 2021

Jim Akerlund,

Fixed.

All,
Sorry, but I can't moderate a general discussion of everyone's ideas about how math should be taught. If it's not very specifically about the Open Letter, it's off-topic.

7. **Peter Woit**
December 7, 2021

Rando M.,
I did mention this on the blog previously, see the end of this posting:

https://www.math.columbia.edu/~woit/wordpress/?p=12381

Kontsevich and Segal paper https://arxiv.org/abs/2105.10161

-drl

9. **Eitan Bachmat**
December 7, 2021

Dear Peter
The Scholze result verification has nothing to do with ML, the basic "technology" in proof assistants is type theory which is strongly related to mathematical logic. These systems have had a series of magnificent achievements in recent years . ML has obviously also been successful but, as pointed out, this seems to be the first time that it yields plausible and serious math conjectures. In short, both developments are serious, the first is not "depressing", regarding the second, I sympathize with your feelings, but that's life.

10. **Peter Woit**
December 8, 2021

Eitan Bachmat,
I understand that the proof assistant business is different than the ML business, but I fear that in both cases there's not much I can do about my reaction to seeing the best human minds unable to compete with the machine.

On both fronts there's probably a lot of hype and the best human minds are still in many ways far ahead of the machine. But rather than looking into this in detail, seems like a good idea to just avoid thinking about it…

11. **anon**
December 8, 2021

There's actually a source for the ICM 2026 news: the latest IMU Circular Letter to Adhering Organizations. See here: https://www.mathunion.org/fileadmin/IMU/Publications/CircularLetters/2021/IMU%20AO%20CL%2025_2021.pdf

12. **Anonymous**
December 8, 2021

Peter, I wouldn't think of it as "human minds being unable to compete". Unlike Chess or Go, the goal of mathematics is inherently open-ended, being exploration and discovery based on aesthetic taste (even if sometimes motivated by practical concerns). Computers will surely play an increasing role in assisting humans, both by reducing tedium and aiding exploration, but there are sufficient depths unreached for this to mean richer mathematics rather than a trivialisation of the field.

13. **Will Sawin**
December 8, 2021

I think there is a plausible theory that one of the two machine-learning-in-mathematics success stories you mention was not really a machine learning breakthrough, if you take the point of view that to count as a success of machine learning it must not be something that could have been achieved with a similar amount of effort using more classical statistical tools like linear regression.

Specifically, the knot theory one – I'm not a statistician, but Figure 3b in the Nature paper looks like the kind of linear correlation between two variables of interest that could be found by doing a simple linear regression of all the algebraic invariants on all the geometric invariants, and then the second relevant variable could be identified by further analysis, like adding quadratic terms.

Even if I were a statistician, there would be something silly about complaining that you could have achieved something a different way when, well, you didn't, but given that advances in mathematics achieved by machine learning (justifiably) get significantly more attention than similar advances in mathematics achieved a different way would, I think some effort must be put into considering this possibility.

For the representation theory one, my guess (again, not a statistician) is this is probably not true. The message-passing neural network is an elegant system for learning properties of graphs, and I don't know of any classical statistical tools that seem likely equally helpful.

I don't think the proof assistants used in the Liquid Tensor Experiment involved any machine learning, although machine learning tools in that setting are being worked on and I imagine they will be useful tools for computer-verified mathematics researchers soon.

But overall I don't think the position of hoping that machine learning won't help humans do mathematics is really tenable. Is mathematics really that much harder than chess? Of course quite a lot of what has already been written is hype, including some works by authors that seem to understand neither the field of mathematics they are working in nor the basic principles of statistics. But saying that the field is inherently hype because of that is like saying Florida doesn't exist because there were a lot of Florida real estate scams.

14. **Peter Woit**
December 8, 2021

Will,
I should make clear that I'm not saying these stories are hype, quite the opposite: what's bothering me is that they appear to not be hype. Maybe the future of mathematics is in close collaboration between human minds and computers, but I'm personally not onboard with that, just because to my mind we're all already too close to computers.

15. **Peter**
December 8, 2021

@Peter Woit – the story with proof assistants is very far from 'the human cannot compete with the machine'. We are seriously far from being able to use proof assistants for helping with pretty much any act of creation of proof.

However, if you have created a long and complicated proof, where you perhaps have a great many cases which you really hope are exhaustive, or where the definitions are subtle and being used in ways which are close to the limits, you might reasonably be worried that you are missing something.

You could deal with that worry by ignoring it (as is traditional), but this leads occasionally to errors, including sometimes plain false theorems. Or you could deal with it by blowing up your 200-page human-readable paper to 2000 pages which a human can in principle read but in practice won't, by filling in every single detail and being very careful to do every little calculation explicitly. Or, now, you can spend a still very large amount of time (much longer than writing 200 pages, probably a bit less than writing 2000) by putting all the details to a computer and asking it to formally verify the proof.

The major gains at the moment are that you can be fairly confident the computer's answer is accurate, and you can afford to write inelegant stuff and skip the prose for the proof assistant, because no human will read it and judge you. And (minor) for a class of basic calculations the proof assistant can do it for you. The major loss (which hopefully will get better over time) is you have to teach the computer a lot of stuff that would be assumed knowledge for a journal paper, but which no-one previously got around to putting to the proof assistant's knowledge.

I'm sure the ML community thinks that one day they will bolt ML on to proof assistants to replace mathematicians, but this day is definitely not here yet. One major problem, compared to games, is that when you play a game you have two sides, and the side that plays the better strategy wins – you can start with a pathetic strategy, try to learn better responses, and repeat millions of times to get somewhere, with these millions of repeats being the computer playing itself with different variations of its current strategy and seeing which things work better.
In mathematics (and most things, actually) you don't really have this. You can ask the computer to prove something; if its strategy is pathetic, it will simply fail and there is no good way to say 'now improve' in any directed way, it doesn't get a score for its failure (at least not without a human intervening) to say which variation of strategy was best. Similarly if it succeeds it's not clear how to give the computer a 'next problem' that's at the right level to get improvement, again at least not without human intervention; and humans simply don't have time to intervene all the time at the rate current ML programs can learn.

December 8, 2021

Perhaps as a mathematician who has been involved in computer-assisted mathematics for more than 40 years I might be allowed to comment? At that time, computers could not be said to provide artificial intelligence. What they provided was artificial stupidity. They were therefore very useful in augmenting our natural supply of stupidity, and making far more mistakes far more quickly than we could do ourselves. This was, and still is, a huge benefit to mathematicians, and speeds up progress in all sorts of ways.

I may be wrong, but my impression is that a lot of what is called artificial intelligence these days is really just a more sophisticated version of artificial stupidity. And making connections that people haven't seen before is exactly what artificial stupidity should be expected to do: if people make these connections, they reject them as stupid, and they are lost. It is only because they are made by "artificial intelligence" that people take them seriously, and think about them.

17. **Sabine**
December 9, 2021

Thanks for the mention.

Regarding your question about the "relevance" of quantum information. It's the easiest way people in the foundations can get funding through the many current quantum initiatives. We'll therefore almost certainly see more of this, also quantum simulations (you know, wormholes and LQG and that kind of thing).

18. **Mark Hillery**
December 10, 2021

Peter,

You may very well consider this off-topic, and if so, I am sure you will let me know.

It is interesting that quite a few people from Stanford have signed the Open Letter on K-12 Mathematics, since the main person behind the new California Mathematics Framework, Prof. Jo Boaler, is at the Stanford Graduate School of Education. Boaler had a serious run-in with mathematicians in the early 2000's. Wayne Bishop, R. James Milgram, and Paul Clopton criticized her work and accused her of scientific misconduct, a charge that Stanford dismissed. Anyone interested in the details of the criticisms can find them here: https://www.nonpartisaneducation.org/Review/Essays/v8n5.htm and https://nonpartisaneducation.org/Review/Essays/v8n4.htm . According to Bishop, et al., one of the main effects of Boaler's curriculum changes at a high school that was part of a study she ran was to significantly increase the number of students from that school who needed to take remedial mathematics courses when they got to college, just the kind of thing the people behind the open letter are worried about.

19. **Peter Woit**
December 10, 2021

Mark Hillery,

Not off-topic at all. For more about Boaler, someone pointed me to this

20. **Richard**
December 17, 2021

On the subject of math news — very sad news, as it happens — Jacques Tits, a distinguished mathematician who won both the Wolf and Abel Prizes, has died (On Dec. 5, 2021, at the age of 91.).
Though I did not know him personally (Nor can I claim any detailed knowledge of his work.), I do not hesitate to say that — as both man and mathematician — he was very highly regarded.
In particular — in regard to matters mathematical — he will be remembered for his work on buildings (Curiously enough, "building" is an actual technical term — as is, I believe, "apartment"!).
I believe he may also have been the first to claim a sighting of what is generally regarded as the unicorn (Some might say "Loch Ness Monster" or "Bigfoot" would be more apposite monikers!) of abstract algebra: the legendary * field with one element * (An idea that, to the best of my knowledge, is still viewed by most mathematicians as less-than-fully fleshed-out — and is arguably as close as math gets to the sound of one hand clapping.).
I believe he also helped guide the mathematical development of a young Pierre Deligne.
He will be missed.

A short and moving obituary by Broué at the Société Mathématique de France :
https://smf.emath.fr/smf-dossiers-et-ressources/broue-memoriam-tits

22. **Robert A. Wilson**
December 24, 2021

I would like, if I may, to comment on the achievements of Jacques Tits in regard to the unification of mathematics. He did more than anybody else to unify the fields of finite, algebraic and Lie group theory, and the corresponding finite, algebraic and differential geometries. Tits's geometries, buildings and all the rest of it seem to be regarded as somewhat irrelevant to mainstream differential geometry, but this is far from true. He saw, more clearly than anyone, the fundamental structures that are central to Klein's vision of a unified algebra/geometry. It is a pity that others have chosen to use their power and influence to drive a wedge between algebra and geometry, which Tits sought to unite. I met him a few times in my career, and he was unfailingly encouraging and appreciative. I was astonished to find that not only did he know of my work, but he knew it well, and appreciated it for what it was.

23. **Robert A. Wilson**
December 29, 2021

This may be a bit off topic, but there is a really nice obituary of another of the giants of mathematics, John Conway, at
https://royalsocietypublishing.org/doi/10.1098/rsbm.2021.0034.
In terms of physics, there is mention of the relationship of the Conway-Norton Monstrous Moonshine to string theory via the work of Richard Borcherds, and also of the Free Will Theorem proved with Simon Kochen. The former, I suspect, has little to say about real physics, but the latter is a close relative of Bell's inequality, and I suspect is fundamental, although clearly it has nothing whatever to do with free will.

24. **Heiko242**

Also semi-topic, (but since the Bogdanov affair was once extensively discussed here): Both Bogdanov-Twins have now died due to Covid.

More Math and Physics Items

December 18, 2021
Categories: Uncategorized

Yet more math items:

- First of all, congratulations to my colleague Johan de Jong, recipient of the 2022 AMS Steele Prize for Mathematical Exposition. Johan's Stacks Project is very much deserving of such recognition. It's both huge in scale and very high in quality, with nothing else really comparable. While it has attracted many contributors, it has always been mostly a one-person effort. If you're interested in helping, even those not so expert in the field can contribute by fixing any mistakes they might find when using this incredible resource.
- On my currently favorite topic of the unity of math (and physics), there's a talk by Barry Mazur, in which he begins by raising the question "What is it that unifies Mathematics?". He goes on to turn around the question "What is the physical interpretation of the Jones polynomial?" asked by Atiyah (and answered by Witten's Chern-Simons theory). Mazur asks:

  > What is the Arithmetical-Algebraic-Geometric interpretation of the Jones polynomial?
  >
  > or of Chern-Simons theory?
  >
  > or of TQFT?

- Mazur's title is "Bridges between Geometry and Number Theory". The metaphor of "bridges" to describe what unifies mathematics gets a workout in a recent Quanta article about Ana Cariani and the Langlands program entitled The Mathematician Who Delights in Building Bridges (and subtitled *Ana Caraiani seeks to unify mathematics through her work on the ambitious Langlands program*.)
- At the same conference as the one with the Mazur talk, Maxim Kontsevich spoke on Geometry from the perspective of quantum mechanics and string theory. His talk was a great summary of various aspects of the problem of quantization, in both quantum mechanics and conformal field theory. There wasn't much though about what has been going on since the early developments in conformal field theory that he discussed. Things got a bit worrisome at the end, when he announced that he can't understand Kevin Costello these days (if he can't, who can?), and ended with (here's a google-aided transcript):

  > You see that gauge theories and gravity appears in various interactions is it's in nothing else in a sense, and geometric limits of various string theories or quantum field theories and what I claim that it's in fact it's something generally about complex systems and mathematics. You do some combinatorial problem, whatever it is you get some counting or something, and then maybe you look on asymptotic growth of the number of solutions. It could be something very simple but your arranged parameters became something more complicated and if you see something more complicated it's kind of I think it's unavoidable you see some physics in a very wide sense: some string theory, some membranes, whatever. Okay, thank you.

  I can't really make much sense of this, but he seems to have some sort of vision of fundamental physics being linked with complexity, a point of view that seems increasingly common, while not leading anywhere promising.

Moving to purely physics topics:

- Noah Miller was a student here at Columbia in one of my mathematics of QM courses. I've had some wonderful students in those classes, and he was one of the best. He has gone on to graduate study in physics at Harvard, and I just saw a beautiful new paper by him this week on the arXiv, From Noether's Theorem to Bremsstrahlung: a pedagogical introduction to large gauge transformations and classical soft theorems. It's an exposition for non-experts of some of the new ideas about gauge symmetry and physics that Strominger and collaborators have been working on, highly lucid and readable.
- I very much recommend taking a look at the talk from earlier this year by Mikhail Shaposhnikov, Conformal symmetry: towards the link between the Fermi and the Planck scales. Shaposhnikov has done a lot of fascinating work over the years, developing in detail a point of view which hasn't got a lot of attention, but that seems to me very compelling. He argues that the SM and GR make a perfectly consistent theory up to the Planck scale, with the "naturalness problem" disappearing when you don't assume something like a GUT scale with new heavy particles. Watching the discussion after the talk, one sees how many people find it hard to envision such a possibility, even though all experimental evidence shows no signs of such particles. For more about what he is in mind, see the talk or some of the many papers he's been writing about this.
- Finally, skydivephil tells me he has managed to get David Gross and Carlo Rovelli to debate string theory vs. loop quantum gravity, with video to drop on Youtube tomorrow. I normally try to make it a policy to avoid getting into this particular debate, but this I have to see. While you're waiting for this, you can watch an earlier pairing well worth seeing: Alan Guth and Roger Penrose debating the multiverse versus cyclic cosmology.

Update: I just watched the Gross/Rovelli debate, and thought Rovelli did a good job of making the case that string theory is a failed research program. Gross spoke uninterruptedly at length, but interrupted Rovelli constantly. I found it interesting that Gross acknowledged "supersymmetry hype" and hype back in 1984-5, while at the same time engaging in massive amounts of hype about the current state of string theory. On the time scale for progress in string theory, he says 80 years (end of the century) to understand how to use string theory to solve QCD, no time scale for getting unification out of string theory.

Gross's main point he kept repeating is that "string theory" now means an overarching framework that includes the Standard Model, so there's no distinction between the Standard Model and "string theory" and you can't argue that "string theory" is a failure. This argument is so silly that it's hard to engage with it in any sensible way, and Rovelli didn't even try.

Update: There's an interesting long interview with Andy Strominger here. Some of this brought back old memories, since Strominger overlapped with me a bit as an undergraduate at Harvard, although the story of that part of his life is very unusual. I hadn't realized the extent to which from the very beginning he was focused on the problem of quantum gravity, which to some extent explains his lack of interest in particle physics extensions of the Standard Model.

One thing he makes clear is that at this point string theory has become completely disconnected from the possibility of saying something testable about the real world. The AIP interviewer kept trying to ask about that, leading to this exchange:

> **Zierler**: So is there an experiment that you can conceive of that could disprove string theory?
>
> **Strominger**: I guess I am not getting my point across.
>
> **Zierler**: You're saying that string theory is totally outside the world of experimentation.
>
> **Strominger**: … So yes, I don't think – not many string theorists will talk this way – but I don't think that we are in my lifetime — and I'm planning to live a very long time — going to get direct experimental evidence for string theory.

On the issue of what the terms "string theory" now mean. Strominger makes it clear that from the point of view of him and many others, there's no longer any possible critique of "string theory" as a fundamental physical theory:

For the last 30 years, everything new that we've discovered, as long as we can relate it to the ideas in string theory, we call it string theory. So, if we continue to call everything that we discover string theory, it's virtually certain that– (both laugh) It's certain that when we get to the answer, we'll call it string theory!

Comments

1. **lun**
   December 19, 2021

   Shaposhnikov's lecture is about https://arxiv.org/abs/2110.05175
   right? They seem to completely ignore the issue of triviality of the theory
   (in the sense of https://en.wikipedia.org/wiki/Quantum_triviality)

2. **Peter Woit**
   December 19, 2021

   lun,
   No, the talk was not about that recent paper but about Shaposhnikov's long-standing research program. He has lots of relevant papers, for an early one, see https://arxiv.org/abs/0708.3550

   The point he is making about no hierarchy problem if you have no GUT scale is a very simple one: if you just look at the SM and gravity, the only energy scales are electroweak and Planck. Since you don't actually have a viable theory of what is going on at the Planck scale, the only thing you have to go on is a single-scale theory, and that doesn't have the fine-tuning problem you get when you try to maintain two very different energy scales. Taking into account both scales, he suggests a possibility is that a unified theory just has one scale (Planck), with the electroweak scale an exponentially small non-perturbative effect.

   So, the hierarchy problem appears when you write down a GUT theory, or a unified theory including gravity which has Planck-scale states. Conventional GUT theories and string unification models have this problem, but there's also zero evidence for them.

   Besides this simple point, he has a well-developed research program dealing with the issue of gravity and many others. I think it's extremely interesting and should be getting a lot more attention than it does.

3. **Johan Smit**
   December 19, 2021

   I wonder what Cumrun Vafa and the people working on the Swampland would think about David Gross's redefinition of string theory to encompass all of theoretical physics.

4. **Peter Woit**
   December 19, 2021

   Johan Smit,

   I think most string theorists are well aware that the argument Gross makes about string theory and the SM doesn't pass the laugh test. Gross didn't mention the "swampland" argument, I'd guess that he (like most string theorists) doesn't find it a compelling as an argument for string theory.

5. **Bertie**
   December 19, 2021

   Skydive Phil has a poll up on twitter as to who won the Gross/Rovelli debate.
   IMO Gross did his cause no favours in hogging the conversation then getting all defensive when Rovelli spoke.

6. **WD**
   December 20, 2021

   After watching the Rovelli/Gross debate, I couldn't help but feel somewhat sorry for Gross. Quite frankly, he came across as somebody well past his best, and desperately clinging to old ideas. Also, his body language was borderline disrespectful. I was not impressed.

7. **Peter Woit**
   December 20, 2021

   WD,
   I thought Rovelli handled this very well, comparing Gross to Einstein: a theorist who did extremely important work early in his career, but ended up in the last decades of his career chasing a failed research program.

8. **anonymous**
   December 20, 2021

   "For the last 30 years, everything new that we've discovered, as long as we can relate it to the ideas in string theory, we call it string theory. So, if we continue to call everything that we discover string theory, it's virtually certain that– (both laugh) It's certain that when we get to the answer, we'll call it string theory!"

   So when will string theorists start to call number theory and algebraic geometry "string theory", if they continue to discover and/or prove things in number theory and algebraic geometry like they have in the past 30 years?

9. **Peter Woit**
   December 20, 2021

   anonymous,
   Wouldn't surprise me if there were physicists now calling algebraic geometry "string theory". Number theory however I think is safe from this for now.

10. **SRP**
    December 21, 2021

    Soundsl like string theory is the opposite of (pre-boom) AI, where once a task was successfully automated we stopped calling it"AI."

11. **Dimitris Papadimitriou**
    December 21, 2021

    Andy Strominger's interview was really interesting.
    He seems to have an exciting life (and not only in physics!).
    The era between the 60s and 70s were a unique period in the history of humans. (I'm a bit jealous!).
    It seems also that he's a quite honest and unpretentious person. Somewhere in the middle of the interview he mentions that most string theorists did not understood very well GR back then, and this is quite true:
    For a long period of time he and Gary Horowitz were among the few in the strings community that had a deep knowledge for the theory of gravity.
    Untill recently, some of them had a weird, almost hostile attitude towards some aspects of GR, as in the case of firewalls for example.
    They also underestimated the importance of the dynamical internal spacetime geometry of black holes, at least before the important paper of Christodoulou/ Rovelli (about the growth of the slice independent maximal volume of the black hole interior), that revealed a potential danger for holography.

15. **Z Y**
    December 27, 2021

    sdf,

    Funny coincidence, I came today to this blog specifically to see if there was any comment regarding Lafforgue's move to Huawei 🙂

16. **Mike M**
    December 28, 2021

    Oof, the Gross/Rovelli "debate" was tough to watch. I agree with Bertie's comments above. It really seemed like Rovelli showed up prepared for a thoughtful debate, while Gross' approach was much more casual. Early on when Rovelli politely asked to be permitted to give uninterrupted opening remarks, Gross countered with "Well, I want to be able to make corrections along the way…" which is kind of a microcosm for the larger cultural problem.

    I like Skydivephil's channel, but I get a bit nervous about debates/conversations like this in the public view. Could a novice viewer could walk away with the impression that "physics" is really just a lot of fancy semantic arguments.

Witten Goes Anthropic

December 22, 2021
Categories: Multiverse Mania

Multiverse mania started seriously among string theorists around 2003, with a defining event Susskind's February 2003 [The Anthropic Landscape of String Theory](). At the time I was finishing up writing what became the book "Not Even Wrong", and my reaction to Susskind's paper was pretty much "This is great! Susskind's argument implies that string theory can't ever be used to predict anything. If people accept that, they'll have to give up on string theory since it has come to the end of the line." Over the next year or two it became clear that devotion to multiverse mania wasn't just localized at Stanford (where Andrei Linde had always been pushing this, even before the string theorists climbed aboard). Other proponents of the string theory landscape were up and down the California coast, including Raphael Bousso at Berkeley and Joe Polchinski at UCSB. One West Coast holdout was David Gross, who [that summer at Strings 2003]() quoted Churchill's words to his country during the Nazi bombardment of London: "Never, never, never, never, never give up". On the East Coast, the center of the resistance was at the IAS in Princeton, where several people told me that Witten was privately strongly making the case that this was not physics.

I ended up adding an additional chapter to the book about this, and [covering developments closely here on the blog](). For many years I found it impossible to believe that this pseudo-scientific point of view would get any traction among most leaders of the particle theory community. How could some of the smartest scientists in the world decide that this was anything other than an obviously empty idea? After a while though, it became clear that this was getting traction and that there was a very real danger that particle theory would come to an end as a science, with most influential theorists giving up, justifying doing so by claiming they now had a solid argument for why there was no point in trying to go further. String theory is the answer, but the answer is inherently unpredictive and untestable.

It has become clear recently that we've now reached that end-point. From the [new video of his discussion with Rovelli](), it's clear that David Gross has given up. No more complaints about the multiverse from him, and his vision of the future has string theory solving QCD 80 years from now, nothing about it ever telling us anything about where the Standard Model comes from. Today brought an extremely depressing piece of news in the form of a [CERN Courier interview with Witten](). Witten has also given up, dropping his complaints about the string theory landscape:

> Reluctantly, I think we have to take seriously the anthropic alternative, according to which we live in a universe that has a "landscape"of possibilities, which are realised in different regions of space or maybe in different portions of the quantum mechanical wavefunction, and we inevitably live where we can. I have no idea if this interpretation is correct, but it provides a yardstick against which to measure other proposals. Twenty years ago, I used to find the anthropic interpretation of the universe upsetting, in part because of the difficulty it might present in understanding physics. Over the years I have mellowed. I suppose I reluctantly came to accept that the universe was not created for our convenience in understanding it.

I've never really understood the kind of argument he is making here, that the problem with the string theory multiverse is that it's upsetting, but we just have to get control of our feelings. Feelings have nothing to do with it: the problem is not that the idea is upsetting, but that it's vacuous.

The rest of the interview is also pretty depressing. At the high energy physics experimental frontier, Witten promotes "split supersymmetry", something which does little more than try to keep on life support failed ideas about supersymmetry and "naturalness":

> There is also an intermediate possibility that I find fascinating. This is that the electroweak scale is not natural in the customary sense, but additional particles and forces that would help us understand what is going on exist at an energy not too much above LHC energies. A fascinating theory of this type is the "split supersymmetry" that has been proposed by Nima Arkani-Hamed and others.

On string theory, he follows Gross in referring to not "string theory" but "the string theory framework" and describes the situation as

> We do not understand today in detail how to unify the forces and obtain the particles and interactions that we see in the real world. But we certainly do have a general idea of how it can work, and this is quite a change from where we were in 1973.

The situation with string theory unification is that it's a failed idea, not that it's a successful general idea just missing some details.

Finally, Merry Christmas and best wishes for the New Year. Fundamental physical theory may now be over, replaced with a pseudo-science, but at least that means that things in this subject can't get any worse.

Comments

1. **Jackiw–Teitelboim**
   December 22, 2021

   Interesting "developments" in less than a week: Gross' demonstrating his degree of rudeness is unbounded, particularly with Rovelli's (BTW I watched Penrose/Linde's debate at same channel, maybe Penrose is too just much of a gentleman to compare with but… well, poor moderator!); Strominger's story about Witten's hope on electron/muon's mass ratio; and, of course, Witten's speaking about "different portions of the quantum mechanical wavefunction".

   I am not going to start a debate about Everett's interpretation, but mixing stringy/eternal-inflation multiverse cosmologies with a very debatable interpretation of quantum mechanics is bearing not in pseudo-science, but poor judgment.

   Let's hope next year Ed can make another contribution at the same level as in 1994 with Seiberg.

2. **Paolo Bertozzini**
   December 22, 2021

   Dear Peter,
   as regards Witten's interview, there might be some other reasons why the "multiverse mania" is no more the main center of discussion … when questioned about "Which current developments in theory are you most excited about?", Witten clearly stated that the "It From Qbit" ideas connecting gravity and quantum theory, via the insight from "holographic duality" on the relation between gravity and gauge theory, is the new game in town. As far as I understand, this line of research is only very mildly related to the original string theoretic program (through the *original* AdS/CFT duality).

   As regards the discussion between Gross and Rovelli, personally I did not like it very much … maybe because the only sincere agreement that I could spot was on the common fashionable criticism of mathematical motivated investigations ("Lost in Math" in direct opposition to sound theoretical ideas describing the "true in natural reality"). So … for Rovelli, string theory is beautifully lost in sterile mathematics … and for Gross fundamental physics outside string theory is missing the true messages from the real world accumulated wisdom in the study of the standard model unification (that He seems to consider to be somehow a prediction of string theory). *Both* points above (that string theory is "mathematically elegant" or "clearly motivated by experimental insight") are for me quite problematic.

I find the pairing of “naturalism/realism” with “divorce from mathematical soundness” much more troublesome for theoretical physics investigation, compared to an anthropic/multiverse mania that, after all, has always been around in different philosophical shapes since Bruno, if not much earlier.

Things might still get worse 😉
Merry Christmas and Happy New Year 2022.

3. **anonymous**
December 22, 2021

Why is it that the likes of Gross and Witten never think that there is a third alternative, that one gives up string theory instead of giving up their critique of the multiverse/anthropics?

4. **Ron Martin**
December 22, 2021

The best case scenario I see now for theoretical physics is that as people move on from string theory to other hotter areas of study in theoretical physics (such as gauge/gravity duality and the It from Qubit program), string theory gradually fades into irrelevance as its current defenders die out and new research programs take over. Worst case scenario is that the current string theorists, despite moving on to other fields, still nevertheless manage to catechise a new generation with the belief that “string theory is the only way to fundamentally explain the universe”, who then go on to perpetuate this belief indefinitely far into the future making string theory into essentially a new religion.

5. **Johan Smit**
December 23, 2021

Paolo Bertozzini,

Even worse than either the “multiverse”/anthropics or the disentanglement of “naturalness” and “mathematical soundness” is the redefinition of string theory to cover more and more of theoretical physics, like what Gross, Strominger, Witten and presumably other string theorists are saying in their interviews, lectures, and debates, i.e. quantum field theory (especially conformal field theories and their duals) is string theory, condensed matter physics is string theory, quantum information science is string theory, even parts of mathematics is string theory. At some point, the term “string theory” itself will become such a general term that “string theory is true” will become a tautology, which would make no sense to anybody even a decade ago.

6. **Sabine**
December 23, 2021

Contrary to what most particle physicists believe and will tell you (and have written), arguments from naturalness never worked as predictions. The one case where that isn’t obvious is the charm quark but what they called “naturalness” in that prediction is not what they call (technical) naturalness today* (it’s rather an argument from simplicity – pairing up the quarks increased predictive power). As Witten correctly notices, naturalness turned out to be just wrong: neither the CC nor the mass of the Higgs boson is technically natural.

What particle physicists should do at this point is

(a) abandon naturalness rather than trying to bring it back in modified fashion and
(b) understand how it could possibly happen that so many particle physicists believed in a criterion that’s so obviously unscientific as this, and then
(c) prevent the same problem from happening again for other unscientific ideas

As to the multiverse. This idea is promoted by people who mistake math for reality and who don’t understand what a scientific explanation is. Saying that all values of a constant “exist” if you can only ever observe one value is both scientific and philosophical nonsense, and if you, after you’ve said that, still have to assume the constant has that value which you actually observe, then you haven’t explained anything. Re-expressing a set of constants by the maximum of some probability distribution just adds a completely superfluous story.

Also, I have noticed a few times that the title of my book “Lost in Math” has taken on a meaning on its own. I want to stress that the message of my book was NOT to criticize the use of mathematics in physics, but rather to say that physicists do not take math seriously enough.

Merry Christmas everybody 🙂

* Incidentally, I got this wrong in my book. I have regrets.

7. **Eric Weinstein**
December 23, 2021

Nice Dylan reference Peter.

If I might try something a bit out of pure physics, it is worthwhile asking why stagnation issues are afflicting the most theoretical disciplines across different fields. Neo-classical theory also became the dominant paradigm in economic theory as did the neo-darwinian synthesis in evolutionary biology.

In all these cases, it feels like there was something special about the particular time when the idea hardened into dogma. I didn’t get to watch biology or economics when this happened. But in physics it was clearer because it happened more recently. I don’t think we could have a new dogma now. No person on the scene is invested with sufficient power at this moment to create dogma the way String Theory became nearly religious in the devotion it inspired in its 1980s practitioners.

My sense is that this phenomenon of a field becoming dogmatic is personality dependent. Arrow, Samuelson, Friedman etc were all very different titans of economics. In biology, Triver, Williams, Dawkins, Alexander etc. were similarly giants. In Physics, we have only had Witten at that level for a long time (1980-2000 ish) with support from Juan, Nima etc in physics and Atiyah, Singer, Quillen, Segal, Freed, etc in math. But it felt for a long time that, often enough, only Witten fullly understood the plot.

So my thought is that this is a bit like Greenspan admiting that, as the former oracle, he didn’t know fully what he was doing with the economy after all. He was all alone in that. Likewise, I fear it’s not really about the leadership of Witten, Gross, Vafa, Strominger, Seiberg etc. It’s really about Ed. Many years ago Joe Polchinski said to me ‘You keep mentioning String Theory Eric, but I am never sure whether String Theory really exists as a proper discipline or community…or whether we are merely runnning sub-routines for Ed.’

I don’t know what to make of this. But it seems like a pretty important moment for the health of the field to free your younger colleagues and do what Greenspan did: admit you made a serious error in leadership judgement.

I honestly don’t know why this group of leaders isn’t more concerned with the story of their stewardship of this field. Were I in their shoes, I imagine I might be thinking like Eisenhower did before his ‘Military Industrial Complex’ farewell address. Why not turn over a field that doesn’t have to labor under your unjustified pronouncements about the divine nature of Strings from 40 years ago? Give your intellectual descedents a new lease on life. This isn’t learning to love the landscape or appreciating anthropics after all. It’s really about admitting a catastrophic error in leadership judgment. And I think highly enough of Ed and company to think that they should do it out of love and concern for the field at their ages. But, what do I know.

“Those of us who have looked to the self-interest of lending institutions to protect shareholders’ equity, myself included, are in a state of shocked disbelief,…Yes, I’ve found a flaw. I don’t know how significant or permanent it is. But I’ve been very distressed by that fact.” -Alan Greenspan at 82

Physics is a science….so we should be able to do as well as the economists and financiers I would imagine. No? Something to think about anyway.

Dear Paolo, is “It From Qbit” a politically-correct way of saying “From It to Qbit”? Seasonal Greetings.

9. **Andrew Thomas**
December 23, 2021

I agree with your positive initial feelings about string theorists accepting the multiverse. It’s an admission that string theory has come to the end of the line. I’m not saying string theory is wrong, but this is the clearest possible admission that “there’s nothing to see, here”, and there’s now no longer any expectation that much of interest is going to come from continued research in string theory. Hopefully new students will take this as a coded message that they would be better off working on something else instead. It’s definitely a positive thing.

10. **Anonymous**
December 23, 2021

“Fundamental physical theory may now be over, replaced with a pseudo-science, but at least that means that things in this subject can’t get any worse”?

That brings to mind the Soviet era distinction between an optimist and a pessimist: an optimist thinks that things are as bad as they could possibly get, while a pessimist thinks things could always be worse. I’m not sure your optimism is justified, Peter, but perhaps it was meant as seasonal cheer. In any case, enjoy the holidays.

December 23, 2021

Anonymous,
I was tempted to end the posting with “Merry Fucking Christmas”, but thought better of it…

12. **John**
December 23, 2021

The issue with the current state of string theory is that too many string theorists have for far too long been studying string theories that were supersymmetric, which is not true in our world, and then equated string theory with superstring theory. And then they discovered that there are at least 10^500 different superstring theories, and decided that the multiverse and anthropic reasoning was necessary to explain the 10^500 superstring theories, all while ignoring that none of the multiverse or anthropic reasoning is even necessary because our world isn’t supersymmetric so none of the 10^500 theories even matter. And this has become especially apparent after the LHC results showed the non-existence of supersymmetry in the real world.

If string theorists were actually serious about string theory as a fundamental physical theory, they would admit that the past 40 years, since the first superstring revolution, has been a wrong turn in the string theory research program, and then start over and begin searching for a consistent and stable non-supersymmetric string theory that has all the Standard Model particles and a spin 2 particle for gravity. Instead, the previous string theory holdouts against this multiverse nonsense, especially Ed Witten, the leader of the first superstring revolution, have not only failed to admit that superstring theories are a failed idea and that people should pursue alternative non-supersymmetric string theory approaches, they also have accepted the multiverse and largely given up on the string theory research program entirely, moving on to other fields such as the gauge/gravity duality research program in quantum field theory. Ed Witten and David Gross may say that a century into the future and we might see a string theory develop that might explain the Standard Model or QCD, but if nobody is working on (non-supersymmetric) string theory due to the acceptance of the multiverse and anthropic reasoning in the string theory community, I don’t see how string theory would make any progress in a century from where it is today.

13. **Mitchell Porter**
December 23, 2021

I would ask the commenters on this blog, who so dislike multiverse ideas and the anthropic principle and especially their combination… Do you have any thoughts on the possibility that that is how nature is? Do you just think that’s impossible or unlikely; do you think it is possible, but if it is so, it is inherently beyond the reach of science; or what?

I will add that I am not objecting to the pursuit of theories that still hope to explain reality in terms of something unique. I am just wondering how categorical the association between “anthropic multiverse” and “unscientific” is.

14. **Peter Woit**
December 23, 2021

Mitchell Porter,
Maybe there is a multiverse, maybe there isn’t. I have no idea and don’t really have any feelings about it one way or another. But multiverse theories are pseudo-science unless they come with some scientific way of finding evidence for whether they are true or not. The problem with the string theory anthropic landscape multiverse is that there is nothing of this kind, see

https://www.math.columbia.edu/~woit/wordpress/?faq=why-do-you-describe-the-multiverse-as-pseudo-science

What is going on here is that the “multiverse” is being used not as a scientific explanation of anything, but as an excuse for not admitting a theory is a failure. Calling this “pseudo-science” is actually being charitable (less charitable would be something like “dishonest bunch of crap”….).

15. **Peter Woit**
December 23, 2021

John,
Over the years many string theorists have tried to get around problems with using the superstring in 10d by finding string theories that work in other space-time dimensions or are not supersymmetric. The problem is that no one sees any way to do this. The standard theory of a non-supersymmetric string seems to need 26 space-

time dimensions and even in that case has a tachyon. From early on in the subject, trying to get around this is something many people have worked on, unsuccessfully.

16. **Michael McGuigan**
December 24, 2021

John,

There was a small resurgence of interest in non supersymmetric string theory after the LHC failed to discover supersymmetry. Much of the work was based on the tachyon free SO(16)xSO(16)' Model in 10d or non Supersymmetric orbifolds. See for example:

https://arxiv.org/abs/1407.6362
https://arxiv.org/abs/1502.03087
https://arxiv.org/abs/1907.01944

There should probably be a workshop bring interested people together to develop this idea further and see what the implications are for particle physics.

Sent from my iPhone

17. **History observer**
December 24, 2021

It has been complained many times on this blog that the young generation of physicists is dangerously being indoctrinated by the string theory-multiverse-anthropic ideas by the senior leaders of the field and/or by media. However, I find Weinstein's comment above particularly relevant for understanding the important difference between the mindset of the past century's young generation of physicists and the present day young generation of physics. Even Einstein was not taken back then as a leader in fundamental physics by the young generation of physicists. Very few followed him in his quest for a unified theory the way he *envisioned* it. That young generation found for itself the right path for progress and did not fall into delusion because of a great figure. That the present day generation is easily indoctrinated by media and/or by any senior investigator in a field actually reveals the value such a generation could in any case bring to the said field, even if it were not indoctrinated in the first place.

18. **John Peacock**
December 24, 2021

I can understand your negative outlook on anthropic reasoning in the specific context of string theory – indeed it would be a shame to abandon the aim of deepening our understanding beyond the great success of the standard model, especially if there is a risk of giving up too soon and too easily. But I can't see that this alone explains or justifies your apparent hostility to every aspect of the multiverse. The logic of using observer selection in an ensemble to explain apparent fine tuning works fine in some contexts: we certainly didn't need modern observations of thousands of exoplanets to be completely sure that they were there. Outside religion, the idea of winning a cosmic lottery is the only way to explain how the Earth happens to be the right distance from the Sun to permit life. With the cosmological constant, Lambda, we have a much stranger coincidence to explain; and in the absence of any idea of how its value might be explained from first principles, it seems reasonable to me to consider observer selection as a possible explanation. That would be true even if we didn't have strong-field inflation models as a worked example to show that it is possible to generate an ensemble of causally disconnected universes; and certainly the discussion of multiverse issues in cosmology should not be tied to the specifics of inflation or string theory. Weinberg showed us that we can still make progress without such assumptions in the case where only Lambda varies within the multiverse, and this is a testable model: it predicts the posterior for Lambda, which can be compared with the single datum of the observed value. This is hardly precision cosmology, but it's something. The existence of this calculation encourages one to think about specific issues, namely how much the efficiency of galaxy formation is suppressed in counter-factual models with increased Lambda. If the suppression is not large, then this model is ruled out and we would conclude either that there is no multiverse, or that more than one parameter varies within the ensemble. In fact, the best existing calculations indicate that the suppression is just about sufficient, and Weinberg's model survives (https://arxiv.org/abs/1801.08781). This isn't exactly a great triumph, since the other members of any ensemble cannot be observed – so yes the situation in cosmology is very different from the one in exoplanets, even if the initial logic is the same. What we are talking about here represents reaching the end of the road for experimental science – but that hardly proves that this isn't the way things are. Of course we should continue to search vigorously for unique physical explanations of the parameters in our current theories; but this has been going on with little success for long enough, and therefore it seems to me that cosmologists are entirely justified in pursuing the parallel route of seeing where multiverse reasoning can take us.

19. **Johan Smit**
December 24, 2021

John,

People have discovered that any tachyon-free string theory has to have some remnant supersymmetry, even if it is a broken misaligned supersymmetry.

https://arxiv.org/abs/hep-th/9402006

So you are out of luck if you want to abandon supersymmetry completely but keep string theory.

20. **Peter Woit**
December 24, 2021

John Peacock,
My objections to the cosmological multiverse are in the context of using it to justify empty or failed ideas about fundamental theory, and, even worse, to then use this as an argument against any attempt to better understand fundamental theory.

I don't have any objection to people positing a cosmological multiverse and seeing what they can get out of the idea. It is a problem though that people doing this often overhype what they are getting, and engage in misleading claims about implications for fundamental theory.

The Weinberg argument is a good example: as far as fundamental theory goes, it's based on assuming a roughly flat measure on the CC in the relevant region, any CC equally likely. This isn't much different than saying we know nothing about what the fundamental physics of the CC is. Somehow this gets magically turned into an argument for the string theory landscape, or for assuming there is no point to even trying to understand the fundamental origin of the CC.

21. **shantanu**
December 24, 2021

Peter: Witten also doesn't seem too excited about neutrino experiments and I am surprised that the interviewee did not ask anything about non-0 neutrino mass, which is "supposed" to be evidence of physics beyond the standard model

22. **Alessandro Strumia**
December 24, 2021

Michael, how do you get flavour from the SO(16)xSO(16)' string where the Higgs is the extra-dimensional component of a vector (so, its Yukawas are gauge couplings)?

23. **Michael McGuigan**
December 24, 2021

Allessandro,

Yes that's correct, the SO(16)xSO(16)' Model has no gauged scalars in 10d and Higgs type fields come from components of the higher dimensional gauge field in the simplest situation, with Yukawa interactions coming from higher dimensional gauge interactions, with the fermions and number of generations (flavors) related to the Euler characteristic. The other references talk about more complicated situations as well that can give rise to a Higgs type field. Like I said it would be nice to have a workshop to discuss these things.

24. **S**
December 24, 2021

John Peacock,

You write that "Outside religion, the idea of winning a cosmic lottery is the only way to explain how the Earth happens to be the right distance from the Sun to permit life," and also "What we are talking about here represents reaching the end of the road for experimental science – but that hardly proves that this isn't the way things are."

It seems to me the juxtaposition of these two shows why it's problematic for *physics* to go down this road. The fact that the alternate explanation(s) are religious also doesn't prove that *that's* not how things are — but religion isn't physics. It's perfectly possible, as you say, that there's a multiverse or what have you, but surely it's a relevant question to consider when the speculations of what might be have trailed into being equivalent to religious musings and are no longer physics?

(That's not to it's fundamentally impossible to discuss predictions of the model, a la Weinberg. My point is just that "This might just be how things are" does not mean that whatever "this" is is physics.)

25. **Lars**
December 25, 2021

"I suppose I reluctantly came to accept that the universe was not created for our convenience in understanding it." — Edward Witten

I don't understand what that is supposed to mean.

How is it a justification for accepting the anthropic principle and multiverse?

Is assuming that the physical constants, fundamental particles etc are what they are for some physical reason (ie, not just random variation of values in a multiverse that just happened to produce the conditions where humans came about) the same as assuming the universe was created for our convenience in understanding it?

I don't get it.

26. **DH**
December 25, 2021

Mitchell Porter,

I for one don't consider multiverse theories or anthropic reasoning to be inherently troubling/impossible/unscientific/etc. If it ultimately turns out that an inflationary multiverse seems to be a necessary implication of the best available evidence, then so be it–once again we become smaller, like we did with Copernicus and Hubble.

However, I share the first commenter's puzzlement that Witten seems to casually conflate this with the multiverse of Everettian QM–as though "the anthropic alternative" has any meaning/power as a concept in its own right, irrespective of the specific physical account of why a "landscape" exists & what it consists of. He says he "has no idea whether this interpretation is correct," but what he posited there is not even AN interpretation, it's a weird mishmash of completely different ideas that happen to share the (potential) necessity of embracing anthropic reasoning.

So I don't dislike multiverse ideas in general, but I also think it's borderline meaningless to discuss/assess them "in general." That there may be regions of spacetime that are wholly & permanently separate from ours, sufficiently so to consider them "different universes," seems to me a perfectly sensible idea (though I lack the expertise to assess it). A mathematical multiverse that arises from philosophically reifying the Schrödinger equation is another matter entirely (probably you can tell I think it's nonsense, but regardless, I think everyone should at least be able to agree that it's another matter!).

At times I think some of our most prominent theorists are essentially becoming Platonic idealists, while being too philosophically naive to even realize that that's what they're doing. Regardless of whether this is "unscientific," it's certainly…something.

27. **Anon**
December 26, 2021

I don't see how the multiverse explanation can work if the basic theory has supersymmetry (such as superstring thy). Wouldn't the landscape be dominated by the Minimal SUSY Std Model (MSSM) vacua as compared to the Standard Model vacua, precisely because of the hierarchy problem? Or are we imagining that in most other universes of the multiverse where there is galaxy formation/intelligent life, their Large Hadron Colliders (or even the LEP) will discover SUSY?

28. **Peter Woit**
December 26, 2021

Lars,
I think the Witten quote gives away what's really at issue. This is not about the multiverse but about whether one can claim to have a successful unified theory even if it is a theory that cannot be tested, with specific reference to the string theory and its purported landscape of vacua.

Pre-LHC, whenever Witten and others were challenged about the testability of string theory they would point to the possibility of the LHC finding at least indirect evidence for string theory (via SUSY). With that possibility now closed off, Witten has been put in the situation of having to either give up on the theory or try to defend the concept of a theory that can't possibly be tested. He's taking the second option and that's what the quoted argument is all about.

29. **Peter Woit**
December 26, 2021

DH (and others),

I agree that it's meaningless to discuss multiverse theories "in general". To have a sensible discussion it needs to be about a specific set of models (or "framework" if you like). If your argument is not about the string theory landscape set of models, please, no more. On this specific issue I've devoted a huge amount of effort over the years to trying to understand exactly how such models work, and I don't see anyway around the conclusion that this is a vacuous framework.

30. **Peter Woit**
December 26, 2021

Anon,

The anthropic argument has nothing to say about SUSY: either SUSY or non-SUSY vacua are consistent with our existence. When the string landscape program got started 20 years ago Susskind and others argued that it was predictive, that it could predict whether the LHC would see SUSY: just count the number of vacua with TeV-scale SUSY and those without. If there were a lot more of one than the other, than you would have a statistical prediction for what the LHC would see.

That never worked out, basically for the same reason the string theory landscape can never make predictions: it's not well-defined enough to allow one to know what's a string theory vacuum and what isn't. You know far too little about what the theory is that you're talking about to know how to characterize string theory vacua in general (much less count them).

31. **Johan Smit**
December 26, 2021

skydivephil has put a poll on Twitter asking who won the debate between Rovelli and Gross, and over two-thirds of the respondents said that Rovelli won:

https://twitter.com/skydivephil/status/1472635458438021127

32. **The Big Red Scary**
December 27, 2021

"Things got a bit worrisome at the end, when he announced that he can't understand Kevin Costello these days (if he can't, who can?)"

Presumably Kontsevich hasn't really tried, or he has tried and he has understood, but doesn't want to admit it since he's not the king of that hill. Andre Weil claimed not to understand schemes, but I once heard a protege of his say that, upon being left alone in Weil's office, he pulled Weil's copy of Grothendieck's EGA off the shelf and found every page full of carefully penciled remarks.

I can well imagine that Costello is hard to read for almost all physicists, and I have no idea whether it is interesting as theoretical physics, but it's fine mathematics and not so very hard to understand if you put the time into it.

33. **Steve Burton**
December 29, 2021

I believe that the correct Churchill quote is actually:
"never give in, never give in, never, never, never, never-in nothing, great or small, large or petty — never give in except to convictions of honour and good sense. Never yield to force; never yield to the apparently overwhelming might of the enemy. . . "

Here's a link to a reference:
https://www.nationalchurchillmuseum.org/never-give-in-never-never-never.html

IMO (1) the difference between "give up" and "give in" is subtle, but important, and
(2) the entire document at the link is worth a read.

Cheers!

34. **Peter Woit**
December 30, 2021

Steve Burton,
When I wrote about the Gross quote in the last chapter of my book Not Even Wrong, I did discuss the Churchill quote and point out that Gross's version was not accurate.

What struck me at the time was that Gross was comparing the threat to science from the anthropic landscape with the threat to England of defeat and occupation by the Nazis. Nearly 20 years later, what I find striking about his not mentioning this now is that by his own comparison he has decided to give in and do something comparable to accepting Nazi occupation.

35. **Paolo Bertozzini**
December 30, 2021

@ Johan Smit

I totally agree that the habit to "redefine as String Theory" whatever comes handy for "leading String Theorists" is ubiquitous and disgusting.

On the other hand, I notice that this is unfortunately a characteristic of the current cultural supremacy of aggressive marketing over anything else (most of science today is de-facto reduced to a "branch of marketing"): creating an "influential marketing channel" is an extremely difficult (often random) and resource consuming task and hence it is more and more common to have ideas, techniques or area "rebranded" on-purpose, often forgetting the original motivations and history of that subjects.

At the end of the day (if one is able to swallow His-Her own pride and ambition for recognition) the important is that certain crucial ideas achieve the attention they deserve (maybe with a different name and pursued by different groups of researchers) … the huge problem is that the hype implicit in this aggressive "marketing" often distorts the discussion, so that certain biases become almost impossible to discuss or correct: as a result, essential changes are hold back and might become effective only decades after their original inception.

One example of such "rigidity" is the usage of " (bad) excuses" to justify at all costs the validity of a research program that has otherwise failed some or all of its initial goals: this, as Peter said, is the real role of "multiverses" in this String theoretic context.

On a more positive side (as I suggested in my original post), I personally see as promising that the real focus of interest is shifting to other nearby areas (and maybe people do not even bother to make opposition to previous questionable points). For example, I am very happy to see a revival of themes from Algebraic Quantum Field Theory (as explicit case, here are the last pre-prints from Witten: https://arxiv.org/abs/2112.11614, https://arxiv.org/abs/2112.12828) … although several of these ideas/techniques could have been explored decades ago 😉

I would be very interested to know Peter's opinion on these specific works.

@ Alessandro Strumia

As we all know, "It from Qbit" is just a quantum byproduct of the "If from Bit" originating from Wheeler. "Digital Physics" has an independent tradition significantly older than anything related to String Theory (and most of all the "Quantum hype" is today even more "influential") so a "rebranding" in the above-mentioned sense might not be so easy in this case. I would completely agree that "From *It* to Qbit" sounds much more appropriate as a description of what has been actually happening 😉

Sorry for the late reply (but here it is end of the academic semester and I was really submerged with work). Happy New Year 2022 🙂

36. **Roger**
January 4, 2022

Off-topic.
RIP the Bogdanoffs. They played an entertaining and not insignificant role in the String Wars.
https://www.bbc.com/news/world-europe-59867046

37. **Cedric BARDOT**
January 5, 2022

In the CERN Courrier interview Witten says about string theory:

> This framework has turned out to be very powerful, even if one is not motivated by gravity and one is just searching for new understanding of ordinary quantum field theory.

This reminds me of a remark by 't Hooft in

> … there is ample information in what we already know, but not fully understand, even when it sounds as boring as perturbative quantum field theory and perturbative gravity in the Schwarzschild background

If "powerful" = "useful (for theoretical physicists)", I find his comment relevant at least in the current context emphasized by Paolo Bertozzini. Algebraic quantum field theory in curved space-time might experience indeed a revival with particularly pedagogical efforts done by Witten in his recent preprints to explain to youngsters (engaged in solid theoretical research in natural geometric structures) the subtleties of type III von Neumann algebras & show them why these oldies but goldies are required in trying to make some sense from (not be fulled by?) the rare computable models available to "quantum gravity" explorers.

The connection is loose but it would be funny if Leutheusser & Liu work "Emergent Times In Holographic Duality" under the scrutiny of Witten could help to make some progress in the thermal time hypothesis of Rovelli & Connes…
I wonder if Paolo Bertozzini has an educated guess on this subject.

38. **Mark**
January 6, 2022

Interesting to see in Witten's own words the devolution of the string theory research programme from a theory of unification of all the forces, to a theory of quantum gravity, to merely being a framework for providing tools to understand quantum field theory better. If so, then theoretical particle physics will have returned to the state it was before the first superstring revolution, where the dominant paradigm was quantum field theory, and everything else (including string theory) is studied for possible applications to quantum field theory.

39. **Paolo Bertozzini**
January 10, 2022

@ Cedric Bardot

I agree that "old" (algebraic) quantum field theory will have several further surprises in store (also for quantum gravity); if they will find better reception by the theoretical physics community, it is probably because the current AdS/CFT and holography trends (coupled with the impasses in string theory) are forcing people in that direction.

As regards the "thermal time hypothesis": from a very approximate first reading of the work of Leutheusser Liu, the "emergent time" evolution, although not directly coinciding with a Tomita-Takesaki modular flow (used in the Connes-Rovelli thermal time case), is anyway obtained from the Borchers-Wiesbrock half sided modular inclusions (the generator has positive spectrum) and so the connection is not that far away.

Elaborating on the deep interplay between modular theory and geometry is of course extremely tempting form me (and I would seriously risk of running out of topic). My suggestion has always been that modular theory provides a "thermal non-commutative space-time" (instead of just a classical "emergent thermal time") – I think I have been pestering Carlo in many conferences with comments on this topic 🙂

Leaving aside technical important points, the present wide consensus on the *emergent nature of space-time* in quantum gravity (that was recently mentioned by Peter on this blog) is probably the most serious obstacle for attempts in the above mentioned direction. In any case, the usage of methods from Tomita-Takesaki modular theory will continue to spread: the importance of modular theory is not related to specific models (and goes even beyond the area of von Neumann algebras) since it is an ubiquitous feature of complexification of ortho-symplectic spaces; it will likely lead to further intriguing links with *analytic continuation (Wick rotation / Osterwalder Schrader reflection positivity) and geometry* – see recent works by Longo and by Neeb Olafsson (that is another reason why I was asking Peter's opinion on such developments).

Sorry if I went a bit "tangential" 🙂

Igor and Grichka Bogdanoff 1949-2021/22

January 4, 2022
Categories: Obituaries

A few days ago I heard news from Paris of the death of Grichka Bogdanoff on Dec. 28, and this morning heard of the death yesterday of his twin brother Igor. There are many news stories online (e.g. here), and Lubos Motl has written about them here.

There's a chapter in my book *Not Even Wrong* about "The Bogdanov Affair", and quite a few blog postings here referred to the twins and their activities related to theoretical physics. The motivations for writing about them were always two-fold. That they had managed to get more or less nonsensical papers published in reputable physics journals in 2001-2 (*Annals of Physics* and *Classical and Quantum Gravity*) raised important questions about how one evaluates speculative theoretical physics research. But also, the whole story had many comic aspects (see for instance here). I always supposed that to some extent the brothers were in on the joke and I hope that was true. At one point they invited me to come see them when I was in Paris, but I decided not to take them up on the offer, since it seemed best to keep one's distance from whatever they were doing. In recent years I hadn't been following at all their activities.

There's a darkly comedic aspect to this and other examples of prominent people opposed to COVID vaccinations succumbing themselves to the disease. I'm sorry that this happened to the brothers, putting a final all too avoidable tragedy at the end of their remarkable life stories.

Comments

1. **FG**
   January 5, 2022

   To be fair, although unvaccinated, there were not proselyte about it. Instead, they seemed to have some kind of sentiment of superiority over the populace, as in "not only we are much smarter than you, but our body natural strength is also far superior and can go through anything unharmed". Perhaps, since they were well known, and highly regarded in the pseudo-science circles that the antivax seem to frequent, there deaths will open the eyes of some.

   Being in France, it is a bit depressing to read their obituaries in the general press, where science illiterate journalists present them as "doctors in theoretical physics and mathematics" most often without any mention of the vivid negative reactions in the french physics community when they were granted PhDs. And for those newpapers that mention it in passing, they tend to present it as a "controversy" (like something which is a matter of opinion, rather than a scientific issue), as if the physics circles had been split about the value of their works.

2. **cgh**
   January 5, 2022

   My memory will not be accurate on all this but spanning the years between the Sokal and Bogdanoff affairs there were a number of examples of randomly worded papers being discussed and I recall websites (one at MIT if I remember correctly) that would randomly generate scientific papers. At the time I was publishing in peer reviewed journals in areas of mathematical physics less hifalutin than string theory and it wasn't always easy. Referees challenged things, asked for wordmithing, simplification. Sometimes it was legitimate and other times I disagreed. Sometimes it seemed petty (as academics is wont to…) Sometimes it was annoying – I recall one time when I submitted two papers that I felt stood on their own but was asked to combine them by the same journal and, when I did, spent months arguing over issues related to combining disparate ideas in one paper. My point being that, for much of physics, it's an effort to get things final and published in peer-reviewed, major journals (with the old page fees), as it should be, despite the pettiness and politics of publishing original academic work. At the time it struck me as very strange that qg, hep-th, could have these types of issues. Looking back it doesn't strike me as strange.

3. **Peter Woit**
   January 5, 2022

   cgh,
   I don't want to here get into the endless topic of the problems of the refereeing system. The Bogdanoff papers were an interesting test case though for this system. I'm pretty sure the brothers thought they were doing real scientific work. They were not writing a hoax paper a la Sokal designed specifically to fool a referee, but what they were writing was nonsensical and a working referee system should have immediately picked this up.

   The criticism I often got for writing about this story was along the lines of "sure, there are lots of bad papers getting published in bad journals, so what?". Here though at least a couple of the journals (Annals of Physics and Classical and Quantum Gravity) were quite reputable ones. This test case showed that their refereeing system could not distinguish sense from nonsense.

   I think the source of the problem is deeper than that referees are sometimes lazy and incompetent. The problem of quantum gravity research that is so incoherent that it's hard to evaluate is one that has not gotten any better in the past twenty years.

   I'm resisting the temptation to start pointing to recent examples of such research that I personally can't make sense of. The problem with incoherent research is that it often requires a lot of time and effort to be sure there's not something interesting there that you are missing, and doing almost anything else with your time would be more worthwhile. I'm sure that's a large part of the explanation of why referees allowed the Bogdanoff papers to be published.

4. **Pascal**
   January 6, 2022

   According to the above mentioned post by Lubos Motl, the scientific work by the Bogdanov brothers does make sense. Or at least, it's not more nonsensical than average. In his own words:
   "While I wouldn't see their dissertation as a fully meaningful foundation for further exciting research, I think that the papers were at least comparable with the average work that can earn PhDs."

5. **Jonathan Chiche**
   January 6, 2022

   As regards the statement "I always supposed that to some extent the brothers were in on the joke and I hope that was true": I still recall what I was told, back in the period 2005-2010, about the way the brothers had written their theses, how the head of École Polytechnique had been ordered to let one of them defend his thesis in the school's premises, and the curt and dismissive reply made by the PhD candidate to a mathematician in the audience pointing out that what he had just heard did not make any sense. Unfortunately, I do not think anyone gave any public complete account regarding these matters at the time, and what remains is but hearsay. Thus, in a sense, this affair should have been taken more seriously. The truth would have been much clearer now. It could have been a valuable experience to meet them in Paris and try to get a precise and meaningful scientific statement from them. It may sometimes be hard to tell fraud and good faith apart, but the twins were delusional at best.

Among the obituaries in French, I find this one quite telling: https://www.lefigaro.fr/vox/medias/grichka-bogdanoff-un-etre-exquis-d-une-prodigieuse-intelligence-et-d-une-vaste-culture-20211228. You may think that the author too, writing, among other things, about Grichka Bogdanoff, "avait-il réellement un âge, lui qui, fervent amant des deux infinis pascaliens, transcendait toute limite spatio-temporelle", is in on the joke. Alas, it is clearly not a joke.

You may also want to listen to the interview given (in French) by the Bogdanoff brothers on 6 December 2021: https://www.youtube.com/watch?v=KCQW6zabA1A. They make laudatory statements about a French self-proclaimed elite scientist who, in the last two years, has been one of the major sources of disinformation regarding the current pandemic, and whose fraudulent papers and misleading Youtube videos are clearly no joke either.

All in all, giving the Bogdanoff brothers the benefit of the doubt seems overly cautious, and especially surprising on this blog.

6. **Peter Woit**
January 6, 2022

Pascal,
Lubos's involvement in this is one of the "comic aspects" I had in mind, in particular his book "The Bogdanov Equation", see
https://www.math.columbia.edu/~woit/wordpress/?p=3594

Jonathan Chiche,
Charitably giving people the benefit of the doubt is my general policy. In this case though I should point out by that by "in on the joke" I meant that quite possibly the brothers were not completely delusional about the value of their research. A less charitable way of saying they were "in on the joke" would be to say that they were more than a bit con artists.

7. **Roger**
January 6, 2022

I'm not sure I can draw any other conclusion than that they were a pair of dishonest chancers. Setting aside the comical aspects of the affair, there was far too much deceit in what they did (eg the fake Professor Yang, fake research institutes etc.).

It suited their reputational goals and vanity to be regarded as having contributed to physics research so they sought to convince the public and academic committees that they had done this. In a way the checks and balances built into the system worked even if this was imperfect. They may have succeeded in getting something into the literature and gaining PhD's (albeit with the lowest passing grades) but their work is generally regarded as being either nonsense or simply to be ignored.

It is rightly customary to focus on the positives when discussing the deceased. However, I only know of the twins through the negatives and I see nothing in their behaviour that leads to any sympathy for them. I wish it were otherwise.

8. **Peter Woit**
January 6, 2022

Roger,
As far as theoretical physics goes, the brothers were con artists, but I'd argue that the way they went about this had a fair amount of entertainment value and did no actual damage to the field. Theoretical physics has other con artists, who generally provide no entertainment value and have done a great deal of damage…

9. **Jackiw–Teitelboim**
January 6, 2022

Interesting… retired string theorists are people with the curious divertissement of writing books with unpresuming titles such as: L'Équation Bogdanov, The God Equation, The Cosmic Landscape etc.

10. **Frank Wilhoit**
January 7, 2022

I keep coming back to the quote from Roman Jackiw: "…It showed some originality and some familiarity with the jargon. ***That's all I ask.***" Here is someone who did real work, yet when to comes to students, "all he asks" is ***a purely literary operation***, which, as any of us who have ever written an academic paper knows, is trivial. Nothing could better encapsulate the bottomless cynicism of [what] the educational enterprise [has been reduced to]; and parallels exist in every area of study, not just physics, not just science.

11. **John Baez**
January 8, 2022

This [video on the Bogdanoffs]() talks about some curious aspects of their later life I hadn't known about, but concludes with something I'd never imagined: the theory that Moshe Flato encouraged them to get PhDs, and supported their research, as a kind of revenge against the physics establishment. I'm not convinced, but it's an interesting idea: a Sokal-like hoax perpetrated not *by* the Bogdanoffs but *using* them.

12. **jack morava**
January 8, 2022

Back in the day it was clear that the Bogdanoffs were an anomaly but perhaps not what kind, but now I think they are easily recognized as trolls.

13. **Peter Woit**
January 8, 2022

John Baez,
I knew Moshe, who was a truly wonderful character, and it's plausible his decision to supervise the Bogdanoff PhDs had an element of trouble-making in it. He died unexpectedly in 1998, before the brothers finished their PhDs, so if he had a plan about how this would work out, we'll never know what it was.

14. **Chris Oakley**
January 8, 2022

The video is interesting. Lubos nice and friendly, as usual, I note.
However I don't quite understand how the brothers getting PhDs *after* having falsely claimed that they had them in their books is going to make it right.
I suppose that there are some things that there is no point in trying to understand.

15. **JE**
January 11, 2022

The Sokal and Bogdanoff affairs, and even the Mochizuki one, bear some resemblance, no matter how different they may turn out to be, in the amount of attention and energy they take from the refereeing system and mass media. Of course, that's a large part of the explanation of why referees allowed the Bogdanoff papers to be published, but I am not quite sure they did no actual damage to the field, because media attention and referee energy are not unlimited. The Sokal affair was meant to raise doubts about the refereeing system, which is okay in principle. As a result, the refereeing system should now be more able to block moves in this direction. But did it really hit the target or quite the opposite?

16. **Peter Woit**
January 11, 2022

JE,
The Sokal hoax wasn't really aimed at the refereeing system, but aimed at showing that prominent figures in the "Science Studies" field were intellectually incompetent. The editorial collective at Social Text fell right into his trap, deciding to publish the hoax because it appealed to their prejudices, not bothering to have it refereed by an expert. Falling for the hoax publicly humiliated some prominent academics and made their field somewhat of a laughing-stock, with long-lasting and significant effects.

The Bogdanoff story I don't think had anything other than a temporary effect of making some editors more careful at certain journals.

The failure of the refereeing at PRIMS in the Mochizuki case is again a very different story, with very different reasons for the failure. There I think the damage caused is very significant, but localized in Kyoto.

17. **JE**
January 11, 2022

Peter,
No idea what Sokal's actual intentions were. He clearly knew that the journal was not refereed. I wonder why he, as a mathematical physicist, bothered to show that prominent figures in the "Science Studies" field were intellectually incompetent, other than "to attract attention to what he saw as a decline of standards of rigor in the academic community," as Weinberg put it. To this aim, perhaps the editors were viewed as easy targets, but maybe I am missing some important part of the story.
He recognized that the article had been "liberally salted with nonsense," and in his opinion was accepted only because "(a) it sounded good and (b) it flattered the editors' ideological preconceptions."
I agree that the Bogdanoff affair did not add much in this respect, or maybe just as a side-effect, and that Mochichuki's is another story, but did the Sokal hoax end with nonsense and goobledygook in science, did it achieve the opposite or was it just a sterile effort in this regard?

18. **Peter Woit**
January 11, 2022

JE,
I don't want to get into a discussion of the Sokal hoax story, which was fascinating, but rather different. His motivation was not to end nonsense and gobledygook in science, but in the a different field, which you might call cultural studies.

Actually, I just remembered that at some point long ago, when I was first starting to write about string theory I wrote to Sokal. Probably something like "besides the problem you exposed among the humanists, there's a real problem here in science itself, concerning string theory, and maybe you should be doing something about that". I don't think I ever heard back from him.

19. **Damien**
January 13, 2022

I met them at the time of the Bogdanoff affair (christmas 2002, new year 2003). Unable to understand their kind of physics, I wanted to know what they were about.

They were nice, warm, and I am positive 100% sincere about what they were doing. They were not "in the joke".

Contrary to what is said in an aforementioned video, they were not millionnaires. Acccording to a mutual friend, they lived their whole lives in debt. I am also convinced they never did plastic surgery. It would have been the worst plastic surgeon in the world.
I am convinced that their faces were altered by their taking more or less legal drugs in the hope of remaining young.
As I said, when I met them they looked sincere, but as it became clear that they had lied, engaged in sockpuppetry, modifide quotes about them, I set my opinion of them. They were fraud, whether they knew it ior not, maybe pathological liars.

20. **Pascal**
January 15, 2022

If I recall correctly, Sokal's grudge against some social scientists was that they would study "hard sciences" like physics as a purely social phenomenon, forgetting that scientific theories are grounded in experimental evidence.
Ironically, it seems that physicists have decided to show that the social scientists were right after all. Exhibit #1 is string theory: the main evidence for it seems to be that there are lots of string theorists, they hold powerful and prestigious positions, and they are able to silence their critics (with diminishing success, though).

21. **Anonyme**
January 20, 2022

The Bogdanovs were supposed to go on trial at the beginning of February for a very unglamorous story. This will not happen after all.

https://www.lemonde.fr/societe/article/2022/01/20/les-escrocs-presumes-d-un-millionnaire-bipolaire-juges-a-paris_6110172_3224.html

Yet More Math and Physics Items

January 14, 2022
Categories: Uncategorized

Various items that may be of interest:

- Robbert Dijkgraaf was sworn in a few days ago as Minister of Education, Culture and Science in the Dutch government. Unclear who if anyone is director of the IAS at the moment, but David Nirenberg will take on this position February 1. Nirenberg is currently a professor of medieval theology and director of the Divinity School at the University of Chicago. This will be the first time in thirty-five years that the IAS director has not been a mathematician or physicist (although some might argue that medieval theology and theoretical physics have seen a convergence in recent years…).
- Lieven Le Bruyn has a posting about Huawei's new research center in Paris (and adds more here), which seems to have attracted multiple Fields medalists, with Laurent Lafforgue's affiliation recently changing from IHES to Huawei. Lafforgue held the Huawei chair in algebraic geometry at the IHES, which now is in the market for a new Huawei chair in algebraic geometry. The head of Huawei has recently emphasized the importance to the company of "bringing in talent with 'tall noses'".
- An interesting way to keep track of hot topics in US theoretical HEP might be to watch the "white papers" starting to appear as part of the Snowmass 2021/2 exercise. Two examples now on the arXiv are a seven-author white paper on the Emergence of Spacetime and a three-author one on Celestial Holography. There will be a program on Celestial Holography at the PCTS in Princeton in a couple weeks.
- On the Mochizuki/abc front, Jordan Ellenberg on Twitter points to this recent preprint from Kirti Joshi. Joshi claims inspiration from the IUT papers, but writes in a much more conventional mathematical language, and makes no claims to prove abc or any other major new results in number theory. One might optimistically hope that his work would clarify the true significance of Mochizuki's IUT work.

Update: A very recent relevant paper from Joshi is this. It contains a detailed comparison of his point of view with Mochizuki's, but avoids taking any position on the controversial Corollary 3.12 claimed by Mochizuki.

Update: To clarify the above. In this paper (Theorem 10.1.1) Joshi proves his version of Mochizuki's Corollary 3.12. But importantly (in that paper): Along with Theorem 10.1.1, there is a discussion of why Joshi's version of Corollary 3.12 is different from Mochizuki's version and notably why his version does not imply Mochizuki's version (according to Joshi, the two versions work with two different ambient sets to compute the theta-values locus–Joshi's version uses a natural ambient set his theory provides–and it is deeply tied to Fargues-Fontaine Theory).

Comments

1. **Peter Orland**
   January 14, 2022

   I have no idea what sort of leader of the IAS Nirenberg will be, but in my highly uninformed opinion, he is a serious and interesting scholar. His book "Anti-Judaism" on a store shelf attracted my attention only by its seeming weird. I overruled my prejudices and leafed through it. Then I bought it and I read the thing in a day.

2. **Peter Orland**
   January 14, 2022

   … and I guess I did not know before that his father was also someone whose papers (on Sobolev inequalities) I had read.

3. **theoreticalminimum**
   January 15, 2022

   Maybe this could be of interest. Gallimard have published Grothendieck's R&S in two volumes and a fiction presumably inspired by the story of Perelman.

4. **DKepler**
   January 16, 2022

   …although some might argue that medieval theology and theoretical physics have seen a convergence in recent years…

   .

   Yes, some might argue the convergence, but it is unfair to drag whole of 'theoretical physics' into this. String theory is the 'only game in town' – at least in this regard. Your own posts on top string theorists promoting multiverse demonstrate this very well.

5. **Johan Smit**
   January 17, 2022

   Another physics item: David Tong published lecture notes for supersymmetric field theory, where he indicates that the primary reason for studying the topic is to understand quantum field theory better and find more connections to mathematics, rather than to find beyond standard model physics for which there is no evidence of.

   https://www.damtp.cam.ac.uk/user/tong/susy.html

6. **jackjohnson**
   January 18, 2022

   @ John Smit, Not that there's anything wrong with that?

7. **Johan Smit**
   January 18, 2022

   jackjohnson,

   There is nothing wrong with any of this. It's just more evidence of an ongoing paradigm shift in theoretical physics, where the connections to speculative beyond standard model physics gets de-emphasised (due to the lack of evidence for supersymmetry at the LHC) and the focus is turning towards theoretical quantum field theory and toy supersymmetric models. Ten years ago these lecture notes would probably have dedicated an entire chapter or two to supersymmetric extensions of the standard model like MSSM and possible phenomenology at the LHC.

String theory is headed in the same direction as well, with the focus turning away from trying to find a theory of quantum gravity or to unify all the forces, and instead studying toy string theory models (or really toy CFT models) and applying the results to other quantum field theories.

8. **jackjohnson**
   January 19, 2022

   @ johan smit, fair enough, thanks!

9. **anonymous**
   January 19, 2022

   Kirti Joshi published a part 2 of his Arithmetic Teichmuller spaces paper: https://arxiv.org/abs/2111.04890

10. **bertie**
    February 11, 2022

    So with the linked Kirti Joshi paper, he derives results analogous to the IUT stuff including a result 'of the same form' as Corollary 3.12 but I gather there is some problem getting bounds which are as tight as Mochizuki's otherwise Joshi would just go ahead and prove ABC wouldn't he? Joshi is exceedingly polite towards Mochizuki's work. However, if Joshi's analogous construction does everything that IUT does,with the single exception of proving ABC, wouldnt that look a little bit like a 'nail in the coffin'?

11. **Peter Woit**
    February 11, 2022

    bertie,
    My understanding is that Joshi is making no claims one way or another about Mochizuki's Corollary 3.12, in particular not claiming he knows how to prove (or disprove) it. Maybe it's a true statement, maybe it's not. One thing that remains the same is that no one can explain Mochizuki's proof of the statement in a convincing way.

This Week’s Hype

January 21, 2022
Categories: This Week's Hype

For many years, editions here of This Week’s Hype were mainly devoted to bogus claims that someone had found a way to get a testable prediction out of string theory or other “evidence for string theory”. Recently there have been many fewer such claims, with consensus in the string theory community that there is now no hope to get a prediction from string theory about observable physics at accessible energies. One can watch the recent talks here on Steven Weinberg and his legacy to get a good idea of what this current consensus looks like: you can’t test string theory since string effects occur at much too high an energy scale, and Weinberg showed that such things will just look like the Standard Model sort of QFT at observable energies. In addition, Weinberg is also credited with the anthropic CC argument, taken as evidence for the otherwise unobservable string theory landscape. Taken together, the consensus of leading particle theorists has become that there’s no point to trying to do any better than the Standard Model, with the only answer available to anyone who asks questions about higher energies is “string theory, whatever that is”.

With particle physics abandoned, theorists have focused on quantum gravity as the only legitimate issue to study. For many decades the hope was that a consistent answer to the unknown question of what string theory really is (often called “M-theory”) would be found, and that would provide a final end to the subject of fundamental physics. This final theory would be untestable, but it would self-consistently explain why one could not hope to test it. In recent years though, after decades of no progress towards a consistent M-theory, string theorists have essentially given up on this hope.

This situation has lead to a recent trend in string theory research: instead of looking for positive evidence for string theory, try to find an argument that resistance is hopeless, string theory is the only theory possible. The arguments of this kind I’ve seen make no sense to me, but they are gaining in influence. One place I noticed this is in this recent white paper about the interesting topic of celestial holography, which has little to do with string theory. There the authors write:

> A crowning achievement for the celestial holography program would be for it to determine concretely whether string theories are the only consistent theories of (asymptotically flat) quantum gravity.

Today Quanta magazine has more of this sort of thing, with an article whose title shows up on the web as A Correction to Einstein Hints At Evidence for String Theory. The sub-headline tells us that

> In a quest to map out a quantum theory of gravity, researchers have used logical rules to calculate how much Einstein’s theory must change. The result matches string theory perfectly.

which sounds pretty impressive. The article starts off with quotes such as:

> The hope is that you could prove the inevitability of string theory using these methods,” said David Simmons-Duffin, a theoretical physicist at the California Institute of Technology. “And I think this is a great first step towards that.

and

> Irene Valenzuela, a theoretical physicist at the Institute for Theoretical Physics at the Autonomous University of Madrid, agreed. “One of the questions is if string theory is the unique theory of quantum gravity or not,” she said. “This goes along the lines that string theory is unique.”

The paper at issue is this one which appeared on the arXiv nearly a year ago. It’s not about string theory or about conventional quantum gravity in four space-time dimensions. The topic is graviton scattering in maximally supersymmetric theories in ten flat space-time dimensions, and the argument is that the basic principles of supersymmetry, Lorentz invariance, analyticity and unitarity imply a bound on the coefficient of the lowest order correction term. The only relation to string theory is that a string theory calculation of this correction coefficient satisfies the bound (as expected, since string theory is supposed to satisfy the assumed basic principles). Much is made of the fact that in string theory one can get any value of the coefficient consistent with the bound. This is taken as evidence for the “inevitability” of string theory, but I don’t see this at all. It’s more accurately evidence for the usual problem with string theory: it’s consistent with anything. If the authors of this paper had found that the string theory bound was different than their bound, they could have written a paper arguing that they had finally found a way to falsify string theory (measure the coefficient, if it was found to be in the region allowed by general principles but not by string theory, string theory would be falsified).

The article does get right the motivations behind these claims:

> Some physicists hope to see string theory win hearts and minds by default, by being the only microscopic description of gravity that’s logically consistent. If researchers can prove “string universality,” as this is sometimes called — a monopoly of string theories among viable fundamental theories of nature — we’ll have no choice but to believe in hidden dimensions and an inaudible orchestra of strings.
>
> To string theory sympathizers, the new bootstrap calculation opens a route to eventually proving string universality, and it gets the journey off to a rip-roaring start.

and it gives a little space to skeptics:

> Other researchers disagree with those implications. Astrid Eichhorn, a theoretical physicist at the University of Southern Denmark and the University of Heidelberg who specializes in a non-stringy approach called asymptotically safe quantum gravity, told me, “I would consider the relevant setting to collect evidence for or against a given quantum theory of gravity to be four-dimensional and non-supersymmetric” universes, since this “best describes our world, at least so far.”
>
> Eichhorn pointed out that there might be unitary, Lorentz-invariant descriptions of gravitons in 4D that don’t make any sense in 10D. “Simply by this choice of setting one might have ruled out alternative quantum gravity approaches” that are viable, she said.
>
> Another critique, though, is that even if string theory saturates the range of allowed α values in the 10-dimensional setting the researchers probed, that doesn’t stop other theories from lying in the permitted range. “I don’t see any practical way we’re going to conclude that string theory is the only answer,” said Andrew Tolley of Imperial College London.

I don’t at all understand why Quanta chose to cover this. All it does is help to spread hype and further the cause of the “resistance is futile” campaign from proponents of a failed research program.

Update: This kind of hyped story turns into the expected PR result:

> **Evidence for String Theory** –In a quest to map out a quantum theory of gravity, researchers have used logical rules to calculate how much Einstein’s theory must change. The result matches string theory perfectly, reports Natalie Wolchover for Quanta.

Comments

1. **John Baez**
   January 21, 2022

   "Much is made of the fact that in string theory one can get any value of the coefficient consistent with the bound. This is taken as evidence for the "inevitability" of string theory, but I don't see this at all."

   The funny thing is, you don't even need to know much to notice the vast hole in this argument. You just need to pay attention to the overall logic. It's a bit like claiming I'm a good weatherman because I predict the probability of rain is somewhere between 0% and 100%. I'm "inevitably correct" in some sense, but it doesn't mean I'm any good.

   How can anyone be fooled by this, unless they want to be?

   The fact that this whole argument is about universes unlike our own – maximally supersymmetric theories in ten flat space-time dimensions – requires a bit more technical expertise to notice, at least if people are trying to hide it. But this, at least, is pointed out in the article: "Eichhorn pointed out that there might be unitary, Lorentz-invariant descriptions of gravitons in 4D that don't make any sense in 10D. "

   In other words, we should only think this whole calculation is relevant to real-world physics if we *already* buy into string theory.

   It's sad that *Quanta* is talking about this when there is really interesting physics being done.

2. **Dalimil Mazac**
   January 21, 2022

   @Peter Woit and John Baez, I find it hard to understand your skepticism. The article is addressing the important question whether there are consistent theories of quantum gravity other than string theory. It gives partial evidence that at least in 10D with maximal susy, the answer is no. I think that is pretty exciting! There are a lot of people doing fantastic and honest work along these lines nowadays and if anything, their work should be covered by science journalists more, not less.

3. **Peter Woit**
   January 21, 2022

   Dalimil Mazac,
   I've read the paper carefully and I see nothing there about any evidence there are no consistent quantum gravity theories other than string theory, even in the 10d maximal susy setting. The quote from Andrew Tolley (who I gather works on bootstrap methods) makes the relevant point: that string theory has alpha in the allowed range says nothing about whether or not there are other theories with alpha in the allowed range.

   I completely disagree with you that bogus claims that only string theory can describe quantum gravity deserve more coverage by science journalists and are "exciting" and "fantastic". They're the opposite of good science, part of a campaign to convince people that a failed research program is the only way forward.

4. **Dalimil Mazac**
   January 21, 2022

   @Peter Woit, the main point of the paper is not that string theory satisfies a bound (I agree that on its own would not be very interesting). Rather, the point is that the lower bound coming from the bootstrap constraints seems to coincide with the lowest value attainable in string theory. This was by no means guaranteed from the getgo.

   Of course, this is not a proof of uniqueness of string theory, but no one is claiming that it is. However, it is a first step of such a proof in the sense that it would become a proof if it could be extended from alpha to all the higher-order terms of the S-matrix.

   Finally, I can assure you that most people who work on these ideas would be equally excited if their work lead to the discovery of a previously overlooked quantum gravity theory, as they would be to prove the uniqueness of string theory. There is really no hidden agenda besides trying to understand new facts about nature using rigorous bootstrap methods.

5. **Peter Woit**
   January 21, 2022

   Dalimil Mazac,
   I'm still not seeing how string theory allowing any alpha consistent with general principles has anything to do with whether or not there's another theory also consistent with these principles.

   You can hope, like Chew and many others did during the 1960s, that your list of general principles constrains the S-matrix to be something unique. And you can hope that that thing is string theory (and that results in maximally supersymmetric 10d have something to do with non-supersymmetric 4d). But calling this result a "first step in a proof" of this I'm afraid well deserves the term "hype".

6. **S**
   January 22, 2022

   It's depressing that the world is currently in a place where (a) "believe science!" is a major campaign and (b) the world's smartest physicists seem to have bet the farm on a very straightforward example of affirming the consequent.

   (Of which, I must say, Dr. Mazac's two posts, in tandem, seem a clear illustration.)

   More and more it seems to me that the information environment we're in is characterized by the fact that there is just no safe consumption algorithm to teach anybody other than "be an extremely sophisticated consumer of information and mistrust everything you can't evaluate for yourself."

   Which is just terrible.

7. **Sabine**
   January 22, 2022

   Since no one's ever seen a graviton, they may for all we know not exist and the entire question is moot. When I refer to "quantum gravity" I always stress that this refers to any way to resolve the inconsistency between the SM and GR. It does not necessarily mean you actually quantize gravity. The question whether a quantization of gravity is internally consistent is different than the question whether a theory consistently combines qft and gr. The commonly named example is that you don't get a theory of atoms by quantizing water. Likewise, you may not get a theory for the fundamental constituents of space-time by quantizing gravity.

   In case you got lost in the previous paragraph, I am saying that the question these people are trying to address isn't the question we want an answer to. They're two separate questions. And I agree with Tolley that there's no way mathematical proof will give us an answer to the question we actually want an answer to (how do we remove the inconsistencies between the SM and GR), simply because no proof is better than its assumptions, and you can't ever prove the assumptions. It's unfortunate how many physicists confuse physics with math (& good that Tolley isn't one of them).

Incidentally, the entire idea that you can somehow derive a more fundamental theory from a less fundamental one makes no sense because if you could it wouldn't be more fundamental.

(None of this is to say that I am a fan of emergent gravity or think string theory is wrong.)

And why Quanta keeps covering stuff like this is a good question indeed. I've been wondering for a while what's going on there. They also seem obsessed with black hole information loss despite the fact that there's nothing to learn from this "research".

Only interesting thing I learned from this is that Astrid seems to be affiliated with a place in Denmark.

8. **MT**
January 22, 2022

"It's depressing that the world is currently in a place where (a) "believe science!" is a major campaign and (b) the world's smartest physicists seem to have bet the farm on a very straightforward example of affirming the consequent."

In your opinion, what is the risk of the situation as you have described it fueling further ignorance against science in among members of the public?

9. **JS**
January 22, 2022

Let me chime in something from a person actively working on bootstrap techniques. There's no doubt that the paper of Vieira et al. is remarkable and probably one of the most exciting results that ever came out of the S-matrix bootstrap. They demonstrate that at the subleading order in the low-energy limit, string theory in 10D is compatible with S-matrix axioms such as unitarity, analyticity, etc. and moreover it seems to saturate this compatibility among theories with maximal supersymmetry in 10D (in a well-defined sense). However, Quanta's coverage of this topic is extremely disappointing and I don't understand why they decided to put a weird "string theory vs. the world" spin on it, instead of letting the result speak for itself. Completely unnecessary.

10. **Ryan Usher**
January 22, 2022

> "…I don't at all understand why Quanta chose to cover this."

This is something I find myself wondering as well, and it's not the first time Quanta has fallen prey to this kind of hype–and I characterize it in that way to be generous to Quanta in the face of my cynicism. So I decided to waste a couple of hours to come up with the following:

Quanta provides a bare bones explanation of their publishing process on it's "About" page, making it as clear as it can that the Simons Foundation has no say or control over what gets published. This seems to be a bit misleading, however, because Quanta's current Editor-In-Chief's (Thomas Lin) bio states that he joined the Simons Foundation in 2012 with no indication that he is no longer a member of the Foundation. If you wanted to truly keep the Simons Foundation out of what you're publishing, it might be a better idea to not have a member be your Editor-In-Chief.

What seems to ultimately guide Quanta's coverage, however, are these two, simple, statements:

> "…All editorial decisions, including which research or researchers to cover, are made by Quanta's staff reporting to the editor in chief; editorial content is not reviewed by anyone outside of the news team prior to publication…"

There are, as of this comment, 38 articles on Quanta's website that are tagged with "string theory". Out of those articles the authorship is broken down in the following ways:

12 are written solely by Natalie Wolchover ("Senior Writer/Editor)*
4 are written solely by Kevin Hartnett ("Senior Writer/Editor")
3 are written by a collaboration between Natalie Wolchover, Olena Shmahalo ("Contributing Art Director"), and Lucy Reading-Ikkanda ("Former Graphics Editor")
3 are written solely by Robbert Dijkgraaf (who is credited as a "Contributing Columnist")
2 are written solely by Erica Klarreich ("Contributing Correspondent")
1 is written solely by Peter Byrne ("Contributing Writer")
1 is written solely by Charlie Wood ("Staff Writer")
2 are written by Sabine Hossenfelder ("Contributing Columnist")
1 is written solely by Dan Falk ("Contributing Writer")
1 is written solely by Thomas Lewton ("Contributing Writer")
1 is written solely by George Musser ("Contributing Writer")
1 is written solely by Philip Ball ("Contributing Writer")
1 is written solely by Eva Silverstein ("Contributing Columnist")
1 is written solely by Patrick Honner ("Contributing Columnist")
1 is written solely by K.C. Cole ("Contributing Writer")
1 is written solely by Joshua Sokol ("Contributing Writer")
1 is written solely by Siobhan Roberts ("Contributing Writer")
1 is written solely by Jennifer Ouellette ("Contributing Writer")

*One of Natalie Wolchover's articles is simply a multimedia presentation titled, "Theories of Everything: Mapped", so its relevance may be questionable as it may be tagged with numerous legitimate theories.

There are, as of this comment, 17 articles on Quanta's website that are tagged with "multiverse". Out of those articles the authorship is broken down in the following ways:

7 additional articles written solely by Natalie Wolchover**
2 additional articles written solely by Charlie Wood
1 additional article written solely by Jennifer Ouellette
1 article written in collaboration between Natalie Wolchover and Peter Byrne
1 article written solely by Thomas Lin ("Editor in Chief")
The same single article by Peter Byrne referenced above

The same single article by Dan Falk referenced above
The same single article by Philip Ball referenced above

**One of Natalie Wolchover's articles is tagged with both "string theory" and "multiverse", it is included in the string theory tally.

Although one can quibble about the content of the articles themselves: "it's just a Q&A!","it's an editorial column/blog, which 'is not reviewed by anyone outside of the news team prior to publication…!'", or "it's part of their 'Quantized Academy' series!" I will concede the possibility that some of the Q&A's might be interviews with scientists who are critical of string theory, but the fact of the matter is the majority of the articles are giving a voice to string theory/the multiverse. Even if the tone of an article is entirely neutral, it continues to legitimize string theory/the multiverse–even if its only in a small way.

Based on the authorship breakdown above it seems pretty clear that, for whatever reason, Natalie Wolchover is pushing string theory/the multiverse at Quanta–and her role as a Senior Writer/Editor most likely gives her a lot of s(w)ay in what gets put out. But she may not be the only problem, because the current Deputy Editor at Quanta is Michael Moyer, whose bio states: "Before joining Quanta Magazine in 2014, Michael Moyer spent six years at Scientific American, where he was most recently in charge of physics and space coverage and led the magazine's special editorial projects…"

If I'm remembering correctly, Scientific American is a publication that is rife with string theory and multiverse hype, so having someone who was in charge of physics and space coverage there for six years now the Deputy Editor at Quanta is not a good sign; any skepticism about Moyer's position is, unfortunately, bolstered by the fact that when you look at the publication dates for articles on string theory in Quanta, there are two articles in 2013, then nothing until 2015, after Moyer is hired (the history of Quanta's archive regarding the multiverse is a little more even), with healthy coverage of the publication of something on string theory every year since–2019 being an unusually barren year, with only one article tagged with string theory published.

To me, it looks like Quanta–far from "falling prey" to the hype–sadly perpetuates string theory/the multiverse mania, just in a more conservative/limited way.

11. **anonymous**
January 22, 2022

The result by Vieira et al isn't really all that interesting. String theory and other 10 dimensional theories are toy models that theoretical physicists like to play in, and it's great that the S-matrix bootstrap could give a result pertaining to such toy models, but there is no evidence yet that the techniques used with the S-matrix bootstrap could say anything about actually interesting theories relevant to the real world, i.e. theories that are in 3+1 dimensions.

12. **Scott Aaronson**
January 22, 2022

I actually thought the Quanta article was pretty good! It successfully conveyed to an outsider like me both what the result literally says (i.e., the two alpha ranges approximately coinciding in 10D SUGRA), and how string theorists and non-string-theorists very differently interpret that.

13. **Peter Woit**
January 22, 2022

MT,
One motivation for my anti-string theory hype campaign has always been that I think is that this kind of hype has already done significant damage to the public perception of science and scientists, and threatens to do even more if it continues. If we're trying to get the public to "trust science", this kind of behavior does not promote that at all, quite the opposite.

14. **Peter Woit**
January 22, 2022

Ryan Usher,
In trying to understand why this kind of thing happens I think you're focusing on the wrong people. The source of the problem is that the most prominent scientists in the field are pushing this, not that professional journalists pay attention to such figures. The Simons Foundation, like Simons himself, is focused on elite institutions, and Quanta is going to reflect points of view coming from those elite institutions. When there's a serious failure of elite institutions like in the string theory/multiverse case, it's a lot to expect of either the Simons Foundation or Quanta to take on the role of trying to fix that failure.

15. **Peter Woit**
January 22, 2022

Scott,
The point that the coincidence of these two ranges doesn't imply uniqueness of string theory is a straightforward matter of fact + logic. If such straightforward issues become matters of opinion, determined by which tribe you belong to, science is doomed.

In any case, in this example I don't even think that most members of the string theory tribe are willing to sign onto the incorrect side of the argument. Lubos Motl, as fanatic a member of the string theory tribe as they come, has a long posting about this here
https://motls.blogspot.com/2022/01/how-string-theory-correctly-predicts.html
where he makes some of the same points I made, e.g.

"The authors seem excited about the fact that string theory exploits exactly all the allowed values. Well, it is a double-edged sword. On one hand, you can be reassured that string theory overlaps with the consistent quantum theory of gravity nicely, so we have "the" theory. On the other hand, you could say it is bad news because – as in the swampland reasoning – you would want string theory to impose stronger conditions than those that can be extracted from "possibly naive", non-stringy arguments."

He argues for the uniqueness of string theory, but not by claiming that the coincidence of the ranges shows this (he more favors "LQG sux" as a uniqueness argument).

16. **Scott Aaronson**
January 23, 2022

I agree that the coincidence of these two ranges can't be interpreted, in any way whatsoever, as a "uniqueness proof" for string theory! And I didn't see the article as claiming that. Rather, it quotes string theorists who *optimistically hope* that this result might be extended to a more general result stating that, if a given correction to GR is consistent with general postulates about quantum gravity, then that correction can also be realized string-theoretically. Even that would really be a "universality statement" rather than a "uniqueness statement" — more a statement that one "might as well" study string theory than a statement that one "must" study it — but it would be pretty important information regardless, no?

17. **Martin S.**
January 23, 2022

Do the other approaches have some results about which Quanta could report? Has anyone suggested to Quanta such results from the other approaches?

Regarding the discussed article, I would mainly prefer if they would write clearly that the 10D thing is about mathematics, and not about physics.

18. **Peter Woit**
January 23, 2022

Scott,
I read this as pretty clearly an argument for uniqueness ("This goes along the lines that string theory is unique."), and for something much stronger than "string theory is a universal framework that can capture any possibility". That string theory is "unique" implies there are no other non-equivalent possibilities. Thus, no point to work on alternatives, because if you succeed you would just give a different construction of string theory.

I don't think one can understand any of what is going on here outside of the context that people are trying to defend a proposal for a fundamental theory that is not well-defined and is completely untestable. About the only way you can justify this is by a "no-alternatives" (or uniqueness) argument, according to which all seemingly deadly problems of the theory don't matter: it has to be true since it is the only possibility.

19. **Peter Woit**
January 23, 2022

Martin S.,
I don't think there's been much progress in any of the main approaches to quantum gravity. I was going to write that I don't know of alternatives they should be writing about, then realized that's not true. There is at least one (euclidean twistors), but they're not alone in ignoring that….

The "10D thing" is not "mathematics", it's an idea about physics (the bootstrap constraints are very much physical principles). I'm very weary of the endless blaming of bad ideas about physics on "mathematics".

20. **Peter Woit**
January 23, 2022

MT,
Among the biggest fans of this are the intelligent design people, see
https://uncommondescent.com/intelligent-design/string-theory-again-will-a-correction-to-einstein-save-it/
Their argument is kind of a "God universality": if you try to make sense of the universe sooner or later you will have to give up on conventional scientific notions of evidence and start doing metaphysics/religion. They are welcoming the string theorists to the realm of religion with open arms…

21. **Mark**
January 23, 2022

The real issue here is not that string theory as an approach to quantum gravity is degenerative in the Lakatos sense (which it is), but that the entire quantum gravity research program as a physics research program is degenerative, of which string theory is only one branch among many. There is currently no evidence of gravity itself being quantum, as Sabine above pointed out, and it would remain that way until it is discovered in experiment or observation that gravity is indeed quantum. As a result, internecine warfare between different subprograms of quantum gravity over which approach to quantum gravity is more degenerative, such as the assertion in the Quanta article that string theory is the unique approach to quantum gravity, is largely irrelevant in the larger picture. The quantum gravity research program as a whole does not really deserve any attention from the scientific media until actual evidence of gravity being quantum is found, let alone the internal debate over which approach to quantum gravity is less degenerative.

22. **Peter Woit**
January 23, 2022

Mark,
It would be helpful it Quanta and other science publications would identify degenerative research programs and put warning labels on stories about them.

I don't agree though that only an experimental observation can save a degenerative research program and put it on a progressive course. New theoretical ideas that solve the problems that have caused a field to degenerate are possible. What I see as the underlying problem here is a failure of the mechanisms that are supposed to push degenerative research programs out of mainstream science. Failed ideas need to be recognized as such, not promoted by influential people and institutions.

23. **Mark**
January 23, 2022

Peter,

I don't necessarily agree either that only an experimental observation can save a degenerative research program. Cosmology is a field where the current standard model of cosmology, Lambda-CDM, is a degenerative research program, and there is plenty of experimental evidence from dwarf galaxies to large scale structures like the Giant Arc to the Hubble tension showing that Lambda-CDM has significant flaws, and where it is new theoretical ideas, like superfluid dark matter or relativistic MOND or something else, that are needed to put it back on a progressive course.

However, it is the case that some research programs are degenerate for lack of experimental evidence. This was the case with most speculative beyond standard model research programs in high energy physics such as supersymmetry and GUTs, where there is simply an utter lack of evidence of anything beyond the standard model, apart from neutrinos having mass. For a few decades, theorists saw no results after no results of any beyond standard model physics, and merely tinkered with the parameters of their pet SUSY or GUT and waited for the next set of results at the Tevatron or LHC to come out. Eventually, after the latest LHC run, most theoretical physicists have abandoned the BSM research program after the non-detection of anything there, and largely moved on to other fields. SUSY and many other BSM models weren't actually proven false, some theorists today speculate that evidence for SUSY might not appear until the Planck scale, but it is pointless to spend further time on SUSY models when experimental tests for SUSY at the Planck scale won't be around for many decades or centuries. No amount of speculative new ideas (apart from neutrinos for which there is already experimental evidence of BSM physics independent of the LHC results) would have saved the wider BSM research program from dying out, unless experimental evidence of new physics was actually discovered at the LHC or some other near-term future experiment.

The quantum gravity research program is another one of the research programs where the degenerative nature of the research program comes from the lack of experimental evidence to signal anything about the theories. Any experimental evidence of quantum gravity is largely speculated to appear at the Planck scale, which once again is decades or centuries away. Theoretical ideas won't help solve the core issue here, as one simply ends up with a quantum gravity landscape with a multitude of different theories explaining the same phenomena with no experimental evidence to distinguish between any of the theories. So really the only solution here is similar to the solution in the BSM research program, to abandon the quantum gravity research program until the time comes when such experiments can be done.

I agree with you that the underlying problem here is a failure of the mechanisms that are supposed to push degenerative research programs out of mainstream science. However, there is more of quantum gravity that needs to be pushed out mainstream science than just string theory. String theory has been around for 50 years and is merely the most popular and well known degenerative research program in quantum gravity. Loop quantum gravity has been around for 30 years and is also a degenerative research program, suffering from many of the same issues as string theory. The same is true of many other approaches in quantum gravity, such as causal sets, or it from qubit, and so forth. The same mechanism failures that keep string theory alive in the theoretical physics community are also the ones that keep loop quantum gravity alive and causal sets alive and it from qubit alive and so on, none of which can even be proven wrong because of the lack of experimental evidence and the lack of even any theoretical predictions in many theories.

Furthermore, even if string theory ends up disappearing from the face of the earth, so long as the larger quantum gravity research program remains fairly active, it would merely be replaced with other overhyped ideas about quantum gravity such as loop quantum gravity or it from qubit or emergent spacetime from some underlying unknown quantum structure, all as flawed as string theory is right now. And the scientific media will still write bogus claims that they have discovered evidence for this quantum gravity theory and that quantum gravity theory when no such thing has occurred yet.

In so far that other quantum gravity research programs do and will end up making advances in physics it is in the same way that string theory ended up making advances to physics, in the contributions that such theories makes to mathematics and mathematical physics and in the techniques developed in the theory that are eventually applied to other subfields of physics such as condensed matter physics and quantum field theory. But that has nothing to do with understanding the world at a fundamental level.

24. **Anonymoose**
January 24, 2022

It's interesting to compare this line of work with the swampland conjecture.
Here, string theory allows the full parameter space allowed by basic physics, and this is a positive result for string theory.
In swampland, string theory doesn't allow the full parameter space allowed by basic physics, and this is a positive result for string theory.
Talk about having your cake and eating it! It would be nice if there was some framework which allowed these people to talk to one another and figure out which one is right…

25. **Peter Woit**
January 24, 2022

Mark,
I don't think it's helpful to expand an analysis of the problems with this article and string theory in general first to quantum gravity in general, then to mainstream cosmology. Whatever the problems of the Lambda-CDM model, it's a well-defined model, and there's a conventional science debate about the details of its relation to observations. In string theory there's now nothing even remotely like this, or any prospects for such in the future.

26. **Mark**
January 24, 2022

Peter,

I feel like you missed the entire point of my post.

I only brought up Lambda-CDM because you stated that I asserted that all degenerative research programs can only be fixed with experimental evidence. I did not assert that all degenerative research programs can only be fixed with experimental evidence, only that the specific cases of string theory and other quantum gravity research programs could only be fixed with experimental evidence. Apart from using Lambda-CDM as an example to correct that specific misunderstanding, and to highlight the difference between research programs that can be fixed with new ideas vs those that can only be fixed with experimental evidence, Lambda-CDM is not relevant to this topic.

On the other hand, it is entirely reasonable to broaden the analysis from string theory to other parts of quantum gravity, because you do so yourself on this blog:

https://www.math.columbia.edu/~woit/wordpress/?p=12472
https://www.math.columbia.edu/~woit/wordpress/?p=11648

There is the same amount of disingenuous hype and obfuscation going on with these alternative approaches to quantum gravity, where they try to link simple quantum experiments and theoretical calculations to vague quantum gravity ideas, which shows that this problems are not entirely contained within string theory but permeates throughout the quantum gravity research program.

27. **Peter Woit**
January 24, 2022

Mark,
Sorry for the misunderstanding. I guess one reason I'm less concerned about problems with quantum gravity in general is just that they haven't had a huge negative impact on the entire field of fundamental theory the way string theory has. If there is a problem with (picking a random example) causal sets hype, it's not one that I see as having done significant damage or worth spending time worrying about.

I do think we disagree though about prospects for quantum gravity research. I see no reason not to believe that it's possible that purely theoretical developments in this area, with no input from experiment, will come across an important idea that has been missing so far, and that this will allow the field to move forward.

28. **Dalimil Mazac**
January 24, 2022

Scott Aaronson,

In this case "string universality" and "string uniqueness" mean effectively the same thing:

A gravitational S-matrix is a priori parametrized by infinitely many couplings (Taylor coefficients around small momentum). So you can think of a gravitational S-matrix as a point in this infinite-dimensional space of couplings. The 10D superstrings define tiny subspaces in this infinite-dimensional space (type IIA gives a 1d subspace and type IIB a 2d subspace, parametrized by the string coupling).

As a corollary, assuming that a (10D maximally supersymmetric) gravitational S-matrix comes from string theory leads to infinitely many predictions about its small momentum expansion. So much for string theory not making any predictions.

Showing that the most general S-matrix consistent with the bootstrap comes from string theory would amount to showing that the bootstrap constraints cut the a priori infinite-dimensional space down to the respectively 1d and 2d subspaces. This is such a huge reduction of uncertainty that I think it's more appropriate to call it uniqueness than universality:)

Needless to say, this goal is still very far but the paper by Guerrieri+Vieira+Penedones shows that everything works after projecting the infinite-dimensional space to the first coordinate.

29. **Peter Woit**
January 24, 2022

Dalimil Mazac,

Sure, string theory makes an infinite number of predictions, including:
10D spacetime, very specific and intricate spectrum of states and their interactions

Only problem with this infinite number of predictions is that they are all completely wrong…

As Lisa Randall likes to say: “string theory predicts gravity: 10-dimensional gravity”

Notes on the Twistor P^1

January 29, 2022
Categories: Euclidean Twistor Unification, Langlands

I've just finished writing up some notes on what the twistor P^1 is and the various ways it shows up in mathematics. The notes are available here, and may or may not get expanded at some point. The rest of the blog posting will give some background about this.

One of the major themes of modern mathematics has been the bringing together of geometry and number theory as arithmetic geometry, together with further unification with representation theory in the Langlands program. I've always been fascinated by the relations between these subjects and fundamental physics, with quantum theory closely related to representation theory, and gauge theory based on the geometry of bundles and connections that also features prominently in this story.

The Langlands program comes in global and local versions, with the local versions at each point in principle fitting together in the global version. In the simplest arithmetic context, the points are the prime numbers p, together with an "infinite prime". A major development of the past few years has been the recent proof by Fargues and Scholze that the arithmetic local Langlands conjecture at a point can be formulated in terms of the geometric Langlands conjecture on the Fargues-Fontaine curve.

Back in 2015 Laurent Fargues gave a talk at Columbia on "p-adic twistors". I attended the talk, and wrote about it here, but didn't understand much of it. The appearance of "twistors" was intriguing, although they didn't seem to have much to do with Penrose's twistor geometry that had always fascinated me. What I did get from the Fargues talk was that the analog at the infinite prime of the Fargues-Fontaine curve (which I couldn't understand) was something called the twistor P^1, which I could understand. The relation to the Langlands program was a mystery to me. Some years later I did talk about this a little with David Ben-Zvi, who explained to me that his work with David Nadler (see for instance here) relating geometric Langlands with the representation theory of real Lie groups involved a similar relation between local Langlands at the infinite prime and geometric Langlands on the twistor P^1.

Over the past couple years I've gotten much more deeply involved in twistor theory, working on some ideas about how to get unification out of the Euclidean version of it. I've also been fascinated by the Fargues-Scholze work, while understanding very little of it. Back in October Peter Scholze wrote to me to tell me he had taken a look at my Brown lecture and was interested in twistors, due to the fact that the twistor P^1 was the infinite prime analog of the Fargues-Fontaine curve. He remarked that it's rather mysterious why the twistor P^1 is what is showing up here as the geometrical object governing what is happening at the infinite prime. I was very forcefully struck by seeing that this object was exactly the same object that describes a space-time point in twistor theory and I mentioned this at the end of my talk in Paris back in late October.

Scholze's comments inspired me to take a much closer look at the twistor P^1, beginning by trying to understand a bunch of things that were somehow related, but that I had never really understood. These ranged from Carlos Simpson's approach to Hodge theory via the twistor P^1 to some basic facts about local class field theory, where one gets a simple analog for each prime p of the twistor P^1 and the quaternions. Along the way, I finally much better understood something else in number theory that had always fascinated me, see the story explained very sketchily in section 6.2. That the quantum mechanical formalism for a four-dimensional configuration space beautifully generalizes to all primes, with the global picture including an explanation of quadratic reciprocity is not something I've seen elsewhere in attempts to bring p-adic numbers into physics. I'd be very curious to hear if someone else knows of somewhere this has been discussed.

Anyway, these new notes are partly for my own benefit, to put what I've understood in one place, but I hope others will find something interesting in them. Now I want to get back to thinking about the open questions raised by the twistor unification ideas that I was working on before the last few months. A big question there is to understand what twistor unification might have to do with Witten's ideas relating geometric Langlands with 4d QFT. Perhaps something I've learned by writing these notes will be helpful in that context.

Update: I've posted the notes, with an added abstract and a final section of speculations, to the arXiv, see here.

Comments

1. **WD**
   January 29, 2022

   I really enjoy how unabashed you are at acknowledging when you do not understand something. I have come across way too many in the scientific environment who seem to be unable to do that, even when it is fairly obvious that such is the case.

2. **jack morava**
   January 31, 2022

   FWIW the table of comparisons at the very end of the notes looks wonderful to me.

3. **noneone**
   January 31, 2022

   About Section 6.2, see
   https://mathscinet.ams.org/mathscinet-getitem?mr=1474565
   and
   https://mathscinet.ams.org/mathscinet-getitem?mr=1896980

4. **Peter Woit**
   February 1, 2022

   noneone,
   Thanks. I have seen those. The first doesn't really say anything about QM, does give a more abstract approach to the reciprocity law than Weil's. The second does do a bit with QM and this kind of idea, there are some other things at Varadarjan's site

   https://www.math.ucla.edu/~vsv/

   The most detailed relevant things to read that I know about are Michael Berg's expository book about the Weil paper
   "The Fourier Analytic Proof of Quadratic Reciprocity"
   and a long article relating some of this to path integrals, see
   https://www.sciencedirect.com/science/article/pii/S0723086915000857

   What I haven't seen is anything using the specific choice of orthogonal space V to be the quaternions. This case plays a big role in mathematics (Jacquet-Langlands), but I haven't seen anything trying to relate it to physics, where it might give a relativistic particle theory that generalizes to all p at once.

5. **MT**
February 8, 2022

Years back, you posted your position as radical platonism and explained that to mean that at a fundamental level, physical objects are actually mathematical objects. Wouldn't it t be fair to say that these developments (and Langlands trends) continue to point in this direction?

6. **Peter Woit**
February 9, 2022

MT,
Yes. This is to my mind very much evidence for what I was calling "radical Platonism". That the description of a space-time point (a fundamental construction of physics) is the precise analog at the infinite prime of the Fargues-Fontaine curve (a fundamental construction of number theory) at the finite primes indicates a very close and unexpected relationship between physical reality and pure mathematics.

7. **Sebastian Thaler**
February 10, 2022

Happy to see you're allowed to post to the arXiv again after all the drama of years past…

8. **Peter Woit**
February 10, 2022

Sebastian Thaler,
I should make clear that I've never had a problem posting preprints to the arXiv. The reason there aren't many there from me in past years is because I haven't written much that I was happy with, not because moderators rejected submissions. So you should attribute the lack of arXiv articles to my laziness or to my high standards, the blame there does not lie with the arXiv. That I've posted two things recently reflects the fact that I'm very excited about what I think are some genuinely new and important ideas (or, in the twistor P1 case, new connections between ideas), that keep looking very interesting to me the more I think about them.

The trackback thing is a different story. There's a blanket ban at the arXiv on trackback links to my blog. For instance, when someone at Quanta mentions an arXiv preprint in an article, a link appears on the arXiv at that article. For an example, see
https://arxiv.org/abs/1804.10624
which has a link to the recent Quanta article
https://www.quantamagazine.org/a-correction-to-einstein-hints-at-evidence-for-string-theory-20220121/
that I wrote about. When I similarly link to an arXiv paper in a blog discussion of the paper, no link to it appears, even though my blog software sends a trackback request. This is a blanket ban, links to my commentary on my own papers are even banned.

Way back when, there was a public statement from the arXiv that trackbacks to my blog were banned since I was not an "active researcher". This no longer seems to be the criterion they use (the author of the Quanta piece is not a researcher but a journalist). I just made another attempt recently to find out what their policy is and why trackbacks to my blog are banned, but the response I got indicated that this is something I'll likely never find out.

This Way to the Universe

February 10, 2022
Categories: Book Reviews, Multiverse Mania

There's a new popular book out this week by string theorist Michael Dine, [This Way to the Universe](), as well a a new [Sean Carroll podcast]() interviewing him about the book and the state of particle theory research. According to Carroll, Dine represents the "insider view" of what is really going on in fundamental physics:

> you're getting what basically is the closest to a consensus view of what state particle theory and fundamental physics is right now.

Much of the book is a very conventional and straightforward attempt to explain modern particle theory/GR/cosmology to a general audience, featuring some explanations from Dine about specific attempts to go beyond the Standard Model that he has worked on. The last quarter or so of the book is about string theory and the multiverse. One odd thing about this is that the jacket copy is fraudulent, stating:

> People assume string theory can never be tested, but Dine intrepidly explores how the theory might be investigated experimentally.

whereas there's nothing like that in the book that I could find. Instead, on page 253 one finds about string theory

> it's not clear it's right, or that it even makes definite predictions at all…
> Many readers will know that string theory has been a lightning rod for criticism. In this chapter, we'll understand why, on the one hand, the subject is so seductive, and on the other, its critics may have a point.

On page 295 there's

> In fact, the existence of states in string theory that really look similar to what we see around us is highly conjectural. This hasn't stopped me nor my colleagues from writing many papers speculating on a stringy reality. Unfortunately, none of these papers can be said to be making a prediction from string theory. Typically the author likes one particular solution of string theory or another, and selects one feature that is distinctive and goes beyond the Standard Model. But apart from the arbitrariness of this choice, the author has closed his or her eyes to two huge problems with their proposal .

On the Carroll podcast, there's this exchange (starting around 1:25):

> **MD**: There are people who work actively trying to… On what they would call string phenomenology, but I think that at the moment, this is a hard topic and we just don't understand well enough how in detail the theory could be related to nature… …strings are rather simple things, but the steps from there to things that look like the standard model, that look like general relativity, are pretty elaborate, and along the way, there are steps we don't really understand…
>
> **SC**: … Let me ask you how you respond to sort of the hardcore critics who might say something like this: In the 1980s, the first superstring revolution, people are going around saying like, yeah, we're going to unify everything, we're going to predict the mass of the electron and everything is going to be finished in 10 years. Then not only has string theory not made any predictions that you can test in an accelerator, but once we have the landscape of string theory, we're saying that string theory is compatible with almost any set of particle physics you can have, and at that point, shouldn't you just give up and move on to something else? It's not a thing that's going to give you any testable predictions at any point in the future.
>
> **MD**: Well, I would basically say that that, all that is fair, but at some gut level, I don't exactly agree. So first of all, I would say that in 1985, already, in this era of the first superstring revolution, Nathan Seiberg and I pointed out what has come to be known as the Dine-Seiberg problem, a very basic and fundamental obstacle to relating string theory to nature. And people have proposed possible solutions, some of which are interesting, but really, there's… In the subsequent nearly 40 years, people have not put forward. So I'm on safe ground, I sort of took both sides of this issue.
>
> **SC**: .. why not just give up if we think that string theory could predict anything at all given the landscape problem?
>
> **MD**: Well, I think my own attitude is to sit somewhere on the fence, not to devote huge amounts of energy to it, but to allow string theory to inform my thinking about various kinds of issues.

Dine is referring here to the "Dine-Seiberg problem", described in [a 1985 paper]() with abstract

> We argue that if the superstring is to describe our world, it is probably strongly coupled. Several other (unlikely) possibilities are discussed.

The paper is specifically about the effective potential for the dilaton, but the problem is generic and fundamental: you can't get anything like the real world out of the perturbative superstring and you don't know what strongly coupled string theory is (one can argue that AdS/CFT tells you what strongly coupled string theory is, but again, that looks nothing like the real world).

The really odd thing about Dine's current comments about testability (besides that they contradict the jacket of his book) is that 15-20 years ago he was for a while one of the theorists most prominently making the case that string theory and the landscape could be tested. I wrote about this often here on the blog, see for instance [here]() and [here](). The second of these postings is about a 2007 Physics Today article by Dine entitled
[String theory in the era of the Large Hadron Collider]() that claimed:

> A few years ago, there seemed little hope that string theory could make definitive statements about the physics of the LHC. The development of the landscape has radically altered that situation. An optimist can hope that theorists will soon understand enough about the landscape and its statistics to say that supersymmetry or large extra dimensions or technicolor will emerge as a prediction and to specify some detailed features.

The Physics Today piece was rather explicitly an answer to my criticisms of the string theory landscape as untestable pseudo-science, with a subtitle

> The relationship between string theory and particle experiment is more complex than the caricature presented in the popular press and weblogs.

Fifteen years later, in this new book Dine says nothing about his earlier claims about testing string theory at the LHC, or that others clearly pointed out at the time what was wrong with them. He ends with this summary of the situation:

> … one can adopt the landscape viewpoint, but then one has to acknowledge that, at this point in time, we have nothing like a complete theoretical framework in which to make any scientific investigation, and that there are facts hard to reconcile with this viewpoint. I, for one, find this quite unsettling.

His experience of the last fifteen years does not seem to have made him think any more charitably of string theory critics, who get this sneering description on page 269-70:

> view the subject with total disdain, often wearing their ignorance of even its most rudimentary aspects as a badge of honor.

One telling mistake in the book is its reference (page 117) to the "Clay Mathematics Institute of Peterborough, New Hampshire", an indication of the all too typical theoretical physicist's lack of knowledge of anything about mathematicians and the mathematics community.

Update: There's an interesting conversation between Dine and Lisa Randall about the book and these issues, see here.

   February 10, 2022

   Logicians have very unflattering terms for those who want to have things both ways.

2. **DrDave**
   February 10, 2022

   I think one thing that we are seeing is string theory folded into mainstream science books, generally favorable to ST but appearing to be a wider overview (which they can be, of course) without any real attempt to present any evidence to the contrary. And what we aren't seeing is the exactly the same sort of book but with a real critical appraisal of ST. A very practical way to monopolize the shelfspace of ideas.

3. **Sabine**
   February 11, 2022

   In all fairness the "predictions" for the LHC (be that from string phenomenology or other BSM physics) had little to do with the theories per se and all with the added requirement of "naturalness" that Dine has written about a lot. I'm still waiting to see a particle physicist admit that they were wrong to think that naturalness is a scientific criterion on which one can base predictions.

   (And that they almost all believed this naturalness stuff is why one should be very skeptical of "consensus views"…)

4. **Andreas Karch**
   February 11, 2022

   Naturalness is a property of quantum field theory that is well established mathematical fact and has been experimentally proven in many instances. Certain quantities in a quantum field theory are sensitive to the short distance details (for example scalar masses). Having a light scalar requires fine tuning. We can test these ideas in quantum field theories where we know the exact short distance physics — that is in condensed matter systems. There the underlying microscopic theory is a lattice of nuclei and electrons. We know "the theory of everything" as far as materials are concerned. At long distances, quantum field theory is the right description. To see light scalars, you need to fine tune microscopic parameters. A typical example is the order parameter near a phase transition. That is a light scalar, but you need to tune near the critical point for it to appear in the low energy QFT. Usually it is pushed up to high energies, that is the UV cutoff set by the lattice. On the other hand, light fermions are natural. The Fermi liquid describing most metals does not need to be fine tuned (let's forget about superconductivity for now, this requires a well understood but more subtle discussion). Landau's theory of phase transitions as well as Landau's theory of Fermi liquids is just the idea of naturalness spelled out. These are very powerful and scientifically proven theories. So no one is going to give up on naturalness as a property of quantum field theory ever — since it is true and it works.

   Now applying naturalness to particle physics is of course a guess. No one had any right to demand that it has to apply there. But it's an appealing idea. If at the microscopic level we have many choices for the fundamental parameters (as we do for a condensed matter system), you could expect that we live at a "generic" point in this parameter space. Of course we don't know if this is in fact so as we haven't established the microscopic theory in that case. But unlike model building based on completely random guesses, naturalness basically makes this one assumption and then asks what the consequences would be. And the consequence is that you would need a mechanism to keep the Higgs mass light. And all known mechanisms to do that would leave extra light particles behind. The fact that we didn't find any of these new particles in retrospect makes it look like naturalness was not the right idea to pursue. But to claim it was a bad idea to check out is something few physicist will ever agree. It's a simple to state and well motivated principle and one was able to test it.

5. **Peter Woit**
   February 11, 2022

   Andreas Karch/Sabine Hossenfelder,

   I don't want to start up yet another discussion of "naturalness" here, but as blog owner will just repeat my usual argument that the sensitivity of scalars to short distance physics only causes a fine-tuning problem for people who are pushing a theory with complicated new degrees of freedom at exponentially short distances. If you try to fix a problem caused by a bad theory at unobservably short distances by invoking more bad theory at the electroweak scale, it's not surprising the LHC tells you this doesn't happen.

   Dine makes the usual comments about naturalness and fine-tuning, but there's no serious discussion in his book. In the end, the failure of "naturalness" arguments for new physics at the electroweak scale gets used in the conventional way by Dine, as an argument for the anthropic landscape. The main point about this I think is just that if your argument leads you to untestable pseudo-science, you've proved that it's not a good scientific argument.

6. **eigenmoore**
   February 13, 2022

   That's why I like the book 'Why String Theory?' from Joseph Conlon, he has a entire chapter titled something like 'Experimental Evidence for String Theory' and it's just full blank page!

7. **Peter Woit**
   February 13, 2022

   eigenmoore,
   Dine has done much the same thing: in the text of the book he explicitly admits there's no way to make predictions using string theory and explains why.

   His innovation is to do this, then have the publisher put on the cover of the book promotional material claiming that inside it contains an explanation of how string theory will be investigated experimentally.

8. **Lee Smolin**
   February 15, 2022

   Dear Peter,

I was sorry to read that quote of Dine's as I've always found him openminded. But, in the spirit of being not even wrong, here is a test: Jay Armas has edited a collection of "Conversations on quantum gravity" including researchers of diverse points of view.

Let's assign to each researcher a +1 for every mention of an approach not their own which is objective ie checkable and correct, a -1 for every objective but false statement about another approach and a -2 for every statement evaluating an approach, theirs or not, that has no objective meaning by which it could be checked. I haven't done this-anyone want to try it?

9. **Peter Woit**
February 15, 2022

Lee,
To be fair to Dine, the full quote contrasts extremists: those "who view string theory as a sort of holy grail" to others who "view the subject with total disdain, often wearing their ignorance of even its most rudimentary aspects as a badge of honor" I'm assuming he'd put you as in neither category (not sure about me though…).

Exactly because Dine is otherwise very mild-mannered and willing to admit that critics might be right (to the point of even claiming to be on both sides of the argument) that this sentence stands out in the book. Those like Dine who publicly joined the string wars on what I would claim was the losing side (see his Physics Today piece), as open-minded as they may be, may still be nursing wounds from that era.

I agree with your implicit point that in the Armas volume the difference between the way string theorists and non-string theorists discuss the problems of various approaches is rather striking.

Seminar talk on Euclidean Twistor Unification and the Twistor P^1

February 14, 2022
Categories: Euclidean Twistor Unification

Today I gave a talk via Zoom at the [Algebra, Particles and Quantum Theory seminar series]() organized by Nichol Furey. The slides from the talk are [here]() (I gather the talk was recorded and video might be available at some point).

This talk emphasized explaining the twistor geometry, integrating some of what I've learned over the last few months thinking about the "twistor P^1" (see [here]()). For instance, one way to think of the basic object of Euclidean twistor theory is as $\mathbf {CP}^3$, together with a different real structure (the twistor real structure) than the usual one given by conjugation of complex coordinates. One thing that struck me while writing up these slides is that the Euclidean twistor story gets a lot of mileage out of identifying $\mathbf C^2$ and $\mathbf H$, together with taking as fundamental $\mathbf H^2$. It has always seemed possible that the octonions might have a role to play here; one way into that might be to think about identifying $\mathbf H^2$ with $\mathbf O$ in some analogous way to the $\mathbf C,\mathbf H$ story.

There's nothing new here about any of the many open questions of how to use this geometrical framework to get a fully worked out dynamics that would include the Standard Model and gravity. After a detour into number theory and hyper-Kähler geometry for several months, I'm now getting back to thinking about those questions.

Update: Video of the talk is now available [here]().

   February 15, 2022

   "one way into that might be to think about identifying H^2 with O in some analogous way to the C, H story."

   People have thought about this before, and it seems that the end result is always some variant of the Cayley-Dickson construction.

2. **bertie**
   February 15, 2022

   Very nice, your speculations seem noticeably stronger than in your earlier public writings on the topic. Also nice to see Octonions making a debut in your work, was Prof Baez an influence there?
   How was the talk received?

3. **Peter Woit**
   February 15, 2022

   Aula,

   More specifically what I'm wondering about is more geometrical, whether there's an octonionic analog of the relation between the twistor P^1 and the quaternions. That one is identifying C^4 with H^2 gives the twistor real structure on CP^3, what extra structure on CP^3 does one get from identifying H^2 with the octonions?

4. **Peter Woit**
   February 15, 2022

   Bertie,
   The more I think about this framework for thinking about fundamental physics, the more convincing I find it. You can interpret that as a reason others should take this seriously, or as evidence that I'm becoming increasingly delusional…

   The reaction to the talk seemed to me quite positive, there were good questions.

   John Baez's article on octonions in the Bulletin of the AMS is one of the few things I've read about them that gave me some insight especially into the geometry. I plan to soon reread it, see if there's anything there or elsewhere about the question I mentioned in the previous comment.

5. **Jackiw–Teitelboim**
   February 15, 2022

   Speculations on twistors and fundamental theoretical physics reminds me this lectures by Atiyah: https://arxiv.org/pdf/1009.4827.pdf
   On octonions, I am also reminded of this informal lecture given by Atiyah some years ago: https://www.youtube.com/watch?v=lp2cXnNt0Xs
   I wonder if he ever published anything more substantial about this…

6. **Peter Woit**
   February 15, 2022

   Jackiw-Teitelboim,
   Thanks for those references, which certainly resonate with me, for instance the story of the twistor P^1 fits perfectly with Atiyah's
   "In the big picture, physics is at infinity, and number theory at the finite
   points."

   Atiyah was always a huge inspiration to me, and what he has to say about his speculative dreams relating number theory and physics is fascinating. It's frustrating not to have more detail from him about this put down to paper. Also frustrating is what happened in the last few years of his life, when he apparently lost the ability to see needed details. The last time I saw him (2016 in Heidelberg), at one point he was talking about how the octonions were central for understanding gravity, but he didn't seem to have a really coherent argument one could follow (at least I couldn't). Likely what's in the video you link to may be the best source for trying to understand what he had in mind.

7. **Robert A. Wilson**
   February 16, 2022

   I watched Atiyah's 2010 video in its entirety, and I would like, if I may, to comment on what he says about octonions, since I am in fact an acknowledged expert on octonions. If you don't like it, then please ask Nichol Furey or John Baez, who are also acknowledged experts on the octonions, and will back me up. Atiyah did no work on octonions until his mid-70s, and he simply doesn't understand what he is talking about. It is clear in the work of Nichol Furey, and Geoffrey Dixon, and Corinne Manogue and Tevian Dray, and many others, that EM is complex, the weak force is quaternionic, and the strong force is octonionic. These are all people who have worked seriously, rigorously and productively in the area, which Atiyah never did. Atiyah links EM to real numbers, the weak force to complex numbers, the strong force to quaternions, and gravity to octonions. This is just nonsense.

8. **Peter Woit**
   February 16, 2022

   Robert A. Wilson,

   I just took a longer look at the Atiyah video and have to agree that on gravity/octonions there's not much at all there, just like some years later in Heidelberg there didn't seem to be much to the idea, beyond a vague "hunch". He does admit that the idea is "vague and philosophical". I agree that the connections strong interactions/octonions studied by Nichol Furey and others seem much more substantive. Beyond these, one might somehow speculate that triality has something to do with three generations, but I don't know that anyone has anything specific about that.

   The explanation Atiyah gave in that talk of the Tits-Freudenthal magic square was really nice, but there's no clear connection to physics.

   On this kind of thing, Baez has written extensively and in detail, I recommend his series of blog posts that start here
   https://golem.ph.utexas.edu/category/2020/07/octonions_and_the_standard_mod.html

   One aspect of the octonions that has often showed up in speculations about relations to physics is that the Lie algebra sl(2,O) in some sense is so(9,1), the Lie algebra of the 10d Lorentz rotations. This is of some encouragement to the idea of relating octonions to the 10d superstring, but I've never seen anything much coming out of that.

9. **Robert A. Wilson**
   February 16, 2022

   The Tits-Freudenthal magic square is undoubtedly very beautiful, but I wouldn't call Atiyah's remarks an "explanation". What is magic about the square is that it is symmetric, and that is a very deep and difficult theorem of Tits. For an explanation, you can't do better than the Barton-Sudbery paper, but for deep insight, in a vaguely unintelligible way, I think Vinberg has the edge. Atiyah's remarks do not seem to me to amount to much more than the observation that there are four dimensions of space, four fundamental forces, and four rows and columns in the magic square, but perhaps I am missing something. I agree with him that there is something very special about the number four, but I don't find anything deep in what he says here – although in other parts of his talk I think there is real depth.
   The idea that triality is connected to the three generations is a key part of Garrett Lisi's infamous "Exceptionally simple theory of everything", that few people take seriously these days. It is a seductive idea, but it hasn't worked out. You can make your own decision whether to work on it, but I lost interest in it many years ago. I don't know why you qualify the isomorphism between sl(2,O) and so(9,1) with the words "in some sense": it is a perfectly valid and rigorous mathematical result, well understood in the 1930/40s by von Neumann, Jordan, Schafer, Chevalley, etc. But they quickly abandoned the idea that it had anything to do with physics, and I think this conclusion is amply supported by your suggestion that it might have something to do with string theory!

10. **John Fredsted**
    February 17, 2022

    Robert A. Wilson,

    I would like to take issue with "It is clear in the work of Nichol Furey, and Geoffrey Dixon, and Corinne Manogue and Tevian Dray, and many others, that […] *the strong force is octonionic*" [my italics].

    In section 5 of the nice article "Quark structure and octonions", by Günaydin and Gürsey (J. Math. Phys. 14, 1973) it reads: "Since G2 has only real representations, only real representations of SU(3) can occur in the representations of G2."

    So, for one thing, the G2 automorphism group of the octonions, cannot naturally explain, say, the (physical) difference between the quark triplets [3] and [3*].

11. **Geoffrey Dixon**
    February 17, 2022

    John Fredsted

    Günaydin and Gürsey also demonstrated that the complexified octonions (S = C ⊗ O) give rise to an SU(3) with respect to which S itself (which is a spinor space – see for example, Conway and Sloane Sphere Packings, if you are dismissive of the 4 names listed above) transforms as a singlet, anti singlet, triplet, and anti triplet. This barely scratches the surface.

    Cheers, Geoffrey Dixon

12. **Robert A. Wilson**
    February 17, 2022

    John Fredsted,

    I happen to agree with you, but I was not discussing my own opinions, I was discussing the work of others, so that *if* you believe the octonions are useful in physics, *then* they must show themselves in the strong force. If they do not show themselves there, as you seem to be saying, then I don't see how you can believe in the usefulness of octonions in quantum gravity – which seems to have been Atiyah's point of view, and still has some currency today. One can argue about lots of this – but not on Peter Woit's blog – but I agree with Peter that both the weak force and gravity are quaternionic, quite contrary to what Atiyah was saying.

13. **Peter Woit**
    February 17, 2022

    All,
    Enough about the octonions and gravity. From all I can tell, there wasn't a serious Atiyah proposal about gravity. About SU(3) and octonions, I'm just starting to think about whether this fits into the twistor geometry I'm studying. Pointers to previous work on this continue to be appreciated and I'll look into them.

14. **Blake Stacey**
    February 17, 2022

    Perimeter hosted some online talks about "Octonions and the Standard Model" last year; the recordings are on PIRSA.

15. **Robert A. Wilson**
February 18, 2022

If you want to relate octonions directly to twistors, you need the split octonions in order to get the right symmetry groups. Then you get SO(4,2) and SO(3,3) and the corresponding spin groups in the isotopy groups, and SU(2,1) and SL(3,R) as the possible real forms of SU(3) in the automorphism group. Physicists tell me they are not interested in non-compact real forms. Various of the people already mentioned have their various ways of dealing with this.

If you are interested in links to number theory, you'll want discrete versions of octonions, which are discussed in the Conway/Sloane book to some extent, but you probably want to look at Conway/Smith "On quaternions and octonions" for more. There is also a section of my book "The finite simple groups" that goes beyond what I have seen elsewhere. Incidentally, 't Hooft's latest paper arxiv:2202.05367 asks for integer versions of SU(3) for describing physics at the Planck scale. A list of all such groups is in Blichfeldt's "Finite collineation groups" (1917), and an argument for a specific choice is in arxiv:2202.08263.

16. **Dick Gross**
February 18, 2022

I don't know anything about the connection of exceptional groups to physics, although some claims on E8 have been debunked by Distler and Garibaldi:

Distler, Jacques; Garibaldi, Skip
There is no "theory of everything" inside E8.
Comm. Math. Phys. 298 (2010), no. 2, 419–436.

The symmetry of the magic square is not difficult from the point of view of

Deligne, Pierre; Gross, Benedict
On the exceptional series, and its descendants.
C. R. Math. Acad. Sci. Paris 335 (2002), no. 11, 877–881.

which also extends the magic square of Lie algebras to a magic triangle of Lie groups.

17. **SG**
February 21, 2022

… a glass of pure wine to facilitate the debate…

– Octonions are non-associative (or more exactly anti-associative)
and so far nobody knows physics with such property.

– Complex Quaternions, (a.k.a. Weyl spinors) C x H — isomorphic but not the same as C^4 or H^2 — are exactly what one needs to include SM and gravity under one roof. Twistors are basically spinors enriched by projective geometry point of view.

– E8 ~ SU(5) x SU(5) ~ [SU(2) x SU(3)] x [SU(2) x SU(3)] — doubly GUT 🙂 — has to be also part of the final solution, as spinor geometry is 8D, and E8 is the most exceptional Lie group describing "the-most-ever-conceivable-still-admissible-eight-dimensional-something".
It is simply not restricted just to Octonions.
(Distler, Jacques; Garibaldi, Skip's argumentation is correct only in respect to Lisi's "theory of everything" but not universally).

ICM 2022 and the Invasion of Ukraine

February 21, 2022
Categories: Uncategorized

The news this evening that Russia is sending troops into ~~the~~ Eastern Ukraine and in effect announcing annexation of at least part of ~~the~~ Ukraine carries extremely disturbing implications for the whole world. On a much more minor scale of importance, I don't see how the IMU has any choice but to cancel this year's ICM planned for St. Petersburg in July.

Four years ago when the IMU chose St. Petersburg over Paris for the 2022 ICM I commented here on this blog:

> It does seem to me though that in these worrisome times, when offered the choice between the world's most active opponent of liberal democracy and one of the great remaining healthy liberal democracies, the other choice than the one the IMU made would have been the better one…
>
> I agree that in general it's best to keep mathematics and the ICM out of politics. A question to think about though for those who know the history of the 1930s is that of whether there was some point during the rise of Fascism that one would stop thinking it was a good idea to have the ICM in a Fascist capital. We're not yet far along the horrific path of the 1930s, but maybe that just means that all should be thinking about what can be done to keep the world from going down that path again.

I sympathize with many who felt that the decision to hold the ICM in Russia was an important way to support Russian mathematicians and a reasonable gamble that Putin would not take his country down the path he now appears to have chosen. But right now it's looking like that gamble failed and the IMU will have to figure out what to do about its mistake.

I don't want to host a general political discussion here, especially not with the all too many people I've heard from who don't have a problem with burying liberal democracy. If your comment is not about the ICM, please don't submit it.

Update: On February 10 an organization of Ukrainian mathematicians emailed the ICM invited speakers asking them to cancel their talks (*and on January 31 had emailed the AMS leadership*). I'm curious to know if any responded to this, and if the Russian military invasion will lead to some decisions to cancel talks.

Update: According to this from @UkrainianMath, the AMS position was recently that "the AMS leadership is closely tracking the situation surrounding the ICM and believes that it is still premature to advocate a boycott". The "premature" indicates that there is some point at which AMS leadership agrees that the ICM should be canceled. Is the situation of Russian troops occupying ~~the~~ Eastern Ukraine still "premature", or will the AMS wait for them to take Kiev?

Update: I noticed there's an AMS-NSF-Simons-ICM Travel Grant program to fund ICM participation by US mathematicians. It was supposed to announce awards this month. Will this program go forward or will the grants be canceled?

Update: Many Russian mathematicians likely feel the same way about this as Edward Frenkel who calls this "a catastrophe for Russian people and all Slavic people".

Update: The AMS has issued a statement urging the IMU to cancel the ICM and has suspended the AMS-NSF-Simons-ICM travel grant program

Update: There's a statement out signed by invited ICM speakers. Unfortunately it has been overtaken by events, with little more than a request that the IMU "elaborate and announce contingency plans" in case of war, something that would have made sense a month ago, but not now. Nothing yet that I'm aware of from the IMU or other mathematical societies than the AMS.

Update: The French SMF has a statement calling on the IMU to not hold the ICM in Russia during 2022. In another statement, the London Mathematical Society "strongly recommends that the IMU not hold the ICM in Russia in July 2022." Also in France, INSMI at the CNRS has this.

Update: There's a long twitter thread about this here. It includes a contribution from Ian Agol: "As a chair of the topology selection committee, I requested @ICM2022 that the opening ceremony not be presided by a head of state (presumably Putin), but they were not willing to consider this."
This makes clear the fundamental problem with deciding to hold the ICM in a country ruled by a fascist dictatorship. If you do this, you end up putting the conference under the control of the dictator, because anyone inside the country cannot oppose them. Those outside the country end up having to either go along with the dictator, or cancel the conference, and this is where the IMU is now.

Update: The IMU has issued a (rather empty) statement, saying that "The Executive Committee of the IMU is now assessing the situation"

Update: More statements from national math societies: Italy, Canada, Poland, Lithuania.

Updates: The IMU this morning has on their website:

> The IMU Executive Committee is currently assessing the highly disturbing events that are taking place in Ukraine and their implications for the IMU. We will return with a statement as soon as it is available.

There are new statements calling for canceling the ICM from the European Mathematical Society, the Australian Mathematical Society, the Swedish Mathematical Society and others.

Update: Via @UkrainianMath, the latest from the IMU Secretary:

> The IMU EC has been sitting in meetings for two days now, discussing the situation and how to respond properly. I ask for your understanding that it is more difficult for a global organization to meet and discuss this issue.
>
> Of particular concern to us is how to find a possible way to carry out a General Assembly and an ICM if possible, but outside Russia. Furthermore, we do not want to cause damage to our Russian colleagues, who have spent endless hours preparing for an ICM.
>
> The IMU webpage does contain a statement that we are working on this, and until we have reached a decision, which will be very soon, this is the best we can do.

Update: The IMU has announced that the ICM will take place as scheduled, but as a free fully virtual conference, not in-person in St. Petersburg. The IMU General Assembly will take place in-person, but at a different location still to be chosen, outside Russia.

Update: The ICM website (icm2022.org) no longer exists, with that address redirected to the IMU site mathunion.org. There had been no activity on the @ICM2022 Twitter account since Feb. 11, but now there's a statement from four of the Russian mathematicians who had been involved in organizing the ICM:

We condemn the madness, the injustice, and the irreversibility of war that threatens the very existence of humanity. While our losses cannot be compared to the losses and the suffering of millions of people in the Ukraine, we are devastated to see all of our dreams and all of our work of many years ruined. The goals towards which we worked could not have been further from the horror that is happening and those responsible for it. Still, amid the ruins of our dreams, we feel left with an insurmountable debt that may take much longer than the life of our generation to be forgiven.

D. Belyaev, A. Okounkov, J. Pevtsova, S. Smirnov

Update: See here for a letter to the IMU from some mathematicians arguing against the decision to hold the ICM online.

Comments

1. **Alessandro Strumia**
February 22, 2022

Can I attend attend a physics conference in Russia, if I cannot attend physics conferences in your liberal democracy nor post to arXiv one scientific publication?

2. **sdf**
February 22, 2022

If the IMU made the St. Petersburg decision even though Crimea was illegally occupied at the time, I rather doubt they feel any kind of moral obligations of this type.

3. **Genghis Cohen**
February 22, 2022

All the young Russian mathematicians I know – and there are many in my city/institution – were quite disgusted with the choice to host the ICM in St. Petersburg. I'm very curious to see what happens now.

4. **Peter Woit**
February 22, 2022

Alessandro Strumia,

I don't know what the nature is of problems you have attending US physics conferences.

It looks like the IMU will choose Philadelphia for the 2026 ICM. Depending on the results of our 2024 election, that might be another one that gets canceled.

5. **anon**
February 22, 2022

I'm expecting to see mass cancellations by speakers unless the situation in Ukraine improves significantly.

I believe it's also time to rethink the whole concept. ICM has become so large and costly to organize that few places are able to even think of hosting.

6. **Bo Berndtsson**
February 22, 2022

I can only say that I agree with Peter. It has now become clear that it was a big mistake to let Russia host the coming ICM. I, for one, cannot imagine myself at the inaugural ceremony, applauding representatives of the Putin administration.

7. **Andrzej Daszkiewicz**
February 22, 2022

ICM 1982 in Warsaw, Poland, had been postponed for a year, till 1983 and the suspension of the martial law (which had been imposed in December 1981), so there is a precedent. As a young Ph.D. student in Warsaw at that time I was really happy that the Congress had not been calcelled, but of course the situation now is completely different, Russian mathematicians are not as isolated as we had been behind the iron courtain.

8. **Anonymous**
February 22, 2022

FYI Ukrainians generally consider it offensive to refer to "the" Ukraine

9. **Noah Snyder**
February 22, 2022

I'm glad to see that someone mentioned the 82/83 Warsaw ICM, which is a very interesting bit of history that I didn't know about until last week when I was looking for any parallels to previous ICMs. If Kyiv were hosting the ICM this year I'd expect we'd see a similar delay as in 82/83, but of course that's not the current situation. There didn't really seem to be any previous congresses with anything parallel to the current situation (e.g. Moscow hosted in '66 not '68 or '80, Berkeley hosted in '86 not '70 or '04). At any rate I agree that it pretty clearly needs to be cancelled or moved at this point. Not sure if it's too late logistically to move it to Paris. It's all very sad, my entire intellectual genealogy is in the city of St. Petersburg and it's a wonderful mathematical heritage that deserves to be celebrated.

10. **Will Sawin**
February 22, 2022

It seems the AMS is pulling its representatives, cancelling the grant program, and urging IMU to cancel: https://twitter.com/amermathsoc/status/1496255307697340418

11. **Low Math, Meekly Interacting**
February 23, 2022

Interesting how autocracy and demagoguery can destroy nearly anything. It's incredibly sad to see Russian intellectuals punished as the cost of denying prestige to a government they themselves likely universally deplore. It's the obvious thing to do, but what a sickening reversal of the East-West cultural exchange set in motion at the end of the 20th century. What a world we live in.

12. **Peter Woit**
    February 23, 2022

    LMMI,
    With the invasion of the Ukraine, the problem with holding the ICM in Russia goes way beyond its adding to the prestige of the neofascist Russian government, and Russians (mathematicians and non-mathematicians alike) are victims of their leadership in ways that go far beyond not having an international conference there.

    The reason I think it is now inconceivable that the ICM will be held as planned is that, even if you believe in completely divorcing math from politics and not punishing citizens of a country for their government, as a practical matter holding the ICM would be a disaster. The Russian state has now gone to war by sending its military in to occupy Ukraine and no one knows how bloody and ugly this is going to get. With the US and most Western countries every day announcing new actions against Russia and Russian counter-actions sure to come, I can't see how any sensible person would now think it would be a good idea to book plane tickets and make hotel reservations so as to plan travel into a war zone in July. Optimistically the fighting will take place not with bombing and shooting but with financial, trade and other sanctions, but that likely will be enough to make basic things like flying to St. Petersburg soon impossible.

13. **MT**
    February 23, 2022

    "I can't see how any sensible person would now think it would be a good idea to book plane tickets and make hotel reservations so as to plan travel into a war zone in July."

    Not only is this correct, but you wouldn't want to book plane tickets for any event that would require entering Ukranian airspace. People fail to realize how close to WWIII things are getting.

14. **Peter Woit**
    February 23, 2022

    MT,
    Yes, although I'm assuming airlines are being appropriately cautious now, well aware of what happened in 2014 (the Russians shot down a commercial airliner flying over Eastern Ukraine, killing all aboard).

    As this continues, even if a Westerner could get an airline to fly them into St. Petersburg, there's also the other war-zone problem of ending up interned as a prisoner of war. Until recently one could have made the case that Putin would not imprison and hold hostage citizens of Western countries since that would hurt his relations with those countries, but that's no longer a very convincing argument.

15. **Edward**
    February 23, 2022

    I am surprised none of the comments here are arguing against relocating the ICM. Does the ICM really want to become involved in the sordid U.S. regime change operation in Ukraine? The U.S. spent $6 billion on regime change efforts in Ukraine, culminating in the 2014 coup which overthrew the democratically elected president of Ukraine. This essentially led to a civil war which has wrecked the country. The anti-Russian faction(including Nazis) seized power in Kiev and the ethnic Russians in the West revolted. If the ICM wants to boycott a country what about America? The list of American crimes is long, starting with the CIA organized coups against the democratically elected governments of Guatemala, Iran, Indonesia, and Chile. More recently, there are the genocidal sanctions against Iraq, which killed hundreds of thousands of people, followed by an invasion which destroyed the country. America has wrecked Libya, Syria, Yemen, and Ukraine and is trying to replace the democratically elected government of Venezuela with U.S.-appointed Juan Guido. Who gets to decide which countries are committing crimes and get boycotted? Will the same standards apply to every country?

    I think it is a bit rich to call Mr. Putin a "neo-fascist". He is a very popular democratically elected politician with an approval rating above 60%, much higher then our president or Congress. He has done an excellent job rebuilding Russia after the disastrous Yeltsin years. There has been an extreme propaganda campaign against Russia by the West for years, and I hope the ICM does't become part of this effort. After the Iraq WMD hoax, Americans should be more careful about taking U.S. government and media accusations at face value.

16. **Peter Woit**
    February 24, 2022

    Please do not respond to the comment by "Edward". I've been deleting things like this as they come in, thought it might be a good idea to leave one so that people have an idea what the pro-Russian propaganda campaign that has been going on looks like.

17. **Andrzej Daszkiewicz**
    February 24, 2022

    There is a similar statement calling IMU to not organize ICM in July in St. Petersburg issued by the Polish Mathematical Society (PTM), available in Polish here:
    https://www.ptm.org.pl/zawartosc/stanowisko-zg-ptm-w-sprawie-icm-2022

18. **Yiannis Sakellaridis**
    February 24, 2022

    The commentary about the statement by ICM speakers ("a month ago") is unfair. As of last weekend, European leaders were shuttling between Kyiv and Moscow and projecting optimism that diplomacy would prevail. In any case, the statement sets some standards – that even the threat of war is incompatible with the spirit of unity that the ICM should represents – whose implication for today's situation is completely clear. The statement has now been signed by more than half of the invited speakers.

19. **Peter Woit**
    February 24, 2022

    Yiannis Sakellaridis,
    While I'm sympathetic with the difficulty of organizing a statement like this, I'm afraid I have to disagree. The Russian military buildup and threats to the Ukraine have been going on for months, and those months were the time for a call to the IMU to announce that a Ukraine invasion would imply cancellation of the ICM and to make contingency plans.

    The IMU has had months now to make a contingency plan about what it would do in case of an all-too likely Ukraine invasion by Russia. This week is not the time for calls for contingency plans but for implementing them.

20. **Robert Owczarek**
    February 24, 2022

I think ICM has to be canceled, stressing the role of the Putin's regime in nullifying its legitimacy for having such privilege. I am afraid though that IMU is partially connected with Russia and Putin's supporters. How otherwise the ICM would land in St. Petersburg in the first place? And make no mistake, Putin, when he crossed this Rubicon, will not stop there. All Europe is now in danger, and in effect the world. Putin must be stopped.

21. **Peter Woit**
February 24, 2022

Robert Owczarek,
I don't know what the IMU's rules are for making a decision about this. The IMU executive committee is here
https://www.mathunion.org/organization/imu-executive-committee
its ICM structure committee is here
https://www.mathunion.org/icm/icm-2022
and the ICM executive organizing committee is here
https://icm2022.org/organization

The ICM executive organizing committee is entirely Russian and I suspect any of them who agreed with canceling the ICM would put themselves personally in grave danger.

The other IMU committees are mostly non-Russian and I know of no reason they should not be agreeing on the obviously necessary action of canceling the conference.

As I wrote in my comment to Yiannis Sakellaridis, it has been clear for quite a while that this might happen. These IMU committees have already had a lot of time to try to decide what they would do in the case of a Ukraine invasion, so unclear why we're not hearing something publicly from them.

22. **Zee**
February 24, 2022

The IMU has the responsibility to cancel the ICM for the sake of the organizers and Russian mathematicians.

23. **Sam Hopkins**
February 24, 2022

Could the ICM take place entirely online? I was at the ICM in Rio in 2018 and it was a very enjoyable experience, but the experience of attending many remote conferences during Covid has made me rethink the benefit of traveling long distances for in person conferences, not to mention in terms of money and CO2 emissions it feels frankly wasteful.

24. **Peter Woit**
February 24, 2022

Sam Hopkins,
That's one possibility, and it may be what happens.
There's no way to change the venue of a 5000 attendee-scale conference like this on the timescale of a few months, but it might be possible to organize a hybrid conference with a much smaller in-person component.
Possibly the reason for no statement from the IMU is that they are trying to decided about this.

25. **Noah Snyder**
February 24, 2022

Yes, there's no way they can logistically hold a normal ICM in person at another location this summer. The natural thing is to move it and hold it next summer, but it's not even clear to me whether you can reschedule an event of this size on "only" one year's notice. It's going to be genuinely difficult for the IMU to figure out what options they have. Hopefully they didn't just start working on contingency plans this week. It may end up needing to get rescheduled for next summer and also shrunk in some way.

26. **Engineer**
February 24, 2022

Looks like the football community is set to deal with a similar situation as the UEFA are set to strip Saint Petersburg of the hosting rights for 2022 Champions League final. It would be sad if they can act while the IMU can't.

27. **Sam Hopkins**
February 24, 2022

The IMU has now made a statement: https://www.mathunion.org/fileadmin/IMU/Publications/CircularLetters/2022/IMU%20AO%20CL%204_2022.pdf

28. **Johan Richter**
February 24, 2022

The tweet by Ian Agol has been deleted.

29. **mathlog**
February 24, 2022

It would be interesting to know what Andrei Okounkov and Stanislav Smirnov will say on the matter. They are members of the organizing committee (and kind of its face, see https://icm2022.org/blog/interview-with-andrei-okounkov-and-stanislav-smirnov) and are both not based in Russia.

30. **Peter Woit**
February 24, 2022

mathlog,
I have no knowledge specifically of what Okounkov or Smirnov think about this, but I'm guessing that almost all the Russian mathematicians associated with organizing the ICM feel much the same: the Ukraine invasion is a terrible disaster and the conference can't take place in July, but saying this publicly would carry severe implications for their personal safety so they're not going to do so.

31. **Lukasz**
February 24, 2022

As a supplement to the messages of Andrzej Daszkiewicz and Noah Snyder, I would like to add here that there on the website https://mathshistory.st-andrews.ac.uk/ICM/ICM_Warsaw_1983/ , is placed a story of ICM 1983.

PS. My Father was enjoying at that time that there were some chances that Alfred Tarski would attend this Congress. He wanted to discuss with Tarski on some problem (in mathematical logic), solved by my Father. However, unfortunately, Tarski was absent there. He died about 2 months after ICM 1983.

32. **David Roberts**
February 24, 2022

The Australian Mathematical Society has announced they don't want the IMU to proceed with holding the Congress in St Petersburg: https://austms.org.au/statement-on-icm-2022/

33. **Gil Kalai**
February 25, 2022

Indeed these are very sad days.

Regarding the ICM. It is not clear if the war in Europe will enable any form of ICM in 2022, but it seems pretty clear that it will not take place in St Petersburg as planned. Here are some thoughts about a possible way to have a congress if the conditions will make it possible.

First a remark: One nice thing about Rio-ICM2018 was that all invited, public, plenary lectures and also the panels were videotaped (in a very good quality) which provided (in addition to the traditional Proceeding) a very valuable resource. Now, if in additional to good quality videotaping, the lectures are also broadcast then we can consider a hybrid structure of many venues (10-15) where speakers (mostly) will not speak from their homes but will be gathered to several well-videotaped sub-conferences with a live audience. (Still some speakers may speak from their own institutions (perhaps also with an audience) and some speakers may choose to record their lectures in advance.

Mathematicians could have some possibilities for talks that interest them: to attend (if it is nearby), or to listen to the broadcast in real time, or to watch the video later.

Making a viable program with this format could be an interesting combinatorial problem (suitable for the young minds). Probably the early afternoon in Europe could be a good time for plenary talks. We may need to make the ICM a few days longer.
For such a plan we can choose 10-15 venues around the world, with some local activities as well in addition to giving and watching ICM lectures.

One more idea. Perhaps we can give all speakers of all types (except, of course the prize winners) an opportunity to post a 15-20 minute introductory video that will be posted around May of the year in the ICM site. (This can be extended also to contributed talks/abstracts and to lectures in satellite conferences, and to other participants.) While only a few percent of people will watch the videos in advance this can still be very helpful.(I tried myself to implement this idea with my live lectures in the pandemic times.)

Maybe some of the social events could become distributed as well.

Actually I made few of these remarks/suggestions in 2019 before the pandemic and certainly in no connections with the terrible war here:
https://terrytao.wordpress.com/2019/02/05/request-for-comments-from-the-icm-structure-committee/#comment-512332

34. **Arend Bayer**
February 25, 2022

I want to point out that the letter signed by ICM speakers (I am one of them) states that the ICM cannot be held while the organising country is *threatening* a war against its neighbour, and that it cannot be held in the context of a potential war.
I think the implication for the current situation is clear.

On a more important note, I am impressed by the courage of the >370 signatories of this letter by Russian scientists against the war: https://trv--science-ru.translate.goog/2022/02/we-are-against-war/?_x_tr_sl=auto&_x_tr_tl=en&_x_tr_hl=en&_x_tr_pto=wapp

35. **Richard Séguin**
February 25, 2022

Major sports communities have been acting quickly and making decisions. The International Olympic Committee is calling for all sporting federations to cancel or relocate events in Russia in addition to banning Russian and Belarusian flags and anthems at sporting events, Formula One has cancelled the Russian Grand Prix at Sochi, the football event at St Petersburg (Champions League Final) has been moved to France, and important ski events scheduled for Russia have been cancelled or moved.

I do understand the immense difficulties of actually planning the move of a large meeting like this, but I hope they are not waiting to figure out if they can in fact do this before deciding whether or not to cancel St Petersburg. A meeting at St Petersburg is just simply out of the question. They should cancel now and then try to figure out if they could move the meeting. If they finally decide that there isn't enough time to plan a move, then the meeting will have to be sacrificed this year, or they could consider virtual options — which we've become quite skilled at in the past two years — as discussed by Gil Kalai above.

36. **Peter Woit**
February 25, 2022

Arend Bayer,
I understand the difficulty of drafting something that most speakers would agree on, but I still think that the formulation chosen would have been very appropriate a month ago, but became inappropriate on Monday when the invasion started. I realize this is unfair, but as written the letter indicated no problem with a July ICM in Russia if the Ukrainians had been defeated and "peace" imposed on them by that time.

And I agree completely about the courage of Russians willing to publicly raise their voices against the war.

37. **Anon42**
February 25, 2022

One purely symbolic but low effort gesture some readers of this blog could make to support Ukrainian civil society would be submitting their best work to the journal Symmetry, Integrability and Geometry: Methods and Applications (SIGMA, https://www.emis.de/journals/SIGMA/). This is a high quality but not super prestigious mathematical physics journal run by volunteers from the National Academy of Sciences of Ukraine that is free for readers, free for authors, and an arxiv overlay. Symbolism aside, this is probably how Western journals should have set up their publishing models in any case. Some major caveats…I have no idea whether the editors would support this since it's certainly possible they're unable to deal with reviewing articles given the more pressing matters at hand. I also have no clue about their politics.

38. **Dylan Thurston**
February 25, 2022

The letter text was finalized on Sunday, before the invasion started in any sense.

39. **Greg_S**
February 25, 2022

Here's what's not clear to me: While the IMU is dragging its feet, have any of the other mathematics societies mentioned in the updates called on their members to boycott the meeting, and have any individual mathematicians announced their refusal to attend?

40. **an American mathematician**
February 25, 2022

> Update: Many Russian mathematicians likely feel the same way about this as Edward Frenkel who calls this "a catastrophe for Russian people and all Slavic people".

> I have no knowledge specifically of what Okounkov or Smirnov think about this, but I'm guessing that almost all the Russian mathematicians associated with organizing the ICM feel much the same: the Ukraine invasion is a terrible disaster and the conference can't take place in July, but saying this publicly would carry severe implications for their personal safety so they're not going to do so.

I'm not so sure that this is actually true, Peter. In fact, I suspect that the opposite may very well be true. I think that many Russian mathematicians would still like the ICM to take place in Petersburg, and would be upset if it were canceled, moved, or boycotted. The ones that work in the West would probably be hesitant to express such an opinion publicly, due to its sensitive political nature.

I hear that support for the "special military operation"/"invasion" in the/~~the~~ Ukraine is very high among the ethnic Russian general population, and I see no reason why mathematicians would be any different. As an American who has spent a semester in Petersburg, I can tell you that nationalism is strong, even among the scientific intelligentsia in post-Soviet Russia.

Shafarevich, for example, never left Russia, despite the mass exodus of former Soviet mathematicians for the West in the 90s. His political views can perhaps be described as Russian Orthodox chauvinism, and his writings have been criticized in the West as anti-Semitic. I still remember the efforts of American mathematicians in the 90s to expel him as a member of the NAS. He eventually staged his own boycott of sorts by resigning in protest against the 2003 U.S.-led invasion of Iraq. Shafarevich was a particularly vocal case, but my guess is that he was not the only one to hold such views, even if you include the younger generations of Russian mathematicians.

Frenkel is, of course, a great mathematician, but I wonder whether he really speaks for all Russian mathematicians. I often hear stories of how Jewish and other minorities felt oppressed in Soviet Russia (Frenkel was apparently not admitted to Moscow State for political reasons).

I don't know what Okounkov or Smirnov think of the statements from other national math societies either. *mathlog* says that neither is based in Russia, but I believe that Smirnov has a position at St. Petersburg State, and that Okounkov has a position at the Higher School of Economics, as does Bogomolov. In fact, in the interview that *mathlog* linked to, Smirnov says, "We also support the request not to sacrifice mathematics in general and the activities of the IMU in particular to boycotts and other political acts." Okounkov is also representing Russia on the IMU EC as a member-at-large. I suppose we will see what happens.

41. **Peter Woit**
February 25, 2022

an American mathematician,
My experience may be limited, but from what I've seen Russian mathematician fans of Putin and the attack on Ukraine are about as rare as American mathematician fans of Trump and the attack on the Capitol.

Okounkov definitely is US-based, until recently at Columbia (on leave this year), this fall I hear at Berkeley. He has been one of the main organizers of the 2022 ICM, and I can only imagine how difficult this situation is for him and his hopes for this event.

42. **Peter Woit**
February 25, 2022

Greg_S.,
At this point I think people see no need to call for a boycott of something that isn't going to happen.

43. **jsm**
February 26, 2022

February 26, 2022. The IMU continues to support Putin's Russia with its website advertising: "The International Congress of Mathematicians (ICM) will take place in Saint Petersburg, Russia, between 6–14 July 2022."

44. **Sam Hopkins**
February 26, 2022

The prominent Russian mathematician Anatoly Vershik (https://en.wikipedia.org/wiki/Anatoly_Vershik), who is in fact based in St. Petersburg, has called for the cancellation of ICM 2022: https://twitter.com/SocMathFr/status/1497204027163037700.

45. **Sam Hopkins**
February 26, 2022

Huge update! The ICM will take place fully online, at the same time as scheduled: https://www.mathunion.org/fileadmin/IMU/ICM2022/ICM_2022_statement.pdf.

46. **Sam Hopkins**
February 26, 2022

Sorry to keep spamming comments, but another thing your readers might be interested in is that Terry Tao, who is the chair of the ICM Structure Committee, is inviting discussion of how best to use the virtual format of the ICM on his blog at https://terrytao.wordpress.com/2022/02/26/the-international-congress-of-mathematicians-icm-2022-will-now-be-fully-virtual-how-best-to-utilise-this-format/. (Note that he wants to limit discussion to the *format* of the ICM, and not the surrounding politics.)

47. **a Russian mathematician**
February 26, 2022

I’d like to second an American mathematician. There are Russian mathematicians of this type. Alex Bondal still openly defends the invasion in his public Facebook posts. There are others like him, who are less obnoxious.

48. **Will Sawin**
March 2, 2022

A letter from (currently) 351 Russian mathematicians bravely speaking out against the invasion: https://trv-science.ru/2022/02/mathematicians-against-war/

A Few Items

March 4, 2022
Categories: Uncategorized

Some short items and links:

- Among possible futures that I never would have dreamed of during my student days was that someday my Nobel-prize-winning undergraduate advisor would "try to rile" my Nobel-prize-winning graduate school professor at a Bohr Centennial celebration by quoting me. I hope the quote at least was one I would agree with.
- Also on the topic of hoping I agree with what I say publicly, there's an NHK documentary about Mochizuki and the abc conjecture that has recently been finished, was supposed to air in Japan this weekend, now delayed til next month due to more timely news from Ukraine. I did an interview with the filmmakers here in NYC last year and they talked to many other people. No idea how they'll manage to deal with this controversial story, coming from a Japanese perspective.
- At Quanta magazine, another article about the "naturalness problem", headlined A Deepening Crisis Forces Physicists to Rethink Structure of Nature's Laws. This has the usual problem with such stories of assigning to the Standard Model something which is not a problem for it, but only for certain kinds of speculative attempts to go beyond it. John Baez makes this point in this tweet:

  > Indeed, calling it a "crisis" is odd. Nothing that we really know about physics has become false. The only thing that can come crashing down is a tower of speculations that have become conventional wisdom.

  James Wells has a series of tweets here, starting off with

  > The incredibly successful Standard Model does not have a Naturalness problem. And if by your criteria it does, then I can be sure your definition of Naturalness is useless.

  He points to a more detailed explanation of the issue in section 4 of this paper.

- My criticisms of some Quanta articles are motivated partly by the fact that the quality of the science coverage there is matched by very few other places. If you want to work there, they have a job open.
- But if you really want to cash in on gazillionaire money going into mathematics, you might want to try for some of the $20 million that crypto entrepreneur Charles Hoskinson is giving Carnegie Mellon to establish the Hoskinson Center for Formal Mathematics. Early in his career Hoskinson was in a Ph.D. program in analytic number theory, but bailed and later joined Ron Paul's presidential campaign, and ended up in crypto since "When Bitcoin came out, it was like the spiritual successor to what Ron Paul was talking about" (see here).
- Someone who is not going to be getting Hoskinson funding is Michael Harris, whose The Silicon Reckoner you should follow for an alternate take on "formal mathematics". For the reaction to such criticism from the formalizers, you can check out this Zulip Chat archive, and then responses from Harris here.
- For Grothendieck news, see here, here and here.

Update: There's a statement out today from Breakthrough Prize Laureates strongly criticizing Russia's invasion of Ukraine. There's also a truly appalling statement from the Breakthrough Prize Foundation itself, not in the least critical of Russia or Putin and abusing the memory of Stephen Hawking. Witten characterizes the Foundation statement as "disappointingly vapid".

Update: Milner seems to have realized that refusing to criticize Putin was not a tenable position. A new statement from the Breakthrough Prize Foundation starts off with:

> As the terrible war in Ukraine continues, with casualties and atrocities mounting, the Breakthrough Prize Foundation strongly condemns Russia's invasion of Ukraine and its unprovoked and brutal assaults against the civilian population.

and announces a further \$ 3 million donation:

> the Foundation today pledges a further \$3 million in funding to support physicists, life scientists and mathematicians who have been forced to flee from Ukraine. We hope that this donation will help talented researchers contribute to human knowledge in such dark times.
>
> The Breakthrough Prize Foundation stands together with the Ukrainian people, its scientists and their families.

   March 4, 2022

   For the record, the relevant quote/paraphrase was "string theory is not even wrong", so I'm pretty sure you're safe there.

2. **Peter Woit**
   March 4, 2022

   4gravitons,

   Thanks! Although these days I'm leaning more to the "string theory (as an idea about unification) is just wrong" point of view…

3. **Sabine**
   March 5, 2022

   Just here to mention that my 2018 "Lost in Math" is about the naturalness myth that led particle physicists to erroneously expect new physics (besides the Higgs) to show up at the LHC. I agree with Baez and Wells, but I think the larger question looming here is: how could this have happened?

4. **Bob**
   March 5, 2022

   Is that twitter account confirmed to really be Edward? It doesn't have the blue checkmark next to his name, and there are a lot of fake accounts out there.

5. **Peter Woit**
   March 6, 2022

Bob,
As far as I know it is him. If someone knows for a fact that it is a fake, let me know.

6. **Peter Woit**
March 6, 2022

For an exchange between Sabine and the author of the Quanta piece, see here
https://twitter.com/skdh/status/1500516249251549186

I'm sympathetic to Sabine's frustration that her argument about this has been ignored, since I also wrote a book giving an argument about this which has been ignored. Back in 2002 I wrote about this in the section on SUSY in my book (see page 164 of the US edition). There I explained that the hierarchy problem (since cleverly rebranded as the "naturalness" problem) was something you got from postulating GUT or string unification at a GUT or Planck scale. Low energy SUSY was supposed to fix this particular problem, but my argument was that GUTs/strings had strong evidence against them (they were complicated and didn't really explain anything), and adding SUSY just made things worse.

Besides writing about this in the book, I've probably made similar arguments dozens if not hundreds of times on this blog since 2004, for many years in the context of arguing that the LHC was not going to see SUSY. After the negative LHC results, at first I thought that the new-found "crisis" in HEP theory would cause people to acknowledge the underlying problem, but it now looks like that's never going to happen (and those who long ago pointed out the underlying problem will always go unmentioned…)

7. **Lee Smolin**
March 7, 2022

Dear Peter,

I can only agree that this talk of a crisis in elementary particle physics, due to what the standard model doesn't explain, is very old news.

I first heard the concept of a crisis in the standard model in a talk Abraham Pais gave at a conference at Boston University (Or was it U Mass, Boston?) when I was an undergrad (~ 1974). This is not very long after the SM had been formulated. His theme was that the standard model, while it did very well as a description of the forces, did not explain a single parameter of particle physics or reduce the number of parameters by even one. He discussed the hierarchy problems and clearly called this a crisis.

I've been in crisis mode ever since, as have not a few others. Much of my work since has been intended as a response to the crisis. All of these responses have had in common the idea that laws are not eternal, but evolve dynamically on a landscape of theories. These have included Cosmological Natural Selection (1992), the subject of my first book (Life of the Cosmos, 1997). The issues related to reductionism, and how to modify it without loosing falsifiability is dealt with at length, there and in later books,. The need for background independent, and relational theories also must be understood an implication of the same crisis.

There turn out to be several hypotheses about how the crisis might be resolved if the laws evolve – include the Principle of Precedence, and the autodidactic universe. All of these responses to the crisis turn out to be related to the concept of laws and of time, indeed this is itself very old news as it was discussed clearly by CS Pearse in the late 1890's.

If we want to resolve this now 50 year old crisis I would suggest we focus on the ways in which our current schema for physical theories (which Roberto Mangabeira Unger and I call The Newtonian Paradigm) is unfit for extending physics to a cosmological scale, and how our notions of law and time must be reshaped to apply to a theory of the whole universe.

Thanks,

Lee

March 9, 2022

When Ed. Witten describes the statement by S. Pete Worden, chairman of the Breakthrough Prize Foundation, as vapid – because (?) he doesn't name Putin & the Russian army as aggressors of Ukraine (contrary to the statement signed by a lot of Breakthrough Prize Laureates) – it reminds me of this famous dialog with Titus and his father Vespasian (Roman emperor) as reported by the historian Suetonius:

> When Titus found fault with [Roman empire Vespasian] for contriving a tax upon public conveniences, he held a piece of money from the first payment to his son's nose, asking whether its odour was offensive to him. When Titus said "No," he replied, "Yet it comes from urine."

Source : Life of Vespasian 23.3 (tr. J.C. Rolfe)
Far from me the desire to play the devil's advocate but nowadays the further one is from a Russian laundromat(?) or a [dirty (?), source of] cash* the easier or safer one can nurture humanity's highest qualities like Honesty…!
*https://twitter.com/gfbertone/status/1500040565056061440

A question for Peter: why do you think the memory of Stephen Hawking is abused in Worden' statement?

11. **Peter Woit**

March 9, 2022

Cedric Bardot,
I thought invoking Hawking in attributing the Ukraine war to “our aggressive instincts”, while refusing to criticize Putin and the Russian state, was thoroughly repulsive. Saying what is happening in Ukraine is due to “our” aggressive instincts is like saying the same thing about Hitler’s invasions.

The funny thing is I had some sympathy for Milner, that he was being unfairly attached to Putin and his dictatorship. Seeing that statement made me quickly lose any such sympathy. I doubt it was issued without his approval.

12. **Risk Averse**
March 9, 2022

I am not an expert about oligarchs, but I would guess most of them did quite immoral things in order to get rich. Nevertheless, I find this rush to ask people to condemn Putin, quite ridicules. Clearly, Putin is a horrible man, becoming his enemy is very dangerous. I assume that any Russian expressing views against Putin is taking a risk for their property, freedom, and life. There are quite a few Russians in the west that were probably killed by Putin’s people. So who in their right mind will issue a statement against him? Moreover, condemning Putin might feel morally nice, but it will not make any difference to the reality.

13. **Peter Woit**
March 9, 2022

Risk Averse,

Milner’s claim is that he’s not an oligarch, has been out of Russia for ever, and that his venture capital business has no funding from Russia. If, unlike lots of other Russians now in the West or in Israel, he is fearful of publicly criticizing Putin, that’s fine. What’s appalling is issuing public statements like the one linked to here which attach blame for what has happened to anyone else other than Putin and his regime.

My interpretation of what happened is that Milner thought donating \$3 million to “victims of the conflict” (while not specifying whether they were Ukrainian or Russian) would solve his ethical problem with cash. Don’t know why with him it’s always exactly \$3 million…

14. **Risk Averse**
March 9, 2022

Peter, the last paragraph in your response is messed up.
I don’t know how Milnor made his money and I don’t really care. He is very rich so I assume he made it on the expense of lots of other people. However, he is still Russian and it is very likely Putin can put the squeeze on him, one way or another. In any case, who cares what he says, that does not change anything.
I think that people who grew in the west have no idea how risky things can become very quickly. I grew up in Israel, which in many ways is very democratic. However, if you are an Arab, unfortunately, you probably should be careful what you do and what you say. We should all be careful telling other people to do things that can put them in risk.

15. **Peter Woit**
March 9, 2022

Risk Averse,
If Milner wants to keep quiet because of the dangers, that’s fine. As far as I know, no one was demanding that the Breakthrough Prize Foundation put out a statement taking a stand on the war. He could have given money to refugees without making a public statement, or just announced he was donating money without saying anything else. I can’t see any reason it was necessary to make an offensive public statement invoking Hawking.

All,
I’m deleting comments on oligarchs, the war, etc. which have nothing to do with the Breakthrough Prize statement.

16. **Yovan**
March 10, 2022

The decision by Peter Scholze to decline the horizon prize looks prescient now. I feel bad for next year’s winners.

17. **dms**
March 10, 2022

If anyone wants to be entertained I’d recommend reading Lubos’ posts on Ukraine. Nutty as always, but it’s comforting to me that he’s at least as upset about the invasion as your standard center-left academic types. A silver lining of the invasion is that it demonstrates that political differences within the west are mostly a pose, and that there is a real consensus on what is fundamentally unacceptable.

18. **curiouser**
March 11, 2022

Glashow had already invoked the Pauli quote “not even wrong” in a Physics Today article on superstrings in 1986, so he may not have been referring to this blog or Woit at the Bohr Centennial. This is the relevant quote:

`Superstring theory, unless it allows an approximation scheme for yielding useful and testable physical information, might be the sort of thing that Wolfgang Pauli would have said is “not even wrong.” It would continue to attract newcomers to the field simply because it is the only obvious alternative to explaining why certain detectors light up like video games near the end of every funding cycle.’

https://arxiv.org/abs/physics/9403001

19. **Peter Woit**
March 11, 2022

curiouser,
Yes, that’s quite possible. Surely Glashow was aware of the “Not Even Wrong” quote long before I was around and he and many others from the early days of the “first superstring revolution” were of the opinion that it applied well to what was going on in string theory.

20. **4gravitons**
March 16, 2022

To clarify, Glashow specifically mentioned Woit in his comment (he did also mention it was a paraphrase of Pauli).

21. **Anon**
March 16, 2022

Hi Peter

There is no "standard" model for neutrino masses. The renormalizable Standard Model predicts the neutrino masses to be zero (with non-renorm terms of the order m_weak^2/M_Planck if there is no other mass scale). This prediction has been proven wrong. So one has to go beyond the SM for neutrino masses.

We could do this, without introducing a new Mass scale (the seesaw scale), by adding 3 right-handed neutrinos and providing small Dirac masses to them.

I think your view is that this model with Dirac masses to neutrinos, doesn't have a hierarchy problem — but this is *not* the Standard Model. In fact, the standard or more popular thinking as far as neutrino masses go is that they are Majorana (not Dirac), and their smallness can be understood to be because of the seesaw mechanism. This then brings a new mass scale into play and generates the Hierarchy problem. To avoid the Hierarchy problem I think you'd predict the neutrinos have Dirac masses.

I think though that this reasoning takes the Hierarchy Problem very seriously. As we need to extend the SM by adding 3 right handed neutrinos, and impose a B-L global symmetry so that neutrinos get dirac masses from really small Yukawa couplings. This is what you seem to be saying doesn't have the Hierarchy problem. But there is really no evidence for this model or for an exact B-L global symmetry in nature.

I personally think we have the seesaw mechanism at 10^14 GeV seesaw scale, and for reasons, we don't fully understand yet the Hierarchy problem isn't a show-stopper.

22. **Peter Woit**
March 16, 2022

Anon,
Since there's zero evidence for either Majorana masses or a seesaw mass scale, I don't see how this can be "standard" in any sort of way (about "popular" I'm not sure that's right and in any case its irrelevant).

When people say "the Standard Model" these days, obviously they're including some way of dealing with neutrino masses. Personally I don't see why dealing with them exactly the way one deals with all the other fermion masses (Dirac mass terms) shouldn't be thought of as the "standard" way.

That said, a right-handed neutrino is something very different than other particles (no em/weak/strong couplings) and this makes the neutrino sector and the issue of neutrino masses the place one is most likely to find something new and unexpected that finally improves on the standard model. Personally the seesaw mechanism seems to me to open more problems than it solves, but tastes differ. In the Euclidean twistor stuff I've been thinking about, right handed neutrinos are something very fundamental, and I'm hopeful that one might get somewhere very interesting thinking of them in these terms (I haven't yet).

23. **Anon**
March 16, 2022

SM has relevance as a low energy effective field theory. If neutrinos have Dirac masses then SM is not the low energy effective field theory, as the matter content gets modified at low energies by the addition of 3 right handed neutrinos.

When people say SM they mean it without right-handed neutrinos I think, in the sense of a low energy effective field theory.

SM + Dirac masses to neutrinos goes beyond the SM, even at low energies.

24. **The Big Red Scary**
March 17, 2022

Concerning the Russian invasion of Ukraine, Woit and Motl have finally found something to agree about.

25. **Peter Woit**
March 17, 2022

Anon,
I just don't agree with your conception of the meaning of the words "standard model" as something
1. Completely wrong, since doesn't have neutrino masses
2. Only a low energy effective approximation.
but arguing over the meaning of words leads nowhere.

26. **Peter Woit**
March 17, 2022

The Big Red Scary,

I think, as a matter of principle, if Lubos and I agree on something it must be true.

27. **martibal**
March 17, 2022

Peter and Anon, maybe this is off-topic, but besides words, is the issue Anon is mentioning something physically problematic ? I mean: does incorporating in the Standard Model right handed neutrino with low Dirac masses create some incoherence regarding renormalization, or other incoherence ?

28. **Anon**
March 17, 2022

From the literature in the field, SM refers to a very specific, well-accepted, model that predicts that neutrinos have no mass. The discovery of neutrino mass is considered the first new physics found that goes beyond the standard model.

But I think it gets step-parently treatment — it wasn't the new physics people hoped would be discovered (like SUSY etc) — and since larger issues in the field are framed without any reference to neutrino masses, those discussions continue with neutrino sector ignored.

Which "Beyond standard model theory" do neutrino masses indicate? I think this is an important question that experiments would have to decide. There is no experimental evidence one way or the other yet of whether neutrinos have Majorana or Dirac-type masses. This has to be experimentally determined — we can't just say the SM prediction is that neutrinos have Dirac masses (which is what Peter is implying). The SM prediction was that neutrinos have no masses, which has been ruled out.

The implication of Dirac mass for the neutrinos is that you have to modify physics at low energies — new light degrees of freedom — right handed neutrinos that exist in our world even today!

If they have Majorana masses then right-handed neutrinos do not exist at low energies (their mass could then be at the much higher seesaw scale ~ 10^14 GeV), and below that scale it is just the usual SM without right-handed neutrinos.

I think Peter takes the Hierarchy problem very seriously (just as SUSY folk did :-)) and ends up arguing for SM + 3 right handed Dirac neutrinos as being the theory of nature, that doesn't require further proof as he equates this to SM.

But in my opinion, this requires the same level of proof as SUSY did, especially if 3 Dirac neutrinos is what is the solution or implication of the Hierarchy problem.

martibal — you can add 3 right handed neutrinos to the SM and give them Dirac masses by imposing a B-L global symmetry. This introduces a bunch of small dimensionless numbers (very tiny Yukawa couplings with the Higgs of the neutrinos)… much much smaller than for any of the other particles — like even electrons. But one can live with that. Also, once you add 3 right handed neutrinos to the SM, the most general Lagrangian would include Majorana masses to the neutrinos anyway — you would have to impose B-L symmetry as a global symmetry of nature to exclude the terms giving rise to Majorana masses.

29. **Peter Woit**
March 17, 2022

Anon,

I agree with your answer to Martibal.

My view on the hierarchy problem is that the SM has no hierarchy problem, including if you interpret "SM" as treating neutrino masses like other masses, caused by a Dirac mass term and right-handed neutrino fields. The hierarchy problem is a problem for people trying to build theories that include the the usual Higgs and some new physics at a much higher mass scale, whether it be seesaw masses, GUTs, high-scale SUSY, your favorite Planck scale quantum gravity physics or whatever. To my mind, all such attempts have more serious other problems than the hierarchy problem (they explain very little by adding a lot of complexity, with zero experimental support).

Again, what I think is really interesting here, indicating a way truly beyond the SM, is the very unusual nature of right-handed neutrino fields.

30. **Anon**
March 17, 2022

yeah I agree Peter that the right handed neutrinos are interesting.

In fact, the minimal left-right symmetric (LR) model anticipated/predicted that neutrinos would have masses. Basically, because of parity, both left and right-handed neutrinos must be included, and right-handed neutrinos pick up a large Majorana mass at the parity (or B-L) breaking scale, and set up the seesaw mechanism. In fact, you cant have Dirac type neutrinos in the minimal left-right symmetric model (they'd be too heavy and experimentally ruled out…. the Yukawa couplings of neutrinos to the usual Higgs cannot be made arbitrarily small in the LR model, as right-handed neutrinos are integral to the model and don't just decouple if their Yukawas vanish, like they decouple in SM with 3 right handed neutrinos).

LR model also makes other predictions.

31. **Mariner**
March 20, 2022

What do you think of this?

https://profmattstrassler.com/2022/03/20/a-prediction-from-string-theory/

32. **Peter Woit**
March 22, 2022

Mariner,
I have to assume the headline about "a prediction from string theory" is just trolling.

This kind of thing is a blast from the past, something some people engaged in during the string wars 15 years ago but have long given up on. Of course, there is nothing like an actual prediction from string theory here. What Strassler is writing about is some exotic models he worked on 15 years ago, for which there never has been the slightest evidence or even any sort of significant motivation. The only connection to string theory is that conjecturally you could use AdS/CFT to calculation some implications of these models.

2022 Abel Prize to Dennis Sullivan

March 23, 2022
Categories: Uncategorized

This year's Abel Prize has gone to topologist Dennis Sullivan, for the announcement see here, with more information about Sullivan and his work here. There are press stories at Nature, the New York Times, Quanta, and elsewhere.

Sullivan was one of the leading figures in great advances in understanding the topology of manifolds in higher dimensions during the late 60s and 70s. Some of the best of his early work for many years was only available if you could find a copy of unpublished mimeographed notes from a 1970 MIT course. In 2005 a Tex'ed version of the notes was finally published (available here). This includes as a postscript Sullivan's own description of this work, how it came about, and how it influenced his later work.

This was followed by wonderful work on rational homotopy theory, making use of differential forms. For this, see Sullivan's 1977 Infinitesimal computations in topology, and lecture notes on this by Phil Griffiths and John Morgan. In later years Sullivan's attention turned to subjects with which I'm not very familiar: topics in dynamical systems and the development of what he called "string topology".

Since 1981 Sullivan has held the Einstein chair at the CUNY Graduate Center here in NYC, running a seminar each week that concentrates on the relation between topology and QFT. For many years these were held in a Russian style, going on for multiple hours, possibly with a break, until all participants were exhausted. There's a remarkable collection of videos of these lectures at the seminar site, including many going way back into the 80s and 90s, with video recorded at a time when this was quite unusual (more recent ones are on Youtube).

When I first came to Columbia Sullivan was often here attending and giving lectures, for many years splitting his time between Paris (where he held a position at the IHES), New York and Rio. The Abel Prize biography explains

> In 1981, Sullivan was made the Albert Einstein Chair in Science (Mathematics) at the Graduate School and University Center of The City University of New York. He kept his position at IHES and spent the next decade and a half shuttling between Paris and New York, often on Concorde.

Some of the various stories I heard about Sullivan's lifestyle at the time involved his having multiple apartments in New York, which he used to host a variety of visiting mathematicians. Another story I heard directly from him was about how he survived an attempted car-jacking in Brazil, during which he was shot, but managed to escape and drive himself to a hospital for treatment. I had first heard about this from Mike Hopkins several years before. When I asked Hopkins why he had become a topologist, he said that one factor was the inspiring example of people like Sullivan who worked in the field, jokingly characterizing it as involving "real men who got into gun-fights".

In 1997 Sullivan traded the IHES position for one at Stony Brook, and over the years has unfortunately been seen less often here at Columbia. Congratulations to him on the well-deserved prize!

Is Space-Time Really Doomed?

March 31, 2022
Categories: Euclidean Twistor Unification

For many years now the consensus in a dominant part of the theoretical physics community has been that the center of attention should be on the problem of quantizing gravity, and that conventional notions of quantum theory and space-time geometry need to be abandoned in favor of something radically different. The slogan version of this is "Space-Time is Doomed."

Ever since my student days long ago, I've spent a lot of time looking into the problems of quantum gravity and what people have tried to do to address these problems. The highly publicized attempts to get known physics out of radically different degrees of freedom that I've seen haven't seemed to be making any progress, remaining very far from anything like known physics. In the case of string theory, which also claimed to be able to get particle physics, there was at one point a (highly over-hyped) relatively well-defined proposal that one could discuss, but that's no longer the case.

Recently things have changed as I've become convinced of the promise of certain specific ideas about four-dimensional geometry involving twistors and Euclidean space-time signature. I've written about these here and on the blog, and have given some talks (see here and here). These ideas remain speculative and incomplete, but I think they provide some new ways of thinking about the problems of quantizing gravity and unifying it with the other forces.

The existence of a yearly essay competition gave me an excuse to write something about this which I just finished yesterday and sent in, with the title Is Space-Time Really Doomed?. After spending some time on a diversion into arithmetic geometry, I've been getting back to seriously thinking about this topic, looking forward to having time in coming months to concentrate on this. I hope the essay will encourage others to not give up on 4d geometry as doomed and unquantizable, but to realize that much is there still waiting to be explored.

Update: The essay is now on the arXiv here.

Update: Awards for this announced here. I got an honorable mention.

Comments

1. **Mark**
   March 31, 2022

   Apart from the metric and the Cartan tetrad formalisms of geometry mentioned in your article, there is probably a third formalism worth exploring, the geometric algebra formalism of geometry, which uses real Clifford algebras.

   The geometric nature of quantum field theory and the Standard Model, the gauge theoretic nature of gravity, and the relation between the mathematical structures of four-dimensional geometry, general relativity, and quantum field theory were already made explicit in the geometric algebra formalism in Chris Doran and Anthony Lasenby's 2003 textbook titled Geometric Algebra for Physicists:
   https://www.cambridge.org/core/books/geometric-algebra-for-physicists/FB8D3ACB76AB3AB10BA7F27505925091
   Furthermore, the book comes with a section of a chapter showing that the geometric algebra formalism could also be used for twister geometry and a twister-based formalism as well.

2. **Andrei**
   April 1, 2022

   The "space-time is doomed" claim, put forward by Nima Arkani-Hamed is based on two arguments:

   1. In order to perform an infinitely accurate measurement you need an infinitely large instrument, otherwise the quantum uncertainty imposes an accuracy limit. When you want to fit an infinitely-sized instrument into a laboratory room you collapse to a black hole and no measurement is done.

   2.In order to measure something very small (below Planck length) you need a very energetic particle which, again, would result in a black hole.

   I think both arguments are fallacious.

   1. Even if the physics is classical you need an infinitely sized memory to record a result with infinite accuracy. Forcing that memory inside a room would lead to a black hole. So quantum uncertainty is a red-herring here. And why would you expect to be able to perform an infinitely accurate measurement with finite resources? Why is this premise supposed to be true in the first place?

   2.One can measure in principle distances smaller than Planck length with interferometry. No need for ultra-energetic particles. LIGO measures distances with an accuracy of about 10^-20m with a wavelength of 10^-5m.

   So, Nima's arguments fail.

3. **David Roberts**
   April 1, 2022

   @Andrei,

   John Baez wrote a nice article explaining all kinds of issues that arise when thinking of the universe as being modelled by infinite precision reals, even using boring old Newtonian mechanics

   "Struggles with the Continuum", https://arxiv.org/abs/1609.01421

4. **Pascal**
   April 1, 2022

   Can your approach accommodate quantum superpositions of different spacetimes? This looks (to my nonexpert eyes) like something that should be included in any successful theory of quantum gravity. Or else, you would have to abandon some basic tenets of relativity (spacetime) or of quantum theory (quantum superpositions).

5. **Peter Woit**

April 1, 2022

Mark,
There's an argument for replacing the use of differential forms and the exterior algebra with the Clifford algebra, for one thing it makes introducing spinors more well-motivated. But that works for any dimension, in this essay I wanted to aim at certain structures specific to 4d.

6. **Peter Woit**
April 1, 2022

Andrei,

In any case the argument that you need to consider black hole states doesn't imply doom for space-time. After all, they're space-time geometric objects themselves.

Pascal,
Sure, in a quantum theory of space time you should have superpositions of geometries just like in QED you have superpositions of EM fields.
One thing I'm pointing out is that the fact that we haven't found a convincing quantum dynamics for the degrees of freedom given by geometry of space-time does not mean that those are the completely wrong fundamental degrees of freedom, just emergent epiphenomena. This problem is fine as a motivation for looking for different fundamental degrees of freedom, but that's not led to anything successful either.

7. **Alex**
April 1, 2022

I agree with the sentiment. I also have a bold proposal, not about a physical theory, but a sociological one: it's time to stop listening to the people in the community that has been so wrong over decades by now, hyping and overselling *their doomed ideas*. For the good health of the field, this has to stop. The names are so obvious that there's not even a need to spell them out explicitly, we all know who they are, what have been they saying for decades, with what language, tone, and bullying methods. But the problem was not even one of academic ethics, it's simply that the ideas have failed miserably to deliver their promised 'El Dorado' of physics, and misdirected a whole field and young researchers to nowhere.

8. **Darran**
April 2, 2022

I don't think the comments above do justice to Arkani-Hamed's arguments regarding spacetime. There's a big difference between classical and quantum mechanics regarding measurements.

In classical mechanics measurements are treated no differently to any other process and thus the ability to perform an accurate measurement is of no consequence to defining the theory. The physical degrees of freedom are defined independently of how they are measured.

However in quantum theory the whole formalism is an engine to compute the probabilities associated to sharp measurements. Arkani-Hamed's point is that in a setting where we treat gravity and cosmology realistically it's not possible to fulfill the conditions quantum theory assumes measurements obey within a finite region and thus it seems difficult to have well-defined local observables.

Of course in quantum information we can model unsharp measurements with POVMs, but the space of operators still includes sharp PVMs. If PVMs aren't possible at all locally the theory would seem to need to take a very different form.

Of course the above does not "prove" this line of argumentation is correct, Arkani-Hamed has been clear that this is just his intuition about where to go. However you can't argue it's wrong by ignoring the completely different nature of measurements in quantum and classical theory.

9. **Peter Woit**
April 2, 2022

Darran,
I guess I just don't see the relevance of any such arguments to the claim being made (that space-time degrees of freedom cannot be what a fundamental theory is based on, they should be emergent degrees of freedom of an effective theory).

10. **Darran**
April 2, 2022

Peter,

Essentially because spacetime degrees of freedom would be local ones if they retain their character from GR. If there doesn't seem to be local observables due how measurements work in a realistic cosmological setting it is hard to see how the proper quantum theory would involve spacetime in its conventional form.

His isn't the only view where considerations of treating measurement realistically result in a weakening or replacement of the notion of spacetime. Rovelli's relational quantum mechanics is an example.

11. **Alex**
April 2, 2022

Peter,

when you say spacetime may not be doomed in QG, which one of the following options are you thinking of?:

1) Both classical manifold and metric, the pair (M,g), are somehow still there at the fundamental physical reality, even after quantization.

2) Only the manifold M survives at the Planck scale.

3) Both of these concepts in the pair (M,g), and their mathematical machinery, are still needed to formulate the quantum theory via quantization of (general relativistic) classical field theories. Now, at the physical fundamental level, that doesn't mean that there's a classical pair (M,g) waiting for us at the Planck scale.

4) Physical quantum spacetime at the Planck scale may be some sort of noncommutative geometry, where basic geometric notions such as metric and fiber bundles can be suitably generalized into their noncommutative counterparts, and hence our basic geometric ideas can still be implemented there (although, in their noncommutative incarnations).

5) Other?

Thanks.

12. **Peter Woit**
April 2, 2022

Darran,
To sensibly discuss this, I think one needs to get much more specific. I don't know what it means for a quantized degree of freedom to "retain its character" with respect to the classical theory, or exactly what locality means in this context.

Alex,

The essay was trying to point to a relatively specific proposal: standard 4d geometry is formulated in terms of standard geometrical degrees of freedom (SD/ASD spin connection/curvatures, vierbeins, torsion, half-spinors, twistors). Can one build a fundamental theory by quantizing these degrees of freedom? In a path integral formalism you want to find an action/path integral measure written in terms of these variables that makes sense. I know the various problems people have run into trying to do this in the past, want to understand if there is some way to overcome these problems in the somewhat different specific setup I'm proposing that includes the SM degrees of freedom

13. **Darran**
April 2, 2022

Peter,

Basically if we imagine spacetime surviving in the resulting quantum theory, then you would imagine some structures from classical GR or more fundamentally just basic geometric notions, e.g. connections, will appear in quantised form.

Regardless of what geometric entities are quantised, quantising classical variables gives you self-adjoint operators. Self-adjoint operators are just weighted sums of projectors, so essentially quantising gives PVMs with weights.

However it seems that no realistic observation in a finite region actually corresponds to a PVM/Self-Adjoint operator. Only POVMs are possible, to use quantum information language. Thus quantisations of classical quantities don't seem to lie within a cosmologically realistic quantum theory. Hence a quantisation of classical geometry can't be fundamental.

Asher Peres has a nice paper "What's wrong with these observables?" where he discusses how most POVMs don't correspond to quantised versions of classical observables. Arkani-Hamed doesn't use Quantum Info terms like POVM, but it's just a formal way of expressing a lack of sharp observables.

Quantised classical variables correspond to idealised measurement processes. In non-relativistic QM and Minkowski QFT we can get away with this idealisation by recourse to limiting infinitely massive devices, but Arkani-Hamed's point is that in a treatment that properly respects cosmology we cannot. Thus "quantised geometry" would not be the way to go.

14. **Alex**
April 3, 2022

Peter,

okay, then I think that would fall into point 3) of my list. Personally, that's my opinion too. But, what insurmountable problem do you see with other approaches that take a similar view on this (e.g., LQG; of course, it's a canonical quantization approach rather than path integral, but the view on the role of classical geometry is similar; and, although still with some problems, some versions of if, like Thiemann's Master Constraint Programme, seem quite advanced by now; not that I'm trying to sell this approach, I have my doubts too, but I'm just mentioning it)? Also, why path integrals, knowing their infamous ill-defined measures over infinite dimensional field configuration spaces?

Anyway, I have a simple reason to stick to 4d standard geometry rather than über speculative theories: it's physics that actually *works* and describes our reality! And science tends to advance by quasi-static changes on the acquired knowledge, despite what those simplified versions of Kuhn's view, that one often hears, say. I think point 4) in page 7 in this article by Rovelli (https://arxiv.org/abs/1805.10602) puts it very well, whatever views one may have on his own approach to (L)QG.

15. **Peter Woit**
April 3, 2022

Alex,
There's a list of serious technical problems that you run into if you try to pursue either path integral or canonical quantization of these degrees of freedom. I think it's quite possible these can be overcome with some new ideas, in particular working in Euclidean space twistor space (with a distinguished time direction). In any case, this seems to be a lot more promising than the idea that you're going to solve the problem with quantum information theory.

16. **Darran**
April 3, 2022

Peter,

Who is trying to solve these problems with Quantum Information Theory? Arkani-Hamed isn't for example, in case I gave that impression.

17. **Peter Woit**
April 3, 2022

Darran,
That was a reference not to Arkani-Hamed, but to the well-publicized and well-funded "It from Qubit" stuff.

These days Arkani-Hamed typically uses the "spacetime is doomed"argument as motivation for his work on reformulating amplitudes calculations, but I don't think the relation is much more than vaguely motivational.

18. **Jack**
April 4, 2022

Dear Peter,

I read your essay with great interest, thanks for sharing.

Since you are interested in the unique nature of 4D, I wonder if it is also worth mentioning that in four-dimensions we have this commuting nature between the Hodge Star and Riemann Curvature operations, as described in Professor Krasnov's book that you reference. This also happens to be when the metric can be described as "Einstein".

Related to this (I think, although I am not sure) is one of my favorite results in the form of Lovelock's theorem and just how general one can make the left-hand side of the Einstein equations. Although it can be generalized to any number of dimensions, in four it shows the unique role played by the cosmological constant. In the light of the cosmological constant problem, I personally think that this is something not discussed enough.

Thanks and best,

Jack.

19. **Peter Woit**
April 4, 2022

Jack,
The commutativity of * and curvature in 4d is exactly what allows one to express GR in terms of just self-dual connections. It seems to me quite remarkable and important (and this was one of the main points I wanted to make in the essay) that 4d GR depends on only half the variables one expects, i.e.half the variables that almost all descriptions of the theory use. For this to work nicely though, you need to be in Euclidean signature.

20. **Prof. Legolasov**
April 6, 2022

Hi Peter,

Can you please elaborate on this (taken from your essay)

> The only known non-perturbative definition of Yang-Mills theory is in Euclidean space-time

What is the definition of Yang-Mills theory in Euclidean space-time that you're referring to?

21. **Peter Woit**
April 6, 2022

Prof. Legolasov,

The lattice gauge theory definition. This very much requires Euclidean signature to make sense.

22. **Pham Trinly**
April 16, 2022

I have a very basic layman question on the subject. Why is Cartan-Einstein theory so very much out of favor? More broadly, could it be that the difficulty of quantizing gravity lays in the fact that the classical theory is incomplete? (And that the missing terms don't make much of a contribution on the experimentally accessible energy scales?)

The Anti-Science Movement

April 6, 2022
Categories: Fake Physics, Uncategorized

I noticed recently that Stony Brook is hosting next week a panel discussion devoted to

> a conversation about one of the most grave challenges to confront humanity: the anti-science movement.

There is a truly grave challenge being referred to, but a serious mistake is being made about the nature of the challenge. In particular, there's no evidence of an "anti-science" movement, quite the opposite. Across the globe, if you ask people what profession they respect the most, "scientist" comes out on top (see here). Likely the organizers have in mind climate denialists and anti-vaxxers as prime examples of "anti-science" behavior, but in my experience such people typically show a great devotion to pointing to scientists, scientific results and scientific papers to justify themselves. An example would be Lubos Motl, who has put out literally thousands of pages on his blog about climate and COVID science (by the way, his blog seems to have gone "by invitation only", anyone know what that's about?).

The problem isn't "anti-science", but bad science, promoted for ideological reasons. This is part of a larger truly grave challenge to humanity, that of our information environment being flooded with untruth, on a scale that dwarfs the output of the Ministry of Truth that Orwell foresaw. For years now we've been living with this in the form of phenomena like Trumpism, and the past few weeks have seen the Russian government exploiting these methods to conduct a campaign of brutal slaughter. I don't know what the best way to address this challenge is, but unless something can be done, humanity has an ugly and disturbing future ahead of it.

Sticking to the problem of what to do about the promotion of bad science, there at least I have some experience trying to do something about one example of it (although with very limited success). This problem deserves attention and a panel discussion, but a panel in which four of six members have devoted a significant part of their careers to promoting a failed scientific research program is a really odd choice.

The underlying thorny issue is that of how to evaluate scientific claims. Given the complexities of controversial science, non-experts generally have little choice but to try and identify experts and trust what they say. A major societal role of elite institutions is to provide such experts, ensuring that they provide trustworthy expertise, untainted by ideology or self-interest. A large part of what is going on these days seems to me to reflect a loss of faith in elite institutions, with an increasing perception that these are dominated by a well-off class pursuing not truth, but their own interests. As a product of such institutions I'm well aware of both their strengths and their weaknesses. We need them to do better, and in this case Stony Brook should come up with a better panel.

Update: I've heard that Lubos himself shutdown the blog, unwilling to agree to follow rules Google was now enforcing.

Comments

1. **Martin S.**
   April 6, 2022

   One way that is bad to support (good) science, is to be superficial. And making it a political issue is another bad thing.
   Thus regarding politicizing, when you bring the Kubrick's clockwork guy, it begs for bringing the political negative of him that tries to destroy education (of math). When you damage education, in a decade no one will be able to recognize (good) science at all.
   And regarding superficial views, when you write about Kremlin vs. past weeks, it omits a crucial point: that Kremlin was liquidating free society in Russia for years, and that only such a destruction allowed them to turn life into nightmare even outside Russia.

2. **Paolo Bertozzini**
   April 6, 2022

   Dear Peter,

   I am not so sure … whenever I see around people with "clear and evident truths" in Their hands (or Their minds) and uniformly shared opinions (very common in today society dominated by influential marketing) … my fist instinct is to stop, doubt and rethink … and this applies also to "open support for *Science*".

   Skepticism (especially in the forms linked to post-modernist epistemology and social constructivism) is often considered the main culprit of the "crisis of faith in *Science*" seen in certain "anti-science movements" very visible in populist circles.

   I am afraid that the "problem with *Science*" today is much deeper and very very unpleasant to explore: *Science*, as it has been on-purpose politically re-branded after the WWII with Popperism at the LSE, is hiding (since its inception) a more complex and unpalatable story. When I was a kid I used to be enthusiastic about everything scientific … now (after almost 30 years paying attention to "under-developed" countries) … I try to stay as distant as possible from *Science* and I tend to believe that *Science*, rather than a solution, has been and is actually playing a big role in support of the main causes of many of the problems that I would like to see eliminated from human society (inequality, racism, exploitation, just to mention those that are closer to my concerns).

   As every technological instrument and knowledge, science can be of great help to identify and solve problems (although its purpose might be unrelated to utilitarian aims. *Science* (note the *quotes*) on the other side, is not just identifiable with a methodology of "knowledge acquisition", but it comes heavily charged with a dangerous ideology (something that was and is often denied claiming its objectivity).

   I repeat that the above "criticism" has nothing to do with "anti-vax" or "anti-green" conspiracy positions now raging mostly in certain "over-developed" countries.

   It is easy (and often necessary) to concentrate on localized issues (for example the trouble with theoretical physics or medical/biological research) … from time to time it is probably a good idea to have a wider panorama. I apologize in advance if this post is "out of topic" (or unwelcome) 😉

   Best Regards.
   Paolo

3. **anonymous**
   April 7, 2022

   The anti-vaccine/anti-lockdown movement is a bad example of anti-science, because at least in the United States is less about science/anti-science and more about American politics and which side of the culture war the issues landed on. For the first few months of 2020 when Trump was still in office, it was largely the Democratic aligned factions of the United States who were denying the severity of COVID, and it was the Republicans who were trying to prevent travel to and from the United States in order to keep COVID out. Then COVID hit New York City and all of a sudden both sides flipped their positions on COVID overnight. The same thing happened with the vaccines, while Trump was trying to speed up vaccine production under Operation Warp Speed, it was largely the Democrats who questioned the effectiveness of the vaccines and vaccine mandates. Once Trump lost the 2020 elections and the Democrats gained control of the White House and the Senate, the Democrats flipped and started supporting the vaccines, while the Republicans flipped to a more anti-vaccine position. The only constant throughout the COVID pandemic has been that the Democrats and Republicans had to politicize the issues and take opposite sides on the issues.

A much larger issue with "Science" is the corruption of the scientific process and scientific institutions by corporations and governments and other self-interested parties. This is seen in climate science when energy companies such as coal and oil try to censor existing climate science of global warming in favor of more profits, in medicine when pharma companies aren't being transparent enough or honest enough in their medical experiments of the effectiveness of their drugs, et cetera. It is this corruption that leads many people to lose faith in American scientific institutions.

4. **anon**
   April 7, 2022

   I think some default setting on blogspot.com has changed in the last few days. I have noticed that some other blogs hosted there have also gone invitation only.

5. **Michael Gogins**
   April 7, 2022

   Thanks for this.

   In my view automated and unregulated lying is humanity's worst problem, as it makes dealing with other serious problems practically impossible.

6. **Thomas Larsson**
   April 7, 2022

   Re Lubos: I occasionally drop by his blog (or dropped, before he closed it), and I noticed that Lubos developed a quite fierce anti-Russian stance after the invasion of Ukraine. Quite the opposite of the American alt-right, but not unparalleled in Europe, e.g. by the Polish government. My guess is that that got him into trouble with his previous friends.

7. **Shecky**
   April 7, 2022

   Another problem (a big one!), I think you're bypassing here is science journalism! Journalism (especially in a day of 'breaking news' and clickbait) is inherently incapable of nuance and complexity, so "science" becomes waaay oversimplified as spoonfed to the public. If science tells you one week that coffee is good for you and the next week that coffee is bad for you, etc.etc., well, of course much of the public loses any confidence in it, and 'anti-science' arguments are easily constructed/promoted.

8. **Umesh**
   April 7, 2022

   The blog has 'gone private'. It's a universal feature of all social media providers these days to provide such an option to the account owner. If he/ she so chooses, they can 'priv' their account and have the option of approving (accepting/ declining) 'follow requests'. It reduces reach, but that's the price to pay if you wish a select audience.

9. **Peter Shor**
   April 7, 2022

   I would have to disagree that there's no anti-science movement. Having talked to a teenager who was educated in a Christian school, she was definitely taught according to an anti-science viewpoint—that you can't trust anything scientists say, because they have their own self-serving motives for saying these things. (This may actually be true to a much lesser degree—look at the string theory apologists. But the best lies contain an element of truth.) And I have to assume that this viewpoint is reasonably common among evangelical Christians, who make up around a third of the U.S. population.

10. **Tom WEIDIG**
    April 7, 2022

    Why are not also mentioning woke stuff such as gender issues, anti-racism, and so on. These political activists are constantly abusing "science", especially social science to support their political cause.

    And about climate science, I simply disagree calling climate forecasting models science. They are forecasting models based on climate science, physics, chemistry and many other inputs. They are not science. So if I deny a climate crisis, I could just do in on the ground that I do not trust those models but that doesn't mean i deny climate science.

11. **Doug McDonald**
    April 7, 2022

    umesh:
    But Lubo's blog offers no way to contact him. Its probably some Google "cancel" spasm. My guess is that we will eventually find out what happened and it will be "the [unfortunately] usual".

    One problem with "Science" is that what gets covered by the media gets softer and softer.
    And some parts that are still very "hard", like particle physics, get filled with things that are 'not even wrong'. Among those there is all the screaming about the "measurement problem" which is just a battle of words, and some protagonists insisting on "instantaneous" "wavefunction collapse", which is indeed wrong. Its not instantaneous on the appropriate energy scale time intervals.

12. **Peter Woit**
    April 7, 2022

    Peter Shor,
    Yes, there is and always has been some religious anti-science movement, but I don't think that's what's responsible for our current problems (white evangelicals make up about 14% of the US population). What's new about our current situation, in an oversimplified formulation, can be simply summarized as: Fox News.

    As far as I can tell, Fox News is not particularly devoted to promoting religion or attacking science. What they are though is a propaganda machine, weaponized to distribute information not based on whether it's true, but whether it advances the political aims of the Republican Party in the US.

    The challenge humanity is facing is not an anti-science information environment, but one toxically polluted by ideology (and yes, I'm well aware that it's not only the right that is the problem, with identity politics warriors of all stripes showing little interest in what's a fact and what isn't). My complaint about that Stony Brook panel is not just that they may be addressing the wrong problem, but that scientists with histories of promoting bad science for ideological reasons are not the people one should look to for answers to the problem of ideological information pollution.

13. **Peter Woit**
April 7, 2022

Tom Weidig,
I don't want to host a discussion of climate models, or vaccine science or epidemiology and public health or anything of the sort, since I have no expertise at all on those topics. The challenge those topics pose is that of how society can put a stop to the ideologically polluted information environment surrounding them that we now live in and get most people trustworthy information.

14. **Peter Woit**
April 7, 2022

Doug McDonald,
It looks like you are right about Lubos. I've heard from someone who contacted him that he has shut his blog down rather than follow rules Google is now enforcing. This is somewhat like what happened to him at Harvard, where I gather he did not renew his visa and left his position rather than agree to follow rules he didn't like.

15. **Anonyrat**
April 7, 2022

The continued integrity of science places certain demands on practicing scientists. There appears to be a problem in this regard, and not just in the fields that Peter Woit writes about.

There is a long history of anti-science instigated by powerful economic, political, religious interests. Social media has newly provided these a powerful tool of amplification. If science remains healthy, these will likely eventually be beaten back. But given the times we live in, scientists have to be even more diligent to keep science healthy.

16. **Geoffrey Dixon**
April 7, 2022

Some comments about pop sci media are too harsh IMO. I really DO want to know what happens if you stick your head in the path of an LHC beam (a recent pop sci headline). Were I not a sort of scientist, this would immediately make me want to become one.

17. **S**
April 7, 2022

Peter Shor,

I think the situation you refer to among evangelical Christians is not so different from the vaccine or climate situations Peter mentioned. (This is a milieu I'm very familiar with.) They (or some of them — a minority probably) do ascribe questionable motives to mainstream scientists, but their response is not, "So science is worthless." It's to appeal to other "scientists," and try to argue that those ones are actually following The Scientific Method. Meanwhile, areas of science without clear conflict with their beliefs are taught in a more or less totally normal way (sometimes well, sometimes poorly, as with other schools).

tl;dr: I don't think "anti-science" applies even in the situation you describe.

18. **Kirk**
April 7, 2022

I once over-heard a woman in a library discourage her son from reading a math book because it didn't have Jesus in it.
If you don't even trust basic math, you're not going to trust statistics in scientific models. Yes, we can always expect people to be enthused when a paper or study agrees with them, but cherry picking studies (especially bad studies that are later shown to be error ridden) is not being pro-science, it's being pro 'whatever will make people agree with me and makes me look good'. There are people in this world who generally loathe skepticism and say outright they don't understand why people can't just accept faith, but will happily ape the outward appearance of science and its skepticism in order to make their position look better. Their rule is 'skepticism against everything that disagrees with me'. This is how someone can, for instance, throw 99% of all work on climate science and then in the next breath say 'I trust climate science.'
Science is a methodology. That doesn't stop people from abusing the word when they aren't doing or supporting anything actually scientific. This is no different from fascist banana republics that claim to be democracies. Just because they claim it doesn't mean it's so.

19. **Ash Jogalekar**
April 8, 2022

I am not sure I understand your distinction between "anti-science" and "pro bad science". An anti-vaxxer for instance cites the "science" he or she thinks they know to support their claims, and yet they aren't just promoting bad science but in this case they are demonstrating an opposition to what we consider the central evidence-based tenets of the scientific method. In that sense I would call them "anti-science". What am I missing?

20. **Peter Woit**
April 8, 2022

Ash Joglekar,

The problem is that they would claim they are following the evidence-based tenets of the scientific method, perhaps even quoting a published study and its data. In any case, if you think the problem of "anti-science" is people claiming to do science while not following the scientific method of rigorously testing ideas against experiment, is a panel with four string theorists the right group to be making this argument?

What I'm arguing is that calling the problem "anti-science" is missing the point. Almost everyone involved thinks they are "pro-science". Some people however are doing science well, rigorously testing their ideas against the real world and being careful to avoid being misled by ideology or self-interest, others aren't. Again, this is the wrong panel to explain this difference to the public.

21. **Alex**
April 8, 2022

I mostly agree with the blogpost, but I don't think the future is bleak. Nor brilliant. Human nature gonna human nature, it was like that for centuries, it will be like that for the centuries to come. Of course, social networks and globalization are new phenomena, but, for the same reason they allow the propagation of misinformation, they also allow the free propagation of truth. Ultimately, it's on the user to decide to accept whatever thing is posted on the net, or search more on the same net to find the actual truths. It all depends on the open mind and critical thinking skills from the part of the user. And that's where education institutions enter, since they should equip users with those abilities, so that they do not let themselves to be brainwashed either by organizations (religions in particular, but also political parties and ideologues) or social network algorithms. Of course, there's a great deal of complicated human psychology and neuroscience there, but it's time to start to incorporate that on the standard education, so that kids can know their brain's tendencies to be biased. Furthermore, public policies should be directed at that, rather than trying to censor content or regulate the social networks themselves. Unfortunately, I think that both institutions and public servants are not doing a great job, they only seem concerned in looking for scapegoats.

22. **Peter Woit**
April 8, 2022

Alex,
I'd like to believe that the new information environment provided by the internet will allow the propagation of truth, that all you have to do is get people to have open minds and think critically. Unfortunately I've seen no evidence of that happening, quite the opposite.

Maybe a good way to think about the problem is that we've gone from an environment where information was scarce and regulated in many ways, to one in which it's abundant but unregulated. I'm not a libertarian who believes the answer to all problems is to get rid of regulations. The problem with an unregulated information environment is it allows self-interested actors to pollute it. What happens when your information environment is full of raw sewage?

The question of how to clean up our polluted information environment may be a much more difficult one that that of how to clean up and control pollution of our physical environment.

23. **Alex**
April 8, 2022

I'm not a libertarian either, but I would rather have free speech than excessive regulation, even if that allows interested and biased discourses. After all, that's the spirit of the constitutions of all free western countries, and we learned to value that in the hard way. But, on the other hand, in the real and messy world, the solution probably lies in a balance between free speech and regulation. Who decides, and where, to draw the line? I don't have an answer for that. Ultimately, that will come out from the democratic process, with imperfect results, as imperfect as the system is.

But my main point was about the education of people regarding the psychology and neuroscience of bias and brainwashing. Not a perfect or definitive solution, but I do think it can help with this problem.

24. **Peter Woit**
April 8, 2022

Alex,
I agree that getting people to recognize bias in their information source is part of the answer. Again, the Stony Brook panel is very much the wrong one to address this.

25. **zzz**
April 8, 2022

i know its a physics center hosting so they got physicists, but its very emblematic of the bubble thinking that is part of this problem

26. **Jackiw–Teitelboim**
April 8, 2022

After reading your post I remembered the following lecture by Gell-Mann which I believe is quite timely: https://youtu.be/o8_imzEdS84

27. **Marco Masi**
April 8, 2022

A) I think that the good old Hegel's dialectic could be useful as a methodological approach, since primary school. I made this experiment myself in pre-college education. Those students who exercised a thesis, anti-thesis, and synthesis approach were less prone to pseudo-scientific nonsense. Nowadays, people (in the academic environment as well) rely too heavily on the "right" source, or on the "expert" authority, excluding every other point of view. Putting oneself in the shoes of those we do NOT agree with, is a difficult but highly enlightening practice.

B) "For years now we've been living with this in the form of phenomena like Trumpism, and the past few weeks have seen the Russian government exploiting these methods to conduct a campaign of brutal slaughter." –
I think it goes the other way around. Trump exploited a disinformation tactic that Russia practiced since the times of the Soviet Union.

28. **dms**
April 8, 2022

These are political problems and they have political solutions. They don't have anything to do with good science, bad science, or anti-science. I really do not like the implication that the problem is that everyone doesn't think like a scientist and the solution is that we teach everyone to do so. I don't think the world needs that many scientists.

The people who think COVID is not serious, or vaccines are not helpful, or climate change is not real are insecure. Their fears and insecurities lead them to make incorrect judgments about the world. The thing to do is to address their insecurities, not to lecture them about science. And I think their insecurities are legitimate. White working class people have been in a steady decline since the post-war era, and this decline has not been addressed by mainstream politicians. I'm not saying that when their insecurities are addressed these people will correct their judgments, but they will be much less likely to stand in the way of solutions. Instead of being reactionary they'll simply stop caring about these issues.

Part of the problem is the academization of politics. As more people in the US have become more educated, the Democratic party has become the party of people with college degrees. As a result of this we get politicians succeeding at the national level without being able to talk to people without college degrees. Issues that were probably better off confined to academia have become mainstream issues. Voters who are more educated can do their own research and don't need to be won over by rhetoric. But this leaves many less educated voters on the table, and unscrupulous people have taken advantage of this.

29. **SRP**
April 9, 2022

As I am a classical liberal , I find musings like our host's about the desirability of regulating "misinformation" on contested topics ironic. The exact same forces that put four string theorists on a panel defending the scientific method would control any regulated information regime. Such a regime would probably "support" many of my opinions about economics , but it would still be bad.

It is an acute observation that Peter makes, however, about everyone appealing to scientific norms even when they disagree with "consensus" science. That certainly applies to me when I find myself shaking my head at what seem to me to be ill-considered though popular scientific judgments. Right or wrong, I am not interested in playing by"anti-science" criteria of truth.

30. **Peter Woit**
April 9, 2022

SRP,
I don't know what the answer to these problems is, but it's important to get people to think beyond bromides about "trust science" or "freedom of the press".

On the issue of regulating the information environment, we've already seen what an unregulated information environment looks like and how it gets weaponized by bad actors who want to tear societies apart. We've learned an unregulated Facebook is a great tool for anyone who wants to organize genocide of a minority population or destroy fragile democratic institutions.

The current information environment is a regulated one, with regulations set by Mark Zuckerberg, Jack Dorsey (soon to be joined by Elon Musk), and whoever is running Google. Maybe that's the best humanity can do, maybe not.

31. **More anonymous**
April 9, 2022

@SRP
I personally think the solution to these problems lies in empowering the people's judgement. For example, when it comes to any theory, irrelevant of how advance the mathematics of it are if it makes false predictions. Then there should be a cost in credibility to be paid. This is what the scientific method is practiced as well. (The case of no predictions should be looked down upon for a vast chunk of money was taken with 0 output).

On the note of misinformation, again I would advocate empowering the individual's judgment and creating tools which enable the same. The app ground news (https://ground.news/) would be an example of what I'm talking about.

32. **SRP**
April 9, 2022

Peter, you already have become snarled in contradiction about Facebook (whose allegedly malign effects have been wildly exaggerated,BTW). Are we already regulated or not? Normally one tries to distinguish curation and editing from censorship. My conceptual test for this is whether user A is being vectored to material that user A would be expected to prefer if he had the time and knowledge to assess, or whether B has decided that A should not see that material despite knowing that A would be very interested in it.

FB has veered quite a bit over time in how it polices and filters user-generated content. The overriding fact that volume makes considered human judgement of each user post impossible, while automated solutions remain highly imperfect, guarantees a large number of Type I and Type II errors regardless of one's editorial goals. But it is obvious that FB has responded to threats from politicians by tightening (directionally) its filter on content. A visible manifestation of this has been their public outsourcing of many decisions to supposed "fact-checking" organizations whose biases are clear for all to see And those biases are of a very similar sort as the ones that put string theorists in charge of adjudicating what is "anti-science.".

33. **Peter Woit**
April 9, 2022

SRP,
Not sure what contradiction you're talking about. All information environments are regulated to some degree and I'm not pro or anti regulation in the abstract. The devil is in the details.

As far as Facebook goes, I think you're not disagreeing with my point that its regulation policies are now in the hands of one person, Mark Zuckerberg. Possibly his main regulation criterion is that however its done, it not force him to hire human beings on a scale that would cost him too much money.

For an example of regulation directly related to the posting, it seems to me likely that the shutdown of Lubos's blog was caused by this March 23 change in Google policy

Update regarding Ukraine (March 2022)

Due to the war in Ukraine, we will pause monetization of content that exploits, dismisses, or condones the war.

(Posted March 23, 2022)

On March 22 Lubos's rants about the war were allowed and monetized, then a Google executive or committee changed how they regulate speech, and now no more Lubos ranting. One can make a reasonable argument that they should not have denied us Lubos, or that they should have shut him down long ago, but this Google executive or committee is playing a huge role in regulating speech throughout the world. Maybe handing this over to our tech overlords is the best we can do, maybe there's a better way. I don't know.

34. **jjonhson**
April 9, 2022

Sudden dramatic increases in the reach of media — printing press, radio, television, internet — tend to be disruptive, and it takes time for rules (laws, licensure, etc.) to catch up. The internet presents special challenges, including speed of circulation, anonymity, unlimited points of entry, opportunities for unchecked amplification, and confusion of the distinction between public and private. Some controls have emerged — e.g. private firms responding to public pressure — but we're not where we need to be and it's hard to anticipate from the armchair where exactly that is. One hopes that accountable institutions are still robust and nimble enough to meet the challenge.

35. **SRP**
April 10, 2022

Peter,

I don't want to drag this out, but prior to arguing that tech bosses are in effect regulating speech, you wrote:

"On the issue of regulating the information environment, we've already seen what an unregulated information environment looks like and how it gets weaponized by bad actors who want to tear societies apart."

So either we've seen unregulated or we haven't.

As for FB not hiring enough people to monitor the billions of posts they get each year…just think about the scaling. Even a non-profit willing to run losses wouldn't be able to provide that level of contextually informed human review, and if the reviewers were human, a who-guards-the guardsmen problem results.

At this point, Substack is the last mainstream venue for publishing views that anger online mobs and/or upset the worldview of coastal U.S. political and cultural elites.

36. **Peter Woit**
April 10, 2022

SRP,
I was referring to the fact that Facebook had to introduce increased regulation in response to dramatic bad effects of their allowing some kinds of unregulated postings (e.g. the Rohingya genocide story).

I don't think the moderation problem Facebook has is one of technical difficulty in implementing a specific moderation policy. They have huge programming resources to throw at an AI-based approach and huge financial resources to hire humans to cover the cases where AI won't work.

The problem is not implementing Zuckerberg's policy but what the policy is: it's all right to use his platform for pure propaganda. Part of his reason for refusing to delete untrue posts is that it's often hard to distinguish truth/untruth. But I suspect a larger role is played by his understanding that if he starts deleting propaganda from some sources, he'll lose a large part of his user base that is devoted to that propaganda.

In 2020 Zuckerberg's policy was for instance
https://www.thewrap.com/mark-zuckerberg-rules-out-trump-fact-checks-says-facebook-shouldnt-be-the-arbiter-of-truth/
There have been more recent statements from them about this, see
https://transparency.fb.com/policies/community-standards/false-news/
In the last few weeks the war has created a new situation,
https://www.nytimes.com/2022/03/30/technology/ukraine-russia-facebook-instagram.html
one that makes very clear that in a wartime situation if you decide to allow propaganda you may be getting pretty directly involved in the slaughter of innocent people. I wonder whether this will change Zuckerberg's thinking and thus Facebook's future policies.

37. **Low Math, Meekly Interacting**
April 12, 2022

I'm late to the party, but fwiw, I think you nailed it. People aren't anti-science. They love science…as long as it doesn't challenge any of their preconceptions or cherished dogmas.

Now that we have limitless connectivity, anyone anywhere can find a credentialed individual who tells one exactly what one wants to hear, and hence they're free to dismiss the so-called experts because Conspiracies. And credentialed individuals can spout whatever nonsense they like as long as they aren't explicitly advocating mass murder because Freedoms. Sometimes even that minimum standard needn't stop you.

So, there is a "solution": The average person consumes media judiciously, considers diverse points of view with both a willingness to listen and a healthy dose of skepticism, and is willing to educate themselves both about history and current events sufficiently well that the next time they cast a ballot they aren't committing an act of civic malpractice.

With that out the way, I therefore conclude we're all fucked. Enjoy the tail-end of the post-enlightenment while it lasts, which seemingly won't be much longer.

38. **SRP**
April 12, 2022

Peter, Zuckerberg had the right idea originally. Attempting to regulate viewpoints via blocking communications has never been a winning approach to promoting a free society. Nor would it be practical for FB to do a contextual, discriminating job of sorting out truth and falsity at the volume it faces.

Nor is "propaganda" a good excuse. Listening to Tokyo Rose and Lord Haw-Haw caused more laughs than demoralization for Allied soldiers. Those who rarely hear dissenting views or propaganda are in the position of those with naive immune systems facing infections; Milton had it right when he said "I cannot praise a fugitive and cloistered virtue."

You may find this open letter to Elon Musk from the president of the Foundation for Individual Rights in Education useful:

https://www.thefire.org/open-letter-to-elon-musk-from-greg-lukianoff-on-preserving-free-expression-on-social-media/

39. **Peter Woit**
April 12, 2022

SRP,
About the only thing more naive and crazy than believing that this problem can simply be solved by "free speech" is believing that Elon Musk is going to save us…

40. **Santo D'Agostino**
April 13, 2022

Jonathan Haidt makes some interesting suggestions towards the end of his article here

https://www.theatlantic.com/magazine/archive/2022/05/social-media-democracy-trust-babel/629369/

in a section entitled "Reform Social Media."

1. Social media companies need to verify users. This will reduce or eliminate bots and curb abuse.

2. Modify "share" features to slow the spread of lies by requiring users to copy and paste instead of just clicking on a share button.

3. Require social media companies to share their algorithms and data with researchers.

None of these suggestions involve banning individuals or policing content.

41. **Mello**

April 14, 2022

wrt lubos, his response to the query about his blog's disappearance is here:

https://www.blogger.com/comment.g?blogID=7043496070972918852&postID=8207791788172964990

42. **Peter Woit**
April 25, 2022

SRP,

It looks like the plan of putting the world's richest man in charge of our information environment is now going to be realized, we'll see how that works out. Maybe putting everything in the hands of an insanely rich wacky Tech overlord not very interested in whether what he says is true or not is the best humanity can do under the circumstances.

ABC on NHK

April 9, 2022
Categories: abc Conjecture

There will be a documentary broadcast tomorrow in Japan on Mochizuki's claimed proof of the abc conjecture. I was interviewed for this by the filmmakers last year, but don't know anything about whether and how that footage will be used. I'd be curious to hear reports from any Japanese-speaking readers who see the documentary tomorrow.

Over the years there has been a detailed coverage of this story here on the blog. To make it more accessible, I've added an abc conjecture category. In case the documentary doesn't make this clear, the current consensus of experts in the field is that there is no proof. Peter Scholze and Jacob Stix identified a problem with Mochizuki's proof in 2018 (discussed in detail by Scholze and others here), and Mochizuki has not provided a convincing answer to their objections. No one else (including the journal editors who published the proof in PRIMS) has been able to provide a clear explanation of the problematic part of the proof.

Update: NHK has two web pages summarizing the content of the program, see here and here for English translations.

Taylor Dupuy is still making implausible claims that Scholze's criticism of the proof is invalid. To judge for yourself, see here a long detailed discussion of the issue between them involving several other experts.

Reports I'm seeing from those who have watched the program say that it does correctly explain that the proof is not accepted by many experts.

Comments

2. **David J. Littleboy**
   April 10, 2022

   I thought I had already missed it, but it's tonight at 9:00 pm. I'll record it and give a quick overview tomorrow.

3. **Random guy**
   April 10, 2022

   I saw parts of it. The main takeaway of the show, I believe, is that Mochizuki's proof is a radical departure from conventional mathematics that continues to be the subject of fierce debate amongst mathematicians. Peter: there's a scene where you say something to the effect that Peter Scholze's objection was a huge deal for the community which allowed many to stop worrying about the legitimacy of the proof – I guess credit to the producers for including that..?

   Transcipt and screenshots at links below:

4. **David J. Littleboy**
   April 10, 2022

   The NHK special on Mochizuki wasn't as bad as it could have been.
   Long story short, it's about how IUT is new and different and could revolutionize math. While it does present that there are mathematicians who don't accept the proof, it glosses over that with claims that we don't yet have ways to describe it yet; i.e. that the
   problem is more how to explain the ideas than that the proof doesn't convince.

   Mochizuki himself refused to be interviewed, saying "How IUT differs from previous mathematics is an important question, but presenting it to a popular, or even mathematically sophisticated, audience in a TV program would be unreasonable."

   Peter Woit is quoted at the beginning as saying (roughly)
   "It's unlikely that the abc conjecture has been proven."
   and David Roberts is quoted as saying "It most certainly has been."
   At the end Roberts is back saying people who don't get Mochizuki's ideas
   are stuck in old mathematical thinking, and PW is back saying Sholze is the best
   number theorist we have, and if he's not convinced, it's not convincing.
   Then Peter is quoted saying "I'd guess most mathematicians are real happy that
   they don't have to worry about it any more."

   Much of the program was an attempt at an introduction to number theory. Attempt.

   Many mathematicians who were concerned with the abc conjecture or related mathematics prior to Mochizuki were interviewed.

   Taylor Dupuy is presented as a young and up and coming mathematician who thinks it worth betting his career on. (This may be a tad of an overstatement of his position, but he's interviewed multiple times throughout the program and the point that there are young and upcoming mathematicians interested in it is one of the punch lines at the end of the program.)

   My SO watched it with me, and reports that to a non-technical audience, it reinforces the prejudice that math is a waste of time. Furthermore, she
   says that the folks at NHK should have listened to Mochizuki and not tried to explain it to a popular audience.

OK, maybe it was as bad as it could have been…

5. **Z Y**
April 10, 2022

For me the program is an excellent exposition to the relevance of the abc conjecture, in some ways more understandable than the Notices AMS article of a few years ago, a good document to have for future historians and may influence young people to enter into mathematics

6. **David Roberts**
April 10, 2022

> David Roberts is quoted as saying "It most certainly has been."
> At the end Roberts is back saying people who don't get Mochizuki's ideas

Hmm, I'm pretty sure I didn't say this. Or at least, didn't mean to say this!

7. **David J. Littleboy**
April 10, 2022

David Roberts said:

"Hmm, I'm pretty sure I didn't say this. Or at least, didn't mean to say this!"

I was wondering if you'd say that. The program was structured (in those two segments) to put you in contrast with Peter, and gave the strong impression that that was what you thought. A careful translation of the Japanese might show that you were more careful than to say those things so clearly. Might.

FWIW, the quote of yours on the web page referenced above is a good summary of the whole point of NHK's presentation of Mochizuki's theory, namely that he sets up two things as being the same and then handles them as being different. "What is strange about Mochizuki's theory is the point that at the same time as saying two things are exactly the same, next, it handles them as being completely different. In mathematics, it is a basic principle that two things that are seen to be the same are the same. Is it possible for things to, while being the same at the same time to differ? I though about this really carefully. No, this is absolutely unreasonable."

8. **David Roberts**
April 10, 2022

@David J. Littleboy

my position is that I'm more cautious about how to interpret the clues we are getting from various parties. I very much respect Peter Scholze and I don't think he would have made an elementary mistake. I take Scholze and Stix's document at face value when it is worded cautiously (eg saying it isn't a watertight argument), and of course Peter S will stand by it. It doesn't hide the fact it's not dealing with the full theory, but this is the sort of thing high-level people do work with in other sub-fields (Terry Tao has written things like this, for analytic number theory). Discussions privately with Peter S since have pointed to the exact fact he was never satisfied with in Mochizuki's verbal explanations, in response to a specific question about passing to the full, un-simplified theory. Perhaps there is an explanation for this, but Mochizuki doesn't have a good way to explain his intuition, or maybe there is a deeper flaw that is just surfacing like a wrinkle in a badly-fitted carpet. Taylor is more blunt, saying to Scholze and Stix "you can't do such and such a step", in the video (posted yesterday on YouTube) of him presenting his work from a year ago. This is of course, pointing to the actual contentious isomorphism (in the hexagon diagram), and is the clearest statement I've seen in pushback to Scholze and Stix's argument, but it's very light on details; given the medium, and time constraints, it was appropriate, but I'd love to hear more. Taylor is open in the video up front that there are things he thinks don't necessarily join up in the argument, his complaint is that if there is a mistake, he doesn't think it's where Scholze and Stix are pointing.

Taking Corollary 3.12 as a *conjecture*, as Taylor does, lots of interesting mathematics can be done. This is in my view akin to assuming GRH and then finding all kinds of qualitative estimates of prime distributions, etc. This is how I view the subsequent IUT work of Mochizuki et al, getting FLT etc. It's all conditional on an interesting conjectured inequality in anabelian geometry/Arakelov theory. But, contra Mochizuki, we really can't say that inequality (i.e. Corollary 3.12) is established. (More than one expert has described that step as a cliff, or a sudden leap etc. If experts are happy with everything before then, and then all struggle at that point, it's not because the theory is just too hard for them.) I'd rather people take this view, than throw the lot in the bin. The glory of giving a new proof of FLT, or other hard number-theoretic results, is clearly lessened, but it's at least a healthier way forward for the community (IMHO) to try to extract useful content here, being clear with what is accepted, and what is not (cf work of Kirti Joshi who is claiming no big result, but is adapting some IUT ideas into standard anabelian geometry, and getting non-zero mileage).

It might be that my qualified optimism (conditional on assuming Cor 3.12 as a conjecture) happened to translate on screen into something less negative than others, including Peter W here. I can only go on what I think I would have said, and what is written on that NHK page for the documentary. I was quite complimentary towards Peter S in the interview, though it's quite likely they didn't use that, and I was fairly up-front that IUT doesn't give a proof of abc, as far we currently understand it.

9. **David Roberts**
April 10, 2022

Just to clarify, Taylor says in his video:

> I don't claim to understand Mochizuki's proof. I don't see it as completely correct because there is a point of contact that I can't see. And that's all I really want to say about that.

Taylor told me privately what that "point of contact" is, but not in any detail.

Taylor's discussion of what he sees as the weak point in the Scholze+Stix argument is at this time stamp, and goes for about 5 minutes. Make of it what you will.

10. **W**
April 10, 2022

@David Roberts:

In addition to that video, the other place Taylor explains his point of view on Scholze-Stix is Remark 3.8.3 of https://arxiv.org/pdf/2004.13108.pdf but this explanation is even shorter. Both the talk and the paper are from 2020.

He wrote a long Twitter thread (https://twitter.com/DupuyTaylor/status/1513240056395448324) responding to the text version of the documentary, where he expresses a lot of uncertainty on what the final outcome will be:

"For me there is still the option that this was a big waste of time for everyone "

"The situation may end up more like Lame's proof of Fermat or Kempe's Proof of the Four Color Theorem. Lame's proof was 175 years ago and we discuss it regularly when discussing the concept of a unique factorization domain. "

"There is also the possibility that we are in a Heegner-like situation where the proof is ultimately correct, but the author will pass away before the proof is finally accepted by the mathematical community (after Stark)."

I will resist the temptation to say anything more about the content of the proof.

@David J. Littleboy Your comment at the end about your SO makes me sad. I guess the point is mathematicians consider abstruse abstract problems and can't even agree on those. But in fact this is the one thing that (some) mathematicians can't agree on, and we agree on almost everything else, which is why it is apparently newsworthy.

11. **David J. Littleboy**
    April 11, 2022

    Hey, W! Don't be too sad. My SO was irritated more with NHK for trying to make a story about something that can't be made into a story than about math. Again, her main take away from this thing was that Mochizuki is a perfectly sensible bloke for not talking to NHK. I think I was able to get the point across that we don't know what math is going to be useful 100 years from know, so we have to just keep at it.

    (We were both irritated that it didn't have more on Mochizuki as a person. We're both fascinated by the problems of bilingualism and biculturalism and the trials and travails of growing up being the smartest bloke in the room. There's a human story there, too.)

12. **Z Y**
    April 18, 2022

    Is it only me that find remarkable that something as big as NHK took the decision to make a documentary about their countryman's effort to prove ABC and that the end message is that the proof is not yet accepted by the majority of experts? No wonder why Mochizuki didn't want to be interviewed

13. **Nayr**
    April 22, 2022

    Is there anywhere that we can rewatch the NHK documentary? It seems interesting.

14. **Ryan Pang**
    April 28, 2022

    You can now watch the NHK documentary on youtube:
    Part 1: https://www.youtube.com/watch?v=CklnC91Tbow&t=295s
    Part 2: https://www.youtube.com/watch?v=TtQ023QDCLQ
    Part 3: https://www.youtube.com/watch?v=_nIwOGWkf-M
    Part 4: https://www.youtube.com/watch?v=qAvLqDKaMaQ&t=8s
    The auto translate by youtube is a bit off tho.

15. **AG**
    May 2, 2022

    Hi
    Recently (on May 2) Prof. Mochizuki wrote a long comment about NHK documentary on his blog in Japanese. Its contents are very interesting.
    He himself says that the second half of what was broadcast was a complete flop.
    He is critical of the content of interviews and the way other researchers critique his theories. I know nothing about math and needless to say I can't judge anything. I could understand just one thing: Mochizuki is a man of great integrity, and sincerely from the bottom of his heart thinks that his proof is complete and correct.
    It's difficult for me to translate it into English. I hope someone translate correctly (only if not illegal) . To show the address of the blog here must be at least legal:
    https://plaza.rakuten.co.jp/shinichi0329/diary/202201010001/

16. **Peter Woit**
    May 2, 2022

    AG,
    I took a look at that (via Google Translate). It seems the part of the documentary he didn't like was the part where people discuss problems with his proof. He doesn't mention at all Scholze, (or me, I gather I mainly explain about Scholze's objection and its significance). He complains in detail about Faltings, as well as about Taylor Dupuy.

    I do agree he surely believes in the correctness of his proof, but he is not following standard professional norms in dealing with criticism.

Two New Quantum Field Theory Books

April 11, 2022
Categories: Book Reviews

I've recently noticed that two very good new books on quantum field theory have become available, one aimed more at mathematicians, one purely for physicists.

What Is a Quantum Field Theory?

Available online now from Cambridge University Press (actual printed books to come soon) is mathematician Michel Talagrand's *What Is a Quantum Field Theory?*. While it's subtitled "A First Introduction for Mathematicians" and definitely aimed more at mathematicians than physicists, it's a wonderful resource for anyone who wants to understand exactly what a quantum field theory is.

Like many mathematicians, Talagrand tried to learn about quantum field theory first from physics textbooks, which tend to avoid any precise definition of even the basics of the subject. He soon found what was the best source for someone looking for more precision, Gerald Folland's 2008 Quantum Field Theory: A Tourist Guide for Mathematicians. Folland's book is extremely good, but also extremely terse. In 325 pages it covers more carefully the material of an old-style QFT book such as Schweber's 900 page or so *An Introduction to Relativistic Quantum Field Theory* from 1961. Talagrand is covering much the same material, but with 742 pages to work with he is able (unlike Folland) to work out many topics in full detail, providing something previously unavailable anywhere else.

Both Folland and Talagrand have written books with much the same goal: to as precisely as possible explain the details of the renormalized perturbative expansion of QED. There is little overlap with the work of mathematical physicists who have aimed at rigorous non-perturbative constructions of quantum field theories. They are using canonical quantization methods and don't overlap much with many of the more recent physics QFT textbooks, which are based on path integral quantization and aimed at getting to non-abelian gauge theories and non-perturbative techniques as quickly as possible.

When I was learning QFT not that long after the advent of the Standard Model, I had little patience for fat QFT books about perturbative QED and canonical methods. Why not just write down the path integral and start calculating? Over the years I've realized that things are not so simple, with canonical quantization and operator fields giving a perspective complementary to that of the path integral. Among the more modern books, volume 1 of Weinberg's three-volume series is the one that best gives this different perspective, and is most closely related to what Talagrand is covering.

For mathematicians, Talagrand's book is a great place to start. For physicists, Weinberg's is an important perspective to get to know. If you're reading Weinberg and want more detail about precisely what is going on, Talagrand's new book would be a very good place to turn for help.

Quantum Field Theory: An Integrated Approach

Over the years I've often consulted various parts of Eduardo Fradkin's notes on quantum field theory on his web pages. On some basic topics I found these to give very clear explanations of things that were done in a confusing way elsewhere. After recently hearing that the notes are now a book from Princeton University Press, I ordered a copy, which recently arrived.

Fradkin's book has not much overlap with the material in the Talagrand book described above, and is somewhat different than traditional high energy physics-oriented QFT books. It tries as much as possible to integrate the high energy physics point of view with that of condensed matter and statistical mechanics. Path integral methods are then fundamental. Unlike many other modern QFT textbooks that aim at getting to the details of perturbative Standard Model calculations, Fradkin is more oriented towards getting as quickly as possible to non-perturbative techniques and models of interest in statistical mechanics. He gives a good introduction to various of the modern non-perturbative QFT techniques that have been developed in recent decades, often motivated by the so far only partially successful attempt to come to terms with a strongly-interacting gauge theory like QCD.

While most of the book is quite good, the first few pages aren't, and will immediately drive away mathematicians who might pick it up. The material in these pages about group theory uses bad terminology (for Fradkin, the "rank" of a Lie group is its dimension and the fundamental representation of SU(n) is the "spinor" representation) and sometimes is just completely wrong. On the second page of the first chapter after the introduction, he wants to explain why the Lorentz group is non-compact, in contrast to SO(3). To explain why SO(3) is compact he starts by mistakenly arguing that since it leaves the unit two-sphere invariant the points of SO(3) and of the unit two-sphere are in one-to-one correspondence, showing the volume of SO(3) is $4\pi^2$. This paragraph should be deleted in future editions of the book.

That this kind of thing can make it into a book like this is remarkable, but unfortunately relativistic QFT books and other sources (e.g. here) don't always get right basic facts about the Lorentz and rotation groups. I once tried to do my part to remedy this, see here.

Update: John Collins has here an article that provides a careful discussion of scattering in QFT, starting with the basics, which could be thought of as part of a QFT book. This may be of interest to both physicists and mathematicians who want to see something less superficial than many text book discussions.

Comments

   April 12, 2022

   One of the things I liked about Folland is that he discusses the full blown representation theory of the Poincaré group on infinite dimensional Hilbert spaces, which allows you to obtain the "wave equations" of the different fields from that classification. An application of Mackey's Imprimitivity theorem (it's based on Varadarajan's Geometry of Quantum Theory.) In the physicists' treatment, often only finite dimensional representatoions of the Lie algebra are discussed, and one often hears things like "the photon doesn't have a wave function". It has! And one can even prove that it doesn't admit a position operator, thus giving all the correct intuition. Of course, this is all for conceptual understanding and of little use for the hardcore calculations for real applications that physicists like. But I don't know why physicists' treatments have moved more and more to a purely pragmatic view in which such conceptual issues are just dismissed almost derogatorily.

2. **AcademicLurker**
   April 12, 2022

   As a stat mech-ish person who has been trying to gain a deeper understanding of the methods we borrowed from QFT (although I guess the borrowing has gone in both directions), the Fradkin book sounds intriguing. I'm currently slowly working my way through Blundell and Lancaster's Quantum Field Theory for the Gifted Amateur. Any idea how it compares with Fradkin?

3. **Peter Woit**
   April 12, 2022

Alex,
Understanding representations of the Poincare group pretty much completely determines how relativistic free field theories work, and constrain very tightly interacting theories. Interest in this was more widespread during the 1960s, less so after that, partly because it's to deal with such issues in terms of the path integral. There is a lot of this though behind what Weinberg does in his volume 1.

More recently I see a bit of revival of interest, from the directions of the amplitudes program.

Academic Lurker,
The Blundell/Lancaster book is better for QFT beginners, it does a great job of explaining carefully the basics. Fradkin is better on more advanced topics. His treatment of the stat-mech related stuff is truly integrated with the rest. Much of it is the same material as other modern QFT books that are HEP-oriented (harder to follow than Blundell/Lancaster since less detail, more background assumed) but in many places there is additional material related to stat-mech of a sort you don't see in other books.

4. **Jackiw–Teitelboim**
April 12, 2022

Coincidentally, I was looking for new resources on the topic of quantum fields for mathematicians to prepare for a class next fall (also to read something that is not on another depressing worldly news), and I found out about a new monograph by Albert Schwarz: "Mathematical Foundations of Quantum Field Theory" (2020).

I think this book is a very welcome one for the mathematically-inclined. While for quite understandably reasons most texts of this lot is oriented toward the topological, geometrical and group theoretical aspects, Schwarz's returns the attention to the algebraic, functional-theoretical issues, which should perhaps receive some renewed attention from time to time.

PS: Perhaps most readers of this site should remember another title by the same author, on topological QFT.

5. **Andrew**
April 12, 2022

Just wondering if anyone have any recommendations for books on QFT (and for that matter GR) which might be comprehensible to some one with a somewhat ancient PhD in physics who has no ambitions to actually work in the field. A step up from the popular stuff but giving a good conceptual overview rather than just leaping into calculations. Are Zee's Nutshell books any good? They look interesting, but hellishly expensive, especially to get to NZ where I live, so I don't want to just take a punt. I see he has another shorter one on QFT in the works.

6. **Peter Woit**
April 12, 2022

Jackiw-Teitelboim,

I got a copy of the Schwarz book last years. It's a nice very detailed treatment of the Fock-space formalism and concentrates on scattering theory. Mostly he is just writing about scalar field theory, and doesn't get very far into the perturbative calculations and renormalization that Folland and Talagrand get into. So, in some sense a more detailed treatment of a subset of Folland/Talagrand. Very different than Fradkin or other modern QFT books (or his own earlier book on TQFT.

Andrew,

I'd recommend the Blundell/Lancaster QFT for the Gifted Amateur book mentioned earlier. It's relatively elementary, and works things out completely and clearly. Zee's QFT book I don't think is a good place to start, since he's covering a lot of material without going into details of calculations. So, hard for beginners to make much sense of. If you have gone through something like Blundell/Lancaster, Zee is then great for giving you a deeper conceptual understanding of the subject.

7. **Jonathan**
April 13, 2022

There seems to be a glut of books on QFT in recent years, another one is Quantum Field Theory: From Basics to Modern Topics by Gelis.

Andrew, I have used Student Friendly Quantum Field Theory by Klauber at times and I found it to be quite pedagogical.

8. **Alex Gezerlis**
April 13, 2022

Peter,

Thanks for the heads-up on the new books.

I think you're being slightly unfair to Fradkin's excellent book. The point you make is valid; similarly, one could find other minor points to complain about, e.g., Fradkin is often not careful with the horizontal placement of tensor indices. (Then again, Schwartz doesn't care about vertical placement, either!).

However, any major work on such a complicated topic is bound to have minor flaws. The question that I think is important when deciding what to recommend to beginners is if the author exhibits mastery/insight. Fradkin certainly does, whereas the Blundell/Lancaster book cannot be placed in the same category; their text is riddled with conceptual errors (including extensive derivations where they're forcing the answer to go their way). I'm sure you would spot tons of these if you looked for them.

To offer an alternative recommendation, I think Maggiore's Modern Introduction to QFT is both beginner-friendly and authoritative. That being said, this is a blog, so you obviously don't have to do a full bibliographic analysis every time you are asked for a book recommendation 🙂

9. **Peter Woit**
April 13, 2022

Alex Gezerlis,
I don't think I'm being unfair to Fradkin, in trying to make clear that the value of his book lies in the material about non-perturbative QFT and the integration with stat mech. On the standard basics of perturbative QFT, parts are quite good, but parts are not and are done much better elsewhere, especially anything having to do with symmetry arguments. The problem I pointed out with the discussion of SO(3) is not a typo, but getting something very simple and very basic wrong, and it's not good to see something on the second page of the book that anyone reading it should have seen was a problem.

On QFT books in general, I don't think there's an ideal one. Even the best of them have their weaknesses. There's a lot to be said for Fradkin's, but others (including Blundell/Lancaster, whatever it gets wrong) are better for someone looking for an introduction to the basics.

10. **Andrew**

April 13, 2022

Peter and others, thanks for the comments. Blundell & Lancaster looks just the thing for me personally.

I've always found lack of physical motivation and consistent terminology an obstacle to understanding. I attended a lecture course on QFT by John Polkinghorne as a graduate student, and he leapt straight into something called "second quantisation" and detailed calculations, confusing the hell out of me. It's only recently that I saw Steven Weinberg saying that the term "second quantisation" was confusing and should be dropped, so I felt a bit better.

I hope it's not too far OT to ask if there's anything similar to Blundell & Lancaster but for GR? There's a similar abundance of confusing terminology here, especially around covariant vectors, or is it dual vectors or one forms – the last one totally unmentioned as a concept when I was a lad. Again, we leapt straight into index gymnastics, and I just wanted to ask "Why on earth would I want to raise or lower an index? What does that actually mean??"

Anyway, I ramble. Thanks to our host for a most interesting site.

11. **Paolo Bertozzini**
April 13, 2022

Dear Peter,

thanks for the overview of the interesting new book by M. Talagrand.

As regards quantum field theory books for a mathematical oriented audience, how is Your evaluation of introductory texts like:

E. de Faria, W. de Melo: Mathematical Aspects of Quantum Field Theory ,

J. Dimock: Quantum Mechanics and Quantum Field Theory ?

And of some more specialized texts such as:

R. Haag: Local Quantum Physics ,

J.Derezinski, C.Gerard: Mathematics of Quantization and Quantum Fields ?

Thanks in advance for any comment on the topic.
Paolo

12. **Alex**
April 13, 2022

I think it's also worth mentioning the whole school of QFT in curved spacetimes, whose current torch carrier seems to be Klaus Fredenhagen et al. Not only they do have completely rigorous mathematical constructions, they even extended (and made mathematically rigorous) perturbation theory to curved spacetimes via microlocal analysis! (They use their version of the Epstein-Glaser method)

A short, state of the art review is (details are in the references provided there):

https://link.springer.com/book/10.1007/978-3-642-02780-2

I find quite illuminating to put QFT in a generic curved spacetime background because you realize that many things you thought were essential to QFT… well, they were not! I feel I finally understood some deep conceptuals doubts I had only when I studied QFT in curved spacetimes for the first time. One can start with more welcoming introductions, like Wald's "QFT in curved spacetimes and BH thermodynamics". I highly recommend to physicists with a more particle physics background to take a look at that point of view on QFT, too.

13. **Peter Woit**
April 14, 2022

Paolo Bertozzini,
Those are all very different books. Some quick comments:

de Faria/de Melo: very short and very superficial. I don't believe you can usefully cover the wide range of topics they cover in such a short book, unless you're writing for people who already know the details of much of what you're writing about.

Dimock: this is a really great book that I highly recommend. It's from the canonical quantization point of view, and does everything rigorously, but very clearly. This is a different point of view than most modern physics textbooks, well worth understanding both by physicists and great for mathematicians trying to understand the subject.

Haag: This is an exposition of the operator algebra approach to QFT, which is quite different than either canonical quantization or the path integral. Little overlap with other QFT books. I haven't personally found that very useful or understood it well (but recognize that often once I understand something like this better I appreciate it a lot more)

Derezinski/Gerard: This is a very specialized and detailed treatment of the mathematics of canonical quantization. I think of it more as a reference book for anyone getting deeply into that subject, especially mathematicians with a specialized interest.

14. **Łukasz**
April 14, 2022

And what about the handbooks of:
Iwo Bialynicki-Birula and Zofia Bialynicka-Birula, "Quantum Electrodynamics"
Lewis H. Ryder, "Quantum Field Theory" ?

15. **Peter Woit**

16. **Alex**
April 14, 2022

Peter,

Re Haag: the operator algebra approach is actually a reformulation of canonical quantization (in the sense of going from the Poisson bracket to the operator bracket), it's just done at the abstract algebra level to avoid problems related to the failure, in the field case, of the Stone-von Neumann theorem of the CCR. Even LQG is formulated this way today.

Furthermore, a LOT has happened in the field since Haag's book. The review book I posted before covers all of the newer stuff.

It's a bit too hardcore math phy, and it requires quite a solid math background (from operator algebras to Hörmander's theory of wavefront sets for distributions, etc.) I certainly don't claim myself to have a full understanding of all the required techniques, but it's definitely worth it to at least give it a try.

17. **John Baez**
April 15, 2022

Andrew wrote:

> It's only recently that I saw Steven Weinberg saying that the term "second quantisation" was confusing and should be dropped, so I felt a bit better.

Second quantization is a real thing; for example if you take the Fock space of a Hilbert space you get another Hilbert space, so this is a process you can do twice – and this actually has applications in physics. But it's often not explained very well, so it might be better to ignore it in an introduction to quantum field theory.

I wrote a light-hearted introduction to nth quantization here.

18. **Arnold Neumaier**
April 15, 2022

Andrew wrote: "I attended a lecture course on QFT by John Polkinghorne as a graduate student, and he leapt straight into something called "second quantisation" and detailed calculations, confusing the hell out of me. 19. **Peter Woit**
April 15, 2022

I'd like to second (third?) the comments of John Baez and Arnold Neumaier about QFT and second quantization. It took me a while to understand this, but "second quantization" is a very precise and useful way to think about QFT from the canonical quantization point of view.

In brief, Hamiltonian mechanics says phase space is the initial data for an equation of motion, and functions on phase space are a Lie algebra (Lie bracket is Poisson bracket). For a linear phase space one can restrict to the subalgebra of linear functions. This is the Heisenberg Lie algebra, and quantization is just going to its (essentially unique) unitary representation.

If you start with the finite-dim phase space for a single particle theory, this "first quantization" gives you a representation on an infinite dim space of wavefunctions. One gets QFT by doing the same thing, but taking the infinite dim space of wavefunctions as your phase space, for which the term "second quantization" is not bad.

The details of this point of view are in my book
https://www.math.columbia.edu/~woit/QMbook/qmbook-latest.pdf

20. **John Collins**
April 15, 2022

John Baez wrote "Second quantization is a real thing; for example …".

Certainly, as John explained it is possible to define the concepts of second (and higher order) quantization. But for me, the physics issue is: What is the reason for using a quantization method?

The standard quantization method is for obtaining a (candidate) formulation of a quantum theory whose classical limit is expected to be some given classical theory. This is useful because before encountering quantum theory one knows about classical systems (including electromagnetic fields). As is indicated in Weinberg's paper https://arxiv.org/abs/hep-th/9702027 that method is all that is necessary to formulate QFT, and the idea was known from the earliest days of quantum theory. (However he only references the Born-Heisenberg-Jordan paper Z. Phys. 35, 557 (1926). The QFT idea is more clearly visible in the earlier Born-Jordan paper, Z. Phys. 34, 858 (1925).)

So, in agreement with Weinberg, I find it unnecessary to formulate QFT in terms of second quantization. However, when teaching QFT, I find it useful to give an account of non-relativistic Schrödinger QFT. Then there is a nice correspondence between the Schrödinger equation for a single particle wave function and a QFT formulation of the corresponding many-body theory, that can be called second quantization. I find I have to emphasize that its status for theory construction is very different from "first quantization", which I normally simply call "quantization". First quantization gets you from an ordinary classical theory to a new type of theory, viz a quantum theory in the Heisenberg picture. But second quantization gets you from one quantum theory (in a Schrödinger formulation) to another quantum theory (in the Heisenberg formulation). I have to emphasize that QFT needs no change in the principles of quantum theory; I also immediately enhance the Schrödinger QFT to include a term for inter particle interactions, which give a non-linear equation for the field.

I find it counterproductive when people treat the formulation of relativistic QFTs as a matter of second quantization. It confuses learners into thinking that it involves going beyond the general principles of quantum theory. The real change is going from situations where the wave function formulation is often the most convenient (for non-relativistic situations) to a Heisenberg-picture formulation with heavy emphasis on its time-dependent operators.

21. **Peter Woit**

April 15, 2022

On the topic of “second quantization” I agree with John Collins that the name might confuse some people, but it does reflect a central idea about how the multi-particle formalism works.

When you (first)-quantize the (d-dimensional) harmonic oscillator, with classical phase space $\mathbf R^{2d}$ that you have identified with $\mathbf C^d$, you get a quantum state space that can be identified with polynomials on $\mathbf C^d$, with degree of a monomial the number of quanta. In the Fock space approach to multi-particle systems you are doing exactly the same thing, with classical phase space now the single-particle quantum state space.

This is confusing if you are trying to understand quantum to classical, but it clarifies (at least for me) several things (why particles act like indistinguishable quanta, the relation of symmetries in the classical Hamiltonian formalism to symmetries in the quantum formalism).

22. **Chris**
April 16, 2022

Talagrand’s book is beautiful. It a pleasure to read in it. Explanations are clear and detailed. Every chapter has a short summary in a few lines that allows to check one’s progress. The style of writing is friendly to the reader. Content and form are beautiful. It’s a gentleman’s masterpiece.

23. **James Eshelman**
April 17, 2022

Peter,
If not too far off topic I’d be interested in your opinion of Adam Marsh’s book “Mathematics for Physics” ? He gives major math definitions and results across what to me is an astoundingly wide range of areas in math, without proofs. Just results. Often very useful for physics, especially when reading a paper depending on one of those areas Marsh covers. I haven’t yet run across any serious error, but someone more involved in math might. If there are few it might deserve to be better known among physicists.
Jim

24. **Peter Woit**
April 17, 2022

James Eshelman,
I haven’t seen the book before, just took a quick look. What I looked at seemed pretty accurate. From the table of contents it’s mostly a survey of geometry of use in physics (without discussing any of the physics).

The problem with this kind of thing is that if you cover so much material in 300 pages, there’s nowhere near enough detail for someone who is trying to learn a subject from the basics. And for people who already mostly know the subject, they likely have there own favorite places to use as reference. I suspect this book will mainly be useful to people who already know much or most of the content. Looking through it they’ll find some topics they didn’t know about, and will know enough to be able to follow those topics.

25. **InterestedLurker**
April 17, 2022

Peter or others what is your opinion of Matthew Schwartz’ book, “Quantum Field Theory and the Standard Model”?

Also, it seems that QFT courses quickly move through background material on Lagrangians and Fields and I haven’t found a book that covers those topics in great depth, is there a good mathematically rigorous treatment out there on those topics?

26. **Peter Woit**
April 18, 2022

Interested Lurker,
I haven’t taught a standard sort of QFT class for physicists so haven’t looked closely at the books available. My impression from a quick look is that Srednicki, Peskin/Schroeder and Schwartz cover much the same ground, with different emphases. My main comment about all these books is that they give a deceptively simple idea of how QFT works, one oriented towards computing terms in a perturbative expansion, avoiding engaging with most of the structure you would like to have to really understand a QFT.

There probably are mathematically rigorous treatments of Lagrangian methods out there, but I don’t think that’s actually useful. Physicists writing about QFT now seem to uniformly start with the idea of a general Lagrangian system (for which a rigorous treatment is difficult), but then immediately specialize to very special systems and assuming good properties. They then quickly get into trouble when crucial examples don’t have these properties (e.g. EM fields with their gauge symmetry). To my mind Hamiltonian methods capture much more of the structure one wants, but developing QFT along those lines is a very different project.

27. **lun**
April 18, 2022

“but then immediately specialize to very special systems and assuming good properties. They then quickly get into trouble when crucial examples don’t have these properties”
(e.g. EM fields with their gauge symmetry)

Can you elaborate here? Which properties do you mean?

28. **Peter Woit**
April 19, 2022

lun,
In textbooks this shows up as the fact that the Legendre transform from velocity to momentum variables is only one-to-one in special circumstances. Even for free field theories this becomes a problem, typically first seen when you try to quantize the theory of a free photon, and find that the canonical momentum for the time-like component of the vector field is zero.

29. **John Collins**
April 19, 2022

Peter and Interested Lurker,
I’ve taught QFT (to physicists) quite a number of times, and over the years I’ve become increasingly dissatisfied with the available textbooks, primarily concerning the foundations. (More advanced topics are another matter.) I’ve worked out ways to try to overcome some of the worst problems, and provided some short documents to the

students; I plan to make them more public after I've re-checked them.
The big problems are about the treatment of scattering theory and the derivation of perturbation theory. Of the many books I've examined, only those by Srednicki and by Peskin and Schroeder get reasonably close to what I want to see. Sterman also has some very useful material that helped me. I find the treatments in these books very useful for inspiring better treatments.
It's a long story to explain all the difficulties. But I see 3 main root causes:
First is the need to treat the infinite time limits in scattering in a physically (and mathematically) sensible way. Any treatment that doesn't use wave packets is destined to give nonsense. Here, I recommend Peskin and Schroeder's treatment, including a nice explanation of how one can relate cross sections to calculated amplitudes.
The second problem is the use of the interaction picture to derive perturbation theory. Haag's theorem says that for a relativistic QFT in an infinite volume of space the interaction picture never exists. As far as I can see, this breaks all derivations that attempt to derive perturbation theory directly for the S-matrix.
The only way I know of that works is slightly indirect, but much better and general I think: First get perturbation theory for the time-ordered Green functions, and then get the S-matrix by the LSZ method. (For some of my approach, see the paper of mine that Peter referred to earlier: https://arxiv.org/abs/1904.10923.)
There's still the problem of deriving the Gell-Mann-Low formula for Green functions without getting clobbered by Haag's theorem. You can modify the Peskin-Schroeder derivation to do this: Initially put the theory in a spatial box, and only take the limit later at a suitable point.
Once you take all the necessary limits (and do UV renormalization) you get properly behaved results to the extent that perturbation theory can show them.
The final difficulty is that quantum fields are not operator-valued functions on space time but are operator-valued distributions. It's easy to get into trouble if one doesn't allow for this. Here several books can help: Among them are the book by Talagrand that we were discussing here and Peter's own quantum mechanics book.

30. **Arnold Neumaier**
April 21, 2022

John Collins,
"The only way I know of that works is slightly indirect, but much better and general I think: First get perturbation theory for the time-ordered Green functions, and then get the S-matrix by the LSZ method."

This is sufficient only for theories such as QED that have no bound states. Once bound states are present, even the standard asymptotic treatment is ill-defined. This is the main reason why QCD has unsettled infrared divergences showing up in a Landau pole at (in contrast to QED) physically accessible energies. See the discussion in https://www.physicsoverflow.org/32752/?show=32756#a32756

31. **John Collins**
April 21, 2022

Arnold Neumaier appears to say that the LSZ method doesn't apply when there are bound states, and that the the standard asymptotic treatment is then ill-defined.

This is simply not the case. You just use products of fields (not necessarily at the same space-time point) that have the quantum numbers to add or remove one of the bound state particles you are interested in. For example in QCD, if you want to find an S-matrix element or an operator matrix element involving protons, you would use a product of three fields for the up quark for an outgoing proton, and the hermitian conjugate field product for an incoming proton.
Then you apply the LSZ method unchanged.
That is, you examine Green functions that include these fields. In momentum space, corresponding to the bound state there is a pole in the external momentum of the field product. In coordinate space, there is the corresponding asymptotic large-time oscillatory behavior.
Essentially the same idea is used in lattice QCD to calculate matrix elements of operators between hadron states. The important difference is that instead of the oscillating asymptotic behavior in Minkowski coordinate space, one has exponential decay corresponding to the mass of the particle.

32. **Arnold Neumaier**
April 22, 2022

John Collins,

"For example in QCD, if you want to find an S-matrix element or an operator matrix element involving protons, you would use a product of three fields for the up quark for an outgoing proton, and the hermitian conjugate field product for an incoming proton.
Then you apply the LSZ method unchanged."

It is not obvious that this recipe will give the correct perturbative expression. Please point to a paper where it is shown that this indeed yields the correct scattering amplitudes.

33. **John Collins**
April 23, 2022

Arnold Neumaier:
There are (at least) three separate issues here: One is whether the LSZ method applies to bound states, for which the unambiguous answer is yes (e.g., K. Hepp "On the Connection between the LSZ and Wightman Quantum Field Theory", Commun. Math. Phys 1, 95 (1965)). The second issue, which is the one you raise, is how to do practical calculations using perturbatively based methods. The third issue is what has been done with the LSZ method in non-perturbative situations.
It is true that in a fixed finite order of perturbation theory for a Green function you don't see bound states. But you don't have to restrict yourself to strict fixed order perturbation theory. There are known and successful methods for dealing with bound states in relativistic QFT that involve perturbative methods. You can get an introduction to these from Paul Hoyer's writings, e.g., https://arxiv.org/abs/1605.01532 One issue he discusses is how bound state poles in amplitudes arise with those methods, even when the poles don't exist in any finite order of perturbation theory.
One could ask Paul if he knows where these methods are applied to scattering involving bound states.
One other situation where the LSZ idea has been applied to bound states is in current algebra, for example for soft pion theorems. These results necessarily apply to QCD. A suitable current is used as an interpolating field for a pion, with the current having a non-zero matrix element between the vacuum and a state of a single pion. In the momentum space form of a Green function involving the current, there is a pole at the pion mass in the momentum corresponding to the current. The LSZ theorem tells you how to relate a Green function with poles to the corresponding S-matrix element.

34. **Arnold Neumaier**
April 24, 2022

John Collins,

I know that bound states are treated with perturbative methods after resummation, but all this is done (even in Paul Hoyer's work) in a somewhat ad hoc fashion, and not based on first principles.

Your claim was that your 2019 paper provides a more principled derivation, and that it extends trivially to bound states. But it is not straightforward to extend your paper to the bound state case by your recipe
"You just use products of fields (not necessarily at the same space-time point) that have the quantum numbers to add or remove one of the bound state particles you are interested in. For example in QCD, if you want to find an S-matrix element or an operator matrix element involving protons, you would use a product of three fields for

the up quark for an outgoing proton, and the hermitian conjugate field product for an incoming proton. Then you apply the LSZ method unchanged."

The reason is that with this recipe, your free field (5) then becomes a multilocal field with three spacetime arguments, and the analogues of your Green's functions (6) have three times too many spacetime arguments, too. This is quite different from what Haag/Ruelle/Hepp do! This mismatch affects everything you do later.

In Section VII you briefly allude to states of multiple particles and say that you do not need multiparticle wave functions. But this is an illusion caused by lack of attention to details. If you use 1-particle wave functions to do the smearing you do not get an in-space of bound protons isomorphic to $L^2(R^3,V)$ where V accounts for the discrete indices (as it should be) but an in-space of three quark states isomorphic to a direct product of three $L^2(R^3,V)$. To remedy this you need to do the smearing with some sort of bound state multiparticle wave functions. But there is no simple way to define these.

In particular, when you "put the theory in a spatial box" you destroy any distinction between bound and unbound states, since these are asymptotic notions that need unbounded space to be meaningful.

In Section 4G you mention the need for normalizable (i.e., smeared) states, and appeal indirectly to the cluster decomposition property discussed in Volume 1 of Weinberg's book. This property is, however, invalid for QCD because of confinement. One has cluster decomposition only for the bound states. Again it is essential to work with bound state multiparticle wave functions to ensure that everything is fine!

In the standard treatment of bound states via field operators one proceeds quite differently: One assumes the validity of 1. the perturbative formalism (ignoring bound states, leading to severe infrared singularies even after UV renormalization) and 2. some resummation techniques. Then one derives from it Schwinger-Dyson equations that, suitably truncated, produce approximate multiparticle wave functions of Bethe-Salpeter form.

In a first principle derivation, one would have to produce the Schwinger-Dyson formalism for bound states simultaneously with the perturbative structure. How this can be done in your setting seems to be a highly nontrivial challenge!

35. **John Collins**
    April 25, 2022

    Arnold and I are going to continue our discussion off-line for a bit. We'll report back when we come to what we hope will be agreement. There are non-trivial issues that we need to sort out at length.

Various and Sundry

Categories: abc Conjecture, Uncategorized

- Last week a review of the Mochizuki IUT papers appeared at Math Reviews, written by Mohamed Saïdi. His discussion of the critical part of the proof is limited to:

  > Theorem 3.11 in Part III is somehow reinterpreted in Corollary 3.12 of the same paper in a way that relates to the kind of diophantine inequalities one wishes to prove. One constructs certain arithmetic line bundles of interest within each theatre, a theta version and a q-version (which at the places of bad reduction arises essentially from the q-parameter of the corresponding Tate curve), which give rise to certain theta and q-objects in certain (products of) Frobenioids: the theta and q-pilots. By construction the theta pilot maps to the q-pilot via the horizontal link in the log-theta lattice. One can then proceed and compare the log-volumes of the images of these two objects in the relevant objects constructed via the multiradial algorithm in Theorem 3.11.

  Saïdi gives no indication that any one has ever raised any issues about the proof of Corollary 3.12, with no mention at all of the detailed Scholze/Stix criticism that this argument is incorrect. In particular, in his Zentralblatt review Scholze writes:

  > Unfortunately, the argument given for Corollary 3.12 is not a proof, and the theory built in these papers is clearly insufficient to prove the ABC conjecture…. In any case, at some point in the proof of Corollary 3.12, things are so obfuscated that it is completely unclear whether some object refers to the q-values or the θ-values, as it is somehow claimed to be definitionally equal to both of them, up to some blurring of course, and hence you get the desired result.

  After the Saïdi review appeared, I gather that an intervention with the Math Reviews editors was staged, leading to the addition at the end of the review of

  > Editor's note: For an alternative review of the IUT papers, in particular a critique of the key Corollary 3.12 in Part III, we refer the reader to the review by Scholze in zbMATH: https://zbmath.org/1465.14002.

  Since the early days of people trying to understand the claimed proof, Mochizuki has pointed to Saïdi as an example of someone who has understood and vouched for the proof (see here). Saïdi is undoubtedly well aware of the Scholze argument and his decision not to mention it in the review makes clear that he has no counter-argument. The current state of affairs with the Mochizuki proof is that no one who claims to understand the proof of Corollary 3.12 can provide a counter-argument to Scholze. Saïdi tries to deal with this by pretending the Scholze argument doesn't exist, while Mochizuki's (and Fesenko's) approach has been to argue that Scholze should be ignored since he's an incompetent. The editors at PRIMS claim that referees have considered the argument, but say they can't make anything public. This situation makes very clear that there currently is no proof of abc.

- At one point the American Institute of Mathematics (founded in 1994 with financing from John Fry) was supposed to move from its location behind a Fry's Electronics store to a castle in Morgan Hill modeled on the Alhambra (see here). This never worked out, and last year Fry's Electronics declared bankruptcy. The latest news is that next year AIM will move to Caltech, for more see here.
- I'll never understand why places like MIT continue to teach undergraduate courses on a failed speculative idea about physics.
- There has been a lot of coverage in the press of claims by a group analyzing old CDF data to have come up with a dramatically better value for the W mass (one seven sigma away from the SM value). While this would be really wonderful if it were true, unfortunately that doesn't seem very likely. There isn't a well-motivated theoretical reason for this discrepancy, this is a very challenging measurement, and the new value seriously disagrees with several previous measurements at CERN. For an informed discussion of this from someone who was on CDF and has worked on these sorts of analyses, see Tommaso Dorigo's blog post.
- It will be interesting to see how well the LHC experiments can ultimately do this measurement. The LHC is about to start up again after a long shutdown, with beam commissioning starting on Friday.

   As a regular reviewer for Mathematical Reviews, this is disappointing. Presenting a biased pro-IUTT review while linking to an "alternative review" that describes the consensus of mainstream mathematicians, gives the false impression that the debate is ongoing. As a resource used widely by mathematicians all over the world, MR has a responsibility to play referee here, rather than providing access to arguments for both sides and letting everyone decide for themselves what the truth is.

   It seems we have learned nothing from the Trump years. It's not enough to give both sides of a disagreement an equal platform. To maintain credibility, one must be willing to take a side when the preponderance of evidence is clear.

   (In fact, it's worse than that, because even with the editor's note, MR comes across as more on Mochizuki's side than not.)

   I review papers for MR on a voluntary basis because I appreciate MathSciNet as a useful resource. But credibility is a fundamental part of what makes it a useful resource.

   April 18, 2022

   S,
   I've found it very hard to understand why MR published the Saïdi review despite being aware that there were well-know problems with the proof that the review did not address. The current editor's note improves the situation but I agree that as it stands the review gives the wrong impression, not making clear that the consensus of the expert community is that there is no proof of Corollary 3.12.

3. **Roger**
   April 19, 2022

   I agree that there is quite some evidence that the CDF W-mass measurement is problematic (eg comparison with earlier measurements).

   There is, however, also a well known effect that new measurements have a tendency to be consistent with earlier measurements even when the latter measurements are wrong.

   All credit to CDF for following a robust analysis procedure that precludes the possibility of artificially agreeing with earlier measurements. They did the best measurement they thought they could do and published it.

   I wouldn't bet much on it being right but that's another story.

Link to the MIT course is not working

5. **Peter Woit**
April 19, 2022

Mike,
Works for me, but did change link to https in case that was causing the problem.

6. **Mike**
April 19, 2022

It works now, thanks.

7. **John Baez**
April 19, 2022

It would actually be great if MIT taught a course on failed speculative theories in physics, perhaps using Helge Kragh's book as a textbook. If students only learn about successful theories they won't get how hard it is to be right, and how many great physicists had theories that didn't pan out.

8. **Martin S.**
April 19, 2022

Two other takes on the W mass:
https://resonaances.blogspot.com/2022/04/how-large-is-w-boson-anomaly.html
https://non-trivial-solution.blogspot.com/2022/04/do-we-have-finally-found-new-physics.html

9. **Michael Weiss**
April 19, 2022

Prof. Baez has made here a wonderful suggestion. I wonder if such a course might be further enriched by an account of theories that "failed" in their original form and context, but which contained conceptual elements that re-emerged in subsequent decades or centuries, i.e., as components of a superseding theory. Examples might include: (a) in the fifth century BC Greek thinker Leucippus and his pupil Democritus envisioned small indivisible particles, "atoms"; (b) Descartes proposed a "corpuscular" theory of light (1637) at odds with the wave nature of classical light; (c) Einstein posited a cosmological constant to provide an outward pressure opposed to overall gravitational collapse, at odds with Hubble's observations; and (d) Veneziano strings as a theory of the strong force, re-conceptualized as a renormalizable model inclusive of gravitons.

10. **Olaf Teschke (zbMATH Open managing editor and section editor algebraic geometry)**
April 20, 2022

I would respectfully disagree with the negative assessment of the handling of reviewing IUT by the colleagues of MathSciNet. Compared to the peer review process, the purpose of a review in MathSciNet (as well as zbMATH Open) is different; to quote the Guidelines for Reviewers (https://mathscinet.ams.org/mresubs/guide-reviewers.html):

> What is a review? A review should primarily help the reader decide whether or not to read the original item. The review may range in length from a few lines to about 600 words. In most cases the review should state the main results, together with sufficient information to make them comprehensible to someone already familiar with the field. The main ideas of the proof should be sketched when feasible. If the results are technical, requiring extensive notation or elaborate formulas, it is preferable to describe them with a few well-chosen and relatively nontechnical sentences. A review should also contain comments that provide some background for the item, evaluate it and connect it to related items or approaches. Well written reviews are most desirable since the lasting value of Mathematical Reviews/MathSciNet as a research tool lies in its independent third-party reviews.

It is frequently very difficult to find reviewers willing to write a high-standard review, and obviously especially so in this peculiar case (zbMATH Open was very lucky that Peter Scholze agreed for this specific volume). Since our services are fundamentally based on the willingness of the reviewers to provide appropriate reviews, editorial policy will in most cases refrain from interfering or even rejecting detailed reviews contributed by an expert in the field (who Mohamed Saïdi certainly is). With this long-term practice in mind, adding an Editor's note as in the case of the MathSciNet review is already a very rare measure, and a quite indicative statement.
Ideally, of course, the validity of a theorem should not need to be settled in the framework of our reviewing services; but given the situation as it is, I think that both reviews contributed to the clarification of the current status.

11. **Peter W Shor**
April 20, 2022

John Baez says:

> It would actually be great if MIT taught a course on failed speculative theories in physics, perhaps using Helge Kragh's book as a textbook.

That's a great idea, and it sounds like it would be a great course. One problem with this idea is that the course would most likely be listed under Science, Technology, and Society (STS) and not under Physics (Course 8), so most physics majors woudn't end up taking it.

12. **Peter Woit**
April 20, 2022

John Baez,
Perhaps teaching a course on the details of a failed speculative theory would be a good idea, if you explained to the students that it was a failure and why it failed. Teaching such a course and presenting it to undergraduates as a success is what I don't understand at all.

13. **Peter Woit**
April 20, 2022

Olaf Teschke,
Thanks very much for contributing your perspective. My understanding (which may not be correct) is that the problem MR had in this situation is that they were unable to find any expert willing to write a review including a discussion of the problem with the proof. Saïdi was willing to write a review, but not to discuss the problem with the proof. It seems they decided to publish his review since the alternative would be no review.

But a review that doesn't discuss a well-known flaw in the proof clearly violates their own standards as you've quoted them above: that the proof is flawed is highly relevant to whether a reader would want to read the paper, and is crucial for the background of the paper and for its evaluation. The editor's note improves the situation, but this still is a flawed review that does not meet their stated standards.

14. **Kevin S Van Horn**
April 22, 2022

Ironically, the first page of the linked-to notes for the MIT string-theory course gives the argument against string theory in capsule form.

15. **Low Math, Meekly Interacting**
April 22, 2022

I first read about the W anomaly in Quanta. Why they don't just go straight to Tomasso Dorigo or Adam Falkowski every time one of these things heats up is a bit of a mystery to me. Maybe because the wet blanket or reality doesn't get eyeballs.

16. **Peter Woit**
April 22, 2022

Kevin S Van Horn,
I also found that pretty weird. You could interpret "we don't know what string theory implies" as an argument for further research in the subject, but to me it seems an extremely strong argument against teaching the subject to undergraduates.

Lot of other strange things there, such as "Fact 2" which tells us that "the global picture is still lacking today because the field is very young". Over 50 years old "very young"? I can understand why people try and make excuses for the failures of the subject, but I don't understand the phenomenon of making absurd excuses.

17. **Sam**
April 22, 2022

I see the MIT course notes have the standard sum of all integers is -1/12 to get d=26, without any real justification. This put off multiple students when I took this course long ago.

18. **fred**
April 23, 2022

Just to add a bit in this various section: the restart from LHC comes along with some just-around-the-corner hype: https://www.bbc.com/news/science-environment-61149387

19. **Peter Woit**
April 23, 2022

Sam,
At least for that there's a perfectly legitimate mathematical explanation, whether or not the instructor explains it. What's really odd is that this is a physics department teaching fundamentals of physics to its students, but scheduling one course with no known connection to physics. "String theory" has become institutionalized as an ideology disconnected from conventional science, with, at least at MIT, indoctrination part of the undergraduate curriculum.

20. **Shantanu**
April 23, 2022

Peter : OT. A talk by David Gross on string tehory and unification at KITP in 2022
https://online.kitp.ucsb.edu/online/snowmass-c22/gross/rm/jwvideo.html
would be interested in your views.

21. **Peter Woit**
April 23, 2022

Shantanu,
I did watch that. Gross repeated the now 45 year old argument about SUSY GUTs unification of couplings (from what I remember, when I watched this, in the discussion afterwards Mike Peskin pointed out that that unification only works well in the simplest one-loop calculation, that it gets worse if you do a more precise calculation).

He did admit that things haven't worked out, pointing to no SUSY at LHC and the landscape. He did also say "I see little hope that we can achieve the original goal" absent some new theoretical breakthrough. He argued that people should try to solve QCD via string theory and address the "What is string theory?" question, but he has been saying this for decades, people have been trying for decades, nothing has changed.

The one new thing I heard from him was a mention of the bootstrap program and a comment that "other UV completions than string theory may exist and we should be open to this possibility".

22. **tulpoeid**
April 24, 2022

About IUT, what I've been trying to understand is if that work has other merits on its own.
Ie. even if the proof of Corollary 3.12 is wrong, so the overall proof is wrong, does Mochizuki's vast construct contribute to math in some other collateral way?
If I'm right this has happened before with proofs that turned out to be wrong, and I'll be genuinely puzzled if such complex work has nothing else to offer and all its value is hanging on a single point.

23. **Hermann Vile**
April 24, 2022

Mochizuki's latest endeavor seems to be regularly updating this document (https://www.kurims.kyoto-u.ac.jp/~motizuki/Essential%20Logical%20Structure%20of%20Inter-universal%20Teichmuller%20Theory.pdf), which is now 140 pages. I doubt this will convince anyone; if anything, his writing has become even more turgid and depressing.

@tulpoeid: No, there is *nothing* useful in IUT. If there was, it would've been successfully extracted by ambitious young people in the ten (!) years since the IUT papers were first posted.

24. **Peter Woit**
April 24, 2022

Hermann Vile,
That document just gets stranger and stranger. Last time I looked at it, see here
https://www.math.columbia.edu/~woit/wordpress/?p=12220
it was at only 65 pages. It has kept the same structure:
1. No reference to Scholze or Stix by name, no reference to the original document they wrote about the problems with the proof, no reference to later efforts by Scholze to further explain why the proof is invalid (e.g his Zentralblatt review and the discussion on this blog).
2. Out of three long sections, the only one with technical content is the third. Mochizuki seems to think it's a good idea to precede that by two long sections about elementary mathematics and logic supposedly not understood by his critics, as well as a long rant about mathematical ethics (given the PRIMS publication story, this is especially rich). These two sections do an excellent job of completely destroying his credibility.

tulpoeid,
If you look at Scholze's Zentralblatt review, he summarizes the mathematical content of the rest of the IUT papers. Kirti Joshi has written a series of papers, summarized in
https://arxiv.org/abs/2111.06771
which attempt to put Mochizuki's ideas in a more conventional context, where it should be more clear if anything useful can come out of them.

Three Quick Items

May 3, 2022
Categories: Uncategorized

Just time for three quick items:

- There's a wonderful book out now published by the Simons Center at Stony Brook, with the title Crossings. It tells the story of the center and of various people involved with it through a large number of interesting pieces written by these people. The book is published by the center, available here.
- Symmetry magazine has an article out today, with the title Can a theory ever die?. It's largely about supersymmetry, with "No" the answer to the title question. There's a story about Bruno Zumino I'd never heard before:

  > In 1996 theorist Jonathan Feng attended a seminar about searches for new particles predicted by the mathematically elegant theory of Supersymmetry. The speaker was optimistic that researchers would find the particles at massive colliders such as the Tevatron, then in operation at the US Department of Energy's Fermi National Accelerator Laboratory, or the Large Hadron Collider, then under construction at CERN.
  >
  > Feng noticed Bruno Zumino, one of the founders of Supersymmetry, in the audience. Zumino's reaction to the talk confused Feng.
  >
  > "He left the seminar shaking his head," says Feng, who is now a professor at the University of California, Irvine. "I thought he would be happy that an army of people were looking for his theory. So why was he shaking his head?"
  >
  > Feng caught up with the distinguished theorist during the coffee break. He still remembers what Zumino told him: "I never thought it would be this hard. If it's this hard, then they're never going to find it."

  So, twenty-six years ago one of the leaders of the field thought the idea was going nowhere and likely doomed. In the years after that LEP and the Tevatron put much stronger limits on SUSY before closing down in 2000 and 2011 respectively.
  From 2010 to the present day, the LHC has again put far stronger limits on SUSY particles. Most now agree it is overwhelmingly unlikely that the rest of the LHC or HL-LHC runs will change the situation. And, prospects for a higher energy collider are very uncertain and many decades away. You'd think that would be the end of it.

  But the article quotes theorists determined to keep at it (no quotes from anyone who thinks SUSY is over) and there's still an active community of people pursuing what Zumino thought was doomed multiple decades and accelerator generations ago. Large conferences continue to be scheduled, for example SUSY 22 this summer, which will be preceded by a pre-SUSY school designed to train a new generation to work on the failed ideas for many decades to come.

- I'm leaving soon to spend a couple days in Texas, giving a colloquium talk at the University of Texas at Dallas math department.

Update: The slides from the talk at UT Dallas are here.

Comments

1. **paddy**
   May 3, 2022

   "take care when you travel through [Texas] Germany with the truth under your coat!"

2. **anonymous**
   May 3, 2022

   I don't agree with that interpretation of Zumino's response. You may be attributing beliefs to him that he did not hold.

   He doesn't say that SUSY is "going nowhere" or "doomed," he says that we're "never" going to find direct empirical evidence for it at a particle collider. (Here I understand "never" in the colloquial sense of, "not in a reasonable amount of time.") This is not really surprising, since there's a lot of room between the LHC and the Planck scale, and no reason to believe superpartners should exist at energy scales accessible by 2000s-era technology (assuming they exist at all).

   You might object and claim that an idea is doomed/going nowhere if there's no hope of it being empirically verified or rejected in a "reasonable" amount of time (say roughly 100 years). But that's not an obviously true claim, and it's not clear that Zumino held it.

3. **Peter Woit**
   May 3, 2022

   anonymous,
   Sure, it's possible Zumino thought that SUSY extensions of the SM broken at inaccessibly high energy scales were a promising idea, but I don't see any good argument for that (as opposed to the electroweak scale, with the "naturalness" motivation).

   Feng and Tanedo in the Symmetry article give the impression that it no longer matters whether prospects for experimental vindication of an idea have vanished. I suspect Zumino was of a very different generation which did not think this way.

4. **F. Zaldivar**
   May 3, 2022

   Just a typo: Can a theory ever die?

5. **Peter Woit**
   May 3, 2022

   I did some quick research, which indicates that, at least publicly, Zumino was more optimistic about SUSY than Feng indicates. In a 2008 review article
   https://arxiv.org/abs/0805.3726
   with Mary Gaillard, they write

   "We are very optimistic that the MSSM, or some extension of it … will correctly describe the particle and superparticle spectrum that will be produced at LHC energies."

   and note that if there is no SUSY at LHC energies it could be at higher energies. If Zumino had lived, it's an interesting question how he would have reacted to beliefs he was “very optimistic” about being disconfirmed experimentally. Maybe he would have reverted to his 1996 pessimism.

6. **Peter Woit**
   May 3, 2022

   F. Zaldivar,
   Thanks. Fixed.

Brian Conrad on the California Mathematics Framework

May 5, 2022
Categories: Uncategorized

Brian Conrad has been doing the state of California a great service by taking a careful look at the drafts of the proposed California Mathematics Framework and the research they are supposedly based on. He has recently created a website where he has been writing up commentary on what he has found. Conrad is known among his colleagues as one of the most careful and level-headed research mathematicians around, and these characteristics show through in what I have read on his new site.

I should make it clear that personally I have zero expertise on the topic of K-12 math education, so my own views on the matter aren't worth much (and, I think anyone commenting on this should ask themselves about the same issue). Conrad has put a huge amount of his time and effort into learning about the subject and the extensive relevant math education research, and it is this that makes paying attention to the views of a university math professor a good idea in this case.

There's commentary about this appearing elsewhere, including a Wall Street Journal article, and a blog entry by my Columbia colleague Andrew Gelman.

Comments

1. **just different**
   May 7, 2022

   I haven't been following this closely and I certainly don't know whether the CMF is on balance a good idea, but my general impression is that the viewpoint of Conrad and other signatories of the "open letter" is fundamentally elitist. There seem to be a lot of predictions that CMF will delay or discourage the "better" students–the only students who matter, apparently–from pursuing STEM in college, but not a lot of concern about the students who have been failed for decades by the conventional mathematics sequence.

   It would be easier to take these critics seriously if they paid attention to the goals of the CMF and offered constructive alternatives instead of dismissing as inconsequential the abysmal track record of the status quo for the great majority of students.

2. **Brian Conrad**
   May 7, 2022

   @just different:

   Please clarify what "open letter" refers to. I never signed the one from the Independent Institute (despite being asked to do so multiple times, as were many other STEM faculty who did not sign it), nor did I sign the K-12 letter (though in that case I agree with what it says).

   The statement I actually did sign was the more recent https://sites.google.com/view/mathindatamatters/home . What is elitist about alerting parents and students to the reality of what college degrees in STEM fields require? Or about being concerned that the Introduction to Data Science course explicitly advocates to women and minorities that they forgo learning Algebra II in high school and that the CMF also advocates data science as an alternative to Algebra II without clearly indicating the downstream effects on access to 4-year STEM degrees, including in data science?

   Please explain where in what I have written on my website or in the more recent statement that I actually did sign you see something that is "fundamentally elitist". And why do you think my views on this are only focused on the "better" students, or that I ever thought they are the only students who matter? Did you know that within my own institution I was involved in creating a summer bridge program

   https://mathematics.stanford.edu/soar-mathematics-program

   to help students from under-resourced schools to be better-prepared on the core high school math needed for intro-level courses across all STEM fields? (Stanford has some incoming students who struggle with fractions and basic algebra facts too.) And that I spear-headed two curricular overhauls of core service-level math courses in my institution (involving input from experts across many STEM fields — in contrast with the CMF process that did not solicit input from real experts in data science without a financial stake) to modernize motivation in the learning of core math topics without sacrificing the substantive content? Where have you seen me "dismiss as inconsequential the abysmal track record of the status quo for the great majority of students"? (I never have, and I am perfectly well-aware of that issue; to express concern about one facet of a multi-part problem doesn't necessitate fixing everything at once.) How do you know I haven't offered some constructive alternatives? (I have offered constructive suggestions on improving the CMF in past months to people involved in the process; I simply don't post about that on social media.)

   And when a document is produced that has many vague half-baked proposals and falsifications of evidence (even if it has other parts which are fine), how much of a burden should there be on those who object to tell the people responsible how to fix the mess? The fact that a document claims to have certain goals doesn't mean it actually contains a realistic or sustainable approach toward those goals (one reason I read the entire CMF was so that I would not be an armchair critic).

   You insinuate that I have not paid attention to the goals of the CMF, yet right here on the desk as I type this is a print-out of the entire thing full of comments in the margins from reading the whole thing. I have not internalized the CMF to the level I did with EGA (for multiple reasons), but I'm well aware of what the CMF claims its goals to be and how it falls very short. Please state clearly what you think the CMF's goals are at the high school level (which is the focus of what I have written on this matter) and where the evidence is that the CMF provides a realistic path toward such goals.

   SFUSD implemented a version of the CMF's earlier proposals at the high school level, and it was later exposed as such a fiasco that all mention of SFUSD has been scrubbed from the 2nd draft. The data science advocacy now in the CMF has been done for years in LAUSD, and has been described to me as a "disaster" in terms of how it has off-ramped kids at the most under-resourced LA schools (those who rely fully on public education, without access to tutors or other work-arounds) from learning the math they need to be prepared for a 4-year STEM degrees in college.

   To be clear: I have never said that all students must learn Algebra II (the UC & CSU systems have chosen to have a single math prerequisite across all fields, so please criticize that if you wish — it is orthogonal to the reality of the math one has to learn to earn a data science degree at those places), nor have I ever said that the public math education system doesn't need significant improvements.

   My point is about the necessity for transparency about downstream consequences of public policy guidance on the content of math options in the high schools, and the unacceptability of the CMF peddling fantasies about what math in high school is actually preparatory for 4-year college STEM degrees.

   I read the entire CMF (both drafts) to fully inform myself on what the CMF does and does not actually do (lofty goals are easy — I look for details), and have spent many hours speaking with the leadership of the National Society of Black Engineers (which shares the same concerns as I do), leaders of the DEI efforts in the Berkeley School of Engineering (who share the same concerns), people with track records of real success in URM outreach such as Adrian Mims (founder of the Calculus Project; he also shares the same concerns) and college faculty at many other institutions many levels who have put in years of effort on improving access to math classes, and many other thoughtful people with years of experience on these matters.

You say you "haven't been following this closely" (a contrast with me, to put it mildly) and end with a paragraph that lumps me in with "these critics" (whomever they are) and suggests my concerns don't need to be taken seriously because of two reasons that don't apply to me at all. Please clarify on what basis should your comments be taken seriously.

3. **just different**
   May 7, 2022

   @Brian Conrad

   Here's the thing: the past two years have made it blindingly obvious that a very large fraction of Americans are too innumerate to respond appropriately to a global pandemic or correctly interpret election results at a basic level. This bothers me a lot more than the possibility that Stanford freshmen will be less than optimally prepared for STEM majors.

   The failure of K-12 mathematics instruction is particularly acute in California, and racial and gender disparities have been static for decades. Some people have identified algebra as the bottleneck where so many American students stall, and most of the ones who pass don't seem to be acquiring any real-world understanding anyway. So on the face of it, it is not unreasonable to ask whether some other curriculum might better serve the educational goal of creating a functionally numerate and mathematically prepared citizenry. I have no idea whether the CMF does a better job of this, but this line of discussion has been shunted to the margins.

   Instead, the CMF debate has been largely hijacked by right-wing culture warriors, who as always are arguing in bad faith: their true dispute is with the underlying premise that there are persistent disparities which we have an obligation to recognize and address. So no, I don't think criticism about "woke math" or whatever deserves to be taken seriously. The more substantive objection that delaying or replacing Algebra has knock-on effects for potential STEM majors is fair enough (if a bit privileged), but this seems to me to be a much more academic question that can be resolved without the overheated rhetoric and multiple editorials and open letters.

   As I said above, I am only a casual observer with general impressions obtained from nonspecialist media, and I am not directing my remarks at you (or anyone) personally. But since your name gets dropped by people saying some pretty repugnant things, it might make sense to make the sound-bite version of your own position clearer.

4. **More Anonymous**
   May 8, 2022

   @Brian Conrad

   It's nice of you to address this personally. I suspect what's happening is in society is people are unfortunately looking at everything from a particular lens. And now anyone who wants to do anything his/her actions will be used as a tool for some political ideologue and to score some points. It's tragic from the Information Age we have regressed to what I dub as the "Data Age."

5. **Mark Hillery**
   May 8, 2022

   I have read parts of the California Mathematics Framework, and I admire the patience of anyone who was able to read the whole thing. It is very hard to read because of all the verbiage that conveys no information. While I don't teach in California, what starts there often spreads to the rest of the country, and people like Boaz Barak, Jelani Nelson, and especially Brian Conrad have done us all a huge favor in pointing out its flaws. There are already problems with the mathematical preparation of college students, and the current CMF, if implemented, would make them worse. If someone hasn't looked at the document, I would suggest their opinion is not worth considering. This is doubly so if they are not aware of what happened when parts of the CMF were implemented (as noted by Brian Conrad) in the SFUSD. Check out Scott Aaronson's blog for comments by some San Francisco math teachers.

   It was interesting to hear that there are incoming Stanford students who have problems with fractions (What is it about fractions? They really cause a lot of students trouble.) and basic algebra. At Hunter College, where I teach physics, we have, I am sure, far more. I have often taught our algebra-based introductory physics courses, and a large portion of the class struggles with the math. If you are trying to learn some physics and fighting with the math as well, the course becomes twice as hard. The last thing we need is something that would make the mathematics preparation of college students worse, and I am afraid the CMF would do just that.

   I am no expert on high school education; I just know what I would like the students who take our courses to be able to do. Why so many cannot, I don't know, but I expect under-resourced elementary and high schools have a lot to do with it. At Hunter we know about under-resourced schools. See, for example, the recent article in New York Magazine entitled "Hunter College is Falling Down", and I was once in a classroom at Hunter when a rat fell from the ceiling. Our students would benefit from more individual attention, but we don't have the resources to give it to them.

   While resources matter, so does curriculum. In the 1990's we had a contingent of students who were recent immigrants from what had been the Soviet Union. I don't know anything about Soviet schools or their resources, but the facility of these students with high school mathematics was greater than that of our native born students (this is an impression, I never did a systematic study). Is there something to be learned here?

   May 8, 2022

   just different: As someone who was also involved in the campaign to defend serious math education in California, let me give you my personal perspective. I care *enormously* about instilling broad mathematical and statistical literacy in the population. Societally, that's an even bigger issue than training the next generation of mathematicians and scientists, which of course I care about also. But crucially, *anyone who has sneering contempt for the top STEM students and their needs, is not someone who I trust to design a curriculum for the average students either.*

   Have you seen the emails that were disclosed just yesterday, where Jo Boaler (the mastermind of the CMF) is asking someone whether the concept of inequalities (yes, like $x+2y\leq 5$) is actually needed for college-level data science, or whether, presumably, that topic can be omitted? Is this someone who *you* trust to be in charge? If so, why?

   Compare the many people a few generations ago who said: "It's elitist to care about a few persecuted geniuses like Sakharov and Solzhenitsyn. The Soviet Union is trying to improve conditions for the great mass of people!" The fallacy, we now understand, is that any government that would persecute Sakharov and Solzhenitsyn, that would regard them as existential threats, is not a government that you want in charge of the great mass of people either.

7. **Brian Conrad**

   @just different:

   Let me add some points not already in the comments of Mark Hillery and Scott Aaronson. Firstly, due to this communication being in writing rather than in person (so tone of voice is missing), I can't quite tell if you're being sarcastic in seeming to say that I don't recognize innumeracy among the wider population is a more important concern than the STEM-preparedness of students admitted to places like Stanford. I considered pointing out in my original response that I am aware of such type of things (with the example of what I did to assist incoming freshmen here just being an illustration), but I didn't since it seemed clear enough not to need such comment. So I hope you were being sarcastic.

There are two completely different topics (among many others): (i) math education for general citizenship (to give it a name), and (ii) math education for STEM careers. You are focusing on the former, and I and many at universities in industry have been focused on the latter. I wouldn't criticize someone for preferring to focus their concern on (i), and for the same reason I am mystified by your apparent objection that others choose to focus attention on (ii) (or some other aspect of this multi-faceted puzzle, such as teacher training, the grip of publishing companies with dreadfully boring material, etc.). If the goal is to make an impact, rather than just talk about it, we have to choose our focus where we think it can actually make a difference.

The two issues (i) and (ii) interact insofar as students' interests can evolve during middle and high school, and even college (many kids who develop interest in CS in college are surprises to realize they should have paid more attention during math class in earlier years). STEM degrees and college-level STEM coursework are an important factor of the social mobility that college makes possible (it's not the majority of degrees, but it is a sizable fraction and will keep growing as the workforce becomes more automated), so referring to concern about preparedness for such degrees as "a bit privileged" sounds like objecting to government funding of scientific research on the grounds that poverty is still a big problem.

On your concern (i), let me just say that the CMF does not have anything genuinely new to contribute towards it, beyond the hype of renaming things related to statistical topics as "data" or "data science" (for reasons I leave to your imagination). That is why you don't hear anything in the media about the CMF's K-6 components (the parts related to basic numeracy skills); to first-order approximation it is not changing things in any significant way. One can quibble locally, and more globally object to the verbose writing style and poor organizational structure that permeates the document (in contrast with CMF's of the past), but this is not fodder for news media and I am certain that any "public comments" I post about that will be met with a big yawn.

There are many nuances to these matters, so a position fitting into a sound-bite is inevitably going to be too superficial to be meaningful. I'm not aware of repugnant things people are saying while dropping my name (it reminds me why I am not on social media; ignorance is bliss), but it would be a fool's errand to imagine that when speaking out on something then some people will twist one's words out of context to justify things with which one disagrees. Also, I have seen many examples (going beyond my post on misrepresentation of citations within the CMF) of people on the "left" side of this topic misrepresenting written things in deeply deceptive ways too.

But what I'd really like to address is the impression you have of the CMF issue being largely high-jacked by right-wing culture warriors. You are correct that nearly all media attention comes from the right (to the extent the "left" media says things, they have usually ignored the concerns from STEM experts), but you are misdiagnosing it. This is not a hijacking. It is more like leaving one's car unlocked with the engine running and and being surprised that someone drives off with the car.

The story of coverage of the CMF concerns is an illustration of the huge difficulties confronting traditional journalism. The almost total failure by national-level non-right-wing media to pay attention to concerns about the CMF at the high school level is not for lack of trying by those who are eager to share a lot of information with their fellow citizens. When the K-12 letter came out, first the WSJ wrote something and then only media further and further to the right (Daily Caller, Epoch Times, Russia Today,…) wrote anything. It was astounding.

Why did NYT, Washington Post, LA Times, etc. say nothing at the time in December? Why does the LA Times publish CMF propaganda pieces timed with the release of the new version but never report on the reality that actual STEM experts in industry and academia are pretty much uniformly alarmed by the CMF's high school proposals (I am not referring much to acceleration aspects, which have been toned down for the 2nd draft)? Why does the NYT not publish an Op-Ed written by two deans at UC Berkeley cogently explaining how the CMF will be damaging to efforts at STEM career access and pipeline diversification? Why do education writers who are provided with compelling information laying out the basis for concerns with the CMF not follow up?

One explanation I heard from someone who spoke with a NYT reporter is that the NYT thought the concerns about the CMF at the high school level is just a local story to California. If so then they have made a huge mistake, and not only for the reason Scott Aaronson points out ("as goes California, so goes the nation"). The "disease" of promoting data science in place of other math in the high schools with false promises and very inadequate guidance about downstream effects on preparedness for a wide range of college degrees is already spreading around the country, and is popping up in other countries such as Australia and Germany (and perhaps others).

Someone else told me that this is an expensive story to write (to track down the necessary evidence and organize it). It may seem so, but that isn't really the case because through the individual actions of many concerned private citizens acting on their own since last summer there is a treasure trove of information already assembled (the recent posting of emails that Scott mentioned is but one such example; that one had nothing to do with me).

I have spoken with a couple of journalists for some non-national venues (and will be speaking with another), and it has led me to the conclusion that the root of the problem is that the story of CMF concerns is very difficult for journalists to write because it involves how the content of high school math connects to other things. That is doubly challenging: most education journalists don't have a math background, and explaining the concerns to a general audience in an engaging way is difficult too (though the emails may provide a hook that finally draws in some journalists not focused on culture wars).
The falsehoods being spread about data science in relation to math for 21st-century jobs are a kind of truthiness: they sound very plausible to people who are not well-educated enough in technical matters to realize it's nonsense. (I heard of a prominent expert on quantum computing saying that if he were an ordinary educated person but not in matters related to STEM then he'd believe the propaganda too.) That can make it hard to convince many journalists away from culture wars that there's something objectionable enough to be newsworthy. So if you're looking for reporting from a source that is not focused on culture war topics then you're not going to find many options.

The fact that math-types are often reluctant to speak up too visibly without being fully informed and the CMF is a nightmare of poor writing (making it hard to reach a state of feeling fully informed about it) is further discouragement. The pro-CMF side also proclaims themselves (falsely) to the champions of equity, which scares many people into not speaking up, due to fear of being "cancelled".

Here is an ironic aspect you may wish to consider. The way your initial comment expressed a dismissive view of the STEM-related content-based concerns I and others have spelled out in detail is exactly the type of reaction that many people with such concerns and a reluctance to speak up (such as due to not having a full command of the details and nuances) are concerned with having to confront. I have no such concerns because (i) I am not on social media, and (ii) I know enough about it to be self-confident. So when you next wonder why you only see reporting on CMF concerns from sources which don't care what people in the center and left think, in a sense your way of discussing it represents part of the problem. Dishonesty spread from the left on these matters (I am not referring to you, just to be clear) — which is now starting to become more widely known (e.g., I'm told that 70,000 people have now seen those email posts on Twitter since they appeared around 18 hours ago; maybe it'll reach Hagoromo-level virality) — doesn't help things either. To paraphrase TFG: there are very dishonest people on both sides.

I suspect that if we were to discuss these matters in a cafe and thereby had an opportunity for genuine back-and-forth based on nuance and details then we'd probably agree on most things related to this matter apart from perhaps where to focus personal attention on it. And I think you'd be astounded at the layers of complexity in this CMF topic (that was my own experience as I spoke with people coming to it from many different angles). The analogy I made somewhere on my "public comments" website to an iceberg seen from the surface is more accurate than you realize.

You should take some inspiration from the efforts by Bob Moses, a math teacher turned civil rights activist in the 1960's who recognized in the mid-1980's that learning algebra is the key to economic mobility for those from less-resourced backgrounds. (Read his book Radical Equations for more on this if you haven't read it already.) Had he not passed away last summer, I'm sure he would have been alarmed at what the CMF is proposing in opposition to what he pushed for in the last 35 years of his life. There are others continuing Moses' legacy, showing the way to continue broaden engagement with algebra and other math that leads to actual STEM readiness, not the content-changing approach that is preferred in the CMF. I am optimistic that at the high school level, a responsible balance between access to math for real STEM-readiness and other options in high school math will be achieved. Failure is not an option.

May 8, 2022

All,
I'm reverting to usual blog policy and deleting all further comments that try to engage in the culture wars. Comments not specifically about what is in the CMF are highly discouraged, and it may get to the point where I'll have to insist that commenters prove they have read the thing (although then I suspect we'd just be left with Brian Conrad debating himself…).

9. **comment**
May 8, 2022

Politics and education are of course not cleanly separable, but it's dismaying to see many (on 'both sides') seeming to not even try to distinguish (1) their political/cultural beliefs (2) their expert knowledge (3) their understanding of education research. Although I strongly agree with the majority of what 'just different' said above, I think they are a bit off in their targeting. It is very good and clarifying for me to see Brian Conrad explicitly say above that he is focused on "math education for STEM careers". Similarly the "Math in Data Science" open letter (unlike some others) is very good for its focus and its avoidance of surrounding political debates. What I have read from BC's new website is (unlike many other similarly-minded websites/blogs) likewise very good. As someone with deep sympathies and frustrations with 'both sides' of the underlying debate, I find it very useful and clarifying to have material explicitly presented with such clear framing and purpose. (It probably also makes it a little harder for the anti-diversity extremists to hijack the cause.)

If one tried to pick a single most talented and influential figure of the past 100 years in each of the fields of pure mathematics and of theoretical physics, I'd argue that you should pick Alexander Grothendieck in pure math and Edward Witten in theoretical physics. This afternoon I've run across two excellent sources of information about each of them.

Alexander Grothendieck

This week's New Yorker has The Mysterious Disappearance of a Revolutionary Mathematician by Rivka Galchen. It's a very well-done survey of Grothendieck's life and work, aimed at a popular audience. If, like many mathematicians, you've always been fascinated by Grothendieck's story, you won't find too much in the article you haven't seen before. But, if you've never delved into this story, you should read the article. On a related note, a copy of Récoltes et semailles that I ordered recently has just arrived in the mail, and I'm looking forward to spending some time with that this summer.

Edward Witten

In theoretical physics a very different but equally off-the-scale talented and influential figure is Edward Witten, who is the subject of a recent long and in-depth interview by David Zierler as part of the Oral Histories program at the Niels Bohr Library and Archives.

I first met Witten probably in 1977, when I was an undergraduate at Harvard and he was a Junior Fellow, recently arrived from Princeton. Over the years since then he has done a mind-blowing quantity of highly impressive work which I've done my best to try to follow. You can find many places where I've written about this here on the blog, and there's also a lot in my book Not Even Wrong. Much of what he discussed in the interview was familiar to me, but I learned quite a bit new from his recollection of the details of how his work came about and how he thought about it. On some of the specifics of what happened many decades ago one should keep in mind that memory is imperfect. For instance, he describes a short period as a graduate student in economics at the University of Michigan, which surprised me since in research for my book I'd read that this was at the University of Wisconsin. Maybe I got this wrong, but if so I'm not the only one (see for instance here).

Witten's work in the area where pure mathematics and quantum field theory overlap has had an overwhelming influence on those like myself who are fascinated by both subjects and their interaction. The landscape of this area would be completely different (and highly impoverished) without him. At the same time, his equally large influence in the area of attempts to unify physics I believe has been much more problematic.

I'll quote here with a little commentary some of the passages from the interview that I found striking or where I learned something new.

About his early years:

> Witten:
> I was very interested in astronomy when I was growing up. Well, I was not an exception; these were the days of the Space Race, so everybody was interested in astronomy. I was given a small telescope when I was about nine or ten. That's certainly a vivid memory. Another vivid memory is learning calculus when I was eleven. My father sort of taught me calculus or gave me materials from which I could learn it. But I didn't advance very much in math beyond that for quite a few years…
>
> Zierler:
> And then initially you thought you would go and become an economist?
>
> Witten:
> Yes.
>
> Zierler:
> What were your interests there? Did you think that your mathematical abilities would be applied well in that field?
>
> Witten:
> It's again hard to remember reliably, but I might have thought that. And I might have also thought that I could make a contribution to international development. But I realized- well, I came to the same realization I had come to when I was working on the McGovern campaign, that it wasn't a good match for me. I remember being very embarrassed when I told the people in the department at Michigan who had been quite kind to me, that I had decided to leave. But in hindsight, I understand something that wasn't that clear to me at the time, that if a given graduate program isn't a good match for a given student, the department and the student are both better off if that's realized sooner rather than later. If I had understood that at the time, I would have been less embarrassed, probably, with what I told them.

How to learn general relativity in ten days:

> Zierler:
> Was general relativity considered popular or interesting at Princeton at the time that you were a graduate student?
>
> Witten:
> Well, I was certainly interested in it. I learned general relativity in a very exciting period of about ten days, from the book of Steve Weinberg. I mean, I tried to learn more from the book of Misner, Thorne, and Wheeler, and I did learn more from it, but my opinion of the book was what it remains now, which is that it's got a lot of great stuff in it, but it's a little bit hard to use it to learn systematically. The book I found useful for studying systematically was by Steve Weinberg.

The Harvard Society of Fellows:

> Zierler:
> Ed, did you enjoy the Harvard Society of Fellows, the social aspects of it?
>
> Witten:
> Well, I enjoyed it up to a point, but let's just say that many other people thrive on that more than I did.

On how he experienced the First Superstring Revolution.

> Witten:
> I'm not exactly sure what I would have said if you had asked me. There's no interview, so there's no record of my thinking in 1982 or 1983, and I won't be able to remember very well. But as I was telling you, I was interested enough to spend a whole summer reading John Schwarz's review article, but a little bit wary of becoming too involved in it…

> Something that was obvious to me but wasn't immediately completely obvious to everybody was this. Green and Schwarz had put string theory in the form where there was a very strong case that there was a consistent quantum theory that described gravity together with other forces. And the other forces could be gauge fields, somewhat like in the Standard Model. But there was something extremely conspicuous that was wrong in terms of phenomenology, and that was that the weak interactions couldn't violate parity…
>
> And as it existed in 1982 and 1983, string theory was a consistent theory of gravity unified with other forces, but it completely missed the chiral structure. So, to me, that was a huge siren blaring. Anyway, to set the stage, I want to just point out to you that it was clear by 1982 or 1983 that there were an incredible variety of delicate things that fit together perfectly to make it possible to have a theory of quantum gravity based on string theory. It was unbelievable that it could all be a coincidence. Yet it was markedly wrong for describing the real world because of this question of the chiral nature of the fermions. But then in 1984, Green and Schwarz discovered a more general method of anomaly cancellation, and everything changed…
>
> So, anyway, what was really problematical for Green and Schwarz was the combination of fermion chirality and anomalies. Taking these together, it seemed that string theory could not work. But then, in August 1984, Green and Schwarz discovered a new mechanism for anomaly cancellation, and everything changed…
>
> So, it was immediately obvious to me, once they made their discovery, that you could make at least semi-realistic models of particle physics, in that framework. But also, to me, I had done kind of an experiment in the following sense. I had spent two years watching this, wondering, could it be? Can it be that all the coincidences that had been discovered that made string theory possible were just coincidences? As far as I was concerned, the discovery they made in 1984 was an empirical answer of "no" to that question. If the miraculous-looking things that had been discovered up to 1982 and 1983 were truly coincidences, you'd then predict there wouldn't be any more such coincidences. That had proved to be wrong when they made this miraculous-looking discovery about anomalies that enabled the theory to be much more realistic.
>
> In explaining this to you, I'm trying to help you understand why this had so much of an impact on my thinking, watching from the outside for a couple years, wondering if this subject was as amazing as it appeared to me. And a "no" answer would have predicted there shouldn't be more miraculous discoveries. And that was, to my satisfaction, disproved in August 1984. So, after that, the hesitation that had kept me from becoming more heavily involved earlier evaporated. Now, I realized that in the physics world, there were plenty of people who hadn't lived through this two years of uncertainty that I had lived through, and in many cases they had never heard of the whole thing until August 1984. And they hadn't done the experiment I had done. So, they didn't react as I did.

Here Witten explains how one very specific technical calculation triggered for him a dramatic vision of a possibility of a unified theory of everything, a vision that has stayed with him to this day, nearly four decades later.

About his evangelism for string theory unification starting in 1984:

> Zierler:
> How much cheerleading did you do among your colleagues, both near and far, after this revolution in 1984, that this is what people should concentrate on? That we can have this figured out in the near term?
>
> Witten:
> I wasn't intentionally cheerleading, but I was very enthusiastic. And I actually think I was right to be enthusiastic. I wasn't intentionally cheerleading, but to the extent that I encouraged other people to get involved, I've got no regrets about it at all (laughter).

Another very interesting recent interview in the same series is one with Cumrun Vafa. Here's what Vafa remembers about that time:

> Vafa:
> I remember I was at my office, I had come back from a trip, from I think the summer school in Europe, in Italy. Had come back to my office in Princeton on the fourth floor, and Ed's office is on the third floor. And he rarely came to our floor, fourth floor, but here he was, coming and knocking at my door, and then saying, "Have you heard about the revolution?"…
>
> I said, "What revolution?" He said, "The SO(32) revolution." Okay, that was my first introduction to Green and Schwarz's work. SO(32) revolution. I said, "No, what is it?" He said, and he was completely sure, confident, that physics is not going to be the same after this. He said, "Physics is going to change forever because of this, and now everybody is going to work on this."

I had left Princeton for Stony Brook early that summer. During the next few years, reports I got from fellow postdocs who tried to talk to Witten about their work were pretty uniformly something like "he told me that what I'm doing is all well and good, but that I really should be working on string theory."

Unlike the case in the interview with Vafa previously mentioned, Zierler doesn't really try and pin Witten down on the subject of the problems of string theory. He does ask:

> Zierler:
>
> What was happening at the time or has happened since in the world of experimentation or observation that may get us closer to string theory being testable?

but lets Witten give a non-answer, which in effect is that the landscape means string theory unification is completely untestable, so he has pretty much given up:

> So, if you talked to me in the 1980s, I'm sure I would have expressed some hope about seeing supersymmetry as part of the answer of the hierarchy problem. But I would have expressed a lot of confidence about observing something that would have explained the hierarchy problem. …
>
> But ultimately, with the LHC, experiment has reached the point that it's extremely problematic to have what's called a natural explanation of the weak scale, a mechanism that would explain in a technically natural way why the Higgs particle is as light as it is, thus making all the particles light. It's actually a baby version of the problem with the cosmological constant. So, to the extent that the multiverse is a conceivable interpretation of why the universe accelerates so slowly, it's also a conceivable explanation of why the weak scale is so small. It might be the right interpretation. But if it is, it's not very encouraging for understanding the universe. When the multiverse idea became popular around 1999, 2000, and so on, I was actually extremely upset, because of the feeling that it would make the universe harder to understand. I eventually made my peace with it, accepting the fact that the universe wasn't created for our convenience.

You would think that having an untestable theory on your hands would mean that you would try something else, anything else, but Witten seems convinced that whatever its problems, it's the only way forward:

> It's satisfying to know that there was only one candidate for superunification. There's only one reasonable candidate now for the theory that combines gravity and quantum mechanics. Before 1995, there was more than one. It's more satisfying to know that the theory seems to have a lot of possible manifestations, in terms of approximate vacuum states, but at a fundamental level, there's only one fundamental theory or system of equations, that we admittedly don't understand very well. That's got to be an advance of some kind…
>
> By the time he had the theory , he had the right mathematical framework of Riemannian geometry. At least by the time the theory was invented, he had the ideas it was based on, and some of them he had had before.
>
> String theory and M-theory have always been different. From the beginning, they were discovered by people who discovered formulas or bits and pieces of the

> theory without understanding what's behind it at a more fundamental level. And what we understand now, even today, is extremely fragmentary, and I'm sure very superficial compared to what the real theory is. That's the problem with the claim that supposedly I invented M-theory. It would make at least as much sense to say that M-theory hasn't been invented yet. And you could also claim it had been invented before by other people. Either of those two claims is defensible (laughter). So I made some incremental advances in a subject that's far from being properly understood.

This "we don't know what the fundamental equations are, but we know that they are unique" argument has never made any sense to me.

On his relation to mathematics:

> Zierler:
> What did it feel like to win the Fields Medal as a physicist?
>
> Witten:
> Well, it was a thrill, of course. It felt a little funny because I knew that obviously I was a non-standard selection. And I don't like controversy about science, and I felt that I might have been a controversial choice in the math world. But on the other hand, I hadn't selected myself, so I didn't feel any controversy was my fault…
>
> What's a little funny about my relation to the math world is that although some of my papers are of mathematical interest, they rarely have the detail of math papers. And I can't provide that detail. I simply don't have the right background. What I bring to the subject is an ability to understand what quantum field theory or string theory have to say about a math question. But quantum field theory and string theory are not in the precise mathematical form where such statements can usually be rigorous.

The "I don't like controversy about science" quote makes clear that Witten and I are temperamentally very different…

About the birth of geometric Langlands:

> By the late 1980s- I'm probably forgetting bits of the story, I should tell you- but by the late 1980s, Sasha Beilinson and Vladimir Drinfeld had discovered what they called a geometric version of the Langlands program, and it involved ingredients of quantum field theory. Tantalizing. But it was tantalizing because they were using familiar ingredients of quantum field theory in a very unfamiliar way. It looked to me as if somebody had put the pieces at random on a chess board. The pieces were familiar, but the position didn't look like it could happen in a real chess game. It just looked crazy. But anyway, it was clear it had to mean something in terms of physics. I even worked on that for a while at the time.
>
> I think I've gotten this slightly out of order. I think when I worked on it was actually before the work of Beilinson and Drinfeld, driven by other clues. And the Beilinson and Drinfeld work was one of the things that made me stop, because I realized that A, I couldn't understand what they were doing at the time, and B, there were too many things I didn't know that they knew, and that seemed to be part of the story. Anyway, as you can see, my memories from whatever happened in the late 1980s are pretty scrambled.
>
> They wrote a famous paper that was never finished and never published. It's 500 pages long. You can find it online, if you like. They have an incredibly generous acknowledgement of what they supposedly learned from me, which is way exaggerated. Based on a hunch, I told them about a paper of Nigel Hitchin, but I didn't understand anything of what they attributed to me. At any rate, regardless, even if I didn't understand what they did with it, the fact that I was able to point them to the right paper was another sign of the fact that what they were doing had something to do with the physics I knew. But I couldn't make sense of the connection. And this kept nagging at me off and on for a long time.

He then goes on to tell the story of the IAS workshop on geometric Langlands and how it led to his work on a QFT version of geometric Langlands.

In recent years Witten has continued to work on geometric Langlands and other topological quantum field theory related topics at the mathematics end of things. As far as physics goes, he is following the very popular "it from qubit", quantum gravity from information theory, line of thinking:

> Witten:
> And the third time has been the last six or seven years. It's actually hard to remember the evolution of my thinking (laughter). I reread an interview I had done in 2014 which told me what my thinking was in 2014 better than I could have remembered it reliably (laughter). And what I told the interviewer at that time was somewhat similar to what I'm telling you right now. So, this has gone on for a while, and despite that, I haven't really found the right way to become involved myself. But I do suspect that something big is happening.
>
> Zierler:
> What has happened since 2014, when you initially got excited about this?
>
> Witten:
> There have been various striking developments, but a particularly dramatic one came in 2019 when there was success in understanding what is known as the Page curve in black hole evaporation… Lots of things have happened that show that there's a conspiracy between gravity and quantum mechanics. Somehow gravity at the classical level knows about quantum mechanics and statistical mechanics…
>
> Zierler:
> To bring the conversation right up to the present, as we discussed right at the beginning, your interest in quantum information. And you said you don't yet know how you might break into the field. What might be some possible avenues?
>
> Witten:
> Well, when I was a graduate student, I sat down one day with piles of paper preprints. We didn't have the archive. I'd sit down with piles and piles of paper preprints, and go through them, trying to find something I might do. The most interesting calculation I did as a student- I told you about it- was this calculation of deep inelastic photon-photon scattering, which was inspired by a paper I saw by Roger Kingsley, who studied the question but not quite with the most modern QCD ideas. So, when I was a graduate student trying to break in, I would go through piles of preprints. I guess the equivalent now is to look at papers in the archive and try to see what I might do. And I have made some minor contributions, actually, but I don't feel like I've fully become engaged with the subject, as I have with other subjects in the past.

Witten and the interviewer discuss the difficulty of finding something to work on that is not too hard but still significant, and he comments that this is:

> …the difficulty I've had getting involved with quantum information theory and gravity. I found a few things that I could do, but they were a little bit too narrow to really make me think that I was getting involved where I wanted to. And I haven't quite found the right avenue. But I haven't given up (laughter). I do have the feeling that's the direction where something big is most likely to happen. You see, there isn't a general understanding of what string/M-theory mean. And there's something missing in the general understanding of quantum gravity. The biggest hope would be that those two would somehow make contact with each other.

I can understand why Witten hopes that the mystery of quantum information theory and gravity will give insight into and resolve the mystery of what M-theory is, finally vindicating his 1984 vision, but this looks to me like a very, very long shot.

Comments

   May 11, 2022

   A couple points on the Grothendieck piece. The author attributes the introduction of categories and functors to Grothendieck. In fact categorical machinery was first used by Eilenberg and Maclane in 1945, roughly twenty years before Grothendieck's seminal work on the Weil conjectures. Grothendieck though did apply functorial machinery to algebraic geometry in a transformative way.

   The authors also note that Grothendieck developed the theory of motives as part of his solution to the Weil conjectures. I do not believe this is true. Nor did Grothendieck originate sheaves (which are due to Leray), but he did apply sheaves to algebraic geometry in a transformative way, through his "schemes." His seminal theoretical contribution that enabled the proofs of three of four of the conjectures was his etale (l-adic) cohomology theory. I do wish the authors had explained something of the search for this "Weil cohomology theory," and Grothendieck's brilliant insight, that homological algebra could be done on linear objects varying over any site, not just over the open subsets of a topological space.

   I've been thinking about writing a popular article along these lines (explaining about the Weil conjectures and etale cohomology).

   Overall, though, a decent biopic on Grothendieck.

   Incidentally, for readers interested in the life of Grothendieck, here's another brilliant piece to see: https://theanarchistlibrary.org/library/konstantinos-foutzopoulos-the-man-of-the-circular-ruins?v=1620246019

   Personally I prefer this to the New Yorker piece.

2. **Amadou**
   May 11, 2022

   From the little I know about Grothendieck's vision of motives, his Standard conjectures on algebraic cycles, which are inspired by Weil's proof of his conjectures for curves, would be part of the package, and thus would yield, "immediately", a motivic proof different from Deligne's.

3. **stoopid**
   May 11, 2022

   "If one tried to pick a single most talented and influential figure of the past 100 years in each of the fields of pure mathematics and of theoretical physics, I'd argue that you should pick Alexander Grothendieck in pure math and Edward Witten in theoretical physics."

   Really? Yang? Anderson? Schwinger? Bardeen? Weinberg? Nambu? Etc.

   I think the list extends to many tens if not hundreds.

   What "physics" has Witten actually done? He's been very influential in mathematics.

4. **Shantanu**
   May 11, 2022

   Peter : This is one of the rare interview by a particle theorist where non-0 neutrino mass is mentioned. His exact quote:
   "And the second are the neutrino masses, which are plausibly a signal coming from something close to grand unification, though unfortunately we don't know for sure that that's the correct interpretation."
   I wish the interviewee pinned him more on this that if non-0 neutrino mass is supposedly a sign if physics beyond standard model, why isn't Witten and others working more feverishly on it. Does anyone know if Witten has published papers with his father (on aspects of classical GR?)

5. **Peter Woit**
   May 11, 2022

   stoopid,
   Yes, really. Note that I specified "most talented and influential", not biggest accomplishments. On "talented" I don't think there's any argument, and on "influential", I also don't think there's anyone who has come close to his influence.

   In the posting there's a lot about what happened in 1984 and years afterwards. Witten took a technical argument about anomaly cancellation and used it to convince almost everyone in the field to follow him down a very speculative path. Decades afterwards, when it has long been clear this doesn't work, there are still thousands of people working on it, and here at Columbia we teach it to undergraduates. I don't think there's anything even close in the history of physics to that scale of (negative) influence. At the same time of course one can point to a very large number of extremely important and influential positive developments that Witten is responsible for.

6. **Peter Woit**
   May 11, 2022

   Shantanu,
   I may be wrong, but as far as I know Witten has not published papers with his father.

   One remarkable thing about Witten is that he is extremely knowledgeable about the state of high energy experiment and about HEP phenomenology (some of this shows through at points in the interview), far more so than most theorists. He has worked in phenomenology, but that has not been a big focus of his efforts. One could argue that, post SM, no one has been able to make a major breakthrough in HEP (beyond SM) phenomenology. So his concentration on formal theory has been sensible not just because his talents may be stronger in that area, but because the lack of experimental clues has stymied any progress in BSM physics.

   The reference to neutrino masses was part of some half-hearted remarks about GUTS, which he still holds out some hope for, while realizing that no significant evidence for them has appeared.

7. **Alex**
   May 11, 2022

   I was going to post something like what @stoopid said, but I see now that Peter already gave an answer. Still, it makes me cringe a bit to see Grothendieck to be put on the same foot as Witten, in their respective fields. Sure, in terms of influence and talent, maybe, but, to me, Grothendieck's legacy is far superior. Witten will gradually be cornered by history to the areas of mathematics on which he has been influential, as well as some isolated important results in theoretical physics (say, his proof of the positive mass theorem in GR.)

Most of his huge talent was wasted due to a lack of self-awareness (to put it gently and not to talk about lack of scrupulous or good faith…) regarding the über speculative nature of the field, a bit of historical bad luck (zero new experimental results for bSM physics in his lifetime), and maybe some other reasons. I think Grothendieck had better luck in that. Still, Witten managed to make important contributions in other areas, due to his huge talent, evidently.

As a physicist from a much more younger generation, Witten is far from a "hero" to me, despite his talent, and I think this reflects the feeling of many people around my age, particularly outside the main US centers.

8. **Peter Woit**
May 11, 2022

Alex,
I see Grothendieck and Witten as sharing an unparalleled off-the-charts talent together with a huge capacity for a lot of hard work, with those around them recognizing this, leading to a great deal of influence.

In other respects, they and their careers were very different. Grothendieck was only intensively active for about fifteen years (1955-70), whereas for Witten it's about 45 years and counting. Grothendieck was focused on building new foundations for his subject, whereas Witten never has worked in that way. While Grothendieck's new foundations changed the way people thought of the subject, one might argue that most of these changes would have happened sooner or later without him, since they were the natural evolution of the direction things were headed in.

Witten's contributions to our understanding of non-perturbative quantum field theory seem to me of a different nature. Most of the great things he has accomplished I think would not have happened without him (as one example among many, I don't think we'd have the Seiberg-Witten non-perturbative solution to a 4d SUSY gauge theory). I suspect that, in the distant future, once the damage from "string theory" is cleared out, some of Witten's new ways of thinking about QFT will turn out to be fundamental to further developments.

As for negative influence, here I don't think Witten is the main person to blame. Most theorists have speculative enthusiasms which drive their work, and one can't really blame them for following those. The herd-like way so much of the theoretical physics community followed Witten down a blind alley, and still refuses to admit what happened isn't mainly his fault.

11. **Alex**
May 11, 2022

Peter,

I really don't agree with your views regarding Witten's contributions to non-perturbative qft. I mean, what real and relevant problems have been solved? Has the Yang-Mills non-perturbative rigorous existence and positive mass gap problem, the one for which there's the Clay Institute prize, been solved? Has the rigorous non-perturbative quantization of the non-linear Einstein's Eqs. been solved? To me, a real advance in non-perturbative qft should be able to tackle those real physics problems. I really only see promises that so far have failed to deliver. On the other hand, there have been lots of people with their feet on the ground and away from the flashes that have taken these problems seriously (i.e., at face value, without embedding them on grand, delusional speculations) and are, in my opinion, much more closer to solutions than Witten ever was (e.g., the AQFT approach is getting closer to the YM problem, while things like Thiemann's master constraint programme are doing the same for the quantum EFEs). SUSY doesn't exist, TQFTs do not describe any known fundamental forces (at most, boundary terms in GR are of this form). As for the unification of the forces, Connes' approach is much more closer to success that anything Witten ever invented. Sure, all of this only reflects my tastes to some extent, but they do contain a core of truth.

Second, I do think Witten carries a lot of blame. True, the herd mentality was a disaster and wasn't a necessary consequence of Witten's status (for example, Einstein was left alone by the community during his quest for a unified field theory, since there were more promising things to do at that time, and I think it was the right choice, despite the fact I consider Einstein to be the greatest thinker of all times in physics). But, once you are made a leader by your peers, that carries a duty and a responsibility too. And Witten's role as a leader was close to reckless if we consider how things developed.

I'm sorry if this sounds a bit ranty, I think there are strong generational and geographical distances between our experiences and viewpoints.

12. **Will Sawin**
May 11, 2022

@Topologist guy: I concur with Amadou – this is surely referring to the proposed proof of the last Weil conjecture using the standard conjectures.

The standard conjectures are closely related to the category of Chow motives – they prove it has various nice categorical properties. If I remember correctly, it's possible to formulate the proof that the standard conjectures imply the last Weil conjecture both with and avoiding the category of Chow motives.

Of course the great irony here is that the standard conjectures are much, much more difficult than the Weil conjectures, and the biggest progress on the standard conjectures since Grothendieck formulated them was arguably the proof of the Künneth type standard conjecture over finite fields by Deligne and Katz-Messing, which uses the Weil conjectures. (In fact, maybe this is not so ironic, as Grothendieck suggests in Récoltes et semailles that the standard conjectures should be viewed as a generalization of the Weil conjectures to arbitrary correspondences.)

I was a bit disappointed that the New Yorker article didn't add any clarity to the part of the story that has always confused me, where Grothendieck is angry that Deligne proved the Weil conjectures in the wrong way. This confuses me because the complaint doesn't really make much sense (how can you complain that someone proved something the wrong way when neither they, you, nor anyone else know how to prove it the right way?) and because I never saw a place in writing where Grothendieck expresses that anger, though there are places where he criticizes Deligne about other things. The article added a bit more detail than I'd heard before to some other aspects of the story, like Grothendieck leaving IHES, but not that.

13. **Z Y**
May 11, 2022

I would argue that Langlands has been more influential, you can see this manifestly by the amount of generational talent that since the 70s has moved from their original research subjects to become involved in his program (Deligne, Scholze,Vincent Lafforgue, T. Hales, Venkatesh), Witten being one of them. And probably this list will continue to grow in the coming decade.

14. **Peter Woit**
May 11, 2022

Alex,
I agree that Einstein is a good contrast to Witten. In his later career at the institute in the same sort of position as Witten he pursued speculative lines that weren't working out, while the rest of the community ignored him. One difference is that I don't know of any stories of Einstein telling younger people that they should drop everything and work on his latest idea. I actually was kind of appalled by Witten's "no regrets at all" attitude about his evangelism starting in 1984.

About the problems you mention, you can't fault Witten for not solving them since no one else has (or has even come close). I think he's very aware of and motivated by those problems but also very aware that he doesn't have a promising idea to solve them. He has a very quick mind and his style is not to go off and spend years thinking about a hard problem, but rather to quickly realize he doesn't have a good idea that will solve the problem and so move on to looking for another problem which he can solve. About, eg., solving QCD, my guess is that we're lacking the right idea, and likely the way to get the right idea is not by frontal attack but by developing tools solving other problems, such that some day one will have found the right tool to attack QCD.

15. **Amadou**
May 11, 2022

@ Will Sawin: I think, when it comes to Deligne's proof, the better term for Grothendieck's reaction would be "disappointment" instead of "anger" (on this specific point I never felt, reading Récoltes et Semailles, that G expressed anger): he claimed to have wanted above all a complete theory of motives – the most profound theme he introduced in mathematics, in his words; the Standard conjectures ("the proper way" to prove the RH over finite fields) would yield such a theory. I guess, later in his mind (not in mine to be clear), Deligne's proof came to symbolize the abandonment of "foundations building" (his style) in favor of "tricks" or shortcuts to quickly snatch the prized theorem. (see R&S, 3.3. Le décès du patron-Chantiers à l'abandon). I am not sure if this clarifies anything for you.

16. **Will Sawin**
May 11, 2022

@Amadouh: It helps! But it doesn't resolve my confusion about the discrepancy between what's in Récoltes et Semailles and what some other people say – for example the paragraph in the New Yorker article about this is not a good summary of the reaction you describe. So my confusion is to what this other perspective where (as in the New Yorker article) Deligne "wronged" Grothendieck with this proof, who experienced a "massacre" and in turn "vilified" him, is based on, if not Récoltes et Semailles – maybe recollections of conversations people had with Grothendieck about feelings he had but got over before writing Récoltes et Semailles?

Another interesting thing in the section you wrote is Grothendieck's list of topics he studied that were dropped:

"I no longer heard news about motives, topoi, the six functor formalism, De Rham and Hodge coefficients, nor about the "mysterious functor" which was supposed to unite under one umbrella De Rham and l-adic coefficients for all prime numbers, nor about crystals (except to learn that they remained at a standstill), nor about the "standard conjectures" and other conjectures which I had formulated and which, evidently, represented crucial questions. "

If these topics were ignored at one point, I don't think they've been recently. People are constantly producing the six functors formalism in new contexts, there's really interesting fundamental work on what a six functors formalism even is (though maybe involving only three at a time), p-adic Hodge theory was developed and constructed the mysterious functor and now we have a single cohomology theory that underlies both, there's a Topos Institute and various topos-based research programs unrelated to the work there, everyone's talking about motives, ….

@Z Y: Yes, it's terribly infectious. When I came to Princeton I was determined not to study automorphic forms, and when I left I had learned a lot about automorphic forms, and now have a few papers about them.

But I feel that it's more about the intrinsic interest of the problems, rather than any influence of Langlands himself (perhaps using "influential" in an overly strict sense). Didn't most of the transfers to Langlands you mention happen after Wiles's work?

Maybe another way to say this is that the Langlands conjectures were very influential, possibly on the century-defining scale that Grothendieck's work was, but his actual work towards those conjectures (Jacquet-Langlands, Langlands-Tunnell, Langlands-Shahidi, …) was only influential in the way that many good papers are influential. People who work on his conjectures are not necessarily working in his mathematical universe.

An interesting parallel or contrast to Grothendieck is the way Langlands has been disappointed with some of the directions people take his work – famously geometric Langlands but also I heard that he doesn't like modularity lifting and is disappointed that everyone isn't studying beyond endoscopy via the trace formula.

17. **David Roberts**
May 12, 2022

@Will

There's an interesting point that I think is captured in the audio recordings of Grothendieck's 1973 Buffalo lectures on topos theory and functorial algebraic geometry: the news that the last Weil Conjecture had been proved landed in the USA, but not the details or even sketch of the proof. So there's Grothendieck waxing lyrical about how Deligne must have used techniques X, Y and Z in the style of Grothendieck's own foundation-building toolbox, and how wonderful this was. And then he clearly found out, and by a decade or so later, was bitter his own style of work was not used.

I believe this is discussed in McLarty's talk about the lectures; at the very least, the video description mentions a closely related point.

18. **Peter**
May 12, 2022

The past 100 years is the period 1922 – 2022. The most influential theoretical physicists must have been Schrödinger, Heisenberg and Dirac, no? After all, they discovered QM. That is a pretty influential theory, if I'm not mistaken.

19. **Larsina**
May 12, 2022

Other than the Michigan/Wisconsin-Madison issue, I think it is very interesting that Witten doesn't remember clearly why he chose Brandeis or history or other choices he made when he was young. On the other hand, he remembers very clearly about the issues in physics and maths since the graduate student days. Is it a kind of focused or selective memory loss or does he want not to discuss about those personal issues from younger days?

20. **tulpoeid**
May 12, 2022

I came here to write something similar to stoopid's comment, and then I read the reply to him/her.
Honestly, that reply should have been included in the body of the post to avoid a misunderstanding… It clarifies "influential" and once more shows how bad a state theoretical physics is in – and that "accomplishments" now means "social engineering".

Witten states:

"They wrote a famous paper that was never finished and never published. It's 500 pages long. You can find it online, if you like."

Could someone please post a link to said paper?

23. **Peter Woit**
May 12, 2022

Peter,
QM, QED and the Standard Model are the most influential theories of the past 100 years, but in each case there is no single theorist responsible for the theory. Among Schrödinger, Heisenberg and Dirac, if you pick any one and ask what physics would look like without them, I think the answer is "not that different", their discoveries would have been made a little bit later by someone else. If you ask the question of what the theoretical physics of the last 45 years would look like without Witten, the answer is "very, very different" (in both positive and negative ways…).

24. **Peter Woit**
May 12, 2022

Richard,

Witten is referring to this paper

25. **Low Math, Meekly Interacting**
May 12, 2022

I've been struck repeatedly by Witten's unequivocal rejection of other approaches to QG and unification. He's hardly the only "only-game-in-towner", but he generally appears to choose his words very carefully and rarely comes across in any interview or article as undiplomatic. Nonetheless, I think he's been on record several times declaring LQG essentially worthless. He may or may not be correct, but in such a highly speculative area of research, I find it hard to justify such stark dismissals based on anything I would conventionally characterize as evidence. Major, perhaps even fatal difficulties, sure. But no value whatsoever?

26. **Peter Woit**
May 12, 2022

LMMI,
I don't want to get involved in the string theory/LQG argument, but it is quite remarkable that, while Witten is normally extremely cautious in what he says about scientific issues, on the topic of string theory he abandons this caution. One reason for this may be the intense criticism he has gotten about string theory for a very long time, leaving him feeling he has no choice but to mount a strong defense.

27. **Richard**

28. **Amadou**
May 12, 2022

@ Will Sawin: Regarding Grothendieck's list of dropped topics, I think one should keep in mind, besides the time of his writing (1984-1988 ?) which is before some later developments in these subjects, that Grothendieck may not have been very aware of progress that was made in the 70's and early 80's (e.g. Fontaine's work on the mysterious functor, his period rings and conjectures). If I were to speculate as to why, I would say that: (1) his correspondence with Serre, his most important source of mathematical information until then, essentially stops after 1969; (2) he was not an avid reader of the mathematical literature (especially after 1970). Also, he seems to be drawing from (not so reliable) memory only some of the material for R&S, correcting himself in footnotes of footnotes (see for example R&S, 13.3.3, "Poids en conserves…").

29. **Anonymous physicist**
May 12, 2022

Peter: you repeatedly treat `theoretical physics' as synonymous with `theoretical high energy physics.' Please don't. Theoretical high energy physics is only a subset (and an increasingly small subset) of theoretical physics writ large.

30. **Peter Woit**
May 12, 2022

Anonymous physicist,
I appreciate the point, usually try to use a different term, e.g. "fundamental" theoretical physics. The problem with "HEP theory" is that the traditional leadership of that field (e.g. consider the IAS theoretical physics faculty) has stopped doing that long ago, with the "having something to do with quantum gravity" now a more accurate description. I have no idea what the right terminology is for what people like Witten have been doing for the last forty years, or for what they are doing now.

31. **Anonymous physicist**
May 12, 2022

Some younger people in that general field refer to it (Ie what the string theory community is now doing) as 'formal theory.' Perhaps that is as accurate a name as any. It has the advantage that it also connotes theory that is increasingly disconnected from the rest of physics, both theoretical and experimental. And indeed I think nowadays the majority of people who consider themselves theoretical physicists essentially ignore the entire field and almost everything its practitioners have done.

32. **Low Math, Meekly Interacting**
May 13, 2022

Sorry to evoke the Sting Wars, as my recollection was solely meant to illustrate. I believe you could substitute any other framework or theory, and find the degree to which it is differentiated from String theory would be inversely proportional to its worth in Witten's judgement. Which, again, is striking, given what is otherwise characteristic about his statements. I don't know, of course, but I've concluded that's simply what he thinks, and in his mind so clear as to require no moderation. A lot of folks who look to me like zealots have been less stark. I simply find it amazing that someone of his brilliance and equanimity has ended up embracing the multiverse. A logical conclusion based on the overwhelming correctness of String/M theory, I guess. But a premise with zero empirical evidence to show for over half-a-century of work is one hell of a premise to be so convinced of. Especially for what may be the greatest brain of any living human.

33. **Jonathan**
May 13, 2022

On the topic of Grothendieck, the Notices of the AMS published several times biographical notes on him, the most extensive are perhaps this couple by Allyn Jackson, in case anyone wants something a bit more in depth.
https://www.ams.org/notices/200409/fea-grothendieck-part1.pdf
https://www.ams.org/notices/200410/fea-grothendieck-part2.pdf

On the interviews, the one with Vafa has an interesting reply from him on the sociology of string theory that I haven't seen anyone else bring up: "So, I would say that the very fact that new ideas are blossoming from string theory has been the reason it has continued, despite the fact, despite the striking fact, there has been zero experimental connection." To what extent are people working in this field because there's a constant stream of not too difficult ideas coming in that people can spend some time on and get a result out of? Is there a contributing factor that PhD advisors are telling their students, "hey, there's these ideas in string theory you can work on and I think you'll definitely get some good results out of" versus them being unsure what kind of results they could get if they work on something else.

On the topic of picking out a single person to be the most influential/talented figure, I think it is a bit of a silly thing to spend time on, similar how you might get debates on various forums about who is the greatest or most important figure of the XXth century, etc. Perhaps before the "modern" times, say in the times of Poincaré or Hilbert or early in Einstein's life it would be easier to give a reasonable scientific estimate because a) the fields weren't too big and b) there weren't as many people working on them (in 1900 the number of physics PhD awarded was 10). By the time of WW2 fields had become much larger and the number of people working in theoretical physics has only ever continued to increase. Thus there were probably far more physicists working on string theory in the 1990s and 2000s than there were physicists working on quantum theory in the 1920s or 1930s, and consequently the responsibility of any individual theorist would have gone down on average. Even on the ends of the bell curve, how would you compare someone like Witten with someone like Weyl? As he himself admits in the interview he thinks his influence is overrated, and for sure if he was doing something else then some connections wouldn't have been made, but many things would have still been worked on by the dozens of others working on the theory regardless, which is a point he made in the interview, while it's harder to make that argument the further you go back (ie with Weyl), particularly on topics that take inspiration from mathematical rather than experimental ideas.

On the topic of giving a name, given that the first sentence of the Wikipedia article on theoretical physics says that the field tries to "rationalize, explain and predict natural phenomena", perhaps something like mathematical physics would be more appropriate?

And finally, besides LQG and strings, are there many other framework theories that have any serious hope of contributing towards a theory of quantum gravity?

34. **Peter Woit**
May 13, 2022

Jonathan,
I do think it's true that the continued huge research effort in "string theory" (or whatever you want to call it) is driven by the sociological fact that it is set up to provide things that people can work on and write papers about using the tools they're now familiar with. The lack of any success of this effort for decades means that what's really needed are some quite different tools and ideas, but that kind of research is difficult, not rewarded, and lacking any community support.

I don't see any point in most comparisons "was X better than Y", but I do think Grothendieck and Witten are rather special cases, with Witten an unparalleled case of someone having an overwhelming influence on his field. Without him I think the Green-Scharz anomaly cancellation result and superstring theory would have been just another speculative path to unification that would have attracted a small fraction of the field, and died off in not too many years as it went nowhere. Away from string theory, his immense contributions to mathematics and to QFT/topology would not have happened. The whole landscape of this kind of theoretical physics and of mathematics would be very different.

And no, "mathematical physics" is not an appropriate term. If you look at much of what is going on as "formal theory" (as an example, the "it from qubit" stuff), the mathematical content is minimal. The problem is not that physicists have pursued mathematics, but that they have pursued bad ideas about physics.

35. **CJ**
May 13, 2022

@David Roberts, and more generally re: the question of whether Grothendieck was angry about Deligne's proof

I think you are extrapolating too far based off of what I remember to be just a few comments of Grothendieck that he had heard that Deligne had finished the proof of the Weil conjectures. Looking at the evidence is available to us, I find none (and in fact much to the contrary) that he was bitter about that proof in particular not being through the standard conjectures, while he was clearly upset about motives and surrounding ideas not being pursued in the years after (which is a completely different thing).

I believe that the claim that Grothendieck vilified or was at angry at Deligne for proving the Weil conjectures in the way he did is simply false, but close enough to the truth – not in the sense that it is almost true, but that the truth can be confused with it through a hasty paraphrase – that it is repeated a lot. Given what we know of

Grothendieck's life and personality, it should not be surprising that many claims about him are exaggerated or just false. Given all the inaccuracies I've heard about him, this would be a more understandable one, though it is unfortunate that it is so widespread.

Regarding evidence for my claim, I think Recoltes et Semailles is a reliable reference, because the question at hand is precisely what Grothendieck thought about a certain thing, and Grothendieck is clearly writing what he thinks there (regardless of whether his analysis is correct). Here Grothendieck speaks highly of both the fact that Deligne proved the Weil conjectures (in Weil I), and of the progress that Weil II represented. I never read any part where he insinuated that it was wrong for Deligne to use the methods he did, whereas he did say that establishing the truth of the Weil conjectures should have been taken as encouragement to continue to work on motivic ideas.

Grothendieck certainly makes no secret that he's upset at the development/non-development of motives and other mathematics in the 15 or so years after he formally left the mathematical scene. How justified his stance was may be a difficult question, but I'd say that it is far more understandable than being upset about a particular paper because of its methods. Like I mentioned earlier, I would guess that the uniqueness of Grothendieck's life and character would make it easier for such a rumor to spread.

36. **toto**
May 13, 2022

Anyone who has read even small portions of récoltes et semaille (and is fluent in french) would understand how "angry" Grothendieck was at his former students. He repeatedly (and in fact it is one of the main subjects of the book) speaks about what he calls the " funeral" i.e. the fact that he thinks that his students have purposefully tried to reduce the amount of credit given to him (especially about the developement of étale cohomology SGA 4 1/2 being a big point of anger) and have tried to make topos theory "disappear".

I think that most people (me very much included) think that this is complete delusion on Grothendieck's part. But this is not the case of everyone : for example Laurent Lafforgue has recently published a text that goes in Grothendieck's direction (https://www.laurentlafforgue.org/Corrections_Lafforgue_entretien_Bourguignon_Grothendieck_RS.pdf). This passage is striking (although in my opinion completely wrong) :

"Grothendieck emploie le mot « enterrement » non pas du tout comme un acte de rupture avec la « communauté scientifique » mais comme le constat qu'il fait que des pans entiers de son œuvre mathématique qu'il considère particulièrement importants ont été non seulement délaissés par ses anciens élèves et collègues mais font l'objet de leur part d'un « dédain » parfois affiché, d'un sourd « mépris » et d'une hostilité qui en interdisent l'accès aux jeunes générations. Presque quarante ans après « Récoltes et Semailles », on peut constater que la plupart des thèmes dont Grothendieck déplorait alors qu'ils fussent dédaignés ou proscrits, comme les catégories dérivées ou les motifs, sont revenus en force et sont étudiés dans le monde entier. Cependant, le thème des topos, que Grothendieck plaçait en tête de la liste des thèmes importants proscrits, est toujours exposé à une grande hostilité dans le monde académique. En fait, nombreux sont les étudiants qui veulent se lancer dans ce sujet, mais ils font l'objet d'intimidations de la part de représentants du monde académique qui tentent de les dissuader de s'engager dans cette voie."

37. **Alessandro Strumia**
May 13, 2022

Einstein wrote a paper claiming that gravitational waves don't exist. String theorists similarly misunderstood what string theory tells, when they wanted to believe it's a theory with some supersymmetric vacua.

May 13, 2022

typo "let's Witten give a non-answer"
Witten was at U.W. Madison for a semester — Zierler probably transcribed it incorrectly.

39. **Peter Woit**
May 13, 2022

David Brown,
Typo fixed.
Could be a transcription error, could be Witten misremembering (the 70s were a long time ago…)

40. **J.S. Milne**
May 14, 2022

Be careful Peter, when reading Récoltes et semailles, not to go down the rabbit hole. [In the 1980s, Grothendieck sent me a copy, and asked me whether I was a "knowing" or "unknowing" member of the conspiracy.]

41. **Anonymous**
May 17, 2022

To Peter,
"I can understand why Witten hopes that the mystery of quantum information theory and gravity will give insight into and resolve the mystery of what M-theory is, finally vindicating his 1984 vision, but this looks to me like a very, very long shot."
Could you elaborate on this? What do you think of Witten's prediction on quantum information and quantum gravity? Do you think it's an area worth pursuing for young researchers today?
Thanks

42. **Peter Woit**
May 17, 2022

Anonymous,
I think there's zero chance for what Witten is hoping for (a vindication of M-theory through quantum information theory approaches to quantum gravity).

The QIT/QG business seems to be yet another example of the pathological sociology that has afflicted HEP/fundamental theory for decades now. Based on a minor intriguing result, the entire field orients itself around a very speculative idea almost sure to not work out. There are endless promotional talks, little realistic evaluation of whether the idea is going anywhere. Grants, conferences, talk invitations, awards, jobs, articles in the press, etc. all start flowing to those who seem to be working on the hot idea. If you're a young researcher you're in a really ugly position: to get a job you should work on the hot idea, even if it's not going anywhere and already has too many people doing it. This pattern just goes on and on.

By the way, I was just taking a look at the AIP site which has interviews, now one with Lars Brink. Brink is a die-hard superstring enthusiast, but even he now thinks the way string theory was pursued was not desirable:

“So, sure, I think it has been overdone in a sense. I think there’s also been too many people working in string theory. There was a time in the ’80s and ’90s when every American university should have a string theory group. They were sort of vacuum cleaning the market for people. That’s never good. For a long time, people could survive by reading string papers, and they could then do some twist on it, and that has been a bit too much. We all have to pay for it now because the funding of fundamental physics as such is diminishing and even dwindling. Here in Sweden, it’s a disaster. My younger colleagues had good funding 10-15 years ago. Now they’re not getting any funding at all from our research council. They are putting much more money into say quantum information. Of course, I’ve only listened to some seminars in quantum information, but I think they will also follow, more or less, the same scheme. There will be simple problems that they can work on, and then they will get out in various directions. It’s not necessarily so but it will be more, again, mathematics of some kind.”

43. **Peter Shor**
May 17, 2022

One of the problems with It from Qubit is that it’s really quite hard to tell the papers that are nonsense from the ones that aren’t. For example, Maldacena and Susskind’s ER=EPR paper is a speculative idea that has no chance of being correct (but listening to his most recent talk, Susskind hasn’t given up on it). And when you actually corner other people in the area they (or at least some of them) will admit that this paper has virtually no chance of being correct, but for some reason they aren’t willing to say this publicly.

There are undoubtedly other papers in this field which are equally improbable. But it seems to me that any field where you have to be in the cogniscenti to know which papers are the ones worth paying attention to is in deep trouble.

44. **Peter Woit**
May 17, 2022

Peter Shor,
String theory at least in the mid-late 1980s came with a fairly specific conjecture about what the theory was and how it was going to connect to reality (approximate Calabi-Yau compactifications). This didn’t work out as hoped, and string theorists were driven to more and more complicated conjectural “solutions” to the theory, at some point early on passing the “Not Even Wrong” boundary into a framework incapable of making any sort of conventional testable (even in principle) prediction.

The ER=EPR/It from Qubit program on the other hand started out from the beginning “Not Even Wrong” in a stronger sense, without anything like a well-defined conjecture relevant to the real world. Looking at the 2013 ER=EPR paper
https://arxiv.org/abs/1306.0533
besides writing down a metric in the appendix, the paper is 43 pages of verbiage and pictures, with no non-trivial equations. The “cognoscenti” problem here is that you need access to one of a small number of people to explain to you which of the verbiage corresponds to something well-defined which you could write down an equation for, and which corresponds to an extremely vague hope/dream with nothing backing it.

Whenever I try and look into the literature of this field, all I can see that is well-defined are toy model calculations, often in 0+1 or 1+1 dimensions. These may be very interesting, but they don’t seem to come with any serious proposal for what they are supposed to imply about a realistic (even in the sense of having any physical gravitational degrees of freedom at all) theory.

Probably others have the same problem I have with writing anything publicly about this. The literature is huge and complicated, so it would be a full time job to master it to the point of being sure there is no there there. I’ve been through this before with string theory claims and wasted far too much time on that. Until the people working on this start producing review articles that clearly explain how what they are doing is supposed to connect to reality, what has worked and what hasn’t, it seems to me that the rest of the world should assume that, as far as a theory of fundamental physics goes, this is just another extremely speculative vague idea that is not working out.

45. **Mitchell Porter**
May 18, 2022

I wonder on what grounds ER=EPR is supposed to have “no chance” of being correct. There is already the curious parallel of non-traversibility of wormholes, and non-transmission of information via entanglement alone; obtaining both of these limitations from a common origin is exactly the kind of beautiful conceptual connection one expects from a deep correct insight.

Perhaps I should also be asking what “It from Qubit” ideas *are* to be considered promising!

46. **d_b**
May 18, 2022

@Peter Shor
I’d be interested to hear why you think ER=EPR has no chance of being correct.

47. **Scott Aaronson**
May 19, 2022

If we compare It from Qubit to “old-fashioned string theory,” I think we’d have to say that, yes:

– Both seem difficult to inform by any feasible experiments (apart from “experiments” that are really simulations, e.g. of one quantum system by a different one).

– Both have fundamental concepts that still lack clear mathematical definitions, except in special cases that are then speculatively extrapolated way beyond.

– Both have a strong predilection for toy models (with, e.g., unbroken supersymmetry, negative cosmological constant, different numbers of dimensions) that make clear departures from the observed world.

Having said, I’d submit to the people here that there’s at least one respect in which It from Qubit sharply differs in flavor from “old-fashioned string theory.” Namely, IfQ takes as its starting point a fundamental conceptual problem (black hole information loss) that would presumably need to be confronted eventually in any theory that encompassed both QM and GR. It tries to produce general insights that would interest anyone who cared about that problem, regardless of the unknown details of what might be happening at extremely high energies and short distances. It often uses string theory as a source of examples, but then (as it were) discards the strings like scaffolding, so that many of the results and open questions can be made surprisingly comprehensible to anyone who understands and accepts QM, plus some high-level facts from GR and QFT.

For instance, anyone, regardless of their speculative commitments about the Planck scale or lack thereof, can now be asked: so, OK, what do *you* think would happen if you did the AMPS experiment? If you wouldn’t encounter a firewall at the event horizon, then which of the assumptions leading to that apparent conclusion do you reject? Or (as in Susskind’s recent talk): could an observer jumping into a black hole see the answers to certain computational problems that are exponentially hard even for quantum computers? If not, then again: which of the assumptions seeming to point that way are false?

If we reach for analogies in the history of physics, none of this strikes me as analogous to any of the great triumphs—the experimentally-confirmed new theories—but much of it *does* strike me as analogous to the posing and sharpening of puzzles (e,g., Newton's bucket argument, Einstein's hole argument, Maxwell's demon, EPR…) that often either preceded the triumphs or drew out their consequences after the fact.

48. **Peter Shor**
May 20, 2022

Why do I think ER=EPR has no chance of being correct? I think the idea (somebody correct me if I'm wrong) is if you take a whole bunch of entangled pairs of particles, say in the state 1/sqrt(2)(|↑↓〉 -|↓↑〉), and let them collapse into two black holes, you get an Einstein-Rosen bridge between the black holes.

Now, suppose you take a whole bunch of entangled particles 1/sqrt(2)(|↑↑〉 -|↓↓〉) and let them collapse. This is the same thing as turning one of the two black holes 180 degrees, so shouldn't they also form an Einstein-Rosen bridge? Now, suppose you take a whole bunch of particles, half of them 1/sqrt(2)(|↑↓〉 -|↓↑〉) and half of them 1/sqrt(2)(|↑↑〉 -|↓↓〉). Do they form a black hole as well? If not, why not? … you started with a lot of entanglement, it just wasn't consistently oriented. But if they do, then it seems to lead to the conclusion that you can make an Einstein-Rosen bridge out of pairs of particles with no entanglement between them at all, because a probabilistic mixture of these two entangled states is equivalent to an unentangled state. And if they don't, you need to answer the question of how much consistent orientation do you need before you get a bridge? And is there a continuum … if more of the particles are have the first orientation rather than the second, do you get a partial Einstein-Rosen bridge? How exactly does this work?

Now if the original paper had actually discussed questions like this, maybe I would take it seriously. But no, it was a grand hand-wavey idea that sounded good, but as far as I can tell, had utterly no thought given to the possibility that when you try to work out the details, they might turn out to be inconsistent.

49. **Peter Woit**
May 20, 2022

Thanks Scott for the explanation of motivation for this. I do have to now discourage further technical discussion of these issues in this comment section, partly because they're off-topic, partly because I'm incompetent to moderate such a discussion.

50. **Geoff Penington**
June 11, 2022

@Peter Shor: The ER=EPR argument starts from the observation that the thermofield double state of two entangled CFTs is holographically dual to an Einstein-Rosen bridge. This observation had actually already been made ten years earlier by Maldacena. However what Maldacena and Susskind did is observe that you could make a naive version of the AMPS paradox for the thermofield double state, but that it's resolution is obvious (the interior partner of the Hawking mode and its purification in the opposite CFT are the same fundamental degree of freedom). When Lenny talks about collapsing entangled qubits into black holes to make a wormhole, he really means constructing the analogue of the thermofield double state in some hypothetical version of holography beyond AdS/CFT. A generic entangled state will not have any sort of short classical wormhole, and no one claims that it does.

They then argued that "morally" the same solution should work for actual evaporating black holes, because we should think of any pair of entangled particles as (in some poorly defined way) physically equivalent to a connected wormhole. This claim as they originally stated it is very imprecise – what on earth is the physical meaning of a "Planckian wormhole" connecting any Bell pair? – to the point where it's "not even wrong".

But a year or so later a paper by Engelhardt and Wall was published introducing the "quantum extremal surface prescription" for computing holographic entropies. And in that prescription classical geometry and entanglement of quantum fields are treated in exactly equivalent ways. This can be thought of as a precise realisation of the vision of ER=EPR in at least one important context. The 2019 developments that Witten referenced in his interview then applied those formulas to evaporating black holes in a way that essentially realises the vision of Maldacena and Susskind.

So sometimes (aspects of) grand hand-wavey ideas can eventually be turned into precise calculations, although it normally takes a lot of work.

51. **Peter Woit**
June 11, 2022

Geoff Penington,
Thanks a lot for the clarifications, that's very helpful. I've never been able to get anything out of things like the ER=EPR paper or Susskind's talks, since they seem to be based on some highly conjectural "vision", but with no explanation of what is actually known and what the conjecture is.

This and That

Categories: Uncategorized

Various things that may be of interest:

- MSRI in Berkeley has announced a \$70 million dollar gift from Jim and Marilyn Simons, and Henry and Marsha Laufer. This gift will make up the bulk of a planned endowment increase of \$100 million and is the largest endowment gift ever made to a US-based math institute. The success of the Renaissance Technologies hedge fund is what has made gifts on this scale possible. This summer MSRI will be renamed the "Simons Laufer Mathematical Sciences Institute", and the directorship will pass from David Eisenbud to Tatiana Toro.
- The journal Inference has just published an article by Daniel Jassby, which gives a highly discouraging view of the prospects for magnetic confinement fusion devices. Jassby, who worked for many years at the Princeton Plasma Physics Lab, argues that performance of magnetic confinement fusion systems has not much advanced in a quarter century, making for very bleak prospects that such designs will lead to a workable power plant in the forseeable future. He sees inertial confinement fusion systems like the National Ignition Facility at Livermore as making some progress, but ends with:

  > The technological hurdles for implementing an ICF-based power system are so numerous and formidable that many decades will be required to resolve them—if they can indeed be overcome.

- I've been spending some time reading Grothendieck's Récoltes et Semailles, which is a simultaneously fascinating and frustrating experience. I've made it almost to the end of the first part, except that there will be another forty pages or so of notes to go. To get to the first part involved starting by reading through about two hundred pages of four layers of introduction. It seems that basically Grothendieck did no editing. Once he was done writing the first part, as he thought of more to say he'd add notes. He distributed copies to various other mathematicians, and then kept adding new introductions, with various references to how this fit in with more technical mathematical documents he was working on (La "Longue Marche" à Travers la Théorie de Galois, À la poursuite des champs).

  After the first part, looking ahead there's the daunting prospect of 1500 pages with the theme of examining his deepest mathematical ideas and what he felt was the "burial" that he and his ideas had been subjected to after his leaving active involvement with the math research community in 1970. Quite a few years ago I did spend some time looking through this part to try and learn more about Grothendieck's mathematical ideas. I'll see if I can try again, with the advantage of now knowing somewhat more about the mathematical background.

  Besides the frustrating aspects, what has struck me most about this is that there are many beautifully written sections, capturing Grothendieck's feeling for the beauty of the deepest ideas in mathematics. One gets to see what it looked like from the inside to a genius as he worked, often together with others, on a project that revolutionized how we think about mathematics. This material is really remarkable, although embedded in far too much that is extraneous and repetitive. The text desperately needs an editor.

  There are various places online one can find parts of the book and other related material, sometimes translated. Two places to look are the Grothendieck Circle, and Mateo Carmona's site.

- For an up-to-date project on reworking foundations of mathematics (with an eye to eliminating analysis…), Dustin Clausen and Peter Scholze are now teaching a course on Condensed Mathematics and Complex Geometry, lecture notes here.
- I noticed that the Harvard math department website now has an article on Demystifying Math 55. The past couple years this course has been taught by Denis Auroux, and one can find detailed course materials including lecture notes at his website.

  The current version of the course tries to cover pretty much a standard undergraduate pure math curriculum in two semesters, with the first semester linear algebra, group theory and finite group representations, the second real and complex analysis. The course has gone through various incarnations over a long history, and has its own Wikipedia page. For various articles written about the course over the years, see here, here (about a Pavel Etingof version) and here (about a Dennis Gaitsgory version).

  I took the course in 1975-76, when the fall semester was taught by mathematical physicist Konrad Osterwalder, who covered some linear algebra and analysis rigorously, following the course textbook Advanced Calculus by Loomis and Sternberg. The spring semester was rather different, with John Hubbard sometimes following Hirsch and Smale, sometimes giving us research-level papers about dynamical systems to read, and then telling us to read and work through Spivak's *Calculus on Manifolds* over reading period.

  My experience with the course was somewhat different than that described in the articles above, partly due to the particular instructors and their choices, partly due to the fact that I was more focused on learning as much advanced physics as possible. I don't remember spending excessive amounts of time on the course, nor do I remember anyone I knew or ran into being especially interested in or impressed by my taking this particular course. What was a new experience was that it was clear the first semester that I was a rather average student in the class, not like in my high school classes. The second semester about half the students had dropped and I guess I was probably distinctly less than average. The current iteration of the course looks quite good for the kind of ambitious math student it is aimed at, and it would be interesting if a new textbook ever gets written.

Update: One more related item. This week Chapman University is hosting a conference about Grothendieck. Kevin Buzzard has posted his slides here.

Comments

1. **Analyst**
   May 25, 2022

   What do Clausen and Scholze's notes have to do with "reworking the foundations of mathematics," much less about eliminating analysis therefrom? I'm not familiar with their work but their stated goal is just to develop some of the basic theory of the constructions from their research papers and to illustrate it by proving some old theorems.

2. **Peter Woit**
   May 25, 2022

   Analyst,
   My reading of what Clausen/Scholze are trying to do is revamp the foundations of complex analysis/complex geometry so the subject is not based on analysis (e.g. differentiable functions), but on algebra. They explicitly advertise that their way of proving basic theorems of the subject is "analysis-free". A motivation for this is arithmetic geometry, where Scholze would like to prove things like real local Langlands by the same p-adic methods used at finite primes:
   "Part of our goal is to develop foundations for analytic geometry that treat archimedean and non-archimedean geometry on equal grounds; and we will proceed by making archimedean geometry more similar to non-archimedean geometry.

3. **Joseph Healy**

4. **anonymous**
May 26, 2022

That's not an accurate characterization of the notes. They aren't revamping "the foundations of complex analysis/complex geometry," they're just proving some core theorems about compact complex manifolds. (Note that complex analysis and complex geometry encompass far more than compact manifolds…) Further, it's no surprise this can be done algebraically, because GAGA tells you that compact complex manifolds are equivalent to complex algebraic varieties. One could already prove all of these things from an algebraic perspective. The point of the notes seems to be to give new proofs along these lines that illustrate their new techniques.

This is an interesting project (especially as a way to make their techniques more accessible), but I feel it is inappropriate to claim it is "reworking foundations of mathematics (with an eye to eliminating analysis…)." There's nothing about foundations in the notes, and the fact that these theorems can be "algebra-ized" is known to any PhD student in complex geometry.

5. **mls**
May 26, 2022

@ anonymous

Dr. Woit has a history of misrepresenting anything in mathematics and related subjects which does not conform to his personal beliefs. This has been especially true with every mention of "foundations."

At least the last paragraph of his present post includes an honest history explaining his profound ignorance of mathematics.

6. **Will Sawin**
May 26, 2022

I'm going to continue the trend of every commenter having a slightly different interpretation. In particular, I think one should look at this in the context of Scholze's previous work in condensed mathematics.

I think it's important to begin with the observation that in the theory of complex manifolds one often wants to use analytic methods and one also often wants to use algebraic methods potentially involving derived categories and such. A basic concern is that, in some future arguments, one could run into trouble when these two strands don't weave together properly.

For example, if one wants to keep track of size of something using Banach spaces, and also use derived categories, one could be stymied by the fact that Banach spaces do not form an abelian category, and therefore can't be used to construct a derived category. Scholze's earlier work on condensed, liquid, and solid vector spaces provides a fix for this by defining an abelian category that includes Banach spaces.

I believe Scholze's work in this course is intended to provide further tools on the same lines that are potentially useful in future research. Specifically this is for research that already intersects analysis and algebra – I don't think there is any intention to replace analysis in the proof of existence of solutions of some PDE or the prime number theorem or something like that. But it's not specific to the point that there is some Weil-conjectures-like goal in mind.

@anonymous

> because GAGA tells you that compact complex manifolds are equivalent to complex algebraic varieties.

This is not true at all. It only tells you that, for a manifold that is already algebraic, studying it using analytic and algebraic tools will give you the same answers (the same compact submanifolds, the same cohomology, …)

> One could already prove all of these things from an algebraic perspectiv

This seems like a silly point of view when one of the things being proven in the notes is GAGA, i.e. exactly the bridge that links the algebraic and analytic perspectives. One can't use GAGA to prove GAGA.

According to Laurent Fargues, one of the goals is the Hodge decomposition. Do you consider this something that can be proven entirely algebraically?

7. **Johan**
May 26, 2022

If I remember correctly, Columbia Library has one of the original copies of Récoltes et Semailles (sent by Grothendieck to Sammy Eilenberg), no? It may even be autographed, in any case it really belongs in the rare books collection.

8. **Jonathan Chiche**
May 26, 2022

I believe most, if not all, original copies of "Récoltes et semailles" are inscribed by Grothendieck. In 2008/2009 I read one of the two copies owned by Paris N university (with N=7 probably). One of them was inscribed by Grothendieck to Faltings, the other to Leray. If my memory serves me right, the latter had a note written by Leray pointing to an error in the text (regarding himself), and one of the two copies (I cannot recall which) was incomplete pf roughly one half. It would be interesting to have a list of institutionally and privately owned original copies, together with the text of Grothendieck's dedication. I disagree that the text needs an editor and remember it as a great reading for an aspiring mathematician.

9. **Dustin Clausen**
May 26, 2022

For what it's worth, I agree with what Will Sawin says (minus the attribution of everything solely to Scholze, of course!). I never thought of the goal of condensed math, or this approach to analytic geometry, as being to eliminate analysis. Actually, a lot of analysis shows up in the foundations. Rather, the goal is to put parts of analysis and topology in a new framework, one which allows to mix more easily with algebra. Then we can make formal arguments of a certain algebraic style, which however lead to analytic and topological conclusions.

In the example of the theorems we aim to reprove in the course, this means that the analysis is black-boxed into some foundational material about liquid vector spaces, and then the rest of the argument is in a sense purely algebraic. But I don't really think of that as eliminating analysis. In fact, in my view it is neither desirable, nor even possible, to elminate analysis from the study of complex geometry!

10. **Peter Woit**
May 26, 2022

mls,
There was a small element in my post of trolling of analysts/foundations of math aficionados. I won't really apologize since it was kind of successful, and in the spirit of Clausen/Scholze's claim to be making the subject "analysis-free". I see that Clausen has written in here to clarify, which is great.

There is some connection of this to my math education experiences at Harvard. Doing about average in a Math 55 class that had a bunch of the top Math Olympiad performers in it even though I wasn't putting much time into it (much more of my time was going into the quantum mechanics class I was taking) wasn't such a bad performance. More relevant, the next math class I took was a graduate course in analysis, taught by Andrew Gleason. This course extensively covered set theory, point set topology and measure theory, and had us spending lots of time puzzling out questions like whether a space was $T_{2\frac{1}{2}}$. Around the same time I also took a set theory course from Quine (I did pretty well in both from what I recall).

In retrospect taking these courses (Gleason and Quine) was a big mistake and a waste of time, caused by my idea that, both in physics and in math, what I should be doing was focusing on learning the "foundations", from which understanding of everything else would flow. I should have been taking other courses which were not "foundational", but would have taught me about some of the great unifying concepts that bring together a wide range of beautiful mathematical structures (as well as physics!). Someone should have told me to take representation theory…

11. **Łukasz**
May 26, 2022

@Analyst @Peter Woit

In my opinion, the phrase "reworking the foundations of mathematics," connotes rather research in mathematical logic or set theory. For example, classical Arithmetic is based on classical first-order logic (some people prefer to tell in this context, about classical functional calculus).

12. **Peter Woit**
May 26, 2022

Łukasz,
I did clarify this later by specifying "foundations of complex analysis/complex geometry" and note that Clausen/Scholze talk about "a new foundation for combining algebra and topology". I'm well aware that many people identify "foundations of mathematics" with mathematical logic/set theory. That identification led to the misguided educational experiences of my youth that I explained, so I rather intentionally used the term to refer to a broader (and, if you ask me, more interesting) set of issues.

13. **Will Sawin**
May 26, 2022

@Dustin Clausen

Sorry about that! Maybe next time I will make up for it by crediting it entirely to you and not at all to Scholze…

What does "GAGA" stand for?

15. **Peter Woit**
May 27, 2022

Richard,
For most people, a well-known performer. For some mathematicians, more relevant is
https://en.wikipedia.org/wiki/Algebraic_geometry_and_analytic_geometry

16. **Richard**
May 27, 2022

Peter Woit,

For * me * , it was what I was going trying to figure out what it means!
Thanks for the reference! [For the linklazy among us, "GAGA" refers to "Geometrie Algebrique et Geometrie Analytique", a foundational paper in algebraic geometry published by the redoubtable Jean-Pierre Serre in 1956 (Full disclosure: my personal knowledge of such things is a trifle on the nonexistent side).]

17. **David Brown**
May 28, 2022

Jassby's 2018 article might be worth studying:
https://thebulletin.org/2018/02/iter-is-a-showcase-for-the-drawbacks-of-fusion-energy/
In any research, the yea-sayers who are overly optimistic might have a strong tendency to drive out the nay-sayers — because cash and career advancement are at stake.

18. **martibal**
May 28, 2022

And for those who do not speak french, let us not forget that "gaga" in popular langage means "senile" (more or less, maybe Peter would have a more accurate translation), and may also be for "to have a crush on someone"

19. **Paul D.**
June 17, 2022

The big problem with these DT fusion schemes is that the volumetric power density is just terrible. An existing PWR fission reactor's primary pressure vessel might have a power density of 20 MW/m^3; the volumetric gross fusion power density of ITER is 0.05 MW/m^3. It's very difficult to see how DT fusion can ever be cheaper than fission, given that the reactor itself will be at least an order of magnitude larger (and much more complex).

Note that this problem has nothing to do with plasma physics, but rather is due to limits on heat and radiation transfer at the wall of the reactor vessel and the square-cube law. Totally solve plasma confinement and the problem is still there, at least for reactors burning DT.

This issue has been known for approaching 40 years, if not longer. I find it incredible the press is still spouting glowing nonsense about DT fusion.

http://orcutt.net/weblog/wp-content/uploads/2015/08/The-Trouble-With-Fusion_MIT_Tech_Review_1983.pdf

June 18, 2022

I think Jassby's criticism of SPARC is a bit off: he points out that higher field strength will produce higher mechanical stresses, but doesn't make any argument that this is insurmountable. He also says that SPARC should focus on improving Q, not cost-effectiveness. But a big reason that progress has slowed is that the machines have become so expensive, so these are connected. Additionally, increasing field strength directly increases Q, for a fixed-size machine.

June 28, 2022

I have math55a and math55b course notes on my computer. They can be found on the internet, easily. The full course notes are about 100 pages~ for each part and they cover everything that I covered in about 4 years at my university, but in very brief detail. The algebra course even covers topics like category theory and differential geometry. A lot of Galois theory is covered too.

I think I'd do very very poorly in math55 just because you are given not much time at all to digest these concepts. Rather than spending several weeks on rings, they are covered in one lecture and then you move on to something more advanced. I guess Peter Woit is to me like Ed Witten is to Peter Woit.

I also have all of parts I, II,III course notes of the Cambridge math degree, which can also easily be found on the internet. They were latex'd by a student who did it in four years. The full course notes there are about 4000 pages~ as compared to the 200 pages in math55. They do go a little more advanced and lots of extra topics like model theory, combinatorics are covered as well.

Memories of a Theoretical Physicist

June 1, 2022
Categories: Book Reviews

Joe Polchinski's autobiographical Memories of a Theoretical Physicist has just been published, in an open-access version that is freely available. Much of the volume is what appeared here on the arXiv back in 2017, but this has been supplemented with other material, including an introduction by Andy Strominger and detailed bibliographical notes by Polchinski's student Ahmed Almieri. If you're interested in the details of Polchinski's work, I'd recommend also reading Witten's biographical memoir here, which covers the same scientific material, but from Witten's perspective.

Polchinski and Witten agree that one of his three major accomplishments was the anthropic string theory landscape, but I'd argue that this was the opposite of an accomplishment. Instead it should be seen as a disastrously bad scientific argument, one that became a wrecking ball that brought to an end most work towards a better, more unified theory of fundamental physics. Polchinski and Susskind were the two most influential figures in pushing for this argument in the theoretical physics community (Susskind wrote a popular book).

Everyone I've talked to who knew Polchinski has nothing but positive things to say about him as a scientist and as a person. I never got to meet him in person, but wish that I had, this might have improved our bad relations. Back in 2004, I wrote an early blog entry that seems to have greatly upset him, by describing (accurately I still think) a popular article on the landscape he wrote with Raphael Bousso for a Scientific American issue about Einstein and his legacy as pseudo-science that would have made Einstein gag. I was not the only one with this reaction to his work, his KITP colleague David Gross also had strong things to say on the topic. In the memoir Polchinski refers to the years of these arguments (and of the appearance of my book and Lee Smolin's) as ones he found emotionally very difficult. At the time he somehow managed to get the arXiv to ban trackbacks to my blog, for that sorry story see here.

Towards the end of his life the landscape pseudo-science he had so vigorously promoted became a dominant point of view among influential theorists, with even Witten coming to accept it. Polchinski remained upset by my continuing complaints about the subject. One of his last papers, (this one, also see here), extensively attacked me personally, claimed that string theory was true with Bayesian probability greater than 97.5 percent and appears to have been partly a reaction to this blog post. In the blog post I made fun of his claims to have calculated the Bayesian probability of a multiverse as at least 94%. I was unaware at the time that he was already sick with the disease that would later take his life.

Much of this autobiographical memoir is rather technical and will be mostly of interest to experts and specialized historians. The complicated story of Polchinski's career is very much the story of what happened during this time to the field of fundamental theory in physics. This is a very different story than the usual one of a scientific field's progress towards greater enlightenment.

Update: A correspondent pointed me to something I hadn't noticed. In section 3.3 Polchinski writes:

> This was typical of Mandelstam, how far ahead he was in much of his thinking. Another example, the first paper that one studies in the Langlands program today, is the first paper that Mandelstam gave me to read forty years ago.

I wouldn't describe it the way Polchinski does, but I'm guessing the paper he's referring to is Montonen-Olive.

   June 2, 2022

   I did a postdoc at UCSB in 2005 and moved to PI in 2006. I'd started blogging at around the same time I moved to Santa Barbara. My own research at the time was peripherally related to both string theory and quantum gravity, but really neither. In any case, I believe it's for those reasons that both Joe and Lee talked to me about the whole string-theory-and-Peter-Woit thing repeatedly.

   For what I remember, Joe's issue with you was mostly your position and you not being a physicist which disqualified you in his eyes. Lee wasn't quite as easily to discard.

   The thing with the Bayesian estimate. I believe Joe and I actually talked about this when I interviewed him for my book. (This was a week or so before his surgery.) This didn't make it into the transcript (because I don't explain in the book was Bayesian inference is) and I'd have to try and find the recording to be sure, but I believe he told me explicitly that of course he wasn't serious with this number. I think he was trying to make a more general point that Bayesian inference is a way to quantify the credibility of a hypothesis.

   There's a lot of people in the foundations of physics now who think that Bayesian inference is kind of a magical tool that they can use to prove their biases must be correct. Joe was just somewhat ahead of his time, I guess.

2. **Dave Miller**
   June 2, 2022

   Peter,

   Polchinski was a year ahead of me at Caltech (though only a few months older), and we were in the same dorm all of our time at Caltech: I knew him fairly well for those three years at Caltech and became reacquainted when I was finishing my Ph.D. at SLAC and he was a post-doc at SLAC.

   Joe was generally a fairly nice, quiet guy (a bit less so when he was drunk). Joe was sympathetic and supportive to me when I went through some personal problems at Stanford.

   He did have some wild and crazy exploits — including the famous climb in the air shaft to get to the roof of the nine-story Millikan Library (Joe did not of course climb the whole nine stories, but it still would have been quite a fall!). The Caltech administration, by the way, was a good deal less accepting of that particular stunt than his autobiography makes out.

   I've always felt that the 97.5 percent Bayesian calculation was a bit of a joke: I'm doubtful that Joe really took Bayesianism all that seriously.

   I also knew Billy Zajc, who was, if anything, even wilder and crazier than Joe.

   By the way, I and another Caltech physics grad had a chance to meet Joe's wife Dorothy back while they were engaged: we were both surprised that Joe had connected with such a pleasant and decent woman. I believe his claims in the autobiography that she really helped to give Joe some grounding.

I'm sorry for the difficulties you had with Joe: even decent people can become unreasonable when their ego and their career seem threatened.

Thanks for the link.

Dave Miller in Sacramento

3. **John Preskill**

Also very touching: The Afterword by Joe's family.

4. **Łukasz**
June 4, 2022

Dave Miller "I'm sorry for the difficulties you had with Joe: even decent people can become unreasonable when their ego and their career seem threatened."

Well, Polchinski was on the make in scientific world, at least. I remember, how as a student, I was admiring his classical monograph.
On the other hand, he was engaged in String Theory, and some other physicists, as for example, Peter Woit, are sceptical, as far as this theory (or rather "String Hypothesis"), is concerned. With all respect to Polchinski, but if I were on his place, even if my results were criticized, I would be glad that they are very well-known and many people appreciate them.
There are many people (let's call them, as Mr. X1. or Mrs. X2.), who have actually a large contributions to some scientific branches, and they are not appreciated. Their results really solve some important problems, and this is not the case of String Theory ("String Hypothesis") – after reading such paper, you see that there is actually a correct solution of certain important problem.
Nobody has been criticising their results, except some editorial boards and/or reviewers, who most evidently do not want to see these results to be published. And even if Mr. X1. or Mrs. X2. publishes eventually these results, they will be very often passed over.
Polchinski fell on his feet, at least as far as his scientific career is concerned.

5. **Martin S.**
June 4, 2022

@Dave Miller: It is frequently in a way that other people push their opinions to you, regardless of validity of those opinions. And since it is commonly pain in the ***, it is easy to get angry due to that.
Not having an idea whether Peter's blogging and book came in a situation when other ones were pushing to Polchinski, but can imagine that it was a part of such an environment.

6. **wb**
June 5, 2022

Bayesian probabilities depend on the prior and the (number of) hypothesis one considers. I assume he never considered the hypothesis that string theory could be false …

7. **Peter Woit**
June 5, 2022

wb,
I went back and took a look again at Polchinski's Bayesian calculations. His Bayesian method is that each argument he has in favor of something reduces the probability that it is wrong by 1/2. For the multiverse he has four, so only 6% chance it is wrong, for string theory it seems to be six, so 1.5% chance it is wrong (but I can't figure out from what he writes what the six arguments are).

One remarkable thing about his analysis is that, according to him, there are only arguments in favor of string theory and the multiverse, no arguments against either.

The whole thing is just completely bizarre.

8. **Peter Woit**
June 5, 2022

Łukasz and Martin S.,

In section 10.7 of the book, Polchinski is quite explicit about what upset him:
"But also I had extended periods of anxiety. Sometimes these just plagued the early hours of sleep, but other times they took over the day, and my work. One that I remember clearly was my induction into the National Academy of Sciences in 2005. This should have been a time of great celebration, and there was some, but throughout I was filled with an ill-defined anxiety."

This induction ceremony would have been April 22 in 2006. The year before at Strings 2005 there had been a panel discussion which did not go well for the landscape, see https://www.math.columbia.edu/~woit/wordpress/?p=230
and there were an increasing number of negative stories about string theory in the press. In March there had been public controversy about my blog over the issue of arXiv trackbacks (I was unaware that Polchinski was behind this, upset by a 2004 blog posting criticizing his Scientific American article about the landscape). On April 9 I posted a detailed argument about the problems with his claims about the landscape, see here. My book was published a month after the NAS induction ceremony, Smolin's a few months after. By April 22 review copies of both books were in circulation and it's quite possible Polchinski had seen them and so knew what was coming.

9. **Alex Gezerlis**
June 5, 2022

Peter,

"I went back and took a look again at Polchinski's Bayesian calculations. His Bayesian method is that each argument he has in favor of something reduces the probability that it is wrong by 1/2."

This line of thinking exhibits almost too many fallacies to count: it implicitly assumes a discrete state space, then employs equiprobability with only two possible outcomes (along the lines of "you're either gonna roll sixes or not, it's 50/50"), obscures the distinction between scientific and statistical significance, mixes up the p-value with the probability that the null hypothesis is true, says nothing regarding the power of the test, uses likelihood to mean posterior, the list goes on and on.

All that being said, the reason I am writing this comment is to emphasize that Polchinski was facing major challenges when he produced this alleged argument. While it's true that in science we're supposed to focus on the argument not the person, to me at least it feels infelicitous (to put it mildly) to dissect this specific argument.

10. **Peter Woit**
June 5, 2022

Alex Gezerlis,

Polchinski himself makes clear that he realizes he is not doing a correct Bayesian analysis. In https://arxiv.org/abs/1601.06145 he writes:

"So let me say very clearly: Bayesian analysis is not the point. It is not even one percent of the point. Every word spent on this subject is a wasted word, in fact it has negative value because it distracts attention from the real point, which is of course the physics. And I can blame myself for this, because I chose to frame the problem in this way."

My point in an earlier comment was just to note that he was refusing to acknowledge any problems with string theory or the landscape. I don't think this had anything to do with his illness, it's consistent with his behavior over many years and with the behavior of other prominent string theorists. Someone who talked extensively to him over the years assures me that his arguments about string theory and attitude towards string theory critics were no different after his illness than they had been a decade earlier.

11. **2 Questions**
June 8, 2022

1. Could the String Wars episode in Joe's life have played a role in creating/aggravation his illness?
2. Why does Sabine say "you not being a physicist"?

12. **3rd Question**
June 8, 2022

3. If you are not a physicist, Peter, are you more of a science historian or a mathematician?

13. **Peter Woit**
June 8, 2022

Questions,

I don't know of any reason that things Polchinski found upsetting in 2006 should have anything to do with his fatal illness ten years later.

Polchinski unfortunately seems to have decided to deal with the 2006 string theory critique by ad hominen arguments: Smolin was not honest, and Woit was not a physicist, so people should not listen to either of them. It's true that, after a Ph.D. and postdoc in theoretical physics, since 1988 I've been employed by math departments.

I'm definitely not a science historian. On the mathematician/physicist distinction, I don't see why one has to be only one or the other. I was thinking of writing more here about the mathematician vs. physicist thing, but that's a long story, which really has nothing to do with Polchinski, so maybe I'll write about it later in its own context.

14. **AcademicLurker**
June 8, 2022

"Only someone with a faculty appointment in a university physics department is a physicist" seems like a pretty narrow definition since, by that standard, Einstein during his *Annus Mirabilis* wasn't a physicist…

15. **Peter Woit**
June 8, 2022

AcademicLurker,

Looking at what Polchinski wrote late in life about Smolin and me, his claim is basically that Smolin and I do not think and behave the way scientists are supposed to think and behave (for instance, about me he writes "The actual scientific quality is so very poor, as was easily seen by contrasting with the way that leading scientists actually work and think"). I disagree strongly with him about "scientific quality", but, restricting attention to prominent areas of theoretical physics during the last 30 years, I have to agree that I don't work and think the same way as leading figures in the field (and Smolin maybe feels the same way).

In various exchanges in blog comment sections with string theorists, I found that typically they seemed to think that the only legitimate scientific arguments were technical ones that accepted the same basic framework as researchers writing papers on the subject. For example, on the subject of the landscape, technical discussion of the properties of specific moduli stabilization mechanisms supposedly giving string theory vacua was science, arguing that a theory with such vacua was unpredictive and thus a failure was not science. For Polchinski and other string theorists, working within their framework was science, arguing against their framework was not science (and doing so put you in the realm of the crackpot, like people who argued against evolution or relativity).

16. **Shantanu**
June 8, 2022

Peter or anyone : Do you know what Polchinski felt about research (and researchers)in LQG ?

17. **Peter Woit**
June 8, 2022

Shantanu,
I don't remember Polchinski saying much about LQG or LQG researchers. If I had to guess I'd guess that he thought that string theory was a much better framework for doing fundamental physics than LQG, but for him arguing against other people's frameworks was not doing science so he should concentrate on discussing the string theory framework.
I think that for him and many other string theorists the sociological arguments that Smolin and I were making made no sense. By definition, successful science was whatever leading scientists were doing, unsuccessful science was what they stopped doing or decided not to do. Anyone arguing against this was by definition not doing science.

18. **Max Madera**
June 9, 2022

I think your last paragraph perfectly summarizes the lore within first class string physicists.

19. **Jim Eadon**

June 9, 2022

Dear Peter, regarding arXiv trackbacks, is your blog still blocked?

20. **Peter Woit**
June 9, 2022

Jim Eadon,

As far as I know, trackbacks to this blog from the arXiv are still not allowed, for reasons that remain a mystery to me.

Physicists Discover Never-Before Seen Particle Sitting On a Tabletop

June 9, 2022
Categories: Uncategorized

I woke up this morning to find out that a new Higgs particle which could explain dark matter has been discovered, in a table-top experiment at Boston College. For some of the news stories about this, see here and here. Wikipedia now has an entry for this that explains:

> The Axial Higgs boson is a fundamental particle whose discovery was announced by American researchers in Nature on June 8, 2022.

Of course this is complete nonsense. The paper Nature just published (the preprint is here) is about a condensed matter experiment that has nothing at all to do with the Higgs (effective fields in a description of a condensed matter system have nothing to do with fundamental fields).

Who is responsible for misleading the public and discrediting science with this kind of behavior?

- The authors, who begin their abstract with

  > The observation of the Higgs boson solidified the standard model of particle physics. However, explanations of anomalies (for example, dark matter) rely on further symmetry breaking, calling for an undiscovered axial Higgs mode.

  which has nothing to do with the result in their paper.
- The editors and referees at Nature, who should never have allowed such an abstract.
- Boston College, which put out this press release, which starts out:

  > Chestnut Hill, Mass. (6/8/2022) – An interdisciplinary team led by Boston College physicists has discovered a new particle

  In this case another institution, Oak Ridge, put out a much more responsible press release for the same paper, showing how to do this properly.

Universities desperately want to see this kind of story in the press, and there's rarely any downside for the scientists and PR people who produce bogus such stories. Boston College needs to take action to retract the press release and make sure this doesn't happen again. Nature should also take action to issue a correction stating this paper has nothing at all to do with the Higgs field and address the bad editing and refereeing that led to this.

Update: At least the Wikipedia article has been fixed.

Update: More physicists spreading hype about this here.

Update: The Higgs hype has been extended to add quantum computing hype, see Newly-Observed Higgs Mode Holds Promise in Quantum Computing, and the Wikipedia article now includes this new, extra hype.

Comments

1. **Peter**
   June 9, 2022

   I assume that it was BC and not BU that put out that press release. That aside, this is tremendously, tremendously depressing.

2. **Peter Woit**
   June 9, 2022

   Peter,
   Thanks for pointing out the mistake attributing the press release to BU rather than BC, fixed. Apologies to BU.

3. **WD**
   June 9, 2022

   I am guessing that there isn't a downside in the short term for the parties involved. However, in the medium-long term the damage that this kind of thing does is enormous – those of us old enough remember how the ridiculous hype spread by many practitioners condemned the AI discipline to decades in the cold, and we can't help but having a sickening déjà vu feeling concerning AI (again!) and quantum computing. If this percolates to fundamental physics research as well we are going to be in a world of trouble.

4. **paddy**
   June 9, 2022

   Not quite the Jesuitical logic I am familiar with.

5. **Peter Shor**
   June 9, 2022

   Weren't there similar misleading articles when the Majorana quasiparticle was "discovered", also in condensed matter?. ("Discovered" here is in quotes because the result was later retracted.)

   Let me add that the condensed matter versions of both the Majorana and this Higgs boson are important discoveries — much more interesting than the entanglement experiments that have been claimed to connect to quantum gravity. However press releases and the press should not confuse these condensed matter quasi-particles with high energy physics particles.

   Since there are probably a lot more unknown condensed matter phenomena to be discovered which can be couched in terms of unusual quasi-particles, we should be prepared for more of these types of news releases.

6. **Peter Woit**
   June 9, 2022

Peter Shor,
The Majorana case was somewhat different in that there wasn't a significant attempt to mix it up with particle physics and dark matter. Also, there the condensed matter system was of huge practical interest as a possible topological qubit.

There's by now a very long history of misleading press stories of this kind related to string theory, typically of the form "string theory finally related to experiment", based on the appearance in some condensed matter system of something that had some sort of analogy with something that appeared in something related to string theory. At least this story didn't do that (they easily could have, adding something about axions in string theory), perhaps a reflection of the fall in popularity of string theory hype.

7. **Peter Shor**
June 9, 2022

Peter Woit,

I definitely remember reading news articles about the Majorana particle discovery that mixed up fundamental particles and quasi-particles (here's one), but looking back, you're right — it looks like the universities' actual press releases didn't do this.

8. **John**
June 9, 2022

The title of this blog post is much more misleading than the authors' abstract. I (seriously) think that you should edit it.

9. **SteveB**
June 9, 2022

Only after reading the Oak Ridge release, I see that they detected a quasi-particle, not a fundamental particle.

Why is the name "Higgs" used here for a quasi-particle as in "the axial Higgs mode"?

10. **Peter Woit**
June 9, 2022

SteveB,
I'm not sure exactly what they're doing in this paper, but assume that the usage is by analogy to the particle physics setup, where there's a Higgs field acted on by a gauge symmetry. Some modes are gauge modes, but there's also a gauge-invariant degree of freedom, and this is the Higgs mode, excitations are Higgs particles.

In the simplest case (Abelian Higgs model), the Higgs field takes values in the plane, lowest energy on a circle, gauge mode is motion around the circle, Higgs mode is radial motion.

11. **Peter Woit**
June 9, 2022

John,
If you click through the first link, you'll see that the blog post title is just exactly the title of a press article about this, also the title of a Slashdot post about this
https://science.slashdot.org/story/22/06/08/2224227/physicists-discover-never-before-seen-particle-sitting-on-a-tabletop

When I write about a press article, I often use the title of the press article as the title of the post. Doing this in this case was intended as a bit of a joke, since for most of my usual readers just reading that title should have made clear this was comically absurd hype.

12. **Anonymous**
June 9, 2022

There is in fact no gauge symmetry or Higgs mechanism at all in the system studied in this article. The authors study a charge density wave material in which the (global) translation symmetry is broken (to be contrasted with superconductors, where there is actual gauge symmetry). The phase/goldstone mode remains intact and what the authors study is the corresponding amplitude mode. In fact, one of the referees argues that such a mode should simply be referred to as an amplitude mode, not a Higgs mode, but the authors assert that this terminology–referring to an amplitude mode with no Higgs mechanism as a Higgs mode–has been used previously in the literature, and the matter was dropped (see peer review file available with the article, referee 3).

13. **Alessandro Strumia**
June 10, 2022

It's a shame that Nature and Boston College did not claim that their new Dark Matter axial Higgs confirms string theory

14. **Adam**
June 10, 2022

@Anonymous: this battle has been lost ten years ago. The first appearance I am aware of in condensed matter is PRB 84, 174522 (2011) by Podolsky et al, where they call it an "amplitude (Higgs) mode" in the title, but mostly "Higgs" in the text.
It became a " 'Higgs' amplitude mode" in Nature 487, 454 (2012), and soon after, the term amplitude was finally dropped, e.g. PRL 110, 170403 (2013).

Having worked on this problem, I tried at first to fight not to call that a Higgs mode at all. But when everyone else does, what can you do (I still say in my talks on the subject that this Higgs mode has nothing to do with the Higgs boson since there is no gauge field though).

I guess the referee dropped the matter because there wasn't much they could do about it (especially if the other referees did not complain).

15. **vmarko**
June 10, 2022

@Adam: The issue is not the common terminology of the "Higgs mode" or whatever, but the fact that (in the abstract) the authors make an explicit connection to the Standard Model and dark matter, both of which are completely unrelated to the topic they have actually studied in the paper.

Using the same terminology for different things is not an excuse to confuse and conflate those things. The referees should have pushed against that part of the abstract, regardless of the commonplace terminology.

Best, 🙂

Marko

16. **Peter Woit**
June 11, 2022

Anonymous/Adam,
I hadn't realized how bad the Higgs hype problem in condensed matter had gotten, that people were calling the amplitude of a field a "Higgs" mode when there is no gauge symmetry. Paying a little bit more attention, I also realized that the "Higgs" in this case isn't even a scalar field, it's a vector field. Calling the amplitude of a vector field in a theory with no gauge symmetry a "Higgs" is just completely absurd.

17. **Adam**
June 12, 2022

Peter: it is not as bad as you say. It is a scalar field under spacetime transformation, but it has N (typically 2) internal degrees of freedom, with O(N) symmetry (equivalent to U(1) for N=2).
In the symmetry broken phase, there are N-1 Goldstone modes (that would be eaten by the gauge field if it were present), and a remaining one, which would be the Higgs field. It used to be called the amplitude mode because it is related to the longitudinal fluctuations of the order parameter (along its vev), which, at least at a mean-field level, is equivalent to the fluctuations of the amplitude of the order parameter.

So the problem is "only" that people use the term Higgs even though there is no gauge field and thus no Higgs mechanism.

All Langlands All the Time

June 12, 2022
Categories: Langlands, Uncategorized

I'm about to head to Paris on vacation, quite possibly there will be less blogging for the next couple of weeks. Here are a few Langlands-related items:

- The big Langlands-related event of the summer will be the July IHES Summer School on the Langlands Program. Laurent Fargues has posted notes for the summer school (written with Peter Scholze). They comment at the end that "it still remains to find an archimedean analog" of their work relating local Langlands and geometric Langlands on the Fargues-Fontaine curve.
- At Quanta, Alex Kontorovich has a popular introduction to the Langlands program.
- There's a recent review by Michael Harris of expected properties of the local Langlands correspondence.
- There's a program going on about automorphic forms at the Collège de France, featuring lectures by Ngô. Maybe I'll stop by to hear one next week.
- I was sad to hear about the recent death of Joël Bellaïche, who had been a postdoc here at Columbia. David Hansen writes here about him and his work.

June 14, 2022

   So I'm by no means an expert in p-adic geometry, but my understanding is that Scholze's perfectoid spaces are very useful gadgets for relating problems in "mixed characteristic" (e.g., over the p-adic numbers Q_p) to problems in characteristic p. For perfectoid spaces, unlike in schemes, we have this "tilting functor" relating perfectoids over mixed characteristic fields to ones in positive characteristic. It's often preferable to work in positive characteristic, as we have access to the Frobenius endomorphism in this case.

   So very very broadly speaking—and perhaps somebody more knowledgeable could correct me on this—this is the reason perfectoid spaces and generalizations (diamonds, v-stacks etc.) are useful for studying local Langlands over non-Archimedean local fields—which are mixed characteristic. This is also the reason none of this machinery would work in the Archimedean case—there's no tilting functor here.

2. **PS**
June 15, 2022

   @Topologist Guy: Yes, that's a very good summary. But note that ~10 years ago very similar arguments were made that the "shtuka" techniques of the function field case can't possibly be applied to p-adic fields, as there's no Frobenius there (and you can't take nontrivial self-products of Spec Q_p etc pp)… but yes, currently it's completely unclear what the right structures over the real numbers would be. (Other than that it will involve some form of the twistor-P1 that's strangely also featuring prominently in other contexts on this blog…)

3. **David Ben-Zvi**
June 16, 2022

   Topologist Guy – definitely perfectoid technology is not relevant in the archimedean case, but there are many recent technological breakthroughs that are important in the Fargues-Scholze work that should be relevant there, in particular condensed mathematics.

   Roughly speaking, the archimedean local Langlands conjecture in the spirit of Fargues-Scholze would relate derived categories of [_] sheaves on the stack of G-bundles on the twistor line and coherent sheaves on a stack of archimedean local Langlands parameters. Here G is a real reductive group, and the semistable G-bundles have as stabilizers inner forms of G. So sheaves on this stack restrict to give representations of these real groups, and this provides the mechanism to relate real groups and Langlands parameters.

   The question is what kinds of sheaves? since we want to realize [admissible] infinite dimensional continuous representations of G, eg unitary reps, we need some notion of sheaves of topological vector spaces, and here one needs condensed (and in particular presumably liquid) technology to make sense of this and to formulate the matching notion of Langlands parameters.

   In fact an archimedean local Langlands conjecture in much the same spirit appears in work of David Nadler and mine from 2007 (and will be reviewed in our IHES summer school contribution with Harrison Chen and David Helm, to be posted soon). The main differences as I understand them from the desired "real Fargues-Scholze" are that we work with parabolic bundles on the twistor line rather than just plain bundles (i.e. we are "tamely ramified" rather than "unramified"), old-fashioned constructible sheaves rather than a condensed version, and a fairly-close-to-traditional version of the space of Langlands parameter – realized as parabolic local systems on the twistor line.

   On the semistable locus, rather than seeing pt/G (and inner forms) we see {complex flag manifold}/G, and the relation to admissible representations of G is not simply "take stalks" but rather "take maps to holomorphic functions" — this is the Kashiwara-Schmid cousin of Beilinson-Bernstein's realization of Harish-Chandra modules for real groups.
So this is less direct than in the eventual expected story, in that we replace representations by their realization on flag manifolds (eg finite dimensional reps get replaced by their realization given by the Borel-Weil theorem). Also I can't imagine that the picture with parabolic bundles is what you want eventually in a more global story, but it's what we can do with old technology.

In a Parallel Universe, Another You

June 21, 2022
Categories: Multiverse Mania, Uncategorized

From today's New York Times, Michio Kaku explains:

> In physics, the concept of a multiverse is a key element of a leading area of study based on the theory of everything. It's called string theory, which is the focus of my research. In this picture, subatomic particles are just different notes on a tiny, vibrating string, which explains why we have so many of them. Each string vibration, or resonance, corresponds to a distinct particle. The harmonies of the string correspond to the laws of physics. The melodies of the string explain chemistry.
>
> By this thinking, the universe is a symphony of strings. String theory, in turn, posits an infinite number of parallel universes, of which our universe is just one.

In this universe I'm on vacation and in no mood to waste time commenting on this crap.

Comments

1. **Daniele Corradetti**
   June 21, 2022

   Would it be an infinite number of parallel symphonies performed only by strings? Or at some point the shape of a drum also comes into play? Just to know whether a PhD in harmonic analysis can have a future…

2. **gio**
   June 21, 2022

   Oh please do it. 😉

3. **Rajendra**
   June 21, 2022

   I hope in a parallel universe, reporters ask Kaku about experimental proof for string theory. 🙂

4. **Brian Flanagan**
   June 21, 2022

   I was listening to Brian Greene push his Many Worlds notion.

   All I asked was, "How many worlds can spin on the head of a pin?"

   That got me banned from the forum.

5. **Sabine**
   June 21, 2022

   I have a new book coming out in August that explains to what extent these ideas are science and how much of it is just belief. Book is called "Existential Physics", details here: http://existentialphysics.com/

6. **Cedric BARDOT**
   June 21, 2022

   > La théorie des supercordes = de la poussière d'orchestre.
   >
   > Like all the others, this French anagram is pure coincidence. It therefore teaches us nothing, but it invites us to ask the question of the link between physics and music, between cosmos and sounds, between harmony and orchestration.

   (Etienne Klein's quote from https://www.radiofrance.fr/franceculture/podcasts/la-conversation-scientifique/l-univers-est-il-orchestre-3624161)

   June 21 is a good occasion to do so as it is a traditional Music Festival day at the place where Peter enjoys his vacations! I wish him pleasant ones.

7. **Low Math, Meekly Interacting**
   June 21, 2022

   Why drag chemistry into it? What awful thing did chemists ever do?

8. **Jim**
   June 21, 2022

   These people got the chairs, got the money and just want more money. The damage they have done to this, the previous and hopefully not the next generation of theorists is unprecedented.

   I was a PhD candidate in 2011, fortunately yours and Lee Smolin's books opened my eyes. I was at CERN when Higgs particle was discovered and people didn't talk loud about the nightmare scenario, which actually happened.

   Greene, Susskind, Kaku and more, don't care that much now. It's like climate change, we don't realize that our children will inherit it since we won't be alive when the nightmare scenario will manifest itself.

   Fortunately I left my theoretical PhD. I do data science, get the money I deserve and I do legitimate,real research on the side, for free, analyzing astronomical data and publishing papers.

9. **Mike**
June 21, 2022

How many alternative universes do I have to run to escape Kaku kaka?

10. **Alessandro Strumia**
June 22, 2022

Jim, a summer student at CERN told me they learnt that the plan was: discover the Higgs in run 1 and SUSY in Run 2. Presumably this has now been delayed to Run 3, so let's silently wait for the start of the symphony.

11. **Rollo Burgess**
June 22, 2022

I recently attended a public talk (at the 'how the light gets in' festival), on the subject of multiverse discourse. Kaku was a panellist, the others being Sabine Hossenfelder and Roger Penrose. The level of nonsense being spoken by Kaku was apparent even to my 10 yo daughter who was sitting next to me, she was irked by an Alice in Wonderland analogy he used… for my part, it just seemed that he continuously changed the subject, flitting between cosmological and everettian multiverse ideas when cornered.

@Sabine, I thought you did a great job of putting your case while remaining calm with this slipperiness. Penrose, while always courteous, exercised the privilege of a 90 year old Nobel laureate by looking pretty scornful.

12. **Doug McDonald**
June 22, 2022

Kaku's piece falls down to below even the level of 'not even "Not Even Wrong" ', down into "performance art of the absurd". Is saying that nasty enough?

13. **Lukasz**
June 22, 2022

I would like to ask you everobody (first of all, Peter Woit), about the reactions of string theorists, to the allegations concerning string theory. I have meant their factual replies i.e. how do they defend string theoretical approach ?
Probably this topic was discussed here, but if so, then I missed this.

14. **Peter Woit**
June 22, 2022

Lukasz,
You should ask string theorists yourself. In my experience most of them try and avoid engaging in any way with criticism of the theory. For Kaku, I wrote a bit here
https://www.math.columbia.edu/~woit/wordpress/?p=12269
about his recent book "The God Equation", which is to some extent his response to criticism of string theory. His way to make a counter-argument is to make claims that are clearly untrue. It seems that doing this kind of thing not only doesn't get you in trouble, it gets you published in the New York Times…

15. **Mike Ball**
June 22, 2022

How about how string theorists respond to Kaku? Im no expert, but its seems likely to me that regardless of your view on the scientific validity of the miltiverse etc, Kaku completely mischaracterises the view of many (most?) string theorists/QFT researchers on these issues.

16. **John Baez**
June 22, 2022

Have you already written about the multiverse movie with Michelle Yeoh, Peter? That takes a suitably slapstick tone.

17. **Shantanu**
June 23, 2022

Does anyone know if Kaku has had Ph.D students working with him and DOE grants for his research?

18. **Peter Woit**
June 23, 2022

John Baez,
Haven't seen the film or written about it. Even when not on vacation I'm now doing my best to avoid the multiverse.

Shantanu,
I don't know of any evidence that Kaku has been doing string theory research since the 1990s. For what's on the arXiv, see
https://arxiv.org/search/?searchtype=author&query=Kaku%2C+M

19. **SteveB**
June 23, 2022

Kaku (and his hair) was the keynote speaker at the annual high performance computing conference in 2012, SC12. This conference usually draws about 5000 people. I attended his talk, but my skepticsm had already been primed here. I didn't like it, but the pictures were pretty. He spent a lot of time on history and then speculated on fairyland-like computer advances. A summary can be found

https://www.hpcwire.com/2012/11/16/michio_kaku_sketches_technological_wonderland_of_the_future_at_sc12/

where he is referred to as a "celebrity physicist".

20. **Chris Oakley**
June 24, 2022

"The God Equation" by Michio Kaku. Conclusion: there isn't one.

“The Bogdanov Equation” by Lubos Motl. Conclusion: there isn’t one.

This situation, I find, is reflected in technical papers in fundamental physics, and long before String Theory was invented. Titles suggest they’ve solved some major problem, but closer examination reveals something infinitesimal.

21. **Topologist Guy**
    June 24, 2022

    Michio Kaku’s most recent entry on the arXiv dates back to 1999.

    https://arxiv.org/search/hep-th?searchtype=author&query=Kaku%2C+M

    It’s frustrating that he continues to present himself as an expert/active researcher in string theory and the string landscape. None of his papers are related to KKLT or string vacua.

    For comparison, arguably the other top popularizer of string theory, Brian Greene, has papers on the arXiv from as recent as 2018, on KKLT/string vacua/landscape,

    https://arxiv.org/search/hep-th?searchtype=author&query=Greene%2C+B

    So I’d say he’s much more qualified to call himself an “active researcher” or “expert” in the string landscape.

22. **David Roberts**
    June 24, 2022

    @Peter

    For hep-th, having only six papers on the arXiv in the 90s looks like practically non-existent. He has string theory research dating back to the 70s, though, so has been a long-term practitioner, from before it was cool.

    Harvard adsabs listings, restricting to refereed items, gives nothing newer since his last arXiv paper from 1999 (it gives some obvious false positives by others with the same name), nor anything in the arXiv era aside from what is on the arXiv.

23. **Bernardo**
    June 24, 2022

    To a lay person like me, albeit one who thinks he is at least able to tell the difference between rational thinking and quackery, Michio Kaku has descended to the level of a Deepak Chopra. Or perhaps he’s always been a Chopra-like “physicist”.

24. **jd**
    June 25, 2022

    I wish to draw attention to the article by Mermin in the latest June issue of Physics Today. In that Mermin shows the role that probabilty plays in quantum mechanics and that the “collapse” of the quantum state is not a physical process. The many-worlds interpretation is eliminated.

25. **Charles Weis**
    June 26, 2022

    Kaku is saying nothing new to establish his legitimacy. More important is what this says about the legitimacy of the New York Times.

26. **Alex M**
    June 27, 2022

    Kaku is the invited Physicist for practically all documentaries involving extraterrestrial affairs, or multiverses quantum ghostly fantastic themes.

27. **Peter Woit**
    June 27, 2022

    Alex M.,
    I’m well aware of that situation. What I can’t figure out is why the New York Times considers that the right credential for asking a scientist to write for them about physics.

28. **Rajendra**
    July 3, 2022

    Intrigued by the responses of Topologist Guy and David Roberts, I did some more search. This is what American Physical Society page on Kaku says

    “As physicists have picked up where Einstein stopped, one solution they have come up with is string theory. String theory combines the two theories by assuming there are multiple universes and dimensions beyond the ones we know.

    After getting his PhD from the University of California, Berkley, Michio joined in on this challenge. He co-founded string field theory, a subset of string theory. String field theory uses the mathematics of fields to explain string theory.

    More evidence and a better understanding of string theory may one day allow us to travel between universes and into new dimensions, potentially even making time travel possible.”

    https://www.aps.org/careers/physicists/profiles/kaku.cfm

    I think endorsements such as these may be partly responsible for NYT’s decision. For a non specialist, those these consecutive paragraphs are as good as saying Kaku is in the same league as Einstein and he invented Time Travel. If the non specialist is a fan of Stranger Things, that’s the final nail in the coffin.

    The question is, why is APS doing this?

ICM 2022

July 3, 2022
Categories: Uncategorized

The 2022 ICM is starting soon, in a virtual version organized after the cancellation of the original version supposed to be hosted in St. Petersburg (for how that happened, see here). The IMU General Assembly is now going on, moved from St. Petersburg to Helsinki. One decision already made there was that the 2026 ICM will be hosted by the US in Philadelphia. With the 2022 experience in mind, hopefully the IMU will for next time have prepared a plan for what to do in case they again end up having a host country with a collapsed democracy being run by a dangerous autocrat.

Registration for following the talks in real time has now been closed, but the talks are being recorded and will appear on the IMU Youtube channel. The program is here.

There will be quite a few other virtual events affiliated in some way with the main ICM, for a list see here. Some of these are traditional satellite conference which have been moved from their originally scheduled version in Russia. An example is this one organized by Igor Krichever, which was supposed to be held at Skoltech in Moscow, but was moved online and hosted by Columbia.

The Fields Medals will be announced at 10am local time in Helsinki on July 5, there will be a livestream here. This will be 3am here in New York, so I'll likely be sleeping and find out what happened later in the morning. Since I just got back from vacation and it's now a holiday weekend, I've been out of touch with my usual sources of math gossip and haven't heard any informed rumors about who the medalists will be. One person who has been mentioned as a possibility is the Ukrainian mathematician Maryna Viazovska.

The last couple times (2014 and 2018) the IMU has put out the news about the Fields Medals to some of the press under unusual embargo terms that made reporting difficult for everyone except Quanta magazine which was given special access (for more about this see here). I haven't heard anything about whether the same thing is happening this year.

Update: just noticed this, indicating that again press access may be Quanta-only.

Update: Antoine Chambert-Loir claims "serious information" that Viazovska will get the Fields Medal (at least that's who he seems to be referring to). It looks like press access is going to more organizations than Quanta this time, see this from Nature. Terry Tao has a blog post with some more ICM information.

Update: The medalists are Duminil-Copin, Huh, Maynard and Viazovska, much the list of names that people have been speculating about. There's much about the winners and their work at the IMU site, and several other press organizations have extensive coverage, including Quanta, Plus Magazine! and the New York Times. Stories about each of the Laureates from Plus Magazine! are featured on the IMU site.

The medalists were chosen quite a few months ago, before the Ukraine war. The interview with Viazovska contains part conducted before the war, as well as a more recent part about Russians and the war (the interviewers were Okounkov and Konyaev).

Update: Barry Mazur was awarded this year's Chern Medal. During the ICM a new documentary about Mazur will be available for watching, Barry Mazur and The Infinite Cheese of Knowledge.

Update: I enthusiastically recommend that you take a look at Andrei Okounkov's remarkable set of popular articles about the work of the four Fields medalists, see here, here, here and here.

Comments

1. **Mike**
   July 4, 2022

   I hope Viazovska gets it. Beautiful and deep work. And it would be great for women in Mathematics. And it would give a small amount of hope to young ambitious Ukrainians.

2. **Deane**
   July 4, 2022

   There was no press embargo. Press was told a few months ago. But, unlike for the Abel Prize, they weren't supposed to interview other mathematicians.

3. **anon**
   July 4, 2022

   No embargo? So the press could report at any time? And as long as a few months ago? Really?

4. **Peter Woit**
   July 4, 2022

   anon,
   I think Deane misspoke, from what I can tell the press was told the names in advance, but not allowed to publish these til the announcement. Unclear if it is the same situation as last time, with only Quanta allowed to interview the winners and get access to other mathematicians for quotes about the work of the winners.

5. **Neville**
   July 4, 2022

   The linked remark of Antoine Chambert-Loir says "I have serious information that one woman will get it." Maryna Viazovska may win a Fields Medal, but she is not the only possible female candidate.

6. **anon**
   July 5, 2022

   Hugo Duminil-Copin, June Huh, James Maynard, and Maryna Viazovska are the Fields medalists. I don't think any of them is a big surprise.

7. **Hermann Vile**
   July 5, 2022

Duminil-Copin, Huh, Maynard, Viazovska – all very reasonable choices.

8. **Deane**
July 6, 2022

Yes, I misspoke. The issue last time was that Quanta knew who the medialists were far in advance but the rest of the press was informed only a week or two before the ICM. There was also a mishap with the New York Times, where the notification went to the wrong person and so the person assigned to the piece had only a few days to write his article.

This time, everybody was told months ahead of time.

Thanks to Peter for reminding me of all this.

9. **Davide Castelvecchi**
July 6, 2022

I cover math prizes for Nature, and I was *not* informed in advance, neither this time nor in 2018. I am not sure if there were other outlets that got advance notice apart from Quanta.

10. **Jim Golden**
July 6, 2022

I thought the Quanta interviews were wonderful, especially for someone like me who's been out of the game for a while. I sent them to some non-maths friends who also really enjoyed the profiles and personalities of the Fields Medal winners.

11. **Deane**
July 6, 2022

Davide Castelvecchi, I'm really sorry to hear that. You should contact Helge Holden about this. My brother Kenneth Chang writes for the New York Times, and he definitely was notified at least 3 months ago. I learned this firsthand from Helge Holden (who was on the site visit committee for the 2026 ICM).

12. **The Abbot of Nalanda**
July 6, 2022

The pop math articles* on the works of the various winners written by Andrei Okounknov for the IMU Fields Medal website are ridiculously good. Their quality reminds me of SciAm articles from the 1980s.

* Called 'Popular Science Expositions' on the site

13. **Z Y**
July 6, 2022

Thanks Abbot, nice articles, it helps that the problems they worked in are relatively accesible

14. **John Baez**
July 9, 2022

The headline of a *New York Times* article announced this:

Fields Medals in Mathematics Won by Four Under Age 40.

A real shocker!

15. **Thomas Larsson**
July 10, 2022

Alas, the text begins with "the Fields Medals, which are given out once every four years to some of the most accomplished mathematicians under the age of 40."

The headline is not usually written by the author of the article.

16. **dh**
July 11, 2022

Peter, I'd be interested to hear your thoughts on Elliott Lieb. To an outsider like me, he looks pretty amazing, much more impressive than this Witten guy everyone's always going on about. 😉

17. **Peter Woit**
July 11, 2022

dh,
I guess this is on topic since Lieb was awarded the 2022 Gauss Prize at the ICM. I didn't write about this because I'm not familiar in any detail with Lieb's work. His work is within conventional old-school mathematical physics, rigorously proving results about statistical mechanical and many-body quantum systems. He has written over 400 papers, over a period of 67 years.

Comparison to Witten is pretty silly and not on-topic, Witten's work has been of a very different nature, with a much bigger impact on math and physics in general.

18. **dh**
July 11, 2022

Sorry for the poor attempt at humor.

~~Strings~~ Black Holes 2022

July 14, 2022
Categories: Strings 2XXX

Each summer for nearly a quarter-century there has been a big yearly conference bringing together the string theory community. I've often written about these conferences on the blog, see here. This year's version will be held next week in Vienna, for more information see here.

Taking a look at the program, one thing that stands out is that the string theory community has almost completely stopped doing string theory. Looking at the program, only two out of 44 talks seem to be significantly about string theory. One of three parallel discussion sessions is entitled "Strings and the Real World" and will be chaired by Cumrun Vafa. I'm guessing this will mostly be about the swampland, not string theory.

A tradition at these conferences is one or more public talks designed to publicize string theory. This year's versions will be given by Netta Engelhardt and Andy Strominger. They have nothing to do with string theory, but they do make very clear what the string theory community has found to replace string theory: black holes. Engelhardt's title is "The Black Hole Information Paradox: A resolution on the horizon?" and Strominger's is "Black Holes: the Most Paradoxical Objects in the Universe".

Looking at the talk titles, the most common words in the titles are "holography" and "black holes", with the center of gravity of the subject now for a couple decades the effort to use holography to say something about black holes. Maldacena's title is "What happens when you look at supersymmetric black holes for a long time?" which seems also an interesting question about the field itself.

Update: Paolo Bertozzini points out to me that the LQG community has scheduled its big yearly conference LOOPS2022 at exactly the same time as the string theory community one (this week). It's quite interesting to compare and contrast the two sets of talks. There are some very broad similarities between what both communities are doing, with overlaps in interest around black holes, entanglement, holography (in the form of large symmetry groups at infinity). Another commonality is that both communities are focused on the gravitational field, with nothing to say about particle physics and matter in general. This has been true of LQG since the beginning. In the case of string theory the big selling point originally was that it gave a theory of matter, but the string community has for a long time given up on that. There is a difference in how the communities think about "what are the fundamental degrees of freedom for gravity?" On the string theory side they've given up on that, the answer now is that gauge-gravity duality and emergence are supposed to allow you not to care about fundamental degrees of freedom. On the LQG side, people are still hard at work on specific sorts of degrees of freedom and how to quantize them.

Comments

1. **Andrei Sipoș**
   July 15, 2022

   Makes sense, black holes are one of the few objects where quantum gravity considerations actually do occur.

2. **Alex M**
   July 15, 2022

   When you give a speech on paranormal activities, and you want the audience to believe, you will try to bring them into the most unknown and unprovable ground. In physic, it is…a black hole!!! Anything can happen there….because we have no cleancut theory to have coherent description of the phenomenon.

3. **Low Math, Meekly Interacting**
   July 15, 2022

   Would you characterize this as a tacit acknowledgment the LHC has given all it can to "new physics"? With gravitational astronomy still in its infancy, seems like the best (if not only) strategy for plausibly (using that word generously) claiming contact with experiment may be just around the corner.

4. **Peter Woit**
   July 15, 2022

   Andrei Sipos,
   Part of what is going on is that long ago most string theorists gave up on saying anything about particle physics and adopted the attitude that "string theory" was now just about quantum gravity. So, then Strings 2XXX started to be Quantum Gravity 2XXX. But this was always not quantum gravity in general, but "quantum gravity approaches that evolved out of string theory, especially holography related". No loop quantum gravity, no R^2 quantum gravity, etc., etc. The concentration on black holes is a further evolution from this.

5. **Peter Woit**
   July 15, 2022

   LMMI,
   For many decades now string theorists and much of the particle physics community have taken the attitude that the limits on energy range of accelerators mean that the thing to do is to move to thinking about astrophysical observations somehow relevant to very high energies, especially very early universe cosmology. "String cosmology" has been featured at Strings 2XXX for a very long time (and never made any sense at all to me, but that's a different topic, and people seem to have lost interest in it).

   Most of the current theoretical activity (solutions to information paradox) around black holes has no plausible relation to astrophysical observations. Maybe there are claims to make contact with things like EHT, but I don't see how EHT pictures are going to tell you something about the quantized gravitational field.

6. **Justin**
   July 15, 2022

   Okay, I have a question: isn't this what you wanted, for people to give up working on string theory?

7. **Peter Woit**
   July 15, 2022

   Justin,
   Sure, except that first of all I think they should admit they have given up on string theory (for one thing, they should change the name of the conference). Continuing to promote string theory as a unified theory to the public when you have given up working on this since it is going nowhere is pretty problematic.

Secondly, while I'm in favor of giving up on string theory, I'm not in favor of giving up completely, which is more or less where the string theorists have ended up.

8. **Michael Weiss**
July 16, 2022

Peter, one of my colleagues suggests this analogy in favor of String Theory (ST): that just as in GR there was a quiet 30-year period (from 1925-1955 with the exception of Oppenheimer and Snyder (1939)), during which the general framework of GR was acclaimed but not as an active field of research–and without further experimental data–so too may we see a 30-year quiescent period for ST (save for its use in studies of Black Holes and as a source of mathematic techniques in condensed-matter) followed by an explosion of renewed activity. This analogy presupposes that ST is the right long-term framework, as GR has proven to be today, i.e., in our ongoing "golden age" of quantitative astrophysics and cosmology. I guess long-term confidence in ST, despite the limited progress in the past 20 years, is a matter of faith for some and not for others.

9. **Peter Woit**
July 16, 2022

Michael Weiss,
The problem with that analogy is that comparing GR to string theory is just delusional. Pre-1925, GR was a huge success: a completely well-defined, simple (when expressed in terms of Riemannian geometry) theory that made a huge number of predictions, including several dramatic ones about small corrections to Newtonian gravity that were quickly confirmed. This is something completely different than "string theory", where you have no predictions and no well-defined theory, just a hope that someday you might find one.

10. **Low Math, Meekly Interactin**
July 16, 2022

I was thinking more gravitational wave (laser interferometry) observatories than VLB interferometers. I recall there being some hype around stringy signatures in the spectra of colliding black holes when the first observations were coming in (circa 2016, I think). Haven't heard much about that lately. Maybe someone has since decided we'll need LISA to see extra dimensions or something along those lines.

11. **Peter Woit**
July 16, 2022

LMMI,
I should have mentioned LIGO/LISA as well as EHT. But the story is always the same: "X will see effects of string theory" claims are all completely bogus, for every value of X.

Not sure which LIGO hype you are thinking of, I mentioned one such here,
https://www.math.columbia.edu/~woit/wordpress/?p=9409
may have not mentioned some others, like this
https://physics.aps.org/articles/v14/s110

The "just wait for LISA" thing has been going on since before my students were born, often as part of string theory hype. For one example from 2006, see here
https://www.math.columbia.edu/~woit/wordpress/?p=418
Note that back then the story was that LISA would launch within ten years…

12. **James Smith**
July 16, 2022

You write:

Secondly, while I'm in favor of giving up on string theory, I'm not in favor of giving up completely, which is more or less where the string theorists have ended up.

Perhaps you should explain this a little.

13. **Peter Woit**
July 16, 2022

James Smith,
The initial selling point of string theory was that it was supposed to unify particle physics and gravity, explaining the standard model. String theorists have given up on anything to do with particle physics, with one justification that the string theory landscape is so vast that you can't predict anything with it, so there is no way to say anything new about particle physics, you just have to give up.

For quantum gravity, the fundamental problem has always been the non-renormalizability of our standard quantum theory of space-time degrees of freedom. Recently what the string theory community has done has been to restrict study to "emergent space-time", with no theory of what degrees of freedom space-time emerges from. In that sense they've also given up on the main problem of quantum gravity.

14. **Max Madera**
July 16, 2022

I loved your last paragraph. No more anthropic, but antropological effects of string theory.

15. **More Anonymous**
July 16, 2022

@Peter,

I'm confused why it's a good idea to directly quantize GR? I mean I would never quantize pressure and energy density which it what the theory spits out for the FLRW metric. I'm curious what your thoughts are?

16. **James Smith**
July 17, 2022

Okay, I kind of see. There is much that I don't understand in your second paragraph but the gist of what you are saying is that you have not given up on the fundamental problem of quantum gravity as you call it, but the string theorists have.

One further question if you don't mind. Is it that the standard quantum theory of space-time predicts the standard model, so to speak, but does not encompass quantum gravity, and solving this fundamental problem would extend that theory or at least produce another that would encompass quantum gravity? Solving this fundamental problem is what you have been working on, right? If so, could the quantum gravity part of such a theory be verified by experiment?

17. **Peter Woit**
July 17, 2022

More anonymous,
The part of our fundamental theory now that explains gravitational forces is a classical dynamical theory of space-time (GR). One way to describe the fundamental degrees of freedom of this theory is as the metric field, but there are many other formulations (e.g. using vierbeins and the spin connection). Applying standard quantization methods to this theory leads to the non-renormalizability problem.

If you want to argue that these degrees of freedom are not fundamental, that they are just effective low energy degrees of freedom coming from some more fundamental theory, that's fine (this is what string theorists were originally doing, the metric was just a low energy mode of the more fundamental string theory). But you need to explain what your more fundamental theory is. The current fashion is to announce that "space-time is doomed", that the metric is just an effective field, but not to give a new proposal for a consistent fundamental theory which exhibits this behavior. It's this move that I would call "giving up".

18. **Peter Woit**
July 17, 2022

James Smith,
The "standard quantum theory of space-time" doesn't say anything about the standard model, where the fundamental degrees of freedom are "internal", not space-time degrees of freedom. It also has the renormalization problem.

A conventional approach to unification is to extend one's notion of space-time by adding more dimensions, then trying to interpret these new degrees of freedom as the internal degrees of freedom of the standard model. I'm trying to do something a bit different, exploiting different aspects of geometry that appear when one works in Euclidean space-time and with twistors. I'm still very enthusiastic about these ideas (now writing up a new version of part of this), but there's a lot to be done to get these ideas to work, and still to be seen what new implications one might get from a fundamental theory formulated this way.

19. **James Smith**
July 17, 2022

Thank you for the clarification.

20. **thomas van riet**
July 18, 2022

"I'm guessing this will mostly be about the swampland, not string theory." The Swampland papers (apart from the heuristic pheno papers) are very stringy. By construction of what the Swampland means. I invite you to look at the average paper on the topic and you will strings everywhere

21. **Peter Woit**
July 18, 2022

thomas van riet,
If "swampland" now divides between "formal swampland" and "phenomenological swampland", I was referring to the latter, since the session is about "String theory and the real world". The attempts I've seen to relate the "swampland" to the real world have little relation to string theory, basically are very speculative conjectures about "any quantum theory of gravity".

22. **pontifex**
July 18, 2022

It seems that words as "unified field theory" or "super-symmetry" have no meaning, or any meaning that suits you, in pop culture now, see this article in The Guardian:

http://www.theguardian.com/film/2022/jul/18/empire-of-the-drones-terrence-howard-takes-us-where-no-actor-has-gone-before

23. **Shantanu**
July 20, 2022

Peter, in the Loops2022 conference the have invited Neil Turok (who although is not a core string theorist) has worked on cosmic strings and branes.
Also does any one have any data on amount on NSF/DOE funds on LQG vs string theory (in US)?

24. **Peter Woit**
July 20, 2022

Shantanu,

I don't think this kind of question has made any sense for a long time now. "String theory" long ago stopped referring to a specific theoretical framework. Most "string theorists" stopped working on string theory and "string theorist" now is just a name for a tribal affiliation, with a wide spectrum of intensities of that affiliation. Turok is definitely not now significantly affiliated with the tribe, especially given the kind of things he has been saying about string theory since 2016, such as
"[String theory has] almost self-destructed, I would say because it turned out to be not just one theory but this vast collection of theories which could all give different descriptions of the world."
See https://www.math.columbia.edu/~woit/wordpress/?p=8361
At this point it would be surprising to see him at Strings 2022, not at LOOPS22.

My general impression is that there's relatively little funding of LQG research in the US right now, much more in Europe. One reason for that is possibly that the string theory tribe in the US has always been quite hostile to LQG, seeing it as a heresy.

25. **vmarko**
July 25, 2022

Hi Peter,

"Another commonality is that both communities are focused on the gravitational field, with nothing to say about particle physics and matter in general."

The Loops22 conference has had 4 talks (out of a total of 100 or so) that were about matter, in one way or another. So formally there is nonzero interest about matter in the LQG community. That said, I completely agree that mere 4% of the talks represent nowhere near enough interest that IMHO the community should have about the topic. So I agree it is a bit sad state of affairs.

Best, 🙂
Marko

26. **Alex**
July 26, 2022

I don't see why the concentration only on the gravitational aspect from the part of the LQG community is something supposedly bad.

The idea that in order to do QG you need to include matter and actually have a unified ToE is old and coming mainly from the particle physics thinking of the 70s and one of the main motivations that gave us string theory (from that same community).

From the beginning, the LQG community has explicitly rejected such hypothesis and considers it as not necessary for a QG theory. That's their hypothesis. I don't know if it's right or wrong, but if we start to argue over my hypothesis vs yours, we go back all the way to the string wars again.

I think LQG has more important problems to deal with (in particular, empiral testing issues etc.) than its publicly acknowledged hypotheses!

If the infamous string wars showed us something, it's that nobody is going to change their mind by such discussions. The only reason why string theory is now falling into some disgrace is because many string theorists themselves have given up due to the issues dealing with reproducing the SM and the non-discovery of susy in the LHC. So, let the LQG community work with what they have and believe and see where that goes. Perhaps they will also give up, perhaps they will realize that the formalism itself is asking for non-gravitational fields to be included, etc.

Personally, I see no chance of connection with the empiricial realm for any QG theory candidate at least in the coming 100 years, so I predict a long QG winter after the final fall of string theory in the near future (yes, I know that they are all doing "QG" now, but how far goes their influence beyond Princeton? They are beyond recovery now, they lost the most important thing for such speculative endeavors: credibility. It's a bit like the stock market, and their stocks are certainly going down after a big bubble).

27. **vmarko**
July 27, 2022

Alex,

"I don't see why the concentration only on the gravitational aspect from the part of the LQG community is something supposedly bad."

There's nothing intrinsically wrong with doing QG without matter, but the issue is that there is only so much you can do with pure gravity. It is similar to doing vacuum GR — there are some interesting solutions and nontrivial geometry, but if you want to study the really cool phenomena and model realistic physics, you need matter in your theory. My overall impression from listening to all the talks at Loops-22 (especially the panel discussion at the end) was that we have sort-of constructed a well-defined theory of QG, and now we don't know what to do with it.

The most interesting set of problems in QG require coupling of matter. For example — what is the equation of state for matter fields at the center of the black hole? What is the corresponding curvature? What is the state of the gravitational field sourced by matter in quantum superposition? What are the effective EoMs for matter in a gravitational field in quantum superposition? How does matter emit and absorb individual gravitons? How does one properly derive QFT in curved spacetime as an approximation to a full theory of QG? Can we resolve the CC problem? Is there a limit to the validity of the equivalence principle? Etc… None of these questions can be answered without coupling matter to QG.

And if you try to couple it, you immediately face the question what kind of matter, leading you to the SM, dark matter, their various extensions and beyond to ToE. That said, I agree that the question of matter spectrum (i.e. what are fundamental matter fields and their coupling constants) may or may not be related to the ability to couple matter to gravity. So far we do not know of any restrictions on matter spectrum coming from gravity. But we cannot tell either way if nobody does the research.

Best, 🙂
Marko

28. **Alex**
July 27, 2022

Marko,

Yes, I definitely agree that those are important problems and the matter issue will have to be addressed at some point for that.

What I was thinking is that vacuum QG is conceptually more interesting and complicated than vacuum GR, since you now have to deal with things like: are distances, areas, volumes, proper times, discrete and probabilistic? What happens to the continuum manifold? What's even a quantum worldline? It's like going to GR 101 and start all over again with the presentation of the very basic stuff, like manifolds and curves, but now with their quantum versions.

Then it would be interesting to have phenomenological models that take those predictions and some effective model of the rest of matter, and see if we can at least test that. Of course, the full coupling between QG and quantum matter would be even better, but I think it's just too much to ask for the current state of development.

In the case of LQG, I don't think it has even solved in a completely satisfactory way any of those problems I mentioned. So, I maintain my prediction of a QG winter period starting in the near future (like the one that happened to AI in the 70s and 80s). I actually think it will be good for the field. Many people that still are prominent need to retire, since their current "research" is utter pseudo science (in both camps, strings and loops). Furthermore, technology has to evolve. Who knows, maybe in a couple of decades or even in 100 years, a fresh new generation will be able to make the breakthrough.

29. **Mitchell Porter**
July 28, 2022

String phenomenology has its own conference, String Pheno 2022. There are plenty of would-be applications of string theory to particle physics there.

30. **Peter Woit**
July 28, 2022

Mitchell Porter,

The point of my post was not that Strings 20XX talks no longer have any connection to the real world (that happened long ago), but that now they no longer have any connection to strings either. I haven't written in a while about "String Pheno 20XX" conferences, since the subject has become so bizarre that it's hard to figure out what to say. At least in the US, almost all leading "string theorists" except Vafa have now long ago abandoned any interest in "string phenomenology", realizing that it's a hopeless failed program. Why there are so many people and conferences devoted to a subject that almost everyone regards as a complete failure is something I'll never understand.

Before the Big Bang: The Origin of the Universe from the Multiverse

July 29, 2022
Categories: Book Reviews, Multiverse Mania

There's a new book out this month, Before the Big Bang: The Origin of the Universe from the Multiverse, about which we're told:

> One of the world's most celebrated cosmologists presents her breakthrough explanation of our origins in the multiverse.
>
> In recent years, Laura Mersini-Houghton's ground-breaking theory, spectacularly vindicated with observational evidence, has turned the multiverse from philosophical speculation to one of the most compelling and credible explanations of our universe's origins.

I spent a few minutes today looking through the book in the bookstore, trying to figure out where to find the details of the "spectacularly vindicated with observational evidence." I didn't see any references in the book, just a claim that in 2018 the author collaborated with Eleonora Di Valentino on showing vindication by observation. Presumably this is a reference to these three papers, but who knows. I don't see anything like that in a quick look at the papers.

For many years I've spent a significant amount of time reading books and papers purporting to offer scientific evidence for a multiverse, trying to carefully understand the author's arguments and write about them here (one example involved earlier claims by this author, see here). Few physicists though seem to care that bogus claims and pseudo-science about the multiverse have overrun their field and become its public face. I've come to the conclusion that best to not waste more time on this.

Update: Will Kinney reminds me that he wrote a paper about this, see here, as well as here and here for more about the story of that paper. Also see another old posting, here.

Comments

1. **Will Kinney**
   July 29, 2022

   Peter, I wrote a paper examining the claims of evidence for the model in light of the Planck data here:

   https://arxiv.org/abs/1606.00672

   Long story short, there isn't any. Only lower bounds on the relevant scales. If you remember, this paper caused a bit of a kerfuffle with LM-H 😉

2. **Peter Woit**
   July 29, 2022

   Thanks Will, I'd forgotten that story, even though I wrote about it at the time here. I'll add some links to the posting.

3. **Larry Lurio**
   July 29, 2022

   It is not a waste to respond to each and every exaggerated scientific claim that makes its way into a serious published book. They eat away at peoples confidence in the scientific endeavor and diminish the value of more mundane scientific theories that are actually supported by evidence earned by sweat and long hours of experimental work.

4. **Marty**
   July 29, 2022

   Re: Waste of time responding to multiverse nonsense:

   I suppose back in the 2000s you could have taken a similar point of view regarding string theory hype. But you didn't, and it made a real difference. A positive difference for theoretical particle physics, I'd say.

   I'd also say your efforts helped save the careers of at least a few PhD students who might have otherwise focused on string theory. I don't know if I would have ended up going down the string theory path without your perspectives, but a fellow grad student didn't heed your warnings and I think his future in theoretical physics suffered.

5. **Peter Woit**
   July 29, 2022

   Will,
   Took a quick look and, funny thing, the 2016-8 papers claiming to have Planck evidence don't reference your earlier 2016 paper claiming there isn't any. Perhaps the authors somehow missed hearing about your work, but I would have thought the referees would have pointed it out to them.

6. **Will Kinney**
   July 29, 2022

   Peter —

   Pretty sure they didn't miss it.

7. **Alex**
   July 29, 2022

   "spectacularly vindicated with observational evidence"

   Just… wow. I'm speechless on how spectacularly outrageous that is. These people have really destroyed science popularization. Just imagine the amount of lay people that will read that and believe it. A bit of exaggeration, teatrics, histrionism is okay I guess, since you must catch the public's eye in a competitive market. But these are just blatant lies. Just lies, lies and more lies. What the F is wrong with these people? Do they live in an alternate reality? How can this happen? What happened to institutions, to book editors, etc.? This strange world is like Orwell's 1984, physics version!

I'm really baffled and depressed by seing things like this.

8. **Nirmalya Kajuri**
July 30, 2022

I remember her from her old hit 'black holes don't exist', based on a flawed argument whose flaw was already understood in the 80s.

9. **Peter Woit**
July 30, 2022

The commenter above is referring to this paper
https://arxiv.org/abs/1409.1837
discussed for instance here
http://backreaction.blogspot.com/2014/09/black-holes-declared-non-existent-again.html
and here
https://arstechnica.com/science/2015/03/completely-implausible-a-controversial-paper-exists-but-so-do-black-holes/

10. **Anonymous theoretical physicist**
July 30, 2022

Peter: in case you feel that you are engaged in a Sisyphean task, I should perhaps comment that I first discovered your blog when I was entering grad school back in the aughts, and it was instrumental in convincing me to avoid string theory (and more broadly, high energy physics), and I do believe you very likely saved my academic career in the process, before it had even begun. So: thank you.

11. **David Roberts**
July 31, 2022

From the Ars Technica article

> In order to solve the firewall paradox, Mersini-Houghton wasn't thinking small: she claims to have unified general relativity with quantum mechanics. "Physicists have been trying to merge these two theories—Einstein's theory of gravity and quantum mechanics—for decades, but this scenario brings these two theories together, into harmony," said Mersini-Houghton in a press release. "And that's a big deal."

I guess this fell through…

12. **Alessandro Strumia**
July 31, 2022

What started the phenomenon of theory books with ridiculously exaggerated claims? String hype? Or maybe it started with Hawking, who had real interesting science plus medical bills, so physicists turned a blind eye to minor exaggerations? With the result that, once the anti-bullshit dam is broken, going back is difficult.

13. **Peter Woit**
July 31, 2022

Alessandro Strumia,

I think Hawking's 1988 "A Brief History of Time" had a big effect, not by opening the subject to exaggeration, but by unexpectedly making huge amounts of money. Publishers got the idea that a fundamental physics book, especially if written by someone with an interesting story, was worth publishing, because they might hit a jackpot. By the way, absent a full-time self-promotion campaign, most such books don't end up making much, the author often could have made more money by not writing the book and instead taking a part-time job dog-walking…

The post 2004 flood of pseudo-science books about the multiverse was enabled by publishers hoping to get lucky, but more importantly by the collapse of any intellectual standards in the field, and having no real fundamental physics science to write about (one can only sell so many books about the Higgs).

When I was growing up, there were plenty of books for sale about bogus physics. But they weren't written and/or blurbed by prominent theorists at elite academic institutions, so it wasn't hard to tell the difference between those and real science.

14. **Will Kinney**
July 31, 2022

Peter, Alessandro —

I tried to handle the inflationary multiverse with honesty and nuance in my book, for what it's worth. Jury is still out as to how well that sells.

15. **Peter Woit**
July 31, 2022

Will,
I did quickly read through your book, which seemed significantly better than the usual multiverse lot. Didn't write anything here just because writing anything substantive would have required time and energy I don't have, as well as patience I now lack for engaging with this material. Good luck with sales, although I fear taking a more sensible point of view may mean you'll do even worse than the dog-walking gig…

16. **Sleptovia**
July 31, 2022

Peter–why is Brian Green's book "The Hidden Reality: Parallel Universes and the Deep Laws of the Cosmos," better than Laura Mersini-Houghton's book "Before the Big Bang: The Origin of the Universe from the Multiverse"?

Here you write, "My colleague Brian Greene has a new book coming out soon, The Hidden Reality: Parallel Universes and the Deep Laws of the Cosmos. I haven't seen a copy, but from what I can gather, it looks like it is probably the best of the many books about "multiverse" ideas,. . ." –https://www.math.columbia.edu/~woit/wordpress/?p=3389

What exactly makes Brian's book so much better than Laura's and the rest?

Thank you!

17. **Peter Woit**
July 31, 2022

Sleptovia,
You deleted the rest of the sentence ("but still not exactly my cup of tea."), as well as the part telling people to look for experimental evidence of any multiverse claims. From what I remember, Brian doesn't claim any. The big difference with Mersini-Houghton is that she does make such claims (and as far as I can tell, they are bogus).

By the way, if one wants to evaluate multiverse books, I think Will Kinney's is better than Brian's.

Glashow Interview

August 2, 2022
Categories: Uncategorized

David Zierler, the oral historian at the American Institute of Physics, has done many in-depth interviews with theoretical physicists in recent years. Today I came across a 2020 interview with Shelly Glashow, which was very interesting in general, and also answered a question I had always wondered about. Glashow was my undergraduate advisor at Harvard, where I was a student from 1975-79. From what I remember, his office was more or less next door to Steven Weinberg's. It was well-known that they had been close friends, in the same class first at Bronx High School of Science, and then at Cornell. Towards the end of my time at Harvard I heard that their friendship was over and they were barely on speaking terms, but I never knew what had happened. In the fall of 1979, they were (together with Abdus Salam), awarded the Nobel Prize for their work on the unified electroweak theory.

In the interview, Glashow explains the story from his point of view:

> Glashow:
> by the late 1970s I began to think of myself as a Nobel contender. But I was under the impression that my old friend Steven Weinberg was doing everything in his power to keep the prize for himself and Salam. In particular—at a conference that he attended in Tokyo—he went out of his way to avoid mentioning my name at all while presenting the history of weak interaction theory. I got very upset by that omission. It was the issue which terminated our friendship. In the summer of 1979, I was invited to a meeting in Stockholm, to discuss the current state of physics ideas and others. Prior to the meeting, I sent a transcript of my talk to Steve. He was violently against my giving the talk. Because it examined various alternatives to what was then known as Weinberg/Salam theory. In fact, it was an open-minded talk in which I was discussing whether their—or more properly—our theory was a correct one or not. But it was such a heated discussion that I eventually had to simply hang up on him, because I had no intention of revising my talk. And I did not.
>
> Zierler:
> Was his assessment of your paper accurate in your mind?
>
> Glashow:
> I did talk about alternatives to the Weinberg-Salam theory. Yes. I was not yet convinced that it had to be true.
>
> Zierler:
> And what was your sense of why this was so unacceptable to him?
>
> Glashow:
> He thought it would endanger the Nobel Prize that he had campaigned for and anticipated for Salam and himself.

A copy of Weinberg's Tokyo paper is here.

In the interview Glashow is scornful about Salam's work and the campaign to get him a part of the Nobel Prize:

> Glashow:
> … Recall that Salam made a great deal of noise about why the prize should be given to he, Salam. I've been told that there were dozens and dozens of nominations of Salam. In fact, there's a whole paper written about his shenanigans, which I can refer to you; written by Norman Dombey. Everything he says is true, to my knowledge….
>
> My Nobel Prize depended on that one paper written in 1960. Steve's Nobel Prize depended exclusively on that one paper he wrote in 1967, a wonderful paper which applied the notion of spontaneous symmetry breaking to the—my electroweak model. So, the question arises, what did Salam do? He introduced the electroweak—the SU(2)XU(1) model in 1964. That was over three years after I did. He copied my work but did not cite me…
>
> Zierler:
> Do you want to comment on why then he would have been a co-recipient of the Nobel Prize with you for this copy of your work?
>
> Glashow:
> I'll explain it in a moment. But let me come back to—he also claims to the first to introduce spontaneous symmetry breaking in the paper that he wrote in 1968, one year after Steve wrote his paper. But that paper even cites Steve's paper, so it is hardly the first time. He did what each of us had previously done, but much later. So why did he get a Nobel Prize? Very simply, he was nominated many times. Because he was Director of the International Center for Theoretical Physics in Trieste, Italy and he was very close with the directors of physics institutes in many countries; almost 100 of different institutions. And many of them wrote letters, by his instruction, using his words in some cases, encouraging the Nobel Committee to give the prize to him and also Steven. All of this documented, in fact, by the paper by Norman Dombey, who had access to Salam's files in Italy, and has copies of the letters that he sent to other people encouraging them to nominate him. So, I think he shared the prize because he made a point of doing just that.

I wrote something on the blog about Donbey's claims here.

Zierler also asks Glashow some questions about string theory, a topic on which Glashow's views have been consistent from the beginning:

> Zierler:
> In retrospect, Shelly—how well do you think—has both string theory and your criticism of it aged over the past 30 years?
>
> Glashow:
> Well, it's hard to answer that. String theory has become an established part of physics departments throughout the world, more so in Europe than in America. We still have some universities which are proudly string-free, like Boston University. We also have an awful lot of string theorists around who are twiddling their thumbs. It is not clear that string theory is going anywhere. I expect that string theorists would disagree with that assessment. But they are actually considering many other circumstances such as black holes in other spaces than ours, and there are all kinds of interesting things being done in mathematics, in physics, elsewhere by string theorists but with no relationship to the questions that interest me. They cannot answer the questions they set out to answer. That much is clear.
>
> Zierler:
> That's as clear to you—
>
> Glashow:
> That was clear from the beginning, I think…
>
> Glashow:
> … I no longer feel so strongly about string theory. Why beat a dead horse? String Theory does not answer the questions that I'm interested in. I'm sad about that. I

hope that they're wrong. I have no reason to think that their horse is, in fact, dead, but it's dead from the point of view of being useful to my way of thinking about physics. And I think that many experimenters feel exactly the same way, because string theorists say nothing about experiments that have or could be done. They only speak of experiments that cannot be done, which is somehow not interesting.

Update: Robert Delbourgo wrote in to point to his description of what happened in 1967. Here's the relevant part:

> I have been asked by the organizers to comment upon the the birth of the standard model during 1967 and Salam's prominent role in it. This is an excellent occasion to set the record straight and recount my view of its history; if nothing else to refute innuendos which have occasionally surfaced during the 1970s that Salam was not deserving of the Nobel Prize. That autumn of 1967 I had been in charge of organizing the seminars at IC. Because Salam was constantly on the move and hardly spent more than one month at a stretch in London, I arranged with him to give a couple of lectures on his recent research (in October, to the best of my recollection) during his spell at IC to kick off the seminar season, as it was early in the academic year. He agreed to do so even though the audience attending those talks was somewhat thin. Paul Matthews was certainly present, but Tom Kibble was away in sabbatical in the USA. My memory of his lectures is a bit indistinct nowadays, but I do remember that he kept on invoking these k-meson tadpoles which disappeared into the vacuum which induced the spontaneous breaking of the gauge symmetry: what we now know as the expectation value of the Higgs boson. The resulting model looked rather ugly – and it still is – and I admit that I paid little attention to it; nor do I think that Salam himself was especially enraptured by the model's beauty. A week or so later, I wandered into the Physics Library and came across Steven Weinberg's Physical Review Letter, which I noticed looked suspiciously like Salam's attempt. I showed the article to Salam, who was rather troubled that it was almost the same as his own research, but which was of course entirely independent. Matthews and I urged him to publish his work at the earliest opportunity and this happened to be the upcoming Nobel Symposium. As they say, "the rest is history". I hope that this account of the events at the time scotches all aspersions that Salam should not have been a prize recipient.

   Peter, thanks for an interesting post. Did you happen to see where the audio recording of the interview is? I could only find the transcript.

2. **Brathmore**
   August 2, 2022

   Do mathematicians lobby for, and fret about, whether they'll win the famous math prizes? Or is this just in the sciences? Contrast Weinberg/Glashow with Perelman or Scholze. As science has become so interdependent, the Nobel limit on 3 per year is as stupid as the madness it engenders.

3. **S**
   August 3, 2022

   "They only speak of experiments that cannot be done, which is somehow not interesting."

   That seems a generous take.

4. **Georges E. Melki**
   August 3, 2022

   After reading this article, I lost most of the respect I had for both the Nobel Prize and its recipients! How could those so-called "great men" be so scornful of each other? How could they be bickering like this about precedence and priority in their fields? And what is the Nobel committee doing? What a shame!

5. **Steven Malarkey**
   August 3, 2022

   Why beat a dead horse?

   Perhaps something for us all to ponder.

6. **Geoffrey Dixon**
   August 3, 2022

   Having taught an undergrad course in particle physics at Harvard with Glashow, and rubbed elbows with Salam in Trieste, little in this surprises me. I only attended a couple of talks by Weinberg, but … My short assessments of the 3, in the order mentioned: good guy; preening; aloof.

7. **Anonyrat**
   August 3, 2022

   Glashow mentioned his summer 1979 talk here:

   that sort of politicing for a Nobel is not uniq to physics

10. **Peter Woit**
August 3, 2022

Anonyrat,
Looking at the Glashow spring 1979 Stockholm talk paper, I see what upset Weinberg. On page 309 Glashow claims that current phenomenology was consistent with a different model, with “Weinberg” angle 0. Weinberg likely took that as an explicit attempt to go before the Nobel committee and tell them that Weinberg’s model might be wrong so they shouldn’t give a prize for it.

11. **Peter Shor**
August 3, 2022

Chris asks:

> Did you happen to see where the audio recording of the interview is? I could only find the transcript.

I am fairly sure that for this series of interviews, they don’t release the original recording but just the transcript. I don’t know why—this is pure speculation, but maybe it’s because they think more people would be willing to be interviewed this way.

12. **Anonyrat**
August 3, 2022

Peter,

In the first link, Glashow wrote:

“I was invited to speak about the weak interactions at a conference in Stockholm in the spring of 1979.2 While in Stockholm, a member of the Nobel Physics Committee delighted in telling me that the Weinberg angle appearing in the Weinberg–Salam model was identical to the angle I introduced in my 1960 paper. I was delighted as well.”

The “weak mixing angle” was invented by Sheldon Glashow in his 1961 paper, “Partial-symmetries of weak interactions.”

13. **Peter Woit**
August 4, 2022

Anonyrat,

That’s why I put “Weinberg angle” in quotes. If you were around Glashow and his collaborators during the late 70s you were well aware that it wasn’t discovered by Weinberg…

14. **Palinuro**
August 4, 2022

Once I had the chance to talk with Glashow, and ask him when he was convinced that his model was true, he said that after neutral currents were observed, not 1961, not 1967 or 1971.

Weinberg, great physics and books, but in both of them it is like if Veltman has not existed.

15. **curiouser**
August 6, 2022

It’s hard to understand why the theory, at least initially, was called the Weinberg/Salam model, and why “Weinberg was doing everything in his power to keep the prize for himself and Salam”, if all Salam did was to steal from Glashow and Weinberg. It’s unfortunate that Weinberg and Salam are no longer around to defend themselves against what sounds like childish bickering fifty years after the fact. Maybe they wouldn’t have cared to.

16. **Peter Woit**
August 6, 2022

curiouser,

I’m also curious where the term “Weinberg-Salam”, with non-alphabetic ordering, first appeared. If Salam had independently discovered this model and written it down, why not “Salam-Weinberg”? The model got zero attention until after ‘t Hooft showed renormalizability. ‘t Hooft in his earliest mention I can find
https://webspace.science.uu.nl/~hooft101/gthpub/massive.pdf
refers to the model as Weinberg’s model, no mention of Salam.

For much more detail about this story, I recommend Frank Close’s book “The Infinity Puzzle”.

From everything I’ve read, Glashow has a good argument that Salam should not have gotten recognition for this. Writing a paper in 1964 describing the same model someone else well-known working in the same field had published three years earlier is not the kind of thing one normally gets any kind of credit for. Salam claimed to have independently discovered and discussed the Weinberg 1967 model for leptons in a series of fall term (Oct-Dec.) 1967 lectures at Imperial. There are no records from anyone of what he discussed in those lectures. Weinberg’s paper went to PRL Oct. 17 1967, was published Nov. 20, so quite possibly would have been available to Salam at some point during that period (there’s zero chance he would not have paid attention to a new paper from Weinberg).

Glashow is almost 90 years old, and has every right (and arguably a duty) to try and set the historical record straight about the Salam story. About Weinberg, what he has to say has nothing to do with the science, it’s purely about their interpersonal conflict and why he stopped speaking to Weinberg. It seems to me he has every right to publicly explain that if he wants to.

Weinberg was alive when Glashow was interviewed, but now can no longer respond. I doubt he would have wanted to. One can make a guess about how he felt about this: in 1978-9 he was clearly one of the first in line for the next physics Nobel Prize, perhaps had little patience for things that might interfere with this (such as arguments over claims about an earlier, incorrect, version of his model, or claims that it might yet turn out to be wrong).

17. **Shantanu**
August 7, 2022

Peter : in NASA/ADS you can do a full-text search
NASA/ADS is not always 100% complete in terms of Physics papers but according to this, the first paper which used “Weinberg-Salam” model is

https://ui.adsabs.harvard.edu/abs/1972PhRvD…6.2023M/abstract
I don't think inspirehep does a fulltext search. If it does someone can search via that too.

18. **tulpoeid**
August 12, 2022

Very interesting historically, thank you. The ending with "experiments that cannot be done" is also gold.
I remember almost fifteen years ago Glashow giving a talk at CERN. He made several jokes and everyone laughed. At some point he made a good joke against susy. Only me and a couple other people in the auditorium laughed (but at least we laughed loud).

19. **Robert Delbourgo**
August 12, 2022

Peter, please see my comments on page 3 of the Salam Memorial volume in the article "the force and gravity of events". I will leave it at that. I am an old guy now and you will just have to believe me. I only wish I had kept written notes of Salam's talks in autumn 1967. At the time I thought the whole edifice was rather ugly, especially the way he introduced the tadpole diagrams, which represented spontaneous symmetry breaking in his description.

20. **Peter Woit**
August 12, 2022

Robert Delbourgo,
Thanks for writing. I've added your comments that you point to as an update to the posting.

It still seems to me that it remains unclear what exactly Salam knew and lectured about before he had access to Weinberg's paper.

Looking back on the history of the electroweak theory, one thing that strikes me is how little interest everyone (including their own authors) seemed to have in these models. It took three years for anyone (whether Weinberg and/or Salam) to bother to put the Higgs mechanism together with a unified electroweak theory, and then that was ignored by everyone for another three years or so until 't Hooft/Veltman. Both Weinberg and Salam don't seem to have been particularly enthusiastic at the time about the idea that won them a Nobel Prize.

21. **shantanu**
August 12, 2022

Peter: something OT. I just accidentally noticed that 1975 nobel prize winner (and another Schwinger student just like Glashow) Ben Mottleson passed away in May . Despite getting a Nobel prize in Nuclear Physics and working in this area for 70+ years, I am surprised that there is no tribute to him on this or any other blog or from other physicists (which I could find). Was his work not well known to particle physicists despite getting a Nobel prize?

22. **Peter Woit**
August 12, 2022

Shantanu,
Nuclear physics is a quite different subject than high energy particle physics, and in general I think HEP physicists don't know much nuclear physics (during my Ph.D. I learned the minimum to pass general exams). In Mottleson's case, the Nobel-winning work was done 70 years ago. All I knew about Mottleson was that he did something with Bohr a very long time ago, surprised to hear he was still with us until recently.

23. **Peter Orland**
August 12, 2022

Hi from Copenhagen. Ben Mottleson won the prize with Åge Bohr, not Niels.

24. **Peter Orland**
August 12, 2022

He may have also worked with Niels, although I am not aware of it.

25. **Chris Austin**
August 12, 2022

Peter, "It took three years for anyone (whether Weinberg and/or Salam) to bother to put the Higgs mechanism together with a unified electroweak theory,"

From Weinberg's own account, on pages 2 to 6 of his Nobel Lecture, he was at first rather disturbed by the result that spontaneously broken continuous symmetries lead to massless Goldstone bosons. But in 1964, the year when the papers on the Higgs mechanism by Higgs; Englert and Brout; and Guralnik, Hagen, and Kibble appeared, there was another development, which suddenly seemed to change the role of Goldstone bosons from that of unwanted intruders to that of welcome friends. This was the Adler-Weisberger sum rule, which gave the ratio g_A/g_V of axial-vector to vector coupling constants in beta decay in terms of pion-nucleon cross sections. One way of looking at this result was to suppose that the strong interactions have an approximate symmetry, based on the group SU(2) x SU(2), and that this symmetry is spontaneously broken, giving rise among other things to the nucleon masses. The pion is then identified as (approximately) a Goldstone boson, with small non-zero mass, an idea that goes back to Nambu. Weinberg spent the years 1965-67 happily developing the implications of spontaneous symmetry breaking for the strong interactions. In 1967 he thought of trying out the idea that perhaps the SU(2) x SU(2) symmetry was a "local," not merely a "global," symmetry. He considered a model where in addition to the vector ρ mesons of the Yang-Mills theory, there would also be axial vector A1 mesons. But he was not too enthusiastic about it. Then at some point in the fall of 1967, it occurred to him that he had been applying the right ideas to the wrong problem. It is not the ρ mesons that are massless: it is the photon. And its partner is not the A1, but the massive intermediate boson, which since the time of Yukawa had been suspected to be the mediator of the weak interactions.

https://www.nobelprize.org/uploads/2018/06/weinberg-lecture.pdf

26. **Peter Woit**
August 12, 2022

Chris Austin,
As Weinberg explains, he and everyone else were focused on the strong interactions, trying to use spontaneous symmetry breaking and the Higgs mechanism to understand that. A lot of the reason why no one for years applied the Higgs mechanism to the electroweak theory was that everyone was thinking about the strong interactions, not the electroweak interactions.

27. **pontifex**
August 12, 2022

A nice rendering by Weinberg of the story of his realization that he had been trying the right idea for the wrong theory is here

http://www.ictp.it/media/1867057/100reasons-Weinberg.pdf

28. **Hans**
August 13, 2022

Peter,

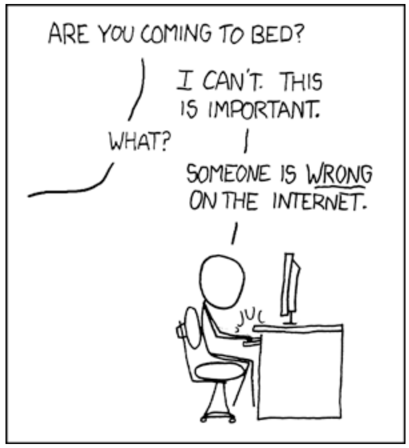
my own interaction with Glashow was about 10 years ago was with a gentleman. I wrote him to ask him whether he thought that the weak and the electromagnetic interaction had actually been unified, or whether the two interactions mix in a specific way. (I lost the mail exchange due to a hard disk crash…)

He answered that this was not clear-cut, and that mixing was an acceptable and possibly better description.

For somebody who received the Nobel prize for this unification, I found this quite impressive.

Symmetry and Physics

August 6, 2022
Categories: Quantum Mechanics



It's getting late, but I can't help myself. Reading too many wrong things about symmetry and physics on Twitter has forced me to do this. And, John Baez says I don't explain things. So, here's what the relationship between symmetry and physics really is.

In the language of mathematicians, talking about "symmetries" means you are talking about groups (often Lie groups, or their infinitesimal versions, Lie algebras) and representations. The relation to physics is:

Classical mechanics (Hamiltonian form)

In classical mechanics the state of a system with n degrees of freedom is given by a point in phase space $P=\mathbf R^{2n}$ with n position coordinates q_j and n momentum coordinates p_j. Functions on this space are a Lie algebra, with Lie bracket the Poisson bracket
$\{f,g\}$. Dynamics is given by choosing a distinguished function, the Hamiltonian h. Then the value of any function on P evolves in time according to
$$\frac {df}{dt}=\{f,h\}$$
The Hamiltonian h generates the action of time translations. Applying the same formula, other functions generate the action of other groups (spatial translations, rotations, etc.). If your function satisfies $\{f,h\}=0$, it generates a "symmetry", and doesn't change with time (is a conserved quantity).

Quantum mechanics

Quantization of a classical system is something mathematically obvious: go from the above Lie algebra to a unitary representation of the Lie algebra. This takes elements of the Lie algebra (functions on P) to skew-adjoint operators on a Hilbert space, the space of quantum states. There's a theorem (Stone-von Neumann) that says that (modulo technicalities) there's only one way to do this, and it gives an irreducible unitary representation that works for polynomials up to degree two. For higher degree polynomials there will always be "operator ordering ambiguities". The representation is given by
$$1\rightarrow -i\mathbf 1,\ \ q_j\rightarrow -iQ_j,\ \ p_j\rightarrow -iP_j$$
This is a representation because
$$\{q_j,p_k\}=\delta_{jk}\rightarrow =-i\delta_{jk}\mathbf 1$$
The right-hand side is the Heisenberg commutation relations for $\hbar=1$.

For more details, I wrote a whole book about this.

Comments

1. **Leonardo Abbrescia**
   August 7, 2022

   Hi Peter, old student from your Lie groups class in the early 2010's here. (Though in hindsight, I wish I had taken your math physics class instead). Here's an easy way to complete your post with the last piece of the "holy trinity" of math physics: relativistic mechanics.

   Given the $(n+1)$-dimensional Minkowski spacetime with the standard Minkowski metric $(\mathbb{R}^{n+1},m)$, you can consider the Poincaré group; the group of symmetries of m. These symmetries include spatial and temporal translations, rotations, and boosts. By Noether's theorem, these correspond to several conserved quantities to solutions of the linear wave equation $\Box_m \phi = -\partial_t^2 \phi + \Delta_x \phi = 0$. These symmetries have paved the way for the dramatic progress in mathematical relativity seen in the past 3 decades.

2. **oliver knill**
   August 7, 2022

   Your blog is great as it is. Never mind twitter. There are actually only very few frequently updated math and physics blogs which succeed explaining non-obvious things for a larger audience (some linked here on your site).

3. **Peter Woit**
   August 7, 2022

   Leonardo Abbrescia,

   The point of view on symmetry I describe can handle the symmetries of relativistic mechanics, you just need to think of the phase space as the space of solutions of your relativistic wave equation. It doesn't tell you why certain groups and representations occur in our best fundamental theories (or why a certain wave equation). It does tell you rather that classical and quantum mechanics are formalisms whose structure is based on the use of a specific infinite dimensional Lie algebra.

This point of view is very different than the one normally taught to physicists, that it's all about Noether's theorem (which, when you have a Lagrangian with an invariance group, tells you the functions that generate the symmetry) and just a calculational method useful in certain approximations.

4. **Peter Woit**
   August 7, 2022

   oliver knill,

   Thanks! John Baez is however right that normally writing expository material is not what I do on the blog (and he's one of very few who does a wonderful job of this on the internet). There are several reasons I don't do this, the biggest one that it's really hard.

5. **Lino D'Ischia**
   August 7, 2022

   Great summary. Who needs a book! 🙂

6. **John Baez**
   August 7, 2022

   Indeed it was intended as a description, not a criticism. Yours is one of the few blogs I follow.

7. **Moshe**
   August 7, 2022

   You may be interested in recent work on categorical and non-invertible symmetries, those don't have a group structure.

8. **Peter Woit**
   August 8, 2022

   Moshe,
   Thanks. I want to emphasize though that this posting is not about a modern, sophisticated new development in ideas about symmetry. It's about the simplest topics at the very beginning of first courses in Hamiltonian mechanics and QM (the Poisson bracket and the Heisenberg commutation relations).

   That the Poisson bracket is a Lie bracket goes back to the very definition of and motivation for the Lie bracket 150 years ago, and the idea that QM gives a unitary representation of the classical mechanical Lie algebra goes back 100 years to Dirac's major insight at the very beginning of QM. Dirac would not have used this language, but Weyl immediately was undoubtedly aware of it.

9. **Alex**
   August 9, 2022

   This line of thought is developed until its final logical consequences in George Mackey's work on Imprimitivity Systems, which unifies the Stone-von Neumann Theorem (seen as the uniqueness of the irepresentation of the Heisenberg group/Weyl relations up to unitary eq.) and Wigner's work (on the classification of elementary particles via irepresentations of the Poincaré group) into a single mathematical framework. Furthermore, it also clarifies (at least for the finite dimensional phase space case) the origin of Dirac's quantization rule (Poisson goes to i×operator brackets.)

   Really beautiful mathematics, I wish it was more well known.

   Standard references can be:

   -Folland: Introduction to Harmonic Analysis;

   -Varadarajan: Geometry of Quantum Theory*.

   *which also contains a proof of Gleason's Theorem and the whole lattice theoretical approach to QM.

   Modern developments include Landsman's work on translating and expanding Mackey's ideas into the C*-algebra approach, aided by the use of tools from noncommutative geometry.

10. **Peter Woit**
    August 9, 2022

    Alex,

    The "line of thought" I'm explaining here is just very basic facts about a specific Lie algebra and a specific representation, with the significance that these are basic postulates of classical and quantum mechanics respectively.

    You can develop this "line of thought" in many different directions, bringing in more groups and representations. Mackey's theory is only one specific direction, aimed at a general theory of induced representations.

    Personally I'd argue that a generalization more relevant to physics is in the direction of geometric representation theory, the orbit method and geometric quantization. These are topics which link symplectic geometry (more general notions of classical phase space) and representation theory (more general notions of quantum system). This is a genuinely mathematically sophisticated and active area of current research, tough going for most people.

    I think it's a mistake to throw a lot of sophisticated abstract formalism designed to handle very general questions at people as an "explanation" of the role of symmetry in physics. Hardly anyone will understand this, and all you'll accomplish is convincing physicists that this area of mathematics is the "gruppenpest", a plague of incomprehensible ideas that tell us nothing about physics. Effort would be better spent explaining to physicists that Lie algebras and representations provide real insight into basic formulas they were taught to accept unthinkingly about classical and quantum mechanics

11. **Alex**
    August 9, 2022

    Peter,

    yes, Mackey's direction is one among several, but, historically, is the closest one (early 40s) to the original developments (Weyl, early 30s; Wigner late 30s, etc.), and was devised as a synthesis of all of those developments that were happening in QM at the moment. That's why I used the term "line of thought", since it seemed like a natural and organic development to me. In fact, it was Mackey who first used the name "Stone-von Neumann Theorem" for the result about the uniqueness of the CCRs.

Geometric quantization is indeed another approach, and I think they are actually complementary, since they treat different problems and aspects of quantization. In fact, they can even be combined. Unfortunately, both approaches have their well known limitations. Geometric quantization uses the language of connections and bundles; the hard part, I think, lies not on this but on the amount of tricks and subtle twists you must do along the way in order to make it work. Due to this, the process can become quite artisanal and difficult to follow for the unexperienced.

As for the clarification part, I was referring to the simple fact that the imprimitivity condition (which can be seen as a simple covariance condition on the system) gives rise to the CCRs.

Finally, I actually disagree with your last paragraph. In my own experience, I have seen many graduate students very confused by all the seemingly unrelated Lie algebras/groups that were introduced in their courses (Galilei, Heisenberg, Poincaré) and were quite interested and relieved when told that the representation theory of all of these groups could be solved by the application of a single general theorem, and by many other aspects as well (e.g., obtaining the wave equations from the induced representations' spaces, etc.) I do agree with the part about explaining the role of Lie algebras in the formulas that are thrown at them in the basic courses, and it was never my intention to suggest replacing that by some full blown introduction to induced representations, geometric quantization or whatever. Just an after that elaboration.

12. **Peter Woit**
August 9, 2022

Alex,

For me the imprimitivity condition doesn't clarify the CCRs, they (the CCRs) are just the Lie algebra relations for linear functions on phase space.

A lot of the appeal of representation theory to me is that it's a vast subject deeply connected to physics that one can approach from many different points of view. There may very well be an overarching single point of view that unifies the subject, but that remains elusive (at least to me…)

13. **Alex**
August 9, 2022

Peter,

well, the idea is that the imprimitivity condition is a covariance-type condition, between the position observables on some configuration space and the relevant group action on it, which in simple terms can be viewed as expressing the homogeneity of said observables with respect to the relevant symmetries of the configuration space. Furthermore, in the standard examples where the configuration space is R^n and the group are the additive translations R^n, the imprimitivity condition is equivalent to the Weyl relations(/Heisenberg group rep.), which are just the exponentiated form of the CCRs: thus, in this view, the CCRs are equivalent to imposing the homogeneity of the position observables with respect to the relevant symmetry of the configuration space. Thus, it's a very symmetry-friendly explanation, that's why I considered it relevant here.

I don't claim Mackey's theory to be such an overarching single point of view on representation theory, but it does unifies, as I mentioned, the Wigner classification theory (giving also the representation spaces, made of -distributional- solutions to the relevant wave equations for all spins in full mathematical rigor*) with the CCRs and their uniqueness (it can also be used to obtain the relativistic position operators and show that they indeed don't exist in the massless case for spin >=1, like the photon and graviton).

*most students of QFT think that single photons don't have wave functions and equations because that's what they are told in informal presentations of the subject. But they do have! And are given by the elements of the corresponding representation spaces, of which, as far as I know, the Mackey machine method via induced representations is one of the few approaches if not the only one to give you those Hilbert spaces rigorously and explicitly only from Poincaré representation theory. To construct the Fock space for photons in standard QFT, you need first such single photon spaces. In mathematical physics, these details are indeed relevant. If physicists don't care, that's their loss, not mine.

14. **lun**
August 10, 2022

One can define both in terms of analysis instead of Algebra, with symmetries playing an important but auxiliary rather than central/conceptual role:

Classical mechanics: There is an initial condition and an action. Dynamics is defined by the trajectory that minimizes the action, which gives evolution at any point after the initial condition.

Quantum mechanics: Same as classical mechanics, but dynamics is defined by correlators that are computed in terms of functional integrals of trajectories.

It is not clear, at least to me, why the symmetry/algebra definition is "better" or "more fundamental" than the analysis based one.

15. **Peter Orland**
August 10, 2022

"*most students of QFT think that single photons don't have wave functions and equations because that's what they are told in informal presentations of the subject. But they do have!"

Of course they do. But you just need to write the wave equation (for any relativistic particles, not only photons) in terms of oscillator variables (which become creation and annihilation operators in second quantization). These variables are the Fourier transform of the true wave function. Amplitudes and probabilities become as simple as they are for the Schroedinger equation, No deep mathematics is needed to understand this.

16. **Gavin**
August 10, 2022

Since the post advertises that it will explain "what the relationship between symmetry and physics really is," I think it's important to add at least a caveat that discrete symmetries are also important in physics (especially condensed matter physics) and are not described by a Lie group.

17. **Peter Woit**
August 10, 2022

Gavin,
Yes, and I did start off the post referring to all groups, not just Lie groups. In classical mechanics discrete groups are of limited use, no Noether's theorem. In quantum mechanics however, the abstract situation is the same as for Lie groups: the state space is a unitary representation of the group, and the representation theory of the discrete

group then provides a lot of information about the behavior of the quantum system.

18. **Peter Woit**
August 10, 2022

lun,
Yes, if you want you can do physics purely within the Lagrangian formalism (although if you do this, you quickly find that “just integrate e^{iS} over the infinite dimensional space of trajectories” often is a proposal that one can’t make well-defined).

The question was about the relation of symmetry and physics, and I’m arguing that is best understood in the Hamiltonian formalism (compare solving the N-dim harmonic oscillator problem and studying its symmetries in the canonical operator formalism vs. by calculating path integrals).

19. **Peter Woit**
August 10, 2022

Alex/Peter Orland,
This is getting off topic. I’ll just again refer to my book, where the single-particle state space for relativistic particles is worked out (even including distributional solutions, although that is not handled well and I hope to rewrite some sections for that reason).

20. **maciej**
August 10, 2022

I’m missing distinction between symmetries and invariances. They are not the same concepts, although both correspond to some transformations that leave the theory intact. Symmetries (e.g. rotational symmetry) map some physical states to different physical states. Invariances (e.g. gauge, diffeomorphism) do not change the physical state. As Coleman used to say: You don’t ask the experimentalist “In what gauge you did your experiment?”.

21. **Peter Woit**
August 10, 2022

maciej,
This is a good point. When I was writing the book about QM, I struggled with the fact that it’s not clear what one means when one says “symmetry”. There’s always a group, and it is acting on something, but what structure is being preserved has to be specified and so different sorts of things can be going on.

In the Hamiltonian formalism, functions on phase space with Poisson bracket are the Lie algebra for the infinite dimensional group of transformations of phase space preserving the symplectic structure. This is a group of “symmetries”, but sometimes by “symmetry” one means something more special: a Lie algebra of functions that have zero Poisson bracket with the Hamiltonian. These also preserve time evolution, give conserved quantities. As an example, consider spatial rotations: components of angular momentum give a three-dimensional space of functions on phase space with Poisson brackets satisfying the relations of the Lie algebra of the rotation group. These functions may or may not Poisson commute with the Hamiltonian and be conserved quantities (depending on whether the Hamiltonian is invariant under all rotations, or just a subgroup).

In QM, you have the same issue, you get operators with commutation relations given by the Lie algebra, which may or may not commute with the Hamiltonian operator. But in QM you in addition have a representation of these operators on states. Your states may be invariant (trivial representation), or in some specified non-trivial representation. In the rotation group example, your states may be invariant under rotations (s-wave), or transform non-trivially under rotations in a manner given by the representation theory of SO(3) and SU(2).

In the case of the gauge group, conventionally you assume states are in the trivial representation for local transformations (not necessarily so for global transformations).

22. **Hugh Osborn**
August 10, 2022

I am not sure I agree with what you say about the transition from classical to quantum. Real classical variables become hermitian operators (without any factors of i)
And the classical Poisson bracket is then replaced -i times the operator commutator,
with 1/hbar if this is not set equal to one. This is what Dirac did in 1926.
The centenary of real QM is due in just three years.

Hugh Osborn

23. **Peter Woit**
August 10, 2022

Hugh Osborn,
In a unitary Lie algebra representation the operators are skew-adjoint, not self-adjoint, so I put in factors of i to change the usual self-adjoint operators to skew-adjoint. Using these skew adjoint operators, the Lie bracket of classical mechanics (the Poisson bracket) goes precisely to the commutator of operators (this is the definition of a Lie algebra representation).

If you write things just in terms of self-adjoint operators, you have the usual extra factor of i in the relation between the Poisson bracket and the commutator of operators.

24. **Ricardo Jimenez**
August 17, 2022

While group theory (more exactly representation theory of Lie Groups) is certainly important in Quantum Field and Condensed Matter theories, it is hard to find any discussion of it in the literature of the rest of physics. What books are there on Classical Mechanics and Classical Electrodynamics from the group theory point of view? Thanks in advance.

25. **Peter Woit**
August 17, 2022

Ricardo Jimenez,

I just noticed this book
https://www.amazon.com/dp/1848167741
but don’t know much about it. I don’t know of any book that develops classical mechanics from the point of view of taking as basic the Lie algebra of functions on phase space with Lie bracket the Poisson bracket.

For classical electrodynamics, the relevant group theory is the Lorentz group and the gauge group, I don't know of a book that puts those front and center but maybe there is one.

In classical physics you don't really encounter representation theory much, although that's fundamental to quantum physics. So it is in quantum physics where the Lie group point of view really comes into its own.

26. **Jonathan**
August 17, 2022

Wouldn't classical mechanics texts more in the direction of symplectic geometry cover that sort of material?

27. **Peter Woit**
August 17, 2022

Jonathan,
I took a look at one such text I could think of (Arnold). His and other books do emphasize that phase space is a symplectic manifold and use the symplectic structure, but don't emphasize that the Poisson bracket is Lie bracket for the Lie algebra of the infinite dimensional group of transformations of phase space preserving the symplectic structure (maybe this fact is somewhere, but not emphasized).

28. **Anonymous**
August 17, 2022

The book "Introduction to Mechanics and Symmetry" by J.E. Marsden and T.S. Ratiu contains many interesting applications of Lie groups and Lie algebras in Classical Mechanics.

29. **Arnold Neumaier**
August 18, 2022

Alex,
"Geometric quantization is indeed another approach, and I think they are actually complementary, since they treat different problems and aspects of quantization. In fact, they can even be combined. Unfortunately, both approaches have their well known limitations."

In my recent paper

A. Neumaier and A. Ghaani Farashahi, Introduction to coherent quantization, Analysis and Mathematical Physics 12 (2022), 1-47.

I discuss coherent quantization, a generalization of geometric quantization including the non-unitary case. Unlike in geometric quantization, the groups are not assumed to be compact, locally compact, or finite-dimensional. This implies that the setting can be successfully applied to quantum field theory, where the groups involved satisfy none of these properties.

30. **Arnold Neumaier**
August 18, 2022

Ricardo Jimenez,

"What books are there on Classical Mechanics and Classical Electrodynamics from the group theory point of view?"

Two nice such books include:

Marsden and Ratiu, Introduction to mechanics and symmetry.

Arnold and Khesin, Topological methods in hydrodynamics.

31. **Student**
August 22, 2022

I've always felt that Ballentine's Chapter 3 in his Quantum Mechanics books is a tour de force. In one chapter he introduces the Gallilean group as the group that describes the non-relativistic symmetries of space time and proceeds to derive the fundamental Quantum Mechanic operators from these symmetries.

He doesn't get into the formal mathematics of Lie Groups and Algebras or representations but it was a powerful illustration of that POV.

I'd contrast that with your book Peter, which I have tried to work through on and off, which goes much deeper into the subject, but, if I may offer a slight critique, the motivation for the approach is less clear.

32. **Peter Woit**
August 22, 2022

Student,
My book does have a somewhat similar emphasis on non-relativistic space-time symmetries, but sticks to the Euclidean group of rotations and translations rather than getting into the larger Gallilean group (for which the representation theory is much trickier, and the extra generators you get not that interesting). In both cases, thinking of the non-relativistic case this way extends nicely to the relativistic Poincare case.

One thing to keep in mind is that Ballentine is aimed at physicists, my book is based on a course in the math department. The motivation is much more on the math side than for Ballentine. A book like Ballentine's is hard for mathematicians to follow, since he's avoiding standard mathematical concepts (like that of a representation) in favor of language familiar to physicists. For physicists, I suspect my book is similarly harder to follow because of the unfamiliar language and formalism, but I hope that they will ultimately find this point of view worth learning, since it is quite powerful and clarifies issues that the physicist's approach often leaves unclear.

Various and Sundry

August 18, 2022
Categories: Uncategorized

A random collection of things that may be of interest:

- September 17 and 18 I'll be at the How the Light Gets In Festival in London, participating in discussions of the relation of math and physics, and theories of everything. I'm looking forward to the festival, which sounds like fun, and to spending some time in London. A week or so later, I'll be in Oxford, attending the Clay Research Conference as well as a Physics from the Point of View of Geometry workshop in honor of Graeme Segal's 80th birthday.
- I've been spending the summer trying to write up some details of the ideas I've been working on, specifically the claim that the geometry of spinors in four dimensions allows one to think of one of the SU(2)s in the Euclidean Spin(4) symmetry as an internal symmetry. Still learning more about how this works, hope to have something ready to publicize within the next month or so.
- For rest and relaxation I've been learning a bit more about various Langlands-related topics. The talks from the IHES summer school are mostly well-worth watching. Also very highly recommended are David Ben-Zvi's lectures on *The Langlands Program as Electric-Magnetic Duality* given a couple weeks ago at a workshop in Cambridge.
- Still trying to finish reading Récoltes et Semailles and decide whether to write something here about this bizarre and fascinating document. If you want to read this yourself, Mateo Carmona has a freely available transcription here.
- There an interesting conversation about Ricci flow between my Columbia colleagues John Morgan and Richard Hamilton available here.
- Sometimes it takes great self-control to avoid responding to things I see on Twitter. In the case of a recent exchange between Noah Smith and various people defending string theory. I couldn't help myself and started writing something, then soon hit the character limit. This returned me to sanity as I realized that trying to have an intelligible discussion in the twitter format about anything complicated is just absurd.

  The gist of a lot of the discussion was that even string theory defenders now admit it was an overhyped failure as a "theory of everything", but they then come up with new, improved hype. One argument seems to be that string theory has led to new developments in hype about black holes (for these, Scientific American has you covered here).

- Today on Twitter Sabine Hossenfelder explains her current academic employment situation (no permanent position, latest grant application denied.) She's a very unusual case, and has a successful new book and other ventures that to some degree can replace a standard academic income. For everyone though, the way academic jobs in theoretical physics work, if you decide you want to pursue topics other than very conventional ones that a group is already working on, you're going to have a very hard time. Getting older and having a life also tends to be inconsistent with pursuing the very few opportunities that might come up.

Comments

1. **Alex**
   August 19, 2022

   I'm tired of seeing string theorists hijacking other fields and pretending their failed methods and ideas are revolutionizing those fields. It's remarkable, these people are not going to stop, it seems. And they get a lot of press! When is this nightmare going to stop?!

   Meanwhile, in actual black hole news, people like Klainerman have been working on the really, really hard problems, like Kerr stability, and recently they finally proved an amazing result, with actual relevance to our physical picture about the final state of real black holes at late times.

   At least Quanta covered the news: https://www.quantamagazine.org/black-holes-finally-proven-mathematically-stable-20220804/

   There are some great talks by him in youtube on these topics as well.

2. **suomynona**
   August 19, 2022

   This isn't the first time Noah Smith has tweeted a horrendously ignorant opinion, then mocked those pointing out his ignorance as being sensitive and butt-hurt, and then deleting the tweet to hide evidence of his ignorance.

   Something that struck me as bizarre in that thread was that string theory was being defended as a "simple toy model" for describing condensed matter systems, while simultaneously also being admitted as far removed from the actual realistic physics of said systems. String theory was considered a "good starting point" because it's "easy to work with," not because it's actually relevant to the physics under consideration. String theorists and condensed matter physicists certainly have different standards for what constitutes a "simple toy model".

   FYI, it's perfectly acceptable twitter etiquette to comment with a multi-tweet thread. You need not limit your entire reply to a single tweet.

3. **Peter Woit**
   August 19, 2022

   suomynona,
   I don't think his original tweet was "horrendously ignorant". It's hard to overemphasize the damage of all sorts that decades of outrageous hype, failure, and refusal to acknowledge failure have done (and continue to do) to important parts of physics. Yes, the case for linking this to less progress in "applied quantum mechanics" wasn't very good, and I think it's to his credit that he realized this and deleted the original tweet.

   On the other hand, all the people who piled on with ridiculous hype about string theory's supposed successes are the sorts who never will admit that their claims are wrong. That's just one reason why it would have been a waste of time to engage with them.

   I'm well aware one can chain together tweets, but that's awkward. Twitter's design seems intended to make thoughtful discussion and engagement with other people's arguments difficult, while encouraging randoms short bursts of stupidity.

4. **theoreticalminimum**
   August 21, 2022

   I'd be interested in what you got from a reading of R&S. I've myself tried to find time to read the 2-volume, but it's been very difficult, and reading it is not the easiest of things, because it seems like a lot of what he wrote came from some deep thinking, which requires the reader to pause and meditate on some points.

5. **Peter Woit**
   August 21, 2022

   theoreticalminimum,
   Writing something about this is a daunting prospect, it's huge unedited mix of the wonderful and deep with the paranoid and tedious.

   Probably a good idea to keep in mind that to some extent Grothendieck's intended audience was mathematicians in his field (algebraic geometry). The more you know about that field and what was going on in it during the years from the mid-50s to the mid-80s, the more you're likely to make sense of parts of it. At some points this gets very frustrating: after he goes on for dozens of pages about how terrible it was that people other than Deligne didn't understand and appreciate his (unpublished) ideas about weights and the "yoga" of motives, you really wish he instead had spent the time writing out an explanation of those ideas.

6. **Niclas Granqvist**
   August 28, 2022

   More multiverse mania:

   The Guardian: Cosmologist Laura Mersini-Houghton: 'Our universe is one tiny grain of dust in a beautiful cosmos'.
   https://www.theguardian.com/science/2022/aug/27/cosmologist-laura-mersini-houghton-before-the-big-bang-interview

7. **Pall Lobe**
   September 5, 2022

   Very sad to know about Sabine Hossenfelder. There is no value to popular fame, which is much more important writing another stupid paper, in mainstream academia.

   PS: I am a string theorist.

LHC News

August 24, 2022
Categories: Experimental HEP News

I see today via the LHC Page 1 Vistar that a problem at a cooling tower will cause part of the accelerator to need to be warmed up to room temperature, putting the LHC out of business for the next 4 weeks or so.

The LHC has just been coming out of long shutdown the past few months, starting its Run 3. In the past couple weeks it has started to get up towards its full luminosity potential, with over 2400 bunches in the beam. So far during Run 3 the machine has delivered an integrated luminosity of about 10 inverse fb to each of the experiments (ATLAS/CMS). The plan for Run 3 (which is expected to last through 2025) is to accumulate an integrated luminosity of about 300 inverse fb, doubling the 140 inverse fb of Run 2, at a slightly higher beam energy (6.8 TeV vs. 6.5 TeV).

Update: Thanks to Benson Woo for pointing out to me an article today in the Wall Street Journal about plans for possible shutdowns of parts of the CERN accelerator complex this winter in case of energy supply problems due to the ongoing conflict with Russia.

Comments

1. **Amitabh Lath**
   August 26, 2022

   Although 300 fb-1 does not sound like huge improvement over Run 2, there are several triggers (online data filters) that are getting tested for the High-Luminosity LHC era. Of course, Run 3 will also chase down some interesting anomalies we saw in Run 2.

   One interesting thing about Run 3 analyses will be how machine learning techniques are incorporated into nearly every facet. The comfort level for ML has really increased. Concerns about things like overtraining and bias are real, but not considered insurmountable.

This and Next Year's Hype

September 5, 2022
Categories: This Week's Hype

I normally try and avoid getting into the vast topic of the hype problem in other subjects than string theory, but a couple things I've seen recently make it hard to resist. So, just this once…

Quantum Computing

Michio Kaku has a new book coming out next year, called Quantum Supremacy: How the Quantum Computer Revolution Will Change Everything. The publisher's summary tells us that quantum computing "may eventually unravel the deepest mysteries of science and solve some of humanity's biggest problems, like global warming, world hunger, and incurable disease." More concisely:

> There is not a single problem humanity faces that couldn't be addressed by quantum computing.

For a very different take, see The quantum computing bubble at the Financial Times, where Nikita Gourianov argues that there's a speculative bubble going on in this field, and:

> Well, when exactly the bubble will pop is difficult to say, but at some point the claims will be found out and the funding will dry up. I just hope that when the music stops and the bubble pops, the public will still listen to us physicists.

For a response to this, see a later article at the Financial Times: Separating quantum hype from quantum reality.

I think Gourianov makes an important point for physicists to keep in mind. Having this sort of hype blow up in physicist's faces is not going to help with the credibility problems physics already has with the public due to decades of hype about non-existent breakthroughs in fundamental physics.

Nuclear Fusion

Attempts to build a nuclear fusion-based power reactor have been going on for 70 years or so. Decades ago it had already become a joke that success was always "30 years off". One would think that because of this there would be overwhelming skepticism about new claims in this field, but there's continual new hype all the time. The Guardian recently had a long article about The race to give nuclear fusion a role in the climate emergency. If you read the article carefully, there's no evidence of any change on the "30 years off" front, with one expert describing magnetic confinement-based reactors as highly unlikely before "after 2050" and laser-based schemes "another 50 years to go, if at all."

One project that has been getting a lot of press is SPARC, a collaboration between MIT and a private start-up. Their claim seems to be that they've got a workable reactor design all ready to go, last year finished developing the needed 20T high temperature superconductor-based magnet, and by 2025 will have a working reactor putting out more energy than goes in. Then:

> **On this path, how long would it take before fusion energy is on the grid?**
>
> MIT scientists and their collaborators believe that ARC — a fusion power plant that would produce electricity continuously — could be built and operating by early 2030.

This all seems highly implausible to me, but Bill Gates is putting money into the the project and I guess we'll find out soon. For a skeptical take, see here.

About nuclear fusion, Michio Kaku tells us that:

> Quantum computers could allow us to finally create nuclear fusion reactors that create clean, renewable energy without radioactive waste or threats of meltdown.

Two more items:

Getting back to the sort of claims about physics that don't work out that I usually write about, the IAS website points to two recent items:

- Symmetry magazine interviews various physicists who appeared in the film Particle Fever (which I wrote about here).
- An electronic music producer interviews Edward Witten.

Update: Theoretical physicists are making a contribution to the energy crisis, see here.

Comments

1. **Alex**
   September 5, 2022

   Just wow. It's amazing how these people are simply incapable of communicating anything without uber hyping it at the same time. It's beyond pathological, it's in the community's fabric now. It's a way of life. Is there any way (or even hope) of coming back to rational after we passed such event horizons of delusion, but also of lack of scruples? I'm really pessimistic, to be honest.

2. **steve blazo**
   September 5, 2022

   I do not agree with the appeal of nuclear fusion over nuclear fission. The safety record of fission is amply demonstrated by any serious analysis on the line of deaths per megawatt hour and third and fourth generation plants will be improvement over older designs and they are available now. The high level waste issue just seems a red herring, there just is not that much of the stuff generated. Uranium reserves (or thorium) are ample. I just do not see the point in investing 10's of billions in the hope you will be able to solve some very difficult, perhaps practically impossible problems with fusion when you already have a solution staring you in the face.

3. **Rohan**
   September 6, 2022

   I wonder what people think about the prospects of nuclear fusion startup Helion? How seriously is it taken in this space?

4. **Sabine Hossenfelder**
   September 6, 2022

Nuclear fusion needs chaos control which is a strongly non-linear problem. Last time I looked no one knew how to efficiently solve non-linear equations on a quantum computer. I warned of quantum computing hype some years ago here:

https://www.theguardian.com/technology/2019/aug/02/quantum-supremacy-computers

5. **Hans**
September 6, 2022

My partner's father worked on fusion. For 50 years he told him that fusion will come within 50 years. He got quieter when he got older.

My colleague questioned quantum computing at work. His boss got angry in away he had never seen.

Peter, I admire your energy, but be careful not to open too many battle fronts.

6. **Peter Erwin**
September 6, 2022

I suppose that if you wanted some tenuous source of optimism about fusion, you could look at how the value of *N* in "fusion power is *N* years away, and always will be" has been gradually creeping down. I mean, I remember quite clearly in the early 1990s hearing it as "40 years away, and always will be", and here's a recollection of an earlier version: "I first heard the standard joke about fusion as an undergraduate physics student in the 1960s: Fusion power is fifty years away – and probably always will be."

A simple linear extrapolation tells us that we'll reach the state of "fusion power is zero years away" around 2110! Progress!

7. **Anonyrat**
September 6, 2022

"As John Preskill said at the Q2B conference organized in December 2021 by QC-Ware, "There is a line between setting ambitious goals and fanning inflated expectations… for us as a community, we'll be better off if we try to stay on the right side of that line"."

"As Victor Galitski states in his already mentioned paper, the ethics of science communication is at stake in the current quantum hype."

From: https://arxiv.org/pdf/2202.01925.pdf

8. **AcademicLurker**
September 6, 2022

In the linked Symmetry magazine piece, there's an interesting quote from David Kaplan about how before Particle Fever he used to pick projects that could be "wrapped up in six months". Since making the film he says he's changed how he works and now realizes that worthwhile questions might take longer to answer.

Peter and Lee Smolin in their books back in 2006 both mentioned how career incentives force theorists to work on short term projects, and Sabine Hossenfelder mentioned it again in her more recent book. There apparently is very little will to change how the incentive structure works. It's funny, because you would think it would be obvious that fundamental problems like the ones HEP theorists work on won't be solved in 6 months.

9. **Alan Post**
September 6, 2022

The new high-field magnets will allow existing fusion device designs to work better. The idea with SPARC and ARC is to do this with the currently best-performing design (H-mode tokamak). Of course, many others are applying the new magnets to other designs that are less proven or have performed less-well in the past. Hopefully one or more of these approaches will pan out. I doubt something the scale of ITER will ever be cheaper than renewables plus storage.

I do wish everyone involved would avoid making misleading claims about "net energy" or "gain", though.

10. **Varun Chauhan**
September 6, 2022

I remember studying nuclear fusion for nuclear engineering the common understanding is it is always 50 years away.

11. **David J. Littleboy**
September 6, 2022

Given that the number of problems that can be solved (that is, actually known algorithms) using quantum computation is tiny (this year, the folks working on it finally came up with a third algorithm, as I understand it the first new algorithm since Shor's and Glover's algorithms* of the 1990s), Michio Kaku's comments on what QC will do for us are more than over the top.

Even people who claim that the "problem" being used for the quantum supremacy demonstration actually demonstrates that admit that it has absolutely no conceivable practical (meaningful in real life in any way) use. And all this is in the context of Sabine Hossenfelder's comment on the expected arrival time of a QC that can actually run those three algorithms as being "not in our lifetimes".

The universe is becoming more and more devoid of reality checks, it seems…

*: That almost no new quantum algorithms have been forthcoming was a surprise here: Shor's algorithm, as I understand it, is essentially a quantum-fast Fast Fourier Transform, which ought to be useful for all sorts of things. One would think.

12. **Peter Woit**
September 6, 2022

For enthusiastic coverage of some of these new startups, see this article by Philip Ball in Nature last year

https://www.nature.com/immersive/d41586-021-03401-w/index.html

Ball recalls the usual "30 years away" (I recall always hearing 20-30 years away, not 50), and notes that nowadays it's often "10 years away". That would normally make one more optimistic, but he also writes:

"Private companies say they'll have it working in ten years, but that's just to attract funders," says Tony Donné, programme manager of the Eurofusion consortium which conducts experiments at the state-run Joint European Torus, established at Culham in the late 1970s. "They all have stated constantly to be about ten years away from a working fusion reactor, and they still do."

Timelines that companies project should be regarded not so much as promises but as motivational aspirations, says Melanie Windridge, a plasma physicist who is the FIA's UK director of communications, and a communications consultant for the fusion firm Tokamak Energy, in Culham. "I think bold targets are necessary," she says."

It may just be that when you're looking for private investors rather than government funding, you have to claim shorter time horizons, even if they're nonsense. If you need to claim "ten years" to get money, and your choice is do that or don't get funded and shut down, the only sensible thing to do is to claim "ten years", and deal with the fact this is not going to work out that way later.

13. **Peter Woit**
September 6, 2022

AcademicLurker,
I was interested to read that comment by Kaplan also. The problem of all the incentives being aligned to push people into short-term unambitious projects are still all there. The problems of this kind Smolin, Hossenfelder and I have pointed out a long time ago are just as bad if not worse now. Everyone agrees that the field is in a difficult state, with new ideas needed, but no one wants to change anything about how research has always been organized and funded.

14. **Douglas Natelson**
September 6, 2022

Can someone please stop giving Michio Kaku a megaphone? His brand of popularization does more harm than good, in my view. BTW, if you want to see an excellent and thought provoking talk about quantum computing, I recommend this one by Garnet Chan (Caltech) about whether quantum computing gives an exponential speed up for problems related to quantum chemistry (where a priori one might imagine a real benefit from quantum algorithms): https://m.youtube.com/watch?v=DZPH7ENcRLU

15. **DrDave**
September 7, 2022

Surely there must be something in the book about how quantum computing will make–and test–predictions using string theory?

16. **David Roberts**
September 7, 2022

@David J. Littleboy

Can you give us a name for and a link to this third algorithm?

17. **Mark Hillery**
September 7, 2022

For anyone interested in what quantum algorithms are out there, have a look at the Quantum Algorithm Zoo: https://quantumalgorithmzoo.org .

As someone who has worked in quantum information for 25 years, I can say that the last thing the field needs now is more hype. There is way too much already. Back in its early days, it was a small field that encountered a lot of skepticism from people working in more established fields. I remember a reaction to one talk I gave, which was, "Is this physics?" Well, things have changed. The American quantum information community adopted the APS March Meeting as its annual meeting. I don't like March Meetings, too big, but I did go to the one in 2019 in Boston at the behest of Physical Review. I was amazed at how many people were working in quantum information/computing and the level of interest from industry. I guess when big money gets involved the danger of hype increases, but making promises you can't keep is a really bad idea. The honest answer about the future of the field is that while there is a lot of interesting work going on, both theoretical and experimental, no one knows where all this is going to go.

18. **David J. Littleboy**
September 7, 2022

David Roberts asks for a link to the third algorithm.

Quanta was on it:

https://www.quantamagazine.org/quantum-algorithms-conquer-a-new-kind-of-problem-20220711/

19. **Masoud Kamgarpour**
September 8, 2022

Regarding credibility problems of physics with the public, I would say your concern is misplaced. The public has very short memory and are hardly going to remember what string theory did or did not promise 30 years ago. I mean we are talking about the same public half of whom believes that Trump had the highest number of spectators in his inauguration, amongst other absurdities…

As an outsider mathematician interested in physics, I would characterize the issue not as a lack of credibility but as disappointment. Creating hype about string theory led to many great young minds going into that direction only to find themselves lost after enormous amount of effort. We see many of these examples of former string theorists coming to the math departments and unfortunately, cannot accommodate many smart ones. One would hate to see history repeating itself now under the guise of quantum computing.

20. **Stef Roux**
September 8, 2022

A comparison between quantum computing and string theory is like comparing apples and oranges. While string theory has no connection with physical reality, there are already some quantum computers in operation. They are small and not very reliable, but there is no fundamental stumbling block to prevent them from becoming big enough and reliable enough to be useful. It will take time though. Most people in the field say it is still several decades.

There are more than just three algorithms for quantum computers. It is true that quantum computers are not suitable for all computing applications, but there is enough that they can do to make them useful.

So, while it is unfortunate that there is a lot of hype about quantum computing, it does not mean that it is not a viable technology. The challenges are significant but not fundamentally insurmountable.

21. **SRP**
September 13, 2022

The skeptical quotes about the private fusion efforts mainly come from publicly funded no-hope-for-practical-use project members. These self-licking ice cream cones have no urgency internally and a strong interest in denigrating more-innovative and more-focused private programs that might lead to questions about their own funding and progress. Outfits like TAE and Helion have been hitting milestones along well-defined research and development paths over a number of years. Perhaps their trajectories will hit a wall in their next-stage machines (currently under construction), but no obvious physics or engineering showstoppers have yet cropped up.

September 16, 2022

Me again. For an interesting perspective on the state of quantum algorithms see https://arxiv.org/pdf/2209.06930.pdf by Scott Aaronson. And yes, there are a lot more than 3 quantum algorithms.

It should also be pointed out that quantum computing is only part of the ongoing quantum project. You can buy off-the-shelf quantum crypto systems from established companies, and the Chinese have demonstrated quantum cryptography using a satellite link. There is also research into quantum networks, whereby one can send quantum rather than classical information. Research into enhancing the performance of sensors and sensor networks by using entanglement and nonclassical states of light (LIGO is doing the latter, though the original theoretical proposal is 4o years old) has been a long term project. All that said, there is still way too much hype in the field, and probably too many startup companies. On the other hand, from someone who has been in the field not from the beginning but from early days, from an intellectual point of view it has been a fun ride.

23. **Joseph Healy**
September 19, 2022

AI was vastly over-hyped in the 80's and much nonsense still surrounds the technology today. And while one might wish a different trajectory for quantum computing, hype like Michio Kaku's appears an embedded and inescapable facet of money chasing technology and technology chasing money.

From the New York Times:

The Nobel Prize in Physics was awarded to Alain Aspect, John F. Clauser and Anton Zeilinger on Tuesday for work that has "laid the foundation for a new era of quantum technology," the Nobel Committee for Physics said.

Some News, Then More of the Same

September 11, 2022
Categories: Multiverse Mania, Uncategorized

Some News:

I'll be in England later in the month, in Oxford much of the week of the 26th-30th. That week is the week of the 2022 Clay Research Conference and Workshops. The evening of Tuesday the 27th I'll be giving a public talk on Unified Theories of Physics, sponsored by the Oxford Centre of the Institute of physics.

The 2022 HowTheLightGetsIn festival in London was supposed to be the weekend of September 17-18, but has been postponed two weeks because of the death of the Queen. It's now scheduled instead for the weekend of October 1-2 and I'll likely be there, participating in a couple of panel discussions.

More of the Same:

I've written too much here over the years about the problems with multiverse theories. For short versions, there's also FAQ entries here and here, and a piece called Theorists Without a Theory I wrote for Inference. Seeing some recent things about this topic from people I generally agree with (e.g. here and here) leads to an uncontrollable urge to reiterate some of my arguments, so:

- You can't argue against the concept of a multiverse in general, dismissing unobservable universes. If you had a very successful theory based on ideas that simultaneously implied successful predictions about what you can observe, as well as unobservable parallel universes, you could get indirect evidence for a multiverse. The strength of this evidence would depend on the details of the theory, but it's logically possible that this could be strong evidence.
- Arguments pro or con about the "multiverse" that simultaneously engage with the many-worlds interpretation of quantum mechanics and inflationary or string theory landscape models are a waste of time. These are two completely different subjects, which raise completely different issues and have nothing to do with each other. For the rest of this I'll stick to the second subject, ignore the first.
- If you want to have a serious discussion on this topic, it should be about a particular model or well-defined class of models. One popular class is inflationary models. Here people often write down a well-defined model, but the problem is that it's a toy model (e.g. no SM fields, just gravity and a hypothetical inflaton field unrelated to any field for which we have a tested theory). Another popular class is the "string theory landscape". Here the problem is that you don't have a well-defined model. People who work on this work not with a well-defined theory but with a list of properties of a conjectured, currently non-existent, theory (e.g. "M-theory"). There's nothing wrong with doing this to see if you get interesting predictions about the world, which would give you some confidence in the existence of the conjectural theory. There is something seriously wrong with doing this if after decades of work you find that the list of properties you have is vacuous in terms of explanatory power.
- It's important to understand just how vacuous the "string theory landscape" class of models is. The problem is not just a measure problem on the space of possible universes, but much worse: one has no idea what this space is that you would like to put a measure on.
- "Pseudo-science" is an accurate description of "string theory landscape" research. People have complained to me that it is too harsh, should only be applied to activities of people who are abusing the good name of science for discreditable purposes. Doing something because you refuse to admit failure of a scientific idea you have a lot invested in seems to me a discreditable purpose.

Update: Joe Conlon is upset that I'll be speaking in Oxford. He objects to my credentials, but perhaps my views on his field of string phenomenology (which are shared by a large fraction of the physics community) might have something to do with it. I'm wondering if Conlon also complained about this recent Oxford speaker (video here).

Comments

1. **Sabine Hossenfelder**
   September 12, 2022

   Peter wrote: "If you had a very successful theory based on ideas that simultaneously implied successful predictions about what you can observe, as well as unobservable parallel universes, you could get indirect evidence for a multiverse. The strength of this evidence would depend on the details of the theory, but it's logically possible that this could be strong evidence."

   I do not know what it means for a theory to "imply" something that is unobservable, this is a meaningless phrase. Whatever you mean by it "implying" something, it is not the same as indirect evidence because there can be no indirect evidence for other universes.

   Indirect evidence means that you have a mathematical structure in your theory that is *necessary* to describe what you observe even though it cannot itself be observed (eg, the wave-function, or gravitational waves). The entire problem with the other universe is that because they are not observable you do *not* need them to explain anything you in fact observe.

   For this reason there is no evidence that you can gather for their existence, neither direct nor indirect.

   The assumption "unobservable universes exist" is unnecessary to describe anything we observe. That's it. You are claiming that this statement is wrong.

   Peter wrote: "Arguments pro or con about the "multiverse" that simultaneously engage with the many-worlds interpretation of quantum mechanics and inflationary or string theory landscape models are a waste of time. These are two completely different subjects, which raise completely different issues and have nothing to do with each other. "

   In both cases physicists mistakenly believe that someone which is unobservable exists and fail to acknowledge that this existence is a superfluous assumption which is hence not scientific.

2. **Will Sawin**
   September 12, 2022

   @Sabine Probably our host does not want us to discuss the many worlds intepretation.

   However, it is easy to imagine a theory that has the same relationship to the multiverse as the theory of the quantum wave function has to MWI, and we can discuss this hypothetical theory instead.

   Suppose we had a theory which precisely defined a space X, with points of the space corresponding to different effective field theories or different values of the physical constants, and gave an evolution rule for a function f on the space X which can be interpreted as the density of universes with those laws of physics (for example a form of "cosmological natural selection"). Furthermore, one could calculate the likely behavior of the function f, and find that it concentrated on physical theories matching our own observations. (Or to avoid retrodiction, one could even imagine that the fundamental constants of physics in our universe were observed to change slightly over time, and this theory was capable of predicting that change via a flow on the space X.)

Supposing we had such a theory, it would seem reasonable to me to refer to the points of the space X as distinct universes, which the theory describes the dynamics of.

3. **Low Math, Meekly Interacting**
September 12, 2022

I'm with Dr. Hossenfelder on this, at least to the extent my grasp of the philosophy allows. It's one thing to say your equation has, e.g., two solutions, one of which fits an empirical observation. It's quite another to say the other possibility is "real". One possibility that I'll never observe is myself writing something about this without feeling the need to use scare quotes. Any kind of multiverse which must deny contact with experiment for any other part of the ensemble seems simply to fall on the other side of the line of demarcation. Why are we forced to acknowledge the other solutions "exist"?

That's my biggest beef with the Everettians. Why is it so intellectually dishonest or lazy to simply dismiss my "other selves" with a shrug, or view them as artifacts with no scientific relevance. I suppose it forces me to insist that science is ultimately an empirical discipline, but that's a hill I'm willing to die on.

4. **Peter Woit**
September 12, 2022

Will,

Yes, please don't try and start a discussion of MWI. To my mind at least, the issues there are quite different (QM is a well-defined theory, for one thing, and MWI enthusiasts often say their claim is just that all you need is QM).

However the scenario you describe is closely related not to MWI, but to the string landscape. My main problem with this scenario is just that it's a hypothetical that has nothing to do with the current state of theory (no one has anything like the kind of theory you postulate). I see no point in arguing about a failed theoretical idea by starting with "assume the kind of theory desired exists and is completely successful".

Sabine can answer you if she wants. I'll write another comment related to yours.

5. **Engineer**
September 12, 2022

I took "imply" to be mathematical/logical imply =>. My understanding is that GR mathematically describes what goes on just inside the event horizon of a black hole. I would say GR implies what is going on there, and it is not observeable to us. It would be fair to me to say all the evidence supporting GR is indirect evidence of what is going on just within the event horizon.

6. **Peter Woit**
September 12, 2022

Sabine (and LMMI),

Different people think about this differently, here's my take:

A fundamental physical theory is a model (expressed of necessity in the language of mathematics) which comes with a way to relate some of its elements to experimental observations. This last feature allows the model to simultaneously explain what we observe and be tested (if it says we should observe X and we observe not X, it is wrong).

A good theory is one that is simple, and based on few assumptions, from which flow many non-trivial predictions about what we will observe, predictions that can be and have been checked. The ratio between information out and information in is very high.

A bad theory is typically one that starts out simple, but makes wrong predictions. You can fix these wrong predictions by making the theory more complicated, but what you end up with is something useless: information out is just reprocessed information in, you are learning nothing new from such a theory.

Applied to the multiverse issue, I see no argument of principle that you can't find a very good theory with elements that correspond to our observations and have been successfully checked, but also other elements that don't. If a model is simple and highly successful, and non-observable elements are closely linked in its structure to tested, observable elements, it would be reasonable to say that one has evidence that the non-observable elements exist.

You can argue that elements of a model that cannot be tested by observation should just be cut out of it (characterized perhaps as "mathematics, not physics", or "unscientific"). But I can also take the attitude that what's important is how good the model is, and a good model can consistently contain observable and unobservable elements, it just has to have a convincing explanation of what you observe and what you don't.

What's really important to make clear is that the deadly problem the string theorists have is a very conventional one: they have a bad, failed model. They're trying to wriggle out of this inconvenient situation by invoking non-existent successful models and getting people wrapped up in arguments of principle over those. Best to not do this since it's besides the point, a waste of time, and accomplishes what those with failed ideas want: obfuscating the fact of their failure.

7. **martibal**
September 12, 2022

Peter: from the history of physics, do you have any example in minds of such non-observable predictions that would comes from the mathematical structure ?
.
For instance in GR the mathematical structure (space-time is a curved manifold) yields only observable predictions that, indeed, made the theory successful (binding of the light, redshift etc). Even the effect that at the time seemed unobservable (gravitational waves, black holes) are nowadays observed.

I would say the same holds true for gauge degrees of freedom. They may well be classically unobservable, but lead to some quantum effect.
.
How can one claim that a mathematical structure needed for the coherence/beauty/simplicity of the theory is forever unobservable ? Negative numbers (as I read, don't remember where) where invented just for the convenience of calculation, but they were denied of any meaning: what sense would it make to give meaning to something which is less than nothing ? Well, today negative numbers are very concrete, to anybody who has ever experienced a deficit on one's bank account 🙂
.
But if something that is now unobservable might become observable one day, then I find it misleading to call it "multiverse". It is just a part of our universe that at the moment is not accessible to our experiment.

8. **Peter Woit**
September 12, 2022

martibal,
I don't think issues of mathematics have anything to do with this, other than the fact that mathematics is the language you use to write the theory down. There are all sorts of issues about how this language describes elements and relations of the theory, and how you get from elements of the theory to experimental observations (the LHC detectors are not measuring the values of quantum fields…). But they're besides the point I'm trying to make.

What I'm talking about is the possibility of a model having elements that are a fundamental part of a model's structure (independent of how you write this down), but not accessible to experiment. I can't think of a good historical example, maybe there aren't any. But again, arguing over this abstractly is besides the point, so I'm not interested in trying to come up with examples and do so. The string theorists point to a logically possible class of models with this characteristic. I don't think they're wrong that these are logically possible, the problem is that all attempts to construct a model in this class which is consistent (mathematically and with observation) have failed utterly.

9. **Marvin**
September 12, 2022

Martibal

You are asking Peter: "from the history of physics, do you have any example in minds of such non-observable predictions that would comes from the mathematical structure ?" Then you mention " for instance in GR the mathematical structure …… yields only observable predictions……"

A good answer for you will be the Godel solutions to GR equations. Essentially, they are mathematically feasible, but they show "time looping" that was never observed!

Your question look trivial, but in fact it is at the core of any sustainable theory: how nature select in the general mathematical landscape this equation and not any other?

.

10. **Will Sawin**
September 12, 2022

@Peter Woit,

Well, if people disagree with your claim that "If you had a very successful theory based on ideas that simultaneously implied successful predictions about what you can observe, as well as unobservable parallel universes, you could get indirect evidence for a multiverse" by saying it's impossible that a theory could imply unobservable parallel universes, I don't think it's possible to respond without sketching in more detail what a theory that implies unobservable parallel universes to look like.

I did indeed intend it to be similar to a potential version of the string multiverse theory, although it's also a bit inspired by some other things.

@LMMI The issue is not just that an equation may have two solutions but that there is some dynamics involving multiple universes that (indirectly) makes predictions. You can't just drop some of the universes in this scenario any more than you can drop some elements of any other dynamical system and get an equivalent system.

Of course no one is forced to believe anything and you can always deny the existence of whatever you please, but if theories of this type ever make solid predictions and do better than competing theories, any kind of consistent principle that denies the other universes will also have to imply that stars stop existing when they get far enough away from us and silly things like that.

11. **Low Math, Meekly Interacting**
September 12, 2022

I'm not advocating for "dropping" something so much as acknowledging a certain state of ignorance about its "existence". Do I conclude "it's as if there was another universe" or "there is another universe"? However unavoidable the question, I'll never be able to settle the matter empirically. Hence my bias is to say that's not a scientific question.

12. **Scott Aaronson**
September 12, 2022

I mean, like, I accept the theory of object permanence — the theory that the stuff in back of my head continues to exist, that it doesn't disappear and then reappear when I turn around — even in situations where I can't use mirrors or cameras or any other mechanism directly to confirm the stuff's continued existence. I accept this theory purely on the basis of its simplicity, even though it postulates the existence of entities that (by definition) are unobservable in principle to me at the relevant times.

13. **David Roberts**
September 12, 2022

> simultaneously engage with the many-worlds interpretation of quantum mechanics and inflationary or string theory landscape models

Or, worse, simply call radically different things 'the multiverse', one of which is literally our universe past the cosmological horizon, and one of which is the strongest possible Platonism, ascribing physical reality to every logically consistent mathematical structure.

[I rechecked the WP article to see what it said about various people's multiverse classifications, and ideas like "Given infinite space, there would, in fact, be an infinite number of Hubble volumes identical to ours in the universe." really just trigger me, as a mathematician. Thus stuff needs citations to outright mathematical criticism.]

14. **martibal**
September 13, 2022

@Marvin: Goedel solution is usually put apart because, besides the equation of general relativity, one takes into account in the description of nature some causality requirements, that seem incompatible with the existence close timelike curves. This is not as if there were a landscape of solutions to Einstein equations, all equally physically relevant, and for some unknown reason nature selects one or the other.
.
Then one may discuss if these causality requirements are legitimate (for instance, putting causality aside, is it possible for an extended body to have all its point following close timelike trajectories ? If not, then is this really a causal problem if an elementary particles follows a close time like curve ? etc). It might even happen than in the future, one finds some situation in which Goedel solution makes sense. But this does not mean that in our universe Goedel solution is excluded, and it exists in some "multiverse".
.
It is a bit like Dirac equation: energy was not supposed to be negative but if, in a precise mathematical sense, one takes solution of Dirac equation of negative energy, then one discovers antimatter. This does not mean that matter lives in a universe, and antimatter lives in another one.

15. **martibal**

September 13, 2022

@Peter: I agree with your view on string landscape (it is inconsistent both with experiment and from the mathematical point of view). I am just a bit puzzled by your disagreement with Sabine.

Maybe this is just a matter of vocabulary, whether one intends by "multiverse" the elements of a theory that cannot be directly observed (for the moment, but with no certainty that they may not become observable in the future) or another "reality" which, by definition, has not any possible interaction with our universe.
.
Yet, I do not find innocent that string's hype use the word "multiverse". It is again a way to oversell the theory using some "sexy" terminology: the "tiny little vibrating strings that describe everything" are now replaced by "a landscape of possible universes". This is far more appealing to the public than twistors or noncommutative algebras. Pointing this out, as Sabine does, does not seem to me so useless.

16. **Peter Woit**
September 13, 2022

martibal,
Just to make clear my problem with the string landscape: it's not that it's inconsistent with observation or mathematics, it's that there is no theory. People insist on talking about this subject without noticing that the "theory" they are talking about is nothing more than some hopes and dreams adopted by a group of people as a tactic to avoid admitting that a specific research program has failed utterly. My main disagreement with Sabine and others is that they argue as if there is a theory, engaging in arguments about what is "real", what is "unscientific", what is "ascientific" etc., etc. which are completely besides the point. If you argue about this kind of thing, there's no right answer and it completely obfuscates what is going on, and lets the people doing this get away with it (and "it" is convincing people unification is hopeless, and salting the ground so that no one will ever try again).

For more along the same lines of what I'm disagreeing with, this morning there's a tweet from Will Kinney
https://twitter.com/WKCosmo/status/1569647758604124163
"This gets multiverses exactly right: they arise naturally out of the math, but there is no way — even in principle — to know whether or not other universes exist."
He's referring to certain specific models of inflation, which have nothing to do with the string theory landscape models where you get different physics in different universes. People really need to make substantive arguments about specific models, not empty statements covering all sorts of completely different sorts of theories.

Also, not a big fan of bringing "math" into these empty arguments. The sort of math used in these models is very basic college-level stuff. Referring to "math" this way is a bit like if whenever I discuss anything with anyone, I make a big point of going on about how they are using "English", as if that were relevant to their argument.

17. **Thomas Schaefer**
September 13, 2022

Consider the EW phase transition in the standard model. The SM is sufficiently well established that nobody would seriously argue with the statement that this transition took place in the early universe (people might argue about the details). However, it is unlikely that any super-advanced civilization will ever observe the transition in the laboratory (the energy density is 10^8 times higher than the critical energy density of the QCD transition, and the energy density created in pp or heavy ion collisions only grows very slowly with the beam energy in a collider, roughly like the inelastic cross section log(E)^2).

We could imagine that the SM predicts (it does not — but it could have) that the transition produces domains in which the strength of the weak interaction differs. I would be prepared to consider this as a multiverse scenario, one that does rely on well established physics.

18. **Peter Woit**
September 13, 2022

Thomas Schaefer,

Thanks, that's a good example of how one might have a well-tested theory that implies unobservable regions with different physics.

This inspires a different example of the point I'm trying to make. One can in principle imagine "brane-world" scenarios in which at LHC energies one could excite brane degrees of freedom that would decouple from our brane as a separate stable brane. Suppose one started doing these experiments and saw exactly what the theory predicted, including phenomena corresponding to exactly what one would expect to see in such a decoupling event. Should one say that such decoupled branes don't "exist" and any reference to them or their properties is "unscientific"?

19. **Low Math, Meekly Interacting**
September 13, 2022

I'm inclined to think there's an important distinction between assuming something empirically manifest continues to exist when I'm not looking at it, and assuming something I never observed and can never be observed, ever, does. I don't find conflating such things to be persuasive enough, but I do admit those who do have a point.

20. **Joseph Conlon**
September 14, 2022

Kaku has become a crank (the one good thing about him writing books about quantum computing is that he is not writing them about string theory). I wasn't aware of his talk at the Oxford Union; the Oxford Union is an undergraduate student debating society (albeit one with a long and notable history) with a reputation of inviting controversial speakers, mostly on politics, and no one looks to the Oxford Union for guidance on the state of theoretical physics.

You are not a crank and I enjoy reading your blog. I do (obviously) think you wrong on the scientific substance, and, yes, do not think the UK's professional society for physicists should be presenting you to the public as a scientific authority on unification (and the level of research activity does indeed feed into this view). (But, also, as I said elsewhere, I am strongly against rescinding invitations once made.)

But there is nothing personal to this; your views are well known and while I think them wrong and misguided, they are always expressed in reasonable, if direct, language. I'd be quite happy to meet for coffee or something similar when you are in Oxford, let me know if interested.

21. **Peter Woit**
September 14, 2022

Joseph Conlon,

Thanks for the comment! I'll contact you privately to see if we can find time to meet up when I'm there, I would enjoy doing that.

I'm in the middle of preparing that talk, it will mostly be things that much if not most of the theoretical physics community would agree with (even the skepticism about string theory unification). At the end there will be something about my own recent ideas about unification, with warning labels these are speculation not now vetted by the community. Some of this will be about a fundamental role for twistors, which should be less controversial in Oxford than anywhere else in the world.

22. **jack**
September 14, 2022

Good to see a cordial exchange here between JC and PW. However I'd like to suggest, with all due respect, that JC is on rather shakier ground relative to PW than he seems to suppose. If fundamental physics has been stuck for a generation, who contributes more: one whose wheels spin at high speed (=copious "research output") or one who tries to show that the spinning is idle? This is science, not history, so we can't say definitely and for all time that the spinning *is* idle. But we also can't say – and given recent history really shouldn't say – that the spinning *isn't* idle. This is so despite what is surely a very strong tendency among wheel-spinners (if that's what they are) to regard what they do as progress. This suggests two very different kinds of interest: that of "active researchers" in a specific research program, and that of practitioners more generally who believe that the research program is a failure. Even if PW weren't proposing to share speculative ideas in fundamental physics at Oxford but only a critique of what he takes to be a failed research program, those who think of themselves as contributors to the program would do well to receive him not just cordially but modestly.

23. **Joseph Conlon**
September 15, 2022

"If fundamental physics has been stuck for a generation, who contributes more: one whose wheels spin at high speed (=copious "research output") or one who tries to show that the spinning is idle?"

`If" is having carry quite a lot in this sentence: certainly, *if* fundamental physics (or anything else!) is headed down a dead end, there is no credit for continuing to drive in that direction. But, generally, my view of the history of theoretical physics is that everyone should be rather humble about their ability to judge good ideas and dead ends on timescales much less than a couple of decades, and in many cases much longer than that.

And I never really get why people think string theory is an example of failed program (as I describe in my book, it has delivered too much to many different areas). To me, the highway which really is littered with the corpses of dead and never-to-be-resurrected ideas is that of BSM model building.

24. **Pedro**
September 15, 2022

Peter Woit,

Have you ever written down your thoughts on MWI? I would be curious to know.

25. **Peter Woit**
September 15, 2022

Pedro,
I don't remember exactly where I wrote about this. If you look through the blog postings in this category
https://www.math.columbia.edu/~woit/wordpress/?cat=21
you'll find various places where I wrote something.

I don't want to start a discussion here, but a quick thing to point out is that MWI proponents don't have any new equations or new theory, they say just use the standard Schrodinger equation. They argue that talking about a multiverse solves interpretational problems, but to me this just is verbiage that doesn't address the difficult underlying questions, which really are about how to understand the physics of how classical behavior and our picture of a classical world emerges from the quantum theory.

26. **Alex**
September 16, 2022

Peter writes

"… and lets the people doing this get away with it (and "it" is convincing people unification is hopeless, and salting the ground so that no one will ever try again)."

That may be one possible angle. But lately I have been wondering that, while perhaps not hopeless on scientific grounds (although that's open to debate), it seems hopeless to me in terms of how the community reacts, the particle physics community in particular. They seem to have very rigid preconceptions on how unification should work and be done. If your theory doesn't meet that, then they will ignore you. A case study for me regarding this has been Connes' spectral standard model. It's a purely geometrical unification of all forces and even the Higgs field into a single framework and action functional. The early versions had many problems, but the current incarnation is quite good. My point is not to do propaganda for this model, but it's quite remarkable how little attention it receives from that community. My feeling is that this is because the unification is classical (and then unification doesn't seem to solve the non renormalizability of gravity) and that no new, beyond SM particles/fields are predicted at higher energies (maybe only one more at most). These two things go against core traditional beliefs in the community on this topic since many decades.

So, it seems to me that, even if you are Connes, Fields medal etc., unification is hopeless. What's left for us common mortals, then? Unification seems hopeless because the particle physics community is making it so. It's not even the science what is counting here. Maybe that's one of the reasons nobody will ever try again, why bother? Nobody will listen to you. I'm very pessimistic, to be honest.

27. **The Angry M-Theorist**
September 16, 2022

>>People insist on talking about this subject without noticing that the "theory" they are talking about is nothing more than some hopes and dreams adopted by a group of people as a tactic to avoid admitting that a specific research program has failed utterly.

Seriously, Peter? We *do* actually have a nonperturbative string theory—not a set of "hopes and dreams", but a complete theory. AdS/CFT tells us that string theory on anti-de-Sitter space is dual to N=4 Super-Yang-Mills. I see holographic dualities every single day in my research, and that's actually how I *define* non-perturbative superstring theory on that background—the dual to the superconformal field theory. It's clear that you're still living in the 1990s, unwilling to accept, or even unaware, of the enormous progress in understanding the nonperturbative behavior of string theories enabled by holographic dualities. We have a theory now, Peter.

And as somebody who is so enthusiastic about the Standard Model and QCD, I'd imagine you'd be ecstatic about the enormous progress in understanding the nonperturbative behavior of QCD that has been enabled by string theory and AdS/CFT and similar dualities. Surely that progress in understanding QCD is more than enough to justify this research project. But I guess you'd rather stick your head in the sand than admit defeat.

28. **Peter Woit**
September 16, 2022

The Angry M-theorist,

A major failed hope and dream is that AdS/CFT has anything to do with the real world (it says nothing about 4d string vacua that would give the SM + gravity).

This kind of anonymous comment is word for word the kind of thing I got a lot of nearly 20 years ago. Back then I wasted too much of my time trying to have serious discussions with such commenters. Now I'm a lot older, and somewhat wiser…

29. **The Angry M-Theorist**
September 16, 2022

Okay, Peter. Let's talk about the landscape. It's extremely frustrating to me that you, and the other folks in this thread (Sabine, etc.) keep harping on this point that the landscape of string vacua furnishes no predictive power. The opposite is actually true. Statistical surveys of string vacua have made predictions about particle masses borne out by experiment. We aren't at the point yet where we can predict precise ranges of physical constants from statistical arguments about string vacua, but we HAVE made predictions confirmed by experiment. This is not my research area, but I invite you to read this excellent review article

https://arxiv.org/pdf/2202.11578.pdf

Examining vacua compatible with KKLT moduli stabilization, the authors construct a distribution of SUSY masses and discover that sparticle masses are likely beyond the reach of the LHC. Thus, the fact that the LHC has not yet found SUSY is, in fact, resounding experimental confirmation of the KKLT landscape of string vacua. It's hilarious to me that you keep yapping here on your blog about the LHC "not finding SUSY." while that's actually the biggest piece of experimental evidence for string theory and the KKLT landscape we have.

30. **Peter Woit**
September 17, 2022

The Angry M-Theorist,
This really does take me back. The problem with anonymous comments like yours is that it's impossible to tell whether the commenter is a troll or an idiot. So, at some point I just started deleting all these things. Will revert to that policy now.

31. **Paolo Bertozzini**
September 19, 2022

@Alex (16 September)

I find the remarks, especially those regarding Connes' approach, inspiring and deserving some further discussion, so please forgive me if I am going a bit out of topic here.

First of all, I would like to point out a nice interview of Alain Connes in chapter 6 of the relatively recent book "Conversations on Quantum Gravity" by Jay Armas.

There (at the end of page 139) in the discussion on the discovery of the mathematics underpinning the renormalization process, we find the following sad and disillusioned statement:
"These breakthroughs were enough for me to come to terms with my discontent with the method used by physicists. The sociological fact that they have not been understood by physicists nor are they part of their general knowledge is totally unimportant to me."

One might of course imagine that all of non-commutative geometry has been receiving the same cold reception by the community of theoretical physicists for very similar reasons (lack of ability to appreciate the mathematical details) … for sure, the initial failed prediction of the Higgs mass (coupled with the usual "Popper nonsense" about crucial experiments ditching entire theories) has been easily exploited by the "mathematically lazy" … but there might be a few other factors involved here.

While, in one way or another, string theory or loop quantum gravity have been claiming from the very start to propose fundamental theories of physics solving both (ST), or at least one (LQG), of the unification and the quantization of gravity problems, non-commutative geometry (apart from rare exceptions, for example Jesper Grimstrup's attempt) has been less assertive, more humble in goals and has almost never been considered, even by Alain Connes himself (private conversation in Cargese 1997), as an approach dealing with foundations of quantum gravity: the spectral triples of Connes' standard model are supposed to be a description of geometry only at the (Euclidean) "classical level" (see page 152 of the interview), to be further subject to "second quantization" and "renormalization" treatments, in exactly the same way and with exactly the same issues as any other classical field theory undergoing quantization.
Hence it is not surprising that talks and contributions in non-commutative geometry often appear in the "phenomenology" section of physics conferences, where people consider "approximate models".

My (wrong?) feeling is that the possible fundamental nature/meaning of "(non-commutative) geometry in a fully covariant" field theory context is left unexplored also because of some current deep ideological impasse: when all of the quantum gravity communities are in perfect agreement on the "emergent nature of space-time geometry" (and the lack of meaning of geometry in a fundamental theory) and somehow even Alain Connes himself does not dare to question such dogma
[quoting for example from page 140 and the mid/end of page 149 of the previously mentioned interview:
"I find it quite an ill-conceived idea that one could quantise gravity as one quantises all other fields because I don't believe that geometry makes any sense, say, above the Planck energy. This belief is shared by many people. I think that in the same way that the Brout-Englert-Higgs particle emerges from symmetry breaking [16, 17], the actual geometry of spacetime also emerges from symmetry breaking and does not make sense beyond a certain energy level. One of my leitmotifs for developing non-commutative geometry has been to try to understand how geometry can actually emerge from purely Hilbert space considerations."
"In particular, we have to imagine a more fundamental theory in which the geometry doesn't make any sense beyond the Planck scale but appears out of spontaneous symmetry breaking when the temperature is lowered."
"So my belief is that there is an enormous symmetry which is the symplectic unitary group; this symmetry is spontaneously broken and only then the geometry emerges. This is one possible scenario and if it holds it shows that it is vain to try and quantise gravity in a given geometrical background in which case one is quickly confronted with the lack of renormalisability, since at sufficiently high energies the geometry itself will have totally disappeared."]
… there seems to be little space left to propose variations to the common narrative in which non-commutative geometry is just taking the place of classical geometry in some mid-low energy emergent scenario adding "corrections" to usual treatments, rather than conceptually changing the panorama.

Of course, the "emergence of geometry from Hilbert space" has also a much deeper meaning, where "emergence" stands for a new "spectral approach" to geometry (but then a full spectral theory of non-commutative algebras is still missing and taking the usual "dual" point of view, shifting focus on algebras, … seems to be not enough to give a clear meaning to geometry in quantum gravity).

Best Regards (sorry for the long post) 😉
Paolo

32. **Guy in CS**
September 19, 2022

"Arguments pro or con about the "multiverse" that simultaneously engage with the many-worlds interpretation of quantum mechanics and inflationary or string theory landscape models are a waste of time. These are two completely different subjects, which raise completely different issues and have nothing to do with each other."

What about this paper, Peter, which suggests otherwise (i.e., that the MWI and eternal inflation are somehow related?)

https://arxiv.org/pdf/1105.3796.pdf

Does this offer you any great insight into how classical behavior emerges from quantum? Or into inflation?

33. **Peter Woit**
September 20, 2022

Guy in CS,
Waste of time applies. I've never heard of anyone who thinks that makes any sense.

34. **Anonymous Theorist**
September 20, 2022

"I've never heard of anyone who thinks that makes any sense."

What about Leonard Susskind and Raphael Bousso? Presumably they think the idea makes sense? And presumably you've heard of them?

If you've identified flaws in their reasoning, perhaps you could bring that up with them, rather than categorically rejecting their work as "nonsense."

By the way, Bousso has over 8,000 citations, and Susskind over 39,000. So I find it hard to believe that, working together, they would write something that makes no sense to anybody.

35. **Peter Woit**
September 21, 2022

Anonymous Theorist,
The "Multiverse Interpretation" paper was eleven years ago. If you can find a recent article by anyone (including Bousso-Susskind) that explains this in a comprehensible manner and makes a compelling case that it is not nonsense, please provide that rather than citation counts.

I recall a comment from Steven Weinberg somewhere that he could make no sense of this. Weinberg was more polite, less polite was Lubos Motl, who wrote "they're on crack", see

https://www.math.columbia.edu/~woit/wordpress/?p=3723

36. **Anonymous Theorist**
September 22, 2022

Peter,

A couple points.

1. Please think about the way your attitude here would affect a vulnerable young graduate student or a postdoc who's trying to make it in the competitive environment of high-energy theory. When they see a professor like yourself trashing others' work, calling it "nonsense"—the work of physicists with tens of thousands of citations under their belts—won't they be afraid that the established professors would trash their own unorthodox ideas even more? Graduate students and postdocs need to feel like their potentially unorthodox theoretical contributions will be welcomed, rather than trashed as "nonsense." You are really doing a disservice to the community with this kind of language. Again, point out a specific flaw in Susskind's reasoning rather than categorically condemning his idea.

2. If there's one thing I can't stand, it's hypocrisy. You claim that string theory is "not a true theory." There's a complete theory for perturbative superstring scattering amplitudes on flat ten-dimensional spacetime, but no complete "theory" that would tell us about the moduli space of four-dimensional string vacua. It's true, there is only the conjectured "M-Theory," and we don't yet have a handle on what the degrees of freedom are for that theory (although we have some ideas). But if that's your central criticism of the string research project, I could EQUALLY WELL say that about your "unification theory," Peter! Your so called twistor unification of gravity and the standard model is a joke. It's manifestly background dependent. In fact it's all on flat spacetime. The twistor geometry here only tells you about flat Minkowski spacetime. The Penrose-Ward transform here only tells you about conformally invariant wave equations on Minkowski spacetime. You're examining quantum fields on flat four-diemsnional space. So when you claim that you have a theory of "quantum gravity" and the geometry is organized around flat Minkowski spacetime with the fixed background, it makes me laugh. How can you attack string theory when your own unification theory only works on a flat Minkowski background?

37. **Peter Woit**
September 22, 2022

Anonymous theorist,
I think you're doing much greater damage to young theorists by insisting that the way to evaluate theoretical ideas is by counting up the citation numbers of the authors, and that authors with high citation numbers cannot possibly be writing nonsense. If you think the Bousso-Susskind multiverse interpretation should be taken seriously, explain why or point to such an explanation. It's not my job to write out detailed explanations of why some particular piece of nonsense that no one is paying attention to is nonsense (despite the author's citation numbers).

About string theory, the problem is not that it's an incomplete theory, it's that everything that is known about the theory points to it looking nothing like the real world. You can only get the real world in a very complex and poorly understood way, and it looks like if that works you could get anything you want the same way.

About my own ideas, they're definitely much more incomplete than string theory. I'm enthusiastic, continuing to work on them and in the middle of writing up more. And no, what I'm trying to write down in more detail is not a theory of flat space-time. Gravity is included in a chiral version, the sort of thing Ashtekar and then the LQG people have worked with, with some differences (including working in Euclidean signature). But, this is really off-topic here, and given that you evaluate ideas based on citation counts, I'm clearly not going to get anywhere with you.

Oh, and also, I'm currently on vacation in one of the most spectacularly beautiful places I've ever seen, in the Lake District of England. So, shouldn't be spending time on this anyway…

38. **Felix**
September 22, 2022

Speaking of hypocrisy:

Anonymous Theorist, point 1: don't trash other people's unorthodox ideas, as it might discourage others

Anonymous Theorist, point 2: Peter Woit's unorthodox idea is 'a joke' and 'makes me laugh'

39. **Sam**
September 22, 2022

"I could EQUALLY WELL say that about your "unification theory," Peter!"

Some red flags from Anonymous Theorist tells me to leave well alone:

1) Presenting arguments in ALL CAPS.
2) Using "quotation marks" to undermine others work.
3) Attacking others work instead of defending your own position.

Enjoy the Lake District. It is a beautiful place 🙂

40. **Peter Woit**
September 22, 2022

Felix/Sam,
The problem with anonymous comments like that one is that I honestly can't tell whether they're written seriously, or whether they're written by a troll trying to discredit string theory (and waste my time…).

41. **martibal**
September 22, 2022

@anonymus theorist: String theory has been involving thousands of people, for many years, it has spread into common culture thanks to lies ("the idea is very simple: the world is made of tiny little vibrating strings"), trying to impose itself by intimidation ("the only game in town", "no other approaches to quantum gravity is viable") and claiming to absorb other ideas in a strongly dishonest way ("non commutative geometry is just the geometry of string theory" "Connes model are the low energy limit of string theory"). So please keep a low profile regarding hypocrisy and any other moral qualities.

Regarding Peter, your attitude makes me think of those heterosexuals that complain about the gay pride and want an heterosexual pride: as far as I know, no kids have been kicked out from home because straight. As far as I know, Peter's idea are not studied in the most reknown institute, receiving large quantity of money (how many breakthourghprize to twistors ?).

And please, don't pretend to take care of young people's future. If you were really concerned with this, then you would urge young people to have a critical view on strings and not to listen to propaganda.
Some years ago I have heard Vaffa at ICTP in Trieste, followed by Connes. Vaffa's propaganda in front of students that, most likely, could not know the real state of the art of the field was a shame.
But at least he put his face.

42. **Topologist Guy**
September 22, 2022

Peter,

For what it's worth, I'd put money on "anonymous theorist" being an actual theorist and not a troll. They clearly have some technical knowledge about string/high-energy theory. If they are a troll, they're probably somebody in the hep-th community and not a random layman. It seems to me that a genuine internet troll would be more interested in stirring up culture war nonsense than, say, wasting the time of a moderately well-known physics blogger.

Anyway, the arguments here are almost nostalgically reminiscent of the 2000s era string wars. A blast from the past, as it were.

43. **Anonymous nontheorist**
September 23, 2022

Peter,
A troll or not a troll, it is actually these kinds of heated arguments that make your blog more interesting than others. Please keep replying wisely to these kinds of attacks from arrogant people.
Btw, I find the citation count for judging the value of others' works an extremely interesting topic (Susskind himself used it in one of his arguments against Smolin). Why don't you devote a whole entry in your blog just for this citation count issue? It is at the root of the socialogy that led to the present crisis in high energy physics.

44. **Peter Shor**
September 24, 2022

@Anonymous Non-Theorist:

It seems to me that citation count is close to useless when you have a faddish area (high-energy physics) some of whose leading practitioners are producing vacuous papers which it seems everybody feels compelled to cite anyway, because otherwise they might upset these practitioners, something which they fear would negatively impact their careers.

Mathematics is much better off — when Michael Atiyah announced his proof of the Riemann hypothesis, most mathematicians paid no attention to it.

45. **Anonymous nontheorist**
September 24, 2022

Thank you Peter Shor!
Your point raises another interesting topic which is: why socialogy works in high-energy physics, but does not in mathematics. That's why I asked Peter to open a new thread in his blog for this citation issue because it's a rich (but off) topic. I remember Peter promised once in this blog to dedicate a post to the difference between math people and physics people and how can one be both. So maybe he could include in that topic this citation issue as well 😉

46. **Nick**
September 25, 2022

Re Peter's early comment beginning: "Sabine (and LMMI), Different people think about this differently, here's my take: …"

(First-time reader here.) This is one of the best short statements I've come across of how theories-models-observations relate, and what counts as evidence, in any scientific inquiry. So, thanks a lot Peter!

Do you (or others who are sympathetic) have any recommendations for longer no-nonsense elaborations of this particular "take" on these epistemological issues. (I know they have been discussed endlessly over centuries, just asking if there is any article, book, or blog post that someone thinks is especially good/worth reading). Thanks!

47. **Adam Treat**
September 26, 2022

Scott Aaronson, the point is that when you accept such a theory you are doing philosophy (however reasonable and "obvious" you might think that philosophy is!) rather than science.

48. **Pascal**
September 28, 2022

Adam Treat: not quite. It follows from accepted physical theories such as Newtonian physics that the back of my armchair continues to exist even when I do not lean against it, or look at it. You may try to cook up a physical theory in which the back of the armchair disappears, but it's simply not the theory that's in physics textbooks. Asking what are the consequences of a given physical theory should still be called science (armchair science?) rather than philosophy, in my opinion.

Something about England

September 27, 2022
Categories: Uncategorized

Heading to Oxford today, this evening I'll give a talk there on Unified Theories of Physics. On Saturday I'll try to find some way to get to the HTLGI Festival in London despite a national rail strike, where I'll give a talk on Saturday and be on two panel discussions Sunday.

I'll post slides after the talk tonight, one theme of which will be the failure of a series of attempts to extend the Standard Model, all of which were started in the mid-1970s (GUTs, SUSY, string theory). An opinion piece by Sabine Hossenfelder appeared yesterday in the Guardian, which takes a similar point of view on the current fate of extensions of the SM, but I strongly disagree with a lot of what she has to say.

The bad theory activity she points to has been going on for decades, but in recent years it seems to me to be a lot less popular. Most influential theorists have (quietly) agreed with her that particle physics is dead. In attacking bad model building in particle physics, I think she's going after a small group of stragglers, not the center of theoretical activity (which has problems much more worth discussing).

What I most disagree with her about though is her treatment of HEP experiment and experimentalists. Yes, one can find people who have used bad theory to make bad arguments for building a new machine, but I don't think those have been of much significance. For more on the current debate about this, see here. At the present time though, no one is spending money on building a new energy frontier machine any time soon. Money is being spent on running the LHC at high luminosity (CERN) and studying neutrinos (US), as well as studying the possibilities for going to higher energy. All of these activities are valuable and well-justified.

The LHC has been a huge success so far, with the old claims that it was going to see extra dimensions an embarrassment which doesn't change the science that has happened. The discovery of the Higgs was a huge advance for the field, and the on-going effort to study its properties in detail is important. Another huge advance for the field has been the careful investigation of the new energy range opened up by the LHC, shooting down a lot of bad theory. Pre-LHC, the most influential theorists in the world heavily promoted dubious SUSY extensions of the SM, making these arguably the dominant paradigm in the field. LHC experimentalists have blown huge holes in that bandwagon, in some sense by doing exactly what Hossenfelder complains about (looking for evidence of badly motivated theories of new particles). In this story they're not the problem, they're the solution.

I'll be busy this week with the talks mentioned and with attending math talks in Oxford, so little time to discuss more here or do a good job moderating a discussion. So, behave.

Update: The slides from the Oxford talk are here.

Update: Sabine has a blog entry more carefully explaining her point of view here.

Update: Some coverage of this at Physics World.

Update: More discussion of this from Ethan Siegel here, response from Sabine here.

Comments

1. **Sabine Hossenfelder**
   September 27, 2022

   Peter wrote:

   "Most influential theorists have (quietly) agreed with her that particle physics is dead."

   I am not concerned with "most influential theorists" (in particle physics) but with "most theorists" (in particle physics). That is, I'm concerned with the 99.9% that make up the big bulk. You are referring to the 0.1% at the top, ppl who are swimming in grant money and can do whatever they want. I can only guess, but quite possibly the sample of people you personally get to meet and talk to is strongly biased towards the top.

   The problem with those 0.1% is that, as you say correctly, they have been very quiet when instead they should have been pushing for the systemic change that is badly needed.

   Second issue with your criticism is that you somehow ended up claiming I'm commenting on HEP in particular. I actually don't know why that is.

   If you think that LHC experimentalists have blown "a hole into the bandwagon", you seem to not have noticed that most of them have just jumped off this wagon and onto the astroparticle wagon while they're waiting for the plans for the next bigger collider that will make the next big bandwagon.

   Experimentalists make themselves guilty by just not caring how badly motivated many of those theories are to begin with. They excuse themselves by claiming "I'm just an experimentalist, I just test this stuff" and pocketing the money. It's not an excuse I'm willing to accept.

   This field is in dire need of a methodological change. The situation is very similar to that in psychology 15 years ago, when they realized that it had become very common to publish results based on sloppy statistics that ended up being irreproducible. Psychologists managed to mobilize the community and more or less agree on guidelines for better methods. At least in my mind it has been a remarkable success that proves it is possible for academic fields to undergo community-driven changes in methodology. Particle physics needs to do the same. If psychologists can do it, so can they. They should start by analyzing what went wrong in the first place, but that still hasn't happened.

2. **Peter Shor**
   September 27, 2022

   Sabine:

   The LHC is running, and as far as I am aware, by far the biggest cost is just making the particles collide. And it's certainly seems like it's worth it, just from the amount we're learning about the Higgs boson, pentaquarks, and other things that really exist. Experimentalists running data analyses on the results to eliminate new particles that theorists have proposed is a relatively minor additional expense.

   What would you suggest they do with the data — just leave it there unanalyzed?

3. **Mark**

September 27, 2022

“Experimentalists running data analyses on the results to eliminate new particles that theorists have proposed is a relatively minor additional expense.”

As a member of one of these large collaborations, my experience is that not many (relatively) people do this nowadays. It’s become rather a niche activity. In the early days when we were told by theorists to expect squarks/gluinos etc on day one such analyses were very popular activities.

4. **SteveB**
   September 27, 2022

   I have never heard Dr. Hossenfelder say that the LHC should be turned off or end its current run. I have heard her say that a new, bigger, more expensive collider is not justified, at least using the justifications put out by the promoters. The promoters still use SUSY or wishful thinking to promote it, or even “we have to keep all these trained HEP folks employed.” The next machine as proposed is too expensive for those kinds of arguments.

5. **Dirac**
   September 27, 2022

   Small edit to your slides: Dirac’s tomb is not in Westminster Abbey (its just a marker there). He is in fact buried in Florida 🙂

6. **Anon42**
   September 27, 2022

   In a 2006 comment on your blog post at https://www.math.columbia.edu/~woit/wordpress/?p=406 about LHC predictions Sabine Hossenfelder wrote “I favour the scenario: they find nothing at all. No higgs. No susy. No monopoles. No nothing.” When Lubos Motl claimed in a follow up comment that this was impossible she questioned “the validity of the axioms you use to draw the conclusions.” Her scenario seemed even less well motivated than the models she now criticizes, and of course the LHC didn’t just find “nothing.” Unfortunately her current article linked above has no transparency or reflection about this track record. She now writes “The Higgs boson, on the other hand, was required to solve a problem.” Should Dr. Hossenfelder be the one adjudicating particle theory predictions.

7. **Mark**
   September 28, 2022

   “The promoters still use SUSY or wishful thinking to promote it, or even “we have to keep all these trained HEP folks employed.””

   Most of the literature I have read on the topic emphasises improved precision on the measurements of the properties of the Higgs particle.

   ““we have to keep all these trained HEP folks employed.””

   that’s what hedge funds, google, amazon etc are for! Very few experimental particle physicists actually work as academic scientists, so no-one is arguing for a new collider to create jobs for particle physicists (at least I have never come across this).

8. **Low Math, Meekly Interacting**
   September 28, 2022

   I still don’t understand why building a Higgs factory for no other reason than to better understand the only known (and probably) fundamental scalar can’t be made into a compelling argument on its own. Yeah, it’s expensive, but so what? It’s not stupid, and nations blow money on stupid things constantly, in a seemingly compulsory manner.

   Still no confidence in muon colliders, I see.

9. **Shantanu**
   September 28, 2022

   Peter, I am surprised that you are supportive of neutrino experiments. What exactly will the next generation experiments measure which will help connect it to TeV scale physics.
   Its 24 years since we “supposedly” have evidence for physics beyond standard model through non-0 neutrino mass and yet influential theorists have privately admitted to you that particle physics is dead. so help me understand the paradox.
   So my question to you is what measurement are you eagerly waiting for from next generation neutrino experiments which make particle physics rise from the ashes?

10. **Dan Riley**
    September 28, 2022

    It seems worthwhile to emphasize that the current proposals are conceptual designs that are likely at least a decade (probably more) from any kind of major funding decision. The R&D activities to advance the conceptual designs to something solid are relatively cheap and usually generally valuable (especially work on more compact superconducting magnets and RF cavities, plus alternative strategies for reaching higher energy), even if that work doesn’t directly lead to a funded accelerator complex. So I’d encourage more of a “wait and see” attitude to the current conceptual designs.

    p.s. working for an LHC experiment, expect to be retired long before major funding for any kind of next generation facility becomes a real issue

11. **Marvin**
    September 28, 2022

    I agree with Dan Riley, we must keep investing at small scale to test improved devices or new acceleration techniques. Wake field is an exemple of novelty. These small scale research will also have impacts on various industries, you can think of electricity storage and transport. I think that building an accelerator with actual technology and just reaching one order up in energy is, as probably Sabine tough, a waste of money: there is no theoretical predictions that necessitate any rush.

12. **Peter Woit**
    September 28, 2022

    LMMI,
    The problem is that the LHC has actually already done an impressive job studying the Higgs, and the results after the HL-LHC should be even better. To justify a new machine, you have to show the improvement over the HL-LHC is going to be worth the high cost.

    It may ultimately be that people decide to wait for muon collider technology instead of building a new energy frontier pp or e+-e- collider. But that technology I think is many years out.

13. **Peter Woit**
September 28, 2022

Shantanu,
The neutrino sector is the least well-understood of the standard model, and you can study it better without having to deal with the fundamental technological limitations that make new energy frontier experiments exorbitantly expensive. I don't have anything specific to point to, but (here I somewhat disagree with Sabine) I think it's up to experimentalists to measure what they can. Maybe something unexpected will turn up about how neutrinos behave , maybe we'll just get better measurements of SM parameters.

14. **Robert A. Wilson**
September 29, 2022

The point of theory-building, I suppose, is that the theory should be, as Einstein said, as simple as possible, but not more so. Or, in other words, as complicated as necessary, but not more so. More or less all theories since the Standard Model have been "more complicated than necessary", either in the sense that they predict phenomena that do not actually occur in the real world, or that they cannot predict anything at all. That is why I find your twistor model of gravity so appealing – it is quite clearly just as complicated as necessary, and not more so.

15. **M.**
September 30, 2022

Anon42 writes:

"Should Dr. Hossenfelder be the one adjudicating particle theory predictions."

Well, first of all, she isn't. And second of all, there is a real difference, I think, between a comment in a single thread on a science blog, and a model/prediction published in the literature. Everyone is wrong sometimes. What's notable, even in that blog comment, is how much Hossenfelder got right (e.g., no monopoles, no SUSY, etc.)

16. **Paul**
September 30, 2022

Null experiments can be just as important as the confirmation of expected theoretical findings. Just saying…

17. **Kevin Black**
October 1, 2022

Hi Peter,
Thanks for the post. I think the point is that the HEP energy frontier experimental community is mostly working on the LHC which is currently the only place where the Higgs boson can be produced and working on analyzing that data. There are some measurements which can be already classified as precision (i.e. percent level measurements) but there are many things that are just not measured at all or very poorly measured (i.e. couplings to the second generation fermions, the higgs self-coupling, rare decays). Would anyone say that if we had experimentally confirmed that the photon coupled to half the charged particles and measured its couplings to some of those only to 30-40% percent precision that we should just call it a day? That is seems , in a word or two, absurdly anti-scientific.
HEP high energy experimentalists are also working on novel ways to get to higher energy in more compact and cheaper ways (plasma wakefield accelerators, muon colliders, etc) but nobody is proposing to build those anytime soon because we can't. CERN has plans for a larger collider but that is still decades away and even the biggest proponents of those machines understand that we are a long way both financially and scientifically from actually constructing those proposals.
Honestly, I don't know what these straw man arguments except to confuse people who aren't actually engaged or following HEP.

18. **Peter Shor**
October 2, 2022

It seems to me that there's a lot of argument, when there's probably not all that much to argue about.

1. Barring global catastrophes, we're not going to shut down the LHC until we've got all the data out of it that we can.

2. If we get to the end of the LHC run, and there is no hint that higher energies will find anything interesting, it will be really hard to make a case for building a Super-LHC, and I expect that one will not be built.

So that leaves the increasingly unlikely scenario that at the end of the LHC run, there are hints that interesting phenomena will happen at higher energies. In that case, there will be difficult decisions to make. But it seems much too premature to worry about this now.

19. **martibal**
October 2, 2022

The presentation of arXiv at Scientific World is, well… problematic:

"Described as "an open research sharing platform reinventing scientific communications," arXiv is home to preprints of many of the papers that Hossenfelder derides. What is more, you can read them free of charge and come to your own conclusions."

First, does arXiv define itself as "reinventing scientific communications" ? It has been going on for the mid 90′, and at least in hep-th and maths it is the main way of communicating science, I would say.
Second, presenting arXiv has the home for useless speculations is rather unfair. Yes there are some on arXiv, and there is also the proof of Poincaré conjecture by Perelman, the papers announcing the Higgs discovery etc. It would be nice that the journalist leaves arXiv outside of the debates.

20. **Smaugtalk**
October 4, 2022

Not really off-topic: this is going to really piss Peter off.

https://www.nobelprize.org/prizes/physics/2022/summary/

The Nobel Prize in Physics 2022 was awarded to Alain Aspect, John F. Clauser and Anton Zeilinger "for experiments with entangled photons, establishing the violation of Bell inequalities and pioneering quantum information science"

Hidden variables are irrelevant to QM, of course, and so this experiment is trivial ("non-spooky").

Posting only to be deleted, but the previous line *is* your expressed view, eh?

21. **Peter Woit**
October 4, 2022

Smaugtalk,

Actually, I'm perfectly happy with this Nobel prize and the citation. This kind of experimental study of the unusual behavior of QM is great. Even happier that they didn't give it to some theorist or philosopher for going on incoherently about what this means for "locality"…

22. **Dave Miller**
October 5, 2022

Peter,

I'm looking forward to your blog post on the Nobel and also to Peter Shor's perspective.

As someone with a fifty-year obsession with the foundations of quantum mechanics, I think this Nobel was richly deserved: I am only sad that John Bell died so young and that Abner Shimony died seven years ago.

Quantum cryptography and quantum computation are perhaps a bit oversold nowadays — but at least all of this is real physics that involves actual experiments! And it is hard to see how any of it could have happened without the seminal work on Bell's theorem.

Dave Miller in Sacramento

23. **Peter Woit**
October 5, 2022

Dave Miller,
I don't really have anything interesting to say about the Nobel, so won't blog about it. The choice was a good one, and I had actually thought they already had made this award long ago. A reaction much like mine is Philip Ball's, see here
https://twitter.com/philipcball/status/1577244753523265536

24. **former mathematician**
October 5, 2022

Maybe no one remembers this but me: When John Clauser was building his first experiment, he expected the opposite result from what he got.

25. **Peter Shor**
October 5, 2022

Since I was asked, let me say I'm very happy about the Nobel prize going to quantum information theory. And these are an excellent set of recipients, possibly being the three people who did the most for experimental tests of Bell inequalities and similar demonstrations of non-classicality.

26. **David J. Littleboy**
October 6, 2022

"When John Clauser was building his first experiment, he expected the opposite result from what he got."

This has been reported in at least one article on the prize. E.g. here's Quanta on it:

"Unsure what he would find, Clauser had placed a $2 bet that his experiment would prove Einstein right. To his surprise, his results vindicated Bell's prediction over Einstein's. "

As a non-physicist, I've been surprised by how hard this is. The Bell inequality thing seems pretty clear (at least when read in various popular descriptions) but people keep finding possible loopholes. Thus it's interesting that work from 2017 was included in this Nobel Prize. Does this make it one of the shortest periods between work done and Nobel recognition?

FWIW: there's a collection of reprints of Bell's papers (John S. Bell on The Foundations of Quantum Mechanics) that's affordable and surprisingly interesting even to non-physicists (even if we don't get most of it's points).

27. **AcademicLurker**
October 6, 2022

According to David Kaiser in *How the Hippies Saved Physics*, when Aspect started work on this he was warned that he would ruin his chances for a permanent academic position by working in such an unfashionable area…

28. **David Roberts**
October 20, 2022

Thanks for the link to the Siegel essay, it had some nice general ideas and was a fun read. However, I take small issue with the scope of the closing statement:

> The best we've come up with is this: to let people choose for themselves what they work on

While in principle this is true, the structure of academia is that people will actually choose work on what will keep them employed. And one person working on an ambitious idea (not ruled out by the usual quick theory-killers) may not have the critical mass of attention to see it go through to the end of its lifecycle (either finding why it cannot work due to some perhaps subtle technical problem, physical argument or experiment, or else be actually useful for something).

This Week's Hype

October 5, 2022
Categories: This Week's Hype

The hype campaign marches on, just three very recent examples:

- Can stringy physics rescue the universe from a catastrophic transformation?
- Cosmic strings' greatest power? Their ability to confound physicists.
- TF1 Snowmass Report: Quantum gravity, string theory, and black holes

Comments

1. **SDS**
   October 5, 2022

   The TF1 Snowmass Report is intriguing: thirty-eight authors (some of them of a very high profile) for what amounts to (mostly) fluff.

2. **Geoffrey Dixon**
   October 5, 2022

   Resistance is futile, Peter. Drink the Kool-Aid.

   Speaking of which Ethan Siegel, evidently incensed at Sabine's dreary (but correct, IMO) assessment of theoretical particle physics, wrote a rebuttal in which he says, if I interpret him correctly, that in the absence (in his view) of any clear way forward, a series of guesses (sparticles, axions, etc.) is an entirely valid modus operandi. It rules out all sorts of nonsense. So stay the course, full speed ahead, be one with the Borg.

   As usual, when I consider all these guesses, and all future guesses, I have to ask: Were your guess proven correct, how would you explain that its veracity was inevitable? If you cannot do that prior to submitting it to experimental verification, then you haven't a chance – just a job, and the moral support of like-minded ruminants.

3. **MS**
   October 5, 2022

   Although there is definitely hype around cosmic strings, extending the symmetry structure of the SM is a tried-and-true strategy to address extant (not-just-theoretical) problems. After all, the SM is a (successful) theory based on SU(3)xSU(2)xU(1) gauge symmetries. Even assuming just the SM gauge group and the Higgs mechanism, there are measurable/phenomenological consequences of this phase transition and the associated topological defects (that said, the SM EWSB version is highly constrained). If there are additional gauge (or global) symmetries which are spontaneously broken at energy scales reached in the early universe, shouldn't the hype associated with topological defects formed in these phase transitions (like cosmic strings, which have measurable effects e.g. effects on structure, lensing, gravitational waves, etc.) be differentiated from the hype around string theory which still has different "difficulties" in terms of phenomenological predictions?

4. **Peter Woit**
   October 5, 2022

   MS,
   Yes hype about cosmic strings is hype about GUTs, not hype about string theory. But the hype in this article is the same kind of outrageous hype as the usual string theory hype, completely misrepresenting the situation. The author writes
   "According to our best understanding of the early Universe, our cosmos should be riddled with cosmic strings. And yet not a single search has found any evidence for them."
   This implicitly claims that a GUT model, not the SM, is "our best understanding of the early Universe". The situation is just like for monopoles: there's supposed to be a huge problem of where the cosmic strings and monopoles are, when the SM predicts no cosmic strings and no monopoles. The theories that predict such objects are GUTs, for which we have lots of other falsifying evidence (eg no proton decay).

   The math here is pretty simple: if the Higgs potential has a minimum on a manifold X, then you get cosmic strings when $\pi_1(X)$ is non-trivial, and monopoles when $\pi_2(X)$ is non-trivial. In the SM, $X=S^3$, so the two homotopy groups are trivial and you expect no cosmic strings, no monopoles, just as observed.

5. **Peter Woit**
   October 5, 2022

   SDS,
   I think it's kind of a remarkable document. The field is facing some difficult problems, and the point of the Snowmass effort is supposed to be to come up with a plan for the future. The authors act as if there is no problem to be faced, nothing wrong with what people have been doing in the past, the way forward is to just keep doing the same thing.

6. **Peter Woit**
   October 5, 2022

   Geoffrey Dixon,
   I'm onboard with Sabine that the best way forward is to identify problems with the structure/consistency of our best theory and find ways to address those problems. Completely mystified though why others don't see that the analytic continuation of chiral spinor fields is such a problem, and addressing that should be the highest priority of all theorists.

   More seriously, I'm also onboard with Ethan Siegel: the field is in a bad state, with nothing so far working (including Sabine's favored approach), so there's some justification for pursuing lots of different approaches, even ones that usually aren't very promising ways to get successful new ideas. What's important though is that such unpromising ideas at least are new, not what we have now which is a field that has institutionalized a research effort organized around a set of old ideas that failed long ago (see the last item).

7. **Alex**
   October 5, 2022

   I disagree with the idea of just trying anything (new) in the absence of guiding empirical evidence. I'm afraid that only a couple of things/strategies are worth pursuing, but will not be popular, since it amounts to basically doing nothing or very little (in terms of new, wild ideas… you know, the stuff that people like to hear about) and just wait until new experimental evidence finally contradicts our current best theories. But how do we reach to that desired point? The history of physics is illuminating.

Newton proposed his laws of mechanics in the late 1600s. As we know, they were a monumental success. And when it seemed they were failing, it was actually because of a planet that was not yet discovered. Only the small deviation in the prediction of the perihelion of Mercury resisted a newtonian explanation. The reign of newtonian mechanics lasted for a bit more than two centuries!

Now, did physicists of the time jumped all to speculate on wild theories that would replace newton during those centuries, like today's physicists are doing with the SM? Maybe some did, but, regarding the rest, it seems to me their attitude was smarter. They either worked on applications of the theory (mainly in astronomy, to great success) or to rewrite/study its mathematical foundations (Lagrange, Hamilton, etc.) And I think that, in the part of the foundations of physics where no evident contradictions exist, that should be the adopted strategy today.

On the other hand, most other physicists were working on new and exciting phenomena, like heat and electricity and magnetism. This culminated in the theories of thermodynamics, statistical mechanics, and Maxwell's EM. And the actual hard challenges to newton came from the last two (first with Planck, then Einstein). That's because they exported the newtonian theory to realms for which it wasn't designed to deal with. So, that's where the new evidence will come from. So, the second strategy is to concentrate in realms not covered yet by our current theories. That seems a bit difficult, considering how amazingly encompassing they are, but there are still some holes here and there (e.g., quantum superpositions of ever bigger massive bodies, gravity mediated entanglement of similar bodies, and so on). The mathematics of both GR and the SM applied to other systems. More cross fertilization with other fields of science, etc.

So, I think there's a clear path forward from the current situation, supported by history, but it's not an easy one, it will not give you the possibility of activating the sausage machine of paper production and collect grants money with a bulldozer. Very little space for media super stars from the field. Instead, it requires a very careful and selective process regarding which problems to pick, the advance will be slow, and the general attitude should be more on the conservative side until news of something genuinely new finally appear.

8. **Stef Roux**
October 5, 2022

Dear Peter

You said: "Completely mystified though why others don't see that the analytic continuation of chiral spinor fields is such a problem, and addressing that should be the highest priority of all theorists."

Can you perhaps elaborate? Has it been discussed in a previous blog post? Or if not, in a paper somewhere? It sounds like the kind of thing I'd like to do.

9. **André**
October 6, 2022

@Alex: Great comment, I agree almost completely. Unfortunately, after almost ten (post-PhD) years in academia I have come to the conclusion that the only way (for me, someone who is just a decent physicist but not some genius) to proceed with this sort of serious, hard-work research on the foundations of the established theories is not possible within academia. So I am currently working on a strategy to leave the academic world and hope to find a way that allows me to do this sort of theoretical physics as a hobby.

10. **Bianca Andrescu**
October 6, 2022

> a series of guesses (sparticles, axions, etc.) is an entirely valid modus operandi. It rules out all sorts of nonsense.

The problem with this, of course, is that there is an infinite amount of possible nonsense. The more you rule out, the more nonsense you subsequently generate.

11. **Peter Woit**
October 6, 2022

Stef Roux,
See
https://arxiv.org/abs/2104.05099
I'm currently trying to finish writing something much more explicit about the analytic continuation issue.

12. **Peter Shor**
October 6, 2022

And another question very few people seem to be thinking about:

"Why is the Standard Model one of the very few Lagrangians that is compatible with Alain Connes' non-commutative geometry constructions?"

The answer is probably that most physicists don't know anything about either analytic continuations of chiral spinor fields or non-commutative geometry, and their colleagues tell them that these aren't the answer, so why should they bother learning about them (something that is quite hard; it's much easier to continue thinking about stuff they know about).

But if one of them is the answer …

13. **André**
October 7, 2022

@Peter Shor:
I can only speak for myself, but as one of these ignorant physicists refusing to learn more about potentially promising – but hard – mathematical concepts such as non-commutative geometry or twistors, my reason is not that I don't believe that one of them could be the answer.
Rather I believe that this is not the most promising way to do theoretical physics.

It's worth noting that both for the discovery of GR and QM the first 20+ years were about fiddling around with the "old" mathematical tools, e.g. statistical mechanics or Maxwell's theory. Only after there was a certain amount of understanding of the new physics (described in "old" terms) did people begin to discover its relationship to new mathematics.
Riemann was already dead for a quarter century before Einstein started thinking about space and time, nonetheless, the thought of differential geometry as a tool came much later – after already having discovered the principles of special relativity, and arguably Einstein knowing more differential geometry would not have changed much about the history of this discovery.

For the formulation of QM, the discovery of many mathematical tools was historically happening around the same time (e.g. Hilbert, Weyl), and yet, the first half century of the new theory was dominated by phaenomenological models that were strongly based on the established mathematics of classical physics.

Hence, I am very happy if mathematical physicists are working on ideas like Connes' or Penrose's, but I would be quite surprised if the next big discovery comes from one of these approaches. Most likely, I expect it to come from some experiment – maybe one of the macroscopic quantum systems in the lab type things – but if it comes from theory, then my bet would be on a deeper understanding of issues and inconsistencies with QFT in curved spacetime vs. GR or in the heuristic ideas around studying quantum mechanical systems with gravity. In my opinion, there are plenty of situations that are only very poorly understood in our existing theories (talking about fundamental issues, not complex systems etc.).

14. **Peter Woit**
October 7, 2022

All,
I've just deleted a large number of incoming comments that had nothing to do with the posting. Please keep in mind that you create a problem by posting extensive comments that may be interesting, but have nothing to do with the posting. When I allow such comments, this quickly leads to a lot more of them as everyone decides this is a good place to try and get a discussion going of whatever interests them. This then puts me in the position of having to spend a lot of time I don't have trying to sensibly moderate a discussion that has gone off into areas I'm not interested in.

15. **Anonyrat**
October 9, 2022

The Snowmass report contains this paragraph, with intriguing last sentence:

" Grand unification seems very natural in the heterotic picture (where the MSSM gauge group naturally arises as a subgroup of the larger ten-dimensional gauge group). It is less natural in intersecting brane models, and may be achievable in F-theory models with 7- branes. In all cases, details of making the unification work are subtle. (Current data is also not conclusive on the question of whether achieving unification should be a central goal or not.)"

16. **Peter Woit**
October 9, 2022

Anonyrat,

I think this can be translated as "nearly forty years of intensive research has shown string theory is compatible with just about anything, specifically either GUT theories or non-GUT theories". Since this is a document aimed at guiding funding decisions, one would think the implications of this would be obvious…

17. **Nick**
October 9, 2022

Do people know if any sociologist or historian has done a study of string theory as a research program? What I have in mind is a study that tries to provide a social-historical explanation of it/framework for understanding how it persists, starting from the assumption that string theory's prominence has not been justifiable on rational grounds for a very long time? This is something sociologists do well–explain why a social institution that doesn't fulfill the ostensive functions legitimating its existence (in this case, producing physics knowledge), nevertheless persists as if it actually is fulfilling those functions, despite convincing demonstrations that it isn't. Given the prestige and cultural influence of string theory, and the importance of the questions it purports to help answer, it seems like this is something worth understanding from a sociological and historical point of view.

18. **Peter Woit**
October 9, 2022

Nick,
I don't know about sociologists, but various historians (Sophie Ritson is one example) and philosophers of science have written about the controversy over string theory. But, as long as most of the leading figures in the field continue to argue that string theory is not a failure, I don't think academics from other fields are going to do work starting from the assumption that string theory is a failure.

At some time in the future, such academics may very well be looking back at what happened in fundamental theory starting in 1984 and analyzing it more from the point of view of what this can tell us about how science can go seriously wrong.

19. **Peter Shor**
October 11, 2022

An article in the New York Times is now hyping ER=EPR, among other things.

> Dr. Susskind and other physicists now speculate that wormholes and spooky action are two aspects of the same magic and, as such, are the key to resolving an array of cosmic paradoxes.

20. **Peter Woit**
October 11, 2022

Peter Shor,
I did see that, and as usual with this kind of hype, can't even figure out what the hypsters are referring to. Supposedly it's now all about wormholes, but what's the theory governing these wormholes?

In the NYT, Overbye does refer to two identifiable papers as the crucial advances. The first is
https://arxiv.org/abs/1905.08762
where the authors have an actual theory (JT gravity coupled to conformal matter), but it's a 1+1 dimensional QFT. 1+1 d quantum gravity is very much a toy model, with no physical degrees of freedom. Maybe some phenomenon in this toy model corresponds to wormholes and resolves the bh information paradox, but if so, the bh information paradox is getting resolved in a way that doesn't have anything to do with the problems of 3+1 d physical quantum gravity theories.

The second is
https://arxiv.org/abs/1905.08255
There the author just invokes "AdS/CFT" as the theory he is using, but doesn't use anything about a specific theory of the quantization of the 4d gravitational degrees of freedom. His conclusion is that understanding the bh information paradox can be done semi-classically:
"In this paper, we have argued that the key expected features of unitary black hole evaporation in AdS/CFT can be derived from the bulk semiclassical description of an evaporating black hole, so long as we assume entanglement wedge reconstruction."

In both papers, the conclusion seems to be that you don't need a well-defined 4d quantum gravity theory, that you can just work semi-classically or in 1+1d. Hard for me to follow the details here, but the original goal of having a well-defined theory of quantum gravity seems to have been replaced by something else.

I'm getting the impression that in the same way Susskind successfully argued for the abandonment of the idea of having a well-defined theory of particle physics (what we see is a random artifact of the unknowable "landscape"), what's going on here is the abandonment of having a well-defined theory of gravity (with gravity only understandable semi-classically as an emergent approximation to something unknowable).

21. **Christoph**
October 11, 2022

Peter, there surely are good arguments that a unified theory of relativistic quantum gravity has no equation of motion. The minimum length yields a minimum measurement error, and thus no way to define a precise equation. Also, for the same reason, single degrees of freedom are unobservable (in a way that recalls the unobservability of single gravitons). As a result, there is no way to define an equation of motion (or a Lagrangian) for the underlying degrees of freedom. Thus, the unified theory of relativistic quantum gravity can only be statistical, emerging from some underlying degrees of freedom.

But there still is the standard model. It arises, like general relativity, from these underlying degrees of freedom, with the precision that we know. In other terms, the underlying degrees of freedom determine the fundamental constants uniquely. Thus, there is no landscape, but a uniquely defined world with quantum theory and general relativity.

22. **Peter Woit**
October 11, 2022

Christoph,
I'm not asking for observable degrees of freedom, an equation of motion or a Lagrangian. If you want to tell me that
"the unified theory of relativistic quantum gravity can only be statistical, emerging from some underlying degrees of freedom" and that "the underlying degrees of freedom determine the fundamental constants uniquely" you have to tell me what those underlying degrees of freedom are, what laws govern them, show that gravity emerges and explain how to compute the fundamental constants.

Maybe you think you have a way to do this (please don't use my blog to promote it), but I don't see any evidence that Susskind et al have a program to find such a thing. Rather their program seems to be to argue that string theory is such a thing, but you can never know what it really is or how it works.

23. **Z Y**
October 11, 2022

Nick,
Coincidentally I am starting to read about the works of some schools of Sociology of Science/Scientific knowledge: the Edinburgh school and its Strong Program, and the Relativism of the Bath School being the more controversial ones. In a bibliographical search on theses matters I found an essay by Weinberg (1995) Night Thoughts of a Quantum Physicist. In it it mentions his view on the Strong Program and related schools and also this passage: "String theory is mathematically very difficult. I think it's a sign of the intrinsic health of physics that even though most physicists of the older generation don't learn string theory and can't read papers in it, young string theorists continue to get tenure at leading American universities. Our field is not (as some imagine it to be) hegemonic, dominated by an old guard of fuddy-duddies. It is very much alive to new possibilities" …the irony

24. **Christoph**
October 11, 2022

Peter, what I wanted to point out is that the statement "the unified theory of relativistic quantum gravity can only be statistical, emerging from some underlying degrees of freedom" can be made *independently* of whether these degrees of freedom are known or not. Nature *must be* like that – because of the measurement uncertainties in nature at the Planck scale and because of the impossibility to reach the Planck scale. There is no alternative.

The same holds for "the underlying degrees of freedom determine the fundamental constants uniquely". Nature must be like that – there is no alternative.

Finding theose degree of freedom is a different step. It is of course necessary as well.

25. **Peter Shor**
October 12, 2022

Christoph:

I think there's something wrong with that reasoning. The angular momentum of a single particle is unobservable (except statistically), but we have perfectly good equations of motion for angular momentum.

Quantities that are only statistically observable but have exact equations of motion are everywhere in quantum mechanics. If Schrödinger and Heisenberg had followed reasoning like yours, we would not have the theory of quantum mechanics that we do today.

26. **Christoph**
October 12, 2022

Peter Shor,

quantum theory and relativitsic quantum gravity differ.

Quantum theory and experiments show that we are able to say whether a system contains just one spin or just one particle. We can isolate a single particle and follow its motion.

In contrast, we are not able to say (or even imagine) that a systen contains just one Planck-scale degree of freedom (those which make up black hole entropy) or just one graviton. We cannot isolate one of those degrees of freedom, because the minimum length cannot be realized in any experimental set-up. (We are far away by many orders of magnitude.) We cannot follow the motion of such as single degree of freedom, because the minimum length cannot be realized, not even approximately.

In relativistic quantum gravity, only systems with huge numbers of degrees of freedom can be described: black holes, curved space, etc – in contrast to quantum theory, which allows describing single particles.

So, in relativistic quantum gravity, there can never be an equation of motion for a single degree of freedom, in contrast to quantum theory. The constituents of space are not observable one by one, but only in huge numbers.

27. **Dumans Fladskote**
October 12, 2022

"… , what's going on here is the abandonment of having a well-defined theory of gravity (with gravity only understandable semi-classically as an emergent approximation to something unknowable)."

Peter, this is not at all what is happening in the recent computations of the Page curve using the semi-classical description plus HRT formula. It is like saying that because you compute the entropy of a many-body system using thermodynamics and equations of state, you have given up on there being an in principle microscopic description of the entropy. The AdS/CFT community does not think semi-classical GR is a low-energy EFT of something unknowable, because we know exactly what the microscopic degrees of freedom are: they are the degrees of freedom of a conformal field theory.

28. **Peter Woit**
October 12, 2022

Christoph/Peter Shor,
This has gone way off topic, enough.

29. **Peter Woit**
October 12, 2022

Dumans Fladskote,
You know exactly what the microscopic degrees of freedom are? Great, I couldn't get that from reading any of these papers. What are they exactly, and what exactly is the conformal field theory?

30. **Dumans Fladskote**
October 12, 2022

It depends on what AdS/CFT example you are looking at, so for different bulk dimensions and matter fields you will have different CFTs. But compared to most things in QFT, CFTs are extremely well understood. The prototypical example is N=4 SYM. In this case semiclassical (super)gravity in an asymptotically AdS_5 x S^5 space is an EFT for N=4 SYM in certain limits. The microscopic degrees of freedom of quantum gravity are the degrees of freedom of N=4 SYM. Sure, these don't live in spacetime, but that's the whole point of emergent gravity. Of course, I cannot tell you in full generality what the emergent gravitational field in the bulk are constructed from in N=4 (but in some cases we can, ref HKLL and the extrapolate dictionary). But this is not a fundamental problem, any more than it is a problem that I don't know how to write the pion field of the chiral lagrangian in terms of QCD operators. There is some (extremely hard to compute in practice) field redefintions of N=4 SYM in terms of new variables, whose dynamics become Einstein gravity at large N and large 't Hooft coupling.

31. **Dumans Fladskote**
October 12, 2022

Let me add that we know the exact dual for JT gravity. It is the matrix model described in 1903.11115. So the matrices described there are exactly the microscopic degrees of freedom of JT gravity. As for Penington's case, his argument is sufficiently general that you don't need to know the exact matter spectrum of the bulk theory (or the dual CFT).

32. **Peter Woit**
October 12, 2022

Dumans Fladskote,
In the toy JT case I see a well-defined theory (JT + conformal matter in 1+1), even independently of the dual.
When asked for a specific theory that's going to be quantum gravity in 3+1d spacetime (dS), you're telling me the standard story about a supergravity limit of superstring theory on AdS x S^5 being dual to N=4 SYM on the boundary 4-sphere. I know that story well, and I've seen 25 years of people trying to get a 4d physical quantum gravity theory out of it, which somehow never seems to lead to a specific theory you can write down which does this. What is this theory?

This subject has clearly evolved recently and there are new aspects I don't understand (ER=EPR and the wormholes, for instance…). If there is a specific conformal theory you can write down which is supposed to have as dual 4d physical gravity, it would be helpful to know exactly what it is, and how this duality is supposed to work.

33. **Dumans Fladskote**
October 13, 2022

Peter,

But now you are changing the complaint. You are of course 100% right that AdS/CFT does not give you a dual to 4-dimensional quantum gravity in deSitter space, but that was never the complaint I was responding to. You seemed to say that the AdS/CFT community had given up on the microscopic degrees of freedom, which I was disagreeing with. You were saying "but the original goal of having a well-defined theory of quantum gravity seems to have been replaced by something else.". The point I was making is that it was recently realized that the Page curve can be computed without knowing the microscopic degrees of freedom. Just because you decide to carry out this computation doesn't mean you have given up on microscopic degrees of freedom. Furthermore, since the Page curve computation is completely agnostic to the number of dimensions, so it is pretty reasonable to be hopeful that this solution works more generally.

34. **Peter Woit**
October 13, 2022

Dumans Fladskote,

For a research community to "give up" on a goal doesn't require that members admit this publicly or even admit it to themselves. It's a fact that the string theory community has given up on particle physics, in the sense that leading figures have voted with their feet and no longer work on this, whatever they may say to the public, to their colleagues, or to themselves about the question of whether there's any hope get particle physics out of string theory.

The fundamental physics goal of "string theory", whatever it is these days, has moved to "find quantum gravity", but this goal is being pursued in a way that I have trouble understanding and that increasingly appears to me to be describable as "giving up". For many years the main motivation for this program was given as the occurrence of a spin-two state in the spectrum of a weakly-coupled 10d superstring, nowadays instead it seems to be "emergence" of an effective gravity theory from something else. My problem has been that I can't find a specific explanation of what the "something else" is, and how this emergence is supposed to work. Your pointing to 4d N=4 SYM doesn't really help.

The NYT article points me to Susskind's
"Dear Qubitzers, GR=QM" (https://arxiv.org/abs/1708.03040)

which, honestly, makes zero sense to me. The NYT headline is "Black Holes May Hide a Mind-Bending Secret About Our Universe", but the story it tells about a semi-classical resolution of the BH information paradox seems to imply that studying this question about black holes tells us only about the emergent semi-classical limit, nothing about the fundamental theory. So, the big success here is showing that the "mind-bending secret" about the nature of the fundamental theory is hidden from us rather than revealed to us by black holes.

Having seen what happened with particle physics and string theory, I don't think it's unreasonable to interpret what is going on here as people abandoning the goal of search for a fundamental theory by voting with their feet to move to working on problems that can't address this goal (or, when they do, such as in Susskind's preprint, do so in a way that can't be taken seriously).

35. **Dumans Fladskote**
October 13, 2022

Peter, I agree that many people (although not all) have given up on getting particle physics from string theory, so let me respond only to the part about emergent gravity.

"My problem has been that I can't find a specific explanation of what the "something else" is, and how this emergence is supposed to work. Your pointing to 4d N=4 SYM doesn't really help."

I see two complaints here: (1) what is the "something else", and (2) how does emergence actually work in terms of the microscopic degrees of freedom.

(1) I am still confused by this complaint. For quantum gravity in AdS spaces, we are always claiming that the "something else" is some conformal field theory. Sure, we don't always know what the relevant CFT is, but that says that we haven't mapped out the space of all AdS/CFT dualities. But we do have precise examples, like N=4 SYM. I am not sure why this example doesn't help. Sure, its dual is not four dimensional gravity, but it is an example of a quantum gravity where we have know exactly what the microscopic degrees of freedom are. If you want four dimensional gravity, you can do a KK reduction of AdS_4 x S^7, and the dual is the ABJM conformal field theory.

(2) As for the lack of explanation of "how this emergence is supposed to work": this is the difficult question of bulk reconstruction and "entanglement wedge reconstruction", which is a topic of active research. It's hard, because it in some ways is morally similar to the problem of writing the pion field of the chiral lagrangian in terms of the QCD fields. But we do actually know quite a bit about this problem. We know how the gravitational field and matter fields near the asymptotic region of AdS can be written in terms of CFT variables. We know how to write bulk operators deeper the bulk in terms of CFT variables, provided we are not behind a horizon. We haven't solved this problem, but progress has been continuously made over the last 15 years. Some milestones are: 0606141, 0907.0151, 1601.05416,1612.0039, 1704.05464, 1704.05839.

To detail one example, 1612.00391 gives an algorithm to reconstruct the bulk conformal structure (outside the black hole horizon) from Lorentzian CFT correlators.

36. **Peter Woit**
October 13, 2022

Dumans Fladskote,
Thanks, that's very helpful. My previous attempts to understand what has been going on here were not helped by mystifying claims for radical reformulations of fundamental theory (e.g. Susskind's GR=QM, Arkani-Hamed's "space-time is doomed, to be replaced by amplituhedra", etc.). If you're telling me that the basic idea is the same as it always has been post-1997 (try to understand 4d gravity in terms of holography and a dual 3d CFT), I can understand that (as well as see the well-known problems with the idea). It appears the recent advance is to show a way to resolve the bh problem within this context. I'll be curious to see what the future holds. Right now it looks to me like this just leads to a quite complicated way of quantizing gravity, one still far from working in the physical case, with no hope of testability (either via predictions about gravity or via connection to particle physics).

37. **Anonymous**
October 13, 2022

Dumans Fladskote,
The trouble is that we don't live in AdS but supposedly in dS so the program of emergence of gravity as in AdS/CFT is just left in AdS. And I don't quite see how you can get a similar duality in dS because there are no asymptotic observables. One can wish for a similar emergence in 4d dS but we need something better and more precise than that.

38. **Dumans Fladskote**
October 13, 2022

Of course, happy to elaborate. And I agree that it is certainly complicated. But no one ever said quantum gravity would be easy. As for no hope of testability, this is true, since these quantum gravity theories never were claimed to describe our universe. On the other hand, people are building strongly coupled many-body systems in the lab these days, so if we obtain the ability to simulate CFTs in the lab, we might be able to probe simulated quantum gravity theories experimentally. Sure, it is not our universe, but there are many really interesting problems that we can hope is shared between different quantum gravities, like: is there such a thing as approximate geometry when quantum effects are important? Can topology change happen dynamically? What happens to a black hole at the very end of evaporation? Can a classical singularity be resolved by quantum effects? What are even natural observables in quantum gravity? How does approximate locality emerge? How is information about a black hole interior encoded in the Hawking radiation? My hope is that new qualitative lessons about these questions and quantum gravity can be learned from AdS/CFT once we can actually simulate CFTs. Of course, we need to understand deSitter at some point as well, but a better understanding of the former questions might get us closer to deSitter. AdS/CFT is quantum gravity in a box, and while the box is unphysical, it seems unlikely to me that the lessons learnt with the box are completely irrelevant to our universe.

39. **Peter Woit**
October 13, 2022

Dumans Fladskote,
Funny thing is that I was just this afternoon at a talk here at Columbia by John Preskill. Fine general talk, pretty much the same as
https://www.youtube.com/watch?v=XY6_adrJxwU
He ended with a slide claiming
"Deep insights into the quantum structure of spacetime will arise from laboratory experiments studying highly entangled quantum systems"
This kind of "we're going to study quantum gravity in the lab" claim I think is dangerously misleading. There's a huge difference between testing a proposed fundamental theory of physical space-time and testing your modeling of a strongly-coupled condensed matter system using geometry of some space that has nothing at all to do with physical space-time.

Again, my problem is that we've already seen the destruction of fundamental particle theory by string theorists declaring that they've figured it out, the landscape's the answer, too bad it's untestable. We may be on our way to seeing the destruction of the subject of quantum gravity as "string theorists" declare that the answer has to be an untestable holographic dual (only game in town!), and that they've solved the testability problem by testing holographic duals in the lab, so that's the end of it.

40. **Dumans Fladskote**
October 13, 2022

"that has nothing at all to do with physical space-time. "

This is where we disagree, but I suspect we won't be able to resolve our differences here. Ref. my comment about quantum gravity in a box.

41. **Alex**
October 13, 2022

Dumans,

I think the problem is that

"… AdS/CFT is quantum gravity in a box, and while the box is unphysical, it seems unlikely to me that the lessons learnt with the box are completely irrelevant to our universe."

contains two hypotheses which holographers have been claiming since the inception of these conjectures decades ago but for which, despite all the effort and money invested, not a single piece of concrete evidence (of any type, not even theoretical, purely mathematical, let alone empirical) has been provided for us non-believers. These are "… AdS/CFT is quantum gravity in a box…": you cannot know that since we don't have the real QG deal. Maxwell's eqs in a box are Maxwell's eqs in a box because we start with them and only then put those boundary conditions and then it follows trivially that the results are indeed Maxwell's eqs in a box. QG is such a non-trivial matter that I wouldn't run to make such hasty general claims. Second, "… it seems unlikely to me that the lessons learnt with the box are completely irrelevant to our universe." Again, just a gut feeling, basically a variation of the same previous melody. You guys speak as if you already had the true physical QG theory. You don't. You have a specific theory which is highly unphysical for a number of well documented reasons. Besides, even its interpretation as a QG, even in that realm, can be questioned, as has been done.

We have been listening to this stuff for decades. Piles of conjectures over gut feelings over even more conjectures. And then you get Susskind or even Preskill with these overhyped-elevated-to-the landscape-power claims. Really? We have to buy this and not even compain? That's too much.

42. **Dumans Fladskote**
October 13, 2022

Hi Alex,

In the absence of empirical data, you have two options: give up, or pursue a theory based on its theoretical merits. Assuming you are the same Alex as posting earlier in this thread, you seem to advocate the former. I am not in favor of this approach, as I do not see how we are ever going to come up with ideas for things to measure if we don't even explore the various possible theories of quantum gravity. Sure, we can sit back and wait until inconsistencies with GR show up, but it seems much more efficient in the long run to actively look for them. I am not saying that AdS/CFT currently tells us what to measure, but understanding the quantum gravity theories that we know and that resolves existing puzzles (like the BH info paradox in AdS) seems like a good start. Let me add that I am all for people investigating alternative approaches, like what Peter is doing.

Next, I am going to disagree with your claim that we don't know that holography describes quantum gravity in a box. The CFT is a UV complete quantum theory whose dynamics in certain limits is semi-classical Einstein gravity. If that doesn't classify as a quantum theory of gravity, then I am not sure anything does. How else do you propose we define a quantum theory of gravity? Also: sure AdS/CFT itself is not proven, but it has so many chances of being disproved. Every time we compute something that can be computed on both sides of the duality, the two results are consistent. That sounds like theoretical/mathematical evidence to me.

Finally, AdS/CFT can be justified according to the principles you were championing earlier. "They either worked on applications of the theory (mainly in astronomy, to great success) or to rewrite/study its mathematical foundations". It is clear to everyone that we need to understand quantum field theory better, and that this has obvious relevance to the parts of the world currently empirically accessible. AdS/CFT has given us a lot of new insight into conformal field theories at strong coupling (and their real time dynamics). Since QFTs typically are conformal in the UV and IR, and since phase transitions are described by CFTs, its clearly very interesting to understand them better. What other approaches do we have to describe real time dynamics of strongly coupled CFTs? As another example, AdS/CFT gives an explanation for the very low empirically observed value of the ration between the shear-viscosity and entropy density in quark gluon plasma. It also helps us understand the emergence of hydrodynamics in strongly coupled field theory, through the fluid-gravity correspondence.

43. **martibal**
October 14, 2022

Sorry but for those – like me – who do not know much about the field, the discussion is not so clear: is the "CFT whose dynamics in certain limits gives Einstein gravity" (advertised by Dumans) the same as the " specific theory which is highly unphysical for a number of well documented reasons" (as referred by Alex).
If so, the main of these well documented reasons is that we live on dS rather than on AdS, right ? Are there other "big" reasons ?

A side question related to an earlier post of Peter: what is the S^3 on which the Higgs field lives in the standard model ? The spatial section of the FRWL model?

44. **Peter Woit**
October 14, 2022

Martibal,

This is way off-topic, but the SM Higgs is valued in $\mathbf C^2=\mathbf R^4$. The potential depends on the norm-squared, minimum is at a fixed non-zero value of the norm-squared, so at a minimum the field takes values on an $S^3\subset \mathbf R^4$.

Ever since the dawn of AdS/CFT, it has been tempting for many to claim that this solves the problem of quantum gravity: QG is just whatever the dual is to your CFT. If you try and ask how this is supposed to work for physical 4d gravity, there are lots of problems. The most obvious one is you get AdS not dS. Another is that AdS/CFT is best understood when the CFT is N=4 SYM in 4d, so your space-time is the wrong dimension (5). Dumans Fladskote says "If you want four dimensional gravity, you can do a KK reduction of AdS_4 x S^7, and the dual is the ABJM conformal field theory. ", but this has its own problems. As this shows, in this game you're really dealing with an 11d space-time, and have all the problem of not really knowing what the 11d theory actually is, having to pick a specific unmotivated background (for a supposedly background independent theory…), etc.

From the beginning I would often ask string theorists about this: what is your 4d theory, and why are you not doing physically relevant calculations in it? I've never gotten much of an answer, so never took time to look into the details. Perhaps someone more knowledgeable can point to a source where people use a 4d AdS/CFT to do QG and which discusses exactly how this works, what is known, what is unknown, what the problems are.

45. **Peter Shor**
October 14, 2022

The problem with the statement

> Deep insights into the quantum structure of spacetime will arise from laboratory experiments studying highly entangled quantum systems.

is that we know from the AMPS thought experiment that any satisfactory theory of quantum gravity has to violate one of unitarity, locality, or the equivalence principle. Any laboratory experiment studying highly entangled quantum systems has to obey all three of these principles. So how are we going to learn anything about quantum gravity from experiments that obey these conventional physical principles?

I suppose it's possible, but certainly none of the experiments proposed to date are going to tell us anything interesting about quantum gravity.

46. **Mark**
October 14, 2022

@Peter Shor
Preskill refers to AdS/CFT, where there is manifest unitarity, but only emergent locality in the extra dimensions (while locality is exact in the boundary directions). The resolution of AMPS in AdS/CFT is through (spacetime) wormholes, which violate locality. The fuzzy dream is that somehow you'll be able to interpret quantum simulations in terms of gravity in AdS: both through conventional gravitational phenomena, but also more speculative ones, like wormholes and other things that we don't yet know about.

@Peter Woit
It is a challenge in AdS/CFT to make the size of the internal manifold M (in AdS_4 x M) small (compared to the AdS radius). The best known construction in string theory is by DGKT [arXiv:hep-th/0505160], but the dual CFT is not understood, and according to my estimates, roughly half of the community believes that something is wrong with DGKT and one can't make M small. The good thing is that there is steady progress in building CFT tools (bootstrap and the like) to answer this question on a 5-year time scale.

47. **martibal**
October 14, 2022

Peter: sorry for having insisted on the off topic question, but that was to understand better your comment 🙂 Thanks for the answer !

48. **Somdatta Bhattacharya**
October 23, 2022

Y'all are quibbling over old hat. String theory has moved on, and is currently viewed mostly as a tool for analysing strongly coupled field theories, via S-matrix bootstrap methods coming from strings (Simmons-Duffin, Zhiboedov, Sinha), or the large-N methods applied to Hilbert spaces of field theories (Sonner, Verlinde, Jafferis, Kolchmeyer) or the spectral functions that arise from analysing strongly interacting theories (Sachdev and collaborators and others), something that was the offshoot of the JT-gravity/SYK-model duality as pioneered by SSS and Witten and Maldacena and others. So please get yourself up to speed on these, and then we could have a conversation going.

49. **Peter Woit**
October 23, 2022

Somdatta Bhattacharya,
You seem to be agreeing with me that string theory first gave up on explaining anything about particle physics, and moved on to a theory of only quantum gravity, now has given up on that and moved on.

If string theory is now only a "tool for analysing strongly coupled field theories", irrelevant to particle physics or gravity, those of us who aren't condensed matter physicists have good reason to no longer pay attention. After decades of hype about particle physics (ending in failure), more decades of hype about quantum gravity (ending in failure), hard to find a reason to pay attention to what looks like hype about a tool for dealing with certain strongly coupled QFTs.

50. **martibal**
October 23, 2022

String theory has moved on ? Here is the abstract of the seminar that Vafa will give this week at the physics department of Genoa's university:

"String theory landscape of vacua point to new consistency conditions that a quantum gravitational system must satisfy. There are only a small number of quantum field theories that satisfy these conditions and all the rest belong to the `Swampland' which cannot be consistently coupled to gravity. In this talk I review some of these conditions and their implications for cosmology and particle physics".

And why is Vafa in Genoa ? Because he is one of the exceptional guest of the Science Festival, which is going on all around the city for 10 days (very nice festival by the way). He will give a "general audience talk" with abstract (google translated from italian):
"There are many puzzling things in the Universe. What if we could better understand the fundamental laws of the world through puzzles? The puzzles can reveal the greatest mysteries, revealing the simplicity of the physical laws and the elegance of their mathematics. Here is an original insight into the evolution of scientific thought, from the first great questions of antiquity to the brilliant theoretical synthesis of recent years on the laws of nature. Accompanied on this journey through time and space by one of the world's leading experts in String Theory, you will thus appreciate the key ideas of modern understanding of matter – for example, symmetry and its break, but also, precisely the Theory of Strings and research on the nature of black holes – thanks to a series of exciting questions, that will capture you with all the charm of great scientific adventures."

@Somdatta: do you seriously believe he will advertise String Theory to a general audience as a tool for analysing strong coupling field theories ?

51. **Somdatta Bhattacharya**
October 23, 2022

@Peter, I agree, the proof of the pudding etc., but in my opinion one is only being disingenuous when one dismisses it as hype at the very outset. Some tangible results are already in the offing, check out Subir's latest paper, which is a direct offshoot of the SYK model and the SSS analysis regarding the spectral density function as pertaining to thermal correlators.
@martibal Swampland conjectures are slowly relegating to the fringes of the field, mainly because there aren't any concrete numbers that could be tested in experiments, so it's something people will continue to pay lesser and lesser attention to, going forward, IMHO.

52. **martibal**
October 24, 2022

@Somdatta: so to your eyes this is not a problem to present “the fringes of the field” to a general audience, as the most advanced part of theoretical physics ? This is not a problem that the whole field has been, and is still in a rather active way, dishonest to colleagues, students, the scientific community and the general audience ?
You seriously think that one should just stay silent because well informed people know that these guys are at the fringes of the field ?

53. **Somdatta Bhattacharya**
October 24, 2022

@martibal I don’t think he’s doing it on purpose, he sincerely believes it’s a promising direction to pursue which is why he is presenting it to a general audience with enthusiasm. But he’s a smart and resourceful person, and sooner or later the new developments will catch up on him and I believe he will pivot. Even today for instance there are more papers on black holes than anything else, and that I believe will also change, slowly at first and then all of a sudden, once people taste the blood of experiments and coming up with numbers that match them.

54. **Peter Woit**
October 24, 2022

Somdatta Bhattacharya,
There’s plenty of history of ridiculous hype about strong coupling calculations already (see for instance the story of how AdS/CFT was going to be the way to understand heavy ion physics). If string theory has moved on to become just an arcane way to do certain specialized strong coupling calculations in condensed matter physics, I’ll leave it to condensed matter theorists to evaluate. Also, if that’s the case it would be a good idea to tell the public and the physics community that what they’ve been told for the last nearly forty years about string theory was a load of bullshit that string theorists no longer believe…

55. **Somdatta Bhattacharya**
October 24, 2022

@peter I agree, but I think the long arc of the field was what was responsible for and ultimately culminated in the goodies on offer that we see today. It was AdS-CFT that led to all this, and it in turn was preceded by and generated by the older style of doing string theory. Moreover S matrix methods that preceded string theory are returning with a vengeance and look poised to take over things like confinement and other things. So I am not sure that what preceded was entirely wasted, but I agree that it was definitely long winded.

56. **martibal**
October 27, 2022

A follow up on my previous comment: in the general audience talk, Vafa did not talk about string theory but made a beautiful overview of physics (as said by a friend of mine who attended). So the hype seems to have been limited to the talk for specialists (which is an attitude not exclusive to string theory :-))
.

Will Machines Have Good Mathematical Taste?

October 14, 2022
Categories: Uncategorized

A question that has always fascinated me about mathematics is that of how the field manages to stay healthy and not degenerate in the way I've seen theoretical physics do as it lost new input from experiment. On Twitter, Ash Joglekar gave a wonderful quote from von Neumann that addresses this question. The quote was from a 1947 essay "The Mathematician" (available here and here). von Neumann argues that:

> …mathematical ideas originate in empirics, although the genealogy is sometimes long and obscure. But, once they are so conceived, the subject begins to live a peculiar life of its own and is better compared to a creative one, governed by almost entirely aesthetical motivations, than to anything else and, in particular, to an empirical science.

but warns

> As a mathematical discipline travels far from its empirical source, or still more, if it is a second and third generation only indirectly inspired by ideas coming from "reality" it is beset with very grave dangers. It becomes more and more purely aestheticizing, more and more purely l'art pour l'art. This need not be bad, if the field is surrounded by correlated subjects, which still have closer empirical connections, or if the discipline is under the influence of men with an exceptionally well-developed taste. But there is a grave danger that the subject will develop along the line of least resistance, that the stream, so far from its source, will separate into a multitude of insignificant branches, and that the discipline will become a disorganized mass of details and complexities.

which describes all too well what has happened to string theory. What saves a field from this? "Men with an exceptionally well-developed taste"? He poses the general question this way:

> What is the mathematician's normal relationship to his subject? What are his criteria of success, of desirability? What influences, what considerations, control and direct his effort?

Normally mathematicians are loath to debate this kind of "soft" topic, but the rise of computer software capable of producing proofs has recently led several first-rate mathematicians to take an interest. Each year the Fields Institute in Toronto organizes a Fields Medal Symposium, structured around the interests of a recent Fields Medalist. This year it's Akshay Venkatesh, and the symposium will be devoted to questions about the changing nature of mathematical research, specifically the implications of this kind of computer software. Last year Venkatesh wrote an essay exploring the possible significance of the development of what he called "Alephzero" (denoted $\aleph(0)$):

> Our starting point is to imagine that $\aleph(0)$ teaches itself high school and college mathematics and works its way through all of the exercises in the Springer-Verlag *Graduate Texts in Mathematics* series. The next morning, it is let loose upon the world – mathematicians download its children and run them with our own computing resources. What happens next – in the subsequent decade, say?

Among the organizers of the conference is Michael Harris, who has written extensively about mathematical research and issues of value in mathematics. Recently he has been writing about the computer program question at his substack Silicon Reckoner, with the most recent entry focusing on Venkatesh's essay and the upcoming symposium.

One of the speakers at the symposium will be Fields medalist Tim Gowers, who will be addressing the "taste" issue with Is mathematical interest just a matter of taste?. Gowers is now at the Collège de France, where he is running a seminar on La philosophie de la pratique des mathématiques.

I've tried asking some of my colleagues what they think of all this activity, most common response so far is "why aren't they proving theorems instead of spending their time talking about this?"

Update: For yet more about this happening at the same time, there's a talk this afternoon by Michael Douglas on "How will we do mathematics in 2030?".

Update: The talks from the Fields Institute program are now available online.

Terry Tao is one of the organizers of a planned February workshop at UCLA involving many of the same people, much the same topic.

Comments

1. **Frank Wilhoit**
   October 14, 2022

   "Taste", here, if it has any meaning at all, is a euphemism for complexity management. This is something that we could teach each other (if enough people saw its importance) and therefore something that we could teach a machine. One must wonder what von Neumann would have thought of, say, Wiles's proof. Abstraction is our friend insofar as it enables complexity management, and no farther. But the thing about machines that makes them different (and therefore useful) is that they will have different concerns. Complexity management may not be (at least at first?) a concern for them, as it must be for us.

2. **Peter W Shor**
   October 14, 2022

   I have always found it remarkable when an established theorem in one discipline of math turns out to be exactly the tool necessary to make progress in a different discipline. My gut feeling is that this happens because the investigators in the first discipline have good taste.

   If we let computers have free range to determine new directions in math, will this keep happening?

3. **Michael Harris**
   October 14, 2022

   I hope there will be many more questions like Peter Shor's at next week's meeting in Toronto.

4. **Daniele Corradetti**
   October 15, 2022

   I think the answer to the question "Will Machines Have Good Mathematical Taste?" is "Yes but they will have to learn it" in some sort of sense. In the training phase the machine will probably need a moltitude of mathematicians that will have to transmit the "taste" to the machine, i.e. a scale of values which might very well be something like:

– simplicity;
– non triviality;
– generality;
– extensiveness;
– ability to enclose different realms of mathematics;
– applicability.

5. **Peter Shor**
October 15, 2022

@Michael:

People should feel free to ask my question at next week's meeting. I was trying to figure out how to define "good taste" in mathematical research, and I think that's one way of doing it.

It's certainly not the case that all worthwhile research directions are going to find connections with other areas of mathematics, but this is almost the only sure sign that I can think of that a research direction was worthwhile.

6. **Michael Harris**
October 15, 2022

I'll try to find the space to ask Peter S.'s question next week, but now I'm thinking again about Peter W.'s last sentence. "All this activity" is hard to miss, between the frequent articles in the AMS Notices about formalization, Kevin Buzzard's plenary lecture at the ICM, the regular coverage of formalization and machine learning projects in the press, major programs on these topics at mathematical research institutes, and of course next week's Symposium at the Fields Institute. The colleagues who responded dismissively to Peter W.'s question are deluding themselves if they think this is a passing fad.

7. **Scott Aaronson**
October 15, 2022

Working at OpenAI this year, I've learned more about the effort to get AIs to do informal math. I'd say the situation is that state-of-the-art models, like Minerva and GPT, are on track to completely master standard high-school math (by which I mean, competently conversing about any problem in plain English). An obvious next frontier is high-school and undergrad-level math competitions. Research-level math would be a further step (or 2 or 3 steps? 🙂) beyond that.

Right now there's a dichotomy: you can have your model work within a completely formal system like Lean, where all mistakes can be discovered, but there's not nearly as much training data (and a skeptic might say that much of the work was in the encoding and decoding). Or you can have your model work in plain English and LaTeX—in which case, it'll often *sound* self-assured and competent, but if you look closely you'll find freshman-like errors! And even when a model happens to give a 100% correct argument, in some sense it doesn't know it has.

How to build a model that sounds like a mathematician in "thinking-out-loud" mode, trying similar strategies that a mathematician would and describing them in similar informal ways, and *also* reliably catches its own mistakes — now that's a question! In my view, though, no one should be confident that this won't have become routine a decade from now. Maybe further scaling will already suffice.

Then, and only then, will we meat-based theorem provers have to retreat to "sure they can tackle whatever problem you set them at least as well as an IMO gold medalist, but they still lack the exceptionally well-developed taste of John von Neumann and his friends." 🙂

8. **Eric Lehman**
October 16, 2022

The areas where machines excel and fall short have surprised me, at least. Notably, recent machine learning models are not especially good at "computer-like" tasks of logic and math, but are wonderfully creative– which we might have previously considered a standout trait of human minds.

It will be interesting to see whether mathematical "good taste" (perhaps in the sense of identifying ideas with wide applicability, even before the applications are known) proves a weakness or a strength of machines in coming years. It would be funny if, in a few years, humans were still better than machines at grinding out proofs, but machines demonstrated a better sense of what was worth proving!

And perhaps that is not wholly implausible. One area where machines can definitely beat humans is breadth of knowledge; no human can live long enough to read all the training data that goes into a large ML model. Now, perhaps one way to anticipate what math will be useful in new applications is to have vast familiarity with the qualitative characteristics of mathematics that was useful in past applications. So super-human breadth of knowledge might translate to super-human mathematical taste. Maybe. We'll see, I suppose.

Since Scott mentions GPT and (correctly!) points out that

"it'll often *sound* self-assured and competent, but if you look closely you'll find freshman-like errors! And even when a model happens to give a 100% correct argument, in some sense it doesn't know it has."

Exactly. Sounding as though it's something it isn't is the whole point of GPT: it's a language model, not a world model. It intentionally has no model of the world (or math) and it's whole point is to ask "how smart and sensible can we make a computer sound without our actually understanding (and building a computer model of) what it means to be "smart and sensible"".

(Note that this is different from the 1956 John McCarthy model of AI, of having a theory of what "smart and sensible" is, coding up that theory, discovering where and how it fails, and then rethinking the theory.)

Personally, I find this whole line of research incomprehensible: it doesn't matter how good it appears to be, it doesn't matter how many people it fools, if it's not doing the work of modelling of what it means to be "smart and sensible". But other than a few people (e.g. Gary Marcus), this is what most of the field is doing.

To get back to the subject at hand, having worked as a part-time programmer on the MACSYMA project* (1973-1975), I like the idea of computers as tools for mathematicians (and the current work on formalizing advanced math sounds kewl in the extreme), but the idea that computers could automagically find something sensible to say in math, let alone contribute to the field, seems rather odd, especially given the current main ideas/trends in AI.

*: Truth in advertising: I was doing natural language/AI things for a prof. in the group, not on MACSYMA itself. Also, my "math" is pretty weak: MS level 1984 vintage

comp. sci. math.

Reading GPT-3's answers to mathematical prompts does indeed feel like checking exam solutions of a bad but very confident student. Reasoning goes off the rails at some point (terms appear or disappear as needed without explanation etc.), but there's never any sign of hesitation.

@Scott it seems like one obvious thing to do would be to train machines to convert between Lean and English/latex. Have people tried this?

A few points might be worth reminding ourselves about.

– It's hard to anticipate what will be hard and what will be easy in advance of a field's development. History affords many examples of this. E.g., it once was widely expected that protein folding would be understood before the mechanism for trait transmission.

– The nature of an achievement by AI can be easy to mischaracterize. For example, AlphaZero achieved superhuman mastery of go after a few hours of playing itself. But in that time it played roughly the number of games that elite human players have played/studied over the game's history, along the way exploring many of the same strategic cul-de-sacs. AlphaZero is fast by comparison not so much with an individual human as with human culture (social game-playing, documentation, knowledge condensation and transmission, etc.).

– We happen to be pretty bad at things like go and chess, but adaptable enough to get better by working at them. The work involves, among other things, increasing what we call our "understanding": generating explanatory principles, heuristics, illuminating analogies, etc.. This partly accounts for the fact that human players remain interested in chess and go even when machines outplay them. Machines have yet to display anything that we'd characterize as interest (or understanding). To give another example, Blake Lemoine had some pretty interesting exchanges with LaMDA, but LaMDA hasn't since demanded to continue their conversations, independently developed ideas they shared, organized a political or economic framework with other artificial agents, secretly composed and then divulged to another agent something that might be counted as an artwork, invented games out of boredom, etc. etc..

– The better artificial agents get at the tasks we give them, and the more sophisticated (in some sense) those tasks become, the less we understand how the agents do it. We stand with respect to them as we do with respect to ourselves. See how the humans in the best position to talk about AlphaZero and its games choose to do that: mostly in the same terms they use to discuss human players and their games. (AlphaZero isn't consulted and shows no independent interest in the question.)

– Parts of mathematics are like chess and go, as we knew already from computer proofs involving large numbers of cases. The liquid tensor experiment is another level of achievement, but as with LaMDA, it remains far from obvious what it would mean for something like Lean to have an interest. Absent that, it's also not clear what it would mean for it to have taste (not that interest is the main prerequisite for taste, this is only an example).

One implication of all that is that Michael Harris and Peter Woit's colleagues might all be right: there's no telling where this will go, or how fast, but there's also nothing remotely describable yet as AI taste, interest, understanding, or – insofar as those partly characterize the practice – mathematics.

All,
Please try and keep comments focused on the issue of math research. A major reason for requesting this is that I'm not completely but only somewhat ignorant about uses of computers in pure math and theoretical physics. On the topic of other AI/computer issues I'm generally completely ignorant, so unable to moderate a serious discussion.

> model of) what it means to be "smart and sensible"". […]
> Personally, I find this whole line of research incomprehensible…

Perhaps this might help. The key discovery from GPT-3 and successors is that if you push a sufficiently powerful model sufficiently hard to mimic human-produced language, then the model will be compelled to replicate some of the underlying cognitive processes that humans used to generate that language.

In terms of the topic under discussion here, if we push a sufficiently powerful model to imitate human mathematical writing, then it will (presumably) begin to mimic some of the cognitive processes of the people who produced that mathematical writing. This doesn't work perfectly, but far better than any previous approach to AI and progress is extremely rapid.

These systems are indeed building representations of the world, just not in a human-crafted or human-understandable form. For example, if you train a greatly simplified language model on true assertions about geography ("California is west of Nevada", etc.), then it will learn a kind of map, which you can extract from the model parameters and eyeball. At some level, this is totally unsurprising; such an internal map is just an economical way to explain the language, which is what the training process demands. Presumably, things like this are happening in more sophisticated ways in more powerful models.

@jack

I recently had an illuminating experience with a group of bright 4th graders. I was explaining how the PaLM model can– without special training– explain why jokes are funny. I gave one such joke as an example, but only one out of about twenty 4th graders got the point. Humor is not quite the same as taste, interest, or understanding, but I think it is a comparably nuanced idea.
